r6a.24xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	17080
YARN_PROXYSERVER_HEAPSIZE	17080
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	17080
HADOOP_NAMENODE_HEAPSIZE	75161
HADOOP_DATANODE_HEAPSIZE	4096

r6a.32xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	22077
YARN_PROXYSERVER_HEAPSIZE	22077
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	22077
HADOOP_NAMENODE_HEAPSIZE	100147
HADOOP_DATANODE_HEAPSIZE	4096

r6a.48xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	32071
YARN_PROXYSERVER_HEAPSIZE	32071
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	32071
HADOOP_NAMENODE_HEAPSIZE	150118
HADOOP_DATANODE_HEAPSIZE	4096

r6g instances

r6g.xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	2713
YARN_PROXYSERVER_HEAPSIZE	2713
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	2713
HADOOP_NAMENODE_HEAPSIZE	3328
HADOOP_DATANODE_HEAPSIZE	1075

r6g.2xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	3338
YARN_PROXYSERVER_HEAPSIZE	3338
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	3338
HADOOP_NAMENODE_HEAPSIZE	6451
HADOOP_DATANODE_HEAPSIZE	1699

r6g.4xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	4587
YARN_PROXYSERVER_HEAPSIZE	4587
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	4587
HADOOP_NAMENODE_HEAPSIZE	12697
HADOOP_DATANODE_HEAPSIZE	2949

r6g.8xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	7086
YARN_PROXYSERVER_HEAPSIZE	7086
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	7086
HADOOP_NAMENODE_HEAPSIZE	25190
HADOOP_DATANODE_HEAPSIZE	4096

r6g.12xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	9584
YARN_PROXYSERVER_HEAPSIZE	9584
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	9584
HADOOP_NAMENODE_HEAPSIZE	37683
HADOOP_DATANODE_HEAPSIZE	4096

r6g.16xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	12083
YARN_PROXYSERVER_HEAPSIZE	12083
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	12083
HADOOP_NAMENODE_HEAPSIZE	50176
HADOOP_DATANODE_HEAPSIZE	4096

r6gd instances

r6gd.xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	2713
YARN_PROXYSERVER_HEAPSIZE	2713
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	2713
HADOOP_NAMENODE_HEAPSIZE	3328
HADOOP_DATANODE_HEAPSIZE	1075

r6gd.2xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	3338
YARN_PROXYSERVER_HEAPSIZE	3338
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	3338
HADOOP_NAMENODE_HEAPSIZE	6451
HADOOP_DATANODE_HEAPSIZE	1699

r6gd.4xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	4587
YARN_PROXYSERVER_HEAPSIZE	4587
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	4587
HADOOP_NAMENODE_HEAPSIZE	12697
HADOOP_DATANODE_HEAPSIZE	2949

r6gd.8xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	7086
YARN_PROXYSERVER_HEAPSIZE	7086
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	7086
HADOOP_NAMENODE_HEAPSIZE	25190
HADOOP_DATANODE_HEAPSIZE	4096

r6gd.12xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	9584
YARN_PROXYSERVER_HEAPSIZE	9584
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	9584
HADOOP_NAMENODE_HEAPSIZE	37683
HADOOP_DATANODE_HEAPSIZE	4096

r6gd.16xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	12083
YARN_PROXYSERVER_HEAPSIZE	12083
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	12083
HADOOP_NAMENODE_HEAPSIZE	50176
HADOOP_DATANODE_HEAPSIZE	4096

r6i instances

r6i.xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	2713
YARN_PROXYSERVER_HEAPSIZE	2713
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	2713
HADOOP_NAMENODE_HEAPSIZE	3328
HADOOP_DATANODE_HEAPSIZE	1075

r6i.2xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	3338
YARN_PROXYSERVER_HEAPSIZE	3338
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	3338
HADOOP_NAMENODE_HEAPSIZE	6451
HADOOP_DATANODE_HEAPSIZE	1699

r6i.4xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	4587
YARN_PROXYSERVER_HEAPSIZE	4587
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	4587
HADOOP_NAMENODE_HEAPSIZE	12697
HADOOP_DATANODE_HEAPSIZE	2949

r6i.8xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	7086
YARN_PROXYSERVER_HEAPSIZE	7086
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	7086
HADOOP_NAMENODE_HEAPSIZE	25190
HADOOP_DATANODE_HEAPSIZE	4096

r6i.12xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	9584
YARN_PROXYSERVER_HEAPSIZE	9584
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	9584
HADOOP_NAMENODE_HEAPSIZE	37683
HADOOP_DATANODE_HEAPSIZE	4096

r6i.16xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	12083
YARN_PROXYSERVER_HEAPSIZE	12083
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	12083
HADOOP_NAMENODE_HEAPSIZE	50176
HADOOP_DATANODE_HEAPSIZE	4096

r6i.24xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	17080
YARN_PROXYSERVER_HEAPSIZE	17080
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	17080
HADOOP_NAMENODE_HEAPSIZE	75161
HADOOP_DATANODE_HEAPSIZE	4096

r6i.32xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	21544
YARN_PROXYSERVER_HEAPSIZE	21544
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	21544
HADOOP_NAMENODE_HEAPSIZE	97484
HADOOP_DATANODE_HEAPSIZE	4096

r6id instances

r6id.xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	2713
YARN_PROXYSERVER_HEAPSIZE	2713
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	2713
HADOOP_NAMENODE_HEAPSIZE	3328
HADOOP_DATANODE_HEAPSIZE	1075

r6id.2xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	3338
YARN_PROXYSERVER_HEAPSIZE	3338
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	3338
HADOOP_NAMENODE_HEAPSIZE	6451
HADOOP_DATANODE_HEAPSIZE	1699

r6id.4xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	4587
YARN_PROXYSERVER_HEAPSIZE	4587
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	4587
HADOOP_NAMENODE_HEAPSIZE	12697
HADOOP_DATANODE_HEAPSIZE	2949

r6id.8xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	7086
YARN_PROXYSERVER_HEAPSIZE	7086
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	7086
HADOOP_NAMENODE_HEAPSIZE	25190
HADOOP_DATANODE_HEAPSIZE	4096

r6id.12xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	9584
YARN_PROXYSERVER_HEAPSIZE	9584
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	9584
HADOOP_NAMENODE_HEAPSIZE	37683
HADOOP_DATANODE_HEAPSIZE	4096

r6id.16xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	12083
YARN_PROXYSERVER_HEAPSIZE	12083
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	12083
HADOOP_NAMENODE_HEAPSIZE	50176
HADOOP_DATANODE_HEAPSIZE	4096

r6id.24xlarge

Parameter	Value
YARN_RESOURCEMANAGER_HEAPSIZE	17080
YARN_PROXYSERVER_HEAPSIZE	17080
YARN_NODEMANAGER_HEAPSIZE	2048
HADOOP_JOB_HISTORYSERVER_HEAPSIZE	17080

HDFS configuration

The following table describes the default Hadoop Distributed File System (HDFS) parameters and their settings. You can change these values using the `hdfs-site` configuration classification. For more information, see Configure applications.

> **Warning**
>
> 1. Setting `dfs.replication` to 1 on clusters with fewer than four nodes can lead to HDFS data loss if a single node goes down. If your cluster has HDFS storage, we recommend that you configure the cluster with at least four core nodes for production workloads to avoid data loss.
> 2. Amazon EMR will not allow clusters to scale core nodes below `dfs.replication`. For example, if `dfs.replication = 2`, the minimum number of core nodes is 2.
> 3. When you use managed Scaling, auto-scaling, or choose to manually resize your cluster, we recommend that you set `dfs.replication` to 2 or higher.

Parameter	Definition	Default value
dfs.block .size	The size of HDFS blocks. When operating on data stored in HDFS, the split size is generally the size of an HDFS block. Larger numbers provide less task granularity, but also put less strain on the cluster NameNode.	134217728 (128 MB)
dfs.repli cation	The number of copies of each block to store for durability. Amazon EMR sets this value based on the number of core nodes the cluster is provisioned with. Adjust the value to meet your needs. To overwrite the default value, use the hdfs-site classification.	1 for clusters that are provisioned with less than four core nodes 2 for clusters that are provisioned with less than ten core nodes 3 for all other clusters

Transparent encryption in HDFS on Amazon EMR

Transparent encryption is implemented through the use of HDFS *encryption zones*, which are HDFS paths that you define. Each encryption zone has its own key, which is stored in the key server specified using the `hdfs-site` configuration classification.

Beginning with Amazon EMR release version 4.8.0, you can use Amazon EMR security configurations to configure data encryption settings for clusters more easily. Security configurations offer settings to enable security for data in-transit and data at-rest in Amazon Elastic Block Store (Amazon EBS) storage volumes and EMRFS data in Amazon S3. For more information, see Encrypt data in transit and at rest in the *Amazon EMR Management Guide*.

Amazon EMR uses the Hadoop KMS by default; however, you can use another KMS that implements the KeyProvider API operation. Each file in an HDFS encryption zone has its own unique *data encryption key*, which is encrypted by the encryption zone key. HDFS data is encrypted end-to-end (at-rest and in-transit) when data is written to an encryption zone because encryption and decryption activities only occur in the client.

You cannot move files between encryptions zones or from an encryption zone to unencrypted paths.

The NameNode and HDFS client interact with the Hadoop KMS (or an alternate KMS you configured) through the KeyProvider API operation. The KMS is responsible for storing encryption keys in the backing keystore. Also, Amazon EMR includes the JCE unlimited strength policy, so you can create keys at a desired length.

For more information, see Transparent encryption in HDFS in the Hadoop documentation.

> **Note**
>
> In Amazon EMR, KMS over HTTPS is not enabled by default with Hadoop KMS. For more information about how to enable KMS over HTTPS, see the Hadoop KMS documentation.

Configuring HDFS transparent encryption

You can configure transparent encryption in Amazon EMR by creating keys and adding encryption zones. You can do this in several ways:

- Using the Amazon EMR configuration API operation when you create a cluster
- Using a Hadoop JAR step with command-runner.jar
- Logging in to the master node of the Hadoop cluster and using the `hadoop key` and `hdfs crypto` command line clients
- Using the REST APIs for Hadoop KMS and HDFS

For more information about the REST APIs, see the respective documentation for Hadoop KMS and HDFS.

To create encryption zones and their keys at cluster creation using the CLI

The `hdfs-encryption-zones` classification in the configuration API operation allows you to specify a key name and an encryption zone when you create a cluster. Amazon EMR creates this key in Hadoop KMS on your cluster and configures the encryption zone.

- Create a cluster with the following command.

```
aws emr create-cluster --release-label emr-7.2.0 --instance-type m5.xlarge --
instance-count 2 \
--applications Name=App1 Name=App2 --configurations https://s3.amazonaws.com/
mybucket/myfolder/myConfig.json
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

`myConfig.json`:

```
[
  {
    "Classification": "hdfs-encryption-zones",
    "Properties": {
      "/myHDFSPath1": "path1_key",
      "/myHDFSPath2": "path2_key"
    }
  }
]
```

To create encryption zones and their keys manually on the master node

1. Launch your cluster using an Amazon EMR release greater than 4.1.0.
2. Connect to the master node of the cluster with SSH.
3. Create a key within Hadoop KMS.

```
$ hadoop key create path2_key
path2_key has been successfully created with options Options{cipher='AES/CTR/
NoPadding', bitLength=256, description='null', attributes=null}.
KMSClientProvider[http://ip-x-x-x-x.ec2.internal:16000/kms/v1/] has been updated.
```

> **Important**
>
> Hadoop KMS requires your key names to be lowercase. If you use a key that has uppercase characters, then your cluster will fail during launch.

4. Create the encryption zone path in HDFS.

```
$ hadoop fs -mkdir /myHDFSPath2
```

5. Make the HDFS path an encryption zone using the key that you created.

```
$ hdfs crypto -createZone -keyName path2_key -path /myHDFSPath2
Added encryption zone /myHDFSPath2
```

To create encryption zones and their keys manually using the AWS CLI

- Add steps to create the KMS keys and encryption zones manually with the following command.

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF --steps Type=CUSTOM_JAR,Name="Create
 First Hadoop KMS Key",Jar="command-runner.jar",ActionOnFailure=CONTINUE,Args=[/
bin/bash,-c,"\"hadoop key create path1_key\""] \
Type=CUSTOM_JAR,Name="Create First Hadoop HDFS Path",Jar="command-
runner.jar",ActionOnFailure=CONTINUE,Args=[/bin/bash,-c,"\"hadoop fs -mkdir /
myHDFSPath1\""] \
Type=CUSTOM_JAR,Name="Create First Encryption Zone",Jar="command-
runner.jar",ActionOnFailure=CONTINUE,Args=[/bin/bash,-c,"\"hdfs crypto -createZone
 -keyName path1_key -path /myHDFSPath1\""] \
Type=CUSTOM_JAR,Name="Create Second Hadoop KMS Key",Jar="command-
runner.jar",ActionOnFailure=CONTINUE,Args=[/bin/bash,-c,"\"hadoop key create
 path2_key\""] \
Type=CUSTOM_JAR,Name="Create Second Hadoop HDFS Path",Jar="command-
runner.jar",ActionOnFailure=CONTINUE,Args=[/bin/bash,-c,"\"hadoop fs -mkdir /
myHDFSPath2\""] \
Type=CUSTOM_JAR,Name="Create Second Encryption Zone",Jar="command-
runner.jar",ActionOnFailure=CONTINUE,Args=[/bin/bash,-c,"\"hdfs crypto -createZone
 -keyName path2_key -path /myHDFSPath2\""]
```

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

Considerations for HDFS transparent encryption

A best practice is to create an encryption zone for each application where they may write files. Also, you can encrypt all of HDFS by using the hdfs-encryption-zones classification in the configuration API and specify the root path (/) as the encryption zone.

Hadoop key management server

Hadoop KMS is a key management server that provides the ability to implement cryptographic services for Hadoop clusters, and can serve as the key vendor for Transparent encryption in HDFS on Amazon EMR. Hadoop KMS in Amazon EMR is installed and enabled by default when you select the Hadoop application while launching an EMR cluster. The Hadoop KMS does not store the keys itself except in the case of temporary caching. Hadoop KMS acts as a proxy between the key provider and the client trustee to a backing keystore—it is not a keystore. The default keystore that is created for Hadoop KMS is the Java Cryptography Extension KeyStore (JCEKS). The JCE unlimited strength policy is also included, so you can create keys with the desired length. Hadoop KMS also supports a range of ACLs that control access to keys and key operations independently of other client applications such as HDFS. The default key length in Amazon EMR is 256 bit.

To configure Hadoop KMS, use the hadoop-kms-site classification to change settings. To configure ACLs, you use the classification kms-acls.

For more information, see the Hadoop KMS documentation. Hadoop KMS is used in Hadoop HDFS transparent encryption. To learn more about HDFS transparent encryption, see the HDFS transparent encryption topic in the Apache Hadoop documentation.

Note

In Amazon EMR, KMS over HTTPS is not enabled by default with Hadoop KMS. To learn how to enable KMS over HTTPS, see the Hadoop KMS documentation.

Important

Hadoop KMS requires your key names to be lowercase. If you use a key that has uppercase characters, then your cluster will fail during launch.

Configuring Hadoop KMS in Amazon EMR

Using Amazon EMR release version 4.6.0 or later, the `kms-http-port` is 9700 and `kms-admin-port` is 9701.

You can configure Hadoop KMS at cluster creation time using the configuration API for Amazon EMR releases. The following are the configuration object classifications available for Hadoop KMS:

Hadoop KMS configuration classifications

Classification	Filename
hadoop-kms-site	`kms-site.xml`
hadoop-kms-acls	`kms-acls.xml`
hadoop-kms-env	`kms-env.sh`
hadoop-kms-log4j	`kms-log4j.properties`

To set Hadoop KMS ACLs using the CLI

- Create a cluster with Hadoop KMS with ACLs using the following command:

```
aws emr create-cluster --release-label emr-7.2.0 --instance-type m5.xlarge --
instance-count 2 \
--applications Name=App1 Name=App2 --configurations https://s3.amazonaws.com/
mybucket/myfolder/myConfig.json
```

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

`myConfig.json`:

```
[
    {
      "Classification": "hadoop-kms-acls",
      "Properties": {
        "hadoop.kms.blacklist.CREATE": "hdfs,foo,myBannedUser",
        "hadoop.kms.acl.ROLLOVER": "myAllowedUser"
      }
    }
  ]
```

To disable Hadoop KMS cache using the CLI

- Create a cluster with Hadoop KMS `hadoop.kms.cache.enable` set to `false`, using the following command:

```
aws emr create-cluster --release-label emr-7.2.0 --instance-type m5.xlarge --
instance-count 2 \
--applications Name=App1 Name=App2 --configurations https://s3.amazonaws.com/
mybucket/myfolder/myConfig.json
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

`myConfig.json`:

```
[
    {
      "Classification": "hadoop-kms-site",
      "Properties": {
        "hadoop.kms.cache.enable": "false"
      }
    }
  ]
```

To set environment variables in the kms-env.sh script using the CLI

- Change settings in kms-env.sh via the hadoop-kms-env configuration. Create a cluster with Hadoop KMS using the following command:

```
aws emr create-cluster --release-label emr-7.2.0 --instance-type m5.xlarge --
instance-count 2 \
--applications Name=App1 Name=App2 --configurations https://s3.amazonaws.com/
mybucket/myfolder/myConfig.json
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

myConfig.json:

```
[
  {
    "Classification": "hadoop-kms-env",
    "Properties": {
    },
    "Configurations": [
      {
        "Classification": "export",
        "Properties": {
          "JAVA_LIBRARY_PATH": "/path/to/files",
          "KMS_SSL_KEYSTORE_FILE": "/non/Default/Path/.keystore",
          "KMS_SSL_KEYSTORE_PASS": "myPass"
        },
        "Configurations": [
        ]
      }
    ]
  }
]
```

For information about configuring Hadoop KMS, see the Hadoop KMS documentation.

HDFS transparent encryption on EMR clusters with multiple master nodes

Apache Ranger KMS is used in an Amazon EMR cluster with multiple primary nodes for transparent encryption in HDFS.

Apache Ranger KMS stores its root key and Encryption Zone (EZ) keys in your Amazon RDS for an Amazon EMR cluster with multiple primary nodes. To enable transparent encryption in HDFS on an Amazon EMR cluster with multiple primary nodes, you must provide the following configurations.

- Amazon RDS or your own MySQL server connection URL to store the Ranger KMS root key and EZ key
- User name and password for MySQL
- Password for Ranger KMS root key
- Certificate Authority (CA) PEM file for SSL connection to MySQL server

You can provide these configurations by using `ranger-kms-dbks-site` classification and `ranger-kms-db-ca` classification, as the following example demonstrates.

```
[
  {
    "Classification": "ranger-kms-dbks-site",
    "Properties": {
      "ranger.ks.jpa.jdbc.url": "jdbc:log4jdbc:mysql://mysql-host-url.xx-
xxx-1.xxx.amazonaws.com:3306/rangerkms",
      "ranger.ks.jpa.jdbc.user": "mysql-user-name",
      "ranger.ks.jpa.jdbc.password": "mysql-password",
      "ranger.db.encrypt.key.password": "password-for-encrypting-a-master-key"
    }
  },
  {
    "Classification": "ranger-kms-db-ca",
    "Properties": {
      "ranger.kms.trust.ca.file.s3.url": "s3://rds-downloads/rds-ca-2019-root.pem"
    }
     }
]
```

The following are configuration object classifications for Apache Ranger KMS.

Hadoop KMS configuration classifications

Classification	Description
ranger-kms-dbks-site	Change values in dbks-site.xml file of Ranger KMS.
ranger-kms-site	Change values in ranger-kms-site.xml file of Ranger KMS.
ranger-kms-env	Change values in the Ranger KMS environme nt.
ranger-kms-log4j	Change values in kms-log4j.properties file of Ranger KMS.
ranger-kms-db-ca	Change values for CA file on S3 for MySQL SSL connection with Ranger KMS.

Considerations

- It is highly recommended that you encrypt your Amazon RDS instance to improve security. For more information, see Overview of encrypting Amazon RDS resources.
- It is highly recommended that you use separate MySQL database for each Amazon EMR cluster with multiple primary nodes for high security bar.
- To configure transparent encryption in HDFS on an Amazon EMR cluster with multiple primary nodes, you must specify the `hdfs-encryption-zones` classification while creating the cluster. Otherwise, Ranger KMS will not be configured or started. Reconfiguring `hdfs-encryption-zones` classification or any of the Hadoop KMS configuration classifications on a running cluster is not supported on Amazon EMR cluster with multiple primary nodes.

Create or run a Hadoop application

Topics

- Process data with a custom JAR

Build binaries using Amazon EMR

You can use Amazon EMR as a build environment to compile programs for use in your cluster. Programs that you use with Amazon EMR must be compiled on a system running the same version of Linux used by Amazon EMR. For a 32-bit version, you should have compiled on a 32-bit machine or with 32-bit cross compilation options turned on. For a 64-bit version, you need to have compiled on a 64-bit machine or with 64-bit cross compilation options turned. For more information about EC2 instance versions, see Plan and configure EC2 instances in the *Amazon EMR Management Guide*. Supported programming languages include C++, Python, and C#.

The following table outlines the steps involved to build and test your application using Amazon EMR.

Process for building a module

1	Connect to the master node of your cluster.
2	Copy source files to the master node.
3	Build binaries with any necessary optimizations.
4	Copy binaries from the master node to Amazon S3.

The details for each of these steps are covered in the sections that follow.

To connect to the master node of the cluster

- Follow the instructions at Connect to the master node using SSH in the *Amazon EMR Management Guide*.

To copy source files to the master node

1. Put your source files in an Amazon S3 bucket. To learn how to create buckets and how to move data into Amazon S3, see the Amazon Simple Storage Service User Guide.
2. Create a folder on your Hadoop cluster for your source files by entering a command similar to the following:

```
mkdir SourceFiles
```

3. Copy your source files from Amazon S3 to the master node by typing a command similar to the following:

```
hadoop fs -get s3://mybucket/SourceFiles SourceFiles
```

Build binaries with any necessary optimizations

How you build your binaries depends on many factors. Follow the instructions for your specific build tools to setup and configure your environment. You can use Hadoop system specification commands to obtain cluster information to determine how to install your build environment.

To identify system specifications

- Use the following commands to verify the architecture you are using to build your binaries.

  a. To view the version of Debian, enter the following command:

  ```
  master$ cat /etc/issue
  ```

  The output looks similar to the following.

  ```
  Debian GNU/Linux 5.0
  ```

  b. To view the public DNS name and processor size, enter the following command:

  ```
  master$ uname -a
  ```

  The output looks similar to the following.

  ```
  Linux domU-12-31-39-17-29-39.compute-1.internal 2.6.21.7-2.fc8xen #1 SMP Fri
   Feb 15 12:34:28 EST 2008 x86_64 GNU/Linux
  ```

  c. To view the processor speed, enter the following command:

  ```
  master$ cat /proc/cpuinfo
  ```

The output looks similar to the following.

```
processor : 0
vendor_id : GenuineIntel
model name : Intel(R) Xeon(R) CPU E5430 @ 2.66GHz
flags : fpu tsc msr pae mce cx8 apic mca cmov pat pse36 clflush dts acpi mmx
 fxsr sse sse2 ss ht tm syscall nx lm constant_tsc pni monitor ds_cpl vmx est
 tm2 ssse3 cx16 xtpr cda lahf_lm
...
```

Once your binaries are built, you can copy the files to Amazon S3.

To copy binaries from the master node to Amazon S3

- Type the following command to copy the binaries to your Amazon S3 bucket:

```
hadoop fs -put BinaryFiles s3://mybucket/BinaryDestination
```

Process data with streaming

Hadoop streaming is a utility that comes with Hadoop that enables you to develop MapReduce executables in languages other than Java. Streaming is implemented in the form of a JAR file, so you can run it from the Amazon EMR API or command line just like a standard JAR file.

This section describes how to use streaming with Amazon EMR.

Note

Apache Hadoop streaming is an independent tool. As such, all of its functions and parameters are not described here. For more information about Hadoop streaming, go to http://hadoop.apache.org/docs/stable/hadoop-streaming/HadoopStreaming.html.

Using the Hadoop streaming utility

This section describes how use to Hadoop's streaming utility.

Hadoop process

1	Write your mapper and reducer executable in the programming language of your choice. Follow the directions in Hadoop's documentation to write your streaming executables. The programs should read their input from standard input and output data through standard output. By default, each line of input/output represents a record and the first tab on each line is used as a separator between the key and value.
2	Test your executables locally and upload them to Amazon S3.
3	Use the Amazon EMR command line interface or Amazon EMR console to run your application.

Each mapper script launches as a separate process in the cluster. Each reducer executable turns the output of the mapper executable into the data output by the job flow.

The `input`, `output`, `mapper`, and `reducer` parameters are required by most streaming applications. The following table describes these and other, optional parameters.

Parameter	Description	Required
-input	Location on Amazon S3 of the input data. Type: String Default: None Constraint: URI. If no protocol is specified then it uses the clust er's default file system.	Yes
-output	Location on Amazon S3 where Amazon EMR uploads the processed data. Type: String Default: None	Yes

Parameter	Description	Required
	Constraint: URI Default: If a location is not specified, Amazon EMR uploads the data to the location specified by `input`.	
-mapper	Name of the mapper executable. Type: String Default: None	Yes
-reducer	Name of the reducer executable. Type: String Default: None	Yes
-cacheFile	An Amazon S3 location containing files for Hadoop to copy into your local working directory (primarily to improve performance). Type: String Default: None Constraints: [URI]#[symlink name to create in working directory]	No
-cacheArchive	JAR file to extract into the working directory Type: String Default: None Constraints: [URI]#[symlink directory name to create in working directory	No

Parameter	Description	Required
-combiner	Combines results Type: String Default: None Constraints: Java class name	No

The following code sample is a mapper executable written in Python. This script is part of the WordCount sample application.

```
#!/usr/bin/python
import sys

def main(argv):
  line = sys.stdin.readline()
  try:
    while line:
      line = line.rstrip()
      words = line.split()
      for word in words:
        print "LongValueSum:" + word + "\t" + "1"
      line = sys.stdin.readline()
  except "end of file":
    return None
if __name__ == "__main__":
  main(sys.argv)
```

Submit a streaming step

This section covers the basics of submitting a streaming step to a cluster. A streaming application reads input from standard input and then runs a script or executable (called a mapper) against each input. The result from each of the inputs is saved locally, typically on a Hadoop Distributed File System (HDFS) partition. After all the input is processed by the mapper, a second script or executable (called a reducer) processes the mapper results. The results from the reducer are sent to standard output. You can chain together a series of streaming steps, where the output of one step becomes the input of another step.

The mapper and the reducer can each be referenced as a file or you can supply a Java class. You can implement the mapper and reducer in any of the supported languages, including Ruby, Perl, Python, PHP, or Bash.

Submit a streaming step using the console

This example describes how to use the Amazon EMR console to submit a streaming step to a running cluster.

To submit a streaming step

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. In the **Cluster List**, select the name of your cluster.
3. Scroll to the **Steps** section and expand it, then choose **Add step**.
4. In the **Add Step** dialog box:
   - For **Step type**, choose **Streaming program**.
   - For **Name**, accept the default name (Streaming program) or type a new name.
   - For **Mapper**, type or browse to the location of your mapper class in Hadoop, or an S3 bucket where the mapper executable, such as a Python program, resides. The path value must be in the form *`BucketName`*/*`path`*/*`MapperExecutable`*.
   - For **Reducer**, type or browse to the location of your reducer class in Hadoop, or an S3 bucket where the reducer executable, such as a Python program, resides. The path value must be in the form *`BucketName`*/*`path`*/*`MapperExecutable`*. Amazon EMR supports the special *aggregate* keyword. For more information, go to the Aggregate library supplied by Hadoop.
   - For **Input S3 location**, type or browse to the location of your input data.
   - For **Output S3 location**, type or browse to the name of your Amazon S3 output bucket.
   - For **Arguments**, leave the field blank.
   - For **Action on failure**, accept the default option **(Continue**).
5. Choose **Add**. The step appears in the console with a status of Pending.
6. The status of the step changes from Pending to Running to Completed as the step runs. To update the status, choose the **Refresh** icon above the Actions column.

AWS CLI

These examples demonstrate how to use the AWS CLI to create a cluster and submit a Streaming step.

To create a cluster and submit a streaming step using the AWS CLI

- To create a cluster and submit a streaming step using the AWS CLI, type the following command and replace *myKey* with the name of your EC2 key pair. Note that your argument for `--files` should be the Amazon S3 path to your script's location, and the arguments for `-mapper` and `-reducer` should be the names of the respective script files.

```
aws emr create-cluster --name "Test cluster" --release-label emr-7.2.0 --
applications Name=Hue Name=Hive Name=Pig --use-default-roles \
--ec2-attributes KeyName=myKey --instance-type m5.xlarge --instance-count 3 \
--steps Type=STREAMING,Name="Streaming Program",ActionOnFailure=CONTINUE,Args=[--
files,pathtoscripts,-mapper,mapperscript,-reducer,reducerscript,aggregate,-
input,pathtoinputdata,-output,pathtooutputbucket]
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

When you specify the instance count without using the `--instance-groups` parameter, a single master node is launched, and the remaining instances are launched as core nodes. All nodes use the instance type specified in the command.

> **Note**
>
> If you have not previously created the default Amazon EMR service role and EC2 instance profile, type aws `emr create-default-roles` to create them before typing the `create-cluster` subcommand.

For more information on using Amazon EMR commands in the AWS CLI, see https://docs.aws.amazon.com/cli/latest/reference/emr.

Process data with a custom JAR

A custom JAR runs a compiled Java program that you can upload to Amazon S3. You should compile the program against the version of Hadoop you want to launch, and submit a `CUSTOM_JAR` step to your Amazon EMR cluster. For more information about how to compile a JAR file, see Build binaries using Amazon EMR.

For more information about building a Hadoop MapReduce application, see the MapReduce Tutorial in the Apache Hadoop documentation.

Topics

Submit a custom JAR step

A custom JAR runs a compiled Java program that you can upload to Amazon S3. You should compile the program against the version of Hadoop you want to launch, and submit a `CUSTOM_JAR` step to your Amazon EMR cluster. For more information about how to compile a JAR file, see Build binaries using Amazon EMR.

For more information about building a Hadoop MapReduce application, see the MapReduce Tutorial in the Apache Hadoop documentation.

This section covers the basics of submitting a custom JAR step in Amazon EMR. Submitting a custom JAR step enables you to write a script to process your data with the Java programming language.

Submit a custom JAR step with the console

This example describes how to use the Amazon EMR console to submit a custom JAR step to a running cluster.

To submit a custom JAR step with the console

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. In the **Cluster List**, select the name of your cluster.
3. Scroll to the **Steps** section and expand it, then choose **Add step**.
4. In the **Add Step** dialog:

- For **Step type**, choose **Custom JAR**.
- For **Name**, accept the default name (Custom JAR) or type a new name.
- For **JAR S3 location**, type or browse to the location of your JAR file. JAR location maybe a path into S3 or a fully qualified java class in the classpath..
- For **Arguments**, type any required arguments as space-separated strings or leave the field blank.
- For **Action on failure**, accept the default option (**Continue**).

5. Choose **Add**. The step appears in the console with a status of Pending.
6. The status of the step changes from Pending to Running to Completed as the step runs. To update the status, choose the **Refresh** icon above the Actions column.

Launching a cluster and submitting a custom JAR step with the AWS CLI

To launch a cluster and submit a custom JAR step with the AWS CLI

To launch a cluster and submit a custom JAR step with the AWS CLI, type the `create-cluster` subcommand with the `--steps` parameter.

- To launch a cluster and submit a custom JAR step, type the following command, replace *myKey* with the name of your EC2 key pair, and replace *mybucket* with your bucket name.

```
aws emr create-cluster --name "Test cluster" --release-label emr-7.2.0 \
--applications Name=Hue Name=Hive Name=Pig --use-default-roles \
--ec2-attributes KeyName=myKey --instance-type m5.xlarge --instance-count 3 \
--steps Type=CUSTOM_JAR,Name="Custom JAR
 Step",ActionOnFailure=CONTINUE,Jar=pathtojarfile,Args=["pathtoinputdata","pathtooutputbuck
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

When you specify the instance count without the `--instance-groups` parameter, a single primary node launches, and the remaining instances launch as core nodes. All nodes use the instance type that you specify in the command.

> **Note**
>
> If you have not previously created the default Amazon EMR service role and EC2 instance profile, type `aws emr create-default-roles` to create them before typing the `create-cluster` subcommand.

For more information on using Amazon EMR commands in the AWS CLI, see https://docs.aws.amazon.com/cli/latest/reference/emr.

Third-party dependencies

Sometimes it may be necessary to include in the MapReduce classpath JARs for use with your program. You have two options for doing this:

- Include the `--libjars s3://URI_to_JAR` in the step options for the procedure in Launching a cluster and submitting a custom JAR step with the AWS CLI.
- Launch the cluster with a modified `mapreduce.application.classpath` setting in `mapred-site.xml`. Use the `mapred-site` configuration classification. To create the cluster with the step using AWS CLI, this would look like the following:

```
aws emr create-cluster --release-label emr-7.2.0 \
--applications Name=Hue Name=Hive Name=Pig --use-default-roles \
--instance-type m5.xlarge --instance-count 2  --ec2-attributes KeyName=myKey \
--steps Type=CUSTOM_JAR,Name="Custom JAR
 Step",ActionOnFailure=CONTINUE,Jar=pathtojarfile,Args=["pathtoinputdata","pathtooutputbucket
 \
--configurations https://s3.amazonaws.com/mybucket/myfolder/myConfig.json
```

`myConfig.json`:

```
[
    {
      "Classification": "mapred-site",
      "Properties": {
        "mapreduce.application.classpath": "path1,path2"
      }
    }
```

```
  ]
```

The comma-separated list of paths should be appended to the JVM classpath for each task.

Read restored objects

With Amazon EMR release 7.2.0 and higher, you can read restored Glacier objects from the S3 location of the table with the `S3A` protocol. Engines in previous releases don't distinguish between Glacier and Glacier Deep Archive files, which means you would get an `AmazonS3Exception` if you tried to access an in-progress Glacier file with `S3A`. This read operation ignores archived Glacier files if they still in progress of being restored. To enable this behavior, use the setting `fs.s3a.glacier.read.restored.objects`. This setting can be three values:

- **READ_ALL** – this value indicates that Amazon EMR shouldn't account for the storage classes retrieved from Amazon S3. This is the default behavior.
- **SKIP_ALL_GLACIER** – this value indicates that Amazon EMR should ignore any S3 objects that are tagged with the Glacier storage class and retrieve all other objects. This is the default behavior for Amazon Athena with respect to Glacier objects.
- **READ_RESTORED_GLACIER_OBJECTS** – this value indicates that Amazon EMR should check the restored status of the Glacier object. If Amazon EMR can restore the object, you can read them like a normal S3 object. Otherwise, Amazon EMR ignores the object from S3 Glacier

Examples

Spark

To read restored objects when you use Spark, use the following configuration:

```
--conf spark.hadoop.fs.s3a.glacier.read.restored.objects=<value>
```

If you use spark-sql, use the following configuration instead;

```
spark-sql --conf spark.hadoop.fs.s3a.glacier.read.restored.objects=<value>
```

Flink

If you use Flink, you can set the configuration in the `flink-conf.yaml` file

```
fs.s3a.glacier.read.restored.objects: <value>
```

You can also set the `flink-conf` classification:

```
[
    {
      "Classification": "flink-conf",
      "Properties": {
        "fs.s3a.glacier.read.restored.objects":"<value>"
      }
    }
]
```

Hive

If you use Hive, set the configuration in the `hive-site.xml` file.

```
<property>
    <name>fs.s3a.glacier.read.restored.objects</name>
    <value><value></value>
</property>
```

You can also use the Hive CLI to set the property `--hiveconf`:

```
hive --hiveconf fs.s3a.glacier.read.restored.objects=<value>
```

Considerations

When you read restored objects from S3 Glacier, note the following considerations:

- You can only read restored objects if you use the `S3A` scheme or the `S3AFileSystem` to access the data.
- When you read a restored Glacier object, Amazon EMR doesn't restore the object itself. To do so, you must use the AWS CLI or the AWS SDK.

Turn on non-uniform memory access awareness for YARN containers

With Amazon EMR versions 6.x and later, you can use non-uniform memory access (NUMA) for multiprocessing your data on clusters. NUMA is a computer memory design pattern where the processor can access its own local memory faster than memory on another processor or shared between processors. YARN containers have better performance with NUMA because they can bind to a specific NUMA node that serves all subsequent memory allocations. This reduces the amount of times that your cluster has to access remote memory.

You can turn on NUMA support for YARN container when the worker node machine is a multi-NUMA node. To confirm if a worker node is a single-NUMA or multi-NUMA node, run the following command.

```
lscpu | grep -i numa
NUMA node(s): 2
```

In general, instances that are larger than 12x have two NUMA nodes. This does not apply to metal instances.

To turn on NUMA awareness for YARN containers

1. Use the following `yarn-site` configuration in your Amazon EMR 6.x cluster.

```
 [
    {
        "classification":"yarn-site",
            "properties":{
                "yarn.nodemanager.linux-container-executor.nonsecure-mode.local-
user":"yarn",
                "yarn.nodemanager.linux-container-executor.group":"yarn",
                "yarn.nodemanager.container-
executor.class":"org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor",
                "yarn.nodemanager.numa-awareness.enabled":"true",
                "yarn.nodemanager.numa-awareness.numactl.cmd":"/usr/bin/numactl",
                "yarn.nodemanager.numa-awareness.read-topology":"true"
            },
        "configurations":[]
     }
 ]
```

2. Provide the following bootstrap action in your cluster.

```
#!/bin/bash

sudo yum -y install numactl
echo 1 | sudo tee /proc/sys/kernel/numa_balancing

echo "banned.users=mapred,bin,hdfs" >> /etc/hadoop/conf/container-executor.cfg
rm -rf /var/log/hadoop-yarn/
sudo chown -R yarn:hadoop /var/log/hadoop-yarn/
sudo chmod 755 -R /var/log/hadoop-yarn/

sudo chmod 6050 /etc/hadoop/conf/container-executor.cfg

mkdir /mnt/yarn && sudo chmod 755 -R /mnt/yarn && sudo chown -R yarn:hadoop /mnt/
yarn
mkdir /mnt1/yarn && sudo chmod 755 -R /mnt1/yarn && sudo chown -R yarn:hadoop /
mnt1/yarn
mkdir /mnt2/yarn && sudo chmod 755 -R /mnt2/yarn && sudo chown -R yarn:hadoop /
mnt2/yarn
```

3. Every container must be aware of NUMA. You can notify the Java virtual machine (JVM) in each container with a NUMA flag. For example, to notify the JVM to use NUMA in a MapReduce job, add the following properties in `mapred-site.xml`.

```
<property>
    <name>mapreduce.reduce.java.opts</name>
    <value>-XX:+UseNUMA</value>
</property>
<property>
    <name>mapreduce.map.java.opts</name>
    <value>-XX:+UseNUMA</value>
</property>
```

4. To verify that you turned NUMA on, search any of the NodeManager log files with the following command.

```
grep "NUMA resources allocation is enabled," *
```

To verify that NodeManager has assigned NUMA node resources to a container, search the NodeManager log with the following command, replacing *<container_id>* with your own container ID.

```
grep "NUMA node" | grep <container_id>
```

Hadoop version history

The following table lists the version of Hadoop included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Hadoop version information

Amazon EMR Release label	Hadoop Version	Components installed with Hadoop
emr-7.2.0	3.3.6	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server
emr-5.36.2	2.10.1	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server,

Amazon EMR Release label	Hadoop Version	Components installed with Hadoop
		hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server
emr-7.1.0	3.3.6	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server

Hadoop release notes by version

Topics

Amazon EMR 7.2.0 - Hadoop release notes

Amazon EMR 7.2.0 - Hadoop changes

Type	Description
New Feature	HADOOP-18850: S3A: Enable dual-layer server-side encryption with AWS KMS keys
New Feature	Support S3 Glacier read restored objects
Improvement	Dynamically Scaling S3A maximum connections based upon the cores when running Spark Jobs

Type	Description
Improvement	HADOOP-18797: Support Concurrent Writes With S3A Magic Committer
Improvement	HADOOP-19047: Support InMemory Tracking Of S3A Magic Commits
Improvement	Add "Export", "Publish" & "AbortPublish" method in MagicV2 Committer
Improvement	Implement ReadFullyIntoBuffers FileSystem API in S3A
Bug Fix	HADOOP-18793: S3A StagingCommitter does not clean up staging-uploads directory
Upgrade	HADOOP-19008: S3A: update aws-sdk version to 2.21.41
Upgrade	HADOOP-18613: Upgrade ZooKeeper to version 3.8.3

Amazon EMR 7.2.0 - Hadoop features

See the following list for new Hadoop features in Amazon EMR 7.2.0.

- S3 glacier support to read restored objects – With Amazon EMR release 7.2.0 and higher, you can read restored Glacier objects from the S3 location of the table with the S3A protocol. This read operation ignores archived Glacier files if they still in progress of being restored.
- Support concurrent writes with the S3A magic committer – Amazon EMR 7.2.0 introduces support for concurrent writes with the S3A magic committer. This feature was added to the OSS Hadoop community as part of HADOOP-18797.

Amazon EMR 6.6.0 - Hadoop release notes

Amazon EMR 6.6.0 - Hadoop changes

Type	Description
Bug	Fixed duplicated records when reading BZip2 text files.
Backport	HADOOP-18136: Verify `FileUtils.unTar()` handling of missing .tar files
Backport	HADOOP-17627: Backport to branch-3.2 HADOOP-17371, HADOOP-17621, HADOOP-17625 to update Jetty to 9.4.39
Backport	HADOOP-17655: Upgrade Jetty to 9.4.40
Backport	HADOOP-17796: Upgrade jetty version to 9.4.43
Backport	HADOOP-17661: mvn versions:set fails to parse pom.xml
Backport	HADOOP-17236: Bump up snakeyaml to 1.26 to mitigate CVE-2017-18640
Backport	HADOOP-16717: Remove GenericsUtil isLog4jLogger dependency on Log4jLoggerAdapter
Backport	HADOOP-17633: Bump json-smart to 2.4.2 and nimbus-jose-jwt to 9.8 due to CVEs
Backport	HADOOP-17844: Upgrade JSON smart to 2.4.7
Backport	HADOOP-17972: Backport HADOOP-17683 (Update commons-io to 2.8.0) for branch-3.2

Type	Description
Backport	HADOOP-16555: Update commons-compress to 1.19
Backport	HADOOP-17370: Upgrade commons-c ompress to 1.21
Backport	HADOOP-17096: Fix ZStandardCompressor input buffer offset
Backport	HADOOP-17112: Whitespace not allowed in paths when saving files to s3a via committer
Backport	HADOOP-13500: Synchronizing iteration of Configuration properties object
Backport	HDFS-14099: Unknown frame descriptor when decompressing multiple frames in ZStandardDecompressor
Backport	HDFS-16410: Insecure Xml parsing in Offli neEditsXmlLoader
Backport	HDFS-14498: LeaseManager can loop forever on the file for which create has failed
Backport	HDFS-15290: NPE in HttpServer during NameNode startup
Backport	HDFS-15293: Relax the condition for accepting a fsimage when receiving a checkpoint
Backport	HDFS-12979: StandbyNode should upload FsImage to ObserverNode after checkpointing
Backport	YARN-10538: Add recommissioning nodes to the list of updated nodes returned to the AM

Type	Description
Backport	YARN-10472: Backport YARN-10314 (YarnClient throws NoClassDefFoundError for WebSocketException with only shaded client jars) to branch-3.2
Backport	YARN-9968: Public Localizer is exiting in `NodeManager` due to `NullPointerException`
Backport	YARN-10651: `CapacityScheduler` crashed with `NPE` in `AbstractYarnScheduler.updateNodeResource()`
Backport	YARN-9339: Apps pending metric incorrect after moving app to a new queue
Backport	YARN-10438: Handle null `containerId` in `ClientRMService#getContainerReport()`
Backport	YARN-7266: ATS 1.5 fails to start if `RollingLevelDb` files are corrupt or missing
Backport	YARN-9063: ATS 1.5 fails to start if `RollingLevelDb` files are corrupt or missing
Backport	YARN-9848: Revert YARN-4946 (RM should not consider an application as `COMPLETED` when log aggregation is not in a terminal state).

Apache HBase

HBase is an open source, non-relational, distributed database developed as part of the Apache Software Foundation's Hadoop project. HBase runs on top of Hadoop Distributed File System (HDFS) to provide non-relational database capabilities for the Hadoop ecosystem. HBase is included with Amazon EMR release version 4.6.0 and later.

HBase works seamlessly with Hadoop, sharing its file system and serving as a direct input and output to the MapReduce framework and execution engine. HBase also integrates with Apache Hive, enabling SQL-like queries over HBase tables, joins with Hive-based tables, and support for Java Database Connectivity (JDBC). For more information about HBase, see Apache HBase and HBase documentation on the Apache website. For an example of how to use HBase with Hive, see the AWS Big Data Blog post Combine NoSQL and massively parallel analytics using Apache HBase and Apache Hive on Amazon EMR.

With HBase on Amazon EMR, you can also back up your HBase data directly to Amazon Simple Storage Service (Amazon S3), and restore from a previously created backup when launching an HBase cluster. Amazon EMR offers additional options to integrate with Amazon S3 for data persistence and disaster recovery.

- **HBase on Amazon S3** - With Amazon EMR version 5.2.0 and later, you can use HBase on Amazon S3 to store a cluster's HBase root directory and metadata directly to Amazon S3. You can subsequently start a new cluster, pointing it to the root directory location in Amazon S3. Only one cluster at a time can use the HBase location in Amazon S3, with the exception of a read-replica cluster. For more information, see HBase on Amazon S3 (Amazon S3 storage mode).
- **HBase read-replicas** - Amazon EMR version 5.7.0 and later with HBase on Amazon S3 supports read-replica clusters. A read-replica cluster provides read-only access to a primary cluster's store files and metadata for read-only operations. For more information, see Using a read-replica cluster.
- **HBase Snapshots** - As an alternative to HBase on Amazon S3, with EMR version 4.0 and later you can create snapshots of your HBase data directly to Amazon S3 and then recover data using the snapshots. For more information, see Using HBase snapshots.

Important

For Amazon EMR HBase cluster scaling, we do not recommend using managed scaling or scaling with custom policies with HBase clusters.

The following table lists the version of HBase included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with HBase.

For the version of components installed with HBase in this release, see Release 7.2.0 Component Versions.

HBase version information for emr-7.2.0

Amazon EMR Release Label	HBase Version	Components Installed With HBase
emr-7.2.0	HBase 2.4.17	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, emr-wal-cli, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-rest-server, hbase-thrift-server, hbase-operator-tools, zookeeper-client, zookeeper-server

The following table lists the version of HBase included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with HBase.

For the version of components installed with HBase in this release, see Release 6.15.0 Component Versions.

HBase version information for emr-6.15.0

Amazon EMR Release Label	HBase Version	Components Installed With HBase
emr-6.15.0	HBase 2.4.17	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, emr-wal-cli, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-rest-server, hbase-thrift-server, hbase-operator-tools, zookeeper-client, zookeeper-server

Note

Apache HBase HBCK2 is a separate operational tool for repairing HBase regions and system tables. In Amazon EMR version 6.1.0 and later, the hbase-hbck2.jar is provided in `/usr/lib/hbase-operator-tools/` on the primary node. For more information about how to build and use the tool, see HBase HBCK2.

The following table lists the version of HBase included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with HBase.

For the version of components installed with HBase in this release, see Release 5.36.2 Component Versions.

HBase version information for emr-5.36.2

Amazon EMR Release Label	HBase Version	Components Installed With HBase
emr-5.36.2	HBase 1.4.13	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-rest-server, hbase-thrift-server, zookeeper-client, zookeeper-server

Creating a cluster with HBase

The procedures in this section cover the basics of launching a cluster using the AWS Management Console and the AWS CLI. For detailed information about how to plan, configure, and launch Amazon EMR clusters, see Plan and configure clusters in the *Amazon EMR Management Guide*.

Creating a cluster with HBase using the console

For quick steps to launch clusters with the console, see Getting started with Amazon EMR in the *Amazon EMR Management Guide*.

To launch a cluster with HBase installed using the console

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create cluster** and **Go to advanced options**.
3. For **Software Configuration**, choose an **Amazon Release Version** of 4.6.0 or later (we recommend the latest version). Choose **HBase** and other applications as desired.
4. With Amazon EMR version 5.2.0 and later, under **HBase Storage Settings**, select **HDFS** or **S3**. For more information, see HBase on Amazon S3 (Amazon S3 storage mode).
5. Select other options as necessary and then choose **Create cluster**.

Creating a cluster with HBase using the AWS CLI

Use the following command to create a cluster with HBase installed:

```
aws emr create-cluster --name "Test cluster" --release-label emr-7.2.0 \
--applications Name=HBase --use-default-roles --ec2-attributes KeyName=myKey \
--instance-type m5.xlarge --instance-count 3
```

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

If you use HBase on Amazon S3, specify the `--configurations` option with a reference to a JSON configuration object. The configuration object must contain an `hbase-site` classification that specifies the location in Amazon S3 where HBase data is stored using the `hbase.rootdir` property. It also must contain an `hbase` classification, which specifies `s3` using the `hbase.emr.storageMode` property. The following example demonstrates a JSON snippet with these configuration settings.

```
[
    {
        "Classification": "hbase-site",
        "Properties": {
            "hbase.rootdir": "s3://MyBucket/MyHBaseStore"
        }
    },
    {
        "Classification": "hbase",
        "Properties": {
            "hbase.emr.storageMode": "s3"
        }
    }
]
```

For more information about HBase on Amazon S3, see HBase on Amazon S3 (Amazon S3 storage mode). For more information about classifications, see Configure applications.

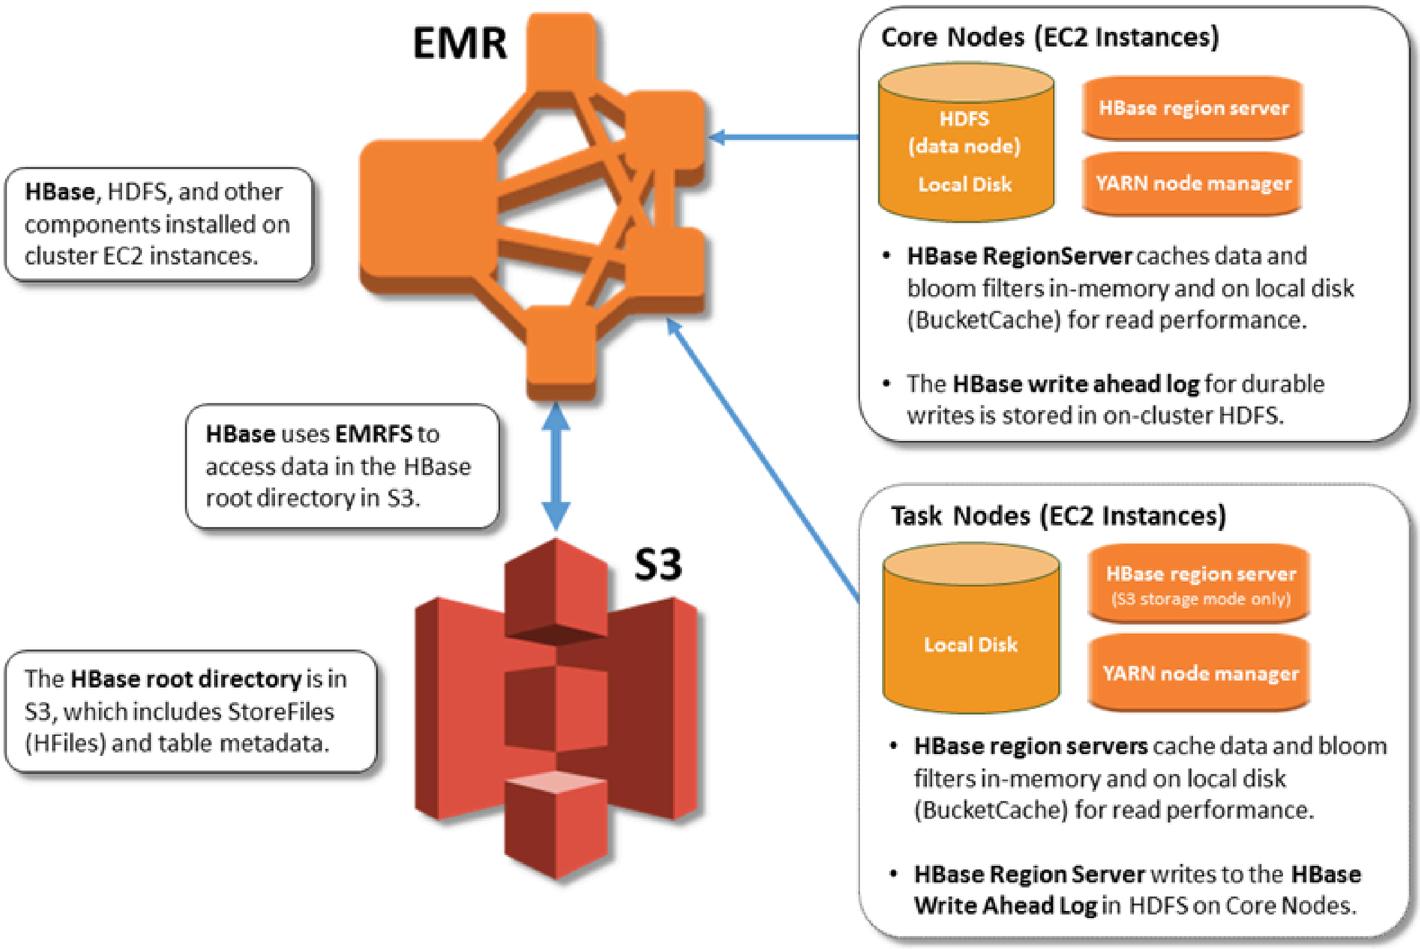
HBase on Amazon S3 (Amazon S3 storage mode)

When you run HBase on Amazon EMR version 5.2.0 or later, you can enable HBase on Amazon S3, which offers the following advantages:

- The HBase root directory is stored in Amazon S3, including HBase store files and table metadata. This data is persistent outside of the cluster, available across Amazon EC2 Availability Zones, and you don't need to recover using snapshots or other methods.

- With store files in Amazon S3, you can size your Amazon EMR cluster for your compute requirements instead of data requirements, with 3x replication in HDFS.
- Using Amazon EMR version 5.7.0 or later, you can set up a read-replica cluster, which allows you to maintain read-only copies of data in Amazon S3. You can access the data from the read-replica cluster to perform read operations simultaneously, and in the event that the primary cluster becomes unavailable.
- In Amazon EMR version 6.2.0 and later, persistent HFile Tracking uses a HBase system table called `hbase:storefile` to directly track the HFile paths used for read operations. This feature is enabled by default and does not require manual migration to be performed.

The following illustration shows the HBase components relevant to HBase on Amazon S3.



Enabling HBase on Amazon S3

You can enable HBase on Amazon S3 using the Amazon EMR console, the AWS CLI, or the Amazon EMR API. The configuration is an option during cluster creation. When you use the console, you choose the setting using **Advanced options**. When you use the AWS CLI, use the `--configurations` option to provide a JSON configuration object. Properties of the configuration object specify the storage mode and the root directory location in Amazon S3. The Amazon S3 location that you specify should be in the same region as your Amazon EMR cluster. Only one active cluster at a time can use the same HBase root directory in Amazon S3. For console steps and a detailed create-cluster example using the AWS CLI, see Creating a cluster with HBase. An example configuration object is shown in the following JSON snippet.

```
{
  "Classification": "hbase-site",
  "Properties": {
    "hbase.rootdir": "s3://my-bucket/my-hbase-rootdir"}
},
{
  "Classification": "hbase",
  "Properties": {
  "hbase.emr.storageMode":"s3"
  }
}
```

Note

If you use an Amazon S3 bucket as the `rootdir` for HBase, you must add a slash at the end of the Amazon S3 URI. For example, you must use `"hbase.rootdir: s3://my-bucket/"`, instead of `"hbase.rootdir: s3://my-bucket"`, to avoid issues.

Using a read-replica cluster

After you set up a primary cluster using HBase on Amazon S3, you can create and configure a read-replica cluster that provides read-only access to the same data as the primary cluster. This is useful when you need simultaneous access to query data or uninterrupted access if the primary cluster becomes unavailable. The read-replica feature is available with Amazon EMR version 5.7.0 and later.

The primary cluster and the read-replica cluster are set up the same way with one important difference. Both point to the same `hbase.rootdir` location. However, the `hbase` classification for the read-replica cluster includes the `"hbase.emr.readreplica.enabled":"true"` property.

For example, given the JSON classification for the primary cluster as shown earlier in the topic, the configuration for a read-replica cluster is as follows:

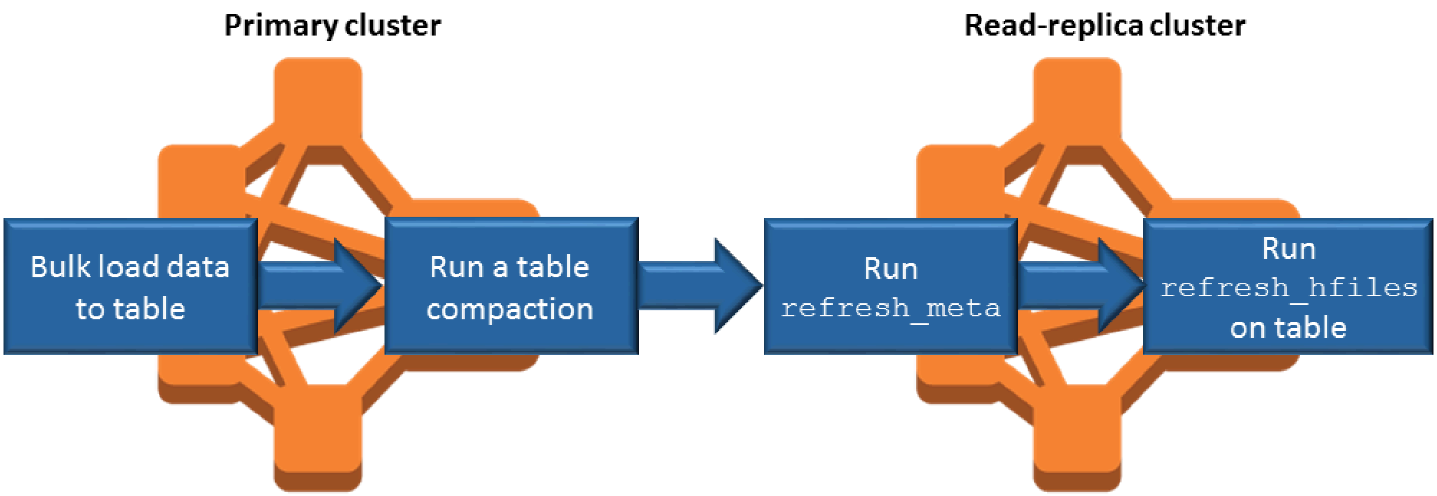
```
{
  "Classification": "hbase-site",
  "Properties": {
    "hbase.rootdir": "s3://my-bucket/my-hbase-rootdir"}
},
{
  "Classification": "hbase",
  "Properties": {
  "hbase.emr.storageMode":"s3",
  "hbase.emr.readreplica.enabled":"true"
  }
}
```

Synchronizing the read replica when you add data

Because the read-replica uses HBase StoreFiles and metadata that the primary cluster writes to Amazon S3, the read-replica is only as current as the Amazon S3 data store. The following guidance can help minimize the lag time between the primary cluster and the read-replica when you write data.

- Bulk load data on the primary cluster whenever possible. For more information, see Bulk loading in Apache HBase documentation.
- A flush that writes store files to Amazon S3 should occur as soon as possible after data is added. Either flush manually or tune flush settings to minimize lag time.
- If compactions might run automatically, run a manual compaction to avoid inconsistencies when compactions are triggered.
- On the read-replica cluster, when any metadata has changed - for example, when HBase region split or compactions occur, or when tables are added or removed - run the `refresh_meta` command.

- On the read-replica cluster, run the `refresh_hfiles` command when records are added to or changed in a table.



Persistent HFile tracking

Persistent HFile tracking uses a HBase system table called `hbase:storefile` to directly track the HFile paths used for read operations. New HFile paths are added to the table as additional data is added to HBase. This removes rename operations as a commit mechanism in the critical write path HBase operations and improves recovery time when opening a HBase region by reading from the `hbase:storefile` system table instead of filesystem directory listing. This feature is enabled by default on Amazon EMR version 6.2.0 and later, and does not require any manual migration steps.

> **Note**
>
> Persistent HFile tracking using the HBase storefile system table does not support the HBase region replication feature. For more information about HBase region replication, see [Timeline-consistent high available reads](#).

Disabling Persistent HFile Tracking

Persistent HFile tracking is enabled by default starting with Amazon EMR release 6.2.0. To disable persistent HFile tracking, specify the following configuration override when launching a cluster:

```
{
  "Classification": "hbase-site",
```

```
  "Properties": {
    "hbase.storefile.tracking.persist.enabled":"false",

 "hbase.hstore.engine.class":"org.apache.hadoop.hbase.regionserver.DefaultStoreEngine"
  }
}
```

> **Note**
>
> When reconfiguring the Amazon EMR cluster, all instance groups must be updated.

Manually Syncing the Storefile Table

The storefile table is kept up to date as new HFiles are created. However, if the storefile table becomes out of sync with the data files for any reason, the following commands can be used to manually sync the data:

Sync storefile table in an online region:

`hbase org.apache.hadoop.hbase.client.example.RefreshHFilesClient <table>`

Sync storefile table in an offline region:

- Remove the storefile table znode.

```
echo "ls /hbase/storefile/loaded" | sudo -u hbase hbase zkcli
[<tableName>, hbase:namespace]
# The TableName exists in the list
echo "delete /hbase/storefile/loaded/<tableName>" | sudo -u hbase hbase zkcli
# Delete the Table ZNode
echo "ls /hbase/storefile/loaded" | sudo -u hbase hbase zkcli
[hbase:namespace]
```

- Assign the region (run in 'hbase shell').

```
hbase cli> assign '<region name>'
```

- If the assignment fails.

```
hbase cli> disable '<table name>'
hbase cli> enable '<table name>'
```

Scaling the Storefile Table

The storefile table is split into four regions by default. If the storefile table is still under heavy write load, the table can be manually split further.

To split a specific hot region, use the following command (run in 'hbase shell').

```
hbase cli> split '<region name>'
```

To split the table, use the following command (run in 'hbase shell').

```
hbase cli> split 'hbase:storefile'
```

Operational considerations

HBase region servers use BlockCache to store data reads in memory and BucketCache to store data reads on local disk. In addition, region servers use MemStore to store data writes in-memory, and use write-ahead logs to store data writes in HDFS before the data is written to HBase StoreFiles in Amazon S3. The read performance of your cluster relates to how often a record can be retrieved from the in-memory or on-disk caches. A cache miss results in the record being read from the StoreFile in Amazon S3, which has significantly higher latency and higher standard deviation than reading from HDFS. In addition, the maximum request rates for Amazon S3 are lower than what can be achieved from the local cache, so caching data may be important for read-heavy workloads. For more information about Amazon S3 performance, see Performance optimization in the *Amazon Simple Storage Service User Guide*.

To improve performance, we recommend that you cache as much of your dataset as possible in EC2 instance storage. Because the BucketCache uses the region server's EC2 instance storage, you can choose an EC2 instance type with a sufficient instance store and add Amazon EBS storage to accommodate the required cache size. You can also increase the BucketCache size on attached instance stores and EBS volumes using the `hbase.bucketcache.size` property. The default setting is 8,192 MB.

For writes, the frequency of MemStore flushes and the number of StoreFiles present during minor and major compactions can contribute significantly to an increase in region server response times. For optimal performance, consider increasing the size of the MemStore flush and HRegion block multiplier, which increases the elapsed time between major compactions, but also increases the lag in consistency if you use a read-replica. In some cases, you may get better performance using larger file block sizes (but less than 5 GB) to trigger Amazon S3 multipart upload functionality in

EMRFS. Amazon EMR's block size default 128 MB. For more information, see HDFS configuration. We rarely see customers who exceed 1 GB block size while benchmarking performance with flushes and compactions. Additionally, HBase compactions and region servers perform optimally when fewer StoreFiles need to be compacted.

Tables can take a significant amount of time to drop on Amazon S3 because large directories need to be renamed. Consider disabling tables instead of dropping.

There is an HBase cleaner process that cleans up old WAL files and store files. With Amazon EMR release version 5.17.0 and later, the cleaner is enabled globally, and the following configuration properties can be used to control cleaner behavior.

Configuration property	Default value	Description
`hbase.regionserver.hfilecleaner.large.thread.count`	1	The number of threads allocated to clean expired large HFiles.
`hbase.regionserver.hfilecleaner.small.thread.count`	1	The number of threads allocated to clean expired small HFiles.
`hbase.cleaner.scan.dir.concurrent.size`	Set to one quarter of all available cores.	The number of threads to scan the oldWALs directories.
`hbase.oldwals.cleaner.thread.size`	2	The number of threads to clean the WALs under the oldWALs directory.

With Amazon EMR 5.17.0 and earlier, the cleaner operation can affect query performance when running heavy workloads, so we recommend that you enable the cleaner only during off-peak times. The cleaner has the following HBase shell commands:

- `cleaner_chore_enabled` queries whether the cleaner is enabled.

- `cleaner_chore_run` manually runs the cleaner to remove files.
- `cleaner_chore_switch` enables or disables the cleaner and returns the previous state of the cleaner. For example, `cleaner_chore_switch true` enables the cleaner.

Properties for HBase on Amazon S3 performance tuning

The following parameters can be adjusted to tune the performance of your workload when you use HBase on Amazon S3.

Configuration property	Default value	Description
`hbase.bucketcache.size`	8,192	The amount of disk space, in MB, reserved on region server Amazon EC2 instance stores and EBS volumes for BucketCache storage. The setting applies to all region server instances. Larger BucketCache sizes generally correspond to improved performance
`hbase.hregion.memstore.flush.size`	134217728	The data limit, in bytes, at which a memstore flush to Amazon S3 is triggered.
`hbase.hregion.memstore.block.multiplier`	4	A multiplier that determines the MemStore upper limit at which updates are blocked. If the MemStore exceeds `hbase.hregion.memstore.flush.size` multiplied by this value, updates are blocked. MemStore flushes and compaction may happen to unblock updates.

Configuration property	Default value	Description
`hbase.hstore.blockingStoreFiles`	10	The maximum number of StoreFiles that can exist in a store before updates are blocked.
`hbase.hregion.max.filesize`	10737418240	The maximum size of a region before the region is split.

Shutting down and restoring a cluster without data loss

To shut down an Amazon EMR cluster without losing data that hasn't been written to Amazon S3, you should flush your MemStore cache to Amazon S3 to write new store files. First, you'll need to disable all tables. The following step configuration can be used when you add a step to the cluster. For more information, see Work with steps using the AWS CLI and console in the *Amazon EMR Management Guide*.

```
Name="Disable all tables",Jar="command-runner.jar",Args=["/bin/bash","/usr/lib/hbase/
bin/disable_all_tables.sh"]
```

Alternatively, you can run the following bash command directly.

```
bash /usr/lib/hbase/bin/disable_all_tables.sh
```

After disabling all tables, flush the `hbase:meta` table using the HBase shell and the following command.

```
flush 'hbase:meta'
```

Then, you can run a shell script provided on the Amazon EMR cluster to flush the MemStore cache. You can either add it as a step or run it directly using the on-cluster AWS CLI. The script disables all HBase tables, which causes the MemStore in each region server to flush to Amazon S3. If the script completes successfully, the data persists in Amazon S3 and the cluster can be terminated.

To restart a cluster with the same HBase data, specify the same Amazon S3 location as the previous cluster either in the AWS Management Console or using the `hbase.rootdir` configuration property.

Write-ahead logs (WAL) for Amazon EMR

With Amazon EMR 6.15 and higher, you can write your Apache HBase write-ahead logs (WAL) to the Amazon EMR WAL. With lower Amazon EMR releases, when you create a cluster with the **HBase on Amazon S3** option, WAL is the only Apache HBase component that gets stored in the local disk for clusters, and you can store other components such as the root directory, store files (HFiles), table metadata, and data on Amazon S3.

You can use Amazon EMR WAL to recover data that didn't flush to Amazon S3. To fully back up your HBase clusters, opt in to use the Amazon EMR WAL service. Behind the scenes, `RegionServer` writes your HBase write-ahead logs (WAL) to the WAL for Amazon EMR.

In the event that your cluster or the AZ becomes unhealthy or unavailable, you can create a new cluster, point it to the same S3 root directory and Amazon EMR WAL workspace, and automatically recover the data in WAL within a few minutes. For more information, see Restoring from Amazon EMR WAL.

> **Note**
>
> Amazon EMR retains your write-ahead log and its data for 30 days from the time you create your cluster. After 30 days, Amazon EMR automatically deletes your Amazon EMR WAL and its data. However, if you launch a new WAL-enabled cluster from the same S3 root directory, you can extend the use of your WAL for 30 days from the launch time of the new cluster. Amazon EMR will still clean up any WAL data from the first cluster after the initial 30-day period. For more information, see Restoring from Amazon EMR WAL.

The following sections describe how to set up and use Amazon EMR WAL with your HBase-enabled EMR cluster.

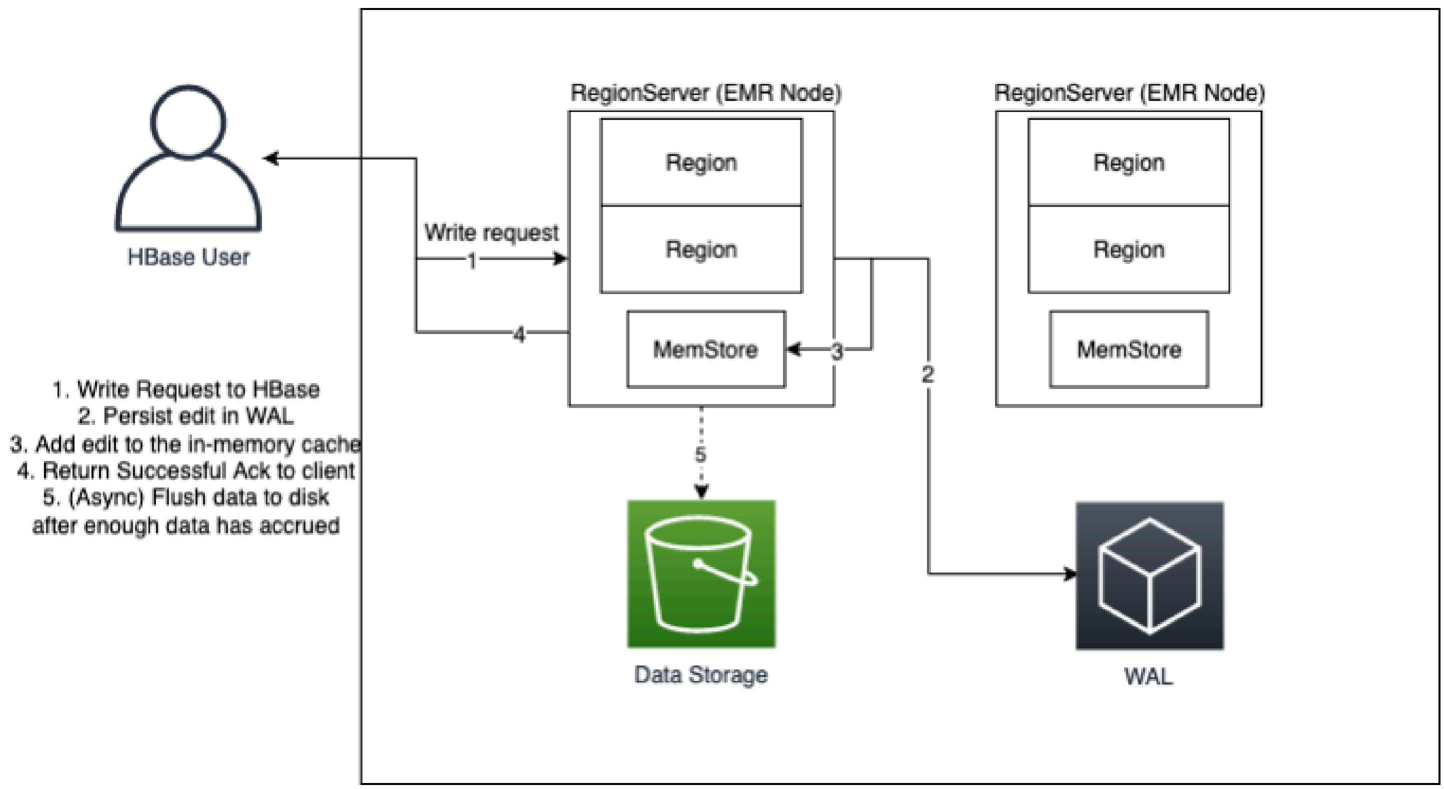
Topics

- Access Amazon EMR WAL through AWS PrivateLink
- Understanding Amazon EMR WAL pricing and metrics
- Tagging WAL workspaces
- Considerations and Regions for Amazon EMR WAL
- Amazon EMR WAL (EMRWAL) CLI reference

Amazon EMR WAL workspaces

Amazon EMR WAL adds the concept of WAL workspaces. A *WAL workspace* is a logical container of WALs. Each write-ahead log in Amazon EMR WAL is encapsulated by a WAL workspace. An EMR cluster writes WALs to exactly one WAL workspace that you configure at cluster launch, or to the `defaultWALworkspace` if you don't specify a workspace. WAL workspaces are not related to any existing HBase terminologies such as namespaces.

You can use WAL workspaces to scope down Amazon EMR WAL IAM permissions to only include the workspaces that the cluster needs to access. You can also tag your WAL workspace for tag-based access control. For more information on tagging, see Tagging WAL workspaces.



Required permissions for Amazon EMR WAL

For your cluster to connect to Amazon EMR WAL, the instance profile for the cluster requires certain IAM permissions:

- Amazon EMR WAL uses the AWSServiceRoleForEMRWAL service-linked role to retrieve a cluster status. Amazon EMR automatically creates this service-linked role when you create a WAL workspace, or HBase will create the service-linked role when you configure a workspace for Amazon EMR WAL and the service-linked role doesn't yet exist.

  Before you can enable Amazon EMR WAL for a cluster, you must configure the permissions to allow automatic creation of the AWSServiceRoleForEMRWAL service-linked role. For more information and an example statement that adds this capability, see Using service-linked roles for write-ahead logging.
- Because Amazon EMR WAL uses HBase Write Ahead Log (WAL), your clusters must use HBase WAL. The following are the minimum IAM permissions that you need to run HBase. Add these to the permissions policy for your instance profile:

```
emrwal:DeleteWal
emrwal:CreateWal
emrwal:CreateWorkspace
emrwal:AppendEdit
emrwal:ReplayEdits
emrwal:GetCurrentWalTime
emrwal:CompleteWalFlush
```

> **Note**
>
> If you scope permissions for Amazon EMR WAL to only the minimal set, some EMRWAL CLI commands won't have the necessary permissions to run.

Enabling Amazon EMR WAL

Use the following steps to enable writing to the Amazon EMR WAL when you create a cluster with the AWS Command Line Interface.

Note

You can't enable Amazon EMR WAL for a cluster that is already running, and you can't launch two clusters with the same S3 root directory. For more information, see Considerations and Regions for Amazon EMR WAL.

1. Before you can create an Amazon EMR WAL enabled cluster, you must add the required permissions to the instance profile that you plan to use with your cluster. For more information, see Required permissions for Amazon EMR WAL.
2. Create a cluster from the AWS CLI. Use the `--configurations` option to provide a JSON configuration object that specifies the `hbase.emr.wal.enabled` property, as shown in the example below.
   - Specify the storage mode and the root directory location in Amazon S3. The Amazon S3 location that you specify should be in the same Region as your EMR cluster, but only one active cluster can use the same HBase root directory in S3 at a time.
   - Create your cluster with the instance groups configuration. You can't use Amazon EMR WAL with the instance fleets configuration. For more information on creating clusters with instance groups, see Configure uniform instance groups in the *Amazon EMR Management Guide*.
   - For console steps to create a cluster, and a detailed `create-cluster` example that uses the AWS CLI, see Creating a cluster with HBase.
3. To enable WAL for the new cluster, set the `hbase.emr.wal.enabled` property to `true`. The following command contains a JSON snippet with an example configuration object.

```
aws emr create-cluster --name "hbasewal" --release-label emr-6.x.y \
--applications Name=HBase --use-default-roles --ec2-attributes KeyName=myKey \
--instance-type m6i.xlarge --instance-count 1 --configurations hbase.json
$cat hbase.json
[
    {
        "Classification": "hbase-site",
        "Properties": {
            "hbase.rootdir": "s3://MyBucket/MyHBaseStore"
        }
    },
    {
```

```
        "Classification": "hbase",
        "Properties": {
            "hbase.emr.storageMode": "s3",
            "hbase.emr.wal.enabled": "true"
        }
    }
]
```

When HBase is online on the newly created cluster, HBase will automatically write WAL data to the Amazon EMR WAL and use the Amazon EMR WAL for recovery purposes.

Example 1: Creating an EMR cluster that uses Amazon EMR WAL

```
[
    {
        "Classification": "hbase-site",
        "Properties": {
            "hbase.rootdir": "s3://MyBucket/MyHBaseStore"
        }
    },
    {
        "Classification": "hbase",
        "Properties": {
            "hbase.emr.storageMode": "s3",
            "hbase.emr.wal.enabled": "true"
        }
    }
]
```

Example 2: Creating an EMR cluster with a custom WAL workspace

```
[
    {
        "Classification": "hbase-site",
        "Properties": {
            "hbase.rootdir": "s3://MyBucket/MyHBaseStore",
            "emr.wal.workspace": "customWorkspaceName"
        }
    },
    {
        "Classification": "hbase",
        "Properties": {
```

```
            "hbase.emr.storageMode": "s3",
            "hbase.emr.wal.enabled": "true"
        }
    }
]
```

Restoring from Amazon EMR WAL

Because the Amazon EMR WAL for your original cluster is retained for 30 days, you can restore and reuse the WAL for a newly-created cluster within that 30-day period. When you launch a new cluster from the same S3 root directory, the 30-day clock restarts from the launch time of the new cluster, as long as the prior 30-day period hasn't expired.

Use the following procedure to restore an existing WAL with a new cluster. This process assumes that you created your original cluster with Amazon EMR WAL enabled.

1. Within 30 days of creating a WAL-enabled cluster, create a new cluster in the same AWS Region as the original cluster. The new cluster can be in the same AZ or in a different AZ within the same Region that the original cluster was created.

   Configure the object properties to specify the storage mode and the root directory location in Amazon S3. The Amazon S3 location that you specify should be in the same Region as your EMR cluster, but only one active cluster can use the same HBase root directory in S3 at a time.

   For console steps to create a cluster, and a detailed `create-cluster` example that uses the AWS CLI, see Creating a cluster with HBase.
2. To use the existing Amazon EMR WAL for the new cluster, set the `hbase.emr.wal.enabled` property to `true`. The following JSON snippet shows an example configuration object.

```
[
    {
        "Classification": "hbase-site",
        "Properties": {
            "hbase.rootdir": "s3://MyBucket/MyHBaseStore"
        }
    },
    {
        "Classification": "hbase",
        "Properties": {
            "hbase.emr.storageMode": "s3",
```

```
            "hbase.emr.wal.enabled": "true"
        }
    }
]
```

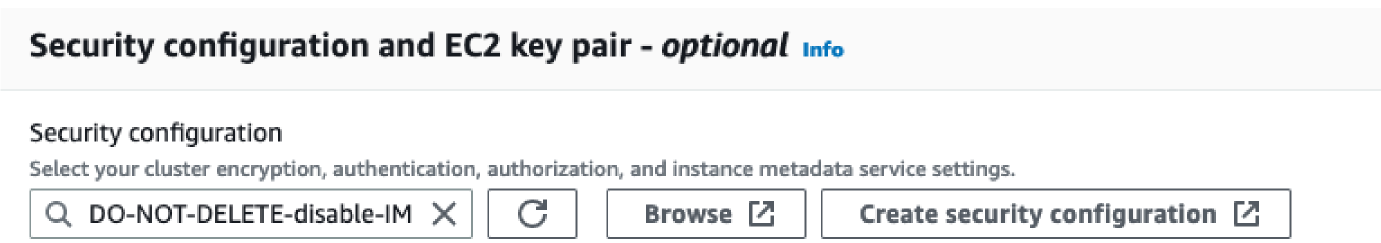
Using security configurations with Amazon EMR WAL

Amazon EMR automatically encrypts both data in transit between your cluster and Amazon EMR WAL service, and the data at rest in Amazon EMR WAL. For more information, see Encryption at rest for Amazon EMR WAL. You can also use a security configuration to bring your own keys from AWS Key Management Service (KMS) service and encrypt the data that you store in Amazon EMR WAL.

Use one of the following methods to select a security configuration when you create a cluster:

Console

From the AWS Management Console, specify the configuration under **Security configuration and EC2 key pair**.



CLI

From the AWS CLI, set the `--security-configuration` parameter when you use the create-cluster command.

For more information, see Encryption at rest for Amazon EMR WAL and Use security configurations to set up cluster security in the *Amazon EMR Management Guide*.

For more security-related information about WAL, see Using service-linked roles for write-ahead logging.

Access Amazon EMR WAL through AWS PrivateLink

If you want to keep your connection within the AWS network, Amazon EMR WAL offers AWS PrivateLink support. To set up AWS PrivateLink, use the AWS Management Console or AWS

Command Line Interface (AWS CLI) to create an interface VPC endpoint that connects to Amazon EMR WAL. For more information, see [Access an AWS service using an interface VPC endpoint](#) in the *AWS PrivateLink Guide*.

The basic steps are as follows:

1. Use the Amazon VPC Console to [create a VPC endpoint](#). Select **Endpoints** and then **Create endpoint**.
2. Keep the Service category as **AWS services**.
3. In the search bar for the **Services** panel, type **`emrwal`**, and then select the service labeled `com.amazonaws.region.emrwal.prod`.
4. Select your VPC and save the endpoint. Make sure that you attach the same security groups to the VPC endpoint that you attach to the EMR cluster.
5. If you want to, you can now enable private DNS hostnames for your new endpoint. Set **Enable DNS hostnames** and **Enable DNS Support** to `true` for your VPC. Then, select your endpoint ID, choose **Edit VPC settings** from the **Actions** menu, and enable private DNS names.
   - The private DNS hostnames for the endpoint will follow the format `prod.emrwal.region.amazonaws.com`.
   - If you don't enable private DNS hostnames, Amazon VPC provides a DNS endpoint name for you in the format `endpointID.prod.emrwal.region.vpce.amazonaws.com`.
6. To use your AWS PrivateLink endpoint, modify the `emr.wal.client.endpoint` configuration when you create your [Amazon EMR WAL enabled cluster](#) as shown in the following example:

```
[
    {
        "Classification": "hbase-site",
        "Properties": {
            "hbase.rootdir": "s3://MyBucket/MyHBaseStore",
            "emr.wal.workspace": "customWorkspaceName",
            "emr.wal.client.endpoint": "https://prod.emrwal.region.amazonaws.com"
        }
    },
    {
        "Classification": "hbase",
        "Properties": {
            "hbase.emr.storageMode": "s3",
            "hbase.emr.wal.enabled": "true"
```

```
        }
    }
]
```

You can also use VPCE policy to allow or restrict access to the Amazon EMR WAL APIs. For more information, see [Control access to VPC endpoints using endpoint policies](#) in the *AWS PrivateLink Guide*.

Understanding Amazon EMR WAL pricing and metrics

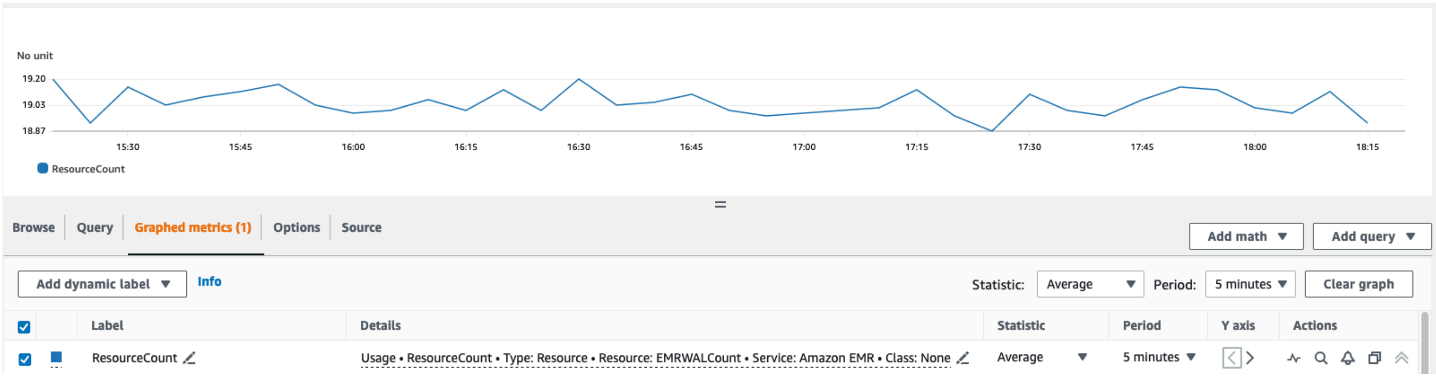
Core feature billing unit	Details
EMR-WAL-Read-GiB	API calls to read data from your table are billed as ReadRequestGiB. This includes `Get and Scan` operations. Reads are charged based on the sizes of the read items. Amazon EMR bills at a minimum of 1 byte. For example, if you read a 1234.12 bytes item, you're charged for 1235 bytes. Reads are aggregated every hour for billing and shown as GiBs.
EMR-WAL-Write-GiB	API calls to write data from your table are billed as Write-GiB. This includes `Put` operations. Writes are charged based on the sizes of the written items. Amazon EMR bills at a minimum of 1 byte. For example, if you write a 1234.12 bytes item, you're charged for 1235 bytes. Writes are aggregated every hour for billing and shown as GiBs.

EMR-WAL-WALHours	The number of WALs that you store on the service are billed as `EMR-WAL-WALHours` . Amazon EMR creates one WAL per HBase Region. For example, if you create 20 HBase tables including system tables, and each table has two HBase Regions, then you use 28,800 WAL hours, calculated as:
	`  20 tables`
	`x  2 Regions per table`
	`x  1 WAL per Region`

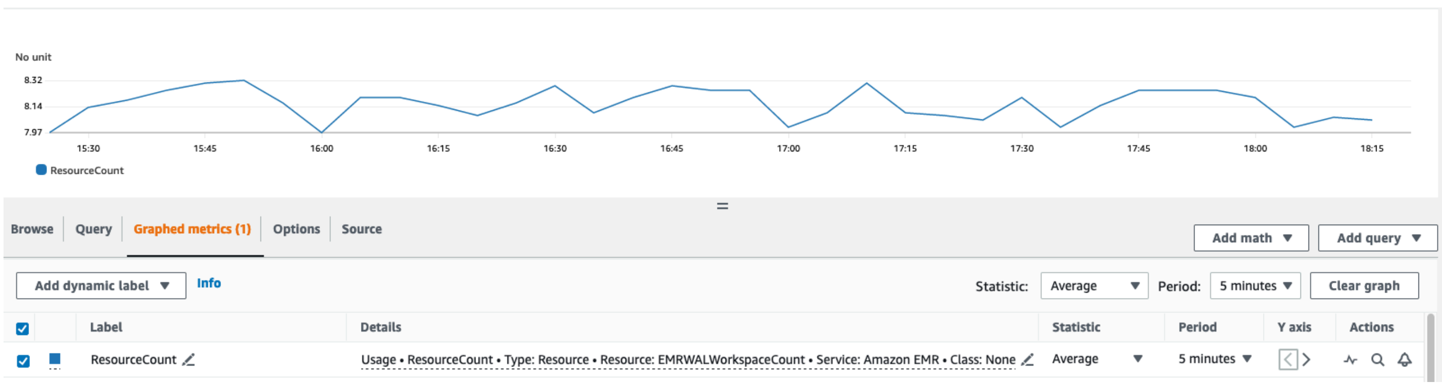
Core feature billing unit	Details

	`x 30 days`
	`x 24 hours`
	`-----------`
	`28,800 EMR-WAL-WALHours`

Example EMRWALCount:



Example EMRWALWorkspaceCount:



Tagging WAL workspaces

You can add tags to a workspace when you create a new workspace and you can add, remove, or list tags from an active workspace for a running cluster. You can't tag the individual resources in the workspace, and you can't update existing tags; instead, remove unwanted tags from the workspace and replace them.

You can tag workspaces from the EMRWAL CLI. For a list of EMRWAL CLI commands for tagging workspaces, see Amazon EMR WAL (EMRWAL) CLI reference.

The following example IAM policy illustrates a scenario that allows workspace CRUDL operations only with the proper tagging key `resource_tag_allow_test_key` and value `resource_tag_allow_test_value`:

```
{
  "Version": "2012-10-17",
  "Statement": [
      {
          "Action": [
              "EMRWAL:*"
          ],
          "Effect": "Allow",
          "Resource": [
              "*",
              "*"
          ],
          "Condition": {
              "StringEquals": {
                  "aws:ResourceTag/resource_tag_allow_test_key": [
                      "resource_tag_allow_test_value"
                  ]
              }
          }
      }
  ]
}
```

To verify that the tag is now required for workspace operations, use the Amazon EMR WAL (EMRWAL) CLI reference to call the `listTagsForResource` command on `tagAllowResourceTag` for the workspace with the desired resource tag. If you configured the condition correctly, the command will succeed.

```
emrwal listTagsForResource -r us-east-1 -arn arn:aws:emrwal:us-east-1:arn:workspace/
tagAllowResourceTag
Tag(Key=resource_tag_allow_test_key, Value=resource_tag_allow_test_value)
```

Considerations and Regions for Amazon EMR WAL

Considerations for Amazon EMR WAL

The following list describes important considerations and limitations of Amazon EMR WAL:

- Amazon EMR WAL is available to use with Amazon EMR releases 6.15.0 and higher.
- Amazon EMR WAL is an opt-in, paid service. You pay for what you use: reads, writes, and data storage. For more information, see Understanding Amazon EMR WAL pricing and metrics and the Amazon EMR pricing page.
- Amazon EMR WAL uses HBase Write Ahead Log (WAL). To use Amazon EMR WAL, your clusters must use HBase WAL.
- To enable Amazon EMR WAL when you create a cluster, you must have the required role permissions. For more information, see Using service-linked roles for write-ahead logging.
- You must enable Amazon EMR WAL when you create the cluster with the AWS Management Console, AWS CLI, or API, and you must use the *instance groups* configuration. You can't enable Amazon EMR WAL in a running cluster if you didn't create the cluster with Amazon EMR WAL. You also can't edit the `hbase-site` configurations to enable Amazon EMR WAL in a running cluster.
- You can only enable Amazon EMR WAL on clusters that use Amazon S3 for the root directory.
- You can't have multiple active clusters on the same HBase root directory in Amazon S3.
- You can't enable Amazon EMR WAL on read replica clusters.
- WAL is replicated across Availability Zones inside the managed service.
- WAL outlives the the cluster, and remains available for the next cluster.
- You can't disable Amazon EMR WAL during launch or when your cluster is operational (in a running state).
- For information on WAL and workspace limits, see Amazon EMR endpoints and quotas.

Region availability for Amazon EMR WAL

Amazon EMR WAL service is available in the following AWS Regions:

- `ap-northeast-1` – Asia Pacific (Tokyo)
- `ap-southeast-1` – Asia Pacific (Singapore)
- `ap-south-1` – Asia Pacific (Mumbai)
- `ap-southeast-2` – Asia Pacific (Sydney)
- `eu-central-1` – Europe (Frankfurt)
- `eu-north-1` – Europe (Stockholm)
- `eu-west-1` – Europe (Ireland)

- `us-east-1` – US East (N. Virginia)
- `us-east-2` – US East (Ohio)
- `us-west-2` – US West (Oregon)
- `ap-northeast-2` – Asia Pacific (Seoul)

Amazon EMR WAL (EMRWAL) CLI reference

The *EMRWAL Command Line Interface (EMRWAL CLI)* is a unified tool to manage your write-ahead log (WAL) for Amazon EMR. The EMRWAL CLI ships with EMR clusters when you enable WAL at the time that you create a cluster. For more information about enabling WAL, see Write-ahead logs (WAL) for Amazon EMR.

The EMRWAL CLI includes the following commands:

Topics

`createWorkspace`

The `createWorkspace` command creates a new Amazon EMR WAL workspace.

Usage:

```
emrwal createWorkspace [-tags <tags>] [-e {endpoint}] [-r {Region}] -w {workspacename}
 [-h]
```

Example:

```
emrwal createWorkspace -w examplews
```

deleteWal

The deleteWals command deletes the Amazon EMR WAL that you specify.

Usage:

```
emrwal deleteWal [-e {endpoint}] [-r {Region}] [-w {workspacename}] [-p <tablePrefix>]
 [-n <walName>] [-N <fullName>] [-R] [-m] [-h]
```

Example:

```
emrwal deleteWal -w examplews -p hbasetable -n examplewal
```

deleteWorkspace

The deleteWorkspace command deletes the Amazon EMR WAL workspace that you specify.

Usage:

```
emrwal deleteWorkspace [-e {endpoint}] [-r {Region}] -w {workspacename} [-h]
```

Example:

```
emrwal deleteWorkspace -w examplews
```

listTagsForResource

The listTagsForResource command lists all of the key-value pair tags for the Amazon EMR WAL workspace that you specify.

Usage:

```
emrwal listTagsForResource -arn {resource-arn} [-e {endpoint}] [-r {Region}] [-h]
```

Example:

```
emrwal listTagsForResource -arn arn:aws:emrwal::1234567891234:workspace/examplews
```

listWals

The `listWals` command lists all of the Amazon EMR WALs in the workspace that you specify.

Usage:

```
emrwal listWals [-nextToken {token-string}] [-pageSize {integer}] [-e {endpoint}] [-
r {Region}] [-w {workspacename}] [-p <tablePrefix>] [-M {integer}] [-h]
```

Example:

```
emrwal listWals -w examplews
```

listWorkspaces

The `listWorkspaces` command lists all of the Amazon EMR WAL workspaces that are available to you.

Usage:

```
emrwal listWorkspaces [-nextToken {token-string}] [-pageSize {integer}] [-e {endpoint}]
 [-r {Region}] [-M {integer}] [-h]
```

Example:

```
emrwal listWorkspaces
```

tagResource

The `tagResource` command assigns one or more key-value pair tags to the Amazon EMR WAL workspace that you specify.

Usage:

```
emrwal tagResource -arn {resource-arn} -tags <tags> [-e {endpoint}] [-r {Region}] [-h]
```

Example:

```
emrwal tagResource -arn arn:aws:emrwal::1234567891234:workspace/examplews -
tags tag_key=tag_value
```

untagResource

The `untagResource` command unassigns one or more key-value pair tags to the Amazon EMR WAL workspace that you specify.

Usage:

```
emrwal untagResource -arn {resource-arn} -tagKeys <tagKeys> [-e {endpoint}] [-
r {Region}] [-h]
```

Example:

```
emrwal untagResource -arn arn:aws:emrwal::1234567891234:workspace/examplews -
tagKeys tag_key
```

Using the HBase shell

After you create an HBase cluster, the next step is to connect to HBase so you can begin reading and writing data (data writes are not supported on a read-replica cluster). You can use the HBase shell to test commands.

To open the HBase shell

1. Use SSH to connect to the main server in the HBase cluster. For information about how to connect to the Amazon EMR primary node using SSH, see Connect to the primary node using SSH in the *Amazon EMR Management Guide*.
2. Run `hbase shell`. The HBase shell opens with a prompt similar to the following.

   ```
   hbase(main):001:0>
   ```

You can issue HBase shell commands from the prompt. For more information about the shell commands and how to call them, type help at the HBase prompt and press Enter.

Create a table

The following command creates a table named 't1' that has a single column family named 'f1'.

```
hbase(main):001:0>create 't1', 'f1'
```

Put a value

The following command puts value 'v1' for row 'r1' in table 't1' and column 'f1'.

```
hbase(main):001:0>put 't1', 'r1', 'f1:col1', 'v1'
```

Get a value

The following command gets the values for row 'r1' in table 't1'.

```
hbase(main):001:0>get 't1', 'r1'
```

Delete a table

The following command drops and deletes table 't1'.

```
hbase(main):001:0>drop 'ns1:t1',false
```

The boolean value corresponds to whether or not you want to archive your table, so you can set it to `true` if you want to save it. You can also run `drop 'ns1:t1'` with no boolean to archive the table.

Access HBase tables with Hive

HBase and Apache Hive are tightly integrated, allowing you run massively parallel processing workloads directly on data stored in HBase. To use Hive with HBase, you can usually launch them on the same cluster. You can, however, launch Hive and HBase on separate clusters. Running HBase and Hive separately on different clusters can improve performance because this allows each application to use cluster resources more efficiently.

The following procedures show how to connect to HBase on a cluster using Hive.

Note

You can only connect a Hive cluster to a single HBase cluster.

To connect Hive to HBase

1. Create separate clusters with Hive and HBase installed or create a single cluster with both HBase and Hive installed.
2. If you are using separate clusters, modify your security groups so that HBase and Hive ports are open between these two primary nodes.
3. Use SSH to connect to the primary node for the cluster with Hive installed. For more information, see Connect to the primary node using SSH in the *Amazon EMR Management Guide*.
4. Launch the Hive shell with the following command.

```
hive
```

5. (Optional) You do not need to do this if HBase and Hive are located on the same cluster. Connect the HBase client on your Hive cluster to the HBase cluster that contains your data. In the following example, *public-DNS-name* is replaced by the public DNS name of the primary node of the HBase cluster, for example: `ec2-50-19-76-67.compute-1.amazonaws.com`.

```
set hbase.zookeeper.quorum=public-DNS-name;
```

6. Proceed to run Hive queries on your HBase data as desired or see the next procedure.

To access HBase data from Hive

- After the connection between the Hive and HBase clusters has been made (as shown in the previous procedure), you can access the data stored on the HBase cluster by creating an external table in Hive.

  The following example, when run from the Hive prompt on the primary node, creates an external table that references data stored in an HBase table called `inputTable`. You can then reference `inputTable` in Hive statements to query and modify data stored in the HBase cluster.

```
set hbase.zookeeper.quorum=ec2-107-21-163-157.compute-1.amazonaws.com;

create external table inputTable (key string, value string)
     stored by 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
      with serdeproperties ("hbase.columns.mapping" = ":key,f1:col1")
      tblproperties ("hbase.table.name" = "t1");

select count(key) from inputTable ;
```

For a more advanced use case and example combining HBase and Hive, see the AWS Big Data Blog post, Combine NoSQL and massively parallel analytics using Apache HBase and Apache Hive on Amazon EMR.

Using HBase snapshots

HBase uses a built-in snapshot functionality to create lightweight backups of tables. In EMR clusters, these backups can be exported to Amazon S3 using EMRFS. You can create a snapshot on the primary node using the HBase shell. This topic shows you how to run these commands interactively with the shell or through a step using `command-runner.jar` with either the AWS CLI or AWS SDK for Java. For more information about other types of HBase backups, see HBase backup in the HBase documentation.

Create a snapshot using a table

```
hbase snapshot create -n snapshotName -t tableName
```

Using command-runner.jar from the AWS CLI:

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps Name="HBase Shell Step",Jar="command-runner.jar",\
Args=[ "hbase", "snapshot", "create","-n","snapshotName","-t","tableName"]
```

AWS SDK for Java

```
HadoopJarStepConfig hbaseSnapshotConf = new HadoopJarStepConfig()
  .withJar("command-runner.jar")
  .withArgs("hbase","snapshot","create","-n","snapshotName","-t","tableName");
```

Note

If your snapshot name is not unique, the create operation fails with a return code of -1 or 255 but you may not see an error message that states what went wrong. To use the same snapshot name, delete it and then re-create it.

Delete a snapshot

```
hbase shell
>> delete_snapshot 'snapshotName'
```

View snapshot info

```
hbase snapshot info -snapshot snapshotName
```

Export a snapshot to Amazon S3

Important

If you do not specify a `-mappers` value when exporting a snapshot, HBase uses an arbitrary calculation to determine the number of mappers. This value can be very large depending on your table size, which negatively affects running jobs during the export. For this reason, we recommend that you specify the `-mappers` parameter, the `-bandwidth` parameter (which specifies the bandwidth consumption in megabytes per second), or both to limit the cluster resources used by the export operation. Alternatively, you can run the export snapshot operation during a period of low usage.

```
hbase snapshot export -snapshot snapshotName \
-copy-to s3://bucketName/folder -mappers 2
```

Using command-runner.jar from the AWS CLI:

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps Name="HBase Shell Step",Jar="command-runner.jar",\
Args=[ "hbase", "snapshot", "export","-snapshot","snapshotName","-copy-
to","s3://bucketName/folder","-mappers","2","-bandwidth","50"]
```

AWS SDK for Java:

```
HadoopJarStepConfig hbaseImportSnapshotConf = new HadoopJarStepConfig()
  .withJar("command-runner.jar")
  .withArgs("hbase","snapshot","export",
      "-snapshot","snapshotName","-copy-to",
      "s3://bucketName/folder",
      "-mappers","2","-bandwidth","50");
```

Import snapshot from Amazon S3

Although this is an import, the HBase option used here is still export.

```
sudo -u hbase hbase snapshot export \
-D hbase.rootdir=s3://bucketName/folder \
-snapshot snapshotName \
-copy-to hdfs://masterPublicDNSName:8020/user/hbase \
-mappers 2
```

Using command-runner.jar from the AWS CLI:

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps Name="HBase Shell Step",Jar="command-runner.jar", \
Args=["sudo","-u","hbase","hbase snapshot export","-snapshot","snapshotName", \
"-D","hbase.rootdir=s3://bucketName/folder", \
"-copy-to","hdfs://masterPublicDNSName:8020/user/hbase","-mappers","2","-chmod","700"]
```

AWS SDK for Java:

```
HadoopJarStepConfig hbaseImportSnapshotConf = new HadoopJarStepConfig()
  .withJar("command-runner.jar")
  .withArgs("sudo","-u","hbase","hbase","snapshot","export", "-D","hbase.rootdir=s3://
path/to/snapshot",
      "-snapshot","snapshotName","-copy-to",
```

```
    "hdfs://masterPublicDNSName:8020/user/hbase",
    "-mappers","2","-chuser","hbase");
```

Restore a table from snapshots within the HBase shell

```
hbase shell
>> disable tableName
>> restore_snapshot snapshotName
>> enable tableName
```

HBase currently does not support all snapshot commands found in the HBase shell. For example, there is no HBase command-line option to restore a snapshot, so you must restore it within a shell. This means that `command-runner.jar` must run a Bash command.

Note

Because the command used here is `echo`, it is possible that your shell command will still fail even if the command run by Amazon EMR returns a `0` exit code. Check the step logs if you choose to run a shell command as a step.

```
echo 'disable tableName; \
restore_snapshot snapshotName; \
enable tableName' | hbase shell
```

Here is the step using the AWS CLI. First, create the following `snapshot.json` file:

```
[
  {
    "Name": "restore",
    "Args": ["bash", "-c", "echo $'disable \"tableName\"; restore_snapshot
 \"snapshotName\"; enable \"tableName\"' | hbase shell"],
    "Jar": "command-runner.jar",
    "ActionOnFailure": "CONTINUE",
    "Type": "CUSTOM_JAR"
  }
]
```

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
```

```
--steps file://./snapshot.json
```

AWS SDK for Java:

```
HadoopJarStepConfig hbaseRestoreSnapshotConf = new HadoopJarStepConfig()
  .withJar("command-runner.jar")
  .withArgs("bash","-c","echo $'disable \"tableName\"; restore_snapshot \"snapshotName
\"; enable \"snapshotName\"' | hbase shell");
```

Configure HBase

Although the default HBase settings should work for most applications, you can modify your HBase configuration settings. To do this, use properties of HBase configuration classifications. For more information, see Configure applications.

The following example creates a cluster with an alternate HBase root directory based on a configuration file, `myConfig.json`, stored in Amazon S3.

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=HBase \
--instance-type m5.xlarge --instance-count 3 --configurations https://s3.amazonaws.com/
mybucket/myfolder/myConfig.json
```

The `myConfig.json` file specifies the `hbase.rootdir` property for the `hbase-site` configuration classification as shown in the following example. Replace *`ip-XXX-XX-XX-XXX.ec2.internal`* with the internal DNS hostname of the cluster's primary node.

```
[
  {
    "Classification":"hbase-site",
    "Properties": {
       "hbase.rootdir": "hdfs://ip-XXX-XX-XX-XXX.ec2.internal:8020/user/
myCustomHBaseDir"
```

```
      }
    }
]
```

Note

With Amazon EMR version 5.21.0 and later, you can override cluster configurations and specify additional configuration classifications for each instance group in a running cluster. You do this by using the Amazon EMR console, the AWS Command Line Interface (AWS CLI), or the AWS SDK. For more information, see [Supplying a Configuration for an Instance Group in a Running Cluster](#).

Changes to memory allocation in YARN

HBase is not running as a YARN application, thus it is necessary to recalculate the memory allocated to YARN and its applications, which results in a reduction in overall memory available to YARN if HBase is installed. You should take this into account when planning to co-locate YARN applications and HBase on the same clusters. The instance types with less than 64 GB of memory have half the memory available to NodeManager, which is then allocated to the HBase RegionServer. For instance types with memory greater than 64 GB, HBase RegionServer memory is capped at 32 GB. As a general rule, YARN setting memory is some multiple of MapReduce reducer task memory.

The tables in [Default values for task configuration settings](#) show changes to YARN settings based on the memory needed for HBase.

HBase port numbers

Some port numbers chosen for HBase are different from the default. The following are interfaces and ports for HBase on Amazon EMR.

HBase ports

Interface	Port	Protocol
HMaster	16000	TCP
HMaster UI	16010	HTTP

Interface	Port	Protocol
RegionServer	16020	TCP
RegionServer Info	16030	HTTP
REST server	8070	HTTP
REST UI	8085	HTTP
Thrift server	9090	TCP
Thrift server UI	9095	HTTP

Important

The `kms-http-port` is 9700 and the `kms-admin-port` is 9701 in Amazon EMR release version 4.6.0 and later.

HBase site settings to optimize

You can set any or all of the HBase site settings to optimize the HBase cluster for your application's workload. We recommend the following settings as a starting point in your investigation.

zookeeper.session.timeout

The default timeout is 40 seconds (40000 ms). If a region server crashes, this is how long it takes the master server to notice the absence of the region server and start recovery. To help the master server recover faster, you can reduce this value to a shorter time period. The following example uses 30 seconds, or 30000 ms:

```
[
  {
    "Classification":"hbase-site",
    "Properties": {
       "zookeeper.session.timeout": "30000"
    }
  }
```

```
]
```

hbase.regionserver.handler.count

This defines the number of threads the region server keeps open to serve requests to tables. The default of 10 is low, in order to prevent users from killing their region servers when using large write buffers with a high number of concurrent clients. The rule of thumb is to keep this number low when the payload per request approaches the MB range (big puts, scans using a large cache) and high when the payload is small (gets, small puts, ICVs, deletes). The following example raises the number of open threads to 30:

```
[
  {
    "Classification":"hbase-site",
    "Properties": {
       "hbase.regionserver.handler.count": "30"
    }
  }
]
```

hbase.hregion.max.filesize

This parameter governs the size, in bytes, of the individual regions. By default, it is set to `1073741824`. If you are writing a lot of data into your HBase cluster, and it's causing frequent splitting, you can increase this size to make individual regions bigger. It reduces splitting but takes more time to load-balance regions from one server to another.

```
[
  {
    "Classification":"hbase-site",
    "Properties": {
       "hbase.hregion.max.filesize": "1073741824"
    }
  }
]
```

hbase.hregion.memstore.flush.size

This parameter governs the maximum size of memstore, in bytes, before it is flushed to disk. By default, it is `134217728`. If your workload consists of short bursts of write operations, you might want to increase this limit so that all writes stay in memory during the burst and get flushed to disk later. This can boost performance during bursts.

```
[
  {
    "Classification":"hbase-site",
    "Properties": {
       "hbase.hregion.memstore.flush.size": "134217728"
    }
  }
]
```

View the HBase user interface

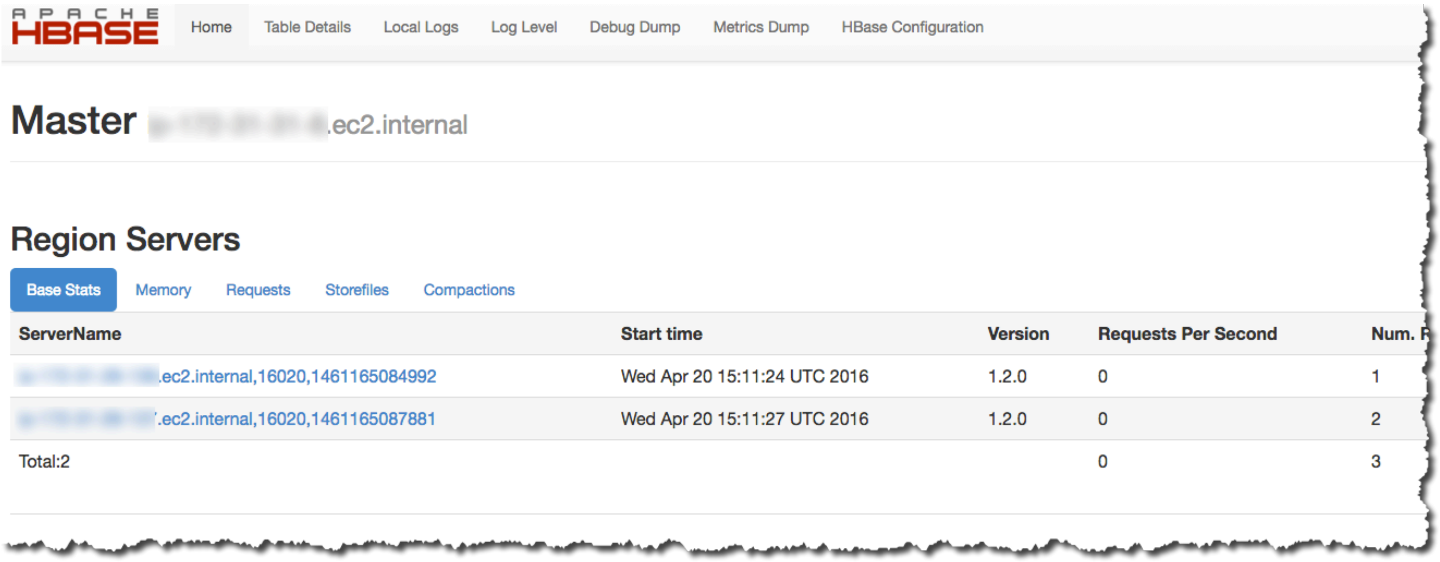
Note

The HBase user interface uses insecure HTTP connections by default. To enable secure HTTP (HTTPS), set the `hbase.ssl.enabled` property for the `hbase-site` classification to `true` in your HBase configuration. For more information about using secure HTTP (HTTPS) for the HBase web UI, see the Apache HBase Reference Guide.

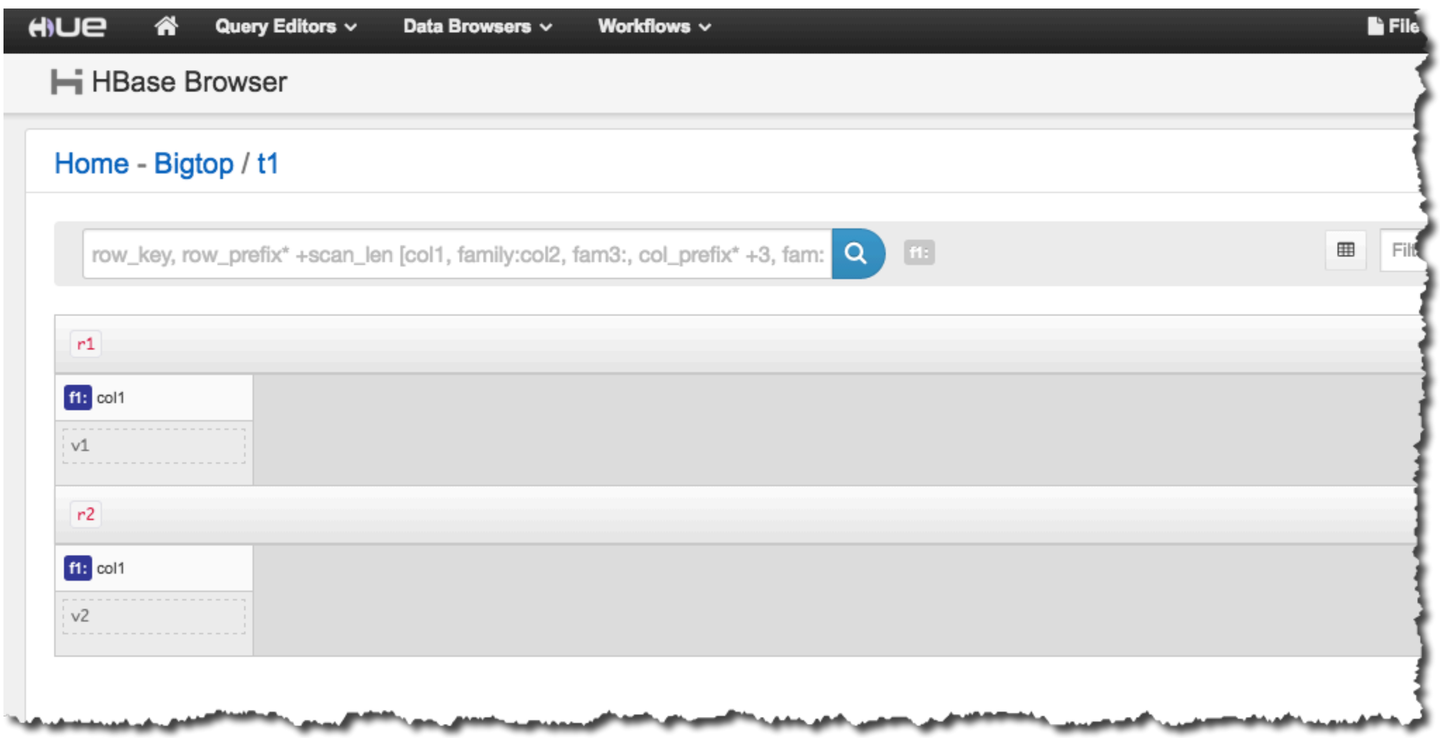
HBase provides a web-based user interface that you can use to monitor your HBase cluster. When you run HBase on Amazon EMR, the web interface runs on the primary node and can be viewed using port forwarding, also known as creating an SSH tunnel.

To view the HBase user interface

1. Use SSH to tunnel into the primary node and create a secure connection. For more information, see Option 2, part 1: Set up an SSH tunnel to the primary node using dynamic port forwarding in the *Amazon EMR Management Guide*.
2. Install a web browser with a proxy tool, such as the FoxyProxy plug-in for Firefox, to create a SOCKS proxy for AWS domains. For more information, see Option 2, part 2: Configure proxy settings to view websites hosted on the primary node in the *Amazon EMR Management Guide*.
3. With the proxy set and the SSH connection open, you can view the HBase UI by opening a browser window with **http://*master-public-dns-name*:16010/master-status**, where *master-public-dns-name* is the public DNS address of the cluster's primary node.



You can also view HBase in Hue. For example, the following shows the table, `t1`, created in [Using the HBase shell](#):



For more information about Hue, see [Hue](#).

View HBase log files

As part of its operation, HBase writes log files with details about configuration settings, daemon actions, and exceptions. These log files can be useful for debugging issues with HBase as well as for tracking performance.

If you configure your cluster to persist log files to Amazon S3, you should know that logs are written to Amazon S3 every five minutes, so there may be a slight delay before the latest log files are available.

To view HBase logs on the primary node

- You can view the current HBase logs by using SSH to connect to the primary node, and navigating to the `/var/log/hbase` directory. These logs are not available after the cluster is terminated unless you enable logging to Amazon S3 when the cluster is launched.

To view HBase logs on Amazon S3

- To access HBase logs and other cluster logs on Amazon S3, and to have them available after the cluster terminates, specify an Amazon S3 bucket to receive these logs when you create the cluster. This is done using the `--log-uri` option. For more information about enabling logging for your cluster, see Configure logging and debugging (optional) in the *Amazon EMR Management Guide*.

Monitor HBase with Ganglia

The Ganglia open-source project is a scalable, distributed system designed to monitor clusters and grids while minimizing the impact on their performance. When you enable Ganglia on your cluster, you can generate reports and view the performance of the cluster as a whole, as well as inspect the performance of individual node instances. For more information about the Ganglia open-source project, see http://ganglia.info/. For more information about using Ganglia with Amazon EMR clusters, see Ganglia.

After the cluster is launched with Ganglia configured, you can access the Ganglia graphs and reports using the graphical interface running on the primary node.

Ganglia stores log files on the primary node in the `/mnt/var/lib/ganglia/rrds/` directory. Earlier release versions of Amazon EMR may store log files in the `/var/log/ganglia/rrds/` directory.

To configure a cluster for Ganglia and HBase using the AWS CLI

- Use a `create-cluster` command similar to the following:

```
aws emr create-cluster --name "Test cluster" --release-label emr-7.2.0 \
--applications Name=HBase Name=Ganglia --use-default-roles \
--ec2-attributes KeyName=myKey --instance-type m5.xlarge \
--instance-count 3
```

> **Note**
>
> If the default Amazon EMR service role and Amazon EC2 instance profile don't exist, an error occurs. Use the `aws emr create-default-roles` command to create them and then try again.

For more information, see Amazon EMR commands in the AWS CLI.

To view HBase metrics in the Ganglia web interface

1. Use SSH to tunnel into the primary node and create a secure connection. For more information, see Option 2, part 1: Set up an SSH tunnel to the primary node using dynamic port forwarding in the *Amazon EMR Management Guide*.
2. Install a web browser with a proxy tool, such as the FoxyProxy plug-in for Firefox, to create a SOCKS proxy for AWS domains. For more information, see Option 2, part 2: Configure proxy settings to view websites hosted on the primary node in the *Amazon EMR Management Guide*.
3. With the proxy set and the SSH connection open, you can view the Ganglia metrics by opening a browser window with http://*master-public-dns-name*/ganglia/, where *master-public-dns-name* is the public DNS address of the master server in the HBase cluster.

To view Ganglia log files on the primary node

- If the cluster is still running, you can access the log files by using SSH to connect to the primary node and navigating to the `/mnt/var/lib/ganglia/rrds/` directory. For EMR 3.x, navigate to the `/var/log/ganglia/rrds` directory. For more information, see Connect to the primary node using SSH in the *Amazon EMR Management Guide*.

To view Ganglia log files on Amazon S3

- The Ganglia log files are not automatically written to Amazon S3 even if you enable logging for your cluster. To view Ganglia log files on Amazon S3, you must manually push the logs from `/mnt/var/lib/ganglia/rrds/` to the S3 bucket.

Migrating from previous HBase versions

To migrate data from a previous HBase version, see Upgrading and HBase version number and compatibility in the Apache HBase Reference Guide. You may need to pay special attention to the requirements for upgrading from pre-1.0 versions of HBase.

HBase release history

The following table lists the version of HBase included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

HBase version information

Amazon EMR Release label	HBase Version	Components installed with HBase
emr-7.2.0	2.4.17	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, emr-wal-cli, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-

Amazon EMR Release label	HBase Version	Components installed with HBase
		kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-rest-server, hbase-thrift-server, hbase-operator-tools, zookeeper-client, zookeeper-server
emr-5.36.2	1.4.13	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-rest-server, hbase-thrift-server, zookeeper-client, zookeeper-server

Apache HCatalog

HCatalog is a tool that allows you to access Hive metastore tables within Pig, Spark SQL, and/or custom MapReduce applications. HCatalog has a REST interface and command line client that allows you to create tables or do other operations. You then write your applications to access the tables using HCatalog libraries. For more information, see Using HCatalog. HCatalog is included in Amazon EMR release version 4.4.0 and later.

HCatalog on Amazon EMR release version 5.8.0 and later supports using AWS Glue Data Catalog as the metastore for Hive. For more information, see Using AWS Glue Data Catalog as the metastore for Hive.

The following table lists the version of HCatalog included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with HCatalog.

For the version of components installed with HCatalog in this release, see Release 6.15.0 Component Versions.

HCatalog version information for emr-6.15.0

Amazon EMR Release Label	HCatalog Version	Components Installed With HCatalog
emr-6.15.0	HCatalog 3.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hcatalog-client, hcatalog-server, hcatalog-webhcat-server, hive-client, mariadb-server

The following table lists the version of HCatalog included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with HCatalog.

For the version of components installed with HCatalog in this release, see Release 5.36.2 Component Versions.

HCatalog version information for emr-5.36.2

Amazon EMR Release Label	HCatalog Version	Components Installed With HCatalog
emr-5.36.2	HCatalog 2.3.9	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hcatalog-client, hcatalog-server, hcatalog-webhcat-server, hive-client, mariadb-server

Topics

Creating a cluster with HCatalog

Although HCatalog is included in the Hive project, you must install it as its own application.

To launch a cluster with HCatalog installed using the console

The following procedure creates a cluster with HCatalog installed. For more information about creating clusters using the console, including **Advanced Options** see Plan and configure clusters in the *Amazon EMR Management Guide*.

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create cluster** to use **Quick Create**.
3. For the **Software Configuration** field, choose **Amazon Release Version emr-4.4.0** or later.
4. In the **Select Applications** field, choose either **All Applications** or **HCatalog**.
5. Select other options as necessary and then choose **Create cluster**.

To launch a cluster with HCatalog using the AWS CLI

- Create the cluster with the following command:

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name "Cluster with Hcat" --release-label emr-7.2.0 \
--applications Name=HCatalog --ec2-attributes KeyName=myKey \
--instance-type m5.xlarge --instance-count 3 --use-default-roles
```

Using HCatalog

You can use HCatalog within various applications that use the Hive metastore. The examples in this section show how to create a table and use it in the context of Pig and Spark SQL.

Disable direct write when using HCatalog HStorer

Whenever an application uses HCatStorer to write to an HCatalog table stored in Amazon S3, disable the direct write feature of Amazon EMR. For example, disable direct write when using the Pig `STORE` command or when running Sqoop jobs that write HCatalog tables to Amazon S3. You can disable the direct write feature by setting the `mapred.output.direct.NativeS3FileSystem` and the `mapred.output.direct.EmrFileSystem` configurations to `false`. The following example demonstrates how to set these configurations using Java.

```
Configuration conf = new Configuration();
conf.set("mapred.output.direct.NativeS3FileSystem", "false");
conf.set("mapred.output.direct.EmrFileSystem", "false");
```

Create a table using the HCat CLI and use that data in Pig

Create the following script, `impressions.q`, on your cluster:

```
CREATE EXTERNAL TABLE impressions (
    requestBeginTime string, adId string, impressionId string, referrer string,
    userAgent string, userCookie string, ip string
  )
  PARTITIONED BY (dt string)
  ROW FORMAT
    serde 'org.apache.hive.hcatalog.data.JsonSerDe'
    with serdeproperties ( 'paths'='requestBeginTime, adId, impressionId, referrer,
 userAgent, userCookie, ip' )
  LOCATION 's3://[your region].elasticmapreduce/samples/hive-ads/tables/impressions/';
ALTER TABLE impressions ADD PARTITION (dt='2009-04-13-08-05');
```

Execute the script using the HCat CLI:

```
% hcat -f impressions.q
Logging initialized using configuration in file:/etc/hive/conf.dist/hive-
log4j.properties
OK
Time taken: 4.001 seconds
OK
Time taken: 0.519 seconds
```

Open the Grunt shell and access the data in `impressions`:

```
% pig -useHCatalog -e "A = LOAD 'impressions' USING
 org.apache.hive.hcatalog.pig.HCatLoader();
B = LIMIT A 5;
dump B;"
<snip>
```

```

Accessing the table using Spark SQL

This example creates a Spark DataFrame from the table created in the first example and shows the first 20 lines:

```
% spark-shell --jars /usr/lib/hive-hcatalog/share/hcatalog/hive-hcatalog-core-1.0.0-
amzn-3.jar
<snip>
scala> val hiveContext = new org.apache.spark.sql.hive.HiveContext(sc);
scala> val df = hiveContext.sql("SELECT * FROM impressions")
scala> df.show()
<snip>

Example: Create an HCatalog table and write to it using Pig

You can create an HCatalog table and use Apache Pig to write to it by way of HCatStorer using a data source in Amazon S3. HCatalog requires that you disable direct write, or the operation fails silently. Set both the `mapred.output.direct.NativeS3FileSystem` and the `mapred.output.direct.EmrFileSystem` configurations to `false` either using the `mapred-site` classification, or manually from within the Grunt shell. The following example shows a table created using the HCat CLI, followed by commands executed in the Grunt shell to populate the table from a sample data file in Amazon S3.

To run this example, connect to the master node using SSH.

Create an HCatalog script file, `wikicount.q`, with the following contents, which creates an HCatalog table named `wikicount`.

```
CREATE EXTERNAL TABLE IF NOT EXISTS wikicount(
col1 string,
col2 bigint
)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\001'
STORED AS ORC
LOCATION 's3://MyBucket/hcat/wikicount';
```

Use an HCat CLI command to execute the script from the file.

```
hcat -f wikicount.q
```

Next, start the Grunt shell with the `-useHCatalog` option, set configurations to disable direct write, load data from an S3 location, and then write the results to the wikicount table.

```
pig -useHCatalog
SET mapred.output.direct.NativeS3FileSystem false;
SET mapred.output.direct.EmrFileSystem false;
A = LOAD 's3://support.elasticmapreduce/training/datasets/wikistats_tiny/' USING
 PigStorage(' ') AS (Site:chararray, page:chararray, views:int, total_bytes:long);
B = GROUP A BY Site;
```

```
C = FOREACH B GENERATE group as col1, COUNT(A) as col2;
STORE C INTO 'wikicount' USING org.apache.hive.hcatalog.pig.HCatStorer();
```

HCatalog release history

The following table lists the version of HCatalog included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

HCatalog version information

Amazon EMR Release label	HCatalog Version	Components installed with HCatalog
emr-7.2.0	3.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hcatalog-client, hcatalog-server, hcatalog-webhcat-server, hive-client, mariadb-server
emr-5.36.2	2.3.9	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-

Apache Hive

Hive is an open-source, data warehouse, and analytic package that runs on top of a Hadoop cluster. Hive scripts use an SQL-like language called Hive QL (query language) that abstracts programming models and supports typical data warehouse interactions. Hive enables you to avoid the complexities of writing Tez jobs based on directed acyclic graphs (DAGs) or MapReduce programs in a lower level computer language, such as Java.

Hive extends the SQL paradigm by including serialization formats. You can also customize query processing by creating table schema that match your data, without touching the data itself. While SQL only supports primitive value types, such as dates, numbers, and strings), Hive table values are structured elements, such as JSON objects, any user-defined data type, or any function written in Java.

For more information about Hive, see http://hive.apache.org/.

The following table lists the version of Hive included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Hive.

For the version of components installed with Hive in this release, see Release 7.2.0 Component Versions.

Hive version information for emr-7.2.0

Amazon EMR Release Label	Hive Version	Components Installed With Hive
emr-7.2.0	Hive 3.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, emr-s3-select, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hive-client,

Amazon EMR Release Label	Hive Version	Components Installed With Hive
		hive-hbase, hcatalog-server, hive-server2, hudi, mariadb-server, tez-on-yarn, tez-on-worker, zookeeper-client, zookeeper-server

The following table lists the version of Hive included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Hive.

For the version of components installed with Hive in this release, see Release 6.15.0 Component Versions.

Hive version information for emr-6.15.0

Amazon EMR Release Label	Hive Version	Components Installed With Hive
emr-6.15.0	Hive 3.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, emr-s3-select, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hive-client, hive-hbase, hcatalog-server, hive-server2, hudi, mariadb-server, tez-on-yarn, tez-on-worker, zookeeper-client, zookeeper-server

The following table lists the version of Hive included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Hive.

For the version of components installed with Hive in this release, see Release 5.36.2 Component Versions.

Hive version information for emr-5.36.2

Amazon EMR Release Label	Hive Version	Components Installed With Hive
emr-5.36.2	Hive 2.3.9	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, emr-s3-select, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hive-client, hive-hbase, hcatalog-server, hive-server2, hudi, mariadb-server, tez-on-yarn

Beginning with Amazon EMR 5.18.0, you can use the Amazon EMR artifact repository to build your job code against the exact versions of libraries and dependencies that are available with specific Amazon EMR releases. For more information, see Checking dependencies using the Amazon EMR artifact repository.

Differences and considerations for Hive on Amazon EMR

Differences between Apache Hive on Amazon EMR and Apache Hive

This section describes the differences between Hive on Amazon EMR and the default versions of Hive available at http://svn.apache.org/viewvc/hive/branches/.

Hive authorization

Amazon EMR supports Hive authorization for HDFS but not for EMRFS and Amazon S3. Amazon EMR clusters run with authorization disabled by default.

Hive file merge behavior with Amazon S3

Apache Hive merges small files at the end of a map-only job if `hive.merge.mapfiles` is true and the merge is triggered only if the average output size of the job is less than the `hive.merge.smallfiles.avgsize` setting. Amazon EMR Hive has exactly the same behavior if the final output path is in HDFS. If the output path is in Amazon S3, the `hive.merge.smallfiles.avgsize` parameter is ignored. In that situation, the merge task is always triggered if `hive.merge.mapfiles` is set to `true`.

ACID transactions and Amazon S3

Amazon EMR 6.1.0 and later supports Hive ACID (Atomicity, Consistency, Isolation, Durability) transactions so it complies with the ACID properties of a database. With this feature, you can run INSERT, UPDATE, DELETE, and MERGE operations in Hive managed tables with data in Amazon Simple Storage Service (Amazon S3).

Hive Live Long and Process (LLAP)

LLAP functionality added in version 2.0 of default Apache Hive is not supported in Hive 2.1.0 on Amazon EMR release 5.0.

Amazon EMR version 6.0.0 and later supports the Live Long and Process (LLAP) functionality for Hive. For more information, see Using Hive LLAP.

Differences in Hive between Amazon EMR release version 4.x and 5.x

This section covers differences to consider before you migrate a Hive implementation from Hive version 1.0.0 on Amazon EMR release 4.x to Hive 2.x on Amazon EMR release 5.x.

Operational differences and considerations

- **Support added for ACID (atomicity, consistency, isolation, and durability) transactions:** This difference between Hive 1.0.0 on Amazon EMR 4.x and default Apache Hive has been eliminated.
- **Direct writes to Amazon S3 eliminated:** This difference between Hive 1.0.0 on Amazon EMR and the default Apache Hive has been eliminated. Hive 2.1.0 on Amazon EMR release 5.x now creates, reads from, and writes to temporary files stored in Amazon S3. As a result, to read from and write to the same table you no longer have to create a temporary table in the cluster's local HDFS file system as a workaround. If you use versioned buckets, be sure to manage these temporary files as described below.
- **Manage temp files when using Amazon S3 versioned buckets:** When you run Hive queries where the destination of generated data is Amazon S3, many temporary files and directories are created. This is new behavior as described earlier. If you use versioned S3 buckets, these temp files clutter Amazon S3 and incur cost if they're not deleted. Adjust your lifecycle rules so that data with a `/_tmp` prefix is deleted after a short period, such as five days. See Specifying a lifecycle configuration for more information.
- **Log4j updated to log4j 2:** If you use log4j, you may need to change your logging configuration because of this upgrade. See Apache log4j 2 for details.

Performance differences and considerations

- **Performance differences with Tez:** With Amazon EMR release 5.x , Tez is the default execution engine for Hive instead of MapReduce. Tez provides improved performance for most workflows.
- **Tables with many partitions:** Queries that generate a large number of dynamic partitions may fail, and queries that select from tables with many partitions may take longer than expected to execute. For example, a select from 100,000 partitions may take 10 minutes or more.

Additional features of Hive on Amazon EMR

Amazon EMR extends Hive with new features that support Hive integration with other AWS services, such as the ability to read from and write to Amazon Simple Storage Service (Amazon S3) and DynamoDB.

Variables in Hive

You can include variables in your scripts by using the dollar sign and curly braces.

```
add jar ${LIB}/jsonserde.jar
```

You pass the values of these variables to Hive on the command line using the `-d` parameter, as in the following example:

```
-d LIB=s3://elasticmapreduce/samples/hive-ads/lib
```

You can also pass the values into steps that execute Hive scripts.

To pass variable values into Hive steps using the console

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create cluster**.
3. In the **Steps** section, for **Add Step**, choose **Hive Program** from the list and **Configure and add**.
4. In the **Add Step** dialog, specify the parameters using the following table as a guide, and then choose **Add**.

Field	Action
Script S3 location*	Specify the URI where your script resides in Amazon S3. The value must be in the form *BucketName* /*path*/*ScriptName* . For example: `s3://elasticmapreduce/samples/hive-ads/libs/response-time-stats.q` .

Field	Action
Input S3 location	Optionally, specify the URI where your input files reside in Amazon S3. The value must be in the form *BucketName* /*path*/. If specified , this will be passed to the Hive script as a parameter named INPUT. For example: `s3://elasticmapreduce/samples/hive-ads/tables/` .
Output S3 location	Optionally, specify the URI where you want the output stored in Amazon S3. The value must be in the form *BucketName* /*path*. If specified, this will be passed to the Hive script as a parameter named OUTPUT. For example: `s3://mybucket/hive-ads/output/` .
Arguments	Optionally, enter a list of arguments (space-separated strings) to pass to Hive. If you defined a path variable in your Hive script named ${SAMPLE} , for example: `CREATE EXTERNAL TABLE logs (requestBeginTime STRING, requestEndTime STRING, hostname STRING) PARTITIONED BY (dt STRING) \ ROW FORMAT serde 'com.amazon.elasticmapreduce.JsonSerde' WITH SERDEPROPERTIES ( 'paths'='requestBeginTime, requestEndTime, hostname' ) LOCATION '${SAMPLE}/tables/impressions';` To pass a value for the variable, type the following in the **Arguments** window: `-d SAMPLE=s3://elasticmapreduce/samples/hive-ads/` .
Action on Failure	This determines what the cluster does in response to any errors. The possible values for this setting are: • **Terminate cluster**: If the step fails, terminate the cluster. If the cluster has termination protection enabled AND keep alive enabled, it will not terminate. • **Cancel and wait**: If the step fails, cancel the remaining steps. If the cluster has keep alive enabled, the cluster will not terminate. • **Continue**: If the step fails, continue to the next step.

5. Select values as necessary and choose **Create cluster**.

To pass variable values into Hive steps using the AWS CLI

To pass variable values into Hive steps using the AWS CLI, use the `--steps` parameter and include an arguments list.

- **Note**

  Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name "Test cluster" --release-label emr-7.2.0 \
--applications Name=Hive Name=Pig --use-default-roles --ec2-attributes
 KeyName=myKey --instance-type m5.xlarge --instance-count 3 \
--steps Type=Hive,Name="Hive Program",ActionOnFailure=CONTINUE,Args=[-f,s3://
elasticmapreduce/samples/hive-ads/libs/response-time-stats.q,-d,INPUT=s3://
elasticmapreduce/samples/hive-ads/tables,-d,OUTPUT=s3://mybucket/hive-ads/output/,-
d,SAMPLE=s3://elasticmapreduce/samples/hive-ads/]
```

  For more information on using Amazon EMR commands in the AWS CLI, see https://docs.aws.amazon.com/cli/latest/reference/emr.

To pass variable values into Hive steps using the Java SDK

- The following example demonstrates how to pass variables into steps using the SDK. For more information, see Class StepFactory in the *AWS SDK for Java API Reference*.

```
StepFactory stepFactory = new StepFactory();

   StepConfig runHive = new StepConfig()
     .withName("Run Hive Script")
     .withActionOnFailure("TERMINATE_JOB_FLOW")
     .withHadoopJarStep(stepFactory.newRunHiveScriptStep(“s3://mybucket/script.q”,
      Lists.newArrayList(“-d”,”LIB= s3://elasticmapreduce/samples/hive-ads/lib”));
```

Amazon EMR Hive queries to accommodate partial DynamoDB schemas

Amazon EMR Hive provides maximum flexibility when querying DynamoDB tables by allowing you to specify a subset of columns on which you can filter data, rather than requiring your query to include all columns. This partial schema query technique is effective when you have a sparse database schema and want to filter records based on a few columns, such as filtering on time stamps.

The following example shows how to use a Hive query to:

- Create a DynamoDB table.
- Select a subset of items (rows) in DynamoDB and further narrow the data to certain columns.
- Copy the resulting data to Amazon S3.

```
DROP TABLE dynamodb;
DROP TABLE s3;

CREATE EXTERNAL TABLE dynamodb(hashKey STRING, recordTimeStamp BIGINT, fullColumn
 map<String, String>)
    STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
    TBLPROPERTIES (
     "dynamodb.table.name" = "myTable",
     "dynamodb.throughput.read.percent" = ".1000",
     "dynamodb.column.mapping" = "hashKey:HashKey,recordTimeStamp:RangeKey");

CREATE EXTERNAL TABLE s3(map<String, String>)
     ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
     LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3 SELECT item fullColumn FROM dynamodb WHERE recordTimeStamp <
 "2012-01-01";
```

The following table shows the query syntax for selecting any combination of items from DynamoDB.

Query example	Result description
SELECT * FROM *table_name* ;	Selects all items (rows) from a given table and includes data from all columns available for those items.
SELECT * FROM *table_name* WHERE *field_name* =*value*;	Selects some items (rows) from a given table and includes data from all columns available for those items.
SELECT *column1_name* , *column2_name* , *column3_name* FROM *table_name* ;	Selects all items (rows) from a given table and includes data from some columns available for those items.
SELECT *column1_name* , *column2_name* , *column3_name* FROM *table_name* WHERE *field_name* =*value*;	Selects some items (rows) from a given table and includes data from some columns available for those items.

Copy data between DynamoDB tables in different AWS Regions

Amazon EMR Hive provides a `dynamodb.region` property you can set per DynamoDB table. When `dynamodb.region` is set differently on two tables, any data you copy between the tables automatically occurs between the specified regions.

The following example shows you how to create a DynamoDB table with a Hive script that sets the `dynamodb.region` property:

> **Note**
>
> Per-table region properties override the global Hive properties.

```
CREATE EXTERNAL TABLE dynamodb(hashKey STRING, recordTimeStamp BIGINT, map<String,
 String> fullColumn)
    STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
    TBLPROPERTIES (
     "dynamodb.table.name" = "myTable",
     "dynamodb.region" = "eu-west-1",
```

```
     "dynamodb.throughput.read.percent" = ".1000",
     "dynamodb.column.mapping" = "hashKey:HashKey,recordTimeStamp:RangeKey");
```

Set DynamoDB throughput values per table

Amazon EMR Hive enables you to set the DynamoDB readThroughputPercent and writeThroughputPercent settings on a per table basis in the table definition. The following Amazon EMR Hive script shows how to set the throughput values. For more information about DynamoDB throughput values, see Specifying read and write requirements for tables.

```
CREATE EXTERNAL TABLE dynamodb(hashKey STRING, recordTimeStamp BIGINT, map<String,
 String> fullColumn)
    STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
    TBLPROPERTIES (
     "dynamodb.table.name" = "myTable",
     "dynamodb.throughput.read.percent" = ".4",
     "dynamodb.throughput.write.percent" = "1.0",
     "dynamodb.column.mapping" = "hashKey:HashKey,recordTimeStamp:RangeKey");
```

Configuring an external metastore for Hive

By default, Hive records metastore information in a MySQL database on the primary node's file system. The metastore contains a description of the table and the underlying data on which it is built, including the partition names, data types, and so on. When a cluster terminates, all cluster nodes shut down, including the primary node. When this happens, local data is lost because node file systems use ephemeral storage. If you need the metastore to persist, you must create an *external metastore* that exists outside the cluster.

You have two options for an external metastore:

- AWS Glue Data Catalog (Amazon EMR release 5.8.0 or later only).

  For more information, see Using the AWS Glue Data Catalog as the metastore for Hive.
- Amazon RDS or Amazon Aurora.

  For more information, see Using an external MySQL database or Amazon Aurora.

Note

If you're using Hive 3 and encounter too many connections to Hive metastore, configure the parameter `datanucleus.connectionPool.maxPoolSize` to have a smaller value or increase the number of connection the database server can handle. The increased number of connections is due to the way Hive computes the maximum number of JDBC connections. To calculate the optimal value for performance, see Hive Configuration Properties.

Using the AWS Glue Data Catalog as the metastore for Hive

Using Amazon EMR release 5.8.0 or later, you can configure Hive to use the AWS Glue Data Catalog as its metastore. We recommend this configuration when you require a persistent metastore or a metastore shared by different clusters, services, applications, or AWS accounts.

AWS Glue is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores. The AWS Glue Data Catalog provides a unified metadata repository across a variety of data sources and data formats, integrating with Amazon EMR as well as Amazon RDS, Amazon Redshift, Redshift Spectrum, Athena, and any application compatible with the Apache Hive metastore. AWS Glue crawlers can automatically infer schema from source data in Amazon S3 and store the associated metadata in the Data Catalog. For more information about the Data Catalog, see Populating the AWS Glue Data Catalog in the *AWS Glue Developer Guide*.

Separate charges apply for AWS Glue. There is a monthly rate for storing and accessing the metadata in the Data Catalog, an hourly rate billed per minute for AWS Glue ETL jobs and crawler runtime, and an hourly rate billed per minute for each provisioned development endpoint. The Data Catalog allows you to store up to a million objects at no charge. If you store more than a million objects, you are charged USD$1 for each 100,000 objects over a million. An object in the Data Catalog is a table, partition, or database. For more information, see Glue Pricing.

Important

If you created tables using Amazon Athena or Amazon Redshift Spectrum before August 14, 2017, databases and tables are stored in an Athena-managed catalog, which is separate from the AWS Glue Data Catalog. To integrate Amazon EMR with these tables, you must upgrade to the AWS Glue Data Catalog. For more information, see Upgrading to the AWS Glue Data Catalog in the *Amazon Athena User Guide*.

Specifying AWS Glue Data Catalog as the metastore

You can specify the AWS Glue Data Catalog as the metastore using the AWS Management Console, AWS CLI, or Amazon EMR API. When you use the CLI or API, you use the configuration classification for Hive to specify the Data Catalog. In addition, with Amazon EMR 5.16.0 and later, you can use the configuration classification to specify a Data Catalog in a different AWS account. When you use the console, you can specify the Data Catalog using **Advanced Options** or **Quick Options**.

Console

To specify AWS Glue Data Catalog as the Hive metastore with the console

1. Sign in to the AWS Management Console, and open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Under **EMR on EC2** in the left navigation pane, choose **Clusters**, and then choose **Create cluster**.
3. Under **Application bundle**, choose **Core Hadoop**, **HBase**, or **Custom**. If you customize your cluster, make sure that you select Hive or HCatalog as one of your applications.
4. Under **AWS Glue Data Catalog settings**, select the **Use for Hive table metadata** check box.
5. Choose any other options that apply to your cluster.
6. To launch your cluster, choose **Create cluster**.

CLI

To specify the AWS Glue Data Catalog as the Hive metastore with the AWS CLI

For more information about specifying a configuration classification using the AWS CLI and EMR API, see Configure applications.

- Specify the value for `hive.metastore.client.factory.class` using the `hive-site` configuration classification as shown in the following example:

```
[
  {
```

```
    "Classification": "hive-site",
    "Properties": {
      "hive.metastore.client.factory.class":
 "com.amazonaws.glue.catalog.metastore.AWSGlueDataCatalogHiveClientFactory"
    }
  }
]
```

On EMR release versions 5.28.0, 5.28.1, 5.29.0, or 6.x, if you're creating a cluster using the AWS Glue Data Catalog as the metastore, set the `hive.metastore.schema.verification` to `false`. This prevents Hive and HCatalog from validating the metastore schema against MySQL. Without this configuration, the primary instance group will become suspended after reconfiguration on Hive or HCatalog.

```
[
  {
    "Classification": "hive-site",
    "Properties": {
      "hive.metastore.client.factory.class":
 "com.amazonaws.glue.catalog.metastore.AWSGlueDataCatalogHiveClientFactory",
      "hive.metastore.schema.verification": "false"
    }
  }
]
```

If you already have a cluster on EMR release version 5.28.0, 5.28.1, or 5.29.0, you can set the primary instance group `hive.metastore.schema.verification` to `false` with following information:

```
    Classification = hive-site
    Property       = hive.metastore.schema.verification
    Value          = false
```

To specify a Data Catalog in a different AWS account, add the `hive.metastore.glue.catalogid` property as shown in the following example. Replace *`acct-id`* with the AWS account of the Data Catalog.

```
[
  {
    "Classification": "hive-site",
    "Properties": {
      "hive.metastore.client.factory.class":
 "com.amazonaws.glue.catalog.metastore.AWSGlueDataCatalogHiveClientFactory",
      "hive.metastore.schema.verification": "false",
      "hive.metastore.glue.catalogid": "acct-id"
    }
  }
]
```

IAM permissions

The EC2 instance profile for a cluster must have IAM permissions for AWS Glue actions. In addition, if you enable encryption for AWS Glue Data Catalog objects, the role must also be allowed to encrypt, decrypt and generate the AWS KMS key used for encryption.

Permissions for AWS Glue actions

If you use the default EC2 instance profile for Amazon EMR, no action is required. The `AmazonElasticMapReduceforEC2Role` managed policy that is attached to the `EMR_EC2_DefaultRole` allows all necessary AWS Glue actions. However, if you specify a custom EC2 instance profile and permissions, you must configure the appropriate AWS Glue actions. Use the `AmazonElasticMapReduceforEC2Role` managed policy as a starting point. For more information, see Service role for cluster EC2 instances (EC2 instance profile) in the *Amazon EMR Management Guide*.

Permissions for encrypting and decrypting AWS Glue Data Catalog

Your instance profile needs permission to encrypt and decrypt data using your key. You do *not* need to configure these permissions if both of the following statements apply:

- You enable encryption for AWS Glue Data Catalog objects using managed keys for AWS Glue.
- You use a cluster that's in the same AWS account as the AWS Glue Data Catalog.

Otherwise, you must add the following statement to the permissions policy attached to your EC2 instance profile.

```
[
    {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Action": [
                    "kms:Decrypt",
                    "kms:Encrypt",
                    "kms:GenerateDataKey"
                ],
                "Resource": "arn:aws:kms:region:acct-
id:key/12345678-1234-1234-1234-123456789012"
            }
        ]
    }
]
```

For more information about AWS Glue Data Catalog encryption, see Encrypting your data catalog in the *AWS Glue Developer Guide*.

Resource-based permissions

If you use AWS Glue in conjunction with Hive, Spark, or Presto in Amazon EMR, AWS Glue supports resource-based policies to control access to Data Catalog resources. These resources include databases, tables, connections, and user-defined functions. For more information, see AWS Glue Resource Policies in the *AWS Glue Developer Guide*.

When using resource-based policies to limit access to AWS Glue from within Amazon EMR, the principal that you specify in the permissions policy must be the role ARN associated with the EC2 instance profile that is specified when a cluster is created. For example, for a resource-based policy attached to a catalog, you can specify the role ARN for the default service role for cluster EC2 instances, *EMR_EC2_DefaultRole* as the `Principal`, using the format shown in the following example:

```
arn:aws:iam::acct-id:role/EMR_EC2_DefaultRole
```

The *acct-id* can be different from the AWS Glue account ID. This enables access from EMR clusters in different accounts. You can specify multiple principals, each from a different account.

Considerations when using AWS Glue Data Catalog

Consider the following items when using the AWS Glue Data Catalog as the metastore with Hive:

- Adding auxiliary JARs using the Hive shell is not supported. As a workaround, use the `hive-site` configuration classification to set the `hive.aux.jars.path` property, which adds auxiliary JARs into the Hive classpath.
- Hive transactions are not supported.
- Renaming tables from within AWS Glue is not supported.
- When you create a Hive table without specifying a `LOCATION`, the table data is stored in the location specified by the `hive.metastore.warehouse.dir` property. By default, this is a location in HDFS. If another cluster needs to access the table, it fails unless it has adequate permissions to the cluster that created the table. Furthermore, because HDFS storage is transient, if the cluster terminates, the table data is lost, and the table must be recreated. We recommend that you specify a `LOCATION` in Amazon S3 when you create a Hive table using AWS Glue. Alternatively, you can use the `hive-site` configuration classification to specify a location in Amazon S3 for `hive.metastore.warehouse.dir`, which applies to all Hive tables. If a table is created in an HDFS location and the cluster that created it is still running, you can update the table location to Amazon S3 from within AWS Glue. For more information, see Working with Tables on the AWS Glue Console in the *AWS Glue Developer Guide*.
- Partition values containing quotes and apostrophes are not supported, for example, `PARTITION (owner="Doe's").`
- Column statistics are supported for emr-5.31.0 and later.
- Using Hive authorization is not supported. As an alternative, consider using AWS Glue Resource-Based Policies. For more information, see Use Resource-Based Policies for Amazon EMR Access to AWS Glue Data Catalog.
- Hive constraints are not supported.
- Cost-based Optimization in Hive is not supported.
- Setting `hive.metastore.partition.inherit.table.properties` is not supported.
- Using the following metastore constants is not supported: `BUCKET_COUNT, BUCKET_FIELD_NAME, DDL_TIME, FIELD_TO_DIMENSION, FILE_INPUT_FORMAT, FILE_OUTPUT_FORMAT, HIVE_FILTER_FIELD_LAST_ACCESS, HIVE_FILTER_FIELD_OWNER, HIVE_FILTER_FIELD_PARAMS, IS_ARCHIVED, META_TABLE_COLUMNS, META_TABLE_COLUMN_TYPES, META_TABLE_DB,`

`META_TABLE_LOCATION`, `META_TABLE_NAME`, `META_TABLE_PARTITION_COLUMNS`, `META_TABLE_SERDE`, `META_TABLE_STORAGE`, `ORIGINAL_LOCATION`.

- When you use a predicate expression, explicit values must be on the right side of the comparison operator, or queries might fail.
  - **Correct**: `SELECT * FROM mytable WHERE time > 11`
  - **Incorrect**: `SELECT * FROM mytable WHERE 11 > time`
- Amazon EMR versions 5.32.0 and 6.3.0 and later support using user-defined functions (UDFs) in predicate expressions. When using earlier versions, your queries may fail because of the way Hive tries to optimize query execution.
- Temporary tables are not supported.
- We recommend creating tables using applications through Amazon EMR rather than creating them directly using AWS Glue. Creating a table through AWS Glue may cause required fields to be missing and cause query exceptions.
- In EMR 5.20.0 or later, parallel partition pruning is enabled automatically for Spark and Hive when AWS Glue Data Catalog is used as the metastore. This change significantly reduces query planning time by executing multiple requests in parallel to retrieve partitions. The total number of segments that can be executed concurrently range between 1 and 10. The default value is 5, which is a recommended setting. You can change it by specifying the property `aws.glue.partition.num.segments` in `hive-site` configuration classification. If throttling occurs, you can turn off the feature by changing the value to 1. For more information, see AWS Glue Segment Structure.

Using an external MySQL database or Amazon Aurora

To use an external MySQL database or Amazon Aurora as your Hive metastore, you override the default configuration values for the metastore in Hive to specify the external database location, either on an Amazon RDS MySQL instance or an Amazon Aurora PostgreSQLinstance.

> **Note**
>
> Hive neither supports nor prevents concurrent write access to metastore tables. If you share metastore information between two clusters, you must ensure that you do not write to the same metastore table concurrently, unless you are writing to different partitions of the same metastore table.

The following procedure shows you how to override the default configuration values for the Hive metastore location and start a cluster using the reconfigured metastore location.

To create a metastore located outside of the EMR cluster

1. Create a MySQL or Aurora PostgreSQL database. If you use PostgreSQL, you must configure it after you've provisioned your cluster. Only MySQL is supported at cluster creation. For information about the differences between Aurora MySQL and Aurora PostgreSQL, see Overview of Amazon Aurora MySQL and Working with Amazon Aurora PostgreSQL. For information about how to create an Amazon RDS database in general, see https://aws.amazon.com/rds/.
2. Modify your security groups to allow JDBC connections between your database and the **ElasticMapReduce-Master** security group. For information about how to modify your security groups for access, see Working with Amazon EMR-managed security groups.
3. Set JDBC configuration values in `hive-site.xml`:

> **Important**
>
> If you supply sensitive information, such as passwords, to the Amazon EMR configuration API, this information is displayed for those accounts that have sufficient permissions. If you are concerned that this information could be displayed to other users, create the cluster with an administrative account and limit other users (IAM users or those with delegated credentials) to accessing services on the cluster by creating a role which explicitly denies permissions to the `elasticmapreduce:DescribeCluster` API key.

   a. Create a configuration file called `hiveConfiguration.json` containing edits to `hive-site.xml` as shown in the following example.

      Replace *`hostname`* with the DNS address of your Amazon RDS instance running the database, and *`username`* and *`password`* with the credentials for your database. For more information about connecting to MySQL and Aurora database instances, see Connecting to a DB instance running the MySQL database engine and Connecting to an Athena DB cluster in the *Amazon RDS User Guide*. `javax.jdo.option.ConnectionURL` is the JDBC connect string for a JDBC metastore. `javax.jdo.option.ConnectionDriverName` is the driver class name for a JDBC metastore.

The MySQL JDBC drivers are installed by Amazon EMR.

The value property can not contain any spaces or carriage returns. It should appear all on one line.

```
[
    {
      "Classification": "hive-site",
      "Properties": {
        "javax.jdo.option.ConnectionURL": "jdbc:mysql://hostname:3306/hive?
createDatabaseIfNotExist=true",
        "javax.jdo.option.ConnectionDriverName": "org.mariadb.jdbc.Driver",
        "javax.jdo.option.ConnectionUserName": "username",
        "javax.jdo.option.ConnectionPassword": "password"
      }
    }
  ]
```

b. Reference the `hiveConfiguration.json` file when you create the cluster as shown in the following AWS CLI command. In this command, the file is stored locally, you can also upload the file to Amazon S3 and reference it there, for example, `s3://DOC-EXAMPLE-BUCKET/hiveConfiguration.json`.

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --release-label emr-7.2.0 --instance-type m5.xlarge --
instance-count 2 \
--applications Name=Hive --configurations file://hiveConfiguration.json --use-
default-roles
```

4. Connect to the primary node of your cluster.

   For information about how to connect to the primary node, see [Connect to the primary node using SSH](#) in the *Amazon EMR Management Guide*.

5. Create your Hive tables specifying the location on Amazon S3 by entering a command similar to the following:

```
CREATE EXTERNAL TABLE IF NOT EXISTS table_name
(
key int,
value int
)
LOCATION s3://DOC-EXAMPLE-BUCKET/hdfs/
```

6. Add your Hive script to the running cluster.

Your Hive cluster runs using the metastore located in Amazon RDS. Launch all additional Hive clusters that share this metastore by specifying the metastore location.

Use the Hive JDBC driver

You can use popular business intelligence tools like Microsoft Excel, MicroStrategy, QlikView, and Tableau with Amazon EMR to explore and visualize your data. Many of these tools require Java Database Connectivity (JDBC) driver or an Open Database Connectivity (ODBC) driver. Amazon EMR supports both JDBC and ODBC connectivity.

The example below demonstrates using SQL Workbench/J as a SQL client to connect to a Hive cluster in Amazon EMR. For additional drivers, see Use business intelligence tools with Amazon EMR.

Before you install and work with SQL Workbench/J, download the driver package and install the driver. The drivers included in the package support the Hive versions available in Amazon EMR release versions 4.0 and later. For detailed release notes and documentation, see the PDF documentation included in the package.

- **The latest Hive JDBC driver package download**

  http://awssupportdatasvcs.com/bootstrap-actions/Simba/latest/

- **Older versions of the Hive JDBC driver**

  http://awssupportdatasvcs.com/bootstrap-actions/Simba/

To install and configure SQL Workbench

1. Download the SQL Workbench/J client for your operating system from http://www.sql-workbench.net/downloads.html.
2. Install SQL Workbench/J. For more information, see [Installing and starting SQL Workbench/J](#) in the SQL Workbench/J Manual User's Manual.
3. **Linux, Unix, Mac OS X users**: In a terminal session, create an SSH tunnel to the master node of your cluster using the following command. Replace *master-public-dns-name* with the public DNS name of the master node and *path-to-key-file* with the location and file name of your Amazon EC2 private key (`.pem`) file.

```
ssh -o ServerAliveInterval=10 -i path-to-key-file -N -L 10000:localhost:10000
 hadoop@master-public-dns-name
```

   Windows users: In a PuTTY session, create an SSH tunnel to the master node of your cluster (using local port forwarding) with `10000` for **Source port** and *master-public-dns-name*`:10000` for **Destination**. Replace *master-public-dns-name* with the public DNS name of the master node.

4. Add the JDBC driver to SQL Workbench.

   a. In the **Select Connection Profile** dialog box, click **Manage Drivers**.

   b. Click the **Create a new entry** (blank page) icon.

   c. In the **Name** field, type **`Hive JDBC`**.

   d. For **Library**, click the **Select the JAR file(s)** icon.

   e. Navigate to the location containing the extracted drivers. Select the drivers that are included in the JDBC driver package version that you downloaded, and click **Open**.

      For example, your JDBC driver package may include the following JARs.

```
hive_metastore.jar
hive_service.jar
HiveJDBC41.jar
libfb303-0.9.0.jar
libthrift-0.9.0.jar
log4j-1.2.14.jar
ql.jar
slf4j-api-1.5.11.jar
slf4j-log4j12-1.5.11.jar
```

```
TCLIServiceClient.jar
zookeeper-3.4.6.jar
```

f. In the **Please select one driver** dialog box, select `com.amazon.hive.jdbc41.HS2Driver`, **OK**.

5. When you return to the **Manage Drivers** dialog box, verify that the **Classname** field is populated and select **OK**.
6. When you return to the **Select Connection Profile** dialog box, verify that the **Driver** field is set to **Hive JDBC** and provide the following JDBC connection string in the **URL** field: `jdbc:hive2://localhost:10000/default`.
7. Select **OK** to connect. After the connection is complete, connection details appear at the top of the SQL Workbench/J window.

For more information about using Hive and the JDBC interface, see HiveClient and HiveJDBCInterface in Apache Hive documentation.

Improve Hive performance

Amazon EMR offers features to help optimize performance when using Hive to query, read and write data saved in Amazon S3.

S3 Select can improve query performance for CSV and JSON files in some applications by “pushing down” processing to Amazon S3.

The EMRFS S3 optimized committer is an alternative to the OutputCommitter class, that eliminates list and rename operations to improve performance when writing files Amazon S3 using EMRFS.

Topics

Enabling Hive EMRFS S3 optimized committer

The Hive EMRFS S3 Optimized Committer is an alternative way using which EMR Hive writes files for insert queries when using EMRFS. The Committer eliminates list and rename operations done on Amazon S3 and improves application's performance. The feature is available beginning with EMR 5.34 and EMR 6.5.

Enabling the committer

If you want to enable EMR Hive to use `HiveEMRFSOptimizedCommitter` to commit data as the default for all Hive managed and external tables, use the following `hive-site` configuration in EMR 6.5.0 or EMR 5.34.0 clusters.

```
[
   {
      "classification": "hive-site",
      "properties": {
         "hive.blobstore.use.output-committer": "true"
      }
   }
]
```

> **Note**
>
> Do not turn this feature on when `hive.exec.parallel` is set to `true`.

Limitations

The following basic restrictions apply to tags:

- Enabling Hive to merge small files automatically is not supported. The default Hive commit logic will be used even when the optimized committer is enabled.
- Hive ACID tables are not supported. The default Hive commit logic will be used even when the optimized committer is enabled.
- File naming nomenclature for files written is changed from Hive's <task_id>_<attempt_id>_<copy_n> to <task_id>_<attempt_id>_<copy_n>_<query_id>. For example, a file named

  `s3://warehouse/table/partition=1/000000_0` will be changed to `s3://warehouse/table/partition=1/000000_0-hadoop_20210714130459_ba7c23ec-5695-4947-9d98-8a40ef759222-1`. The `query_id` here is a combination of the username, time stamp, and UUID.

- When custom partitions are on different file systems (HDFS, S3), this feature is automatically disabled. The default Hive commit logic will be used when enabled.

Using S3 Select with Hive to improve performance

With Amazon EMR release version 5.18.0 and later, you can use S3 Select with Hive on Amazon EMR. S3 Select allows applications to retrieve only a subset of data from an object. For Amazon EMR, the computational work of filtering large datasets for processing is "pushed down" from the cluster to Amazon S3, which can improve performance in some applications and reduces the amount of data transferred between Amazon EMR and Amazon S3.

S3 Select is supported with Hive tables based on CSV and JSON files and by setting the `s3select.filter` configuration variable to `true` during your Hive session. For more information and examples, see Specifying S3 Select in your code.

Is S3 Select right for my application?

We recommend that you benchmark your applications with and without S3 Select to see if using it may be suitable for your application.

Use the following guidelines to determine if your application is a candidate for using S3 Select:

- Your query filters out more than half of the original dataset.
- Your query filter predicates use columns that have a data type supported by Amazon S3 Select. For more information, see Data types in the *Amazon Simple Storage Service User Guide*.
- Your network connection between Amazon S3 and the Amazon EMR cluster has good transfer speed and available bandwidth. Amazon S3 does not compress HTTP responses, so the response size is likely to increase for compressed input files.

Considerations and limitations

- Amazon S3 server-side encryption with customer-provided encryption keys (SSE-C) and client-side encryption are not supported.
- The `AllowQuotedRecordDelimiters` property is not supported. If this property is specified, the query fails.
- Only CSV and JSON files in UTF-8 format are supported. Multi-line CSVs and JSON are not supported.

- Only uncompressed or gzip or bzip2 files are supported.
- Comment characters in the last line are not supported.
- Empty lines at the end of a file are not processed.
- Hive on Amazon EMR supports the primitive data types that S3 Select supports. For more information, see Data types in the *Amazon Simple Storage Service User Guide*.

Specifying S3 Select in your code

To use S3 Select in your Hive table, create the table by specifying `com.amazonaws.emr.s3select.hive.S3SelectableTextInputFormat` as the `INPUTFORMAT` class name, and specify a value for the `s3select.format` property using the `TBLPROPERTIES` clause.

By default, S3 Select is disabled when you run queries. Enable S3 Select by setting `s3select.filter` to `true` in your Hive session as shown below. The examples below demonstrate how to specify S3 Select when creating a table from underlying CSV and JSON files and then querying the table using a simple select statement.

Example CREATE TABLE statement for CSV-based table

```
CREATE TABLE mys3selecttable (
col1 string,
col2 int,
col3 boolean
)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
STORED AS
INPUTFORMAT
  'com.amazonaws.emr.s3select.hive.S3SelectableTextInputFormat'
OUTPUTFORMAT
  'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION 's3://path/to/mycsvfile/'
TBLPROPERTIES (
  "s3select.format" = "csv",
  "s3select.headerInfo" = "ignore"
);
```

Example CREATE TABLE statement for JSON-based table

```
CREATE TABLE mys3selecttable (
```

```
col1 string,
col2 int,
col3 boolean
)
ROW FORMAT SERDE 'org.apache.hive.hcatalog.data.JsonSerDe'
STORED AS
INPUTFORMAT
  'com.amazonaws.emr.s3select.hive.S3SelectableTextInputFormat'
OUTPUTFORMAT
  'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION 's3://path/to/json/'
TBLPROPERTIES (
  "s3select.format" = "json"
);
```

Example SELECT TABLE statement

```
SET s3select.filter=true;
SELECT * FROM mys3selecttable WHERE col2 > 10;
```

MSCK Optimization

Hive stores a list of partitions for each table in its metastore. However, when partitions are directly added to or removed from the file system, the Hive metastore is unaware of these changes. The MSCK command updates the partition metadata in the Hive metastore for partitions that were directly added to or removed from the file system. The syntax for the command is:

```
MSCK [REPAIR] TABLE table_name [ADD/DROP/SYNC PARTITIONS];
```

Hive implements this command as follows:

1. Hive retrieves all the partitions for the table from the metastore. From the list of partition paths that do not exist in the file system then creates a list of partitions to drop from the metastore.
2. Hive gathers the partition paths present in the file system, compares them with the list of partitions from the metastore, and generates a list of partitions that need to be added to the metastore.
3. Hive updates the metastore using ADD, DROP, or SYNC mode.

> **Note**
>
> When there are many partitions in the metastore, the step to check if a partition does not exist in the file system takes a long time to run because the file system's `exists` API call must be made for each partition.

In Amazon EMR 6.5.0, Hive introduced a flag called `hive.emr.optimize.msck.fs.check`. When enabled, this flag causes Hive to check for the presence of a partition from the list of partition paths from the file system that is generated in step 2 above instead of making file system API calls. In Amazon EMR 6.8.0, Hive enabled this optimization by default, eliminating the need to set the flag `hive.emr.optimize.msck.fs.check`.

Using Hive Live Long and Process (LLAP)

Amazon EMR 6.0.0 supports the Live Long and Process (LLAP) functionality for Hive. LLAP uses persistent daemons with intelligent in-memory caching to improve query performance compared to the previous default Tez container execution mode.

The Hive LLAP daemons are managed and run as a YARN Service. Since a YARN service can be considered a long-running YARN application, some of your cluster resources are dedicated to Hive LLAP and cannot be used for other workloads. For more information, see LLAP and YARN Service API.

Enable Hive LLAP on Amazon EMR

To enable Hive LLAP on Amazon EMR, supply the following configuration when you launch a cluster.

```
[
  {
    "Classification": "hive",
    "Properties": {
      "hive.llap.enabled": "true"
    }
  }
]
```

For more information, see Configuring applications.

By default, Amazon EMR allocates about 60 percent of cluster YARN resources to Hive LLAP daemons. You can configure the percentage of cluster YARN resource allocated to Hive LLAP and the number of task and core nodes to be considered for the Hive LLAP allocation.

For example, the following configuration starts Hive LLAP with three daemons on three task or core nodes and allocates 40 percent of the three core or task nodes' YARN resource to the Hive LLAP daemons.

```
[
  {
    "Classification": "hive",
    "Properties": {
      "hive.llap.enabled": "true",
      "hive.llap.percent-allocation": "0.4",
      "hive.llap.num-instances": "3"
    }
  }
]
```

You can use the following `hive-site` configurations in the classification API to override default LLAP resource settings.

Property	Description
hive.llap.daemon.yarn.container.mb	Total LLAP daemon container size (in MB)
hive.llap.daemon.memory.per.instance.mb	The total memory used by executors in the LLAP daemon container (in MB)
hive.llap.io.memory.size	Cache size for LLAP Input/Output
hive.llap.daemon.num.executors	Number of executors per LLAP daemon

Start Hive LLAP on your cluster manually

All dependencies and configurations used by LLAP are packaged into the LLAP tar archive as part of cluster startup. If LLAP is enabled using `"hive.llap.enabled": "true"`, we recommend that you use Amazon EMR reconfiguration to make configuration changes to LLAP.

Otherwise, for any manual changes to `hive-site.xml`, you must rebuild the LLAP tar archive by using the `hive --service llap` command, as the following example demonstrates.

```
# Define how many resources you want to allocate to Hive LLAP

LLAP_INSTANCES=<how many llap daemons to run on cluster>
LLAP_SIZE=<total container size per llap daemon>
LLAP_EXECUTORS=<number of executors per daemon>
LLAP_XMX=<Memory used by executors>
LLAP_CACHE=<Max cache size for IO allocator>

yarn app -enableFastLaunch

hive --service llap \
--instances $LLAP_INSTANCES \
--size ${LLAP_SIZE}m \
--executors $LLAP_EXECUTORS \
--xmx ${LLAP_XMX}m \
--cache ${LLAP_CACHE}m \
--name llap0 \
--auxhbase=false \
--startImmediately
```

Check Hive LLAP status

Use the following command to check the status of Hive LLAP through Hive.

```
hive --service llapstatus
```

Use the following command to check the status of Hive LLAP using YARN.

```
yarn app -status (name-of-llap-service)

# example:
```

```
yarn app -status llap0 | jq
```

Start or stop Hive LLAP

Since Hive LLAP runs as a persistent YARN service, you stop or restart the YARN service to stop or restart Hive LLAP. The following commands demonstrate this.

```
yarn app -stop llap0
yarn app -start llap0
```

Resize the number of Hive LLAP daemons

Use the following command to reduce the number of LLAP instances.

```
yarn app -flex llap0 -component llap -1
```

For more information, see Flex a component of a service.

Encryption in Hive

This section describes the encryption types Amazon EMR supports.

Parquet modular encryption in Hive

Parquet modular encryption provides columnar level access control and encryption to enhance privacy and data integrity for data stored in Parquet file format. This feature is available in Amazon EMR Hive starting with release 6.6.0.

Previously supported solutions for security and integrity, which include encrypting files or encrypting the storage layer, are described in Encryption Options in the Amazon EMR Management Guide. These solutions can be used for Parquet files, but leveraging the new features of the integrated Parquet encryption mechanism provides granular access to the column level, as well as improvements in performance and security. Learn more about this feature on the Apache github page Parquet Modular Encryption.

Users pass configurations to Parquet readers and writers using Hadoop configurations. The detailed configurations for users to configure readers and writers to enable encryption as well as toggle advanced features are documented at [PARQUET-1854: Properties-driven Interface to Parquet Encryption Management]

Usage examples

The following example covers creating and writing to a Hive table using AWS KMS for managing encryption keys.

1. Implement a KmsClient for the AWS KMS service as described in the document [PARQUET-1373: Encryption Key Management Tools]. The following sample shows an implementation snippet.

```
package org.apache.parquet.crypto.keytools;

import com.amazonaws.AmazonClientException;
import com.amazonaws.AmazonServiceException;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.kms.AWSKMS;
import com.amazonaws.services.kms.AWSKMSClientBuilder;
import com.amazonaws.services.kms.model.DecryptRequest;
import com.amazonaws.services.kms.model.EncryptRequest;
import com.amazonaws.util.Base64;
import org.apache.hadoop.conf.Configuration;
import org.apache.parquet.crypto.KeyAccessDeniedException;
import org.apache.parquet.crypto.ParquetCryptoRuntimeException;
import org.apache.parquet.crypto.keytools.KmsClient;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import java.nio.ByteBuffer;
import java.nio.charset.Charset;
import java.nio.charset.StandardCharsets;

public class AwsKmsClient implements KmsClient {

    private static final AWSKMS AWSKMS_CLIENT = AWSKMSClientBuilder
            .standard()
            .withRegion(Regions.US_WEST_2)
            .build();
    public static final Logger LOG = LoggerFactory.getLogger(AwsKmsClient.class);

    private String kmsToken;
    private Configuration hadoopConfiguration;
```

```
    @Override
    public void initialize(Configuration configuration, String kmsInstanceID, String
 kmsInstanceURL, String accessToken) throws KeyAccessDeniedException {
        hadoopConfiguration = configuration;
        kmsToken = accessToken;

    }

    @Override
    public String wrapKey(byte[] keyBytes, String masterKeyIdentifier) throws
 KeyAccessDeniedException {
        String value = null;
        try {
            ByteBuffer plaintext = ByteBuffer.wrap(keyBytes);

            EncryptRequest req = new
 EncryptRequest().withKeyId(masterKeyIdentifier).withPlaintext(plaintext);
            ByteBuffer ciphertext = AWSKMS_CLIENT.encrypt(req).getCiphertextBlob();

            byte[] base64EncodedValue = Base64.encode(ciphertext.array());
            value = new String(base64EncodedValue, Charset.forName("UTF-8"));
        } catch (AmazonClientException ae) {
            throw new KeyAccessDeniedException(ae.getMessage());
        }
        return value;
    }

    @Override
    public byte[] unwrapKey(String wrappedKey, String masterKeyIdentifier) throws
 KeyAccessDeniedException {
        byte[] arr = null;
        try {
            ByteBuffer ciphertext  =
 ByteBuffer.wrap(Base64.decode(wrappedKey.getBytes(StandardCharsets.UTF_8)));
            DecryptRequest request = new
 DecryptRequest().withKeyId(masterKeyIdentifier).withCiphertextBlob(ciphertext);
            ByteBuffer decipheredtext =
 AWSKMS_CLIENT.decrypt(request).getPlaintext();
            arr = new byte[decipheredtext.remaining()];
            decipheredtext.get(arr);
        } catch (AmazonClientException ae) {
            throw new KeyAccessDeniedException(ae.getMessage());
        }
        return arr;
```

```
    }
}
```

2. Create your AWS KMS encryption keys for the footer as well the columns with your IAM roles having access as described in [Creating keys](#) in the *AWS Key Management Service Developer Guide*. The default IAM role is EMR_ECS_default.
3. On the Hive application on an Amazon EMR cluster, add the client above using the `ADD JAR` statement, as described in the [Apache Hive Resources documentation](#). The following is an example statement:

```
ADD JAR 's3://location-to-custom-jar';
```

   An alternative method is to add the JAR to the `auxlib` of Hive using a bootstrap action. The following is an example line to be added to the boostrap action:

```
aws s3 cp 's3://location-to-custom-jar' /usr/lib/hive/auxlib
```

4. Set the following configurations:

```
set
 parquet.crypto.factory.class=org.apache.parquet.crypto.keytools.PropertiesDrivenCryptoFacto
set
 parquet.encryption.kms.client.class=org.apache.parquet.crypto.keytools.AwsKmsClient;
```

5. Create a Hive table with Parquet format and specify the AWS KMS keys in SERDEPROPERTIES and insert some data to it:

```
CREATE TABLE my_table(name STRING, credit_card STRING)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe’
WITH SERDEPROPERTIES (
  'parquet.encryption.column.key’=<aws-kms-key-id-for-column-1>: credit_card’,
  'parquet.encryption.footer.key’='<aws-kms-key-id-for-footer>’)
STORED AS parquet
LOCATION “s3://<bucket/<warehouse-location>/my_table”;

INSERT INTO my_table SELECT
java_method ('org.apache.commons.lang.RandomStringUtils','randomAlphabetic',5) as
 name,
java_method ('org.apache.commons.lang.RandomStringUtils','randomAlphabetic',10) as
 credit_card
```

```
from (select 1) x lateral view posexplode(split(space(100),' ')) pe as i,x;

select * from my_table;
```

6. Verify that when you create an external table at the same location with no access to AWS KMS keys (for example, IAM role access denied), you cannot read the data.

```
CREATE EXTERNAL TABLE ext_table (name STRING, credit_card STRING)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe’
STORED AS parquet
LOCATION “s3://<bucket>/<warehouse-location>/my_table”;

SELECT * FROM ext_table;
```

7. The last statement should throw the following exception:

```
Failed with exception
 java.io.IOException:org.apache.parquet.crypto.KeyAccessDeniedException: Footer key:
 access denied
```

In-transit encryption in HiveServer2

Starting with Amazon EMR release 6.9.0, HiveServer2 (HS2) is TLS/SSL-enabled as part of In-transit encryption in HiveServer2 security configuration. This affects how you connect to HS2 running on an Amazon EMR cluster with in-transit encryption enabled. To connect to HS2, you must modify the `TRUSTSTORE_PATH` and `TRUSTSTORE_PASSWORD` parameter values in the JDBC URL. The following URL is an example of a JDBC connection for HS2 with the required parameters:

```
jdbc:hive2://HOST_NAME:10000/
default;ssl=true;sslTrustStore=TRUSTSTORE_PATH;trustStorePassword=TRUSTSTORE_PASSWORD
```

Use the appropriate instuctions for on-cluster or off-cluster HiveServer2 encryption below.

On-cluster HS2 access

If you are accessing HiveServer2 using the Beeline client after you SSH to the primary node, then reference `/etc/hadoop/conf/ssl-server.xml` to find the `TRUSTSTORE_PATH` and `TRUSTSTORE_PASSWORD` parameter values using configuration `ssl.server.truststore.location` and `ssl.server.truststore.password`.

The following example commands can help you retrieve these configurations:

```
TRUSTSTORE_PATH=$(sed -n '/ssl.server.truststore.location/,+2p' /etc/hadoop/conf/
ssl-server.xml | awk -F "[><]" '/value/{print $3}')
TRUSTSTORE_PASSWORD=$(sed -n '/ssl.server.truststore.password/,+2p' /etc/hadoop/
conf/ssl-server.xml | awk -F "[><]" '/value/{print $3}')
```

Off-cluster HS2 access

If you are accessing HiveServer2 from a client outside the Amazon EMR cluster. you can use one of the following approaches to get the TRUSTSTORE_PATH and TRUSTSTORE_PASSWORD:

- Convert the PEM file that was created during security configuration to a JKS file and use the same in the JDBC connection URL. For example, with openssl and keytool, use the following commands:

```
openssl pkcs12 -export -in trustedCertificates.pem -inkey privateKey.pem -out
 trustedCertificates.p12 -name "certificate"
keytool -importkeystore -srckeystore trustedCertificates.p12 -srcstoretype pkcs12
 -destkeystore trustedCertificates.jks
```

- Alternatively, reference /etc/hadoop/conf/ssl-server.xml to find the TRUSTSTORE_PATH and TRUSTSTORE_PASSWORD parameter values using configuration ssl.server.truststore.location and ssl.server.truststore.password. Download the truststore file to the client machine and use the path on the client machine as the TRUSTSTORE_PATH.

  For more information on accessing applications from a client outside of the Amazon EMR cluster, see Use the Hive JDBC driver.

Hive release history

The following table lists the version of Hive included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

emr-4.8.1	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.8.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server
emr-4.7.4	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.7.3	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server
emr-4.7.2	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.7.1	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server
emr-4.7.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hcatalog-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.6.1	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server
emr-4.6.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.5.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server
emr-4.4.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.3.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server
emr-4.2.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server

Amazon EMR Release label	Hive Version	Components installed with Hive
emr-4.1.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server
emr-4.0.0	1.0.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hive-client, hive-metastore-server, hive-server, mysql-server

Hive release notes by version

Topics

Amazon EMR 7.1.0 - Hive release notes

Amazon EMR 7.1.0 - Hive changes

Type	Description
Bug Fix	HIVE-24381 – Compressed text input returns 0 rows if skip header/footer is included.
Bug Fix	HIVE-24190 – LLAP: ShuffleHandler might return DISK_ERROR_EXCEPTION according to TEZ-4233.
Bug Fix	HIVE-23073 – Shade Netty.
Bug Fix	HIVE-23073 – Shade Netty and upgrade to netty 4.1.48.Final.
Bug Fix	HIVE-23148 – Llap external client flow is broken due to netty shading.
Bug Fix	HIVE-25180 – Upgrades Netty.
Bug Fix	HIVE-24524 – LLAP ShuffleHandler: upgrade to Netty4 and remove Netty3 dependency from hive where it's possible.
Bug Fix	HIVE-28000 – Hive QL: the"not in" clause gives incorrect results when type coercion cannot take place.

Type	Description
Bug Fix	HIVE-27993 – Netty4 ShuffleHandler should use 1 boss thread.
Upgrade	Upgrades Netty to 4.1.100.Final
Upgrade	Upgrades Jetty to 9.4.53.v20231009
Upgrade	Upgrades Zookeeper to 3.9.1

Amazon EMR 7.1.0 - Hive changes

- Amazon EMR 7.1 upgrades Hive to Netty 4.1.100.Final to solve the security vulnerabilities in Netty3. Since hive-druid-handler has a dependency on netty3, Hive doesn't have the `hive-druid-handler` JAR in Hive's classpath in Amazon EMR 7.1. An upcoming Amazon EMR release will include it in Hive's classpath once the Druid handler supports 4.1.100.Final or later versions of Netty. Reach out to AWS support if you need the `hive-druid-handler` JAR in Amazon EMR releases 7.1 or higher.

Amazon EMR 6.15.0 - Hive release notes

Amazon EMR 6.15.0 - Hive changes

Type	Description
Feature	Support for TEZ-4397 – For Tez asynchronous split opening, Hive now supports the Tez configs described in Tez asynchronous split opening.
Bug fix	HIVE-25400 – Move the offset updating in `BytesColumnVector` to `setValPreallocated`.
Bug fix	HIVE-25190 – Fix many small allocations in `BytesColumnVector`.

Type	Description
Upgrade	Upgrade Apache Hadoop to 3.3.6.
Upgrade	HIVE-26684 – Upgrade `maven-shade-plugin` to 3.4.1.
Improvement	To reduce Amazon EMR cluster startup time, remove 15 seconds of sleep time from the HCatalog startup script.

Amazon EMR 6.14.0 - Hive release notes

Amazon EMR 6.14.0 - Hive changes

Type	Description
Improvement	HIVE-26762: Remove operand pruning in `HiveFilterSetOpTransposeRule`
Bug fix	HIVE-27582: Do not cache HBase table input format in FetchOperator
Bug fix	HIVE-26452: NPE when converting JOIN to MAPJOIN and JOIN column referenced more than once
Bug fix	HIVE-26416: `AcidUtils.isRawFormatFile()` throws `InvalidProtocolBufferException` for non-ORC file
Bug fix	HIVE-26105: **Show columns** shows extra values if column **Comments** contains specific Chinese character

Type	Description
Bug fix	HIVE-25864: Hive query optimisation creates wrong plan for predicate pushdown with windowing function
Bug fix	HIVE-25224: Multiple INSERT statements involving tables with different `bucketing_versions` results in error
Bug fix	HIVE-24151: `MultiDelimitSerDe` shifts data if strings contain non-ASCII characters
Bug fix	HIVE-23606: (LLAP) Delay In `DirectByteBuffer` cleanup for `EncodedReaderImpl`
Bug fix	HIVE-22165: Synchronisation introduced by HIVE-14296 on `SessionManager.closeSession` causes high latency in a busy Hive server
Bug fix	HIVE-21304: Make bucketing version usage more robust

Amazon EMR 6.13.0 - Hive release notes

Amazon EMR 6.13.0 - Hive changes

Type	Description
Improvement	Upgrade Python Scripts to Support Python3
Improvement	HIVE-27097: Improve the retry strategy for MetaStore client and server

Type	Description
Bug Fix	HIVE-21778: CBO: “Struct is not null” gets evaluated as nullable always causing filter miss in the query
Bug Fix	HIVE-21009: Adding ability for user to set bind user
Bug Fix	HIVE-22661: Compaction fails on non bucketed table with data loaded inpath
Bug Fix	HIVE-19718: Adding partitions in bulk also fetches table for each partition
Bug Fix	HIVE-22173: Query with multiple lateral views hangs during compilation
Bug Fix	HIVE-27088: Incorrect results when inner and outer joins with post join filters are merged
Bug Fix	HIVE-21935: Hive Vectorization : degraded performance with vectorize UDF
Bug Fix	HIVE-25299: Casting timestamp to numeric data types is incorrect for non-UTC timezones
Bug Fix	HIVE-24626: LLAP: reader threads could be starvated if all IO elevator threads are busy to enqueue to another readers with full queue
Bug Fix	HIVE-27029: hive query fails with Filesystem closed error, Rework done for HIVE-26352
Bug Fix	HIVE-26352: Tez queue access check fails with GSS Exception on Compaction
Bug Fix	HIVE-24590: Operation logging still leaks log4j appenders

Type	Description
Bug Fix	HIVE-24552: Possible HMS connections leak or accumulation in loadDynamicPartitions
Bug Fix	HIVE-27069: Incorrect results with bucket map join
Bug Fix	HIVE-27344: Add a null check in RecordRea derImpl#close
Bug Fix	HIVE-27439: Support space in Decimal
Bug Fix	HIVE-27267: Incorrect results when doing bucket map join on decimal bucketed column with subquery
Bug Fix	HIVE-21986: HiveServer Web UI: Setting the Strict-Transport-Security in default response header
Bug Fix	HIVE-22148: S3A delegation tokens are not added in the job config of the Compactor.
Bug Fix	HIVE-22622: Hive allows to create a struct with duplicate attribute names
Bug Fix	HIVE-22008: LIKE Operator should match multi-line input
Bug Fix	HIVE-23144: LLAP: Let QueryTracker cleanup on serviceStop
Bug Fix	HIVE-22391: NPE while checking Hive query results cache
Bug Fix	HIVE-23305: NullPointerException in LlapTaskSchedulerService addNode due to race condition

Type	Description
Bug Fix	HIVE-22178: Parquet FilterPredicate throws CastException after SchemaEvolution
Bug Fix	HIVE-21517: Fix AggregateStatsCache
Bug Fix	HIVE-21825: Improve client error msg when Active/Passive HA is enabled
Bug Fix	HIVE-23389: FilterMergeRule can lead to AssertionError
Bug Fix	HIVE-22767: Beeline doesn't parse semicolons in comments properly
Bug Fix	HIVE-22996: BasicStats parsing should check proactively for null or empty string
Bug Fix	HIVE-22808: HiveRelFieldTrimmer does not handle HiveTableFunctionScan
Bug Fix	HIVE-22437: LLAP Metadata cache NPE on locking metadata.
Bug Fix	HIVE-22606: AvroSerde logs avro.sche ma.literal under INFO level
Bug Fix	HIVE-22713: Constant propagation shouldn't be done for Join-Fil(*)-RS structure
Bug Fix	HIVE-21624: LLAP: Cpu metrics at thread level is broken
Bug Fix	HIVE-22815: reduce the unnecessary file system object creation in MROutput
Bug Fix	HIVE-23060: Query failing with error "Grouping sets expression is not in GROUP BY key. Error encountered near token"

Type	Description
Bug Fix	HIVE-22236: Fail to create View selecting View containing NOT IN subquery
Bug Fix	HIVE-19886: Logs may be directed to 2 files if —hiveconf hive.log.file is used
Bug Fix	HIVE-20620: manifest collisions when inserting into bucketed sorted MM tables with dynamic partitioning
Bug Fix	HIVE-14557: Nullpointer When both SkewJoin and Mapjoin Enabled
Bug Fix	HIVE-20471: issues getting the default database path
Bug Fix	HIVE-20598: Fix typos in HiveAlgorithmsUtil calculations
Bug Fix	HIVE-14737: Problem accessing /logs in a Kerberized Hive Server 2 Web UI
Bug Fix	HIVE-20733: GenericUDFOPEqualNS may not use = in plan descriptions
Bug Fix	HIVE-20848: After setting UpdateInp utAccessTimeHook query fail with Table Not Found.
Bug Fix	HIVE-18929: The method humanReadableInt in HiveStringUtils.java has a race condition.
Bug Fix	HIVE-20841: LLAP: Make dynamic ports configurable
Bug Fix	HIVE-20930: VectorCoalesce in FILTER mode doesn't take effect

Type	Description
Bug Fix	HIVE-21007: Semi join + Union can lead to wrong plans
Bug Fix	HIVE-21074: Hive bucketed table query pruning does not work for IS NOT NULL condition
Bug Fix	HIVE-21223: CachedStore returns null partition when partition does not exist
Bug Fix	HIVE-19625: Potential NPE and hiding actual exception in Hive#copyFiles
Bug Fix	HIVE-17020: Aggressive RS dedup can incorrectly remove OP tree branch
Bug Fix	HIVE-20168: ReduceSinkOperator Logging Hidden
Bug Fix	HIVE-20879: Using null in a projection expression leads to CastException
Bug Fix	HIVE-20888: TxnHandler: sort() called on immutable lists
Bug Fix	HIVE-19948: HiveCli is not splitting the command by semicolon properly if quotes are inside the string
Bug Fix	HIVE-20621: GetOperationStatus called in resultset.next causing incremental slowness
Bug Fix	HIVE-20854: Sensible Defaults: Hive's Zookeeper heartbeat interval is 20 minutes, change to 2

Type	Description
Bug Fix	HIVE-20330: HCatLoader cannot handle multiple InputJobInfo objects for a job with multiple inputs
Bug Fix	HIVE-20787: MapJoinBytesTableContainer dummyRow case doesn't handle reuse
Bug Fix	HIVE-20331: Query with union all, lateral view and Join fails with "cannot find parent in the child operator"
Bug Fix	HIVE-19968: UDF exception is not throw out
Bug Fix	HIVE-20410: aborted Insert Overwrite on transactional table causes "Not enough history available for…" error
Bug Fix	HIVE-20059: Hive streaming should try shade prefix unconditionally on exception
Bug Fix	HIVE-19424: NPE In MetaDataFormatters
Bug Fix	HIVE-20355: Clean up parameter of HiveConnection.setSchema
Bug Fix	HIVE-20858: Serializer is not correctly initialized with configuration in Utilities.createEmptyBuckets
Bug Fix	HIVE-20424: schematool shall not pollute beeline history
Bug Fix	HIVE-20338: LLAP: Force synthetic file-id for filesystems which have HDFS protocol impls with POSIX mutation semantics

Type	Description
Bug Fix	HIVE-11708: Logical operators raises ClassCast Exceptions with NULL
Bug Fix	HIVE-21082: In HPL/SQL, declare statement does not support variable of type character
Bug Fix	HIVE-16690: Configure Tez cartesian product edge based on LLAP cluster size
Bug Fix	HIVE-21296: Dropping varchar partition throw exception
Bug Fix	HIVE-14516: OrcInputFormat.SplitGenerat or.callInternal
Bug Fix	HIVE-20981: streaming/AbstractRecordWriter leaks HeapMemoryMonitor
Bug Fix	HIVE-20043: HiveServer2: SessionState has a static sync block around an AtomicBoolean
Bug Fix	HIVE-20191: PreCommit patch application doesn't fail if patch is empty
Bug Fix	HIVE-20400: create table should always use a fully qualified path to avoid potential FS ambiguity
Bug Fix	Add null check for skewedInfo before accessing skewed columns

Amazon EMR 6.12.0 - Hive release notes

Amazon EMR 6.12.0 - Hive changes

Type	Description
Improvement	Added Support For JDK 11 and JDK 17 Runtime
Improvement	Add support to query case sensitive and reserved keyword column names when using S3 Select. To use it, define table property in format "s3select.column.mapping" = "*column1*:*fieldName1* , *column2*:*fieldName2* ,..."
Improvement	HIVE-23133: Numeric operations can have different result across hardware archs
Improvement	HIVE-27145: Use StrictMath for remaining Math functions as followup of HIVE-23133
Bug Fix	Fix wildcard incompatibility in get_partitions_by_filter and get_num_partitions_by_filter HMS APIs caused by porting HIVE-22900 in EMR Hive 6.4.0
Bug Fix	HIVE-26736: Authorization failure for nested Views having WITH clause
Bug Fix	HIVE-22416: MR-related operation logs missing when parallel execution is enabled
Bug Fix	HIVE-19653: Incorrect predicate pushdown for groupby with grouping sets
Bug Fix	HIVE-22094: queries failing with ClassCast Exception: hive.ql.exec.vector.Decimal

Type	Description
	ColumnVector cannot be cast to hive.ql.e xec.vector.Decimal64ColumnVector
Bug Fix	HIVE-26340: Vectorized PTF operator fails if query has upper case window function
Bug Fix	HIVE-26184: COLLECT_SET with GROUP BY is very slow when some keys are highly skewed
Bug Fix	HIVE-26373: ClassCastException when reading timestamps from HBase table with Avro data
Bug Fix	HIVE-26388: ClassCastException when there is non string type column in source table of CTAS query Upgrade HIVE-26172: Hive - Upgrade Ant to 1.10.11 due to CVE-2021-36373 and CVE-2021-36374
Bug Fix	HIVE-26114: Fix jdbc connection hiveserve r2 using dfs command with prefix space will cause exceptio
Bug Fix	HIVE-26396: The trunc function has a problem with precision interception and the result has many 0
Bug Fix	HIVE-26446: HiveProtoLoggingHook fails to populate TablesWritten field for partitioned tables.
Bug Fix	HIVE-26639: ConstantVectorExpression and ExplainTask shouldn't rely on default charset
Bug Fix	HIVE-22670: ArrayIndexOutOfBoundsExcept ion when vectorized reader is used for reading a parquet file

Type	Description
Bug Fix	HIVE-23607: Permission Issue: Create view on another view succeeds but alter view fails
Bug Fix	HIVE-25498: Query with more than 31 count distinct functions returns wrong result
Bug Fix	HIVE-25780: DistinctExpansion creates more than 64 grouping sets II
Bug Fix	HIVE-23868: Windowing function spec: support 0 preceeding/following
Bug Fix	HIVE-24539: OrcInputFormat schema generation should respect column delimiter
Bug Fix	HIVE-23476: LLAP: Preallocate arenas for mmap case as well
Bug Fix	HIVE-25806: Possible leak in LlapCache AwareFs - Parquet, LLAP IO
Bug Fix	HIVE-23498: Disable HTTP Trace method on ThriftHttpCliService
Bug Fix	HIVE-25729: ThriftUnionObjectInspector should be notified when fully inited
Bug Fix	HIVE-23846: Avoid unnecessary serialization and deserialization of bitvectors
Bug Fix	HIVE-24233: except subquery throws nullpoint er with cbo disabled
Bug Fix	HIVE-24276: HiveServer2 loggerconf jsp Cross-Site Scripting (XSS) Vulnerability
Bug Fix	HIVE-25721: Outer join result is wrong

Type	Description
Bug Fix	HIVE-25223: Select with limit returns no rows on non native table
Bug Fix	HIVE-25794: CombineHiveRecordReader: log statements in a loop leads to memory pressure
Bug Fix	HIVE-23602: Use Java Concurrent Package for Operation Handle Set
Bug Fix	HIVE-24045: No logging related to when default database is created
Bug Fix	HIVE-24305: avro decimal schema is not properly populating scale/precision if value is enclosed in quote
Bug Fix	HIVE-25844: Exception deserialization error-s may cause beeline to terminate immediately
Bug Fix	HIVE-25040: Drop database cascade cannot remove persistent functions
Bug Fix	HIVE-23501: AOOB in VectorDeserializeR ow when complex types are converted to primitive types
Bug Fix	HIVE-23704: Thrift HTTP Server Does Not Handle Auth Handle Correctly
Bug Fix	HIVE-23529: CTAS is broken for uniontype when row_deserialize
Bug Fix	HIVE-24144: getIdentifierQuoteString in HiveDatabaseMetaData returns incorrect value

Type	Description
Bug Fix	HIVE-23850: Allow PPD when subject is not a column with grouping sets present
Bug Fix	HIVE-24036: Kryo Exception while serializing plan for getSplits UDF call
Bug Fix	HIVE-25919: ClassCastException when pushing boolean column predicate in HBaseStorageHandler
Bug Fix	HIVE-25261: RetryingHMSHandler should wrap the MetaException with short description of the target
Bug Fix	HIVE-24792: Potential thread leak in Operation
Bug Fix	HIVE-23409: If TezSession application reopen fails for Timeline service down, default TezSession from SessionPool is closed after a retry
Bug Fix	HIVE-23615: Do not deference null pointers in Beeline Commands Class
Bug Fix	HIVE-24849: Create external table socket timeout when location has large number of files (affects 3.1.2)
Bug Fix	HIVE-24193: Select query on renamed hive acid table does not produce any output
Bug Fix	HIVE-25209: SELECT query with SUM function producing unexpected result

Type	Description
Bug Fix	HIVE-23666: checkHashModeEfficiency is skipped when a groupby operator doesn't have a grouping set
Bug Fix	HIVE-23873: Querying Hive JDBCStora geHandler table fails with NPE when CBO is off
Bug Fix	HIVE-24149: HiveStreamingConnection doesn't close HMS connection
Bug Fix	HIVE-25561: Killed task should not commit file. (affects 2.x and 3.x versions)
Bug Fix	HIVE-25683: Close reader in AcidUtils .isRawFormatFile
Bug Fix	HIVE-24294: TezSessionPool sessions can throw AssertionError
Bug Fix	HIVE-24182: Ranger authorization issue with permanent UDFs
Bug Fix	HIVE-22805: Vectorization with conditional array or map is not implemented and throws an error
Bug Fix	HIVE-22828: Decimal64: NVL and CASE statements implicitly convert decimal64 to 128
Bug Fix	HIVE-21398: Columns which has estimated statistics should not be considered as unique keys
Bug Fix	HIVE-22490: Adding jars with special character s in their path throws error

Type	Description
Bug Fix	HIVE-22700: Compactions may leak memory when unauthorized
Bug Fix	HIVE-22053: Function name is not normalized when creating function
Bug Fix	HIVE-22595: Dynamic partition inserts fail on Avro table table with external schema
Bug Fix	HIVE-21795: Rollup summary row might be missing when a mapjoin is happening on a partitioned table
Bug Fix	HIVE-22987: ClassCastException in VectorCoa lesce when DataTypePhysicalVariation is null
Bug Fix	HIVE-22814: ArrayIndexOutOfBound in the vectorization getDataTypePhysicalVariation
Bug Fix	HIVE-22523: The error handler in LlapRecor dReader might block if its queue is full
Bug Fix	HIVE-21796: ArrayWritableObjectInspecto r.equals can take O(2^nesting_depth) time
Bug Fix	HIVE-22929: Performance: quoted identifie r parsing uses throwaway Regex via String.re placeAll()
Bug Fix	HIVE-21641: Llap external client returns decimal columns in different precision/scale as compared to beeline
Bug Fix	HIVE-22207: Tez: SplitGenerator throws NumberFormatException when "dfs.block.size" on cluster is "128m"

Type	Description
Bug Fix	HIVE-22114: Insert query for partitioned insert only table failing when all buckets are empty
Bug Fix	HIVE-22165: Synchronisation introduced by HIVE-14296 on SessionManager.closeSession causes high latency in a busy hive server
Bug Fix	HIVE-22744: TezTask for the vertex with more than one outedge should have proportional sort memory
Bug Fix	HIVE-22072: Altering table to make a column change does not update constraints references
Bug Fix	HIVE-22075: Fix the max-reducers=1 regressio n from HIVE-14200
Bug Fix	HIVE-22527: Hive on Tez : Job of merging small files will be submitted into another queue (default queue)
Bug Fix	HIVE-22816: QueryCache: Queries using views can have them cached after CTE expansion
Bug Fix	HIVE-22733: After disable operation log property in hive, still HS2 saving the operation log
Bug Fix	HIVE-22699: Mask UDFs should mask numeric value 0
Bug Fix	HIVE-23356: Hash aggregation is always disabled while processing querys with grouping sets expressions.

Type	Description
Bug Fix	HIVE-21568: HiveRelOptUtil.isRowFilteringPlan should skip Project
Bug Fix	HIVE-21760: Sharedwork optimization should be bypassed for SMB joins
Bug Fix	HIVE-22712: ReExec Driver execute submit the query in default queue irrespective of user defined queue
Bug Fix	HIVE-21397: BloomFilter for hive Managed [ACID] table does not work as expected
Bug Fix	HIVE-23011: Shared work optimizer should check residual predicates when comparing joins
Bug Fix	HIVE-21412: PostExecOrcFileDump doesn't work with ACID tables
Bug Fix	HIVE-22201: ConvertJoinMapJoin#checkShuffleSizeForLargeTable throws ArrayIndexOutOfBoundsException if no big table is selected
Bug Fix	HIVE-21971: HS2 leaks classloader due to \`ReflectionUtils::CONSTRUCTOR_CACHE\` with temporary functions + GenericUDF
Bug Fix	HIVE-21368: Vectorization: Unnecessary Decimal64 ->HiveDecimal conversion
Bug Fix	HIVE-25416: Hive metastore memory leak because datanucleus-api-jdo bug
Bug Fix	HIVE-22219: Bringing a node manager down blocks restart of LLAP service

Type	Description
Bug Fix	HIVE-21793: CBO retrieves column stats even if hive.stats.fetch.column.stats is set to false
Bug Fix	HIVE-22163: CBO: Enabling CBO turns on stats estimation, even when the estimation is disabled
Bug Fix	HIVE-18735: Create table like loses transacti onal attribute
Bug Fix	HIVE-22433: Hive JDBC Storage Handler: Incorrect results fetched from BOOLEAN and TIMESTAMP DataType From JDBC Data Source
Bug Fix	HIVE-19430: ObjectStore.cleanNotificati onEvents OutOfMemory on large number of pending events
Bug Fix	HIVE-20785: Wrong key name in the JDBC DatabaseMetaData.getPrimaryKeys method
Bug Fix	HIVE-16116: Beeline throws NPE when beeline.hiveconfvariables={} in beeline.p roperties
Bug Fix	HIVE-20066: hive.load.data.owner is compared to full principal
Bug Fix	HIVE-20489: Explain plan of query hangs
Bug Fix	HIVE-21033: Forgetting to close operation cuts off any more HiveServer2 output
Bug Fix	HIVE-19888: Misleading "METASTORE_FILTER_HOOK will be ignored" warning from SessionState

Type	Description
Bug Fix	HIVE-20303: INSERT OVERWRITE TABLE db.table PARTITION (...) IF NOT EXISTS throws InvalidTableException
Bug Fix	HIVE-16144: CompactionInfo doesn't have equals/hashCode but used in Set
Bug Fix	HIVE-20818: Views created with a WHERE subquery will regard views referenced in the subquery as direct input
Bug Fix	HIVE-21005: LLAP: Reading more stripes per-split leaks ZlibCodecs
Bug Fix	HIVE-20771: LazyBinarySerDe fails on empty structs.
Bug Fix	HIVE-18852: Misleading error message in alter table validation
Bug Fix	HIVE-21124: HPL/SQL does not support the CREATE TABLE LIKE statement
Bug Fix	HIVE-20935: Upload of llap package tarball fails in EC2 causing LLAP service start failure
Bug Fix	HIVE-20409: Hive ACID: Update/delete/merge does not clean hdfs staging directory
Bug Fix	HIVE-20570: Union ALL with hive.optimize.union.remove=true has incorrect plan
Bug Fix	HIVE-20421: Illegal character entity '\b' in hive-default.xml.template
Bug Fix	HIVE-19133: HS2 WebUI phase-wise performance metrics not showing correctly

Type	Description
Bug Fix	HIVE-18977: Listing partitions returns different results with JDO and direct SQL
Bug Fix	HIVE-20034: Roll back MetaStore exception handling changes for backward compatibility
Bug Fix	HIVE-20672: Logging thread in LlapTaskSchedulerService should report every fixed interval
Bug Fix	HIVE-12812: Enable mapred.input.dir.recursive by default to support union with aggregate function
Bug Fix	HIVE-20147: Hive streaming ingest is contented on synchronized logging
Bug Fix	HIVE-19203: Thread-Safety Issue in HiveMetaStore
Bug Fix	HIVE-20091: Tez: Add security credentials for FileSinkOperator output
Bug Fix	HIVE-16906: Hive ATSHook should check for yarn.timeline-service.enabled before connecting to ATS
Bug Fix	HIVE-20714: SHOW tblproperties for a single property returns the value in the name column
Bug Fix	HIVE-24730: Shims classes override values from hive-site.xml and tez-site.xml silently
Bug Fix	HIVE-22055: select count gives incorrect result after loading data from text file

Amazon EMR 6.11.0 - Hive release notes

Amazon EMR 6.11.0 - Hive changes

Type	Description
Improvement	Added support for multithreaded dropping of partitions to improve the performance of dropping of partitions
Improvement	Support reading encoded Hive query files
Improvement	Enabled Tez Shuffle Handler by default for Hive on Tez jobs
Bug	Added an option to enable deterministic distribution of keys to reducers to fix incorrect result when hive.groupby.skewindata is enabled (reported in HIVE-20220)
Bug	Fixed stats computation failure when default partition name is configured
Bug	Respect any custom SSL classification parameters passed when SSL is configured out of the box for HiveServer2 in a cluster with in-transit encryption enabled
Backport	HIVE-23617: Fixed storage-api FindBug issues
Backport	HIVE-26408: Vectorization: Fix deallocation of scratch columns, don't reuse a child ConstantVectorExpression as an output
Backport	HIVE-23614: Always pass HiveConfig to removeTempOrDuplicateFiles
Backport	HIVE-23354: Remove file size sanity checking from compareTempOrDuplicateFiles

Type	Description
Backport	HIVE-20344: Fixed PrivilegeSynchronizer for SBA throwing AccessControlException. Also introduced property hive.privilege.syn chronizer to disable privilege synchronizer
Backport	HIVE-15826: Support configuring 'serializ ation.encoding' for all SerDes
Backport	HIVE-18284: Fix NPE when inserting data with 'distribute by' clause with dynpart sort optimization
Backport	HIVE-24930: Operator.setDone() short-cir cuit from child op is not used in vectorized codepath (if childSize == 1)
Backport	HIVE-24523: Vectorized read path for LazySimpleSerde does not honor the SERDEPROPERTIES for timestamp
Backport	HIVE-23265: Duplicate rowsets are returned with Limit and Offset set
Backport	HIVE-21492: VectorizedParquetRecordRead er can't to read parquet file generated using thrift/custom tool
Backport	HIVE-22540: Vectorization: Decimal64 columns don't work with VectorizedBatchUti l.makeLikeColumnVector()
Backport	HIVE-22588: Flush the remaining rows for the rest of the grouping sets when switching the vector groupby mode
Backport	HIVE-22551: BytesColumnVector initBuffer should clean vector and length consistently

Type	Description
Backport	HIVE-22448: CBO: Expand the multiple count distinct with a group-by key
Backport	HIVE-22248: Fix statistics persisting issues
Backport	HIVE-22210: Vectorization may reuse computation output columns involved in filtering
Backport	HIVE-21531: Vectorization: all NULL hashcodes are not computed using Murmur3
Backport	HIVE-20419: Vectorization: Prevent mutation of VectorPartitionDesc after being used in a hashmap key
Backport	HIVE-19388: ClassCastException during VectorMapJoinCommonOperator initialization
Backport	HIVE-21584: Java 11 preparation: system class loader is not URLClassLoader
Backport	HIVE-25107: Classpath logging should be on DEBUG level (#2271)
Backport	HIVE-22097: Incompatible java.util.ArrayList for java 11
Backport	HIVE-23938: LLAP: JDK11 - some GC log file rotation related jvm arguments cannot be used anymore
Backport	HIVE-26226: Exclude jdk.tools dep from hive-metastore in upgrade-acid
Backport	HIVE-17879: Upgrade Datanucleus Maven Plugin

Type	Description
Backport	HIVE-27004: DateTimeFormatterBuilder#appendZoneText cannot parse 'UTC+' in Java versions higher than 8
Backport	HIVE-16812: VectorizedOrcAcidRowBatchReader doesn't filter delete events
Backport	HIVE-17917: VectorizedOrcAcidRowBatchReader.computeOffsetAndBucket optimization
Backport	HIVE-19985: ACID: Skip decoding the ROW__ID sections for read-only queries
Backport	HIVE-20635: VectorizedOrcAcidRowBatchReader doesn't filter delete events for original files
Upgrade	Upgrade Javadoc to 3.3.1
Upgrade	Upgrade Javassist to 3.24.1-GA
Upgrade	Update apache-directory-server to 2.0.0-M14

New configurations

Name	Classification	Description
hive.metastore.fs.drop.partition.threads	hive-site	Number of core threads in the drop partition thread pool.
hive.metastore.fs.drop.partition.keepalive.time	hive-site	Time in seconds that an idle drop partition async thread (from the thread pool) will wait for a new task to arrive before terminating.

Name	Classification	Description
hive.metastore.fs.drop.partition.threadpool.max.queue.size	hive-site	Maximum queue size to be used in thread pool for dropping of partitions from file system.
hive.groupby.enable.deterministic.distribution	hive-site	Enable deterministic distribution of keys to reducers. It will pass a constant seed value while calling the rand function used for random partitioning.
hive.privilege.synchronizer	hive-site	Whether to synchronize privileges from external authorizer periodically in HiveServer2.
hive.cli.query.file.encoding	hive-site	File encoding for the all type of query files (query file, init query file, rc file etc) provided in the cli arguments.
hive.emr.tez.shuffle.enabled	hive-site	Hive on Tez jobs now use tez_shuffle by default instead of mapreduce_shuffle as the default Shuffle Handler.

Deprecated configurations

The following configuration properties are deprecated as a result of HIVE-23354 and are no longer supported with Amazon EMR releases 6.11.0 and higher.

Name	Default value
`hive.mapred.reduce.tasks.speculative.execution`	`false`
`tez.am.speculation.enabled`	`false`

Amazon EMR 6.10.0 - Hive release notes

Amazon EMR 6.10.0 - Hive changes

Type	Description
Feature	Enable AWS Lake Formation based access controls for Apache Hive queries **(write)** via IAM Passthrough (HiveCLI/Steps API).
Improvement	Disable config `hive.log.explain.output` by default to reduce log size
Backport	HIVE-26408: Vectorization: Fix deallocation of scratch columns, don't reuse a child ConstantVectorExpression as an output
Backport	HIVE-22269: Fix wrong reducers count in insert queries with dynamic partition due to missing of stats caused by HIVE-20703.
Backport	HIVE-22891: Skip PartitionDesc Extraction In CombineHiveRecord For Non-LLAP Execution Mode
Backport	HIVE-23804: Add default database for column stats specific tables in Hive metastore schema to make then backward compatible
Backport	HIVE-25277: Slow Hive partition deletion for Cloud object stores with expensive ListFiles

Type	Description
Backport	HIVE-19202: CBO failed due to NullPointerException in HiveAggregate.isBucketedInput()
Backport	HIVE-19048: Fix beeline Initscript errors are ignored
Backport	HIVE-21085: Materialized views registry starts non-external tez session
Backport	HIVE-21675: CREATE VIEW IF NOT EXISTS returns an error rather than "OK" if the view already exists. This is a regression from Hive 2.
Backport	HIVE-21646: Tez: Prevent TezTasks from escaping thread logging context
Backport	HIVE-22054: Avoid recursive listing to check if a directory is empty
Backport	HIVE-16587: NPE when inserting complex types with nested null values
Backport	HIVE-22647: Enable session pool by default
Backport	HIVE-13288: Confusing exception message in DagUtils.localizeResource
Backport	HIVE-23870: Optimise multiple text conversions in WritableHiveCharObjectInspector.getPrimitiveJavaObject / HiveCharWritable
Backport	HIVE-21498: Upgrade Thrift to 0.13.0
Backport	HIVE-24378: Leading and trailing spaces are not removed before decimal conversion

Type	Description
Backport	HIVE-21341: Sensible defaults : hive.serv er2.idle.operation.timeout and hive.serv er2.idle.session.timeout are too high
Backport	HIVE-22465: Add ssl conf in TezConfig urationFactory
Backport	HIVE-24710: Optimise PTF iteration for count(*) to reduce CPU and IO cost
Backport	HIVE-15406: Consider vectorizing the new 'trunc' function
Backport	HIVE-21541: Fix missing asf headers from HIVE-15406
Backport	HIVE-24808: Cache Parsed Dates
Backport	HIVE-24746: PTF: TimestampValueBoun daryScanner can be optimised during range computation
Backport	HIVE-25059: Alter event is converted to rename during replication
Backport	HIVE-25142: Rehashing in map join fast hash table causing corruption for large keys
Backport	HIVE-23756: Added more constraints to the package.jdo file
Backport	HIVE-25150: Tab characters are not removed before decimal conversion similar to space character which is fixed as part of HIVE-24378
Backport	HIVE-25093: date_format() UDF is returning output in UTC time zone only

Type	Description
Backport	HIVE-25268: date_format udf returns wrong results for dates prior to 1900 if the local timezone is other than UTC
Backport	HIVE-25338: AIOBE in conv UDF if input is empty
Backport	HIVE-22400: UDF minute with time returns NULL
Backport	HIVE-25058: PTF: TimestampValueBoun daryScanner can be optimised during range computation pt2 - isDistanceGreater
Backport	HIVE-25449: datediff() gives wrong output when run in a tez task with some non-UTC timezone
Backport	HIVE-23688: Vectorization: IndexArra yOutOfBoundsException For map type column which includes null value
Backport	HIVE-22247: HiveHFileOutputFormat throws FileNotFoundException when partition's task output empty
Backport	HIVE-25570: Hive should send full URL path for authorization for the command insert overwrite location
Backport	HIVE-22903: Vectorized row_number() resets the row number after one batch in case of constant expression in partition clause
Backport	HIVE-25549: Wrong results for window function with expression in PARTITION BY or ORDER BY clause

Type	Description
Backport	HIVE-25579: LOAD overwrite appends rather than overwriting
Backport	HIVE-25659: Metastore direct sql queries with IN/(NOT IN) should be split based on max parameters allowed by SQL DB
Backport	HIVE-20502: Fix NPE while running skewjoin_mapjoin10.q when column stats is used.
Backport	HIVE-25765: skip.header.line.count property skips rows of each block in FetchOperator when file size is larger
Bug	Fix NPE on insert in certain scenarios when `hive.stats.column.autogather` and `hive.groupby.skewindata` are both enabled
Bug	Fix NPE when `mapred.tasktracker.expiry.interval` value is not set

Amazon EMR 6.9.0 - Hive release notes

Amazon EMR 6.9.0 - Hive changes

Type	Description
Upgrade	Upgrade Jetty to 9.4.48.v20220622
Upgrade	Support for Hadoop 3.3.3
Feature	Amazon EMR Hive integration with Lake Formation for interactive workloads using GCSC API.

Type	Description
Feature	Amazon EMR Hive integration with Iceberg.
Improvement	Enable SSL in HiveServer2 when in-transit encryption is enabled using Amazon EMR security configurations.
Improvement	Enable Hive EMRFS Amazon S3 optimized committer by default. For more information see, Enabling Hive EMRFS S3 optimized committer.
Improvement	Add `HiveHBaseTableInputFormatV2` that inherits only mapred version of InputFormat to fix SPARK-34210. Set `hive.hbase.inputformat.v2` to `true` to use it.
Improvement	Wait for TezAM to launch in background with hive.cli.tez.session.async instead of terminating it and launching new immediately. Use `hive.emr.cli.tez.session.open.timeout` to set this timeout in seconds.
Improvement	Add option hive.conf.restricted.list.append to append comma-separated configs to existing restricted config list `hive.conf.restricted.list` .
Improvement	Clearer error message when Hive query fails because location is not defined for database.
Backport	HIVE-24484: Upgrade Hadoop to 3.3.1 And Tez to 0.10.2
Backport	HIVE-22398: Remove YARN queue management via ShimLoader.

Type	Description
Backport	HIVE-23190: LLAP: modify IndexCache to pass filesystem object to TezSpillRecord.
Backport	HIVE-22185: HADOOP-15832 will cause problems with tests using MiniYarn clusters.
Backport	HIVE-21670: Replacing `mockito-all` with `mockito-core` dependency.
Backport	HIVE-24542: Prepare Guava for Upgrades.
Backport	HIVE-23751: QTest: Override `#mkdirs()` method in `ProxyFileSystem` to align after HADOOP-16582.
Backport	HIVE-21603: Java 11 preparation: update powermock version.
Backport	HIVE-24083: `hcatalog` error in Hadoop 3.3.0: authentication type needed.
Backport	HIVE-24282: Show columns shouldn't sort output columns unless explicitly mentioned.
Backport	HIVE-20656: Sensible defaults: Map aggregati on memory configs are too aggressive.
Backport	HIVE-25443: Arrow SerDe cannot serialize/ deserialize complex data types when there are more than 1024 values
Backport	HIVE-19792: Upgrade orc to 1.5.2 and enable decimal_64 schema evolution tests.
Backport	HIVE-20437: Handle schema evolution from float, double, and decimal.

Type	Description
Backport	HIVE-21987: Hive is unable to read Parquet int32 annotated with decimal.
Backport	HIVE-20038: Update queries on non-bucketed and partitioned tables throws NPE.

Amazon EMR 6.9.0 - Hive known issues

- With Amazon EMR 6.6.0 through 6.9.x, INSERT queries with dynamic partition and an ORDER BY or SORT BY clause will always have two reducers. This issue is caused by OSS change HIVE-20703, which puts dynamic sort partition optimization under cost-based decision. If your workload doesn't require sorting of dynamic partitions, we recommend that you set the `hive.optimize.sort.dynamic.partition.threshold` property to `-1` to disable the new feature and get the correctly calculated number of reducers. This issue is fixed in OSS Hive as part of HIVE-22269 and is fixed in Amazon EMR 6.10.0.

Amazon EMR 6.8.0 - Hive release notes

Amazon EMR 6.8.0 - Hive changes

Type	Description
Improvement	Reduce file system calls in msck command. Performance improvements (~15-20x on 10k+ partitions)
Backport	HIVE-20678: HiveHBaseTableOutputFormat should implement HiveOutputFormat to ensure compatibility
Backport	HIVE-21040: msck does unnecessary file listing at last level of directory tree
Backport	HIVE-21460: Load data followed by a select * query results in incorrect results

Type	Description
Backport	HIVE-21660: Wrong result when union all and later view with explode is used
Backport	HIVE-22505: ClassCastException caused by wrong Vectorized operator selection
Backport	HIVE-22513: Constant propagation of casted column in filter ops can cause incorrect results
Backport	HIVE-23435: Full outer join result is missing rows
Backport	HIVE-24209: Incorrect search argument conversion for NOT BETWEEN operation when vectorization is enabled
Backport	HIVE-24934: VectorizedExpressions annotation is not needed in GenericUDFSQCountCheck
Backport	HIVE-25278: HiveProjectJoinTransposeRule may do invalid transformations with windowing expressions
Backport	HIVE-25505: Incorrect results with header.skip.header.line.count if first line is blank
Backport	HIVE-26080: Upgrade accumulo-core to 1.10.1
Backport	HIVE-26235: OR Condition on binary column is returning empty result
Bug	Fix multiple SLF4J bindings warning logs in stderr during launch
Bug	Fix SHOW TABLE EXTENDED query failing with Wrong FS error when partition and table are on different file systems.

Amazon EMR 6.8.0 - Hive known issues

- With Amazon EMR 6.6.0 through 6.9.x, INSERT queries with dynamic partition and an ORDER BY or SORT BY clause will always have two reducers. This issue is caused by OSS change HIVE-20703, which puts dynamic sort partition optimization under cost-based decision. If your workload doesn't require sorting of dynamic partitions, we recommend that you set the `hive.optimize.sort.dynamic.partition.threshold` property to `-1` to disable the new feature and get the correctly calculated number of reducers. This issue is fixed in OSS Hive as part of HIVE-22269 and is fixed in Amazon EMR 6.10.0.

Amazon EMR 6.7.0 - Hive release notes

Amazon EMR 6.7.0 - Hive changes

Type	Description
Feature	Amazon EMR Hive integration with LakeFormation.
Feature	Additional audit logging for Hive EMRFS Amazon S3 optimized committer. Hive config: `hive.blobstore.output-committer.logging` , default: `false`
Feature	Deleted target directory on insert overwrite with empty select result to an unpartitioned table/static partition to behave similarly to Hive 2.x. Hive config: `hive.emr.iow.clean.target.dir` , default: `false`
Bug	Fixed intermittent query failure when using Hive EMRFS Amazon S3 optimized committer with partition bucket sorting.
Upgrade	Hive version upgraded to 3.1.3. Refer to Apache Hive 3.1.3 release notes for more details.

Type	Description
Upgrade	Upgraded Parquet to 1.12.2.
Backport	HIVE-20065: Metastore should not rely on jackson 1.x
Backport	HIVE-20071: Migrate to jackson 2.x and prevent usage
Backport	HIVE-20607: TxnHandler should use PreparedStatement to execute direct SQL queries
Backport	HIVE-20740: Remove global lock in ObjectSto re.setConf method
Backport	HIVE-20961: Retire NVL implementation
Backport	HIVE-22059: hive-exec jar doesn't contain (fasterxml) jackson library
Backport	HIVE-22351: Fix incorrect threaded ObjectSto re usage in TestObjectStore
Backport	HIVE-23534: NPE in RetryingMetaStoreC lient#invoke when catching MetaException with no message
Backport	HIVE-24048: Harmonise Jackson components to version 2.10.latest - Hive
Backport	HIVE-24768: Use jackson-bom everywhere for version replacement
Backport	HIVE-24816: Upgrade jackson to 2.10.5.1 or 2.11.0+ due to CVE-2020-25649
Backport	HIVE-25971: Tez task shutdown getting delayed due to cached thread pool not closed

Type	Description
Backport	HIVE-26036: NPE caused by getMTable() in ObjectStore

Amazon EMR 6.7.0 - Hive known issues

- Queries with windowing functions on the same column as join may lead to invalid transformations as reported in HIVE-25278 and cause incorrect results or query failures. A workaround would be to disable CBO at the query level for such queries. The fix will be available in an Amazon EMR release following 6.7.0. For more information, contact AWS support.
- With Amazon EMR 6.6.0 through 6.9.x, INSERT queries with dynamic partition and an ORDER BY or SORT BY clause will always have two reducers. This issue is caused by OSS change HIVE-20703, which puts dynamic sort partition optimization under cost-based decision. If your workload doesn't require sorting of dynamic partitions, we recommend that you set the `hive.optimize.sort.dynamic.partition.threshold` property to `-1` to disable the new feature and get the correctly calculated number of reducers. This issue is fixed in OSS Hive as part of HIVE-22269 and is fixed in Amazon EMR 6.10.0.

Amazon EMR 6.6.0 - Hive release notes

Amazon EMR 6.6.0 - Hive changes

Type	Description
Upgrade	Upgrade Parquet to 1.12.1.
Upgrade	Upgrade jetty jars version to 9.4.43.v2 0210629
Bug	Fixed an issue that was causing Hive to be installed on all task/core nodes when LLAP was enabled on a Hive cluster.
Backport	HIVE-25942: Upgrade commons-io to 2.8.0 due to CVE-2021-29425

Type	Description
Backport	HIVE-25726: Upgrade velocity to 2.3 due to CVE-2020-13936
Backport	HIVE-25680: Authorize #get_table_meta HiveMetastore Server API to use any of the HiveMetastore Authorization model.
Backport	HIVE-25554: Upgrade arrow version to 0.15
Backport	HIVE-25242: Query performs extremely slow with vectorized.adaptor = chosen
Backport	HIVE-25085: MetaStore Clients no longer shared across sessions.
Backport	HIVE-24827: Hive aggregation query returns incorrect results for non text files.
Backport	HIVE-24683: Hadoop23Shims getFileId prone to NPE for non-existing paths
Backport	HIVE-24656: CBO fails for queries with is null on map and array types
Backport	HIVE-24556: Optimize DefaultGraphWalker for case with no grandchild
Backport	HIVE-24408: Upgrade Parquet to 1.11.1
Backport	HIVE-24391: Fix FIX TestOrcFile failures in branch-3.1
Backport	HIVE-24362: AST tree processing is suboptima l for tree with large number of nodes
Backport	HIVE-24316: Upgrade ORC from 1.5.6 to 1.5.8 in branch-3.1

Type	Description
Backport	HIVE-24307: Beeline with property-file and -e parameter is failing
Backport	HIVE-24245: Vectorized PTF with count and distinct over partition producing incorrect results.
Backport	HIVE-24224: Fix skipping header/footer for Hive on Tez on compressed file
Backport	HIVE-24157: Strict mode to fail on CAST timestamp ↔ numeric
Backport	HIVE-24113: NPE in GenericUDFToUnixTi meStamp
Backport	HIVE-23987: Upgrade arrow version to 0.11.0
Backport	HIVE-23972: Add external client ID to LLAP external client
Backport	HIVE-23806: Avoid clearing column stat states in all partition in case schema is extended. This improves runtime of alter table add columns statement.
Backport	HIVE-23779: BasicStatsTask Info is not getting printed in beeline console
Backport	HIVE-23306: RESET command does not work if there is a config set by System.getProperty
Backport	HIVE-23164: Server is not properly terminated because of non-daemon threads
Backport	HIVE-22967: Support hive.reloadable.au x.jars.path for Hive on Tez

Type	Description
Backport	HIVE-22934: Hive server interactive log counters to error stream
Backport	HIVE-22901: Variable substitution can lead to OOM on circular references
Backport	HIVE-22769: Incorrect query results and query failure during split generation for compressed text files
Backport	HIVE-22716: Reading to ByteBuffer is broken in ParquetFooterInputFromCache
Backport	HIVE-22648: Upgrade Parquet to 1.11.0
Backport	HIVE-22640: Decimal64ColumnVector: ClassCastException when partition column type is Decimal
Backport	HIVE-22621: unstable testcase: TestLlapS ignerImpl.testSigning
Backport	HIVE-22533: Fix possible LLAP daemon web UI vulnerabilities
Backport	HIVE-22532: PTFPPD may push limit incorrect ly through Rank/DenseRank function
Backport	HIVE-22514: HiveProtoLoggingHook might consume lots of memory
Backport	HIVE-22476: Hive datediff function provided inconsistent results when hive.fetch.task.co nversion is set to none

Type	Description
Backport	HIVE-22429: Migrated clustered tables using bucketing_version 1 on hive 3 uses bucketing _version 2 for inserts
Backport	HIVE-22412: StatsUtils throw NPE when explain
Backport	HIVE-22360: MultiDelimitSerDe returns wrong results in last column when the loaded file has more columns than those in table schema
Backport	HIVE-22332: Hive should ensure valid schema evolution settings since ORC-540
Backport	HIVE-22331: unix_timestamp without argument returns timestamp in millisecond instead of second
Backport	HIVE-22275: OperationManager.queryIdOpe ration does not properly clean up multiple queryIds
Backport	HIVE-22273: Access check is failed when a temporary directory is removed
Backport	HIVE-22270: Upgrade commons-io to 2.6
Backport	HIVE-22241: Implement UDF to interpret date/timestamp using its internal represent ation and Gregorian-Julian hybrid calendar
Backport	HIVE-22241: Implement UDF to interpret date/timestamp using its internal represent ation and Gregorian-Julian hybrid
Backport	HIVE-22232: NPE when hive.order.columna lignment is set to false

Type	Description
Backport	HIVE-22231: Hive query with big size via knox fails with Broken pipe Write failed
Backport	HIVE-22221: Llap external client - Need to reduce LlapBaseInputFormat#getSplits
Backport	HIVE-22208: Column name with reserved keyword is unescaped when query including join on table with mask column is re-written
Backport	HIVE-22197: Common Merge join throwing class cast exception.
Backport	HIVE-22170: from_unixtime and unix_time stamp should use user session time zone
Backport	HIVE-22169: Tez: SplitGenerator tries to look for plan files which won't exist for Tez
Backport	HIVE-22168: Remove very expensive logging from the llap cache hotpath
Backport	HIVE-22161: UDF: FunctionRegistry synchroni zes on org.apache.hadoop.hive.ql.udf.UDFType class
Backport	HIVE-22120: Fix wrong results/ArrayOutOf Bound exception in left outer map joins on specific boundary conditions
Backport	HIVE-22115: Prevent the creation of query routing appender if property is set to false
Backport	HIVE-22113: Prevent LLAP shutdown on AMReporter related RuntimeException

Type	Description
Backport	HIVE-22106: Remove cross-query synchronization for the partition-eval
Backport	HIVE-22099: Several date related UDFs can't handle Julian dates properly since HIVE-20007
Backport	HIVE-22037: HS2 should log when shutting down due to OOM
Backport	HIVE-21976: Offset should be null instead of zero in Calcite HiveSortLimit
Backport	HIVE-21924: Split text files even if header/footer exists
Backport	HIVE-21913: GenericUDTFGetSplits should handle usernames in the same way as LLAP
Backport	HIVE-21905: Generics improvement around the FetchOperator class
Backport	HIVE-21902: HiveServer2 UI: jetty response header needs X-Frame-Options
Backport	HIVE-21888: Set hive.parquet.timestamp.skip.conversion default to true
Backport	HIVE-21868: Vectorize CAST...FORMAT
Backport	HIVE-21864: LlapBaseInputFormat#closeAll
Backport	HIVE-21863: Improve Vectorizer type casting for WHEN expression
Backport	HIVE-21862: ORC ppd produces wrong result with timestamp

Type	Description
Backport	HIVE-21846: Create a thread in TezAM which periodically fetches LlapDaemon metrics
Backport	HIVE-21837: MapJoin is throwing exception when selected column is having completely null values
Backport	HIVE-21834: Avoid unnecessary calls to simplify filter conditions
Backport	HIVE-21832: New metrics to get the average queue/serving/response time
Backport	HIVE-21827: Multiple calls in SemanticA nalyzer do not go through getTableO bjectByName method
Backport	HIVE-21822: Expose LlapDaemon metrics through a new API method
Backport	HIVE-21818: CBO: Copying TableRelO ptHiveTable has metastore traffic
Backport	HIVE-21815: Stats in ORC file are parsed twice
Backport	HIVE-21805: HiveServer2: Use the fast ShutdownHookManager APIs
Backport	HIVE-21799: NullPointerException in DynamicPartitionPruningOptimization, when join key is on aggregation column
Backport	HIVE-21794: Add materialized view parameter s to sqlStdAuthSafeVarNameRegexes
Backport	HIVE-21768: JDBC: Strip the default union prefix for un-enclosed UNION queries

Type	Description
Backport	HIVE-21746: ArrayIndexOutOfBoundsException during dynamically partitioned hash join, with CBO disabled
Backport	HIVE-21717: Rename is failing for directory in move task.
Backport	HIVE-21685: Wrong simplification in query with multiple IN clauses
Backport	HIVE-21681: Describe formatted shows incorrect information for multiple primary keys
Backport	HIVE-21651: Move protobuf serde into hive-exec.
Backport	HIVE-21619: Print timestamp type without precision in SQL explain extended
Backport	HIVE-21592: OptimizedSql is not shown when the expression contains CONCAT
Backport	HIVE-21576: Introduce CAST...FORMAT and limited list of SQL:2016 datetime formats
Backport	HIVE-21573: Binary transport shall ignore principal if auth is set to delegationToken
Backport	HIVE-21550: TestObjectStore tests are flaky - A lock could not be obtained within the time requested
Backport	HIVE-21544: Constant propagation corrupts coalesce/case/when expressions during folding

Type	Description
Backport	HIVE-21539: GroupBy + where clause on same column results in incorrect query rewrite
Backport	HIVE-21538: Beeline: password source though the console reader did not pass to connection param
Backport	HIVE-21509: LLAP may cache corrupted column vectors and return wrong query result
Backport	HIVE-21499: should not remove the function from registry if create command failed with AlreadyExistsException
Backport	HIVE-21496: Automatic sizing of unordered buffer can overflow
Backport	HIVE-21468: Case sensitivity in identifier names for JDBC storage handler
Backport	HIVE-21467: Remove deprecated junit.framework.Assert imports
Backport	HIVE-21435: LlapBaseInputFormat should get task number from TASK_ATTEMPT_ID conf if present, while building SubmitWorkRequestProto
Backport	HIVE-21389: Hive distribution miss javax.ws.rs-api.jar after HIVE-21247
Backport	HIVE-21385: Allow disabling pushdown of non-splittable computation to JDBC sources
Backport	HIVE-21383: JDBC storage handler: Use catalog and schema to retrieve tables if specified

Type	Description
Backport	HIVE-21382: Group by keys reduction optimization - keys are not reduced in query23
Backport	HIVE-21362: Add an input format and serde to read from protobuf files.
Backport	HIVE-21340: CBO: Prune non-key columns feeding into a SemiJoin
Backport	HIVE-21332: Purge the non locked buffers instead of locked ones
Backport	HIVE-21329: Custom Tez runtime unordered output buffer size depending on operator pipeline
Backport	HIVE-21295: StorageHandler shall convert date to string using Hive convention
Backport	HIVE-21294: Vectorization: 1-reducer Shuffle can skip the object hash functions
Backport	HIVE-21255: Remove QueryConditionBuilder in JdbcStorageHandler
Backport	HIVE-21253: Support DB2 in JDBC StorageHa ndler
Backport	HIVE-21232: LLAP: Add a cache-miss friendly split affinity provider
Backport	HIVE-21214: MoveTask : Use attemptId instead of file size for deduplication of files compareTempOrDuplicateFiles
Backport	HIVE-21184: Add explain and explain formatted CBO plan with cost information

Type	Description
Backport	HIVE-21182: Skip setting up hive scratch dir during planning
Backport	HIVE-21171: Skip creating scratch dirs for tez if RPC is on
Backport	HIVE-21126: Allow session level queries in LlapBaseInputFormat#getSplit
Backport	HIVE-21107: Cannot find field" error during dynamically partitioned hash join
Backport	HIVE-21061: CTAS query fails with IllegalSt ateException for empty source
Backport	HIVE-21041: NPE, ParseException in getting schema from logical plan
Backport	HIVE-21013: JdbcStorageHandler fail to find partition column in Oracle
Backport	HIVE-21006: Extend SharedWorkOptimizer to remove semijoins when there is a reutilization opportunity
Backport	HIVE-20992: Split the config hive.meta store.dbaccess.ssl.properties into more meaningful configs
Backport	HIVE-20989: JDBC - The GetOperationStatus + log can block query progress via sleep
Backport	HIVE-20988: Wrong results for group by queries with primary key on multiple columns

Type	Description
Backport	HIVE-20985: If select operator inputs are temporary columns vectorization may reuse some of them as output
Backport	HIVE-20978: "hive.jdbc.*" should add to sqlStdAuthSafeVarNameRegexes
Backport	HIVE-20953: Remove a function from function registry when it can not be added to the metastore when creating it.
Backport	HIVE-20952: Cleaning VectorizationConte xt.java
Backport	HIVE-20951: LLAP: Set Xms to 50% always
Backport	HIVE-20949: Improve PKFK cardinality estimation in physical planning
Backport	HIVE-20944: Not validate stats during query compilation
Backport	HIVE-20940: Bridge cases in which Calcite's type resolution is more stricter than Hive.
Backport	HIVE-20937: Postgres jdbc query fail with "LIMIT must not be negative"
Backport	HIVE-20926: Semi join reduction hint fails when bloom filter entries are high or when there are no stats
Backport	HIVE-20920: Use SQL constraints to improve join reordering algorithm

Type	Description
Backport	HIVE-20918: Flag to enable/disable pushdown of computation from Calcite into JDBC connection
Backport	HIVE-20915: Make dynamic sort partition optimization available to HoS and MR
Backport	HIVE-20910: Insert in bucketed table fails due to dynamic partition sort optimization
Backport	HIVE-20899: Keytab URI for LLAP YARN Service is restrictive to support HDFS only
Backport	HIVE-20898: For time related functions arguments may not be casted to a non nullable type
Backport	HIVE-20881: Constant propagation oversimplifies projections
Backport	HIVE-20880: Update default value for hive.stats.filter.in.min.ratio
Backport	HIVE-20873: Use Murmur hash for VectorHashKeyWrapperTwoLong to reduce hash collision
Backport	HIVE-20868: SMB Join fails intermittently when TezDummyOperator has child op in getFinalOp in MapRecordProcessor
Backport	HIVE-20853: Expose ShuffleHandler.registerDag in the llap daemon API
Backport	HIVE-20850: Push case conditional from projections to dimension tables if possible

Type	Description
Backport	HIVE-20842: Fix logic introduced in HIVE-20660 to estimate statistics for group by
Backport	HIVE-20839: "Cannot find field" error during dynamically partitioned hash join
Backport	HIVE-20835: Interaction between constraints and MV rewriting may create loop in Calcite planner
Backport	HIVE-20834: Hive QueryResultCache entries keeping reference to SemanticAnalyzer from cached query
Backport	HIVE-20830: JdbcStorageHandler range query assertion failure in some cases
Backport	HIVE-20829: JdbcStorageHandler range split throws NPE
Backport	HIVE-20827: Inconsistent results for empty arrays
Backport	HIVE-20826: Enhance HiveSemiJoin rule to convert join + group by on left side to Left Semi Join
Backport	HIVE-20821: Rewrite SUM0 into SUM + COALESCE combination
Backport	HIVE-20815: JdbcRecordReader.next shall not eat exception
Backport	HIVE-20813: udf to_epoch_milli need to support timestamp without time zone as well.

Type	Description
Backport	HIVE-20804: Further improvements to group by optimization with constraints
Backport	HIVE-20792: Inserting timestamp with zones truncates the data
Backport	HIVE-20788: Extended SJ reduction may backtrack columns incorrectly when creating filters
Backport	HIVE-20778: Join reordering may not be triggered if all joins in plan are created by decorrelation logic
Backport	HIVE-20772: record per-task CPU counters in LLAP
Backport	HIVE-20768: Adding Tumbling Window UDF
Backport	HIVE-20767: Multiple project between join operators may affect join reordering using constraints
Backport	HIVE-20762: NOTIFICATION_LOG cleanup interval is hardcoded as 60s and is too small
Backport	HIVE-20761: Select for update on notificat ion_sequence table has retry interval and retries count too small
Backport	HIVE-20751: Upgrade arrow version to 0.10.0
Backport	HIVE-20746: HiveProtoHookLogger does not close file at end of day.
Backport	HIVE-20744: Use SQL constraints to improve join reordering algorithm

Type	Description
Backport	HIVE-20740: Remove global lock in ObjectStore.setConf method. This cherrypick backports HIVE-20740 intended for Hive 3.2 and 4.x to 3.1.x
Backport	HIVE-20734: Beeline: When beeline-site.xml is and hive CLI redirects to beeline, it should use the system username/dummy password instead of prompting for one
Backport	HIVE-20731: keystore file in JdbcStorageHandler should be authorized
Backport	HIVE-20720: Add partition column option to JDBC handler
Backport	HIVE-20719: SELECT statement fails after UPDATE with hive.optimize.sort.dynamic.partition optimization and vectorization on
Backport	HIVE-20718: Add perf cli driver with constraints
Backport	HIVE-20716: Set default value for hive.cbo.stats.correlated.multi.key.joins to true
Backport	HIVE-20712: HivePointLookupOptimizer should extract deep cases
Backport	HIVE-20710: Constant folding may not create null constants without types
Backport	HIVE-20706: external_jdbc_table2.q failing intermittently
Backport	HIVE-20704: Extend HivePreFilteringRule to support other functions

Type	Description
Backport	HIVE-20703: Put dynamic sort partition optimization under cost based decision
Backport	HIVE-20702: Account for overhead from datastructure aware estimations during mapjoin selection
Backport	HIVE-20692: Enable folding of NOT x IS (NOT) [TRUE|FALSE] expressions
Backport	HIVE-20691: Fix org.apache.hadoop.hive.cli. TestMiniLlapCliDriver.testCliDriver[cttl]
Backport	HIVE-20682: Async query execution can potentially fail if shared sessionHive is closed by master thread
Backport	HIVE-20676: HiveServer2: PrivilegeSynchroni zer is not set to daemon status
Backport	HIVE-20660: Group by statistics estimatio n could be improved by bounding the total number of rows to source table
Backport	HIVE-20652: JdbcStorageHandler push join of two different datasource to jdbc driver
Backport	HIVE-20651: JdbcStorageHandler password should be encrypted
Backport	HIVE-20649: LLAP aware memory manager for Orc writers
Backport	HIVE-20648: LLAP: Vector group by operator should use memory per executor

Type	Description
Backport	HIVE-20646: Partition filter condition is not pushed down to metastore query if it has IS NOT NULL
Backport	HIVE-20644: Avoid exposing sensitive infomation through a Hive Runtime exception
Backport	HIVE-20636: Improve number of null values estimation after outer join
Backport	HIVE-20632: Query with get_splits UDF fails if materialized view is created on queried table
Backport	HIVE-20627: Concurrent async queries intermittently fails with LockException and cause memory leak
Backport	HIVE-20623: Shared work: Extend sharing of map-join cache entries in LLAP
Backport	HIVE-20619: Include MultiDelimitSerDe in HiveServer2 By Default
Backport	HIVE-20618: During join selection BucketMap Join might be choosen for non bucketed tables
Backport	HIVE-20617: Fix type of constants in IN expressions to have correct type
Backport	HIVE-20612: Create new join multi-key correlation flag for CBO
Backport	HIVE-20603: "Wrong FS" error when inserting to partition after changing table location filesystem

Type	Description
Backport	HIVE-20601: EnvironmentContext null in ALTER_PARTITION event in DbNotificationList ener
Backport	HIVE-20583: Use canonical hostname only for kerberos auth in HiveConnection
Backport	HIVE-20582: Make hflush in hive proto logging configurable
Backport	HIVE-20563: Vectorization: CASE WHEN expression fails when THEN/ELSE type and result type are different
Backport	HIVE-20558: Change default of hive.hash table.key.count.adjustment to 0.99
Backport	HIVE-20552: Get Schema from LogicalPlan faster
Backport	HIVE-20550: Switch WebHCat to use beeline to submit Hive queries
Backport	HIVE-20537: Multi-column joins estimates with uncorrelated columns different in CBO and Hive
Backport	HIVE-20524: Schema Evolution checking is broken in going from Hive version 2 to version 3 for ALTER TABLE VARCHAR to DECIMAL
Backport	HIVE-20522: HiveFilterSetOpTransposeRule may throw assertion error due to nullability of fields

Type	Description
Backport	HIVE-20521: HS2 doAs=true has permission issue with hadoop.tmp.dir, with MR and S3A filesystem
Backport	HIVE-20515: Empty query results when using results cache and query temp dir, results cache dir in different filesystems
Backport	HIVE-20508: Hive does not support user names of type "user@realm"
Backport	HIVE-20507: Beeline: Add a utility command to retrieve all uris from beeline-site.xml
Backport	HIVE-20505: upgrade org.openjdk.jmh:jmh-core to 1.21
Backport	HIVE-20503: Use datastructure aware estimations during mapjoin selection
Backport	HIVE-20498: Support date type for column stats autogather
Backport	HIVE-20496: Vectorization: Vectorized PTF IllegalStateException
Backport	HIVE-20494: GenericUDFRestrictInformationSchema is broken after HIVE-19440
Backport	HIVE-20477: OptimizedSql is not shown if the expression contains INs
Backport	HIVE-20467: Allow IF NOT EXISTS/IF EXISTS in Resource plan creation/drop
Backport	HIVE-20462: "CREATE VIEW IF NOT EXISTS" fails if view already exists

Type	Description
Backport	HIVE-20455: Log spew from security.authorization.PrivilegeSynchonizer.run
Backport	HIVE-20439: Use the inflated memory limit during join selection for llap
Backport	HIVE-20433: Implicit String to Timestamp conversion is slow
Backport	HIVE-20432: Rewrite BETWEEN to IN for integer types for stats estimation
Backport	HIVE-20423: Set NULLS LAST as the default null ordering
Backport	HIVE-20418: LLAP IO may not handle ORC files that have row index disabled correctly for queries with no columns selected
Backport	HIVE-20412: NPE in HiveMetaHook
Backport	HIVE-20406: Nested Coalesce giving incorrect results
Backport	HIVE-20399: CTAS w/a custom table location that is not fully qualified fails for MM tables
Backport	HIVE-20393: Semijoin Reduction : markSemiJoinForDPP behaves inconsistently
Backport	HIVE-20391: HiveAggregateReduceFunctionsRule may infer wrong return type when decomposing aggregate function
Backport	HIVE-20383: Invalid queue name and synchronisation issues in hive proto events hook.

Type	Description
Backport	HIVE-20367: Vectorization: Support streaming for PTF AVG, MAX, MIN, SUM
Backport	HIVE-20366: TPC-DS query78 stats estimates are off for is null filte
Backport	HIVE-20364: Update default for hive.map.aggr.hash.min.reduction
Backport	HIVE-20352: Vectorization: Support grouping function
Backport	HIVE-20347: hive.optimize.sort.dynamic.partition should work with partitioned CTAS and MV
Backport	HIVE-20345: Drop database may hang if the tables get deleted from a different call
Backport	HIVE-20343: Hive 3: CTAS does not respect transactional_properties
Backport	HIVE-20340: Druid Needs Explicit CASTs from Timestamp to STRING when the output of timestamp function is used as Strin
Backport	HIVE-20339: Vectorization: Lift unneeded restriction causing some PTF with RANK not to be vectorized
Backport	HIVE-20337: CachedStore: getPartitionsByExpr is not populating the partition list correctly
Backport	HIVE-20336: Masking and filtering policies for materialized views

Type	Description
Backport	HIVE-20326: Create constraints with RELY as default instead of NO RELY
Backport	HIVE-20321: Vectorization: Cut down memory size of 1 col VectorHashKeyWrapper to <1 CacheLine
Backport	HIVE-20320: Turn on hive.optimize.remove.sq_count_check flag
Backport	HIVE-20315: Vectorization: Fix more NULL / Wrong Results issues and avoid unnecessary casts/conversions
Backport	HIVE-20314: Include partition pruning in materialized view rewriting
Backport	HIVE-20312: Allow arrow clients to use their own BufferAllocator with LlapOutputFormatService
Backport	HIVE-20302: LLAP: non-vectorized execution in IO ignores virtual columns, including ROW__ID
Backport	HIVE-20300: VectorFileSinkArrowOperator
Backport	HIVE-20299: potential race in LLAP signer unit test
Backport	HIVE-20296: Improve HivePointLookupOptimizerRule to be able to extract from more sophisticated contexts
Backport	HIVE-20294: Vectorization: Fix NULL / Wrong Results issues in COALESCE / ELT

Type	Description
Backport	HIVE-20292: Bad join ordering in tpcds query93 with primary constraint defined
Backport	HIVE-20290: Lazy initialize ArrowColumnarBatchSerDe so it doesn't allocate buffers during GetSplits
Backport	HIVE-20281: SharedWorkOptimizer fails with 'operator cache contents and actual plan differ'
Backport	HIVE-20277: Vectorization: Case expressions that return BOOLEAN are not supported for FILTER
Backport	HIVE-20267: Expanding WebUI to include form to dynamically config log levels
Backport	HIVE-20263: Typo in HiveReduceExpressionsWithStatsRule variable
Backport	HIVE-20260: NDV of a column shouldn't be scaled when row count is changed by filter on another column
Backport	HIVE-20252: Semijoin Reduction : Cycles due to semi join branch may remain undetected if small table side has a map join upstream.
Backport	HIVE-20245: Vectorization: Fix NULL / Wrong Results issues in BETWEEN / IN
Backport	HIVE-20241: Support partitioning spec in CTAS statements
Backport	HIVE-20240: Semijoin Reduction: Use local variable to check for external table condition

Type	Description
Backport	HIVE-20226: HMS getNextNotification will throw exception when request maxEvents exceed table's max_rows
Backport	HIVE-20225: SerDe to support Teradata Binary Format
Backport	HIVE-20213: Upgrade Calcite to 1.17.0
Backport	HIVE-20212: Hiveserver2 in http mode emitting metric default.General.open_connec tions incorrectly
Backport	HIVE-20210: Simple Fetch optimizer should lead to MapReduce when filter on non-parti tion column and conversion is minimal
Backport	HIVE-20209: Metastore connection fails for first attempt in repl dump
Backport	HIVE-20207: Vectorization: Fix NULL / Wrong Results issues in Filter / Compare
Backport	HIVE-20204: Type conversion during IN
Backport	HIVE-20203: Arrow SerDe leaks a DirectByt eBuffer
Backport	HIVE-20197: Vectorization: Add DECIMAL_6 4 testing, add Date/Interval/Timestamp arithmetic, and add more GROUP BY Aggregati on
Backport	HIVE-20193: cboInfo is not present in the explain plan json

Type	Description
Backport	HIVE-20192: HS2 with embedded metastore is leaking JDOPersistenceManager objects
Backport	HIVE-20183: Inserting from bucketed table can cause data loss, if the source table contains empty bucket
Backport	HIVE-20177: Vectorization: Reduce KeyWrapper allocation in GroupBy Streaming mode
Backport	HIVE-20174: Vectorization: Fix NULL / Wrong Results issues in GROUP BY Aggregation Functions
Backport	HIVE-20172: StatsUpdater failed with GSS Exception while trying to connect to remote metastore
Backport	HIVE-20153: Count and Sum UDF consume more memory in Hive 2+
Backport	HIVE-20152: reset db state, when repl dump fails, so rename table can be done
Backport	HIVE-20149: TestHiveCli failing/timing out
Backport	HIVE-20130: Better logging for information schema synchronizer
Backport	HIVE-20129: Revert to position based schema evolution for orc tables
Backport	HIVE-20118: SessionStateUserAuthenticat or.getGroupNames
Backport	HIVE-20116: TezTask is using parent logger

Type	Description
Backport	HIVE-20115: Acid tables should not use footer scan for analyze
Backport	HIVE-20103: WM: Only Aggregate DAG counters if at least one is used
Backport	HIVE-20101: BloomKFilter: Avoid using the local byte[] arrays entirely
Backport	HIVE-20100: OpTraits : Select Optraits should stop when a mismatch is detected
Backport	HIVE-20098: Statistics: NPE when getting Date column partition statistics
Backport	HIVE-20095: Fix feature to push computation to jdbc external tables
Backport	HIVE-20093: LlapOutputFomatService: Use ArrowBuf with Netty for Accounting
Backport	HIVE-20090: Extend creation of semijoin reduction filters to be able to discover new opportunities
Backport	HIVE-20088: Beeline config location path is assembled incorrectly
Backport	HIVE-20082: HiveDecimal to string conversion doesn't format the decimal correctly
Backport	HIVE-20069: Fix reoptimization in case of DPP and Semijoin optimization
Backport	HIVE-20051: Skip authorization for temp tables

Type	Description
Backport	HIVE-20044: Arrow Serde should pad char values and handle empty strings correctly
Backport	HIVE-20028: Metastore client cache config is used incorrectly
Backport	HIVE-20025: Clean-up of event files created by HiveProtoLoggingHook
Backport	HIVE-20020: Hive contrib jar should not be in lib
Backport	HIVE-20013: Add an Implicit cast to date type for to_date function
Backport	HIVE-20011: Move away from append mode in proto logging hook
Backport	HIVE-20005: acid_table_stats, acid_no_b uckets, etc - query result change on the branch
Backport	HIVE-20004: Wrong scale used by ConvertDe cimal64ToDecimal results in incorrect results
Backport	HIVE-19995: Aggregate row traffic for acid tables
Backport	HIVE-19993: Using a table alias which also appears as a column name is not possible
Backport	HIVE-19992: Vectorization: Follow-on to HIVE-19951 --> add call to SchemaEvo lution.isOnlyImplicitConversion to disable encoded LLAP I/O for ORC only when data type conversion is not implicit

Type	Description
Backport	HIVE-19989: Metastore uses wrong applicati on name for HADOOP2 metrics
Backport	HIVE-19981: Managed tables converted to external tables by the HiveStrictManagedM igration utility should be set to delete data when the table is dropped
Backport	HIVE-19967: SMB Join : Need Optraits for PTFOperator ala GBY Op
Backport	HIVE-19935: Hive WM session killed: Failed to update LLAP tasks count
Backport	HIVE-19924: Tag distcp jobs run by Repl Load
Backport	HIVE-19891: inserting into external tables with custom partition directories may cause data loss
Backport	HIVE-19850: Dynamic partition pruning in Tez is leading to 'No work found for tablescan' error
Backport	HIVE-19806: Sort qtests output to avoid flakiness in test results
Backport	HIVE-19770: Support for CBO for queries with multiple same columns in select
Backport	HIVE-19769: Create dedicated objects for DB and Table names
Backport	HIVE-19765: Add Parquet specific tests to BlobstoreCliDriver

Type	Description
Backport	HIVE-19759: Flaky test: TestRpc#testServer Port
Backport	HIVE-19711: Refactor Hive Schema Tool
Backport	HIVE-19701: getDelegationTokenFromMetaS tore doesn't need to be synchronized
Backport	HIVE-19694: Create Materialized View statement should check for MV name conflicts before running MV's SQL statement.
Backport	HIVE-19674: Group by Decimal Constants push down to Druid table
Backport	HIVE-19668: Over 30% of the heap wasted by duplicate org.antlr.runtime.CommonToken's and duplicate strings
Backport	HIVE-19663: refactor LLAP IO report generation
Backport	HIVE-19661: switch Hive UDFs to use Re2J regex engine
Backport	HIVE-19628: possible NPE in LLAP testSigning
Backport	HIVE-19568: Active/Passive HS2 HA: Disallow direct connection to passive HS2 instance
Backport	HIVE-19564: Vectorization: Fix NULL / Wrong Results issues in Arithmetic
Backport	HIVE-19552: Enable TestMiniDruidKafka CliDriver#druidkafkamini_basic.q
Backport	HIVE-19432: GetTablesOperation is too slow if the hive has too many databases and tables

Type	Description
Backport	HIVE-19360: CBO: Add an "optimizedSQL" to QueryPlan object
Backport	HIVE-19326: stats auto gather: incorrect aggregation during UNION queries
Backport	HIVE-19313: TestJdbcWithDBTokenStoreNoDoAs tests are failing
Backport	HIVE-19285: Add logs to the subclasses of MetaDataOperation
Backport	HIVE-19235: Update golden files for Minimr tests
Backport	HIVE-19104: When test MetaStore is started with retry the instances should be independent
Backport	HIVE-18986: Table rename will run java.lang.StackOverflowError in dataNucleus if the table contains large number of columns
Backport	HIVE-18920: CBO: Initialize the Janino providers ahead of 1st query
Backport	HIVE-18873: Skipping predicate pushdown for MR silently at HiveInputFormat can cause storage handlers to produce erroneous result
Backport	HIVE-18871: hive on tez execution error due to set hive.aux.jars.path to hdfs://
Backport	HIVE-18725: Improve error handling for subqueries if there is wrong column reference

Type	Description
Backport	HIVE-18696: The partition folders might not get cleaned up properly in the HiveMetaS tore.add_partitions_core method if an
Backport	HIVE-18453: ACID: Add "CREATE TRANSACTI ONAL TABLE" syntax to unify ACID ORC & Parquet support
Backport	HIVE-18201: Disable XPROD_EDGE for sq_count_chec
Backport	HIVE-18140: Partitioned tables statistics can go wrong in basic stats mixed case

Amazon EMR 6.6.0 - Hive configuration changes

- As part of OSS change HIVE-20703, the property to sort dynamic partitions, `hive.optimize.sort.dynamic.partition`, has been replaced with `hive.optimize.sort.dynamic.partition.threshold`.

  The `hive.optimize.sort.dynamic.partition.threshold` configuration has the following potential values:

Value	Description
`0` *(default)*	Makes the optimization to sort dynamic partitions a cost-based decision when ORC files are used. The max number of writers allowed in INSERT queries is computed based on (executor/container memory) * (percentage of memory taken by orc) divided by max memory (stripe size) taken by a single writer.
`-1`	Disables the optimization to sort dynamic partitions completely.
1	Enables global sorting of dynamic partitions. This keeps only one record writer open for each partition value in the reducer, thereby reducing the memory pressure on reducers.
2 *(or greater integer)*	Tells Hive to use the specified integer as threshold for the maximum number of writers.

Amazon EMR 6.6.0 - Hive known issues

- Queries with windowing functions on the same column as join may lead to invalid transformations as reported in HIVE-25278 and cause incorrect results or query failures. As a workaround, you can disable CBO at the query level for such queries. Contact AWS support for further information.
- Amazon EMR 6.6.0 includes Hive software version 3.1.2. Hive 3.1.2 introduces a feature that splits text files if they contain a header and footer (HIVE-21924). The Apache Tez App Master reads each of your files to determine offset points in the data range. These behaviors combined could negatively impact performance if your queries read a large number of small text files. As a workaround, use `CombineHiveInputFormat` and tune the max split size by configuring the following properties:

```
SET hive.tez.input.format=org.apache.hadoop.hive.ql.io.CombineHiveInputFormat;
SET mapreduce.input.fileinputformat.split.maxsize=16777216;
```

- With Amazon EMR 6.6.0 through 6.9.x, INSERT queries with dynamic partition and an ORDER BY or SORT BY clause will always have two reducers. This issue is caused by OSS change

HIVE-20703, which puts dynamic sort partition optimization under cost-based decision. If your workload doesn't require sorting of dynamic partitions, we recommend that you set the `hive.optimize.sort.dynamic.partition.threshold` property to `-1` to disable the new feature and get the correctly calculated number of reducers. This issue is fixed in OSS Hive as part of HIVE-22269 and is fixed in Amazon EMR 6.10.0.

Hudi

Apache Hudi is an open-source data management framework used to simplify incremental data processing and data pipeline development by providing record-level insert, update, upsert, and delete capabilities. *Upsert* refers to the ability to insert records into an existing dataset if they do not already exist or to update them if they do. By efficiently managing how data is laid out in Amazon S3, Hudi allows data to be ingested and updated in near real time. Hudi carefully maintains metadata of the actions performed on the dataset to help ensure that the actions are atomic and consistent.

Hudi is integrated with Apache Spark, Apache Hive, and Presto. In Amazon EMR release versions 6.1.0 and later, Hudi is also integrated with Trino (PrestoSQL).

With Amazon EMR release version 5.28.0 and later, EMR installs Hudi components by default when Spark, Hive, Presto, or Flink are installed. You can use Spark or the Hudi DeltaStreamer utility to create or update Hudi datasets. You can use Hive, Spark, Presto, or Flink to query a Hudi dataset interactively or build data processing pipelines using *incremental pull*. Incremental pull refers to the ability to pull only the data that changed between two actions.

These features make Hudi suitable for the following use cases:

- Working with streaming data from sensors and other Internet of Things (IoT) devices that require specific data insertion and update events.
- Complying with data privacy regulations in applications where users might choose to be forgotten or modify their consent for how their data can be used.
- Implementing a change data capture (CDC) system that allows you to apply changes to a dataset over time.

The following table lists the version of Hudi included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Hudi.

For the version of components installed with Hudi in this release, see Release 7.2.0 Component Versions.

Hudi version information for emr-7.2.0

Amazon EMR Release Label	Hudi Version	Components Installed With Hudi
emr-7.2.0	Hudi 0.14.1-amzn-1	Not available.

The following table lists the version of Hudi included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Hudi.

For the version of components installed with Hudi in this release, see Release 6.15.0 Component Versions.

Hudi version information for emr-6.15.0

Amazon EMR Release Label	Hudi Version	Components Installed With Hudi
emr-6.15.0	Hudi 0.14.0-amzn-0	Not available.

> **Note**
>
> Amazon EMR release 6.8.0 comes with Apache Hudi 0.11.1; however, Amazon EMR 6.8.0 clusters are also compatible with the open-source `hudi-spark3.3-bundle_2.12` from Hudi 0.12.0.

The following table lists the version of Hudi included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Hudi.

For the version of components installed with Hudi in this release, see Release 5.36.2 Component Versions.

Hudi version information for emr-5.36.2

Amazon EMR Release Label	Hudi Version	Components Installed With Hudi
emr-5.36.2	Hudi 0.10.1-amzn-1	Not available.

Topics

How Hudi works

When using Hudi with Amazon EMR, you can write data to the dataset using the Spark Data Source API or the Hudi DeltaStreamer utility. Hudi organizes a dataset into a partitioned directory structure under a *`basepath`* that is similar to a traditional Hive table. The specifics of how the data is laid out as files in these directories depend on the dataset type that you choose. You can choose either Copy on Write (CoW) or Merge on Read (MoR).

Regardless of the dataset type, each partition in a dataset is uniquely identified by its `partitionpath` relative to the `basepath`. Within each partition, records are distributed into multiple data files. For more information, see File management in the Apache Hudi documentation.

Each action in Hudi has a corresponding commit, identified by a monotonically increasing timestamp known as an *Instant*. Hudi keeps a series of all actions performed on the dataset as a timeline. Hudi relies on the timeline to provide snapshot isolation between readers and writers, and to enable roll back to a previous point in time. For more information about the actions that Hudi records and the state of actions, see Timeline in the Apache Hudi documentation.

Understanding dataset storage types: Copy on write vs. merge on read

When you create a Hudi dataset, you specify that the dataset is either copy on write or merge on read.

- **Copy on Write (CoW) –** Data is stored in a columnar format (Parquet), and each update creates a new version of files during a write. CoW is the default storage type.
- **Merge on Read (MoR) –** Data is stored using a combination of columnar (Parquet) and row-based (Avro) formats. Updates are logged to row-based *delta* files and are compacted as needed to create new versions of the columnar files.

With CoW datasets, each time there is an update to a record, the file that contains the record is rewritten with the updated values. With a MoR dataset, each time there is an update, Hudi writes only the row for the changed record. MoR is better suited for write- or change-heavy workloads with fewer reads. CoW is better suited for read-heavy workloads on data that changes less frequently.

Hudi provides three logical views for accessing the data:

- **Read-optimized view –** Provides the latest committed dataset from CoW tables and the latest compacted dataset from MoR tables.
- **Incremental view –** Provides a change stream between two actions out of a CoW dataset to feed downstream jobs and extract, transform, load (ETL) workflows.
- **Real-time view –** Provides the latest committed data from a MoR table by merging the columnar and row-based files inline.

When you query the read-optimized view, the query returns all compacted data but does not include the latest delta commits. Querying this data provides good read performance but omits the freshest data. When you query the real-time view, Hudi merges the compacted data with the delta commits on read. The freshest data is available to query, but the computational overhead of merging makes the query less performant. The ability to query either compacted data or real-time data allows you to choose between performance and flexibility when you query.

For more information about the tradeoffs between storage types, see Storage types & views in Apache Hudi documentation.

Hudi creates two tables in the Hive metastore for MoR: a table with the name that you specified, which is a read-optimized view, and a table with the same name appended with `_rt`, which is a real-time view. You can query both tables.

Registering a Hudi dataset with your metastore

When you register a Hudi table with the Hive metastore, you can query Hudi tables using Hive, Spark SQL or Presto as you would any other table. In addition, you can integrate Hudi with AWS Glue by configuring Hive and Spark to use the AWS Glue Data Catalog as the metastore. For MoR tables, Hudi registers the dataset as two tables in the Metastore: a table with the name that you specified, which is a read-optimized view, and a table with the same name appended with `_rt`, which is a real-time view.

You register a Hudi table with the Hive metastore when you use Spark to create a Hudi dataset by setting the `HIVE_SYNC_ENABLED_OPT_KEY` option to `"true"` and providing other required properties. For more information, see Work with a Hudi dataset. In addition, you can use the hive_sync_tool command line utility to register a Hudi dataset as a table in your metastore, separately.

Considerations and limitations for using Hudi on Amazon EMR

- **Record key field cannot be null or empty** – The field that you specify as the record key field cannot have `null` or empty values.
- **Schema updated by default on upsert and insert** – Hudi provides an interface, `HoodieRecordPayload` that determines how the input DataFrame and existing Hudi dataset are merged to produce a new, updated dataset. Hudi provides a default implementation of this class, `OverwriteWithLatestAvroPayload`, that overwrites existing records and updates the schema as specified in the input DataFrame. To customize this logic for implementing merge and partial updates, you can provide an implementation of the `HoodieRecordPayload` interface using the `DataSourceWriteOptions.PAYLOAD_CLASS_OPT_KEY` parameter.
- **Deletion requires schema** – When deleting, you must specify the record key, the partition key, and the pre-combine key fields. Other columns can be made `null` or empty, but the full schema is required.
- **MoR table limitations** – MoR tables do not support savepointing. You can query MoR tables using the read-optimized view or the real-time view (*`tableName`*`_rt`) from Spark SQL, Presto, or Hive. Using the read-optimized view only exposes base file data, and does not expose a merged view of base and log data.
- **Hive**
  - For registering tables in the Hive metastore, Hudi expects the Hive Thrift server to be running at the default port `10000`. If you override this port with a custom port, pass the `HIVE_URL_OPT_KEY` option as shown in the following example.

    ```
    .option(DataSourceWriteOptions.HIVE_URL_OPT_KEY, "jdbc:hive2://localhost:override-port-number
    ```

  - The `timestamp` data type in Spark is registerd as `long` data type in Hive, and not as Hive's `timestamp` type.
- **Presto**
  - Presto does not support reading MoR real time tables in Hudi versions below 0.6.0.

- Presto only supports snapshot queries.
- For Presto to correctly interpret Hudi dataset columns, set the `hive.parquet_use_column_names` value to `true`.
  - To set the value for a session, in the Presto shell, run the following command:

    ```
    set session hive.parquet_use_column_names=true
    ```

  - To set the value at the cluster level, use the `presto-connector-hive` configuration classification to set `hive.parquet.use_column_names` to `true`, as shown in the following example. For more information, see Configure applications.

    ```
    [
      {
        "Classification": "presto-connector-hive",
        "Properties": {
          "hive.parquet.use-column-names": "true"
        }
      }
    ]
    ```

- **HBase Index**
  - The HBase version used to *build* Hudi might be different from what is listed in the EMR Release Guide. To pull in the correct dependencies for your Spark session, run the following command.

  ```
  spark-shell \
  --jars /usr/lib/spark/external/lib/spark-avro.jar,/usr/lib/hudi/cli/lib/*.jar \
  --conf "spark.serializer=org.apache.spark.serializer.KryoSerializer" \
  --conf "spark.sql.hive.convertMetastoreParquet=false"
  ```

Create a cluster with Hudi installed

With Amazon EMR release version 5.28.0 and later, Amazon EMR installs Hudi components by default when Spark, Hive, or Presto is installed. To use Hudi on Amazon EMR, create a cluster with one or more of the following applications installed:

- Hadoop
- Hive
- Spark

- Presto
- Flink

You can create a cluster using the AWS Management Console, the AWS CLI, or the Amazon EMR API.

To create a cluster with Hudi using the AWS Management Console

1. Navigate to the new Amazon EMR console and select **Switch to the old console** from the side navigation. For more information on what to expect when you switch to the old console, see Using the old console.
2. Choose **Create cluster**, **Go to advanced options**.
3. Under Software Configuration, choose **emr-5.28.0** or later for **Release** and select **Hadoop**, **Hive**, **Spark**, **Presto**, and **Tez** along with other applications that your cluster requires.
4. Configure other options as required for your application, and then choose **Next**.
5. Configure options for **Hardware** and **General cluster settings** as desired.
6. For **Security Options**, we recommend that you select an **EC2 key pair** that you can use to connect to the master node command line using SSH. This allows you to run the Spark shell commands, Hive CLI commands, and Hudi CLI commands described in this guide.
7. Choose other security options as desired, and then choose **Create cluster**.

Work with a Hudi dataset

Hudi supports inserting, updating, and deleting data in Hudi datasets through Spark. For more information, see Writing Hudi tables in Apache Hudi documentation.

The following examples demonstrate how to launch the interactive Spark shell, use Spark submit, or use Amazon EMR Notebooks to work with Hudi on Amazon EMR. You can also use the Hudi DeltaStreamer utility or other tools to write to a dataset. Throughout this section, the examples demonstrate working with datasets using the Spark shell while connected to the master node using SSH as the default `hadoop` user.

Launch the Spark shell using Amazon EMR 6.7 and later

When running `spark-shell`, `spark-submit`, or `spark-sql` using Amazon EMR 6.7.0 or later, pass the following commands.

> **Note**
>
> Amazon EMR 6.7.0 uses Apache Hudi 0.11.0-amzn-0, which contains significant improvements over previous Hudi versions. For more information, see the Apache Hudi 0.11.0 Migration Guide. The examples on this tab reflect these changes.

To open the Spark shell on the primary node

1. Connect to the primary node using SSH. For more information, see Connect to the primary node using SSH in the *Amazon EMR Management Guide*.
2. Enter the following command to launch the Spark shell. To use the PySpark shell, replace *spark-shell* with *pyspark*.

```
spark-shell --jars /usr/lib/hudi/hudi-spark-bundle.jar \
--conf "spark.serializer=org.apache.spark.serializer.KryoSerializer" \
--conf
 "spark.sql.catalog.spark_catalog=org.apache.spark.sql.hudi.catalog.HoodieCatalog"
 \
--conf "spark.sql.extensions=org.apache.spark.sql.hudi.HoodieSparkSessionExtension"
```

Launch the Spark shell using Amazon EMR 6.6 and earlier

When running `spark-shell`, `spark-submit`, or `spark-sql` using Amazon EMR 6.6.x or earlier, pass the following commands.

> **Note**
>
> - Amazon EMR 6.2 and 5.31 and later (Hudi 0.6.x and later) can omit the `spark-avro.jar` from the configuration.
> - Amazon EMR 6.5 and 5.35 and later (Hudi 0.9.x and later) can omit `spark.sql.hive.convertMetastoreParquet=false` from the configuration.
> - Amazon EMR 6.6 and 5.36 and later (Hudi 0.10.x and later) must include the `HoodieSparkSessionExtension` config as described in the Version: 0.10.0 Spark Guide:

```
--conf
 "spark.sql.extensions=org.apache.spark.sql.hudi.HoodieSparkSessionExtension"
 \
```

To open the Spark shell on the primary node

1. Connect to the primary node using SSH. For more information, see Connect to the primary node using SSH in the *Amazon EMR Management Guide*.
2. Enter the following command to launch the Spark shell. To use the PySpark shell, replace *spark-shell* with *pyspark*.

```
spark-shell \
--conf "spark.serializer=org.apache.spark.serializer.KryoSerializer" \
--conf "spark.sql.hive.convertMetastoreParquet=false" \
--jars /usr/lib/hudi/hudi-spark-bundle.jar,/usr/lib/spark/external/lib/spark-
avro.jar
```

Use Hudi with Amazon EMR Notebooks using Amazon EMR 6.7 and later

To use Hudi with Amazon EMR Notebooks, you must first copy the Hudi jar files from the local file system to HDFS on the master node of the notebook cluster. You then use the notebook editor to configure your EMR notebook to use Hudi.

To use Hudi with Amazon EMR Notebooks

1. Create and launch a cluster for Amazon EMR Notebooks. For more information, see Creating Amazon EMR clusters for notebooks in the *Amazon EMR Management Guide*.
2. Connect to the master node of the cluster using SSH and then copy the jar files from the local filesystem to HDFS as shown in the following examples. In the example, we create a directory in HDFS for clarity of file management. You can choose your own destination in HDFS, if desired.

```
hdfs dfs -mkdir -p /apps/hudi/lib
```

```
hdfs dfs -copyFromLocal /usr/lib/hudi/hudi-spark-bundle.jar /apps/hudi/lib/hudi-
spark-bundle.jar
```

3. Open the notebook editor, enter the code from the following example, and run it.

```
%%configure
{ "conf": {
            "spark.jars":"hdfs:///apps/hudi/lib/hudi-spark-bundle.jar",
            "spark.serializer":"org.apache.spark.serializer.KryoSerializer",
            "spark.sql.catalog.spark_catalog":
 "org.apache.spark.sql.hudi.catalog.HoodieCatalog",

 "spark.sql.extensions":"org.apache.spark.sql.hudi.HoodieSparkSessionExtension"
          }}
```

Use Hudi with Amazon EMR Notebooks using Amazon EMR 6.6 and earlier

To use Hudi with Amazon EMR Notebooks, you must first copy the Hudi jar files from the local file system to HDFS on the master node of the notebook cluster. You then use the notebook editor to configure your EMR notebook to use Hudi.

To use Hudi with Amazon EMR Notebooks

1. Create and launch a cluster for Amazon EMR Notebooks. For more information, see Creating Amazon EMR clusters for notebooks in the *Amazon EMR Management Guide*.
2. Connect to the master node of the cluster using SSH and then copy the jar files from the local filesystem to HDFS as shown in the following examples. In the example, we create a directory in HDFS for clarity of file management. You can choose your own destination in HDFS, if desired.

```
hdfs dfs -mkdir -p /apps/hudi/lib
```

```
hdfs dfs -copyFromLocal /usr/lib/hudi/hudi-spark-bundle.jar /apps/hudi/lib/hudi-
spark-bundle.jar
```

```
hdfs dfs -copyFromLocal /usr/lib/spark/external/lib/spark-avro.jar /apps/hudi/lib/
spark-avro.jar
```

3. Open the notebook editor, enter the code from the following example, and run it.

```
{ "conf": {
            "spark.jars":"hdfs:///apps/hudi/lib/hudi-spark-bundle.jar,hdfs:///apps/
hudi/lib/spark-avro.jar",
            "spark.serializer":"org.apache.spark.serializer.KryoSerializer",
            "spark.sql.hive.convertMetastoreParquet":"false"
          }}
```

Initialize a Spark session for Hudi

When you use Scala, you must import the following classes in your Spark session. This needs to be done once per Spark session.

```
import org.apache.spark.sql.SaveMode
import org.apache.spark.sql.functions._
import org.apache.hudi.DataSourceWriteOptions
import org.apache.hudi.DataSourceReadOptions
import org.apache.hudi.config.HoodieWriteConfig
import org.apache.hudi.hive.MultiPartKeysValueExtractor
import org.apache.hudi.hive.HiveSyncConfig
import org.apache.hudi.sync.common.HoodieSyncConfig
```

Write to a Hudi dataset

The following examples show how to create a DataFrame and write it as a Hudi dataset.

> **Note**
>
> To paste code samples into the Spark shell, type **`:paste`** at the prompt, paste the example, and then press **`CTRL`** + **`D`**.

Each time you write a DataFrame to a Hudi dataset, you must specify `DataSourceWriteOptions`. Many of these options are likely to be identical between write operations. The following example specifies common options using the *`hudiOptions`* variable, which subsequent examples use.

Write using Scala with Amazon EMR 6.7 and later

Note

Amazon EMR 6.7.0 uses Apache Hudi 0.11.0-amzn-0, which contains significant improvements over previous Hudi versions. For more information, see the Apache Hudi 0.11.0 Migration Guide. The examples on this tab reflect these changes.

```
// Create a DataFrame
val inputDF = Seq(
 ("100", "2015-01-01", "2015-01-01T13:51:39.340396Z"),
 ("101", "2015-01-01", "2015-01-01T12:14:58.597216Z"),
 ("102", "2015-01-01", "2015-01-01T13:51:40.417052Z"),

  DataSourceWriteOptions.RECORDKEY_FIELD_OPT_KEY -> "id",
  DataSourceWriteOptions.PARTITIONPATH_FIELD_OPT_KEY -> "creation_date",
  DataSourceWriteOptions.PRECOMBINE_FIELD_OPT_KEY -> "last_update_time",
  DataSourceWriteOptions.HIVE_SYNC_ENABLED_OPT_KEY -> "true",
  DataSourceWriteOptions.HIVE_TABLE_OPT_KEY -> "tableName",
  DataSourceWriteOptions.HIVE_PARTITION_FIELDS_OPT_KEY -> "creation_date",
  HoodieSyncConfig.META_SYNC_PARTITION_EXTRACTOR_CLASS.key ->
 "org.apache.hudi.hive.MultiPartKeysValueExtractor",
  HoodieSyncConfig.META_SYNC_ENABLED.key -> "true",
  HiveSyncConfig.HIVE_SYNC_MODE.key -> "hms",
  HoodieSyncConfig.META_SYNC_TABLE_NAME.key -> "tableName",
  HoodieSyncConfig.META_SYNC_PARTITION_FIELDS.key -> "creation_date"
)

// Write the DataFrame as a Hudi dataset
(inputDF.write
    .format("hudi")
    .options(hudiOptions)
    .option(DataSourceWriteOptions.OPERATION_OPT_KEY,"insert")
```

```
    .mode(SaveMode.Overwrite)
    .save("s3://DOC-EXAMPLE-BUCKET/myhudidataset/"))
```

Write using Scala with Amazon EMR 6.6 and earlier

```
// Create a DataFrame
val inputDF = Seq(
 ("100", "2015-01-01", "2015-01-01T13:51:39.340396Z"),
 ("101", "2015-01-01", "2015-01-01T12:14:58.597216Z"),
 ("102", "2015-01-01", "2015-01-01T13:51:40.417052Z"),
 ("103", "2015-01-01", "2015-01-01T13:51:40.519832Z"),
 ("104", "2015-01-02", "2015-01-01T12:15:00.512679Z"),
 ("105", "2015-01-02", "2015-01-01T13:51:42.248818Z")
 ).toDF("id", "creation_date", "last_update_time")

//Specify common DataSourceWriteOptions in the single hudiOptions variable
val hudiOptions = Map[String,String](
  HoodieWriteConfig.TABLE_NAME -> "tableName",
  DataSourceWriteOptions.TABLE_TYPE_OPT_KEY -> "COPY_ON_WRITE",
  DataSourceWriteOptions.RECORDKEY_FIELD_OPT_KEY -> "id",
  DataSourceWriteOptions.PARTITIONPATH_FIELD_OPT_KEY -> "creation_date",
  DataSourceWriteOptions.PRECOMBINE_FIELD_OPT_KEY -> "last_update_time",
  DataSourceWriteOptions.HIVE_SYNC_ENABLED_OPT_KEY -> "true",
  DataSourceWriteOptions.HIVE_TABLE_OPT_KEY -> "tableName",
  DataSourceWriteOptions.HIVE_PARTITION_FIELDS_OPT_KEY -> "creation_date",
  DataSourceWriteOptions.HIVE_PARTITION_EXTRACTOR_CLASS_OPT_KEY ->
 classOf[MultiPartKeysValueExtractor].getName
)

// Write the DataFrame as a Hudi dataset
(inputDF.write
    .format("org.apache.hudi")
    .option(DataSourceWriteOptions.OPERATION_OPT_KEY,
 DataSourceWriteOptions.INSERT_OPERATION_OPT_VAL)
    .options(hudiOptions)
    .mode(SaveMode.Overwrite)
    .save("s3://DOC-EXAMPLE-BUCKET/myhudidataset/"))
```

Write using PySpark

```
# Create a DataFrame
inputDF = spark.createDataFrame(
    [
```

```
        ("100", "2015-01-01", "2015-01-01T13:51:39.340396Z"),
        ("101", "2015-01-01", "2015-01-01T12:14:58.597216Z"),
        ("102", "2015-01-01", "2015-01-01T13:51:40.417052Z"),
        ("103", "2015-01-01", "2015-01-01T13:51:40.519832Z"),
        ("104", "2015-01-02", "2015-01-01T12:15:00.512679Z"),
        ("105", "2015-01-02", "2015-01-01T13:51:42.248818Z"),
    ],
    ["id", "creation_date", "last_update_time"]
)

# Specify common DataSourceWriteOptions in the single hudiOptions variable
hudiOptions = {
'hoodie.table.name': 'tableName',
'hoodie.datasource.write.recordkey.field': 'id',
'hoodie.datasource.write.partitionpath.field': 'creation_date',
'hoodie.datasource.write.precombine.field': 'last_update_time',
'hoodie.datasource.hive_sync.enable': 'true',
'hoodie.datasource.hive_sync.table': 'tableName',
'hoodie.datasource.hive_sync.partition_fields': 'creation_date',
'hoodie.datasource.hive_sync.partition_extractor_class':
 'org.apache.hudi.hive.MultiPartKeysValueExtractor'
}

# Write a DataFrame as a Hudi dataset
inputDF.write \
.format('org.apache.hudi') \
.option('hoodie.datasource.write.operation', 'insert') \
.options(**hudiOptions) \
.mode('overwrite') \
.save('s3://DOC-EXAMPLE-BUCKET/myhudidataset/')
```

Note

You might see "hoodie" instead of Hudi in code examples and notifications. The Hudi codebase widely uses the old "hoodie" spelling.

DataSourceWriteOptions reference for Hudi

Option	Description
TABLE_NAME	The table name under which to register the dataset.
TABLE_TYPE_OPT_KEY	Optional. Specifies whether the dataset is created as `"COPY_ON_WRITE"` or `"MERGE_ON_READ"` . The default is `"COPY_ON_WRITE"` .
RECORDKEY_FIELD_OPT_KEY	The record key field whose value will be used as the `recordKey` component of `HoodieKey` . Actual value will be obtained by invoking `.toString()` on the field value. Nested fields can be specified using the dot notation, for example, `a.b.c`.
PARTITIONPATH_FIELD_OPT_KEY	The partition path field whose value will be used as the `partitionPath` component of `HoodieKey` . The actual value will be obtained by invoking `.toString()` on the field value.
PRECOMBINE_FIELD_OPT_KEY	The field used in pre-combining before actual write. When two records have the same key value, Hudi picks the one with the largest value for the precombine field as determined by `Object.compareTo(..)` .

The following options are required only to register the Hudi dataset table in your metastore. If you do not register your Hudi dataset as a table in the Hive metastore, these options are not required.

DataSourceWriteOptions reference for Hive

Option	Description
HIVE_DATABASE_OPT_KEY	The Hive database to sync to. The default is `"default"` .
HIVE_PARTITION_EXTRACTOR_CLASS_OPT_KEY	The class used to extract partition field values into Hive partition columns.
HIVE_PARTITION_FIELDS_OPT_KEY	The field in the dataset to use for determining Hive partition columns.
HIVE_SYNC_ENABLED_OPT_KEY	When set to `"true"`, registers the dataset with the Apache Hive metastore. The default is `"false"`.
HIVE_TABLE_OPT_KEY	Required. The name of the table in Hive to sync to. For example, `"my_hudi_table_cow"` .
HIVE_USER_OPT_KEY	Optional. The Hive user name to use when syncing. For example, `"hadoop"`.
HIVE_PASS_OPT_KEY	Optional. The Hive password for the user specified by `HIVE_USER_OPT_KEY` .
HIVE_URL_OPT_KEY	The Hive metastore URL.

Upsert data

The following example demonstrates how to upsert data by writing a DataFrame. Unlike the previous insert example, the `OPERATION_OPT_KEY` value is set to `UPSERT_OPERATION_OPT_VAL`. In addition, `.mode(SaveMode.Append)` is specified to indicate that the record should be appended.

Upsert using Scala with Amazon EMR 6.7 and later

Note

Amazon EMR 6.7.0 uses Apache Hudi 0.11.0-amzn-0, which contains significant improvements over previous Hudi versions. For more information, see the Apache Hudi 0.11.0 Migration Guide. The examples on this tab reflect these changes.

```
// Create a new DataFrame from the first row of inputDF with a different creation_date
 value
val updateDF = inputDF.limit(1).withColumn("creation_date", lit("new_value"))

(updateDF.write
    .format("hudi")
    .options(hudiOptions)
    .option(DataSourceWriteOptions.OPERATION_OPT_KEY, "upsert")
    .mode(SaveMode.Append)
    .save("s3://DOC-EXAMPLE-BUCKET/myhudidataset/"))
```

Upsert using Scala with Amazon EMR 6.6 and earlier

```
// Create a new DataFrame from the first row of inputDF with a different creation_date
 value
val updateDF = inputDF.limit(1).withColumn("creation_date", lit("new_value"))

(updateDF.write
    .format("org.apache.hudi")
    .option(DataSourceWriteOptions.OPERATION_OPT_KEY,
 DataSourceWriteOptions.UPSERT_OPERATION_OPT_VAL)
    .options(hudiOptions)
    .mode(SaveMode.Append)
    .save("s3://DOC-EXAMPLE-BUCKET/myhudidataset/"))
```

Upsert using PySpark

```
from pyspark.sql.functions import lit

# Create a new DataFrame from the first row of inputDF with a different creation_date
 value
```

```
updateDF = inputDF.limit(1).withColumn('creation_date', lit('new_value'))

updateDF.write \
    .format('org.apache.hudi') \
    .option('hoodie.datasource.write.operation', 'upsert') \
    .options(**hudiOptions) \
    .mode('append') \
    .save('s3://DOC-EXAMPLE-BUCKET/myhudidataset/')
```

Delete a record

To hard delete a record, you can upsert an empty payload. In this case, the `PAYLOAD_CLASS_OPT_KEY` option specifies the `EmptyHoodieRecordPayload` class. The example uses the same DataFrame, `updateDF`, used in the upsert example to specify the same record.

Delete using Scala with Amazon EMR 6.7 and later

> **Note**
>
> Amazon EMR 6.7.0 uses Apache Hudi 0.11.0-amzn-0, which contains significant improvements over previous Hudi versions. For more information, see the Apache Hudi 0.11.0 Migration Guide. The examples on this tab reflect these changes.

```
(updateDF.write
    .format("hudi")
    .options(hudiOptions)
    .option(DataSourceWriteOptions.OPERATION_OPT_KEY, "delete")
    .mode(SaveMode.Append)
    .save("s3://DOC-EXAMPLE-BUCKET/myhudidataset/"))
```

Delete using Scala with Amazon EMR 6.6 and earlier

```
(updateDF.write
    .format("org.apache.hudi")
    .option(DataSourceWriteOptions.OPERATION_OPT_KEY,
 DataSourceWriteOptions.UPSERT_OPERATION_OPT_VAL)
    .option(DataSourceWriteOptions.PAYLOAD_CLASS_OPT_KEY,
 "org.apache.hudi.common.model.EmptyHoodieRecordPayload")
```

```
    .mode(SaveMode.Append)
    .save("s3://DOC-EXAMPLE-BUCKET/myhudidataset/"))
```

Delete using PySpark

```
updateDF.write \
    .format('org.apache.hudi') \
    .option('hoodie.datasource.write.operation', 'upsert') \
    .option('hoodie.datasource.write.payload.class',
 'org.apache.hudi.common.model.EmptyHoodieRecordPayload') \
    .options(**hudiOptions) \
    .mode('append') \
    .save('s3://DOC-EXAMPLE-BUCKET/myhudidataset/')
```

You can also hard delete data by setting `OPERATION_OPT_KEY` to `DELETE_OPERATION_OPT_VAL` to remove all records in the dataset you submit. For instructions on performing soft deletes, and for more information about deleting data stored in Hudi tables, see Deletes in the Apache Hudi documentation.

Read from a Hudi dataset

To retrieve data at the present point in time, Hudi performs snapshot queries by default. Following is an example of querying the dataset written to S3 in Write to a Hudi dataset. Replace *`s3://DOC-EXAMPLE-BUCKET/myhudidataset`* with your table path, and add wildcard asterisks for each partition level, *plus one additional asterisk*. In this example, there is one partition level, so we've added two wildcard symbols.

Read using Scala with Amazon EMR 6.7 and later

> **Note**
>
> Amazon EMR 6.7.0 uses Apache Hudi 0.11.0-amzn-0, which contains significant improvements over previous Hudi versions. For more information, see the Apache Hudi 0.11.0 Migration Guide. The examples on this tab reflect these changes.

```
val snapshotQueryDF = spark.read
    .format("hudi")
    .load("s3://DOC-EXAMPLE-BUCKET/myhudidataset")
```

```
    .show()
```

Read using Scala with Amazon EMR 6.6 and earlier

```
(val snapshotQueryDF = spark.read
    .format("org.apache.hudi")
    .load("s3://DOC-EXAMPLE-BUCKET/myhudidataset" + "/*/*"))

snapshotQueryDF.show()
```

Read using PySpark

```
snapshotQueryDF = spark.read \
    .format('org.apache.hudi') \
    .load('s3://DOC-EXAMPLE-BUCKET/myhudidataset' + '/*/*')

snapshotQueryDF.show()
```

Incremental queries

You can also perform incremental queries with Hudi to get a stream of records that have changed since a given commit timestamp. To do so, set the `QUERY_TYPE_OPT_KEY` field to `QUERY_TYPE_INCREMENTAL_OPT_VAL`. Then, add a value for `BEGIN_INSTANTTIME_OPT_KEY` to obtain all records written since the specified time. Incremental queries are typically ten times more efficient than their batch counterparts since they only process changed records.

When you perform incremental queries, use the root (base) table path without the wildcard asterisks used for Snapshot queries.

> **Note**
>
> Presto does not support incremental queries.

Incremental queries using Scala

```
(val incQueryDF = spark.read
    .format("org.apache.hudi")
    .option(DataSourceReadOptions.QUERY_TYPE_OPT_KEY,
 DataSourceReadOptions.QUERY_TYPE_INCREMENTAL_OPT_VAL)
```

```
    .option(DataSourceReadOptions.BEGIN_INSTANTTIME_OPT_KEY, <beginInstantTime>)
    .load("s3://DOC-EXAMPLE-BUCKET/myhudidataset" ))

incQueryDF.show()
```

Incremental queries using PySpark

```
readOptions = {
  'hoodie.datasource.query.type': 'incremental',
  'hoodie.datasource.read.begin.instanttime': <beginInstantTime>,
}

incQueryDF = spark.read \
    .format('org.apache.hudi') \
    .options(**readOptions) \
    .load('s3://DOC-EXAMPLE-BUCKET/myhudidataset')

incQueryDF.show()
```

For more information about reading from Hudi datasets, see Querying Hudi tables in the Apache Hudi documentation.

Use the Hudi CLI

You can use the Hudi CLI to administer Hudi datasets to view information about commits, the filesystem, statistics, and more. You can also use the CLI to manually perform compactions, schedule compactions, or cancel scheduled compactions. For more information, see Interacting via CLI in the Apache Hudi documentation.

To start the Hudi CLI and connect to a dataset

1. Connect to the master node using SSH. For more information, see Connect to the master node using SSH in the *Amazon EMR Management Guide*.
2. At the command line, type `/usr/lib/hudi/cli/bin/hudi-cli.sh`.

   The command prompt changes to `hudi->`.
3. Type the following code to connect to a dataset. Replace *`s3://DOC-EXAMPLE-BUCKET/myhudidataset`* with the path to the dataset that you want to work with. The value we use is the same as the value established in earlier examples.

```
connect --path s3://DOC-EXAMPLE-BUCKET/myhudidataset
```

The command prompt changes to include the dataset that you're connected to, as shown in the following example.

```
hudi:myhudidataset->
```

Hudi release history

The following table lists the version of Hudi included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Hudi version information

Amazon EMR Release label	Hudi Version	Components installed with Hudi
emr-7.2.0	0.14.1-amzn-1	Not available.

emr-5.28.0	0.5.0-incubating	Not available.

Hue

Hue (Hadoop User Experience) is an open-source, web-based, graphical user interface for use with Amazon EMR and Apache Hadoop. Hue groups together several different Hadoop ecosystem projects into a configurable interface. Amazon EMR has also added customizations specific to Hue in Amazon EMR. Hue acts as a front-end for applications that run on your cluster, allowing you to interact with applications using an interface that may be more familiar or user-friendly. The applications in Hue, such as the Hive and Pig editors, replace the need to log in to the cluster to run scripts interactively using each application's respective shell. After a cluster launches, you might interact entirely with applications using Hue or a similar interface. For more information about Hue, see http://gethue.com.

Hue is installed by default when you launch your cluster using the Amazon EMR console. You can choose not to install Hue by using **Advanced options** in the Amazon EMR console when you launch a cluster, or by explicitly specifying the `--applications` option, and omitting Hue, when you use `create-cluster` from the AWS CLI.

Topics

Hue version information

Hue version for 7.2.0

The following table lists the version of Hue included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Hue.

For the version of components installed with Hue in this release, see Release 7.2.0 Component Versions.

Hue version information for emr-7.2.0

Amazon EMR Release Label	Hue Version	Components Installed With Hue
emr-7.2.0	Hue 4.11.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hue-server, mariadb-server, oozie-client, oozie-server

Hue version for 6.15.0

The following table lists the version of Hue included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Hue.

For the version of components installed with Hue in this release, see Release 6.15.0 Component Versions.

Hue version information for emr-6.15.0

Amazon EMR Release Label	Hue Version	Components Installed With Hue
emr-6.15.0	Hue 4.11.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-ya

Amazon EMR Release Label	Hue Version	Components Installed With Hue
		rn-timeline-server, hue-server, mariadb-server, oozie-client, oozie-server

Hue version for 5.36.2

The following table lists the version of Hue included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Hue.

For the version of components installed with Hue in this release, see Release 5.36.2 Component Versions.

Hue version information for emr-5.36.2

Amazon EMR Release Label	Hue Version	Components Installed With Hue
emr-5.36.2	Hue 4.10.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hue-server, mariadb-server, oozie-client, oozie-server

Supported and unsupported features of Hue on Amazon EMR

With Amazon EMR 7.0.0 and higher, Hue requires Python 3.9 or higher. When you use in-transit encryption, you must use a 2048-bit cipher key.

- Amazon S3 and Hadoop File System (HDFS) Browser

  - With the appropriate permissions, you can browse and move data between the ephemeral HDFS storage and S3 buckets belonging to your account.
  - By default, superusers in Hue can access all files that Amazon EMR IAM roles are allowed to access. Newly created users do not automatically have permissions to access the Amazon S3 filebrowser and must have the `filebrowser.s3_access` permissions enabled for their group.
- Hive — Run interactive queries on your data. This is also a useful way to prototype programmatic or batched querying.
- Pig — Run scripts on your data or issue interactive commands.
- Oozie — Create and monitor Oozie workflows.
- Metastore Manager — View and manipulate the contents of the Hive metastore (import/create, drop, and so on).
- Job browser — See the status of your submitted Hadoop jobs.
- User management — Manage Hue accounts and integrate LDAP users with Hue.
- AWS Samples — There are several "ready-to-run" examples that process sample data from various AWS services using applications in Hue. When you log in to Hue, you are taken to the Hue Home application where the samples are pre-installed.
- Livy Server is supported only in Amazon EMR version 5.9.0 and later.
- To use the Hue Notebook for Spark, you must install Hue with Livy and Spark.
- Trino/Presto — Hue supports connecting to Trino and Presto data servers. With Amazon EMR 7.0.0 and higher, this connectivity is facilitated with `trino-python-client` and `presto-python-client` connectors. Releases lower than 7.0.0 use a JDBC connector through a JDBC gateway.
- The Hue Dashboard is not supported.
- PostgreSQL is not supported.

Considerations

Consider the following limitations when you use Hue on Amazon EMR.

Performance with large Hue metadata tables

If the Hue metadata database gets too big, performance might degrade. To check the size of the tables, first connect to the primary node of the Amazon EMR on Amazon EC2 cluster with SSH and run the command `sudo mysql -u root` to start the MySQL CLI. To get the size of your table, run the query `SELECT COUNT(*) FROM hue.<table_name>`. See the following for what *<table_name>* can be:

- desktop_document
- desktop_document2
- oozie_job
- beeswax_savedquery
- beeswax_session
- beeswax_queryhistory

If running that query returns a count of more than 100000, you should run the following clean up command to delete the old records.

```
cd /opt/cloudera/parcels/CDH/lib/hue # Hue home directory ./build/env/bin/hue
 desktop_document_cleanup
```

For more information about cleaning up your database, see the [reference page in the Hue documentation](#).

Hue doesn't automatically clean the tables, but Amazon EMR releases 5.12.0 and higher provide a method to delete old documents in the tables. Create the following shell script and run it as a step in an Amazon EMR cluster with an integer parameter that represents the maximum number of days of how long to keep documents in the metadata database.

```
#!/bin/bash
if grep isMaster /mnt/var/lib/info/instance.json | grep false;
then
  echo "This is not the primary node; do nothing, exiting"
  exit 0
fi
while [ ! -f /usr/lib/hue/desktop/core/src/desktop/management/commands/
desktop_document_cleanup.py ]
do
  sleep 1
done
sudo systemctl stop hue.service
sudo sed -i 's+  LOG.warn+  # LOG.warn+g' /usr/lib/hue/desktop/core/src/desktop/
management/commands/desktop_document_cleanup.py
```

```
sudo /usr/lib/hue/build/env/bin/hue desktop_document_cleanup --keep-days $1
sudo systemctl start hue.service
```

Incompatibility between Hue versions

If you're using the same Hue metadata database across multiple Hue-enabled clusters, we recommend that these clusters run the same version of Hue. Different versions of Hue can have different schemas for the Hue metadata database. Using the same database for different versions can cause a Hue installation to fail. For example, trying to use the same database for two clusters with 4.10.0 and 4.11.0 installed can cause login errors for the users trying to log in to the 4.10.0 cluster.

For a list of Amazon EMR release labels and the corresponding installed versions of Hue, see Hue release history.

Connecting to the Hue web user interface

Connecting to the Hue web user interface is the same as connecting to any HTTP interface hosted on the master node of a cluster. The following procedure describes how to access the Hue user interface. For more information, see View web interfaces hosted on EMR clusters in the *Amazon EMR Management Guide*.

To view the Hue web user interface

1. Follow these instructions to Set up an SSH tunnel to the master node using dynamic port forwarding in the *Amazon EMR Management Guide*.
2. Type the following address in your browser to open the **Hue** web interface: `http://master public DNS:8888` where *`master public dns`* is the public DNS name of your cluster master node, for example `ec2-11-22-333-44.compute-1.amazonaws.com`.
3. At the Hue login screen, if you are the administrator logging in for the first time, enter a user name and password to create your Hue superaccount and then select **Create account**. Otherwise, type your username and password and select **Create account** or enter the credentials provided by your administrator.

Using Hue with a remote database in Amazon RDS

By default, Hue user information and query histories are stored in a local MySQL database on the master node. Alternatively, you can create one or more Hue-enabled clusters using a configuration stored in Amazon S3 and a MySQL database in Amazon Relational Database Service(Amazon RDS). This allows you to persist user information and query history created by Hue without keeping your Amazon EMR cluster running. We recommend using Amazon S3 server-side encryption to store the configuration file.

First create the remote database for Hue.

To create the external MySQL database

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Click **Launch a DB Instance**.
3. Choose MySQL and click **Select**.
4. Leave the default selection of **Multi-AZ Deployment and Provisioned IOPS Storage** and click **Next**.
5. Leave the Instance Specifications at their defaults, specify Settings, and click **Next**.
6. On the Configure Advanced Settings page, choose a proper security group and database name. The security group you use must at least allow ingress TCP access for port 3306 from the master node of your cluster. If you have not created your cluster at this point, you can allow all hosts to connect to port 3306 and adjust the security group after you have launched the cluster. Click **Launch DB Instance**.
7. From the RDS Dashboard, select **Instances** and select the instance you have just created. When your database is available, make a note of the dbname, username, password, and RDS instance hostname. You use this information when you create and configure your cluster.

To specify an external MySQL database for Hue when launching a cluster using the AWS CLI

To specify an external MySQL database for Hue when launching a cluster using the AWS CLI, use the information you noted when creating your RDS instance for configuring `hue.ini` with a configuration object

Note

You can create multiple clusters that use the same external database, but each cluster will share query history and user information.

- Using the AWS CLI, create a cluster with Hue installed, using the external database you created, and referencing a configuration file with a configuration classification for Hue that specifies the database properties. The following example creates a cluster with Hue installed, referencing a configuration file in Amazon S3, `myConfig.json`, that specifies the database configuration.

  Note

  Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=Hue Name=Spark
 Name=Hive \
--instance-type m5.xlarge --instance-count 3 \
--configurations https://s3.amazonaws.com/mybucket/myfolder/myConfig.json --use-
default-roles
```

  Example contents of the `myConfig.json` file are shown below. Replace *`dbname`*, *`username`*, *`password`*, and *`RDS instance hostname`* with the values that you noted earlier in the RDS Dashboard.

```
[{
  "Classification": "hue-ini",
  "Properties": {},
  "Configurations": [
    {
      "Classification": "desktop",
      "Properties": {},
      "Configurations": [
        {
          "Classification": "database",
          "Properties": {
```

```
            "name": "dbname",
            "user": "username",
            "password": "password",
            "host": "RDS instance hostname",
            "port": "3306",
            "engine": "mysql"
          },
          "Configurations": []
        }
      ]
    }
  ]
}]
```

Troubleshooting

In the event of Amazon RDS failover

It is possible users may encounter delays when running a query because the Hue database instance is non-responsive or is in the process of failover. The following are some facts and guidelines for this issue:

- If you login to the Amazon RDS console, you can search for failover events. For example, to see if a failover is in process or has occurred, look for events such as "Multi-AZ instance failover started" and "Multi-AZ instance failover completed."
- It takes about 30 seconds for an RDS instance to complete a failover.
- If you are experiencing longer-than-normal responses for queries in Hue, try to re-execute the query.

Advanced configurations for Hue

This section includes the following topics.

Topics

- Configure Hue for LDAP users

Configure Hue for LDAP users

Integration with LDAP allows users to log into Hue using existing credentials stored in an LDAP directory. When you integrate Hue with LDAP, you do not need to independently manage user information in Hue. The information below demonstrates Hue integration with Microsoft Active Directory, but the configuration options are analogous to any LDAP directory.

LDAP authentication first binds to the server and establishes the connection. Then, the established connection is used for any subsequent queries to search for LDAP user information. Unless your Active Directory server allows anonymous connections, a connection needs to be established using a bind distinguished name and password. The bind distinguished name (or DN) is defined by the `bind_dn` configuration setting. The bind password is defined by the `bind_password` configuration setting. Hue has two ways to bind LDAP requests: search bind and direct bind. The preferred method for using Hue with Amazon EMR is search bind.

When search bind is used with Active Directory, Hue uses the user name attribute (defined by `user_name_attr config`) to find the attribute that needs to be retrieved from the base distinguished name (or DN). Search bind is useful when the full DN is not known for the Hue user.

For example, you may have `user_name_attr config` set to use the common name (or CN). In that case, the Active Directory server uses the Hue username provided during login to search the directory tree for a common name that matches, starting at the base distinguished name. If the common name for the Hue user is found, the user's distinguished name is returned by the server. Hue then constructs a distinguished name used to authenticate the user by performing a bind operation.

> **Note**
>
> Search bind searches usernames in all directory subtrees beginning at the base distinguished name. The base distinguished name specified in the Hue LDAP configuration should be the closest parent of the username, or your LDAP authentication performance may suffer.

When direct bind is used with Active Directory, the exact `nt_domain` or `ldap_username_pattern` must be used to authenticate. When direct bind is used, if the nt domain (defined by the `nt_domain` configuration setting) attribute is defined, a user distinguished name template is created using the form: `<login username>@nt_domain`. This template is used to search all directory subtrees beginning at the base distinguished name. If the nt domain is not configured, Hue searches for an exact distinguished name pattern for the user (defined by the ldap_username_pattern configuration setting). In this instance, the server searches for a matching ldap_username_pattern value in all directory subtrees beginning at the base distinguished name.

To launch a cluster with LDAP properties for Hue using the AWS CLI

- To specify LDAP properties for hue-ini, create a cluster with Hue installed and reference a json file with configuration properties for LDAP. An example command is shown below, which references a configuration file myConfig.json stored in Amazon S3.

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=Hue Name=Spark
 Name=Hive \
--instance-type m5.xlarge --instance-count 3 --configurations https://
s3.amazonaws.com/mybucket/myfolder/myConfig.json.
```

Example contents of myConfig.json are shown below.

```
[
    {
        "Classification": "hue-ini",
        "Properties": {},
        "Configurations": [
            {
                "Classification": "desktop",
                "Properties": {},
                "Configurations": [
                    {
                        "Classification": "ldap",
                        "Properties": {},
                        "Configurations": [
                            {
                                "Classification": "ldap_servers",
                                "Properties": {},
                                "Configurations": [
                                    {
                                        "Classification": "yourcompany",
                                        "Properties": {
                                            "base_dn":
 "DC=yourcompany,DC=hue,DC=com",
                                            "ldap_url": "ldap://ldapurl",
                                            "search_bind_authentication": "true",
```

```
                                            "bind_dn":
 "CN=hue,CN=users,DC=yourcompany,DC=hue,DC=com",
                                            "bind_password": "password"
                                        },
                                        "Configurations": []
                                    }
                                ]
                            }
                        ]
                    },
                    {

                        "Properties": {
                         "backend": "desktop.auth.backend.LdapBackend"
                              }
                    }
                ]
            }

        ]
    }
]
```

> **Note**
>
> With Amazon EMR version 5.21.0 and later, you can override cluster configurations and specify additional configuration classifications for each instance group in a running cluster. You do this by using the Amazon EMR console, the AWS Command Line Interface (AWS CLI), or the AWS SDK. For more information, see Supplying a Configuration for an Instance Group in a Running Cluster.

To view LDAP settings in Hue

1. Verify you have an active VPN connection or SSH tunnel to the Amazon EMR cluster's master node. Then, in your browser, type *master-public-dns*:8888 to open the Hue web interface.
2. Log in using your Hue administrator credentials. If the **Did you know?** window opens, click **Got it, prof!** to close it.
3. Click the **Hue** icon in the toolbar.

4. On the **About Hue** page, select **Configuration**.
5. In the **Configuration Sections and Variables** section, click **Desktop**.
6. Scroll to the **ldap** section to view your settings.

Hue release history

The following table lists the version of Hue included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Hue version information

Amazon EMR Release label	Hue Version	Components installed with Hue
emr-7.2.0	4.11.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hue-server, mariadb-server, oozie-client, oozie-server
emr-5.36.2	4.10.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hue-serve

Amazon EMR Release label	Hue Version	Components installed with Hue

emr-4.1.0	3.7.1	emrfs, emr-ddb, emr-goodies, emr-kinesis, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hue-server, mysql-server, oozie-server

Iceberg

Apache Iceberg is an open table format for large data sets in Amazon Simple Storage Service (Amazon S3). It provides fast query performance over large tables, atomic commits, concurrent writes, and SQL-compatible table evolution. Starting with Amazon EMR 6.5.0, you can use Apache Spark 3 on Amazon EMR clusters with the Iceberg table format.

The following table lists the version of Iceberg included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Iceberg.

For the version of components installed with Iceberg in this release, see Release 7.2.0 Component Versions.

Iceberg version information for emr-7.2.0

Amazon EMR Release Label	Iceberg Version	Components Installed With Iceberg
emr-7.2.0	Iceberg 1.5.0-amzn-0	Not available.

The following table lists the version of Iceberg included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Iceberg.

For the version of components installed with Iceberg in this release, see Release 6.15.0 Component Versions.

Iceberg version information for emr-6.15.0

Amazon EMR Release Label	Iceberg Version	Components Installed With Iceberg
emr-6.15.0	Iceberg 1.4.0-amzn-0	Not available.

Topics

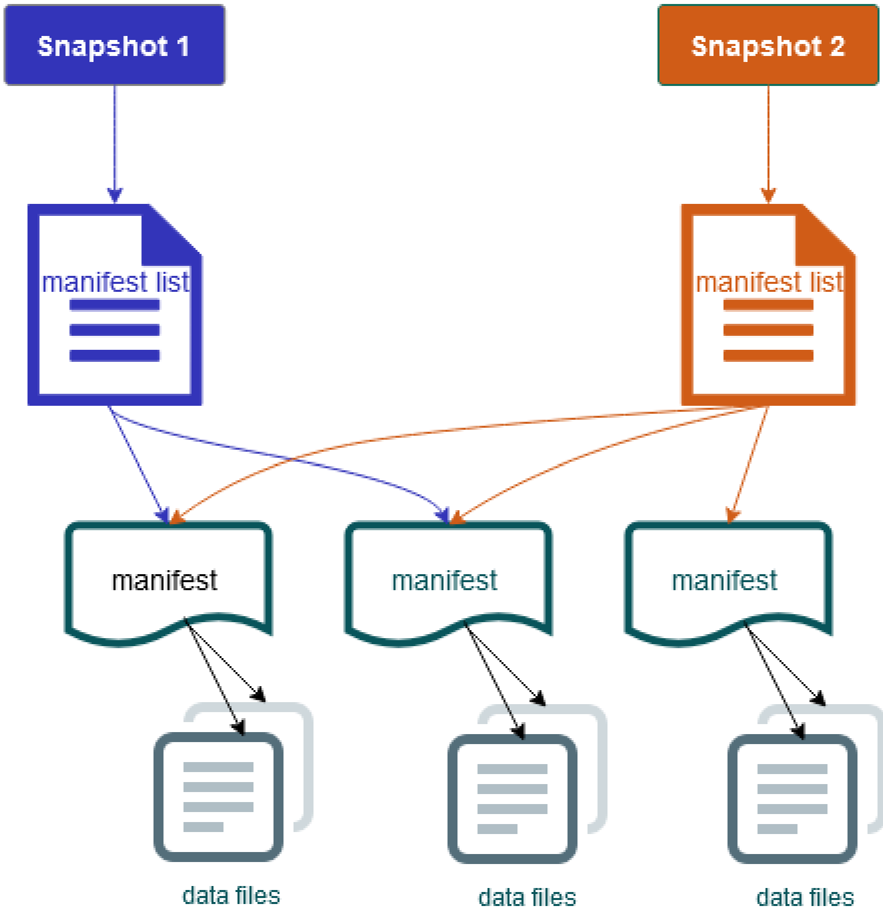
- [Considerations and limitations for using Iceberg on Amazon EMR]
- [Iceberg release history]

How Iceberg works

Iceberg tracks individual data files in a table instead of in directories. This way, writers can create data files in place (files are not moved or changed). Also, writers can only add files to the table in an explicit commit. The table state is maintained in metadata files. All changes to the table state create a new metadata file that atomically replaces the older metadata. The table metadata file tracks the table schema, partitioning configuration, and other properties.

It also includes snapshots of the table contents. Each snapshot is a complete set of data files in the table at a point in time. Snapshots are listed in the metadata file, but the files in a snapshot are stored in separate manifest files. The atomic transitions from one table metadata file to the next provide snapshot isolation. Readers use the snapshot that was current when they loaded the table metadata. Readers aren't affected by changes until they refresh and pick up a new metadata location. Data files in snapshots are stored in one or more manifest files that contain a row for each data file in the table, its partition data, and its metrics. A snapshot is the union of all files in its manifests. Manifest files can also be shared between snapshots to avoid rewriting metadata that changes infrequently.

Iceberg snapshot diagram



Iceberg offers the following features:

- Supports ACID transactions and time travel in your Amazon S3 data lake.
- Commit retries benefit from the performance advantages of optimistic concurrency.
- File-level conflict resolution results in high concurrency.
- With min-max statistics per column in metadata, you can skip files, which boosts performance for selective queries.
- You can organize tables into flexible partition layouts, with partition evolution enabling updates to partition schemes. Queries and data volumes can then change without relying on physical directories.
- Supports schema evolution and enforcement.
- Iceberg tables act as idempotent sinks and replayable sources. This enables streaming and batch support with exactly-once pipelines. Idempotent sinks track write operations that have succeeded in the past. Therefore, the sink can request data again in case of a failure, and drop data if it has been sent multiple times.

- View history and lineage, including table evolution, operations history, and statistics for each commit.
- Migrate from an existing dataset with a choice of data format (Parquet, ORC, Avro) and analytics engine (Spark, Trino, PrestoDB, Flink, Hive).

Use a cluster with Iceberg installed

This section includes information for using Iceberg with Spark, Trino, Flink, and Hive.

Use an Iceberg cluster with Spark

Starting with Amazon EMR version 6.5.0, you can use Iceberg with your Spark cluster with no requirement to include bootstrap actions. For Amazon EMR versions 6.4.0 and earlier, you can use a bootstrap action to pre-install all necessary dependencies.

In this tutorial, you use the AWS CLI to work with Iceberg on an Amazon EMR Spark cluster. To use the console to create a cluster with Iceberg installed, follow the steps in Build an Apache Iceberg data lake using Amazon Athena, Amazon EMR, and AWS Glue.

Create an Iceberg cluster

You can create a cluster with Iceberg installed using the AWS Management Console, the AWS CLI or the Amazon EMR API. In this tutorial, you use the AWS CLI to work with Iceberg on an Amazon EMR cluster. To use the console to create a cluster with Iceberg installed, follow the steps in Build an Apache Iceberg data lake using Amazon Athena, Amazon EMR, and AWS Glue.

To use Iceberg on Amazon EMR with the AWS CLI, first create a cluster with the following steps. For information on specifying the Iceberg classification using the AWS CLI, see Supply a configuration using the AWS CLI when you create a cluster or Supply a configuration using the Java SDK when you create a cluster.

1. Create a `configurations.json` file with the following content:

```
[{
    "Classification":"iceberg-defaults",
    "Properties":{"iceberg.enabled":"true"}
}]
```

2. Next, create a cluster with the following configuration. Replace the example Amazon S3 bucket path and the subnet ID with your own.

```
aws emr create-cluster --release-label emr-6.5.0 \
--applications Name=Spark \
--configurations file://iceberg_configurations.json \
--region us-east-1 \
--name My_Spark_Iceberg_Cluster \
--log-uri s3://DOC-EXAMPLE-BUCKET/ \
--instance-type m5.xlarge \
--instance-count 2 \
--service-role EMR_DefaultRole_V2 \
--ec2-attributes
 InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef0
```

Alternatively, you can create an Amazon EMR cluster including the Spark application and include the file `/usr/share/aws/iceberg/lib/iceberg-spark3-runtime.jar` as a JAR dependency in a Spark job. For more information, see Submitting Applications.

To include the jar as a dependency in a Spark job, add the following configuration property to the Spark application:

```
--conf "spark.jars=/usr/share/aws/iceberg/lib/iceberg-spark3-runtime.jar"
```

For more information about Spark job dependencies, see Dependency Management in the Apache Spark document Running Spark on Kubernetes.

Initialize a Spark session for Iceberg

The following examples demonstrate how to launch the interactive Spark shell, use Spark submit, or use Amazon EMR Notebooks to work with Iceberg on Amazon EMR.

spark-shell

1. Connect to the master node using SSH. For more information, see Connect to the master node using SSH in the *Amazon EMR Management Guide*.
2. Enter the following command to launch the Spark shell. To use the PySpark shell, replace `spark-shell` with `pyspark`.

```
spark-shell \
```

```
--conf
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions"
 \
--conf "spark.sql.catalog.dev=org.apache.iceberg.spark.SparkCatalog" \
--conf "spark.sql.catalog.dev.type=hadoop" \
--conf "spark.sql.catalog.dev.warehouse=s3://DOC-EXAMPLE-BUCKET/example-prefix/"
```

spark-submit

1. Connect to the master node using SSH. For more information, see Connect to the master node using SSH in the *Amazon EMR Management Guide*.
2. Enter the following command to launch the Spark session for Iceberg.

```
spark-submit \
--conf
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions"
 \
--conf "spark.sql.catalog.dev=org.apache.iceberg.spark.SparkCatalog" \
--conf "spark.sql.catalog.dev.type=hadoop" \
--conf "spark.sql.catalog.dev.warehouse=s3://DOC-EXAMPLE-BUCKET/example-prefix/"
```

EMR Studio notebooks

To initialize a Spark session using EMR Studio notebooks, configure your Spark session using the `%%configure` magic command in your Amazon EMR notebook, as in the following example. For more information, see Use EMR Notebooks magics in the *Amazon EMR Management Guide*.

```
%%configure -f
{
"conf":{

 "spark.sql.extensions":"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions",
    "spark.sql.catalog.dev":"org.apache.iceberg.spark.SparkCatalog",
    "spark.sql.catalog.dev.type":"hadoop",
    "spark.sql.catalog.dev.warehouse":"s3://DOC-EXAMPLE-BUCKET/example-prefix/"
    }
}
```

Write to an Iceberg table

The following example shows how to create a DataFrame and write it as an Iceberg dataset. The examples demonstrate working with datasets using the Spark shell while connected to the master node using SSH as the default hadoop user.

> **Note**
>
> To paste code samples into the Spark shell, type `:paste` at the prompt, paste the example, and then press CTRL+D.

PySpark

Spark includes a Python-based shell, `pyspark`, that you can use to prototype Spark programs written in Python. Invoke `pyspark` on the master node.

```
## Create a DataFrame.
data = spark.createDataFrame([
 ("100", "2015-01-01", "2015-01-01T13:51:39.340396Z"),
 ("101", "2015-01-01", "2015-01-01T12:14:58.597216Z"),
 ("102", "2015-01-01", "2015-01-01T13:51:40.417052Z"),
 ("103", "2015-01-01", "2015-01-01T13:51:40.519832Z")
],["id", "creation_date", "last_update_time"])

## Write a DataFrame as a Iceberg dataset to the Amazon S3 location.
spark.sql("""CREATE TABLE IF NOT EXISTS dev.db.iceberg_table (id string,
creation_date string,
last_update_time string)
USING iceberg
location 's3://DOC-EXAMPLE-BUCKET/example-prefix/db/iceberg_table'""")

data.writeTo("dev.db.iceberg_table").append()
```

Scala

```
import org.apache.spark.sql.SaveMode
import org.apache.spark.sql.functions._

// Create a DataFrame.
val data = Seq(
```

```
("100", "2015-01-01", "2015-01-01T13:51:39.340396Z"),
("101", "2015-01-01", "2015-01-01T12:14:58.597216Z"),
("102", "2015-01-01", "2015-01-01T13:51:40.417052Z"),
("103", "2015-01-01", "2015-01-01T13:51:40.519832Z")
).toDF("id", "creation_date", "last_update_time")

// Write a DataFrame as a Iceberg dataset to the Amazon S3 location.
spark.sql("""CREATE TABLE IF NOT EXISTS dev.db.iceberg_table (id string,
creation_date string,
last_update_time string)
USING iceberg
location 's3://DOC-EXAMPLE-BUCKET/example-prefix/db/iceberg_table'""")

data.writeTo("dev.db.iceberg_table").append()
```

Read from an Iceberg table

PySpark

```
df = spark.read.format("iceberg").load("dev.db.iceberg_table")
df.show()
```

Scala

```
val df = spark.read.format("iceberg").load("dev.db.iceberg_table")
df.show()
```

Spark SQL

```
SELECT * from dev.db.iceberg_table LIMIT 10
```

Configure Spark properties to use the AWS Glue Data Catalog as Iceberg tables metastore

To use the AWS Glue Catalog as the Metastore for Iceberg tables, set the Spark configuration properties as below:

```
spark-submit \
```

```
    --conf spark.sql.catalog.my_catalog=org.apache.iceberg.spark.SparkCatalog \
    --conf spark.sql.catalog.my_catalog.warehouse=s3://<bucket>/<prefix> \
    --conf spark.sql.catalog.my_catalog.catalog-
impl=org.apache.iceberg.aws.glue.GlueCatalog \
    --conf spark.sql.catalog.my_catalog.io-impl=org.apache.iceberg.aws.s3.S3FileIO \
    --conf spark.sql.catalog.my_catalog.lock-
impl=org.apache.iceberg.aws.dynamodb.DynamoDbLockManager \
    --conf spark.sql.catalog.my_catalog.lock.table=myGlueLockTable
```

Use an Iceberg cluster with Trino

Starting with Amazon EMR version 6.6.0, you can use Iceberg with your Trino cluster.

In this tutorial, you use the AWS CLI to work with Iceberg on an Amazon EMR Trino cluster. To use the console to create a cluster with Iceberg installed, follow the steps in Build an Apache Iceberg data lake using Amazon Athena, Amazon EMR, and AWS Glue.

Create an Iceberg cluster

To use Iceberg on Amazon EMR with the AWS CLI, first create a cluster with the following steps. For information on specifying the Iceberg classification using the AWS CLI, see Supply a configuration using the AWS CLI when you create a cluster or Supply a configuration using the Java SDK when you create a cluster.

1. Create an `iceberg.properties` file and set a value for your chosen catalog. For example, if you want to use the Hive metastore as your catalog, your file should have the following content.

   ```
   connector.name=iceberg
   hive.metastore.uri=thrift://localhost:9083
   ```

   If you want to use the AWS Glue Data Catalog as your store, your file should have the following content.

   ```
   connector.name=iceberg
   iceberg.catalog.type=glue
   ```

2. Create a bootstrap action that copies `iceberg.properties` from Amazon S3 to `/etc/trino/conf/catalog/iceberg.properties`, as in the following example. For information on bootstrap actions, see Create bootstrap actions to install additional software.

```
set -ex
sudo aws s3 cp s3://DOC-EXAMPLE-BUCKET/iceberg.properties /etc/trino/conf/catalog/
iceberg.properties
```

3. Create a cluster with the following configuration, replacing the example bootstrap actions script path and key name with your own.

```
aws emr create-cluster --release-label emr-6.7.0 \
--applications Name=Trino \
--region us-east-1 \
--name My_Trino_Iceberg_Cluster \
--bootstrap-actions '[{"Path":"s3://DOC-EXAMPLE-BUCKET","Name":"Add
 iceberg.properties"}]' \
--instance-groups InstanceGroupType=MASTER,InstanceCount=1,InstanceType=c3.4xlarge
 InstanceGroupType=CORE,InstanceCount=3,InstanceType=c3.4xlarge \
--use-default-roles \
--ec2-attributes KeyName=<key-name>
```

Initialize a Trino session for Iceberg

To initialize a Trino session, run the following command.

```
trino-cli --catalog iceberg
```

Write to an Iceberg table

Create and write to your table with the following SQL commands.

```
trino> SHOW SCHEMAS;
trino> CREATE TABLE default.iceberg_table (
            id int,
            data varchar,
            category varchar)
       WITH (
            format = 'PARQUET',
            partitioning = ARRAY['category', 'bucket(id, 16)'],
            location = 's3://DOC-EXAMPLE-BUCKET/<prefix>')

trino> INSERT INTO default.iceberg_table VALUES (1,'a','c1'), (2,'b','c2'),
 (3,'c','c3');
```

Read from a table for Iceberg

To read from your Iceberg table, run the following command.

```
trino> SELECT * from default.iceberg_table;
```

Use an Iceberg cluster with Flink

Starting with Amazon EMR version 6.9.0, you can use Iceberg with a Flink cluster without the setup steps required when using the open source Iceberg Flink Integration.

Creating an Iceberg cluster

You can create a cluster with Iceberg installed using the AWS Management Console, the AWS CLI, or the Amazon EMR API. In this tutorial, you use the AWS CLI to work with Iceberg on an Amazon EMR cluster. To use the console to create a cluster with Iceberg installed, follow the steps in Build an Apache Iceberg data lake using Amazon Athena, Amazon EMR, and AWS Glue.

To use Iceberg on Amazon EMR with the AWS CLI, first create a cluster with the following steps. For information on specifying the Iceberg classification using the AWS CLI, see Supply a configuration using the AWS CLI when you create a cluster or Supply a configuration using the Java SDK when you create a cluster. Create a file called `configurations.json` with the following content:

```
[{
"Classification":"iceberg-defaults",
    "Properties":{"iceberg.enabled":"true"}
}]
```

Next, create a cluster with the following configuration, replacing the example Amazon S3 bucket path and subnet ID with your own values:

```
aws emr create-cluster --release-label emr-6.9.0 \
--applications Name=Flink \
--configurations file://iceberg_configurations.json \
--region us-east-1 \
--name My_flink_Iceberg_Cluster \
--log-uri s3://DOC-EXAMPLE-BUCKET/ \
--instance-type m5.xlarge \
--instance-count 2 \
--service-role EMR_DefaultRole \
```

```
--ec2-attributes InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef
```

Alternatively, you can create an Amazon EMR 6.9.0 cluster with a Flink application in it and use the file `/usr/share/aws/iceberg/lib/iceberg-flink-runtime.jar` as a JAR dependency in a Flink job.

Using the Flink SQL Client

The SQL Client script is located under `/usr/lib/flink/bin`. You can run the script with the following command:

```
flink-yarn-session -d # starting the Flink YARN Session in detached mode
./sql-client.sh
```

This launches a Flink SQL Shell.

Flink examples

Create an Iceberg table

Flink SQL

```
CREATE CATALOG glue_catalog WITH (
   'type'='iceberg',
   'warehouse'='<WAREHOUSE>',
   'catalog-impl'='org.apache.iceberg.aws.glue.GlueCatalog',
   'io-impl'='org.apache.iceberg.aws.s3.S3FileIO',
   'lock-impl'='org.apache.iceberg.aws.dynamodb.DynamoDbLockManager',
   'lock.table'='myGlueLockTable'
 );

USE CATALOG  glue_catalog;

CREATE DATABASE IF NOT EXISTS <DB>;

USE <DB>;

CREATE TABLE IF NOT EXISTS `glue_catalog`.`<DB>`.`sample` (id int, data string);
```

Table API

```
EnvironmentSettings settings =
```

```
                EnvironmentSettings.newInstance().inBatchMode().build();

TableEnvironment tEnv = TableEnvironment.create(settings);

String warehouse = "<WAREHOUSE>";
String db = "<DB>";

tEnv.executeSql(
                "CREATE CATALOG glue_catalog WITH (\n"
                        + "   'type'='iceberg',\n"
                        + "   'warehouse'='"
                        + warehouse
                        + "',\n"
                        + "   'catalog-impl'='org.apache.iceberg.aws.glue.GlueCatalog',
\n"
                        + "   'io-impl'='org.apache.iceberg.aws.s3.S3FileIO'\n"
                        + " );");

tEnv.executeSql("USE CATALOG  glue_catalog;");
tEnv.executeSql("CREATE DATABASE IF NOT EXISTS " + db + ";");
tEnv.executeSql("USE " + db + ";");
tEnv.executeSql(
        "CREATE TABLE `glue_catalog`.`" + db + "`.`sample` (id bigint, data string);");
```

Write to an Iceberg table

Flink SQL

```
INSERT INTO `glue_catalog`.`<DB>`.`sample` values (1, 'a'),(2,'b'),(3,'c');
```

Table API

```
tEnv.executeSql(
        "INSERT INTO `glue_catalog`.`"
                + db
                + "`.`sample` values (1, 'a'),(2,'b'),(3,'c');");
```

Datastream API

```
final StreamExecutionEnvironment env =
 StreamExecutionEnvironment.getExecutionEnvironment();
```

```
final StreamTableEnvironment tableEnv = StreamTableEnvironment.create(env);

String db = "<DB Name>";

String warehouse = "<Warehouse Path>";

GenericRowData rowData1 = new GenericRowData(2);
rowData1.setField(0, 1L);
rowData1.setField(1, StringData.fromString("a"));

DataStream<RowData> input = env.fromElements(rowData1);

Map<String, String> props = new HashMap<();
props.put("type", "iceberg");
props.put("warehouse", warehouse);
props.put("io-impl", "org.apache.iceberg.aws.s3.S3FileIO");

CatalogLoader glueCatlogLoader =
        CatalogLoader.custom(
                "glue",
                props,
                new Configuration(),
                "org.apache.iceberg.aws.glue.GlueCatalog");

TableLoader tableLoader =
        TableLoader.fromCatalog(glueCatlogLoader, TableIdentifier.of(db, "sample"));

DataStreamSink<Void> dataStreamSink =
        FlinkSink.forRowData(input).tableLoader(tableLoader).append();

env.execute("Datastream Write");
```

Read from an Iceberg table

Flink SQL

```
SELECT * FROM `glue_catalog`.`<DB>`.`sample`;
```

Table API

```
Table result = tEnv.sqlQuery("select * from `glue_catalog`.`" + db + "`.`sample`;");
```

Datastream API

```
final StreamExecutionEnvironment env =
 StreamExecutionEnvironment.getExecutionEnvironment();

final StreamTableEnvironment tableEnv = StreamTableEnvironment.create(env);

String db = "<DB Name>";

String warehouse = "<Warehouse Path>";

Map<String, String> props = new HashMap<>();
props.put("type", "iceberg");
props.put("warehouse", warehouse);
props.put("io-impl", "org.apache.iceberg.aws.s3.S3FileIO");

CatalogLoader glueCatlogLoader =
        CatalogLoader.custom(
                "glue",
                props,
                new Configuration(),
                "org.apache.iceberg.aws.glue.GlueCatalog");

TableLoader tableLoader =
        TableLoader.fromCatalog(glueCatlogLoader, TableIdentifier.of(db, "sample"));

DataStream<RowData> batch =

 FlinkSource.forRowData().env(env).tableLoader(tableLoader).streaming(false).build();

batch.print().name("print-sink");
```

Using the Hive catalog

Make sure the Flink and Hive dependencies are resolved as described in Configure Flink with Hive Metastore and Glue Catalog.

Running a Flink Job

One way to submit a job to Flink is to use a per job Flink YARN session. This can be launched with the following command:

```
sudo flink run -m yarn-cluster -p 4 -yjm 1024m -ytm 4096m $JAR_FILE_NAME
```

Use an Iceberg cluster with Hive

With Amazon EMR releases 6.9.0 and higher, you can use Iceberg with a Hive cluster without having to perform the setup steps that are required for Open Source Iceberg Hive Integration. For Amazon EMR versions 6.8.0 and earlier, you can use a bootstrap action to install `iceberg-hive-runtime` jar for configuring Hive for Iceberg support.

Amazon EMR 6.9.0 includes all features for Hive 3.1.3 integration with Iceberg 0.14.1 and also includes Amazon EMR added features such as auto selection of supported execution engines at runtime (Amazon EMR on EKS 6.9.0).

Create an Iceberg cluster

You can create a cluster with Iceberg installed using the AWS Management Console, the AWS CLI or the Amazon EMR API. In this tutorial, you use the AWS CLI to work with Iceberg on an Amazon EMR cluster. To use the console to create a cluster with Iceberg installed, follow the steps in Build an Iceberg data lake using Amazon Athena, Amazon EMR, and AWS Glue.

To use Iceberg on Amazon EMR with the AWS CLI, first create a cluster using the steps below. For information on specifying the Iceberg classification using the AWS CLI or the Java SDK, see Supply a configuration using the AWS CLI when you create a cluster or Supply a configuration using the Java SDK when you create a cluster. Create a file named `configurations.json` with the following content:

```
[{
    "Classification":"iceberg-defaults",
    "Properties":{"iceberg.enabled":"true"}
}]
```

Next, create a cluster with the following configuration, replacing the example Amazon S3 bucket path and the subnet ID with your own:

```
aws emr create-cluster --release-label emr-6.9.0 \
--applications Name=Hive \
--configurations file://iceberg_configurations.json \
--region us-east-1 \
--name My_hive_Iceberg_Cluster \
--log-uri s3://DOC-EXAMPLE-BUCKET/ \
--instance-type m5.xlarge \
--instance-count 2 \
```

```
--service-role EMR_DefaultRole \
--ec2-attributes InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef
```

A Hive Iceberg cluster does the following things:

- Loads the Iceberg Hive runtime jar in Hive and enables Iceberg-related configuration for the Hive engine.
- Enables Amazon EMR Hive's dynamic execution engine selection to prevent users from setting supported execution engine for Iceberg compatibility.

> **Note**
>
> Hive Iceberg clusters do not currently support AWS Glue Data Catalog. The default Iceberg catalog is `HiveCatalog`, which corresponds to the metastore configured for the Hive environment. For more information on catalog management, see Using HCatalog in the Apache Hive documentation.

Feature support

Amazon EMR 6.9.0 supports Hive 3.1.3 and Iceberg 0.14.1. The feature support is limited to Iceberg-compatible features for Hive 3.1.2 and 3.1.3. The following commands are supported:

- With Amazon EMR releases 6.9.0 to 6.12.x, you must include the `libfb303` jar in the Hive `auxlib` directory. Use the following command to include it:

  ```
  sudo /usr/bin/ln -sf /usr/lib/hive/lib/libfb303-*.jar /usr/lib/hive/auxlib/
  libfb303.jar
  ```

  With Amazon EMR releases 6.13 and higher, the `libfb303` jar is automatically symlinked to the Hive `auxlib` directory.
- **Creating a table**
  - **Non-partitioned table** – External tables in Hive can be created by providing the storage handler as follows:

    ```
    CREATE EXTERNAL TABLE x (i int) STORED BY
     'org.apache.iceberg.mr.hive.HiveIcebergStorageHandler'
    ```

- **Partitioned table** – External partitioned tables in Hive can be created as follows:

```
CREATE EXTERNAL TABLE x (i int) PARTITIONED BY (j int) STORED BY
 'org.apache.iceberg.mr.hive.HiveIcebergStorageHandler'
```

> **Note**
>
> The `STORED AS` file format of ORC/AVRO/PARQUET is not supported in Hive 3. The default and only option is Parquet.

- **Dropping a table** – The `DROP TABLE` command is used to drop tables, such as in the following example:

```
DROP TABLE [IF EXISTS] table_name [PURGE];
```

- **Reading a table** – `SELECT` statements can be used to read Iceberg tables in Hive, such as in the following example. Supported execution engines are MR and Tez.

```
SELECT * FROM table_name
```

  For information on Hive's select syntax, see LanguageManual Select. For information on select statements with Iceberg tables in Hive, see Apache Iceberg Select.

- **Inserting into a table** – HiveQL's `INSERT INTO` statement works on Iceberg tables with support for the Map Reduce execution engine only. Amazon EMR users don't need to explicitly set the execution engine because Amazon EMR Hive selects the engine for Iceberg Tables at runtime.
  - **Single table insert into** – Example:

```
INSERT INTO table_name VALUES ('a', 1);
INSERT INTO table_name SELECT...;
```

  - **Multi-table insert into** – Non-atomic multi-table insert into statements are supported. Example:

```
FROM source
 INSERT INTO table_1 SELECT a, b
 INSERT INTO table_2 SELECT c,d;
```

Considerations and limitations for using Iceberg on Amazon EMR

This section includes considerations and limitations for using Iceberg with Spark, Trino, Flink, and Hive.

Considerations for using Iceberg with Spark

- Amazon EMR 6.5.0 does not support Iceberg running on Amazon EMR on EKS by default. An Amazon EMR 6.5.0 custom image is available so that you can pass `--jars local:///usr/share/aws/iceberg/lib/iceberg-spark3-runtime.jar` as a `spark-submit` parameter to create Iceberg tables on Amazon EMR on EKS. For more information, see Submit a Spark workload in Amazon EMR using a custom image in the *Amazon EMR on EKS Development Guide*. You can also contact AWS Support for assistance. Starting with Amazon EMR 6.6.0, Iceberg is supported on Amazon EMR on EKS.
- When using AWS Glue as a catalog for Iceberg, make sure the database in which you are creating a table exists in AWS Glue. If you are using services such as AWS Lake Formation and you're unable to load the catalog, make sure you have proper access to the service to execute the command.

Considerations for using Iceberg with Trino

- Amazon EMR 6.5 does not offer Trino Iceberg Catalog support for Iceberg natively. Trino needs Iceberg v0.11, so we recommend launching an Amazon EMR cluster for Trino separate from the Spark cluster and including Iceberg v0.11 on that cluster.
- When using AWS Glue as a catalog for Iceberg, make sure that the database in which you are creating a table exists in AWS Glue. If you are using services such as AWS Lake Formation and you're unable to load the catalog, make sure you have proper access to the service to execute the command.

Considerations for using Iceberg with Flink

When using AWS Glue as a catalog for Iceberg, make sure the database in which you are creating a table exists in AWS Glue. If you are using services such as AWS Lake Formation and you're unable to load the catalog, make sure you have proper access to the service to execute the command.

Considerations for using Iceberg with Hive

- Iceberg supports the following query types:
  - Create table
  - Drop table
  - Insert into table
  - Read table
- Only the MR (MapReduce) execution engine is supported for DML (data manipulation language) operations, and MR is deprecated in Hive 3.1.3.
- AWS Glue Data Catalog is not currently supported for Iceberg with Hive.
- Error handling is insufficiently robust. In cases of misconfiguration, inserts into queries might complete successfully. However, failure to update metadata can result in data loss.

Iceberg release history

The following table lists the version of Iceberg included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Iceberg version information

Amazon EMR Release label	Iceberg Version	Components installed with Iceberg
emr-7.2.0	1.5.0-amzn-0	Not available.
emr-7.1.0	1.4.3-amzn-0	Not available.
emr-7.0.0	1.4.2-amzn-0	Not available.
emr-6.15.0	1.4.0-amzn-0	Not available.

Amazon EMR Release label	Iceberg Version	Components installed with Iceberg
emr-6.14.0	1.3.1-amzn-0	Not available.
emr-6.13.0	1.3.0-amzn-1	Not available.
emr-6.12.0	1.3.0-amzn-0	Not available.
emr-6.11.1	1.2.0-amzn-0	Not available.
emr-6.11.0	1.2.0-amzn-0	Not available.
emr-6.10.1	1.1.0-amzn-0	Not available.
emr-6.10.0	1.1.0-amzn-0	Not available.
emr-6.9.1	0.14.1-amzn-0	Not available.
emr-6.9.0	0.14.1-amzn-0	Not available.
emr-6.8.1	0.14.0-amzn-0	Not available.
emr-6.8.0	0.14.0-amzn-0	Not available.
emr-6.7.0	0.13.1-amzn-0	Not available.
emr-6.6.0	0.13.1	Not available.
emr-6.5.0	0.12.0	Not available.

Iceberg release notes by version

- Amazon EMR 6.9.0 - Iceberg release notes

Amazon EMR 6.9.0 - Iceberg release notes

Amazon EMR 6.9.0 - Iceberg changes

Type	Description
Feature	Amazon EMR Flink integration with Iceberg.
Feature	Amazon EMR Hive integration with Iceberg.
Feature	Support to cache Iceberg metadata files on Amazon FSx for Lustre to improve the query planning time.
Backport	PR 5050: Flink 1.15: Support write options in the in-line insert SQL comments.
Backport	PR 5282: AWS: Fix PUT retry failures by opening new data file streams.
Backport	PR 5318: Flink 1.15: Bridge the gap between FlinkSource and IcebergSource (FLIP-27) and added an opt-in config to use FLIP-27 source in Flink SQL.
Backport	PR 5344: Flink 1.14: Bridge the gap between FlinkSource and IcebergSource (FLIP-27) and added an opt-in config to use FLIP-27 source in Flink SQL.
Backport	PR 5393: Flink 1.14, 1.15: Avoid convertin g Iceberg MetricContext to Flink metrics in FLIP-27 source reader.
Backport	PR 5401: Flink 1.14, 1.15: Missed IcebergSo urceReader group in PR #5393 for FLIP-27 source reader metrics.

Type	Description
Backport	PR 5679: Spark 3.2, 3.3: Fix nullability propagation for MergeRows node.
Backport	PR 5860: Spark 3.3: Fix QueryFailure when running RewriteManifestProcedure on Date partitioned tables.
Backport	PR 5880: Spark 3.3: Fix nullability in merge-on-read projections.
Backport	PR 5917: Spark 3.2: Fix nullability in merge-on-read projections.

Jupyter Notebook on Amazon EMR

Jupyter Notebook is an open-source web application that you can use to create and share documents that contain live code, equations, visualizations, and narrative text. Amazon EMR offers you three options to work with Jupyter notebooks:

Topics

EMR Studio

Amazon EMR Studio is a web-based integrated development environment (IDE) for fully managed Jupyter notebooks that run on Amazon EMR clusters. You can set up an EMR Studio for your team to develop, visualize, and debug applications written in R, Python, Scala, and PySpark.

We recommend using EMR Studio when using Jupyter notebooks on Amazon EMR. For more information, see EMR Studio in the *Amazon EMR Management Guide*.

Amazon EMR Notebook based on Jupyter Notebook

EMR Notebooks is a Jupyter Notebook environment built in to the Amazon EMR console that allows you to quickly create Jupyter notebooks, attach them to Spark clusters, and then open the Jupyter Notebook editor in the console to remotely run queries and code. An EMR notebook is saved in Amazon S3 independently from clusters for durable storage, quick access, and flexibility. You can have multiple notebooks open, attach multiple notebooks to a single cluster, and re-use a notebook on different clusters.

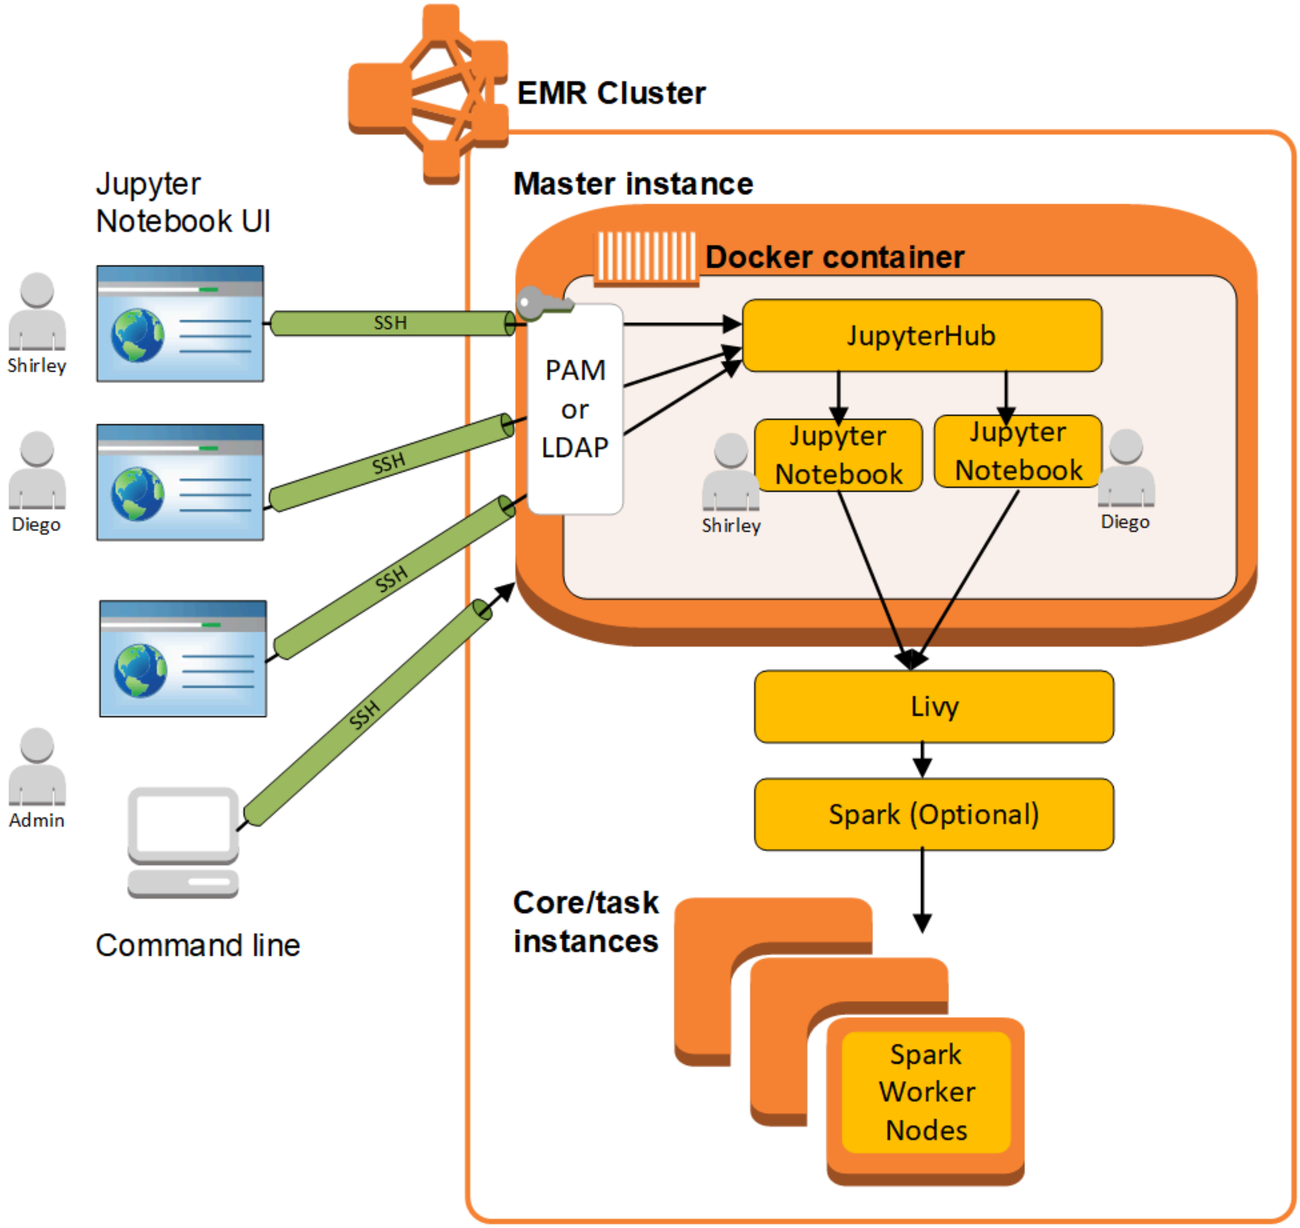
For more information, see EMR notebooks in the *Amazon EMR Management Guide*.

JupyterHub

Jupyter Notebook is an open-source web application that you can use to create and share documents that contain live code, equations, visualizations, and narrative text. JupyterHub allows you to host multiple instances of a single-user Jupyter notebook server. When you create a cluster with JupyterHub, Amazon EMR creates a Docker container on the cluster's master node. JupyterHub, all the components required for Jupyter, and Sparkmagic run within the container.

Sparkmagic is a library of kernels that allows Jupyter notebooks to interact with Apache Spark running on Amazon EMR through Apache Livy, which is a REST server for Spark. Spark and Apache Livy are installed automatically when you create a cluster with JupyterHub. The default Python 3 kernel for Jupyter is available along with the PySpark 3, PySpark, and Spark kernels that are available with Sparkmagic. You can use these kernels to run ad-hoc Spark code and interactive SQL queries using Python and Scala. You can install additional kernels within the Docker container manually. For more information, see Installing additional kernels and libraries.

The following diagram depicts the components of JupyterHub on Amazon EMR with corresponding authentication methods for notebook users and the administrator. For more information, see Adding Jupyter Notebook users and administrators.



The following table lists the version of JupyterHub included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with JupyterHub.

For the version of components installed with JupyterHub in this release, see [Release 7.2.0 Component Versions](#).

JupyterHub version information for emr-7.2.0

Amazon EMR Release Label	JupyterHub Version	Components Installed With JupyterHub
emr-7.2.0	JupyterHub 1.5.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

The following table lists the version of JupyterHub included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with JupyterHub.

For the version of components installed with JupyterHub in this release, see Release 6.15.0 Component Versions.

JupyterHub version information for emr-6.15.0

Amazon EMR Release Label	JupyterHub Version	Components Installed With JupyterHub
emr-6.15.0	JupyterHub 1.5.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resour

Amazon EMR Release Label	JupyterHub Version	Components Installed With JupyterHub
		cemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

The following table lists the version of JupyterHub included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with JupyterHub.

For the version of components installed with JupyterHub in this release, see Release 5.36.2 Component Versions.

JupyterHub version information for emr-5.36.2

Amazon EMR Release Label	JupyterHub Version	Components Installed With JupyterHub
emr-5.36.2	JupyterHub 1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

The Python 3 kernel included with JupyterHub on Amazon EMR is 3.6.4.

The libraries installed within the `jupyterhub` container may vary between Amazon EMR release versions and Amazon EC2 AMI versions.

To list installed libraries using conda

- Run the following command on the master node command line:

```
sudo docker exec jupyterhub bash -c "conda list"
```

To list installed libraries using pip

- Run the following command on the master node command line:

```
sudo docker exec jupyterhub bash -c "pip freeze"
```

Topics

Create a cluster with JupyterHub

You can create an Amazon EMR cluster with JupyterHub using the AWS Management Console, AWS Command Line Interface, or the Amazon EMR API. Ensure that the cluster is not created with the option to terminate automatically after completing steps (`--auto-terminate` option in the AWS CLI). Also, make sure that administrators and notebook users can access the key pair that you use when you create the cluster. For more information, see Use a key pair for SSH credentials in the *Amazon EMR Management Guide*.

Create a cluster with JupyterHub using the console

Use the following procedure to create a cluster with JupyterHub installed using **Advanced Options** in the Amazon EMR console.

To create an Amazon EMR cluster with JupyterHub installed using the Amazon EMR console

1. Navigate to the new Amazon EMR console and select **Switch to the old console** from the side navigation. For more information on what to expect when you switch to the old console, see Using the old console.
2. Choose **Create cluster**, **Go to advanced options**.
3. Under **Software Configuration**:
   - For **Release**, select emr-5.36.2, and choose JupyterHub.
   - If you use Spark, to use the AWS Glue Data Catalog as the metastore for Spark SQL, select **Use for Spark table metadata**. For more information, see Use the AWS Glue Data Catalog as the metastore for Spark SQL.
   - For **Edit software settings** choose **Enter configuration** and specify values, or choose **Load JSON from S3** and specify a JSON configuration file. For more information, see Configuring JupyterHub.
4. Under **Add steps (optional)** configure steps to run when the cluster is created, make sure that **Auto-terminate cluster after the last step is completed** is not selected, and choose **Next**.
5. Choose **Hardware Configuration** options, **Next**. For more information, see Configure cluster hardware and networking in the *Amazon EMR Management Guide*.
6. Choose options for **General Cluster Settings**, **Next**.
7. Choose **Security Options**, specifying a key pair, and choose **Create Cluster**.

Create a cluster with JupyterHub using the AWS CLI

To launch a cluster with JupyterHub, use the `aws emr create-cluster` command and, for the `--applications` option, specify `Name=JupyterHub`. The following example launches a JupyterHub cluster on Amazon EMR with two EC2 instances (one master and one core instance). Also, debugging is enabled, with logs stored in the Amazon S3 location as specified by `--log-uri`. The specified key pair provides access to Amazon EC2 instances in the cluster.

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name="MyJupyterHubCluster" --release-label emr-5.36.2 \
--applications Name=JupyterHub --log-uri s3://MyBucket/MyJupyterClusterLogs \
--use-default-roles --instance-type m5.xlarge --instance-count 2 --ec2-attributes
 KeyName=MyKeyPair
```

Considerations when using JupyterHub on Amazon EMR

Consider the following when using JupyterHub on Amazon EMR.

- **Warning**

  User notebooks and files are saved to the file system on the master node. This is ephemeral storage that does not persist through cluster termination. When a cluster terminates, this data is lost if not backed up. We recommend that you schedule regular backups using `cron` jobs or another means suitable for your application.
  In addition, configuration changes made within the container may not persist if the container restarts. We recommend that you script or otherwise automate container configuration so that you can reproduce customizations more readily.
- Kerberos authentication that has been set up using an Amazon EMR security configuration is not supported.
- OAuthenticator is not supported.

Configuring JupyterHub

You can customize the configuration of JupyterHub on Amazon EMR and individual user notebooks by connecting to the cluster master node and editing configuration files. After you change values, restart the `jupyterhub` container.

Modify properties in the following files to configure JupyterHub and individual Jupyter notebooks:

- jupyterhub_config.py—By default, this file is saved in the /etc/jupyter/conf/ directory on the master node. For more information, see Configuration basics in the JupyterHub documentation.
- jupyter_notebook_config.py—This file is saved in the /etc/jupyter/ directory by default and copied to the jupyterhub container as the default. For more information, see Config file and command line options in the Jupyter Notebook documentation.

You can also use the jupyter-sparkmagic-conf configuration classification to customize Sparkmagic, which updates values in the config.json file for Sparkmagic. For more information about available settings, see the example_config.json on GitHub. For more information about using configuration classifications with applications in Amazon EMR, see Configure applications.

The following example launches a cluster using the AWS CLI, referencing the file MyJupyterConfig.json for Sparkmagic configuration classification settings.

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --use-default-roles --release-label emr-5.14.0 \
--applications Name=Jupyter --instance-type m4.xlarge --instance-count 3 \
--ec2-attributes KeyName=MyKey,SubnetId=subnet-1234a5b6 --configurations file://
MyJupyterConfig.json
```

Sample contents of MyJupyterConfig.json are as follows:

```
[
    {
    "Classification":"jupyter-sparkmagic-conf",
    "Properties": {
      "kernel_python_credentials" : "{\"username\":\"diego\",\"base64_password\":
\"mypass\",\"url\":\"http:\/\/localhost:8998\",\"auth\":\"None\"}"
      }
    }
]
```

Note

With Amazon EMR version 5.21.0 and later, you can override cluster configurations and specify additional configuration classifications for each instance group in a running cluster. You do this by using the Amazon EMR console, the AWS Command Line Interface (AWS CLI), or the AWS SDK. For more information, see [Supplying a Configuration for an Instance Group in a Running Cluster](#).

Configuring persistence for notebooks in Amazon S3

You can configure a JupyterHub cluster in Amazon EMR so that notebooks saved by a user persist in Amazon S3, outside of ephemeral storage on cluster EC2 instances.

You specify Amazon S3 persistence using the `jupyter-s3-conf` configuration classification when you create a cluster. For more information, see Configure applications.

In addition to enabling Amazon S3 persistence using the `s3.persistence.enabled` property, you specify a bucket in Amazon S3 where notebooks are saved using the `s3.persistence.bucket` property. Notebooks for each user are saved to a `jupyter/`*`jupyterhub-user-name`* folder in the specified bucket. The bucket must already exist in Amazon S3, and the role for the EC2 instance profile that you specify when you create the cluster must have permissions to the bucket (by default, the role is `EMR_EC2_DefaultRole`). For more information, see Configure IAM roles for Amazon EMR permissions to AWS services.

When you launch a new cluster using the same configuration classification properties, users can open notebooks with the content from the saved location.

Note that when you import files as modules in a notebook when you have Amazon S3 enabled, this will result in the files uploading to Amazon S3. When you import files without enabling Amazon S3 persistence, they upload to your JupyterHub container.

The following example enables Amazon S3 persistence. Notebooks saved by users are saved in the `s3://MyJupyterBackups/jupyter/`*`jupyterhub-user-name`* folder for each user, where *`jupyterhub-user-name`* is a user name, such as `diego`.

```
[
    {
```

```
        "Classification": "jupyter-s3-conf",
        "Properties": {
            "s3.persistence.enabled": "true",
            "s3.persistence.bucket": "MyJupyterBackups"
        }
    }
]
```

Connecting to the master node and Notebook servers

JupyterHub administrators and notebook users must connect to the cluster master node using an SSH tunnel and then connecting to web interfaces served by JupyterHub on the master node. For more information about configuring an SSH tunnel and using the tunnel to proxy Web connections, see Connect to the cluster in the *Amazon EMR Management Guide*.

By default, JupyterHub on Amazon EMR is available through **port 9443** on the master node. The internal JupyterHub proxy also serves notebook instances through port 9443. JupyterHub and Jupyter web interfaces can be accessed using a URL with the following pattern:

https://*MasterNodeDNS*:9443

You can specify a different port using the `c.JupyterHub.port` property in the `jupyterhub_config.py` file. For more information, see Networking basics in the JupyterHub documentation.

By default, JupyterHub on Amazon EMR uses a self-signed certificate for SSL encryption using HTTPS. Users are prompted to trust the self-signed certificate when they connect. You can use a trusted certificate and keys of your own. Replace the default certificate file, `server.crt`, and key file `server.key` in the `/etc/jupyter/conf/` directory on the master node with certificate and key files of your own. Use the `c.JupyterHub.ssl_key` and `c.JupyterHub.ssl_cert` properties in the `jupyterhub_config.py` file to specify your SSL materials. For more information, see Security settings in the JupyterHub documentation. After you update `jupyterhub_config.py`, restart the container.

JupyterHub configuration and administration

JupyterHub and related components run inside a Docker container named `jupyterhub` that runs the Ubuntu operating system. There are several ways for you to administer components running inside the container.

> **Warning**
>
> Customizations that you perform within the container may not persist if the container restarts. We recommend that you script or otherwise automate container configuration so that you can reproduce customizations more readily.

Administration using the command line

When connected to the master node using SSH, you can issue commands by using the Docker command-line interface (CLI) and specifying the container by name (`jupyterhub`) or ID. For example, `sudo docker exec jupyterhub` *`command`* runs commands recognized by the operating system or an application running inside the container. You can use this method to add users to the operating system and to install additional applications and libraries within the Docker container. For example, the default container image includes Conda for package installation, so you might run the following command on the master node command line to install an application, Keras, within the container:

```
sudo docker exec jupyterhub conda install keras
```

Administration by submitting steps

Steps are a way to submit work to a cluster. You can submit steps when you launch a cluster, or you can submit steps to a running cluster. Commands that you run on the command line can be submitted as steps using `command-runner.jar`. For more information, see [Work with steps using the CLI and console] in the *Amazon EMR Management Guide* and [Run commands and scripts on an Amazon EMR cluster].

For example, you could use the following AWS CLI command on a local computer to install Keras in the same way that you did from the command line of the master node in the earlier example:

```
aws emr add-steps --cluster-id MyClusterID --steps Name="Command
 Runner",Jar="command-runner.jar",Args="/usr/bin/sudo","/usr/bin/
docker","exec","jupyterhub","conda","install","keras"
```

Also, you can script a sequence of steps, upload the script to Amazon S3, and then use `script-runner.jar` to run the script when you create the cluster or add the script as a step. For more information, see Run commands and scripts on an Amazon EMR cluster. For an example, see the section called "Example: Bash script to add multiple users".

Administration using REST APIs

Jupyter, JupyterHub, and the HTTP proxy for JupyterHub provide REST APIs that you can use to send requests. To send requests to JupyterHub, you must pass an API token with the request. You can use the `curl` command from the master node command line to execute REST commands. For more information, see the following resources:

- Using JupyterHub's REST API in the documentation for JupyterHub, which includes instructions for generating API tokens
- Jupyter Notebook server API on GitHub
- configurable-http-proxy on GitHub

The following example demonstrates using the REST API for JupyterHub to get a list of users. The command passes a previously generated admin token and uses the default port, 9443, for JupyterHub, piping the output to jq for easier viewing:

```
curl -XGET -s -k https://$HOST:9443/hub/api/users \
-H "Authorization: token $admin_token" | jq .
```

Adding Jupyter Notebook users and administrators

You can use one of two methods for users to authenticate to JupyterHub so that they can create notebooks and, optionally, administer JupyterHub. The easiest method is to use JupyterHub's pluggable authentication module (PAM). In addition, JupyterHub on Amazon EMR supports the LDAP authenticator plugin for JupyterHub for obtaining user identities from an LDAP server, such as a Microsoft Active Directory server. Instructions and examples for adding users with each authentication method are provided in this section.

JupyterHub on Amazon EMR has a default user with administrator permissions. The user name is `jovyan` and the password is `jupyter`. We strongly recommend that you replace the user with another user who has administrative permissions. You can do this using a step when you create the cluster, or by connecting to the master node when the cluster is running.

Topics

- Using LDAP authentication
- User impersonation

Using PAM authentication

Creating PAM users in JupyterHub on Amazon EMR is a two-step process. The first step is to add users to the operating system running in the `jupyterhub` container on the master node, and to add a corresponding user home directory for each user. The second step is to add these operating system users as JupyterHub users—a process known as *whitelisting* in JupyterHub. After a JupyterHub user is added, they can connect to the JupyterHub URL and provide their operating system credentials for access.

When a user logs in, JupyterHub opens the notebook server instance for that user, which is saved in the user's home directory on the master node, which is `/var/lib/jupyter/home/username`. If a notebook server instance doesn't exist, JupyterHub spawns a notebook instance in the user's home directory. The following sections demonstrate how to add users individually to the operating system and to JupyterHub, followed by a rudimentary bash script that adds multiple users.

Adding an operating system user to the container

The following example first uses the useradd command within the container to add a single user, diego, and create a home directory for that user. The second command uses chpasswd to establish a password of diego for this user. Commands are run on the master node command line while connected using SSH. You could also run these commands using a step as described earlier in Administration by submitting steps.

```
sudo docker exec jupyterhub useradd -m -s /bin/bash -N diego
sudo docker exec jupyterhub bash -c "echo diego:diego | chpasswd"
```

Adding a JupyterHub user

You can use the **Admin** panel in JupyterHub or the REST API to add users and administrators, or just users.

To add users and administrators using the admin panel in JupyterHub

1. Connect to the master node using SSH and log in to https://*MasterNodeDNS*:9443 with an identity that has administrator permissions.

2. Choose **Control Panel**, **Admin**.
3. Choose **User**, **Add Users**, or choose **Admin**, **Add Admins**.

To add a user using the REST API

1. Connect to the master node using SSH and use the following command on the master node, or run the command as a step.
2. Acquire an administrative token to make API requests, and replace *AdminToken* in the following step with that token.
3. Use the following command, replacing *UserName* with an operating system user that has been created within the container.

```
curl -XPOST -H "Authorization: token AdminToken" "https://$(hostname):9443/hub/api/
users/UserName
```

Note

You are automatically added as a JupyterHub non-admin user when you log in to the JupyterHub web interface for the first time.

Example: Bash script to add multiple users

The following sample bash script ties together the previous steps in this section to create multiple JupyterHub users. The script can be run directly on the master node, or it can be uploaded to Amazon S3 and then run as a step.

The script first establishes an array of user names, and uses the `jupyterhub token` command to create an API token for the default administrator, jovyan. It then creates an operating system user in the `jupyterhub` container for each user, assigning an initial password to each that is equal to their user name. Finally, it calls the REST API operation to create each user in JupyterHub. It passes the token generated earlier in the script and pipes the REST response to `jq` for easier viewing.

```
# Bulk add users to container and JupyterHub with temp password of username
set -x
USERS=(shirley diego ana richard li john mary anaya)
TOKEN=$(sudo docker exec jupyterhub /opt/conda/bin/jupyterhub token jovyan | tail -1)
```

```
for i in "${USERS[@]}";
do
   sudo docker exec jupyterhub useradd -m -s /bin/bash -N $i
   sudo docker exec jupyterhub bash -c "echo $i:$i | chpasswd"
   curl -XPOST --silent -k https://$(hostname):9443/hub/api/users/$i \
 -H "Authorization: token $TOKEN" | jq
done
```

Save the script to a location in Amazon S3 such as `s3://mybucket/createjupyterusers.sh`. Then you can use `script-runner.jar` to run it as a step.

Example: Running the script when creating a cluster (AWS CLI)

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name="MyJupyterHubCluster" --release-label emr-5.36.2 \
--applications Name=JupyterHub --log-uri s3://MyBucket/MyJupyterClusterLogs \
--use-default-roles --instance-type m5.xlarge --instance-count 2 --ec2-attributes
 KeyName=MyKeyPair \
--steps Type=CUSTOM_JAR,Name=CustomJAR,ActionOnFailure=CONTINUE,\
Jar=s3://region.elasticmapreduce/libs/script-runner/script-runner.jar,Args=["s3://
mybucket/createjupyterusers.sh"]
```

Running the script on an existing cluster (AWS CLI)

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr add-steps --cluster-id j-XXXXXXXX --steps Type=CUSTOM_JAR,\
Name=CustomJAR,ActionOnFailure=CONTINUE,\
Jar=s3://region.elasticmapreduce/libs/script-runner/script-runner.jar,Args=["s3://
mybucket/createjupyterusers.sh"]
```

Using LDAP authentication

Lightweight Directory Access Protocol (LDAP) is an application protocol for querying and modifying objects that correspond to resources such as users and computers stored in an LDAP-compatible directory service provider such as Active Directory or an OpenLDAP server. You can use the LDAP authenticator plugin for JupyterHub with JupyterHub on Amazon EMR to use LDAP for user authentication. The plugin handles login sessions for LDAP users and provides user information to Jupyter. This lets users connect to JupyterHub and notebooks by using the credentials for their identities stored in an LDAP-compatible server.

The steps in this section walk you through the following steps to set up and enable LDAP using the LDAP Authenticator Plugin for JupyterHub. You perform the steps while connected to the master node command line. For more information, see Connecting to the master node and Notebook servers.

1. Create an LDAP configuration file with information about the LDAP server, such as the host IP address, port, binding names, and so on.
2. Modify `/etc/jupyter/conf/jupyterhub_config.py` to enable the LDAP Authenticator Plugin for JupyterHub.
3. Create and run a script that configures LDAP within the `jupyterhub` container.
4. Query LDAP for users, and then create home directories within the container for each user. JupyterHub requires home directories to host notebooks.
5. Run a script that restarts JupyterHub

> **Important**
>
> Before you set up LDAP, test your network infrastructure to ensure that the LDAP server and the cluster master node can communicate as required. TLS typically uses port 389 over a plain TCP connection. If your LDAP connection uses SSL, the well-known TCP port for SSL is 636.

Create the LDAP configuration file

The example below uses the following place-holder configuration values. Replace these with parameters that match your implementation.

- The LDAP server is running version 3 and available on port 389. This is the standard non-SSL port for LDAP.
- The base distinguished name (DN) is `dc=example, dc=org`.

Use a text editor to create the file ldap.conf, with contents similar to the following. Use values appropriate for your LDAP implementation. Replace *host* with the IP address or resolvable host name of your LDAP server.

```
base dc=example,dc=org
uri ldap://host
ldap_version 3
binddn cn=admin,dc=example,dc=org
bindpw admin
```

Enable LDAP Authenticator Plugin for JupyterHub

Use a text editor to modify the `/etc/jupyter/conf/jupyterhub_config.py` file and add ldapauthenticator properties similar to the following. Replace *host* with the IP address or resolvable host name of the LDAP server. The example assumes that the user objects are within an organizational unit (ou) named *people*, and uses the distinguished name components that you established earlier using `ldap.conf`.

```
c.JupyterHub.authenticator_class = 'ldapauthenticator.LDAPAuthenticator'
c.LDAPAuthenticator.use_ssl = False
c.LDAPAuthenticator.server_address = 'host'
c.LDAPAuthenticator.bind_dn_template = 'cn={username},ou=people,dc=example,dc=org'
```

Configure LDAP within the container

Use a text editor to create a bash script with the following contents:

```
#!/bin/bash

# Uncomment the following lines to install LDAP client libraries only if
# using Amazon EMR release version 5.14.0. Later versions install libraries by default.
# sudo docker exec jupyterhub bash -c "sudo apt-get update"
# sudo docker exec jupyterhub bash -c "sudo apt-get -y install libnss-ldap libpam-ldap
 ldap-utils nscd"

# Copy ldap.conf
```

```
sudo docker cp ldap.conf jupyterhub:/etc/ldap/
sudo docker exec jupyterhub bash -c "cat /etc/ldap/ldap.conf"

# configure nss switch
sudo docker exec jupyterhub bash -c "sed -i 's/\(^passwd.*\)/\1 ldap/g' /etc/
nsswitch.conf"
sudo docker exec jupyterhub bash -c "sed -i 's/\(^group.*\)/\1 ldap/g' /etc/
nsswitch.conf"
sudo docker exec jupyterhub bash -c "sed -i 's/\(^shadow.*\)/\1 ldap/g' /etc/
nsswitch.conf"
sudo docker exec jupyterhub bash -c "cat /etc/nsswitch.conf"

# configure PAM to create home directories
sudo docker exec jupyterhub bash -c "echo 'session required        pam_mkhomedir.so
 skel=/etc/skel umask=077' >> /etc/pam.d/common-session"
sudo docker exec jupyterhub bash -c "cat /etc/pam.d/common-session"

# restart nscd service
sudo docker exec jupyterhub bash -c "sudo service nscd restart"

# Test
sudo docker exec jupyterhub bash -c "getent passwd"

# Install ldap plugin
sudo docker exec jupyterhub bash -c "pip install jupyterhub-ldapauthenticator"
```

Save the script to the master node, and then run it from the master node command line. For example, with the script saved as `configure_ldap_client.sh`, make the file executable:

```
chmod +x configure_ldap_client.sh
```

And run the script:

```
./configure_ldap_client.sh
```

Add attributes to Active Directory

To find each user and create the appropriate entry in the database, the JupyterHub docker container requires the following UNIX properties for the corresponding user object in Active Directory. For more information, see the section *How do I continue to edit the GID/UID RFC 2307 attributes now that the Unix Attributes Plug-in is no longer available for the Active Directory Users and Computers MMC snap-in?* in the article Clarification regarding the status of identity management for Unix (IDMU) and NIS server role in Windows Server 2016 technical preview and beyond.

- `homeDirectory`

  This is the location to the user's home directory, which is usually `/home/username`.
- `gidNumber`

  This is a value greater than 60000 that is not already used by a another user. Check the `etc/passwd` file for gids in use.
- `uidNumber`

  This is a value greater than 60000 that is not already used by a another group. Check the `etc/group` file for uids in use.
- `uid`

  This is the same as the *username*.

Create user home directories

JupyterHub needs home directories within the container to authenticate LDAP users and store instance data. The following example demonstrates two users, *shirley* and *diego*, in the LDAP directory.

The first step is to query the LDAP server for each user's user id and group id information using ldapsearch as shown in the following example, replacing *host* with the IP address or resolvable host name of your LDAP server:

```
ldapsearch -x -H ldap://host \
 -D "cn=admin,dc=example,dc=org" \
 -w admin \
 -b "ou=people,dc=example,dc=org" \
 -s sub \
 "(objectclass=*)" uidNumber gidNumber
```

The `ldapsearch` command returns an LDIF-formatted response that looks similar to the following for users *shirley* and *diego*.

```
# extended LDIF
```

```
# LDAPv3
# base <ou=people,dc=example,dc=org> with scope subtree
# filter: (objectclass=*)
# requesting: uidNumber gidNumber sn

# people, example.org
dn: ou=people,dc=example,dc=org

# diego, people, example.org
dn: cn=diego,ou=people,dc=example,dc=org
sn: B
uidNumber: 1001
gidNumber: 100

# shirley, people, example.org
dn: cn=shirley,ou=people,dc=example,dc=org
sn: A
uidNumber: 1002
gidNumber: 100

# search result
search: 2
result: 0 Success

# numResponses: 4
# numEntries: 3
```

Using information from the response, run commands within the container to create a home directory for each user common name (`cn`). Use the `uidNumber` and `gidNumber` to fix ownership for the home directory for that user. The following example commands do this for the user *`shirley`*.

```
sudo docker container exec jupyterhub bash -c "mkdir /home/shirley"
sudo docker container exec jupyterhub bash -c "chown -R $uidNumber /home/shirley"
sudo docker container exec jupyterhub bash -c "sudo chgrp -R $gidNumber /home/shirley"
```

Note

LDAP authenticator for JupyterHub does not support local user creation. For more information, see [LDAP authenticator configuration note on local user creation](#).
To create a local user manually, use the following command.

```
sudo docker exec jupyterhub bash -c "echo 'shirley:x:$uidNumber:$gidNumber::/
home/shirley:/bin/bash' >> /etc/passwd"
```

Restart the JupyterHub container

Run the following commands to restart the `jupyterhub` container:

```
sudo docker stop jupyterhub
sudo docker start jupyterhub
```

User impersonation

A Spark job running inside a Jupyter notebook traverses multiple applications during its execution on Amazon EMR. For example, PySpark3 code that a user runs inside Jupyter is received by Sparkmagic, which uses an HTTP POST request to submit it to Livy, which then creates a Spark job to execute on the cluster using YARN.

By default, YARN jobs submitted this way run as user `livy`, regardless of the user who initiated the job. By setting up *user impersonation* you can have the user ID of the notebook user also be the user associated with the YARN job. Rather than having jobs initiated by both `shirley` and `diego` associated with the user `livy`, jobs that each user initiates are associated with `shirley` and `diego` respectively. This helps you to audit Jupyter usage and manage applications within your organization.

This configuration is only supported when calls from Sparkmagic to Livy are unauthenticated. Applications that provide an authentication or proxying layer between Hadoop applications and Livy (such as Apache Knox Gateway) are not supported. The steps to configure user impersonation in this section assume that JupyterHub and Livy are running on the same master node. If your application has separate clusters, Step 3: Create HDFS home directories for users needs to be modified so that HDFS directories are created on the Livy master node.

Steps to configure user impersonation

- Step 1: Configure Livy
- Step 2: Add users
- Step 3: Create HDFS home directories for users

Step 1: Configure Livy

You use the `livy-conf` and `core-site` configuration classifications when you create a cluster to enable Livy user impersonation as shown in the following example. Save the configuration classification as a JSON and then reference it when you create the cluster, or specify the configuration classification inline. For more information, see Configure applications.

```
[
  {
    "Classification": "livy-conf",
    "Properties": {
      "livy.impersonation.enabled": "true"
    }
  },
  {
    "Classification": "core-site",
    "Properties": {
      "hadoop.proxyuser.livy.groups": "*",
      "hadoop.proxyuser.livy.hosts": "*"
    }
  }
]
```

Step 2: Add users

Add JupyterHub users using PAM or LDAP. For more information, see Using PAM authentication and Using LDAP authentication.

Step 3: Create HDFS home directories for users

You connected to the master node to create users. While still connected to the master node, copy the contents below and save it to a script file. The script creates HDFS home directories for each JupyterHub user on the master node. The script assumes you are using the default administrator user ID, *jovyan*.

```
#!/bin/bash

CURL="curl --silent -k"
HOST=$(curl -s http://169.254.169.254/latest/meta-data/local-hostname)

admin_token() {
```

```
    local user=jovyan
    local pwd=jupyter
    local token=$($CURL https://$HOST:9443/hub/api/authorizations/token \
        -d "{\"username\":\"$user\", \"password\":\"$pwd\"}" | jq ".token")
    if [[ $token != null ]]; then
        token=$(echo $token | sed 's/"//g')
    else
        echo "Unable to get Jupyter API Token."
        exit 1
    fi
    echo $token
}

# Get Jupyter Admin token
token=$(admin_token)

# Get list of Jupyter users
users=$(curl -XGET -s -k https://$HOST:9443/hub/api/users \
 -H "Authorization: token $token" | jq '.[].name' | sed 's/"//g')

# Create HDFS home dir
for user in ${users[@]};
do
 echo "Create hdfs home dir for $user"
 hadoop fs -mkdir /user/$user
 hadoop fs -chmod 777 /user/$user
done
```

Installing additional kernels and libraries

When you create a cluster with JupyterHub on Amazon EMR, the default Python 3 kernel for Jupyter along with the PySpark and Spark kernels for Sparkmagic are installed on the Docker container. You can install additional kernels. You can also install additional libraries and packages and then import them for the appropriate shell.

Installing a kernel

Kernels are installed within the Docker container. The easiest way to accomplish this is to create a bash script with installation commands, save it to the master node, and then use the `sudo docker exec jupyterhub` *`script_name`* command to run the script within the `jupyterhub` container. The following example script installs the kernel, and then installs a few libraries for that kernel on the master node so that later you can import the libraries using the kernel in Jupyter.

```
#!/bin/bash

# Install Python 2 kernel
conda create -n py27 python=2.7 anaconda
source /opt/conda/envs/py27/bin/activate
apt-get update
apt-get install -y gcc
/opt/conda/envs/py27/bin/python -m pip install --upgrade ipykernel
/opt/conda/envs/py27/bin/python -m ipykernel install

# Install libraries for Python 2
/opt/conda/envs/py27/bin/pip install paramiko nltk scipy numpy scikit-learn pandas
```

To install the kernel and libraries within the container, open a terminal connection to the master node, save the script to `/etc/jupyter/install_kernels.sh`, and run the following command on the master node command line:

```
sudo docker exec jupyterhub bash /etc/jupyter/install_kernels.sh
```

Using libraries and installing additional libraries

A core set of machine learning and data science libraries for Python 3 are pre-installed with JupyterHub on Amazon EMR. You can use `sudo docker exec jupyterhub bash -c "conda list"` and `sudo docker exec jupyterhub bash -c "pip freeze"`.

If a Spark job needs libraries on worker nodes, we recommend that you use a bootstrap action to run a script to install the libraries when you create the cluster. Bootstrap actions run on all cluster nodes during the cluster creation process, which simplifies installation. If you install libraries on core/worker nodes after a cluster is running, the operation is more complex. We provide an example Python program in this section that shows how to install these libraries.

The bootstrap action and Python program examples shown in this section use a bash script saved to Amazon S3 to install the libraries on all nodes.

The script referenced in the following example uses `pip` to install paramiko, nltk, scipy, scikit-learn, and pandas for the Python 3 kernel:

```
#!/bin/bash
```

```
sudo python3 -m pip install boto3 paramiko nltk scipy scikit-learn pandas
```

After you create the script, upload it to a location in Amazon S3, for example, `s3://mybucket/install-my-jupyter-libraries.sh`. For more information, see Uploading objects in the *Amazon Simple Storage Service User Guide* so that you can use it in your bootstrap action or in your Python program.

To specify a bootstrap action that installs libraries on all nodes when you create a cluster using the AWS CLI

1. Create a script similar to the earlier example and save it to a location in Amazon S3. We use the example `s3://mybucket/install-my-jupyter-libraries.sh`.
2. Create the cluster with JupyterHub and use the `Path` argument of the `--bootstrap-actions` option to specify the script location as shown in the following example:

   Note

   Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name="MyJupyterHubCluster" --release-label emr-5.36.2 \
--applications Name=JupyterHub --log-uri s3://MyBucket/MyJupyterClusterLogs \
--use-default-roles --instance-type m5.xlarge --instance-count 2 --ec2-attributes
 KeyName=MyKeyPair \
--bootstrap-actions Path=s3://mybucket/install-my-jupyter-
libraries.sh,Name=InstallJupyterLibs
```

To specify a bootstrap action that installs libraries on all nodes when you create a cluster using the console

1. Navigate to the new Amazon EMR console and select **Switch to the old console** from the side navigation. For more information on what to expect when you switch to the old console, see Using the old console.
2. Choose **Create cluster**, **Go to advanced options**.
3. Specify settings for **Software and Steps** and **Hardware** as appropriate for your application.
4. On the **General Cluster Settings** screen, expand **Bootstrap Actions**.

5. For **Add bootstrap action**, select **Custom action**, **Configure and add**.
6. For **Name**, enter a friendly name. For **Script location**, enter the location in Amazon S3 of your script (the example we use is *s3://mybucket/install-my-jupyter-libraries.sh*). Leave **Optional arguments** blank, and choose **Add**.
7. Specify other settings for your cluster, and choose **Next**.
8. Specify security settings, and choose **Create cluster**.

Example Installing libraries on core nodes of a running cluster

After you install libraries on the master node from within Jupyter, you can install libraries on running core nodes in various ways. The following example shows a Python program written to run on a local machine. When you run the Python program locally, it uses the `AWS-RunShellScript` of AWS Systems Manager to run the example script, shown earlier in this section, which installs libraries on the cluster's core nodes.

```
import argparse
import time
import boto3

def install_libraries_on_core_nodes(cluster_id, script_path, emr_client, ssm_client):
    """
    Copies and runs a shell script on the core nodes in the cluster.

    :param cluster_id: The ID of the cluster.
    :param script_path: The path to the script, typically an Amazon S3 object URL.
    :param emr_client: The Boto3 Amazon EMR client.
    :param ssm_client: The Boto3 AWS Systems Manager client.
    """
    core_nodes = emr_client.list_instances(
        ClusterId=cluster_id, InstanceGroupTypes=["CORE"]
    )["Instances"]
    core_instance_ids = [node["Ec2InstanceId"] for node in core_nodes]
    print(f"Found core instances: {core_instance_ids}.")

    commands = [
        # Copy the shell script from Amazon S3 to each node instance.
        f"aws s3 cp {script_path} /home/hadoop",
        # Run the shell script to install libraries on each node instance.
        "bash /home/hadoop/install_libraries.sh",
```

```
    ]
    for command in commands:
        print(f"Sending '{command}' to core instances...")
        command_id = ssm_client.send_command(
            InstanceIds=core_instance_ids,
            DocumentName="AWS-RunShellScript",
            Parameters={"commands": [command]},
            TimeoutSeconds=3600,
        )["Command"]["CommandId"]
        while True:
            # Verify the previous step succeeded before running the next step.
            cmd_result = ssm_client.list_commands(CommandId=command_id)["Commands"][0]
            if cmd_result["StatusDetails"] == "Success":
                print(f"Command succeeded.")
                break
            elif cmd_result["StatusDetails"] in ["Pending", "InProgress"]:
                print(f"Command status is {cmd_result['StatusDetails']}, waiting...")
                time.sleep(10)
            else:
                print(f"Command status is {cmd_result['StatusDetails']}, quitting.")
                raise RuntimeError(
                    f"Command {command} failed to run. "
                    f"Details: {cmd_result['StatusDetails']}"
                )

def main():

JupyterHub release history

The following table lists the version of JupyterHub included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

JupyterHub version information

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-7.2.0	1.5.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-5.36.2	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn,

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
		spark-yarn-slave, livy-server, jupyterhub
emr-7.1.0	1.5.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-7.0.0	1.5.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.15.0	1.5.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.14.0	1.5.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.13.0	1.5.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.12.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.11.1	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.11.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.10.1	1.5.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.10.0	1.5.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.9.1	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.9.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.8.1	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.8.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-6.7.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-5.36.1	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-5.36.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub
emr-6.6.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Amazon EMR Release label	JupyterHub Version	Components installed with JupyterHub
emr-5.35.0	1.4.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, jupyterhub

Apache Livy

Livy enables interaction over a REST interface with an EMR cluster running Spark. You can use the REST interface or an RPC client library to submit Spark jobs or snippets of Spark code, retrieve results synchronously or asynchronously, and manage Spark Context. For more information, see the Apache Livy website. Livy is included in Amazon EMR release version 5.9.0 and later.

To access the Livy web interface, set up an SSH tunnel to the master node and a proxy connection. For more information, see View web interfaces hosted on EMR clusters.

The following table lists the version of Livy included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Livy.

For the version of components installed with Livy in this release, see Release 7.2.0 Component Versions.

Livy version information for emr-7.2.0

Amazon EMR Release Label	Livy Version	Components Installed With Livy
emr-7.2.0	Livy 0.8.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, nginx

The following table lists the version of Livy included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Livy.

For the version of components installed with Livy in this release, see Release 6.15.0 Component Versions.

Livy version information for emr-6.15.0

Amazon EMR Release Label	Livy Version	Components Installed With Livy
emr-6.15.0	Livy 0.7.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, nginx

The following table lists the version of Livy included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Livy.

For the version of components installed with Livy in this release, see Release 5.36.2 Component Versions.

Livy version information for emr-5.36.2

Amazon EMR Release Label	Livy Version	Components Installed With Livy
emr-5.36.2	Livy 0.7.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-

Amazon EMR Release Label	Livy Version	Components Installed With Livy
		namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, nginx

Topics

Enabling HTTPS with Apache Livy

1. Provision an Amazon EMR cluster with transit encryption enabled. To learn more about encryption, see Encrypt data at rest and in transit.
2. Create a file called `livy_ssl.sh` with the following contents.

```
#!/bin/bash

KEYSTORE_FILE=`awk '/ssl.server.keystore.location/{getline; print}' /etc/hadoop/
conf/ssl-server.xml | sed -e 's/<[^>]*>//g' | tr -d ' \t\n\r\f'`
KEYSTORE_PASS=`awk '/ssl.server.keystore.password/{getline; print}' /etc/hadoop/
conf/ssl-server.xml | sed -e 's/<[^>]*>//g' | tr -d ' \t\n\r\f'`
KEY_PASS=`awk '/ssl.server.keystore.keypassword/{getline; print}' /etc/hadoop/conf/
ssl-server.xml | sed -e 's/<[^>]*>//g' | tr -d ' \t\n\r\f'`

echo "livy.keystore $KEYSTORE_FILE
livy.keystore.password $KEYSTORE_PASS
livy.key-password $KEY_PASS" | sudo tee -a /etc/livy/conf/livy.conf >/dev/null
```

```
sudo systemctl restart livy-server.service
```

3. Run the following script as an Amazon EMR step. This script modifies `/etc/livy/conf/livy.conf` to activate SSL.

```
--steps '[{"Args":["s3://DOC-EXAMPLE-BUCKET/
livy_ssl.sh"],"Type":"CUSTOM_JAR","ActionOnFailure":"CONTINUE","Jar":"s3://
us-east-1.elasticmapreduce/libs/script-runner/script-
runner.jar","Properties":"","Name":"Custom JAR"}]'
```

4. Restart the Apache Livy service so that the changes take effect. To restart Apache Livy, see Stopping and restarting processes.

5. Test that the clients can now communicate using HTTPS. To submit a job, for example, run the following code.

```
curl -k -X POST --data '{"file": "local:///usr/lib/spark/examples/jars/spark-
examples.jar",
"className": "org.apache.spark.examples.SparkPi"}' \
-H "Content-Type: application/json" \
https://EMR_Master_Node_Host:8998/batches
```

If you've enabled HTTPS successfully, Livy sends a response indicating that the command was accepted and that the batch job was submitted.

```
{"id":1,"name":null,"owner":null,"proxyUser":null,"state":"starting","appId":null,"appInfo":
{"driverLogUrl":null,"sparkUiUrl":null},"log":["stdout: ","\nstderr: ","\nYARN
 Diagnostics: "]}
```

Livy release history

The following table lists the version of Livy included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Livy version information

Amazon EMR Release label	Livy Version	Components installed with Livy
emr-7.2.0	0.8.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server, nginx

Amazon EMR Release label	Livy Version	Components installed with Livy
emr-5.9.0	0.4.0	emrfs, emr-goodies, emr-ddb, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, livy-server

Apache MXNet

Apache MXNet is an acceleration library designed for building neural networks and other deep learning applications. MXNet automates common work flows and optimizes numerical computations. MXNet helps you design neural network architectures without having to focus on implementing low-level computations, such as linear algebra operations. MXNet is included with Amazon EMR release version 5.10.0 and later.

For more information, see the Apache MXNet web site.

The following table lists the version of MXNet included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with MXNet.

For the version of components installed with MXNet in this release, see Release 7.2.0 Component Versions.

MXNet version information for emr-7.2.0

Amazon EMR Release Label	MXNet Version	Components Installed With MXNet
emr-7.2.0	MXNet 1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv

The following table lists the version of MXNet included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with MXNet.

For the version of components installed with MXNet in this release, see Release 6.15.0 Component Versions.

MXNet version information for emr-6.15.0

Amazon EMR Release Label	MXNet Version	Components Installed With MXNet
emr-6.15.0	MXNet 1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv

The following table lists the version of MXNet included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with MXNet.

For the version of components installed with MXNet in this release, see Release 5.36.2 Component Versions.

MXNet version information for emr-5.36.2

Amazon EMR Release Label	MXNet Version	Components Installed With MXNet
emr-5.36.2	MXNet 1.8.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv

MXNet release history

The following table lists the version of MXNet included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

MXNet version information

Amazon EMR Release label	MXNet Version	Components installed with MXNet
emr-7.2.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv
emr-5.36.2	1.8.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv
emr-7.1.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-librar

Amazon EMR Release label	MXNet Version	Components installed with MXNet
		y, hadoop-hdfs-nameno de, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv
emr-7.0.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datano de, hadoop-hdfs-librar y, hadoop-hdfs-nameno de, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv
emr-6.15.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datano de, hadoop-hdfs-librar y, hadoop-hdfs-nameno de, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv

Amazon EMR Release label	MXNet Version	Components installed with MXNet
emr-6.14.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv
emr-6.13.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv
emr-6.12.0	1.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mxnet, opencv

Apache Oozie

Use the Apache Oozie Workflow Scheduler to manage and coordinate Hadoop jobs. For more information, see http://oozie.apache.org/.

The Oozie native web interface is not supported on Amazon EMR. To use a front-end interface for Oozie, try the Hue Oozie application. For more information, see Hue. Oozie is included with Amazon EMR release version 5.0.0 and later. Oozie is included as a sandbox application in earlier releases. For more information, see Amazon EMR 4.x release versions.

If you use a custom Amazon Linux AMI based on an Amazon Linux AMI with a creation date of 2018-08-11, the Oozie server fails to start. If you use Oozie, create a custom AMI based on an Amazon Linux AMI ID with a different creation date. You can use the following AWS CLI command to return a list of Image IDs for all HVM Amazon Linux AMIs with a 2018.03 version, along with the release date, so that you can choose an appropriate Amazon Linux AMI as your base. Replace MyRegion with your Region identifier, such as us-west-2.

```
aws ec2 --region MyRegion describe-images --owner amazon --query 'Images[?
Name!=`null`]|[?starts_with(Name, `amzn-ami-hvm-2018.03`) == `true`].
[CreationDate,ImageId,Name]' --output text | sort -rk1
```

The following table lists the version of Oozie included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Oozie.

For the version of components installed with Oozie in this release, see Release 7.2.0 Component Versions.

Oozie version information for emr-7.2.0

Amazon EMR Release Label	Oozie Version	Components Installed With Oozie
emr-7.2.0	Oozie 5.2.1	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-

Amazon EMR Release Label	Oozie Version	Components Installed With Oozie
		server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, oozie-client, oozie-server, tez-on-yarn, tez-on-worker

The following table lists the version of Oozie included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Oozie.

For the version of components installed with Oozie in this release, see Release 6.15.0 Component Versions.

Oozie version information for emr-6.15.0

Amazon EMR Release Label	Oozie Version	Components Installed With Oozie
emr-6.15.0	Oozie 5.2.1	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, oozie-client, oozie-server, tez-on-yarn, tez-on-worker

The following table lists the version of Oozie included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Oozie.

For the version of components installed with Oozie in this release, see Release 5.36.2 Component Versions.

Oozie version information for emr-5.36.2

Amazon EMR Release Label	Oozie Version	Components Installed With Oozie
emr-5.36.2	Oozie 5.2.1	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, oozie-client, oozie-server, tez-on-yarn

Topics

Using Oozie with a remote database in Amazon RDS

By default, Oozie user information and query histories are stored in a local MySQL database on the master node. Alternatively, you can create one or more Oozie-enabled clusters using a configuration stored in Amazon S3 and a MySQL database in Amazon Relational Database Service(Amazon RDS). This allows you to persist user information and query history created by Oozie without keeping your Amazon EMR cluster running. We recommend using Amazon S3 server-side encryption to store the configuration file.

First, create the remote database for Oozie.

To create the external MySQL database

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Launch a DB Instance**.
3. Choose MySQL and then choose **Select**.
4. Leave the default selection of **Multi-AZ Deployment and Provisioned IOPS Storage** and choose **Next**.
5. Leave the Instance Specifications at their defaults, specify Settings, and choose **Next**.
6. On the Configure Advanced Settings page, choose proper security group and database names. The security group you use must at least allow inbound TCP access for port 3306 from the master node of your cluster. If you have not created your cluster at this point, you can allow all hosts to connect to port 3306 and adjust the security group after you have launched the cluster. Choose **Launch DB Instance**.
7. From the RDS Dashboard, select **Instances** and select the instance you have just created. When your database is available, make a note of the dbname, username, password, and RDS instance hostname. You use this information when you create and configure your cluster.

To specify an external MySQL database for Oozie when launching a cluster using the AWS CLI

To specify an external MySQL database for Oozie when launching a cluster using the AWS CLI, use the information you noted when creating your RDS instance for configuring `oozie-site` with a configuration object.

> **Note**
>
> You can create multiple clusters that use the same external database, but each cluster will share query history and user information.

- Using the AWS CLI, create a cluster with Oozie installed, using the external database you created, and referencing a configuration file with a configuration classification for Oozie that specifies the database properties. The following example creates a cluster with Oozie installed, referencing a configuration file in Amazon S3, `myConfig.json`, that specifies the database configuration.

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=Oozie
 Name=Spark Name=Hive \
--instance-type m5.xlarge --instance-count 3 \
--configurations https://s3.amazonaws.com/mybucket/myfolder/myConfig.json --use-
default-roles
```

Example contents of the `myConfig.json` file are shown below. Replace *JDBC URL*, *username*, and *password* with the JDBC URL, user name, and password of your RDS instance.

> **Important**
>
> The JDBC URL must include the database name as a suffix. For example, jdbc:mysql://oozie-external-db.xxxxxxxxxx.us-east-1.rds.amazonaws.com:3306/**dbname**.

```
[{
  "Classification": "oozie-site",
    "Properties": {
        "oozie.service.JPAService.jdbc.driver": "org.mariadb.jdbc.Driver",
        "oozie.service.JPAService.jdbc.url": "JDBC URL",

        "oozie.service.JPAService.jdbc.username": "username",
        "oozie.service.JPAService.jdbc.password": "password"
    },
    "Configurations": []
}]
```

Configure Java version for Oozie

Oozie runs multiple Java Virtual Machine (JVM) processes. This page explains how to configure the Java version for each process.

- **Oozie Server**: Set `JAVA_HOME` in the `oozie-env` classification to update the Java version for the `EmbeddedOozieServer`.
- **Oozie Launcher AM**: *Oozie Launcher AM* is a single-mapper MR job that invokes the appropriate application client libraries such as Hadoop and Hive. Unless otherwise configured, the runtime versions for Oozie Launcher AM are the same as the Java runtimes for Hadoop in the EMR cluster. To configure the Java runtime for Oozie Launcher AM, set the following property in the `workflow.xml` for the job:

```
<property>
     <name>mapred.child.env</name>
     <value>JAVA_HOME=/path/to/JAVA_HOME</value>
 </property>
```

  This property ensures that the Oozie Launcher AM for the Oozie job runs on the Java version that you specify, rather than the Java version that is set in Hadoop.
- **Application Client Executable**: Because Oozie Launcher AM invokes the application client by default, the Java runtime for the client executable is the same as the Oozie Launcher AM.
- **Applications launched by an Oozie job**: Unless otherwise specified, the runtime versions for the actual application JVMs that are launched by an Oozie job are the same as the Java runtimes for Hadoop in the EMR cluster. Depending on the type of Oozie Workflow Action used to launch the application in an Oozie job (Spark or Hive action), you can update the default Java runtime for the actual application JVMs in the `workflow.xml` for the Oozie job.

Oozie release history

The following table lists the version of Oozie included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Oozie version information

Amazon EMR Release label	Oozie Version	Components installed with Oozie
emr-7.2.0	5.2.1	emrfs, emr-ddb, emr-goodi es, emr-kinesis, emr-s3-dist-

Amazon EMR Release label	Oozie Version	Components installed with Oozie

Oozie release notes by version

Topics

Amazon EMR 7.1.0 - Oozie changes

Type	Description
Upgrade	Upgrades Netty to 4.1.100.Final.
Upgrade	Upgrades Jetty to 9.4.53.v20231009.

Apache Phoenix

Apache Phoenix is used for OLTP and operational analytics, allowing you to use standard SQL queries and JDBC APIs to work with an Apache HBase backing store. For more information, see Phoenix in 15 minutes or less. Phoenix is included in Amazon EMR release version 4.7.0 and later.

If you upgrade from an earlier version of Amazon EMR to Amazon EMR release version 5.4.0 or later and use secondary indexing, upgrade local indexes as described in the Apache Phoenix documentation. Amazon EMR removes the required configurations from the `hbase-site` classification, but indexes need to be repopulated. Online and offline upgrade of indexes are supported. Online upgrades are the default, which means indexes are repopulated while initializing from Phoenix clients of version 4.8.0 or greater. To specify offline upgrades, set the `phoenix.client.localIndexUpgrade` configuration to false in the `phoenix-site` classification, and then SSH to the master node to run `psql [zookeeper] -1`.

The following table lists the version of Phoenix included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Phoenix.

For the version of components installed with Phoenix in this release, see Release 7.2.0 Component Versions.

Phoenix version information for emr-7.2.0

Amazon EMR Release Label	Phoenix Version	Components Installed With Phoenix
emr-7.2.0	Phoenix 5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-

Amazon EMR Release Label	Phoenix Version	Components Installed With Phoenix
		region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

The following table lists the version of Phoenix included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Phoenix.

For the version of components installed with Phoenix in this release, see Release 6.15.0 Component Versions.

Phoenix version information for emr-6.15.0

Amazon EMR Release Label	Phoenix Version	Components Installed With Phoenix
emr-6.15.0	Phoenix 5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

The following table lists the version of Phoenix included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Phoenix.

For the version of components installed with Phoenix in this release, see Release 5.36.2 Component Versions.

Phoenix version information for emr-5.36.2

Amazon EMR Release Label	Phoenix Version	Components Installed With Phoenix
emr-5.36.2	Phoenix 4.14.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, phoenix-library, phoenix-query-server, zookeeper-client, zookeeper-server

Topics

- Creating a cluster with Phoenix
- Phoenix clients
- Phoenix release history

Creating a cluster with Phoenix

You install Phoenix by choosing the application when you create a cluster in the console or using the AWS CLI. The following procedures and examples show how to create a cluster with Phoenix and HBase. For more information about creating clusters using the console, including **Advanced Options** see Plan and configure clusters in the *Amazon EMR Management Guide*.

To launch a cluster with Phoenix installed using Quick Options for creating a cluster in the console

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create cluster** to use **Quick Create**.
3. For **Software Configuration**, choose the most recent release appropriate for your application. Phoenix appears as an option only when **Amazon Release Version emr-4.7.0** or later is selected.
4. For **Applications**, choose the second option, **HBase: HBase *ver* with Ganglia *ver*, Hadoop *ver*, Hive *ver*, Hue *ver*, Phoenix *ver*, and ZooKeeper *ver***.
5. Select other options as necessary and then choose **Create cluster**.

> **Note**
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

The following example launches a cluster with Phoenix installed using default configuration settings.

To launch a cluster with Phoenix and HBase using the AWS CLI

- Create the cluster with the following command:

```
aws emr create-cluster --name "Cluster with Phoenix" --release-label emr-7.2.0 \
--applications Name=Phoenix Name=HBase --ec2-attributes KeyName=myKey \
--instance-type m5.xlarge --instance-count 3 --use-default-roles
```

Customizing Phoenix configurations

When creating a cluster, you configure Phoenix by setting values in `hbase-site.xml` using the `hbase-site` configuration classification.

For more information, see Configuration and tuning in the Phoenix documentation.

The following example demonstrates using a JSON file stored in Amazon S3 to specify the value of `false` for the `phoenix.schema.dropMetaData` property. Multiple properties can be specified for a single classification. For more information, see Configure applications. The `create-cluster` command then references the JSON file as the `--configurations` parameter.

The contents of the JSON file saved to /mybucket/myfolder/myconfig.json is the following.

```
[
    {
      "Classification": "hbase-site",
      "Properties": {
        "phoenix.schema.dropMetaData": "false"
      }
    }
  ]
```

The `create cluster` command that references the JSON file is shown in the following example.

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=Phoenix \
Name=HBase --instance-type m5.xlarge --instance-count 2 \
--configurations https://s3.amazonaws.com/mybucket/myfolder/myconfig.json
```

Note

Reconfiguration request for any Phoenix configuration classifications is only supported in Amazon EMR version 5.23.0 and later, and is not supported in Amazon EMR version 5.21.0 or 5.22.0. For more information, see Supplying a configuration for an instance group in a running cluster

Phoenix clients

You connect to Phoenix using either a JDBC client built with full dependencies or using the "thin client" that uses the Phoenix Query Server and can only be run on a master node of a cluster (e.g. by using an SQL client, a step, command line, SSH port forwarding, etc.). When using the "fat" JDBC client, it still needs to have access to all nodes of the cluster because it connects to HBase services directly. The "thin" Phoenix client only needs access to the Phoenix Query Server at a default port 8765. There are several scripts within Phoenix that use these clients.

Use an Amazon EMR step to query using Phoenix

The following procedure restores a snapshot from HBase and uses that data to run a Phoenix query. You can extend this example or create a new script that leverages Phoenix's clients to suit your needs.

1. Create a cluster with Phoenix installed, using the following command:

```
aws emr create-cluster --name "Cluster with Phoenix" --log-uri s3://myBucket/
myLogFolder --release-label emr-7.2.0 \
--applications Name=Phoenix Name=HBase --ec2-attributes KeyName=myKey \
--instance-type m5.xlarge --instance-count 3 --use-default-roles
```

2. Create then upload the following files to Amazon S3:

   copySnapshot.sh

```
sudo su hbase -s /bin/sh -c 'hbase snapshot export \
 -D hbase.rootdir=s3://us-east-1.elasticmapreduce.samples/hbase-demo-customer-data/
snapshot/ \
-snapshot customer_snapshot1 \
-copy-to hdfs://masterDNSName:8020/user/hbase \
-mappers 2 -chuser hbase -chmod 700'
```

   runQuery.sh

```
aws s3 cp s3://myBucket/phoenixQuery.sql /home/hadoop/
/usr/lib/phoenix/bin/sqlline-thin.py http://localhost:8765 /home/hadoop/
phoenixQuery.sql
```

   phoenixQuery.sql

Note

You only need to include `COLUMN_ENCODED_BYTES=0` in the following example when you use Amazon EMR versions 5.26.0 and higher.

```
CREATE VIEW "customer" (
pk VARCHAR PRIMARY KEY,
"address"."state" VARCHAR,
"address"."street" VARCHAR,
"address"."city" VARCHAR,
"address"."zip" VARCHAR,
"cc"."number" VARCHAR,
"cc"."expire" VARCHAR,
"cc"."type" VARCHAR,
"contact"."phone" VARCHAR)
COLUMN_ENCODED_BYTES=0;

CREATE INDEX my_index ON "customer" ("customer"."state") INCLUDE("PK",
 "customer"."city", "customer"."expire", "customer"."type");

SELECT "customer"."type" AS credit_card_type, count(*) AS num_customers FROM
 "customer" WHERE "customer"."state" = 'CA' GROUP BY "customer"."type";
```

Use the AWS CLI to submit the files to the S3 bucket:

```
aws s3 cp copySnapshot.sh s3://myBucket/
aws s3 cp runQuery.sh s3://myBucket/
aws s3 cp phoenixQuery.sql s3://myBucket/
```

3. Create a table using the following step submitted to the cluster that you created in Step 1:

   createTable.json

```
[
  {
    "Name": "Create HBase Table",
    "Args": ["bash", "-c", "echo $'create \"customer\",\"address\",\"cc\",\"contact
\"' | hbase shell"],
    "Jar": "command-runner.jar",
```

```
    "ActionOnFailure": "CONTINUE",
    "Type": "CUSTOM_JAR"
  }
]
```

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps file://./createTable.json
```

4. Use `script-runner.jar` to run the `copySnapshot.sh` script that you previously uploaded to your S3 bucket:

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps Type=CUSTOM_JAR,Name="HBase Copy Snapshot",ActionOnFailure=CONTINUE,\
Jar=s3://region.elasticmapreduce/libs/script-runner/script-
runner.jar,Args=["s3://myBucket/copySnapshot.sh"]
```

   This runs a MapReduce job to copy your snapshot data to the cluster HDFS.

5. Restore the snapshot that you copied to the cluster using the following step:

   restoreSnapshot.json

```
[
  {
    "Name": "restore",
    "Args": ["bash", "-c", "echo $'disable \"customer\"; restore_snapshot
 \"customer_snapshot1\"; enable \"customer\"' | hbase shell"],
    "Jar": "command-runner.jar",
    "ActionOnFailure": "CONTINUE",
    "Type": "CUSTOM_JAR"
  }
]
```

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps file://./restoreSnapshot.json
```

6. Use `script-runner.jar` to run the `runQuery.sh` script that you previously uploaded to your S3 bucket:

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF \
--steps Type=CUSTOM_JAR,Name="Phoenix Run Query",ActionOnFailure=CONTINUE,\
```

```
Jar=s3://region.elasticmapreduce/libs/script-runner/script-
runner.jar,Args=["s3://myBucket/runQuery.sh"]
```

The query runs and returns the results to the step's `stdout`. It may take a few minutes for this step to complete.

7. Inspect the results of the step's `stdout` at the log URI that you used when you created the cluster in Step 1. The results should look like the following:

```
+------------------------------------------+-----------------------------------+
|             CREDIT_CARD_TYPE             |           NUM_CUSTOMERS           |
+------------------------------------------+-----------------------------------+
| american_express                         | 5728                              |
| dankort                                  | 5782                              |
| diners_club                              | 5795                              |
| discover                                 | 5715                              |
| forbrugsforeningen                       | 5691                              |
| jcb                                      | 5762                              |

| maestro                                  | 5816                              |
| mastercard                               | 5697                              |
| solo                                     | 5586                              |
| switch                                   | 5781                              |
| visa                                     | 5659                              |
+------------------------------------------+-----------------------------------+
```

Phoenix release history

The following table lists the version of Phoenix included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Phoenix version information

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-7.2.0	5.1.3	emrfs, emr-ddb, emr-goodi es, emr-kinesis, emr-s3-dist-

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
		cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server
emr-5.36.2	4.14.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, phoenix-library, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-7.1.0	5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-7.0.0	5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.15.0	5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.14.0	5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.13.0	5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.12.0	5.1.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.11.1	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.11.0	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.10.1	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.10.0	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.9.1	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.9.0	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.8.1	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.8.0	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.7.0	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-5.36.1	4.14.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, phoenix-library, phoenix-query-server, zookeeper-client, zookeeper-server
emr-5.36.0	4.14.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, phoenix-library, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-6.6.0	5.1.2	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, hbase-operator-tools, phoenix-library, phoenix-connectors, phoenix-query-server, zookeeper-client, zookeeper-server

Amazon EMR Release label	Phoenix Version	Components installed with Phoenix
emr-5.35.0	4.14.3	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hbase-hmaster, hbase-client, hbase-region-server, phoenix-library, phoenix-query-server, zookeeper-client, zookeeper-server

emr-4.7.0	4.7.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-mapred, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hbase-hmaster, hbase-client, hbase-region-server, phoenix-library, phoenix-query-server, zookeeper-client, zookeeper-server

Apache Pig

Apache Pig is an open-source Apache library that runs on top of Hadoop, providing a scripting language that you can use to transform large data sets without having to write complex code in a lower level computer language like Java. The library takes SQL-like commands written in a language called Pig Latin and converts those commands into Tez jobs based on directed acyclic graphs (DAGs) or MapReduce programs. Pig works with structured and unstructured data in a variety of formats. For more information about Pig, see http://pig.apache.org/.

You can execute Pig commands interactively or in batch mode. To use Pig interactively, create an SSH connection to the master node and submit commands using the Grunt shell. To use Pig in batch mode, write your Pig scripts, upload them to Amazon S3, and submit them as cluster steps. For more information on submitting work to a cluster, see Submit work to a cluster in the *Amazon EMR Management Guide*.

When you use Pig to write output to an HCatalog table in Amazon S3, disable Amazon EMR direct write by setting the `mapred.output.direct.NativeS3FileSystem` and `mapred.output.direct.EmrFileSystem` properties to `false`. For more information, see Using HCatalog. Within a Pig script, you can use the `SET mapred.output.direct.NativeS3FileSystem false` and `SET mapred.output.direct.EmrFileSystem false` commands.

The following table lists the version of Pig included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Pig.

For the version of components installed with Pig in this release, see Release 7.2.0 Component Versions.

Pig version information for emr-7.2.0

Amazon EMR Release Label	Pig Version	Components Installed With Pig
emr-7.2.0	Pig 0.17.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-

Amazon EMR Release Label	Pig Version	Components Installed With Pig
		hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, pig-client, tez-on-yarn, tez-on-worker

The following table lists the version of Pig included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Pig.

For the version of components installed with Pig in this release, see Release 6.15.0 Component Versions.

Pig version information for emr-6.15.0

Amazon EMR Release Label	Pig Version	Components Installed With Pig
emr-6.15.0	Pig 0.17.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, pig-client, tez-on-yarn, tez-on-worker

The following table lists the version of Pig included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Pig.

For the version of components installed with Pig in this release, see Release 5.36.2 Component Versions.

Pig version information for emr-5.36.2

Amazon EMR Release Label	Pig Version	Components Installed With Pig
emr-5.36.2	Pig 0.17.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, pig-client, tez-on-yarn

Topics

Submit Pig work

This section demonstrates submitting Pig work to an Amazon EMR cluster. The examples that follow generate a report containing the total bytes transferred, a list of the top 50 IP addresses, a list of the top 50 external referrers, and the top 50 search terms using Bing and Google. The Pig script is located in the Amazon S3 bucket `s3://elasticmapreduce/samples/pig-apache/do-reports2.pig`. Input data is located in the Amazon S3 bucket `s3://elasticmapreduce/samples/pig-apache/input`. The output is saved to an Amazon S3 bucket.

Submit Pig work using the Amazon EMR console

This example describes how to use the Amazon EMR console to add a Pig step to a cluster.

To submit a Pig step

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create cluster** to create a cluster with Pig installed. For steps on how to create a cluster, see Plan and configure an Amazon EMR cluster.
3. Open a terminal and SSH into the master node of your cluster following the steps outlined in Connect to the master node using SSH. Once you've done that, run the following steps.

```
sudo mkdir -p /home/hadoop/lib/pig/
sudo aws s3 cp s3://elasticmapreduce/libs/pig/0.3/piggybank-0.3-amzn.jar /home/
hadoop/lib/pig/piggybank.jar
```

4. In the console, click **Cluster List** and select the name of the cluster you created.
5. Scroll to the **Steps** section and expand it, then choose **Add step**.
6. In the **Add Step** dialog:
   - For **Step type**, choose **Pig program**.
   - For **Name**, accept the default name (Pig program) or type a new name.
   - For **Script S3 location**, type the location of the Pig script. For example: **`s3://elasticmapreduce/samples/pig-apache/do-reports2.pig`**.
   - For **Input S3 location**, type the location of the input data. For example: **`s3://elasticmapreduce/samples/pig-apache/input`**.
   - For **Output S3 location**, type or browse to the name of your Amazon S3 output bucket.
   - For **Arguments**, leave the field blank.
   - For **Action on failure**, accept the default option (**Continue**).
7. Choose **Add**. The step appears in the console with a status of Pending.
8. The status of the step changes from Pending to Running to Completed as the step runs. To update the status, choose the **Refresh** icon above the **Actions** column. When your step is complete, check your Amazon S3 bucket to confirm your Pig step's output files are there.

Submit Pig work using the AWS CLI

To submit a Pig step using the AWS CLI

When you launch a cluster using the AWS CLI, use the `--applications` parameter to install Pig. To submit a Pig step, use the `--steps` parameter.

1. To launch a cluster with Pig installed, type the following command, replacing *myKey* and *DOC-EXAMPLE-BUCKET/* with the name of your EC2 key pair and Amazon S3 bucket.

```
aws emr create-cluster \
--name "Test cluster" \
--log-uri s3://DOC-EXAMPLE-BUCKET/ \
--release-label emr-5.36.2 \
--applications Name=Pig \
--use-default-roles \
--ec2-attributes KeyName=myKey \
--instance-type m5.xlarge \
--instance-count 3
```

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

When you specify the instance count without using the `--instance-groups` parameter, a single master node is launched, and the remaining instances are launched as core nodes. All nodes use the instance type specified in the command.

Note

If you have not previously created the default EMR service role and EC2 instance profile, type `aws emr create-default-roles` to create them before typing the `create-cluster` subcommand.

2. To submit a Pig step, enter the following command, replacing *myClusterId* and *DOC-EXAMPLE-BUCKET* with your cluster ID and name of your Amazon S3 bucket.

```
aws emr add-steps \
--cluster-id myClusterId \
--steps Type=PIG,Name="Pig Program",ActionOnFailure=CONTINUE,Args=[-f,s3://
elasticmapreduce/samples/pig-apache/do-reports2.pig,-p,INPUT=s3://elasticmapreduce/
samples/pig-apache/input,-p,OUTPUT=s3://DOC-EXAMPLE-BUCKET/pig-apache/output]
```

This command will return a step ID, which you can use to check the `State` of your step.

3. Query the status of your step with the `describe-step` command.

```
aws emr describe-step --cluster-id myClusterId --step-id s-1XXXXXXXXXXA
```

The `State` of the step changes from `PENDING` to `RUNNING` to `COMPLETED` as the step runs. When your step is complete, check your Amazon S3 bucket to confirm your Pig step's output files are there.

For more information about using Amazon EMR commands in the AWS CLI, see the AWS CLI Command Reference.

Call user-defined functions from Pig

Pig provides the ability to call user-defined functions (UDFs) from within Pig scripts. You can do this to implement custom processing to use in your Pig scripts. The languages currently supported are Java, Python/Jython, and JavaScript (though JavaScript support is still experimental.)

The following sections describe how to register your functions with Pig so you can call them either from the Pig shell or from within Pig scripts. For more information about using UDFs with Pig, see Pig documentation for your version of Pig.

Call JAR files from Pig

You can use custom JAR files with Pig using the `REGISTER` command in your Pig script. The JAR file is local or a remote file system such as Amazon S3. When the Pig script runs, Amazon EMR downloads the JAR file automatically to the master node and then uploads the JAR file to the Hadoop distributed cache. In this way, the JAR file is automatically used as necessary by all instances in the cluster.

To use JAR files with Pig

1. Upload your custom JAR file into Amazon S3.
2. Use the REGISTER command in your Pig script to specify the bucket on Amazon S3 of the custom JAR file.

```
REGISTER s3://mybucket/path/mycustomjar.jar;
```

Call Python/Jython scripts from Pig

You can register Python scripts with Pig and then call functions in those scripts from the Pig shell or in a Pig script. You do this by specifying the location of the script with the register keyword.

Because Pig in written in Java, it uses the Jython script engine to parse Python scripts. For more information about Jython, go to http://www.jython.org/.

To call a Python/Jython script from Pig

1. Write a Python script and upload the script to a location in Amazon S3. This should be a bucket owned by the same account that creates the Pig cluster, or that has permissions set so the account that created the cluster can access it. In this example, the script is uploaded to s3://mybucket/pig/python.
2. Start a Pig cluster. If you are accessing Pig from the Grunt shell, run an interactive cluster. If you are running Pig commands from a script, start a scripted Pig cluster. This example starts an interactive cluster. For more information about how to create a Pig cluster, see Submit Pig work.
3. For an interactive cluster, use SSH to connect into the master node and run the Grunt shell. For more information, see SSH into the master node.
4. Run the Grunt shell for Pig by typing pig at the command line:

```
pig
```

5. Register the Jython library and your Python script with Pig using the register keyword at the Grunt command prompt, as shown in the following command, where you would specify the location of your script in Amazon S3:

```
grunt> register 'lib/jython.jar';
```

```
grunt> register 's3://mybucket/pig/python/myscript.py' using jython as myfunctions;
```

6. Load the input data. The following example loads input from an Amazon S3 location:

```
grunt> input = load 's3://mybucket/input/data.txt' using TextLoader as
 (line:chararray);
```

7. You can now call functions in your script from within Pig by referencing them using `myfunctions`:

```
grunt> output=foreach input generate myfunctions.myfunction($1);
```

Pig release history

The following table lists the version of Pig included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Pig version information

Amazon EMR Release label	Pig Version	Components installed with Pig
emr-7.2.0	0.17.0	emrfs, emr-ddb, emr-goodies, emr-kinesis, emr-s3-dist-cp, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, pig-client, tez-on-yarn, tez-on-worker

Amazon EMR Release label	Pig Version	Components installed with Pig

Presto and Trino

Note

PrestoSQL was renamed to Trino in December 2020. Amazon EMR versions 6.4.0 and later use the name Trino, while earlier release versions use the name PrestoSQL.

Presto is a fast SQL query engine designed for interactive analytic queries over large datasets from multiple sources. For more information, see the Presto website. Presto is included in Amazon EMR releases 5.0.0 and later. Earlier releases include Presto as a sandbox application. For more information, see Amazon EMR 4.x release versions. Amazon EMR release versions 6.1.0 and later support Trino (PrestoSQL) in addition to Presto. For more information, see PrestoDB and Trino installation.

The following table lists the version of Presto included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Presto.

For the version of components installed with Presto in this release, see Release 7.2.0 Component Versions.

Presto version information for emr-7.2.0

Amazon EMR Release Label	Presto Version	Components Installed With Presto
emr-7.2.0	Presto 0.285	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hive-client, hudi, hudi-presto, hcatalog-server, mariadb-server, presto-coordinator, presto-worker

The following table lists the version of Presto included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Presto.

For the version of components installed with Presto in this release, see Release 6.15.0 Component Versions.

Presto version information for emr-6.15.0

Amazon EMR Release Label	Presto Version	Components Installed With Presto
emr-6.15.0	Presto 0.283	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hive-client, hudi, hudi-presto, hcatalog-server, mariadb-server, presto-coordinator, presto-worker

The following table lists the version of Presto included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Presto.

For the version of components installed with Presto in this release, see Release 5.36.2 Component Versions.

Presto version information for emr-5.36.2

Amazon EMR Release Label	Presto Version	Components Installed With Presto
emr-5.36.2	Presto 0.267	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode,

Amazon EMR Release Label	Presto Version	Components Installed With Presto
		hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server , hive-client, hudi, hudi-presto, hcatalog-server, mariadb-server, presto-coordinator, presto-worker

The following table lists the version of Trino (PrestoSQL) included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Trino (PrestoSQL).

For the version of components installed with Trino (PrestoSQL) in this release, see Release 6.15.0 Component Versions.

Trino (PrestoSQL) version information for emr-6.15.0

Amazon EMR Release Label	Trino (PrestoSQL) Version	Components Installed With Trino (PrestoSQL)
emr-6.15.0	Trino (PrestoSQL) 426	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server , hive-client, hudi, hudi-trino, hcatalog-server, mariadb-server, trino-coordinator, trino-worker

Topics

Using Presto with the AWS Glue Data Catalog

Using Amazon EMR release version 5.10.0 and later, you can specify the AWS Glue Data Catalog as the default Hive metastore for Presto. We recommend this configuration when you require a persistent metastore or a metastore shared by different clusters, services, applications, or AWS accounts.

AWS Glue is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores. The AWS Glue Data Catalog provides a unified metadata repository across a variety of data sources and data formats, integrating with Amazon EMR as well as Amazon RDS, Amazon Redshift, Redshift Spectrum, Athena, and any application compatible with the Apache Hive metastore. AWS Glue crawlers can automatically infer schema from source data in Amazon S3 and store the associated metadata in the Data Catalog. For more information about the Data Catalog, see Populating the AWS Glue Data Catalog in the *AWS Glue Developer Guide*.

Separate charges apply for AWS Glue. There is a monthly rate for storing and accessing the metadata in the Data Catalog, an hourly rate billed per minute for AWS Glue ETL jobs and crawler runtime, and an hourly rate billed per minute for each provisioned development endpoint. The Data Catalog allows you to store up to a million objects at no charge. If you store more than a million objects, you are charged USD$1 for each 100,000 objects over a million. An object in the Data Catalog is a table, partition, or database. For more information, see Glue Pricing.

Important

If you created tables using Amazon Athena or Amazon Redshift Spectrum before August 14, 2017, databases and tables are stored in an Athena-managed catalog, which is separate from the AWS Glue Data Catalog. To integrate Amazon EMR with these tables, you must upgrade to the AWS Glue Data Catalog. For more information, see Upgrading to the AWS Glue Data Catalog in the *Amazon Athena User Guide*.

Specifying AWS Glue Data Catalog as the metastore

You can specify the AWS Glue Data Catalog as the metastore using the AWS Management Console, AWS CLI, or Amazon EMR API. When you use the CLI or API, you use the configuration classification for Presto to specify the Data Catalog. In addition, with Amazon EMR 5.16.0 and later, you can use the configuration classification to specify a Data Catalog in a different AWS account. When you use the console, you can specify the Data Catalog using **Advanced Options** or **Quick Options**.

Console

To specify AWS Glue Data Catalog as the Hive metastore with the new console

1. Sign in to the AWS Management Console, and open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Under **EMR on EC2** in the left navigation pane, choose **Clusters**, and then choose **Create cluster**.
3. Under **Application bundle**, choose **Presto**.
4. Under **AWS Glue Data Catalog settings**, select the **Use for Presto table metadata** check box.
5. Choose any other options that apply to your cluster.
6. To launch your cluster, choose **Create cluster**.

CLI

To specify the AWS Glue Data Catalog as the default Hive metastore using the AWS CLI

For examples of how to specify the following configuration classifications when you create a cluster, see Configure applications.

Amazon EMR 5.16.0 and later

- Set the `hive.metastore` property to `glue` as shown in the following JSON example.

```
[
  {
    "Classification": "presto-connector-hive",
    "Properties": {
      "hive.metastore": "glue"
    }
  }
]
```

To specify a Data Catalog in a different AWS account, add the `hive.metastore.glue.catalogid` property as shown in the following JSON example. Replace *`acct-id`* with the AWS account of the Data Catalog. Using a Data Catalog in another AWS account is not available using Amazon EMR version 5.15.0 and earlier.

```
[
  {
    "Classification": "presto-connector-hive",
    "Properties": {
      "hive.metastore": "glue",
      "hive.metastore.glue.catalogid": "acct-id"
    }
  }
]
```

Amazon EMR 5.10.0 through 5.15.0

Set the `hive.metastore.glue.datacatalog.enabled` property to `true`, as shown in the following JSON example:

```
[
  {
    "Classification": "presto-connector-hive",
    "Properties": {
      "hive.metastore.glue.datacatalog.enabled": "true"
    }
  }
]
```

Amazon EMR 6.1.0 and later using PrestoSQL (Trino)

Starting with EMR version 6.1.0, PrestoSQL also supports Glue as the default Hive metastore. Use the `prestosql-connector-hive` configuration classification and set the `hive.metastore` property to `glue`, as shown in the following JSON example.

Amazon EMR versions 6.4.0 and later use the new name Trino instead of PrestoSQL. If you use Trino, replace *`prestosql-connector-hive`* in the following configuration classification with `trino-connector-hive`.

```
[
  {
    "Classification": "prestosql-connector-hive",
    "Properties": {
      "hive.metastore": "glue"
    }
  }
]
```

To switch metastores on a long-running cluster, you can manually set these values as appropriate for your release version by connecting to the master node, editing the property values in the `/etc/presto/conf/catalog/hive.properties` file directly, and restarting the Presto server (`sudo restart presto-server`). If you use this method with Amazon EMR 5.15.0 and earlier, make sure that `hive.table-statistics-enabled` is set to `false`. This setting is not required when using release versions 5.16.0 and later; nevertheless, table and partition statistics are not supported.

IAM permissions

The EC2 instance profile for a cluster must have IAM permissions for AWS Glue actions. In addition, if you enable encryption for AWS Glue Data Catalog objects, the role must also be allowed to encrypt, decrypt and generate the AWS KMS key used for encryption.

Permissions for AWS Glue actions

If you use the default EC2 instance profile for Amazon EMR, no action is required. The `AmazonElasticMapReduceforEC2Role` managed policy that is attached to the

EMR_EC2_DefaultRole allows all necessary AWS Glue actions. However, if you specify a custom EC2 instance profile and permissions, you must configure the appropriate AWS Glue actions. Use the AmazonElasticMapReduceforEC2Role managed policy as a starting point. For more information, see Service role for cluster EC2 instances (EC2 instance profile) in the *Amazon EMR Management Guide*.

Permissions for encrypting and decrypting AWS Glue Data Catalog

Your instance profile needs permission to encrypt and decrypt data using your key. You do *not* need to configure these permissions if both of the following statements apply:

- You enable encryption for AWS Glue Data Catalog objects using managed keys for AWS Glue.
- You use a cluster that's in the same AWS account as the AWS Glue Data Catalog.

Otherwise, you must add the following statement to the permissions policy attached to your EC2 instance profile.

```
[
    {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Action": [
                    "kms:Decrypt",
                    "kms:Encrypt",
                    "kms:GenerateDataKey"
                ],
                "Resource": "arn:aws:kms:region:acct-
id:key/12345678-1234-1234-1234-123456789012"
            }
        ]
    }
]
```

For more information about AWS Glue Data Catalog encryption, see Encrypting your data catalog in the *AWS Glue Developer Guide*.

Resource-based permissions

If you use AWS Glue in conjunction with Hive, Spark, or Presto in Amazon EMR, AWS Glue supports resource-based policies to control access to Data Catalog resources. These resources include databases, tables, connections, and user-defined functions. For more information, see AWS Glue Resource Policies in the *AWS Glue Developer Guide*.

When using resource-based policies to limit access to AWS Glue from within Amazon EMR, the principal that you specify in the permissions policy must be the role ARN associated with the EC2 instance profile that is specified when a cluster is created. For example, for a resource-based policy attached to a catalog, you can specify the role ARN for the default service role for cluster EC2 instances, *EMR_EC2_DefaultRole* as the `Principal`, using the format shown in the following example:

```
arn:aws:iam::acct-id:role/EMR_EC2_DefaultRole
```

The *acct-id* can be different from the AWS Glue account ID. This enables access from EMR clusters in different accounts. You can specify multiple principals, each from a different account.

Considerations when using AWS Glue Data Catalog

Consider the following items when using AWS Glue Data Catalog as a metastore with Presto:

- Renaming tables from within AWS Glue is not supported.
- When you create a Hive table without specifying a `LOCATION`, the table data is stored in the location specified by the `hive.metastore.warehouse.dir` property. By default, this is a location in HDFS. If another cluster needs to access the table, it fails unless it has adequate permissions to the cluster that created the table. Furthermore, because HDFS storage is transient, if the cluster terminates, the table data is lost, and the table must be recreated. We recommend that you specify a `LOCATION` in Amazon S3 when you create a Hive table using AWS Glue. Alternatively, you can use the `hive-site` configuration classification to specify a location in Amazon S3 for `hive.metastore.warehouse.dir`, which applies to all Hive tables. If a table is created in an HDFS location and the cluster that created it is still running, you can update the table location to Amazon S3 from within AWS Glue. For more information, see Working with Tables on the AWS Glue Console in the *AWS Glue Developer Guide*.
- Partition values containing quotes and apostrophes are not supported, for example, `PARTITION (owner="Doe's")`.
- Column statistics are supported for emr-5.31.0 and later.

- Using Hive authorization is not supported. As an alternative, consider using AWS Glue Resource-Based Policies. For more information, see Use Resource-Based Policies for Amazon EMR Access to AWS Glue Data Catalog.

Using S3 Select Pushdown with Presto to improve performance

With Amazon EMR release version 5.18.0 and later, you can use S3 select Pushdown with Presto on Amazon EMR. This feature allows Presto to "push down" the computational work of projection operations (for example, `SELECT`) and predicate operations (for example, `WHERE`) to Amazon S3. This allows queries to retrieve only required data from Amazon S3, which can improve performance and reduce the amount of data transferred between Amazon EMR and Amazon S3 in some applications.

Is S3 Select Pushdown right for my application?

We recommend that you benchmark your applications with and without S3 Select Pushdown to see if using it may be suitable for your application.

Use the following guidelines to determine if your application is a candidate for using S3 Select:

- Your query filters out more than half of the original data set.
- Your query filter predicates use columns that have a data type supported by Presto and S3 Select. The timestamp, real, and double data types are not supported by S3 Select Pushdown. We recommend using the decimal data type for numerical data. For more information about supported data types for S3 Select, see Data types in the *Amazon Simple Storage Service User Guide*.
- Your network connection between Amazon S3 and the Amazon EMR cluster has good transfer speed and available bandwidth. Amazon S3 does not compress HTTP responses, so the response size is likely to increase for compressed input files.

Considerations and limitations

- Only objects stored in CSV format are supported. Objects can be uncompressed or optionally compressed with gzip or bzip2.
- The `AllowQuotedRecordDelimiters` property is not supported. If this property is specified, the query fails.

- Amazon S3 server-side encryption with customer-provided encryption keys (SSE-C) and client-side encryption are not supported.
- S3 Select Pushdown is not a substitute for using columnar or compressed file formats such as ORC or Parquet.

Enabling S3 Select Pushdown with PrestoDB or Trino

To enable S3 Select Pushdown for PrestoDB on Amazon EMR, use the `presto-connector-hive` configuration classification to set `hive.s3select-pushdown.enabled` to `true` as shown in the example below. For more information, see Configure applications. The hive.s3select-pushdown.max-connections value must also be set. For most applications, the default setting of *500* should be adequate. For more information, see Understanding and tuning hive.s3select-pushdown.max-connections below.

For PrestoSQL on EMR versions 6.1.0 - 6.3.0, replace *presto-connector-hive* in the example below with `prestosql-connector-hive`.

Amazon EMR versions 6.4.0 and later use the new name Trino instead of PrestoSQL. If you use Trino, replace *presto-connector-hive* in the example below with `trino-connector-hive`

```
[
    {
        "classification": "presto-connector-hive",
        "properties": {
            "hive.s3select-pushdown.enabled": "true",
            "hive.s3select-pushdown.max-connections": "500"
        }
    }
]
```

Understanding and tuning hive.s3select-pushdown.max-connections

By default, Presto uses EMRFS as its file system. The setting `fs.s3.maxConnections` in the `emrfs-site` configuration classification specifies the maximum allowable client connections to Amazon S3 through EMRFS for Presto. By default, this is 500. S3 Select Pushdown bypasses EMRFS when accessing Amazon S3 for predicate operations. In this case, the value of `hive.s3select-pushdown.max-connections` determines the maximum number of client connections allowed for those operations from worker nodes. However, any requests to Amazon S3 that Presto initiates that are not pushed down—for example, GET operations—continue to be governed by the value of `fs.s3.maxConnections`.

If your application experiences the error "Timeout waiting for connection from pool," increase the value of both `hive.s3select-pushdown.max-connections` and `fs.s3.maxConnections`.

Adding database connectors

You can use configuration classifications to configure JDBC connector properties when you create a cluster. Configuration classifications begin with `presto-connector`, for example, `presto-connector-postgresql`. The available configuration classifications depend on the Amazon EMR release version. For the configuration classifications available with the most recent release version, see the section called "5.36.2 configuration classifications" for Amazon EMR 5.36.2. If you are using a different version of Amazon EMR, see Amazon EMR 5.x release versions for the configuration classifications. For more information about the properties that can be configured with each connector, see https://prestodb.io/docs/current/connector.html.

Example —configuring a cluster with the PostgreSQL JDBC connector

To launch a cluster with the PostgreSQL connector installed and configured, first create a JSON file that specifies the configuration classification—for example, `myConfig.json`—with the following content, and save it locally.

Replace the connection properties as appropriate for your setup and as shown in the PostgreSQL connector topic in Presto Documentation.

```
[
  {
    "Classification": "presto-connector-postgresql",
    "Properties": {
      "connection-url": "jdbc:postgresql://example.net:5432/database",
      "connection-user": "MYUSER",
      "connection-password": "MYPASS"
    },
    "Configurations": []
  }
]
```

When you create the cluster, reference the path to the JSON file using the `--configurations` option as shown in the following example, where `myConfig.json` is in the same directory where you run the command:

```
aws emr create-cluster --name PrestoConnector --release-label emr-5.36.2 --instance-type m5.xlarge \
--instance-count 2 --applications Name=Hadoop Name=Hive Name=Pig Name=Presto \
--use-default-roles --ec2-attributes KeyName=myKey \
--log-uri s3://my-bucket/logs --enable-debugging \
--configurations file://myConfig.json
```

Using SSL/TLS and configuring LDAPS with Presto on Amazon EMR

With Amazon EMR release version 5.6.0 and later, you can enable SSL/TLS to help secure internal communication between Presto nodes. You do this by setting up a security configuration for in-transit encryption. For more information, see Encryption options and Use security configurations to set up cluster security in the *Amazon EMR Management Guide*.

When you use a security configuration with in-transit encryption, Amazon EMR does the following for Presto:

- Distributes the encryption artifacts, or certificates, that you specify for in-transit encryption throughout the Presto cluster. For more information, see Providing certificates for in-transit data encryption.
- Sets the following properties using the `presto-config` configuration classification, which corresponds to the `config.properties` file for Presto:
  - Sets `http-server.http.enabled` to `false` on all nodes, which disables HTTP in favor of HTTPS. This requires you to provide certificates that work for public and private DNS when setting up the security configuration for in-transit encryption. One way to do this is to use SAN (Subject Alternative Name) certificates which support multiple domains.
  - Sets `http-server.https.*` values. For configuration details, see LDAP authentication in Presto documentation.
- For PrestoSQL (Trino) on EMR version 6.1.0 and later, Amazon EMR automatically configures a shared secret key for secure internal communication between cluster nodes. You don't need to do any additional configuration to enable this security feature, and you can override the

configuration with your own secret key. For information about Trino internal authentication, see Trino 353 documentation: Secure internal communication.

In addition, with Amazon EMR release version 5.10.0 and later, you can set up LDAP authentication for client connections to the Presto coordinator using HTTPS. This setup uses secure LDAP (LDAPS). TLS must be enabled on your LDAP server, and the Presto cluster must use a security configuration with in-transit data encryption enabled. Additional configuration is required. The configuration options are different depending on the release version of Amazon EMR that you use. For more information, see Using LDAP authentication for Presto on Amazon EMR.

Presto on Amazon EMR uses port 8446 for internal HTTPS by default. The port used for internal communication must be the same port used for client HTTPS access to the Presto coordinator. The `http-server.https.port` property in the `presto-config` configuration classification specifies the port.

Using LDAP authentication for Presto on Amazon EMR

Follow the steps in this section to configure LDAP. See each step for examples and links to more information.

Steps to Configure LDAP Authentication

- Step 1: Gather information about your LDAP server and copy the server certificate to Amazon S3
- Step 2: Set up a security configuration
- Step 3: Create a configuration JSON with Presto properties for LDAP
- Step 4: Create the script to copy the LDAP server certificate and upload it to Amazon S3
- Step 5: Create the cluster

Step 1: Gather information about your LDAP server and copy the server certificate to Amazon S3

You'll need the information and items in the following section from your LDAP server to configure LDAP authentication.

The IP address or host name of the LDAP server

The Presto coordinator on the Amazon EMR master node must be able to reach the LDAP server at the specified IP address or host name. By default, Presto communicates with the LDAP server using

LDAPS over port 636. If your LDAP implementation requires a custom port, you can specify it using the `ldap.url` property with Amazon EMR 5.16.0 or later, or using `authentication.ldap.url` with earlier versions. Substitute the custom port for 636 as shown in the `presto-config` configuration classification examples in Step 3: Create a configuration JSON with Presto properties for LDAP. Ensure that any firewalls and security groups allow inbound and outbound traffic on port 636 (or your custom port) and also port 8446 (or your custom port), which is used for internal cluster communications.

The LDAP server certificate

You must upload the certificate file to a secure location in Amazon S3. For more information, see How do I upload files and folders to an S3 Bucket in the *Amazon Simple Storage Service User Guide*. You create a bootstrap action that copies this certificate from Amazon S3 to each node in the cluster when the cluster launches. In Step 4: Create the script to copy the LDAP server certificate and upload it to Amazon S3. The example certificate is *`s3://MyBucket/ldap_server.crt`*.

The LDAP server's settings for anonymous binding

If anonymous binding is disabled on PrestoDB, you need the user ID (UID) and password of an account with permissions to bind to the LDAP server so that the PrestoDB server can establish a connection. You specify the UID and password using the `internal-communication.authentication.ldap.user` and `internal-communication.authentication.ldap.password` properties in the `presto-config` configuration classification. Amazon EMR 5.10.0 does not support these settings, so anonymous binding must be supported on the LDAP server when you use this release version.

Note that Trino doesn't require the anonymous binding configuration.

To get the status of anonymous binding on the LDAP server

- Use the ldapwhoami command from a Linux client, as shown in the following example:

  ```
  ldapwhoami -x -H ldaps://LDAPServerHostNameOrIPAddress
  ```

  If anonymous binding is not allowed, the command returns the following:

  ```
  ldap_bind: Inappropriate authentication (48)
  additional info: anonymous bind disallowed
  ```

To verify that an account has permissions to an LDAP server that uses simple authentication

- Use theldapwhoami command from a Linux client, as shown in the following example. The example uses a fictitious user, *presto*, stored in an Open LDAP server running on an EC2 instance with the fictitious host name *ip-xxx-xxx-xxx-xxx.ec2.internal*. The user is associated with the organizational unit (OU) *admins* and with the password *123456*:

  ```
  ldapwhoami -x -w "123456" -D uid=presto,ou=admins,dc=ec2,dc=internal -H ldaps://ip-xxx-xxx-xxx-xxx.ec2.internal
  ```

  If the account is valid and has appropriate permissions, the command returns:

  ```
  dn:uid=presto,ou=admins,dc=ec2,dc=internal
  ```

The example configurations in Step 3: Create a configuration JSON with Presto properties for LDAP include this account for clarity, with the exception of the 5.10.0 example, where it is not supported. If the LDAP server uses anonymous binding, remove the `internal-communication.authentication.ldap.user` and `internal-communication.authentication.ldap.password` name/value pairs.

The LDAP distinguished name (DN) for Presto users

When you specify the LDAP configuration for Presto, you specify a bind pattern that consists of `${USER}` along with an organizational unit (OU) and additional domain components (DCs). Presto replaces `${USER}` with the actual User ID (UID) of each user during password authentication to match the distinguished name (DN) that this bind pattern specifies. You need the OUs that eligible users belong to and their DCs. For example, to allow users from the `admins` OU in the `corp.example.com` domain to authenticate to Presto, you specify `${USER},ou=admins,dc=corp,dc=example,dc=com` as the user bind pattern.

> **Note**
>
> When you use AWS CloudFormation, you need to use the Fn::Sub function in order to replace `${USER}` with the actual User ID (UID). For more information, see the Fn::Sub topic in the *AWS CloudFormation User Guide*.

When using Amazon EMR 5.10.0, you can specify only one such pattern. Using Amazon EMR 5.11.0 or later, you can specify multiple patterns separated by a colon (:). Users attempting to authenticate to Presto are compared to the first pattern, then the second, and so on. For an example, see Step 3: Create a configuration JSON with Presto properties for LDAP.

Step 2: Set up a security configuration

Create a security configuration with in-transit encryption enabled. For more information, see Create a security configuration in the *Amazon EMR Management Guide*. The encryption artifacts that you provide when you set up in-transit encryption are used to encrypt internal communication between Presto nodes. For more information, see Providing certificates for in-transit data encryption. The LDAP server certificate is used to authenticate client connections to the Presto server.

Step 3: Create a configuration JSON with Presto properties for LDAP

You use the `presto-config` configuration classification to set Presto properties for LDAP. The format and contents of `presto-config` are slightly different depending on the Amazon EMR release version and the Presto installation (PrestoDB or Trino). Examples of configuration differences are provided later in this section. For more information, see Configure applications.

The following steps assume that you save the JSON data to a file, *`MyPrestoConfig.json`*. If you use the console, upload the file to a secure location in Amazon S3 so that you can reference it when you create the cluster. If you use the AWS CLI, you can reference the file locally.

Example Amazon EMR 6.1.0 and later with PrestoSQL (Trino)

The following example uses the LDAP host name from Step 1: Gather information about your LDAP server and copy the server certificate to Amazon S3 to authenticate to the LDAP server for binding. Two user bind patterns are specified, which indicates that users within the `admins` OU and the `datascientists` OU on the LDAP server are eligible for authentication to the Trino server as users. The bind patterns are separated by a colon (`:`).

Amazon EMR versions 6.4.0 and later use the new name Trino instead of PrestoSQL. If you use Trino, replace *`prestosql-config`* in the following configuration classification with `trino-config` and *`prestosql-password-authenticator`* with `trino-password-authenticator`.

```
[
  {
```

```
      "Classification":"prestosql-config",
      "Properties":{
         "http-server.authentication.type":"PASSWORD"
      }
   },
   {
      "Classification":"prestosql-password-authenticator",
      "Properties":{
         "password-authenticator.name":"ldap",
         "ldap.url":"ldaps://ip-xxx-xxx-xxx-xxx.ec2.internal:636",
         "ldap.user-bind-pattern": "uid=${USER},ou=admins,dc=ec2,dc=internal:uid=
${USER},ou=datascientists,dc=ec2,dc=internal"
      }
   }
]
```

Example Amazon EMR 5.16.0 and later

The following example uses the LDAP user ID and password, and the LDAP host name from Step 1: Gather information about your LDAP server and copy the server certificate to Amazon S3 to authenticate to the LDAP server for binding. Two user bind patterns are specified, which indicates that users within the `admins` OU and the `datascientists` OU on the LDAP server are eligible for authentication to the Presto server as users. The bind patterns are separated by a colon (`:`).

```
[{
        "Classification": "presto-config",
                "Properties": {
                        "http-server.authentication.type": "PASSWORD"
                }
        },
        {
                "Classification": "presto-password-authenticator",
                "Properties": {
                        "password-authenticator.name": "ldap",
                        "ldap.url": "ldaps://ip-xxx-xxx-xxx-xxx.ec2.internal:636",
                        "ldap.user-bind-pattern": "uid=
${USER},ou=admins,dc=ec2,dc=internal:uid=${USER},ou=datascientists,dc=ec2,dc=internal",
                        "internal-communication.authentication.ldap.user": "presto",
                        "internal-communication.authentication.ldap.password": "123456"
                }
        }]
```

Example Amazon EMR 5.11.0 through 5.15.0

The format of the `presto-config` configuration classification is slightly different for these release versions. The following example specifies the same parameters as the previous example.

```
[{
        "Classification": "presto-config",
                "Properties": {
                        "http-server.authentication.type": "LDAP",
                        "authentication.ldap.url": "ldaps://ip-xxx-xxx-xxx-
xxx.ec2.internal:636",
                        "authentication.ldap.user-bind-pattern": "uid=
${USER},ou=admins,dc=ec2,dc=internal:uid=${USER},ou=datascientists,dc=ec2,dc=internal",
                        "internal-communication.authentication.ldap.user": "presto",
                        "internal-communication.authentication.ldap.password": "123456"
                }
        }]
```

Example Amazon EMR 5.10.0

Amazon EMR 5.10.0 supports anonymous binding only, so those entries are omitted. In addition, only a single bind pattern can be specified.

```
[{
        "Classification": "presto-config",
                "Properties": {
                        "http-server.authentication.type": "LDAP",
                        "authentication.ldap.url": "ldaps://ip-xxx-xxx-xxx-
xxx.ec2.internal:636",
                        "ldap.user-bind-pattern": "uid=
${USER},ou=prestousers,dc=ec2,dc=internal"
                }
        }]
```

Step 4: Create the script to copy the LDAP server certificate and upload it to Amazon S3

Create a script that copies the certificate file to each node in the cluster and adds it to the keystore. Create the script using a text editor, save it, and then upload it to Amazon S3. In Step 5: Create the cluster, the script file is referenced as *`s3://MyBucket/LoadLDAPCert.sh`*.

The following example script uses the default keystore password, *changeit*. We recommend that you connect to the master node after you create the cluster and change the keystore password using the keytool command.

```
#!/bin/bash
aws s3 cp s3://MyBucket/ldap_server.crt .
sudo keytool -import -keystore /usr/lib/jvm/jre-1.8.0-openjdk.x86_64/lib/security/
cacerts -trustcacerts -alias ldap_server -file ./ldap_server.crt -storepass changeit -
noprompt
```

Step 5: Create the cluster

When you create the cluster, you specify Presto and other applications that you want Amazon EMR to install. The following examples also reference the configuration classification properties within a JSON, but you can also specify the configuration classification inline.

To create a Presto cluster with LDAP authentication using the Amazon EMR console

1. Navigate to the new Amazon EMR console and select **Switch to the old console** from the side navigation. For more information on what to expect when you switch to the old console, see Using the old console.
2. Choose **Create cluster**, **Go to advanced options**.
3. Choose **Presto** along with other applications for Amazon EMR to install, and under **Software Configuration**, select the **Release** of Amazon EMR to use. LDAP authentication is supported only with Amazon EMR 5.10.0 and later.
4. Under **Edit software settings**, choose **Load JSON from S3** , enter the location in Amazon S3 of the JSON configuration file you created in Step 3: Create a configuration JSON with Presto properties for LDAP, and then choose **Next**.
5. Configure cluster hardware and networking, and then choose **Next**.
6. Choose **Bootstrap Actions**. For **Add bootstrap action**, select **Custom action**, and then choose **Configure and add**.
7. Enter a **Name** for the bootstrap action, enter the **Script location** that you created in Step 4: Create the script to copy the LDAP server certificate and upload it to Amazon S3, for example **s3://MyBucket/LoadLDAPCert.sh**, and then choose **Add**.
8. Under **General Options**, **Tags**, and **Additional Options** choose the settings that are appropriate for your application, and then choose **Next**.

9. Choose **Authentication and encryption**, and then select the **Security configuration** that you created in Step 2: Set up a security configuration.
10. Choose other security options as appropriate for your application, and then choose **Create cluster**.

To create a Presto cluster with LDAP authentication using the AWS CLI

- Use the `aws emr create-cluster` command. At a minimum, specify the Presto application, and also the Presto configuration classification, the bootstrap script, and the security configuration that you created in the previous steps. The following example references the configuration file as a JSON file saved in the same directory where you run the command. The bootstrap script, on the other hand, must be saved in Amazon S3. The following example uses `s3://MyBucket/LoadLDAPCert.sh`.

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster  --applications Name=presto --release-label emr-5.16.0 \
--use-default-roles --ec2-attributes KeyName=MyKeyPair,SubnetId=subnet-1234ab5
 \ --instance-count 3 --instance-type m5.xlarge --region us-west-2 --name
 "MyPrestoWithLDAPAuth" \
--bootstrap-actions Name="Distribute LDAP server cert",Path="s3://MyBucket/
LoadLDAPCert.sh" \
--security-configuration MyPrestoLDAPSecCfg --configurations file://
MyPrestoConfig.json
```

Activating Presto strict mode

In certain situations, long-running queries can lead to high costs and cause Amazon EMR to use more cluster resources. This takes resources away from other workloads on the cluster. With Amazon EMR versions 6.8 and later, you can use a strict mode feature that rejects or warns you about the following types of long-running queries:

- Queries without predicates on the partitioned columns that result in table scans of large amounts of data
- Queries with cross joins between two large tables
- Queries that sort large number of rows without limit

After Presto completely optimizes the query plan, strict mode runs. To use and customize strict mode to your query needs, you can configure Presto in the following ways.

Presto configurations for strict mode

Setting	Description	Default
`strict-mode-enabled`	Turns strict mode on and off. A value of `true` indicates that strict mode is on.	`false`
`strict-mode-fail-query`	Rejects queries if strict mode detects probable long-running queries. If `false`, Amazon EMR only raises a warning.	`false`
`strict-mode-restrictions`	Specifies the restrictions to apply when strict mode is turned on. Strict mode supports the following restrictions: MANDATORY_PARTITION_PREDICATE, DISALLOW_CROSS_JOIN, and LIMITED_SORT.	MANDATORY_PARTITION_PREDICATE,DISALLOW_CROSS_JOIN, LIMITED_SORT

To experiment with strict mode, you can override these configurations, or set them as session properties when you use the Presto client.

To set the configuration at cluster creation with the AWS Management Console

1. Choose **Create cluster** and select Amazon EMR version 6.8.0, and Presto or Trino. For more information, see Installing PrestoDB and Trino.

2. Specify the configuration properties for strict mode directly, or upload a JSON file to Amazon S3. Optionally, select the for your metastore. Specify your VPC, subnets, bootstrap actions, key pair, and security group. Choose **Create cluster** to create your cluster.
3. Log in to the primary node of the cluster and run `presto-cli` or `trino-cli`.
4. Submit your queries. Strict mode validates each query and determines if it is long-running. Depending on your `strict-mode-fail-query` setting, Amazon EMR rejects the query or raises a warning.
5. When you're finished with your queries, terminate the cluster and delete your resources.

To set the configuration on a running cluster with the AWS CLI

1. Log in to the primary node of your cluster with the AWS CLI and run `presto-cli` or `trino-cli`.
2. Run the following commands with your desired values.

```
set session strict_mode_enabled = true;
set session strict_mode_fail_query = false;
set session strict_mode_restrictions = 'DISALLOW_CROSS_JOIN,LIMITED_SORT';
```

Considerations

When you use strict mode, consider the following:

- In some cases, strict mode can reject short-running queries that don’t consume a lot of resources. For example, queries on small tables don’t apply dynamic filtering or replace inner joins with cross joins. This can lead the query to use the mandatory partition predicate or disallow cross join. When this happens, strict mode rejects the query.
- The strict mode check is only applied on SELECT, INSERT, CREATE TABLE AS SELECT, and EXPLAIN ANALYZE query types.
- You can only use the restriction on the mandatory partition predicate with the Hive connector.

Handling Spot Instance loss in Presto

With Spot Instances in Amazon EMR, you can run big data workloads on spare Amazon EC2 capacity at a reduced cost. In exchange for the lower cost, Amazon EC2 can interrupt Spot

Instances with a two-minute notification. When you terminate a node, Presto can take up to 10 minutes before it returns an error. This causes unnecessary delays in error reports and possible retries. Quick termination is a feature that gives you control over the way Presto handles terminated nodes.

The job of the Presto coordinator is to keep track of all the worker nodes with regular polls of their statuses. Without quick termination, the coordinator doesn't consult the YARN NodeManager for the status of each node. This can result in a long retry loop before the query fails. With quick termination, the Presto coordinator consults the node status in the NodeManager as soon as the poll fails to reach the host. If NodeManager shows that the node is inactive, Presto abandons further retries, fails the query, and returns a `NODE_DECOMMISSIONED` error.

The following set of configuration parameters allows you to control and customize Presto behavior in the event of node termination.

Presto configurations for node failure handling

Setting	Description	Default
`query.remote-task.max-backoff-duration`	The duration of time that the coordinator continues attempts to fetch the remote task status from worker nodes.	10 minutes
`query.remote-task.quick-terminate-node-failure`	Activates quick node failure if the coordinator can't reach the node or can't connect to the worker that runs on that node. The value of `query.remote-task.terminate-on-connect-exception` determines if the coordinator must reach the node or connect to the worker. The node fails the query and Amazon EMR removes the	`true`

Setting	Description	Default
	node from the list of available workers. When this happens, you can't use the node to schedule new queries. When you set this value to `false`, Presto reverts to its previous behavior where the Presto coordinator again tries to reach the node (for `query.remote-task.max-backoff-duration`) before it marks the node as unavailable and fails the ongoing query on the node.	
`query.remote-task.terminate-on-connect-exception`	Specifies if Amazon EMR should a node if the host is reachable but the coordinator fails to connect to the worker process of the host. When you set this value to `true`, you activate quick query failure if the host is unreachable.	`false`

Fault-tolerant execution in Trino

Fault-tolerant execution is a mechanism in Trino that a cluster can use to mitigate query failures. To do this, it retries queries or their component tasks when they fail. When fault-tolerant execution is activated, intermediate exchange data is spooled, and another worker can reuse it in the event of a worker outage or other fault during query execution.

For more information on fault-tolerant execution in Trino, see Project Tardigrade delivers ETL at Trino speeds to early users on the Trino blog.

Configuration

Fault-tolerant execution is deactivated by default. To activate the feature, set the `retry-policy` configuration property in the `trino-config` classification to either QUERY or TASK based on the desired retry policy, as follows.

```
{"classification":
    "trino-config",
"properties":
    {
    "retry-policy":
        "QUERY"
    }
}
```

A **QUERY** retry policy instructs Trino to retry a query automatically when an error occurs on a worker node. We recommend that you use a QUERY retry policy when the majority of the workload for the Trino cluster comprises many small queries.

A **TASK** retry policy instructs Trino to retry individual query tasks in the event of failure. We recommend this policy when Trino executes large batch queries. The cluster can more efficiently retry smaller tasks within the query rather than retry the whole query.

Exchange manager

An exchange manager stores and manages spooled data for fault-tolerant execution. It uses external storage to store spilled data beyond the in-memory buffer size. You can configure a file system-based exchange manager that stores spooled data in a specified location, such as Amazon S3, Amazon S3 compatible systems, or HDFS.

Amazon EMR releases 6.9.0 and later include the `trino-exchange-manager` classification to configure the exchange manager. These releases also support HDFS for spooling.

Setting up exchange manager

Use the `trino-exchange-manager` configuration classification to configure an exchange manager. This classification internally creates a `etc/exchange-manager.properties` configuration file on the coordinator and all worker nodes. The classification also sets `exchange-manager.name` configuration property to `filesystem`.

By default, Amazon EMR releases 6.9.0 and later use HDFS as an exchange manager. HDFS is available in the Amazon EMR EC2 clusters, and spooling occurs in the `trino-exchange/` directory by default. To use the default settings, set the following configuration:

```
{"Classification":
    "trino-exchange-manager"
}
```

If you want to provide a custom location, set the following properties in the `trino-exchange-manager` classification:

- Set `exchange.use-local-hdfs` to `true`.
- Set `exchange.base-directories` to the custom directory location in HDFS, for example, `exchange.base-directories=/exchange`. If the custom directory isn't already in HDFS, Amazon EMR will create it.

HDFS exchange manager configurations

Based on internal testing results, we recommend that you spool to local HDFS for better query performance in comparison to other cloud-based file systems. You can set the following configurations for the exchange manager with HDFS.

Configuration	Description	Default setting
`exchange.hdfs.block-size`	Block size for HDFS storage	4 MB
`hdfs.config.resources`	List of file paths to configure HDFS	If `exchange.use-local-hdfs` is `true`, uses the paths to `core-site.xml` , `hdfs-site.xml` files; otherwise `null`

For additional fault-tolerant execution configuration properties, and for information on how to set up Amazon S3 or other Amazon S3 compatible systems for spooling, see the [Fault-tolerant execution](#) page of the Trino documentation.

Considerations and limitations

- If you enable fault-tolerant execution, it disables `write` operations for connectors that do not support `write` when `retry-policy` is set. As of Amazon EMR release 6.9.0, Delta Lake, Hive and Iceberg connectors support `write` operations with `retry-policy`.
- If you use exchange manager and perform expensive I/O operations, your queries may experience degraded performance while exchange manager spools the intermediate data to external storage.

Using Presto automatic scaling with Graceful Decommission

Amazon EMR release versions 5.30.0 and later include a feature you can use to set a grace period for certain scaling actions. The grace period allows Presto tasks to keep running before the node terminates because of a scale-in resize action or an automatic scaling policy request. For more information about scaling rules, see Understanding automatic scaling rules in the *Amazon EMR Management Guide*. Presto autoscaling with Graceful Decommission prevents new tasks from being scheduled on a node that is decommissioning, while at the same time allowing tasks that are already running to complete before the shut down timeout is reached. Queries that are running will complete execution before the node is decommissioned. Autoscaling is not supported on instance fleets.

You can control how much time to allow for Presto tasks to complete after an autoscale shut down request is received. By default, the shut down timeout for Amazon EMR is `0` minutes, which means that Amazon EMR immediately terminates the node and any Presto tasks running on it, if required by a scale-in request. To set a longer timeout for Presto tasks on Amazon EMR to allow running queries to complete before scaling down a cluster, use the `presto-config` configuration classification to set the `graceful-shutdown-timeout` parameter to a value in seconds or minutes greater than zero. For more information, see Configure applications.

For example, increasing the `graceful-shutdown-timeout` value to `"30m"` specifies a timeout period of 30 minutes. After the shut down timeout period ends, the node marked for decommissioning is forcefully terminated if it is waiting for query tasks to complete, and the query fails. If the query tasks finish in five minutes, the node marked for decommissioning terminates at five minutes, provided other YARN applications have completed execution.

Example Example Presto autoscale configuration with Graceful Decommission

Replace the `graceful-shutdown-timeout` value with the number of minutes appropriate for your setup. There's no maximum value. The example below sets a timeout value of `1800` seconds (30 minutes).

```
[
    {
        "classification": "presto-config",
        "properties": {
            "graceful-shutdown-timeout": "1800s"
        }
    }
]
```

Limitations

PrestoDB Graceful Decommission does not work on EMR clusters where HTTP connectivity is disabled, such as when `http-server.http.enabled` is set to `false`. Trino does not support Graceful Decommission at all, regardless of the `http-server.http.enabled` setting.

Considerations with Presto on Amazon EMR

Consider the following limitations when you run Presto on Amazon EMR.

Presto command line executable

In Amazon EMR, PrestoDB and Trino both use the same command line executable, `presto-cli`, as in the following example.

```
presto-cli --catalog hive
```

Non-configurable Presto deployment properties

The version of Amazon EMR that you use determines the Presto deployment configurations that are available. For more information about these configuration properties, see Deploying Presto in the Presto documentation. The following table shows the different configuration options for Presto `properties` files.

File	Configurable
`log.properties`	PrestoDB: Configurable in Amazon EMR versions 4.0.0 and later. Use the `presto-log` configuration classification. Trino (PrestoSQL): Configurable in Amazon EMR versions 6.1.0 and later. Use the `prestosql-log` or `trino-log` configuration classification.
`config.properties`	PrestoDB: Configurable in Amazon EMR versions 4.0.0 and later. Use the `presto-config` configuration classification. Trino (PrestoSQL): Configurable in Amazon EMR versions 6.1.0 and later. Use the `prestosql-config` or `trino-config` configuration classification.
`hive.properties`	PrestoDB: Configurable in Amazon EMR versions 4.1.0 and later. Use the `presto-connector-hive` configuration classification. Trino (PrestoSQL): Configurable in Amazon EMR versions 6.1.0 and later. Use the `prestosql-connector-hive` or `trino-connector-hive` configuration classification.
`node.properties`	PrestoDB: Configurable in Amazon EMR version 5.6.0 and later. Use the `presto-node` configuration classification. Trino (PrestoSQL): Configurable in Amazon EMR versions 6.1.0 and later. Use the `prestosql-node` or `trino-node` configuration classification.

File	Configurable
`jvm.config`	Not configurable.

PrestoDB and Trino installation

The application name *Presto* continues to be used to install PrestoDB on clusters. To install Trino on clusters, use the application name *Trino* (or *PrestoSQL* in older versions of Amazon EMR).

You can install either PrestoDB or Trino, but you can't install both on a single cluster. If you specify both PrestoDB and Trino when you attempt to create a cluster, a validation error occurs and the cluster creation request fails.

EMRFS and PrestoS3FileSystem configuration

With Amazon EMR versions 5.12.0 and later, PrestoDB can use EMRFS. This is the default configuration. EMRFS is also the default file system for Trino (PrestoSQL) in Amazon EMR versions 6.1.0 and later. For more information, see EMR File System (EMRFS) in the *Amazon EMR Management Guide*. With earlier versions of Amazon EMR, PrestoS3FileSystem is the only configuration option.

You can use a security configuration to set up encryption for EMRFS data in Amazon S3. You can also use IAM roles for EMRFS requests to Amazon S3. For more information, see Understanding encryption options and Configure IAM roles for EMRFS requests to Amazon S3 in the *Amazon EMR Management Guide*.

> **Note**
>
> If you query underlying data in Amazon S3 with Amazon EMR version 5.12.0, Presto errors can occur. This is because Presto fails to pick up configuration classification values from `emrfs-site.xml`. As a workaround, create an `emrfs` subdirectory under `usr/lib/presto/plugin/hive-hadoop2/` and create a symlink in `usr/lib/presto/plugin/hive-hadoop2/emrfs` to the existing `/usr/share/aws/emr/emrfs/conf/emrfs-site.xml` file. Then restart the presto-server process (`sudo presto-server stop` followed by `sudo presto-server start`).

You can override the EMRFS default and use the PrestoS3FileSystem instead. To do this, use the `presto-connector-hive` configuration classification to set `hive.s3-file-system-type` to PRESTO as shown in the following example. For more information, see [Configure applications](#).

```
[
   {
      "Classification": "presto-connector-hive",
      "Properties": {
         "hive.s3-file-system-type": "PRESTO"
      }
   }
]
```

If you use PrestoS3FileSystem, use the `presto-connector-hive` configuration classification or `trino-connector-hive` for Trino to configure PrestoS3FileSystem properties. For more information about available properties, see [Amazon S3 configuration](#) in the Hive Connector section of the Presto documentation. These settings do not apply to EMRFS.

Default setting for end user impersonation

By default, Amazon EMR versions 5.12.0 and later enable end user impersonation for access to HDFS. For more information, see [End user impersonation](#) in the Presto documentation. To change this setting with the `presto-config` configuration classification, set the `hive.hdfs.impersonation.enabled` property to `false`.

Default port for Presto web interface

By default, Amazon EMR configures the Presto web interface on the Presto coordinator to use port 8889 (for PrestoDB and Trino). To change the port, use the `presto-config` configuration classification to set the `http-server.http.port` property. For more information, see [Config properties](#) in the *Deploying Presto* section of Presto Documentation.

Issue with Hive Bucket execution in some releases

Presto version 152.3 has an issue with Hive bucket execution that causes significantly slower Presto query performance in some circumstances. Amazon EMR versions 5.0.3, 5.1.0, and 5.2.0 include this version of Presto. To mitigate this issue, use the `presto-connector-hive` configuration classification to set the `hive.bucket-execution` property to `false`, as shown in the following example.

```
[
   {
      "Classification": "presto-connector-hive",
      "Properties": {
         "hive.bucket-execution": "false"
      }
   }
]
```

Presto release history

The following table lists the version of Presto included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Trino (PrestoSQL) release notes by version

- Amazon EMR 6.9.0 - Trino (PrestoSQL) release notes

Amazon EMR 6.9.0 - Trino (PrestoSQL) release notes

Amazon EMR 6.9.0 - Trino (PrestoSQL) new features

- To support long running queries, Trino now includes a fault-tolerant execution mechanism. Fault-tolerant execution mitigates query failures by retrying failed queries or their component tasks. For more information, see Fault-tolerant execution in Trino.

Amazon EMR 6.9.0 - Trino (PrestoSQL) changes

Amazon EMR 6.9.0 - PrestoDB changes

Type	Description
Upgrade	PrestoDB upgrade to 0.276
Upgrade	Support for Hadoop 3.3.3

Type	Description
Upgrade	Hudi upgrade to 0.12.1
Feature	Amazon EMR and Presto integration with AWS Lake Formation for interactive workloads using GCSC API.
Feature	Added Kerberos-related configs inside Security Configs for PrestoDB to enable Keberos.
Bug fix	Reverted OSS pull request #18115 which was added to reduce the number of `hdfsConfiguration` copies. This caused the HDFS configuration copy incorrectly when using EMRFS or Hudi tables.

Amazon EMR 6.9.0 - Trino changes

Type	Description
Upgrade	Trino Upgrade to 398
Upgrade	Support for Hadoop 3.3.3
Feature	Tardigrade support: Add support for exchange spooling on HDFS and Amazon S3. For more information, see Fault-tolerant execution in Trino
Bug fix	When Trino Iceberg is used and Glue catalog is enabled, avoid adding metastore uri in `iceberg.properties.`

Amazon EMR 6.9.0 - Trino (PrestoSQL) known issues

- For Amazon EMR release 6.9.0, Trino does not work on clusters enabled for Apache Ranger. If you need to use Trino with Ranger, contact AWS Support.

Apache Spark

Apache Spark is a distributed processing framework and programming model that helps you do machine learning, stream processing, or graph analytics with Amazon EMR clusters. Similar to Apache Hadoop, Spark is an open-source, distributed processing system commonly used for big data workloads. However, Spark has several notable differences from Hadoop MapReduce. Spark has an optimized directed acyclic graph (DAG) execution engine and actively caches data in-memory, which can boost performance, especially for certain algorithms and interactive queries.

Spark natively supports applications written in Scala, Python, and Java. It also includes several tightly integrated libraries for SQL (Spark SQL), machine learning (MLlib), stream processing (Spark streaming), and graph processing (GraphX). These tools make it easier to leverage the Spark framework for a wide variety of use cases.

You can install Spark on an Amazon EMR cluster along with other Hadoop applications, and it can also leverage the Amazon EMR file system (EMRFS) to directly access data in Amazon S3. Hive is also integrated with Spark so that you can use a HiveContext object to run Hive scripts using Spark. A Hive context is included in the spark-shell as `sqlContext`.

For an example tutorial on setting up an EMR cluster with Spark and analyzing a sample data set, see Tutorial: Getting started with Amazon EMR on the AWS News blog.

Important

Apache Spark version 2.3.1, available beginning with Amazon EMR release 5.16.0, addresses CVE-2018-8024 and CVE-2018-1334. We recommend that you migrate earlier versions of Spark to Spark version 2.3.1 or later.

The following table lists the version of Spark included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Spark.

For the version of components installed with Spark in this release, see Release 7.2.0 Component Versions.

Spark version information for emr-7.2.0

Amazon EMR Release Label	Spark Version	Components Installed With Spark
emr-7.2.0	Spark 3.5.1	delta, emrfs, emr-goodies, emr-ddb, emr-s3-select, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, iceberg, livy-server, nginx, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave

The following table lists the version of Spark included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Spark.

For the version of components installed with Spark in this release, see Release 6.15.0 Component Versions.

Spark version information for emr-6.15.0

Amazon EMR Release Label	Spark Version	Components Installed With Spark
emr-6.15.0	Spark 3.4.1	aws-sagemaker-spark-sdk, delta, emrfs, emr-goodies, emr-ddb, emr-s3-select, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server,

Amazon EMR Release Label	Spark Version	Components Installed With Spark
		hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, iceberg, livy-server, nginx, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave

Note

Amazon EMR release 6.8.0 comes with Apache Spark 3.3.0. This Spark release uses Apache Log4j 2 and the `log4j2.properties` file to configure Log4j in Spark processes. If you use Spark in the cluster or create EMR clusters with custom configuration parameters, and you want to upgrade to Amazon EMR release 6.8.0, you must migrate to the new `spark-log4j2` configuration classification and key format for Apache Log4j 2. For more information, see Migrating from Apache Log4j 1.x to Log4j 2.x.

The following table lists the version of Spark included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Spark.

For the version of components installed with Spark in this release, see Release 5.36.2 Component Versions.

Spark version information for emr-5.36.2

Amazon EMR Release Label	Spark Version	Components Installed With Spark
emr-5.36.2	Spark 2.4.8	aws-sagemaker-spark-sdk, emrfs, emr-goodies, emr-ddb, emr-s3-select, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-

Amazon EMR Release Label	Spark Version	Components Installed With Spark
		hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, livy-server, nginx, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave

Topics

Create a cluster with Apache Spark

The following procedure creates a cluster with Spark installed using **Quick Options** in the Amazon EMR console.

You can alternatively use **Advanced Options** to further customize your cluster setup, or to submit steps to programmatically install applications and then run custom applications. With either cluster creation option, you can choose to use AWS Glue as your Spark SQL metastore. See Use the AWS Glue Data Catalog as the metastore for Spark SQL for more information.

To launch a cluster with Spark installed

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create cluster** to use **Quick Options**.
3. Enter a **Cluster name**. Your cluster name can't contain the characters <, >, $, |, or ` (backtick).
4. For **Software Configuration**, choose a **Release** option.
5. For **Applications**, choose the **Spark** application bundle.
6. Select other options as necessary and then choose **Create cluster**.

> **Note**
>
> To configure Spark when you are creating the cluster, see Configure Spark.

To launch a cluster with Spark installed using the AWS CLI

- Create the cluster with the following command.

```
aws emr create-cluster --name "Spark cluster" --release-label emr-7.2.0 --
applications Name=Spark \
--ec2-attributes KeyName=myKey --instance-type m5.xlarge --instance-count 3 --use-
default-roles
```

Note

Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

To launch a cluster with Spark installed using the SDK for Java

Specify Spark as an application with `SupportedProductConfig` used in `RunJobFlowRequest`.

- The following example shows how to create a cluster with Spark using Java.

```
import com.amazonaws.AmazonClientException;
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.elasticmapreduce.AmazonElasticMapReduce;
import com.amazonaws.services.elasticmapreduce.AmazonElasticMapReduceClientBuilder;
import com.amazonaws.services.elasticmapreduce.model.*;
import com.amazonaws.services.elasticmapreduce.util.StepFactory;

public class Main {

        public static void main(String[] args) {
                AWSCredentials credentials_profile = null;
                try {
                        credentials_profile = new
 ProfileCredentialsProvider("default").getCredentials();
                } catch (Exception e) {
                        throw new AmazonClientException(
                                        "Cannot load credentials from .aws/
credentials file. " +
                                                        "Make sure that the
 credentials file exists and the profile name is specified within it.",
                                        e);
                }

                AmazonElasticMapReduce emr =
 AmazonElasticMapReduceClientBuilder.standard()
                                .withCredentials(new
 AWSStaticCredentialsProvider(credentials_profile))
                                .withRegion(Regions.US_WEST_1)
```

```
                                .build();

                // create a step to enable debugging in the AWS Management Console
                StepFactory stepFactory = new StepFactory();
                StepConfig enabledebugging = new StepConfig()
                                .withName("Enable debugging")
                                .withActionOnFailure("TERMINATE_JOB_FLOW")

 .withHadoopJarStep(stepFactory.newEnableDebuggingStep());

                Application spark = new Application().withName("Spark");

                RunJobFlowRequest request = new RunJobFlowRequest()
                                .withName("Spark Cluster")
                                .withReleaseLabel("emr-5.20.0")
                                .withSteps(enabledebugging)
                                .withApplications(spark)
                                .withLogUri("s3://path/to/my/logs/")
                                .withServiceRole("EMR_DefaultRole")
                                .withJobFlowRole("EMR_EC2_DefaultRole")
                                .withInstances(new JobFlowInstancesConfig()
                                                .withEc2SubnetId("subnet-12ab3c45")
                                                .withEc2KeyName("myEc2Key")
                                                .withInstanceCount(3)

 .withKeepJobFlowAliveWhenNoSteps(true)
                                                .withMasterInstanceType("m4.large")

 .withSlaveInstanceType("m4.large"));
                RunJobFlowResult result = emr.runJobFlow(request);
                System.out.println("The cluster ID is " + result.toString());
        }
}
```

Run Spark applications with Docker on Amazon EMR 6.x

With Amazon EMR 6.0.0, Spark applications can use Docker containers to define their library dependencies, instead of installing dependencies on the individual Amazon EC2 instances in the cluster. To run Spark with Docker, you must first configure the Docker registry and define additional parameters when submitting a Spark application. For more information, see Configure Docker integration.

When the application is submitted, YARN invokes Docker to pull the specified Docker image and run the Spark application inside a Docker container. This allows you to easily define and isolate dependencies. It reduces the time for bootstrapping or preparing instances in the Amazon EMR cluster with the libraries needed for job execution.

Considerations when running Spark with Docker

When you run Spark with Docker, make sure the following prerequisites are met:

- The `docker` package and CLI are only installed on core and task nodes.
- On Amazon EMR 6.1.0 and later, you can alternatively install Docker on a primary node by using following commands.
  - ```
    sudo yum install -y docker
    sudo systemctl start docker
    ```
- The `spark-submit` command should always be run from a primary instance on the Amazon EMR cluster.
- The Docker registries used to resolve Docker images must be defined using the Classification API with the `container-executor` classification key to define additional parameters when launching the cluster:
  - `docker.trusted.registries`
  - `docker.privileged-containers.registries`
- To execute a Spark application in a Docker container, the following configuration options are necessary:
  - `YARN_CONTAINER_RUNTIME_TYPE=docker`
  - `YARN_CONTAINER_RUNTIME_DOCKER_IMAGE={DOCKER_IMAGE_NAME}`
- When using Amazon ECR to retrieve Docker images, you must configure the cluster to authenticate itself. To do so, you must use the following configuration option:
  - `YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG={DOCKER_CLIENT_CONFIG_PATH_ON_HDFS`
- In Amazon EMR 6.1.0 and later, you are not required to use the listed command `YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG={DOCKER_CLIENT_CONFIG_PATH_ON_HDFS` when the ECR auto authentication feature is enabled.
- Any Docker image used with Spark must have Java installed in the Docker image.

For more information about the prerequisites, see Configure Docker integration.
    ```

Creating a Docker image

Docker images are created using a Dockerfile, which defines the packages and configuration to include in the image. The following two example Dockerfiles use PySpark and SparkR.

PySpark Dockerfile

Docker images created from this Dockerfile include Python 3 and the NumPy Python package. This Dockerfile uses Amazon Linux 2 and the Amazon Corretto JDK 8.

```
FROM amazoncorretto:8

RUN yum -y update
RUN yum -y install yum-utils
RUN yum -y groupinstall development

RUN yum list python3*
RUN yum -y install python3 python3-dev python3-pip python3-virtualenv

RUN python -V
RUN python3 -V

ENV PYSPARK_DRIVER_PYTHON python3
ENV PYSPARK_PYTHON python3

RUN pip3 install --upgrade pip
RUN pip3 install numpy pandas

RUN python3 -c "import numpy as np"
```

SparkR Dockerfile

Docker images created from this Dockerfile include R and the randomForest CRAN package. This Dockerfile includes Amazon Linux 2 and the Amazon Corretto JDK 8.

```
FROM amazoncorretto:8

RUN java -version

RUN yum -y update
RUN amazon-linux-extras install R4
```

```
RUN yum -y install curl hostname

#setup R configs
RUN echo "r <- getOption('repos'); r['CRAN'] <- 'http://cran.us.r-project.org';
 options(repos = r);" > ~/.Rprofile

RUN Rscript -e "install.packages('randomForest')"
```

For more information on Dockerfile syntax, see the Dockerfile reference documentation.

Using Docker images from Amazon ECR

Amazon Elastic Container Registry (Amazon ECR) is a fully-managed Docker container registry, which makes it easy to store, manage, and deploy Docker container images. When using Amazon ECR, the cluster must be configured to trust your instance of ECR, and you must configure authentication in order for the cluster to use Docker images from Amazon ECR. For more information, see Configuring YARN to access Amazon ECR.

To make sure that Amazon EMR hosts can access the images stored in Amazon ECR, your cluster must have the permissions from the `AmazonEC2ContainerRegistryReadOnly` policy associated with the instance profile. For more information, see `AmazonEC2ContainerRegistryReadOnly` Policy.

In this example, the cluster must be created with the following additional configuration to ensure that the Amazon ECR registry is trusted. Replace the *`123456789123.dkr.ecr.us-east-1.amazonaws.com`* endpoint with your Amazon ECR endpoint.

```
[
  {
    "Classification": "container-executor",
    "Configurations": [
      {
        "Classification": "docker",
        "Properties": {
          "docker.privileged-containers.registries":
 "local,centos,123456789123.dkr.ecr.us-east-1.amazonaws.com",
          "docker.trusted.registries": "local,centos,123456789123.dkr.ecr.us-
east-1.amazonaws.com"
        }
      }
    ],
```

```
    "Properties": {}
  }
]
```

Using PySpark with Amazon ECR

The following example uses the PySpark Dockerfile, which will be tagged and uploaded to Amazon ECR. After you upload the Dockerfile, you can run the PySpark job and refer to the Docker image from Amazon ECR.

After you launch the cluster, use SSH to connect to a core node and run the following commands to build the local Docker image from the PySpark Dockerfile example.

First, create a directory and a Dockerfile.

```
mkdir pyspark
vi pyspark/Dockerfile
```

Paste the contents of the PySpark Dockerfile and run the following commands to build a Docker image.

```
sudo docker build -t local/pyspark-example pyspark/
```

Create the `emr-docker-examples` ECR repository for the examples.

```
aws ecr create-repository --repository-name emr-docker-examples
```

Tag and upload the locally built image to ECR, replacing *`123456789123.dkr.ecr.us-east-1.amazonaws.com`* with your ECR endpoint.

```
sudo docker tag local/pyspark-example 123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-examples:pyspark-example
sudo docker push 123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-examples:pyspark-example
```

Use SSH to connect to the primary node and prepare a Python script with the filename `main.py`. Paste the following content into the `main.py` file and save it.

```
from pyspark.sql import SparkSession
spark = SparkSession.builder.appName("docker-numpy").getOrCreate()
```

```
sc = spark.sparkContext

import numpy as np
a = np.arange(15).reshape(3, 5)
print(a)
```

On Amazon EMR 6.0.0, to submit the job, reference the name of the Docker image. Define the additional configuration parameters to make sure that the job execution uses Docker as the runtime. When using Amazon ECR, the `YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG` must reference the `config.json` file containing the credentials used to authenticate to Amazon ECR.

```
DOCKER_IMAGE_NAME=123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-
examples:pyspark-example
DOCKER_CLIENT_CONFIG=hdfs:///user/hadoop/config.json
spark-submit --master yarn \
--deploy-mode cluster \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG=
$DOCKER_CLIENT_CONFIG \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG=
$DOCKER_CLIENT_CONFIG \
--num-executors 2 \
main.py -v
```

On Amazon EMR 6.1.0 and later, to submit the job, reference the name of the Docker image. When ECR auto authentication is enabled, run the following command.

```
DOCKER_IMAGE_NAME=123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-
examples:pyspark-example
spark-submit --master yarn \
--deploy-mode cluster \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--num-executors 2 \
main.py -v
```

When the job completes, take note of the YARN application ID, and use the following command to obtain the output of the PySpark job.

```
yarn logs --applicationId application_id | grep -C2 '\[\['
LogLength:55
LogContents:
[[ 0  1  2  3  4]
 [ 5  6  7  8  9]
 [10 11 12 13 14]]
```

Using SparkR with Amazon ECR

The following example uses the SparkR Dockerfile, which will be tagged and uploaded to ECR. Once the Dockerfile is uploaded, you can run the SparkR job and refer to the Docker image from Amazon ECR.

After you launch the cluster, use SSH to connect to a core node and run the following commands to build the local Docker image from the SparkR Dockerfile example.

First, create a directory and the Dockerfile.

```
mkdir sparkr
vi sparkr/Dockerfile
```

Paste the contents of the SparkR Dockerfile and run the following commands to build a Docker image.

```
sudo docker build -t local/sparkr-example sparkr/
```

Tag and upload the locally built image to Amazon ECR, replacing *123456789123.dkr.ecr.us-east-1.amazonaws.com* with your Amazon ECR endpoint.

```
sudo docker tag local/sparkr-example 123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-examples:sparkr-example
sudo docker push 123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-examples:sparkr-example
```

Use SSH to connect to the primary node and prepare an R script with the name `sparkR.R`. Paste the following contents into the `sparkR.R` file.

```
library(SparkR)
sparkR.session(appName = "R with Spark example", sparkConfig =
 list(spark.some.config.option = "some-value"))

sqlContext <- sparkRSQL.init(spark.sparkContext)
library(randomForest)
# check release notes of randomForest
rfNews()

sparkR.session.stop()
```

On Amazon EMR 6.0.0, to submit the job, refer to the name of the Docker image. Define the additional configuration parameters to make sure that the job execution uses Docker as the runtime. When using Amazon ECR, the `YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG` must refer to the `config.json` file containing the credentials used to authenticate to ECR.

```
DOCKER_IMAGE_NAME=123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-
examples:sparkr-example
DOCKER_CLIENT_CONFIG=hdfs:///user/hadoop/config.json
spark-submit --master yarn \
--deploy-mode cluster \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG=
$DOCKER_CLIENT_CONFIG \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_DOCKER_CLIENT_CONFIG=
$DOCKER_CLIENT_CONFIG \
sparkR.R
```

On Amazon EMR 6.1.0 and later, to submit the job, reference the name of the Docker image. When ECR auto authentication is enabled, run following command.

```
DOCKER_IMAGE_NAME=123456789123.dkr.ecr.us-east-1.amazonaws.com/emr-docker-
examples:sparkr-example
spark-submit --master yarn \
--deploy-mode cluster \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
--conf spark.executorEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_TYPE=docker \
```

```
--conf spark.yarn.appMasterEnv.YARN_CONTAINER_RUNTIME_DOCKER_IMAGE=$DOCKER_IMAGE_NAME \
sparkR.R
```

When the job has completed, note the YARN application ID, and use the following command to obtain the output of the SparkR job. This example includes testing to make sure that the randomForest library, version installed, and release notes are available.

```
yarn logs --applicationId application_id | grep -B4 -A10 "Type rfNews"
randomForest 4.6-14
Type rfNews() to see new features/changes/bug fixes.
Wishlist (formerly TODO):

* Implement the new scheme of handling classwt in classification.

* Use more compact storage of proximity matrix.

* Allow case weights by using the weights in sampling?

========================================================================
Changes in 4.6-14:
```

Use the AWS Glue Data Catalog as the metastore for Spark SQL

Using Amazon EMR release 5.8.0 or later, you can configure Spark SQL to use the AWS Glue Data Catalog as its metastore. We recommend this configuration when you require a persistent metastore or a metastore shared by different clusters, services, applications, or AWS accounts.

AWS Glue is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores. The AWS Glue Data Catalog provides a unified metadata repository across a variety of data sources and data formats, integrating with Amazon EMR as well as Amazon RDS, Amazon Redshift, Redshift Spectrum, Athena, and any application compatible with the Apache Hive metastore. AWS Glue crawlers can automatically infer schema from source data in Amazon S3 and store the associated metadata in the Data Catalog. For more information about the Data Catalog, see Populating the AWS Glue Data Catalog in the *AWS Glue Developer Guide*.

Separate charges apply for AWS Glue. There is a monthly rate for storing and accessing the metadata in the Data Catalog, an hourly rate billed per minute for AWS Glue ETL jobs and crawler runtime, and an hourly rate billed per minute for each provisioned development endpoint. The

Data Catalog allows you to store up to a million objects at no charge. If you store more than a million objects, you are charged USD$1 for each 100,000 objects over a million. An object in the Data Catalog is a table, partition, or database. For more information, see Glue Pricing.

> **Important**
>
> If you created tables using Amazon Athena or Amazon Redshift Spectrum before August 14, 2017, databases and tables are stored in an Athena-managed catalog, which is separate from the AWS Glue Data Catalog. To integrate Amazon EMR with these tables, you must upgrade to the AWS Glue Data Catalog. For more information, see Upgrading to the AWS Glue Data Catalog in the *Amazon Athena User Guide*.

Specifying AWS Glue Data Catalog as the metastore

You can specify the AWS Glue Data Catalog as the metastore using the AWS Management Console, AWS CLI, or Amazon EMR API. When you use the CLI or API, you use the configuration classification for Spark to specify the Data Catalog. In addition, with Amazon EMR 5.16.0 and later, you can use the configuration classification to specify a Data Catalog in a different AWS account. When you use the console, you can specify the Data Catalog using **Advanced Options** or **Quick Options**.

> **Note**
>
> The option to use AWS Glue Data Catalog is also available with Zeppelin because Zeppelin is installed with Spark SQL components.

Console

To specify AWS Glue Data Catalog as the Spark metastore with the new console

1. Sign in to the AWS Management Console, and open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Under **Amazon EMR on EC2** in the left navigation pane, choose **Clusters**, and then choose **Create cluster**.
3. Under **Application bundle**, choose **Spark** or **Custom**. If you customize your cluster, make sure that you select Zeppelin or Spark as one of your applications.

4. Under **AWS Glue Data Catalog settings**, select the **Use for Spark table metadata** check box.
5. Choose any other options that apply to your cluster.
6. To launch your cluster, choose **Create cluster**.

AWS CLI

To specify the AWS Glue Data Catalog as the Spark metastore with the AWS CLI

For more information about specifying a configuration classification using the AWS CLI and Amazon EMR API, see Configure applications.

- Specify the value for `hive.metastore.client.factory.class` using the `spark-hive-site` classification as shown in the following example:

```
[
  {
    "Classification": "spark-hive-site",
    "Properties": {
      "hive.metastore.client.factory.class":
 "com.amazonaws.glue.catalog.metastore.AWSGlueDataCatalogHiveClientFactory"
    }
  }
]
```

To specify a Data Catalog in a different AWS account, add the `hive.metastore.glue.catalogid` property as shown in the following example. Replace *`acct-id`* with the AWS account of the Data Catalog.

```
[
  {
    "Classification": "spark-hive-site",
    "Properties": {
      "hive.metastore.client.factory.class":
 "com.amazonaws.glue.catalog.metastore.AWSGlueDataCatalogHiveClientFactory",
      "hive.metastore.glue.catalogid": "acct-id"
    }
  }
]
```

IAM permissions

The EC2 instance profile for a cluster must have IAM permissions for AWS Glue actions. In addition, if you enable encryption for AWS Glue Data Catalog objects, the role must also be allowed to encrypt, decrypt and generate the AWS KMS key used for encryption.

Permissions for AWS Glue actions

If you use the default EC2 instance profile for Amazon EMR, no action is required. The `AmazonElasticMapReduceforEC2Role` managed policy that is attached to the `EMR_EC2_DefaultRole` allows all necessary AWS Glue actions. However, if you specify a custom EC2 instance profile and permissions, you must configure the appropriate AWS Glue actions. Use the `AmazonElasticMapReduceforEC2Role` managed policy as a starting point. For more information, see Service role for cluster EC2 instances (EC2 instance profile) in the *Amazon EMR Management Guide*.

Permissions for encrypting and decrypting AWS Glue Data Catalog

Your instance profile needs permission to encrypt and decrypt data using your key. You do *not* need to configure these permissions if both of the following statements apply:

- You enable encryption for AWS Glue Data Catalog objects using managed keys for AWS Glue.
- You use a cluster that's in the same AWS account as the AWS Glue Data Catalog.

Otherwise, you must add the following statement to the permissions policy attached to your EC2 instance profile.

```
[
    {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Action": [
                    "kms:Decrypt",
                    "kms:Encrypt",
                    "kms:GenerateDataKey"
```

```
                ],
                "Resource": "arn:aws:kms:region:acct-
id:key/12345678-1234-1234-1234-123456789012"
            }
        ]
    }
]
```

For more information about AWS Glue Data Catalog encryption, see Encrypting your data catalog in the *AWS Glue Developer Guide*.

Resource-based permissions

If you use AWS Glue in conjunction with Hive, Spark, or Presto in Amazon EMR, AWS Glue supports resource-based policies to control access to Data Catalog resources. These resources include databases, tables, connections, and user-defined functions. For more information, see AWS Glue Resource Policies in the *AWS Glue Developer Guide*.

When using resource-based policies to limit access to AWS Glue from within Amazon EMR, the principal that you specify in the permissions policy must be the role ARN associated with the EC2 instance profile that is specified when a cluster is created. For example, for a resource-based policy attached to a catalog, you can specify the role ARN for the default service role for cluster EC2 instances, *EMR_EC2_DefaultRole* as the `Principal`, using the format shown in the following example:

```
arn:aws:iam::acct-id:role/EMR_EC2_DefaultRole
```

The *acct-id* can be different from the AWS Glue account ID. This enables access from EMR clusters in different accounts. You can specify multiple principals, each from a different account.

Considerations when using AWS Glue Data Catalog

Consider the following items when using AWS Glue Data Catalog as a metastore with Spark:

- Having a default database without a location URI causes failures when you create a table. As a workaround, use the `LOCATION` clause to specify a bucket location, such as `s3://EXAMPLE-DOC-BUCKET`, when you use `CREATE TABLE`. Alternatively create tables within a database other than the default database.
- Renaming tables from within AWS Glue is not supported.

- When you create a Hive table without specifying a LOCATION, the table data is stored in the location specified by the hive.metastore.warehouse.dir property. By default, this is a location in HDFS. If another cluster needs to access the table, it fails unless it has adequate permissions to the cluster that created the table. Furthermore, because HDFS storage is transient, if the cluster terminates, the table data is lost, and the table must be recreated. We recommend that you specify a LOCATION in Amazon S3 when you create a Hive table using AWS Glue. Alternatively, you can use the hive-site configuration classification to specify a location in Amazon S3 for hive.metastore.warehouse.dir, which applies to all Hive tables. If a table is created in an HDFS location and the cluster that created it is still running, you can update the table location to Amazon S3 from within AWS Glue. For more information, see Working with Tables on the AWS Glue Console in the *AWS Glue Developer Guide*.
- Partition values containing quotes and apostrophes are not supported, for example, PARTITION (owner="Doe's").
- Column statistics are supported for emr-5.31.0 and later.
- Using Hive authorization is not supported. As an alternative, consider using AWS Glue Resource-Based Policies. For more information, see Use Resource-Based Policies for Amazon EMR Access to AWS Glue Data Catalog.

Configure Spark

You can configure Spark on Amazon EMR with configuration classifications. For more information about configuration classifications, see Configure applications.

Configuration classifications for Spark on Amazon EMR include the following:

- **spark** – Sets the maximizeResourceAllocation property to true or false. When true, Amazon EMR automatically configures spark-defaults properties based on cluster hardware configuration. For more information, see Using maximizeResourceAllocation.
- **spark-defaults** – Sets values in the spark-defaults.conf file. For more information, see Spark configuration in the Spark documentation.
- **spark-env** – Sets values in the spark-env.sh file. For more information, see Environment variables in the Spark documentation.
- **spark-hive-site** – Sets values in the hive-site.xml for Spark.
- **spark-log4j** – (Amazon EMR releases 6.7.x and lower) Sets values in the log4j.properties file. For more information, see the log4j.properties.template file on Github.

- **spark-log4j2** – (Amazon EMR releases 6.8.0 and higher) Sets values in the `log4j2.properties` file. For more information, see the log4j2.properties.template file on Github.
- **spark-metrics** – Sets values in the `metrics.properties` file. For settings and more information, see the metrics.properties.template file on Github, and Metrics in Spark documentation.

> **Note**
>
> If you're migrating Spark workloads to Amazon EMR from another platform, we recommend that you test your workloads with the Spark defaults set by Amazon EMR before you add custom configurations. Most customers see improved performance with our default settings.

Topics

Spark defaults set by Amazon EMR

The following table shows how Amazon EMR sets default values in `spark-defaults` that affect applications.

Spark defaults set by Amazon EMR

Setting	Description	Default value
`spark.executor.memory`	The amount of memory to use per executor process. For example: 1g, 2g.	This setting is determined by the core and task instance types in the cluster.
`spark.executor.cores`	The number of cores to use on each executor.	This setting is determined by the core and task instance types in the cluster.
`spark.dynamicAllocation.enabled`	When true, use dynamic resource allocation to scale the number of executors registered with an application up and down based on the workload.	`true` (with Amazon EMR 4.4.0 and higher) **Note** Spark shuffle service is automatically configured by Amazon EMR .
`spark.sql.hive.advancedPartitionPredicatePushdown.enabled`	When true, advanced partition predicate pushdown into Hive metastore is enabled.	`true`
`spark.sql.hive.stringLikePartitionPredicatePushdown.enabled`	Pushes down `startsWith` , `contains`, and `endsWith` filters into Hive metastore. **Note** Glue doesn't support predicate push down for `startsWith` , `contains`, or `endsWith`. If you are	`true`

Setting	Description	Default value
	using Glue metastore and you encounter errors due to the predicate pushdown for these functions, set this configuration to `false`.	

Configuring Spark garbage collection on Amazon EMR 6.1.0

Setting custom garbage collection configurations with `spark.driver.extraJavaOptions` and `spark.executor.extraJavaOptions` results in driver or executor launch failure with Amazon EMR 6.1 because of a conflicting garbage collection configuration with Amazon EMR 6.1.0. For Amazon EMR 6.1.0, the default garbage collection configuration is set through `spark.driver.defaultJavaOptions` and `spark.executor.defaultJavaOptions`. This configuration applies only to Amazon EMR 6.1.0. JVM options not related to garbage collection, such as those for configuring logging (`-verbose:class`), can still be set through `extraJavaOptions`. For more information, see Spark application properties.

Using `maximizeResourceAllocation`

To configure your executors to use the maximum resources possible on each node in a cluster, set `maximizeResourceAllocation` to `true` in your `spark` configuration classification. The `maximizeResourceAllocation` is specific to Amazon EMR . When you enable `maximizeResourceAllocation`, Amazon EMR calculates the maximum compute and memory resources available for an executor on an instance in the core instance group. It then sets the corresponding `spark-defaults` settings based on the calculated maximum values.

Amazon EMR calculates the maximum compute and memory resources available for an executor based on an instance type from the core instance fleet. Since each instance fleet can have different instance types and sizes within a fleet, the executor configuration that Amazon EMR uses might not be the best for your clusters, so we don't recommend using the default settings when using maximum resource allocation. Configure custom settings for your instance fleet clusters.

> **Note**
>
> You should not use the `maximizeResourceAllocation` option on clusters with other distributed applications like HBase. Amazon EMR uses custom YARN configurations for distributed applications, which can conflict with `maximizeResourceAllocation` and cause Spark applications to fail.

The following is an example Spark configuration classification with `maximizeResourceAllocation` set to `true`.

```
[
  {
    "Classification": "spark",
    "Properties": {
      "maximizeResourceAllocation": "true"
    }
  }
]
```

Settings configured in `spark-defaults` when `maximizeResourceAllocation` is enabled

Setting	Description	Value
spark.default.parallelism	Default number of partition s in RDDs returned by transformations like join, reduceByKey, and parallelize when not set by user.	2X number of CPU cores available to YARN containers.
spark.driver.memory	Amount of memory to use for the driver process, i.e. where SparkContext is initialized. (for example, 1g, 2g).	Setting is configured based on the instance types in the cluster. However, because the Spark driver application may run on either the primary or one of the core instances (for example, in YARN client and cluster modes, respectiv ely), this is set based on the

Setting	Description	Value
		smaller of the instance types in these two instance groups.
spark.executor.memory	Amount of memory to use per executor process. (for example, 1g, 2g)	Setting is configured based on the core and task instance types in the cluster.
spark.executor.cores	The number of cores to use on each executor.	Setting is configured based on the core and task instance types in the cluster.
spark.executor.instances	The number of executors.	Setting is configured based on the core and task instance types in the cluster. Set unless `spark.dynamicAllocation.enabled` explicitly set to true at the same time.

Configuring node decommissioning behavior

With Amazon EMR release 5.9.0 and higher, Spark on Amazon EMR includes a set of features to help ensure that Spark gracefully handles node termination because of a manual resize or an automatic scaling policy request. Amazon EMR implements a deny listing mechanism in Spark that is built on top of the YARN decommissioning mechanism. This mechanism helps ensure that no new tasks are scheduled on a node that is decommissioning, while at the same time allowing tasks that are already running to complete. In addition, there are features to help recover Spark jobs faster if shuffle blocks are lost when a node terminates. The recomputation process is triggered sooner and optimized to recompute faster with fewer stage retries, and jobs can be prevented from failing because of fetch failures that are caused by missing shuffle blocks.

> **Important**
>
> The `spark.decommissioning.timeout.threshold` setting was added in Amazon EMR release 5.11.0 to improve Spark resiliency when you use Spot instances. In earlier releases, when a node uses a Spot instance, and the instance is terminated because of bid price, Spark may not be able to handle the termination gracefully. Jobs may fail, and shuffle

recomputations could take a significant amount of time. For this reason, we recommend using release 5.11.0 or later if you use Spot instances.

Spark node decommissioning settings

Setting	Description	Default value
`spark.blacklist.decommissioning.enabled`	When set to `true`, Spark deny lists nodes that are in the `decommissioning` state in YARN. Spark does not schedule new tasks on executors running on that node. Tasks already running are allowed to complete.	`true`
`spark.blacklist.decommissioning.timeout`	The amount of time that a node in the `decommissioning` state is deny listed. By default, this value is set to one hour, which is also the default for `yarn.resourcemanager.decommissioning.timeout`. To ensure that a node is deny listed for its entire decommissioning period, set this value equal to or greater than `yarn.resourcemanager.decommissioning.timeout`. After the decommissioning timeout expires, the node transitions to a `decommissioned` state, and Amazon EMR can terminate the node's	`1h`

Setting	Description	Default value
	EC2 instance. If any tasks are still running after the timeout expires, they are lost or killed and rescheduled on executors running on other nodes.	
`spark.decommissioning.timeout.threshold`	Available in Amazon EMR release 5.11.0 or later. Specified in seconds. When a node transitions to the decommissioning state, if the host will decommission within a time period equal to or less than this value, Amazon EMR not only deny lists the node, but also cleans up the host state (as specified by `spark.resourceManager.cleanupExpiredHost`) without waiting for the node to transition to a decommissioned state. This allows Spark to handle Spot instance terminations better because Spot instances decommission within a 20-second timeout regardless of the value of `yarn.resourcemager.decommissioning.timeout` , which may not provide other nodes enough time to read shuffle files.	`20s`

Setting	Description	Default value
spark.resourceManager.cleanupExpiredHost	When set to true, Spark unregisters all cached data and shuffle blocks that are stored in executors on nodes that are in the decommissioned state. This speeds up the recovery process.	true
spark.stage.attempt.ignoreOnDecommissionFetchFailure	When set to true, helps prevent Spark from failing stages and eventually failing the job because of too many failed fetches from decommissioned nodes. Failed fetches of shuffle blocks from a node in the decommissioned state will not count toward the maximum number of consecutive fetch failures.	true

Spark ThriftServer environment variable

Spark sets the Hive Thrift Server Port environment variable, HIVE_SERVER2_THRIFT_PORT, to 10001.

Changing Spark default settings

You change the defaults in spark-defaults.conf using the spark-defaults configuration classification or the maximizeResourceAllocation setting in the spark configuration classification.

The following procedures show how to modify settings using the CLI or console.

To create a cluster with spark.executor.memory set to 2g using the CLI

- Create a cluster with Spark installed and `spark.executor.memory` set to 2g, using the following command, which references a file, `myConfig.json` stored in Amazon S3.

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=Spark \
--instance-type m5.xlarge --instance-count 2 --service-role EMR_DefaultRole_V2
 --ec2-attributes InstanceProfile=EMR_EC2_DefaultRole --configurations https://
s3.amazonaws.com/mybucket/myfolder/myConfig.json
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

`myConfig.json`:

```
[
    {
      "Classification": "spark-defaults",
      "Properties": {
        "spark.executor.memory": "2G"
      }
    }
  ]
```

To create a cluster with spark.executor.memory set to 2g using the console

1. Navigate to the new Amazon EMR console and select **Switch to the old console** from the side navigation. For more information on what to expect when you switch to the old console, see Using the old console.
2. Choose **Create cluster**, **Go to advanced options**.
3. Choose **Spark**.
4. Under **Edit software settings**, leave **Enter configuration** selected and enter the following configuration:

```
classification=spark-defaults,properties=[spark.executor.memory=2G]
```

5. Select other options, choose and then choose **Create cluster**.

To set maximizeResourceAllocation

- Create a cluster with Spark installed and `maximizeResourceAllocation` set to true using the AWS CLI, referencing a file, `myConfig.json`, stored in Amazon S3.

```
aws emr create-cluster --release-label emr-7.2.0 --applications Name=Spark \
--instance-type m5.xlarge --instance-count 2 --service-role EMR_DefaultRole_V2
 --ec2-attributes InstanceProfile=EMR_EC2_DefaultRole --configurations https://
s3.amazonaws.com/mybucket/myfolder/myConfig.json
```

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

`myConfig.json`:

```
[
  {
    "Classification": "spark",
    "Properties": {
      "maximizeResourceAllocation": "true"
    }
  }
]
```

> **Note**
>
> With Amazon EMR version 5.21.0 and later, you can override cluster configurations and specify additional configuration classifications for each instance group in a running cluster. You do this by using the Amazon EMR console, the AWS Command Line Interface (AWS

CLI), or the AWS SDK. For more information, see Supplying a Configuration for an Instance Group in a Running Cluster.

Migrating from Apache Log4j 1.x to Log4j 2.x

Apache Spark releases 3.2.x and earlier use the legacy Apache Log4j 1.x and the `log4j.properties` file to configure Log4j in Spark processes. Apache Spark releases 3.3.0 and later use Apache Log4j 2.x and the `log4j2.properties` file to configure Log4j in Spark processes.

If you have configured Apache Spark Log4j using an Amazon EMR release lower than 6.8.0, then you must remove the legacy `spark-log4j` configuration classification and migrate to the `spark-log4j2` configuration classification and key format before you can upgrade to Amazon EMR 6.8.0 or later. The legacy `spark-log4j` classification causes cluster creation to fail with a `ValidationException` error in Amazon EMR releases 6.8.0 and later. You will not be charged for a failure related to the Log4j incompatibility, but you must remove the defunct `spark-log4j` configuration classification to continue.

For more information about migrating from Apache Log4j 1.x to Log4j 2.x, see the Apache Log4j Migration Guide and the Spark Log4j 2 Template on Github.

> **Note**
>
> With Amazon EMR , Apache Spark uses a `log4j2.properties` file rather than the .xml file described in the Apache Log4j Migration Guide. Also, we do not recommend using the Log4j 1.x bridge method to convert to Log4j 2.x.

Optimize Spark performance

Amazon EMR provides multiple performance optimization features for Spark. This topic explains each optimization feature in detail.

For more information on how to set Spark configuration, see Configure Spark.

Adaptive query execution

Adaptive query execution is a framework for reoptimizing query plans based on runtime statistics. Starting with Amazon EMR 5.30.0, the following adaptive query execution optimizations from Apache Spark 3 are available on Apache Amazon EMR Runtime for Spark 2.

- Adaptive join conversion
- Adaptive coalescing of shuffle partitions

Adaptive Join Conversion

Adaptive join conversion improves query performance by converting sort-merge-join operations to broadcast-hash-joins operations based on runtime sizes of query stages. Broadcast-hash-joins tend to perform better when one side of the join is small enough to efficiently broadcast its output across all executors, thereby avoiding the need to shuffle exchange and sort both sides of the join. Adaptive join conversion broadens the range of cases when Spark automatically performs broadcast-hash-joins.

This feature is enabled by default. It can be disabled by setting `spark.sql.adaptive.enabled` to `false`, which also disables the adaptive query execution framework. Spark decides to convert a sort-merge-join to a broadcast-hash-join when the runtime size statistic of one of the join sides does not exceed `spark.sql.autoBroadcastJoinThreshold`, which defaults to 10,485,760 bytes (10 MiB).

Adaptive Coalescing of Shuffle Partitions

Adaptive coalescing of shuffle partitions improves query performance by coalescing small contiguous shuffle partitions to avoid the overhead of having too many small tasks. This allows you to configure a higher number of initial shuffle partitions upfront that then gets reduced at runtime to a targeted size, improving the chances of having more evenly distributed shuffle partitions.

This feature is enabled by default unless `spark.sql.shuffle.partitions` is explicitly set. It can be enabled by setting `spark.sql.adaptive.coalescePartitions.enabled` to `true`. Both the initial number of shuffle partitions and target partition size can be tuned using the `spark.sql.adaptive.coalescePartitions.minPartitionNum` and `spark.sql.adaptive.advisoryPartitionSizeInBytes` properties respectively. See the following table for further details on the related Spark properties for this feature.

Spark adaptive coalesce partition properties

Property	Default value	Description
`spark.sql.adaptive.coalescePartitions.enabled`	true, unless `spark.sql.shuffle.partitions` is explicitly set	When true and spark.sql.adaptive.enabled is true, Spark coalesces contiguous shuffle partitions according to the target size (specified by `spark.sql.adaptive.advisoryPartitionSizeInBytes`), to avoid too many small tasks.
`spark.sql.adaptive.advisoryPartitionSizeInBytes`	64MB	The advisory size in bytes of the shuffle partition when coalescing. This configuration only has an effect when `spark.sql.adaptive.enabled` and `spark.sql.adaptive.coalescePartitions.enabled` are both `true`.
`spark.sql.adaptive.coalescePartitions.minPartitionNum`	25	The minimum number of shuffle partitions after coalescing. This configuration only has an effect when `spark.sql.adaptive.enabled` and `spark.sql.adaptive.coalescePartitions.enabled` are both `true`.
`spark.sql.adaptive.coalescePartitions.initialPartitionNum`	1000	The initial number of shuffle partitions before coalescing. This configuration only has an effect when `spark.sql`

Property	Default value	Description
		.adaptive.enabled and spark.sql.adaptive .coalescePartition s.enabled are both true.

Dynamic partition pruning

Dynamic partition pruning improves job performance by more accurately selecting the specific partitions within a table that need to be read and processed for a specific query. By reducing the amount of data read and processed, significant time is saved in job execution. With Amazon EMR 5.26.0, this feature is enabled by default. With Amazon EMR 5.24.0 and 5.25.0, you can enable this feature by setting the Spark property `spark.sql.dynamicPartitionPruning.enabled` from within Spark or when creating clusters.

Spark dynamic partition pruning partition properties

Property	Default Value	Description
`spark.sql.dynamicPartitionPruning.enabled`	`true`	When true, enable dynamic partition pruning.
`spark.sql.optimizer.dynamicPartitionPruning.enforceBroadcastReuse`	`true`	When `true`, Spark performs a defensive check before query execution to ensure that reuse of broadcast exchanges in dynamic pruning filters is not broken by later preparation rules, such as user-defined columnar rules. When reuse is broken and this config is `true`, Spark removes the affected dynamic pruning filters to guard against performance and correctness issues. Correctness issues

Property	Default Value	Description
		may arise when the broadcast exchange of the dynamic pruning filter yields different , inconsistent results from the broadcast exchange of the corresponding join operation . Setting this configuration to `false` should be done with caution; it allows working around scenarios, such as when reuse is broken by user-defined columnar rules. When Adaptive Query Execution is enabled, broadcast reuse is always enforced.

This optimization improves upon the existing capabilities of Spark 2.4.2, which only supports pushing down static predicates that can be resolved at plan time.

The following are examples of static predicate push down in Spark 2.4.2.

```
partition_col = 5

partition_col IN (1,3,5)

partition_col between 1 and 3

partition_col = 1 + 3
```

Dynamic partition pruning allows the Spark engine to dynamically infer at runtime which partitions need to be read and which can be safely eliminated. For example, the following query involves two tables: the `store_sales` table that contains all of the total sales for all stores and is partitioned by region, and the `store_regions` table that contains a mapping of regions for each country. The tables contain data about stores distributed around the globe, but we are only querying data for North America.

```
select ss.quarter, ss.region, ss.store, ss.total_sales
from store_sales ss, store_regions sr
where ss.region = sr.region and sr.country = 'North America'
```

Without dynamic partition pruning, this query will read all regions before filtering out the subset of regions that match the results of the subquery. With dynamic partition pruning, this query will read and process only the partitions for the regions returned in the subquery. This saves time and resources by reading less data from storage and processing less records.

Flattening scalar subqueries

This optimization improves the performance of queries that have scalar subqueries over the same table. With Amazon EMR 5.26.0, this feature is enabled by default. With Amazon EMR 5.24.0 and 5.25.0, you can enable it by setting the Spark property `spark.sql.optimizer.flattenScalarSubqueriesWithAggregates.enabled` from within Spark or when creating clusters. When this property is set to true, the query optimizer flattens aggregate scalar subqueries that use the same relation if possible. The scalar subqueries are flattened by pushing any predicates present in the subquery into the aggregate functions and then performing one aggregation, with all the aggregate functions, per relation.

Following is a sample of a query that will benefit from this optimization.

```
select (select avg(age) from students                    /* Subquery 1 */
                 where age between 5 and 10) as group1,
       (select avg(age) from students                    /* Subquery 2 */
                 where age between 10 and 15) as group2,
       (select avg(age) from students                    /* Subquery 3 */
                 where age between 15 and 20) as group3
```

The optimization rewrites the previous query as:

```
select c1 as group1, c2 as group2, c3 as group3
from (select avg (if(age between 5 and 10, age, null)) as c1,
             avg (if(age between 10 and 15, age, null)) as c2,
             avg (if(age between 15 and 20, age, null)) as c3 from students);
```

Notice that the rewritten query reads the student table only once, and the predicates of the three subqueries are pushed into the `avg` function.

DISTINCT before INTERSECT

This optimization optimizes joins when using INTERSECT. With Amazon EMR 5.26.0, this feature is enabled by default. With Amazon EMR 5.24.0 and 5.25.0, you can enable it by setting the Spark property `spark.sql.optimizer.distinctBeforeIntersect.enabled` from within Spark or when creating clusters. Queries using INTERSECT are automatically converted to use a left-semi join. When this property is set to true, the query optimizer pushes the DISTINCT operator to the children of INTERSECT if it detects that the DISTINCT operator can make the left-semi join a BroadcastHashJoin instead of a SortMergeJoin.

Following is a sample of a query that will benefit from this optimization.

```
(select item.brand brand from store_sales, item
     where store_sales.item_id = item.item_id)
intersect
(select item.brand cs_brand from catalog_sales, item
     where catalog_sales.item_id = item.item_id)
```

Without enabling this property `spark.sql.optimizer.distinctBeforeIntersect.enabled`, the query will be rewritten as follows.

```
select distinct brand from
  (select item.brand brand from store_sales, item
     where store_sales.item_id = item.item_id)
left semi join
   (select item.brand cs_brand from catalog_sales, item
     where catalog_sales.item_id = item.item_id)
 on brand <=> cs_brand
```

When you enable this property `spark.sql.optimizer.distinctBeforeIntersect.enabled`, the query will be rewritten as follows.

```
select brand from
  (select distinct item.brand brand from store_sales, item
     where store_sales.item_id = item.item_id)
left semi join
   (select distinct item.brand cs_brand from catalog_sales, item
     where catalog_sales.item_id = item.item_id)
```

```
on brand <=> cs_brand
```

Bloom filter join

This optimization can improve the performance of some joins by pre-filtering one side of a join using a [Bloom filter](https://en.wikipedia.org/wiki/Bloom_filter) generated from the values from the other side of the join. With Amazon EMR 5.26.0, this feature is enabled by default. With Amazon EMR 5.25.0, you can enable this feature by setting the Spark property `spark.sql.bloomFilterJoin.enabled` to `true` from within Spark or when creating clusters.

The following is an example query that can benefit from a Bloom filter.

```
select count(*)
from sales, item
where sales.item_id = item.id
and item.category in (1, 10, 16)
```

When this feature is enabled, the Bloom filter is built from all item ids whose category is in the set of categories being queried. While scanning the sales table, the Bloom filter is used to determine which sales are for items that are definitely not in the set defined by the Bloom filter. Thus these identified sales can be filtered out as early as possible.

Optimized join reorder

This optimization can improve query performance by reordering joins involving tables with filters. With Amazon EMR 5.26.0, this feature is enabled by default. With Amazon EMR 5.25.0, you can enable this feature by setting the Spark configuration parameter `spark.sql.optimizer.sizeBasedJoinReorder.enabled` to true. The default behavior in Spark is to join tables from left to right, as listed in the query. This strategy can miss opportunities to execute smaller joins with filters first, in order to benefit more expensive joins later.

The example query below reports all returned items from all stores in a country. Without optimized join reorder, Spark joins the two large tables `store_sales` and `store_returns` first, and then joins them with `store` and eventually with `item`.

```
select ss.item_value, sr.return_date, s.name, i.desc,
from store_sales ss, store_returns sr, store s, item i
where ss.id = sr.id and ss.store_id = s.id and ss.item_id = i.id
```

```
and s.country = 'USA'
```

With optimized join reorder, Spark joins `store_sales` with `store` first since `store` has a filter and is smaller than `store_returns` and `broadcastable`. Then Spark joins with `store_returns` and finally with `item`. If `item` had a filter and was broadcastable, it would also qualify for reorder, resulting in `store_sales` joining with `store`, then `item`, and eventually with `store_returns`.

Spark Result Fragment Caching

Amazon EMR 6.6.0 and higher include the optional Spark Result Fragment Caching feature that automatically caches result fragments. These result fragments are parts of results from subtrees of queries that are stored in an Amazon S3 bucket of your choosing. The stored query result fragments are reused on subsequent query executions, resulting in faster queries.

Result Fragment Caching analyzes your Spark SQL queries, and caches eligible result fragments in your specified S3 location. On subsequent query runs, the usable query result fragments are automatically detected and fetched from S3. Result Fragment Caching differs from Result Set Caching, where subsequent queries have to exactly match the original query to return results from the cache. When used for queries that repeatedly target a static subset of your data, result fragment caching speeds performance significantly.

Consider the following query, which counts orders until the year 2022:

```
select
    l_returnflag,
    l_linestatus,
    count(*) as count_order
from
    lineitem
where
    l_shipdate <= current_date
    and year(l_shipdate) == '2022'
group by
    l_returnflag,
    l_linestatus
```

As time progresses, this query needs to run every day to report the total sales for the year. Without Result Fragment Caching, the results for all days of the year will need to be recomputed every day.

The query will get slower over time and will be slowest at the end of the year, when all 365 days of results will need to be recomputed.

When you activate Result Fragment Caching, you use results for the all previous days of the year from the cache. Each day, the feature must recompute only one day of results. After the feature computes the result fragment, the feature caches the fragment. As a result, cache-enabled query times are fast and they remain constant for each subsequent query.

Enabling Spark Result Fragment Caching

To enable Spark Result Fragment Caching, perform the following steps:

1. Create a cache bucket in Amazon S3 and authorize read/write access for EMRFS. For more information, see Authorizing access to EMRFS data in Amazon S3.
2. Set Amazon EMR Spark config to enable the feature.

```
spark.subResultCache.enabled = true
spark.subResultCache.fs.root.path = s3://DOC-EXAMPLE-BUCKET/cache_dir/
```

3. Enable S3 lifecycle management for the bucket to automatically clean cache files.
4. Optionally, configure the reductionRationThreshold and maxBufferSize properties to further tune the feature.

```
spark.sql.subResultCache.reductionRatioThreshold
spark.sql.subResultCache.maxBufferSize
```

Considerations when using Result Fragment Caching

The cost savings when you use results already cached in Amazon S3 rather than recompute them grows with the number of times the same cached results can be used. Queries with large table scans followed by filters or hash aggregations that reduce the result size by factor of at least 8 (that is, a ratio of at least 8:1 in input size:results) will benefit most from this feature. The greater the reduction ratio between the input and the results, the greater is the cost benefit. Queries with smaller reduction ratios, but that contain expensive computation steps between the table scan and filter or aggregations will also benefit, as long as the cost to produce the results is greater than the cost to fetch them from Amazon S3. By default, Result Fragment Caching takes effect only when it detects that a reduction ratio will be at least 8:1.

When your queries repeatedly reuse cached results, the benefits of this feature are greatest. Rolling and incremental window queries are good examples. For instance, a 30-day rolling window query that has already run for 29 days, would only need to pull 1/30th of the target data from its original input source and would use cached result fragments for the 29 previous days. An incremental window query would benefit even more, since the start of the window remains fixed: on every invocation of the query, a smaller percentage of the processing will require reading from the input source.

The following are additional considerations when using Result Fragment Caching:

- Queries that don't target the same data with the same query fragments will have a low cache hit rate, hence will not benefit from this feature.
- Queries with low reduction ratios that do not contain expensive computation steps will result in cached results that are roughly as expensive to read as they were to initially process.
- The first query will always demonstrate a minor regression due to the cost of writing to cache.
- The Result Fragment Caching feature works exclusively with Parquet files. Other file formats are not supported.
- The Result Fragment Caching feature buffers will only attempt to cache scans with file split sizes of 128 MB or larger. With the default Spark configuration, Result Fragment Caching will be disabled if the scan size (total size across all files being scanned) divided by the number of executor cores is less than 128 MB. When any of the Spark configurations listed below are set, the file split size will be:

  ```
  min(maxPartitionBytes, max(openCostInBytes, scan size / minPartitionNum))
  ```

  - spark.sql.leafNodeDefaultParallelism (default value is spark.default.parallelism)
  - spark.sql.files.minPartitionNum (default value is spark.sql.leafNodeDefaultParallelism)
  - spark.sql.files.openCostInBytes
  - spark.sql.files.maxPartitionBytes
- The Result Fragment Caching feature caches at the RDD partition granularity. The previously described reduction ratio that defaults to 8:1 is assessed per RDD partition. Workloads with per-RDD reduction ratios both greater and less than 8:1 may see smaller performance benefits than workloads with per-RDD reduction ratios that are consistently less than 8:1.
- The Result Fragment Caching feature uses a 16MB write buffer by default for each RDD partition being cached.If more than 16mb will be cached per RDD partition, the cost of determining that a write is not possible may result in a performance regression.

- While, by default, Result Fragment Caching will not attempt to cache RDD partition results with a reduction ratio smaller than 8:1 and will cap its write buffer at 16MB, both of these values are tunable through the following configurations:

```
spark.sql.subResultCache.reductionRatioThreshold (default: 8.0)
spark.sql.subResultCache.maxBufferSize (default: 16MB, max: 64MB)
```

- Multiple clusters using the same Amazon EMR release can share the same cache location. To ensure result correctness, Result Fragment Caching will not use cache results written by different releases of Amazon EMR .
- Result Fragment Caching will be disabled automatically for Spark Streaming use cases or when RecordServer, Apache Ranger, or AWS Lake Formation is used.
- The result fragment cache read/writes use EMRFS and Amazon S3 buckets. CSE/ SSE S3/ SSE KMS encryption are supported.

Use the Nvidia RAPIDS Accelerator for Apache Spark

With Amazon EMR release 6.2.0 and later, you can use the RAPIDS Accelerator for Apache Spark plugin by Nvidia to accelerate Spark using EC2 graphics processing unit (GPU) instance types. RAPIDS Accelerator will GPU-accelerate your Apache Spark 3.0 data science pipelines without code changes, and speed up data processing and model training while substantially lowering infrastructure costs.

The following sections guide you through configuring your EMR cluster to use the Spark-RAPIDS Plugin for Spark.

Choose instance types

To use the Nvidia Spark-RAPIDS plugin for Spark, the core and task instance groups must use EC2 GPU instance types that meet the Hardware requirements of Spark-RAPIDS. To view a complete list of Amazon EMR supported GPU instance types, please see Supported instance types in the *Amazon EMR Management Guide*. Instance type for the primary instance group can be either GPU or non-GPU types, but ARM instance types aren't supported.

Set up application configurations for your cluster

1. Enable Amazon EMR to install the plugins on your new cluster

To install plugins, supply the following configuration when you create your cluster:

```
{
 "Classification":"spark",
 "Properties":{
  "enableSparkRapids":"true"
 }
}
```

2. Configure YARN to use GPU

For details on how to use GPU on YARN, see Using GPU on YARN in Apache Hadoop documentation. The following examples show sample YARN configurations for Amazon EMR 6.x and 7.x releases:

Amazon EMR 7.x

Example YARN configuration for Amazon EMR 7.x

```
{
    "Classification":"yarn-site",
    "Properties":{
        "yarn.nodemanager.resource-plugins":"yarn.io/gpu",
        "yarn.resource-types":"yarn.io/gpu",
        "yarn.nodemanager.resource-plugins.gpu.allowed-gpu-devices":"auto",
        "yarn.nodemanager.resource-plugins.gpu.path-to-discovery-executables":"/usr/
bin",
        "yarn.nodemanager.linux-container-executor.cgroups.mount":"true",
        "yarn.nodemanager.linux-container-executor.cgroups.mount-path":"/spark-
rapids-cgroup",
        "yarn.nodemanager.linux-container-executor.cgroups.hierarchy":"yarn",
        "yarn.nodemanager.container-
executor.class":"org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor"
    }
},{
    "Classification":"container-executor",
    "Properties":{

    },
    "Configurations":[
        {
            "Classification":"gpu",
            "Properties":{
```

```
                "module.enabled":"true"
            }
        },
        {
            "Classification":"cgroups",
            "Properties":{
                "root":"/spark-rapids-cgroup",
                "yarn-hierarchy":"yarn"
            }
        }
    ]
}
```

Amazon EMR 6.x

Example YARN configuration for Amazon EMR 6.x

```
{
    "Classification":"yarn-site",
    "Properties":{
        "yarn.nodemanager.resource-plugins":"yarn.io/gpu",
        "yarn.resource-types":"yarn.io/gpu",
        "yarn.nodemanager.resource-plugins.gpu.allowed-gpu-devices":"auto",
        "yarn.nodemanager.resource-plugins.gpu.path-to-discovery-executables":"/usr/
bin",
        "yarn.nodemanager.linux-container-executor.cgroups.mount":"true",
        "yarn.nodemanager.linux-container-executor.cgroups.mount-path":"/sys/fs/
cgroup",
        "yarn.nodemanager.linux-container-executor.cgroups.hierarchy":"yarn",
        "yarn.nodemanager.container-
executor.class":"org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor"
    }
},{
    "Classification":"container-executor",
    "Properties":{

    },
    "Configurations":[
        {
            "Classification":"gpu",
            "Properties":{
                "module.enabled":"true"
            }
        },
```

```
        {
            "Classification":"cgroups",
            "Properties":{
                "root":"/sys/fs/cgroup",
                "yarn-hierarchy":"yarn"
            }
        }
    ]
}
```

3. Configure Spark to use RAPIDS

Here are the required configurations to enable Spark to use RAPIDS plugin:

```
{
 "Classification":"spark-defaults",
 "Properties":{
  "spark.plugins":"com.nvidia.spark.SQLPlugin",
  "spark.executor.resource.gpu.discoveryScript":"/usr/lib/spark/scripts/gpu/
getGpusResources.sh",
  "spark.executor.extraLibraryPath":"/usr/local/cuda/targets/x86_64-linux/lib:/usr/
local/cuda/extras/CUPTI/lib64:/usr/local/cuda/compat/lib:/usr/local/cuda/lib:/usr/
local/cuda/lib64:/usr/lib/hadoop/lib/native:/usr/lib/hadoop-lzo/lib/native:/docker/usr/
lib/hadoop/lib/native:/docker/usr/lib/hadoop-lzo/lib/native"
 }
}
```

XGBoost4J-Spark library in XGBoost documentation is also available when the Spark RAPIDS plugin is enabled on your cluster. You can use the following configuration to integrate XGBoost with you Spark job:

```
{
 "Classification":"spark-defaults",
 "Properties":{
  "spark.submit.pyFiles":"/usr/lib/spark/jars/xgboost4j-spark_3.0-1.4.2-0.3.0.jar"
 }
}
```

For additional Spark configurations that you can use to tune a GPU-accelerated EMR cluster, please refer to the Rapids Accelerator for Apache Spark tuning guide in Nvidia.github.io documentation.

4. Configure YARN Capacity Scheduler

`DominantResourceCalculator` must be configured to enable GPU scheduling and isolation. For more information, please refer to Using GPU on YARN in Apache Hadoop documentation.

```
{
 "Classification":"capacity-scheduler",
 "Properties":{
  "yarn.scheduler.capacity.resource-
calculator":"org.apache.hadoop.yarn.util.resource.DominantResourceCalculator"
 }
}
```

5. Create a JSON file to include your configurations

You can create a JSON file that contains your configuration to use the RAPIDS plugin for your Spark cluster. You supply the file later when you launch your cluster.

You can store the file locally or on S3. For more information of how to supply application configurations for your clusters, see Configure applications.

Use the following sample files as templates to build your own configurations.

Amazon EMR 7.x

Example `my-configurations.json` file for Amazon EMR 7.x

```
[
    {
        "Classification":"spark",
        "Properties":{
            "enableSparkRapids":"true"
        }
    },
    {
        "Classification":"yarn-site",
        "Properties":{
            "yarn.nodemanager.resource-plugins":"yarn.io/gpu",
            "yarn.resource-types":"yarn.io/gpu",
            "yarn.nodemanager.resource-plugins.gpu.allowed-gpu-devices":"auto",
            "yarn.nodemanager.resource-plugins.gpu.path-to-discovery-executables":"/
usr/bin",
            "yarn.nodemanager.linux-container-executor.cgroups.mount":"true",
```

```
            "yarn.nodemanager.linux-container-executor.cgroups.mount-path":"/spark-
rapids-cgroup",
            "yarn.nodemanager.linux-container-executor.cgroups.hierarchy":"yarn",
            "yarn.nodemanager.container-
executor.class":"org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor"
        }
    },
    {
        "Classification":"container-executor",
        "Properties":{

        },
        "Configurations":[
            {
                "Classification":"gpu",
                "Properties":{
                    "module.enabled":"true"
                }
            },
            {
                "Classification":"cgroups",
                "Properties":{
                    "root":"/spark-rapids-cgroup",
                    "yarn-hierarchy":"yarn"
                }
            }
        ]
    },
    {
        "Classification":"spark-defaults",
        "Properties":{
            "spark.plugins":"com.nvidia.spark.SQLPlugin",
            "spark.executor.resource.gpu.discoveryScript":"/usr/lib/spark/scripts/
gpu/getGpusResources.sh",
            "spark.executor.extraLibraryPath":"/usr/local/cuda/targets/x86_64-
linux/lib:/usr/local/cuda/extras/CUPTI/lib64:/usr/local/cuda/compat/lib:/usr/local/
cuda/lib:/usr/local/cuda/lib64:/usr/lib/hadoop/lib/native:/usr/lib/hadoop-lzo/lib/
native:/docker/usr/lib/hadoop/lib/native:/docker/usr/lib/hadoop-lzo/lib/native",
            "spark.submit.pyFiles":"/usr/lib/spark/jars/xgboost4j-
spark_3.0-1.4.2-0.3.0.jar",
            "spark.rapids.sql.concurrentGpuTasks":"1",
            "spark.executor.resource.gpu.amount":"1",
            "spark.executor.cores":"2",
            "spark.task.cpus":"1",
```

```
            "spark.task.resource.gpu.amount":"0.5",
            "spark.rapids.memory.pinnedPool.size":"0",
            "spark.executor.memoryOverhead":"2G",
            "spark.locality.wait":"0s",
            "spark.sql.shuffle.partitions":"200",
            "spark.sql.files.maxPartitionBytes":"512m"
        }
    },
    {
        "Classification":"capacity-scheduler",
        "Properties":{
            "yarn.scheduler.capacity.resource-
calculator":"org.apache.hadoop.yarn.util.resource.DominantResourceCalculator"
        }
    }
]
```

Amazon EMR 6.x

Example `my-configurations.json` file for Amazon EMR 6.x

```
[
    {
        "Classification":"spark",
        "Properties":{
            "enableSparkRapids":"true"
        }
    },
    {
        "Classification":"yarn-site",
        "Properties":{
            "yarn.nodemanager.resource-plugins":"yarn.io/gpu",
            "yarn.resource-types":"yarn.io/gpu",
            "yarn.nodemanager.resource-plugins.gpu.allowed-gpu-devices":"auto",
            "yarn.nodemanager.resource-plugins.gpu.path-to-discovery-executables":"/
usr/bin",
            "yarn.nodemanager.linux-container-executor.cgroups.mount":"true",
            "yarn.nodemanager.linux-container-executor.cgroups.mount-path":"/sys/fs/
cgroup",
            "yarn.nodemanager.linux-container-executor.cgroups.hierarchy":"yarn",
            "yarn.nodemanager.container-
executor.class":"org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor"
        }
    },
```

```
    {
        "Classification":"container-executor",
        "Properties":{

        },
        "Configurations":[
            {
                "Classification":"gpu",
                "Properties":{
                    "module.enabled":"true"
                }
            },
            {
                "Classification":"cgroups",
                "Properties":{
                    "root":"/sys/fs/cgroup",
                    "yarn-hierarchy":"yarn"
                }
            }
        ]
    },
    {
        "Classification":"spark-defaults",
        "Properties":{
            "spark.plugins":"com.nvidia.spark.SQLPlugin",
            "spark.executor.resource.gpu.discoveryScript":"/usr/lib/spark/scripts/
gpu/getGpusResources.sh",
            "spark.executor.extraLibraryPath":"/usr/local/cuda/targets/x86_64-
linux/lib:/usr/local/cuda/extras/CUPTI/lib64:/usr/local/cuda/compat/lib:/usr/local/
cuda/lib:/usr/local/cuda/lib64:/usr/lib/hadoop/lib/native:/usr/lib/hadoop-lzo/lib/
native:/docker/usr/lib/hadoop/lib/native:/docker/usr/lib/hadoop-lzo/lib/native",
            "spark.submit.pyFiles":"/usr/lib/spark/jars/xgboost4j-
spark_3.0-1.4.2-0.3.0.jar",
            "spark.rapids.sql.concurrentGpuTasks":"1",
            "spark.executor.resource.gpu.amount":"1",
            "spark.executor.cores":"2",
            "spark.task.cpus":"1",
            "spark.task.resource.gpu.amount":"0.5",
            "spark.rapids.memory.pinnedPool.size":"0",
            "spark.executor.memoryOverhead":"2G",
            "spark.locality.wait":"0s",
            "spark.sql.shuffle.partitions":"200",
            "spark.sql.files.maxPartitionBytes":"512m"
        }
```

```
    },
    {
        "Classification":"capacity-scheduler",
        "Properties":{
            "yarn.scheduler.capacity.resource-
calculator":"org.apache.hadoop.yarn.util.resource.DominantResourceCalculator"
        }
    }
]
```

Add a bootstrap action for your cluster

For more information on how to supply bootstrap action scripts when you create your cluster, see Bootstrap action basics in the *Amazon EMR Management Guide*.

The following example scripts show how to make a bootstrap action file for Amazon EMR 6.x and 7.x:

Amazon EMR 7.x

Example `my-bootstrap-action.sh` file for Amazon EMR 7.x

To use YARN to manage GPU resources with Amazon EMR 7.x releases, you must manually mount CGroup v1 on your cluster. You can do this with as bootstrap action script, as shown in this example.

```
#!/bin/bash
set -ex

sudo mkdir -p /spark-rapids-cgroup/devices
sudo mount -t cgroup -o devices cgroupv1-devices /spark-rapids-cgroup/devices
sudo chmod a+rwx -R /spark-rapids-cgroup
```

Amazon EMR 6.x

Example `my-bootstrap-action.sh` file for Amazon EMR 6.x

For Amazon EMR 6.x releases, you must open CGroup permissions to YARN on your cluster. You can do this with a bootstrap action script, as shown in this example.

```
#!/bin/bash
set -ex
```

```
sudo chmod a+rwx -R /sys/fs/cgroup/cpu,cpuacct
sudo chmod a+rwx -R /sys/fs/cgroup/devices
```

Launch your cluster

The last step is to launch your cluster with the cluster configurations mentioned above. Here's an example command to launch a cluster from the Amazon EMR CLI:

```
 aws emr create-cluster \
--release-label emr-7.2.0 \
--applications Name=Hadoop Name=Spark \
--service-role EMR_DefaultRole_V2 \
--ec2-attributes KeyName=my-key-pair,InstanceProfile=EMR_EC2_DefaultRole \
--instance-groups InstanceGroupType=MASTER,InstanceCount=1,InstanceType=m4.4xlarge \

                  InstanceGroupType=CORE,InstanceCount=1,InstanceType=g4dn.2xlarge \

                  InstanceGroupType=TASK,InstanceCount=1,InstanceType=g4dn.2xlarge \
--configurations file:///my-configurations.json \
--bootstrap-actions Name='My Spark Rapids Bootstrap action',Path=s3://my-bucket/my-bootstrap-action.sh
```

Access the Spark shell

The Spark shell is based on the Scala REPL (Read-Eval-Print-Loop). It allows you to create Spark programs interactively and submit work to the framework. You can access the Spark shell by connecting to the primary node with SSH and invoking `spark-shell`. For more information about connecting to the primary node, see Connect to the primary node using SSH in the *Amazon EMR Management Guide*. The following examples use Apache HTTP Server access logs stored in Amazon S3.

> **Note**
>
> The bucket in these examples is available to clients that can access US East (N. Virginia).

By default, the Spark shell creates its own SparkContext object called `sc`. You can use this context if it is required within the REPL. sqlContext is also available in the shell and it is a HiveContext.

Example Use the Spark shell to count the occurrences of a string in a file stored in Amazon S3

This example uses `sc` to read a text file that's stored in Amazon S3.

```
scala> sc
res0: org.apache.spark.SparkContext = org.apache.spark.SparkContext@404721db

scala> val textFile = sc.textFile("s3://elasticmapreduce/samples/hive-ads/tables/
impressions/dt=2009-04-13-08-05/ec2-0-51-75-39.amazon.com-2009-04-13-08-05.log")
```

Spark creates the textFile and associated [data structure](). Next, the example counts the number of lines in the log file with the string "cartoonnetwork.com":

```
scala> val linesWithCartoonNetwork = textFile.filter(line =>
 line.contains("cartoonnetwork.com")).count()
linesWithCartoonNetwork: org.apache.spark.rdd.RDD[String] = MapPartitionsRDD[2] at
 filter at <console>:23
<snip>
<Spark program runs>
scala> linesWithCartoonNetwork
res2: Long = 9
```

Example Use the Python-based Spark shell to count the occurrences of a string in a file stored in Amazon S3

Spark also includes a Python-based shell, `pyspark`, that you can use to prototype Spark programs written in Python. Just as with `spark-shell`, invoke `pyspark` on the primary node; it also has the same [SparkContext]() object.

```
>>> sc
<pyspark.context.SparkContext object at 0x7fe7e659fa50>
>>> textfile = sc.textFile("s3://elasticmapreduce/samples/hive-ads/tables/impressions/
dt=2009-04-13-08-05/ec2-0-51-75-39.amazon.com-2009-04-13-08-05.log")
```

Spark creates the textFile and associated [data structure](). Next, the example counts the number of lines in the log file with the string "cartoonnetwork.com".

```
>>> linesWithCartoonNetwork = textfile.filter(lambda line: "cartoonnetwork.com" in
 line).count()
15/06/04 17:12:22 INFO lzo.GPLNativeCodeLoader: Loaded native gpl library from the
 embedded binaries
```

```
15/06/04 17:12:22 INFO lzo.LzoCodec: Successfully loaded & initialized native-lzo
 library [hadoop-lzo rev EXAMPLE]
15/06/04 17:12:23 INFO fs.EmrFileSystem: Consistency disabled, using
 com.amazon.ws.emr.hadoop.fs.s3n.S3NativeFileSystem as filesystem implementation
<snip>
<Spark program continues>
>>> linesWithCartoonNetwork
9
```

Use Amazon SageMaker Spark for machine learning

When using Amazon EMR release 5.11.0 and later, the `aws-sagemaker-spark-sdk` component is installed along with Spark. This component installs Amazon SageMaker Spark and associated dependencies for Spark integration with Amazon SageMaker. You can use Amazon SageMaker Spark to construct Spark machine learning (ML) pipelines using Amazon SageMaker stages. For more information, see the Amazon SageMaker Spark README on GitHub and Using Apache Spark with Amazon SageMaker in the *Amazon SageMaker Developer Guide*.

Write a Spark application

Spark applications can be written in Scala, Java, or Python. There are several examples of Spark applications located on Spark examples topic in the Apache Spark documentation. The Estimating Pi example is shown below in the three natively supported applications. You can also view complete examples in `$SPARK_HOME/examples` and at GitHub. For more information about how to build JARs for Spark, see the Quick start topic in the Apache Spark documentation.

Scala

To avoid Scala compatibility issues, we suggest you use Spark dependencies for the correct Scala version when you compile a Spark application for an Amazon EMR cluster. The Scala version you should use depends on the version of Spark installed on your cluster. For example, Amazon EMR release 5.30.1 uses Spark 2.4.5, which is built with Scala 2.11. If your cluster uses Amazon EMR release 5.30.1, use Spark dependencies for Scala 2.11. For more information about the Scala versions used by Spark, see the Apache Spark documentation.

```
package org.apache.spark.examples
import scala.math.random
import org.apache.spark._
```

```
/** Computes an approximation to pi */
object SparkPi {
  def main(args: Array[String]) {
    val conf = new SparkConf().setAppName("Spark Pi")
    val spark = new SparkContext(conf)
    val slices = if (args.length > 0) args(0).toInt else 2
    val n = math.min(100000L * slices, Int.MaxValue).toInt // avoid overflow
    val count = spark.parallelize(1 until n, slices).map { i =>
      val x = random * 2 - 1
      val y = random * 2 - 1
      if (x*x + y*y < 1) 1 else 0
    }.reduce(_ + _)
    println("Pi is roughly " + 4.0 * count / n)
    spark.stop()
  }
}
```

Java

```
package org.apache.spark.examples;

import org.apache.spark.SparkConf;
import org.apache.spark.api.java.JavaRDD;
import org.apache.spark.api.java.JavaSparkContext;
import org.apache.spark.api.java.function.Function;
import org.apache.spark.api.java.function.Function2;

import java.util.ArrayList;
import java.util.List;

/**
 * Computes an approximation to pi
 * Usage: JavaSparkPi [slices]
 */
public final class JavaSparkPi {

  public static void main(String[] args) throws Exception {
    SparkConf sparkConf = new SparkConf().setAppName("JavaSparkPi");
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);

    int slices = (args.length == 1) ? Integer.parseInt(args[0]) : 2;
    int n = 100000 * slices;
    List<Integer> l = new ArrayList<Integer>(n);
```

```
    for (int i = 0; i < n; i++) {
      l.add(i);
    }

    JavaRDD<Integer> dataSet = jsc.parallelize(l, slices);

    int count = dataSet.map(new Function<Integer, Integer>() {
      @Override
      public Integer call(Integer integer) {
        double x = Math.random() * 2 - 1;
        double y = Math.random() * 2 - 1;
        return (x * x + y * y < 1) ? 1 : 0;
      }
    }).reduce(new Function2<Integer, Integer, Integer>() {
      @Override
      public Integer call(Integer integer, Integer integer2) {
        return integer + integer2;
      }
    });

    System.out.println("Pi is roughly " + 4.0 * count / n);

    jsc.stop();
  }
}
```

Python

```
import argparse
import logging
from operator import add
from random import random

from pyspark.sql import SparkSession

logger = logging.getLogger(__name__)
logging.basicConfig(level=logging.INFO, format="%(levelname)s: %(message)s")

def calculate_pi(partitions, output_uri):
    """
    Calculates pi by testing a large number of random numbers against a unit circle
```

```
    inscribed inside a square. The trials are partitioned so they can be run in
    parallel on cluster instances.

    :param partitions: The number of partitions to use for the calculation.
    :param output_uri: The URI where the output is written, typically an Amazon S3
                       bucket, such as 's3://example-bucket/pi-calc'.
    """

    def calculate_hit(_):
        x = random() * 2 - 1
        y = random() * 2 - 1
        return 1 if x**2 + y**2 < 1 else 0

    tries = 100000 * partitions
    logger.info(
        "Calculating pi with a total of %s tries in %s partitions.", tries, partitions
    )
    with SparkSession.builder.appName("My PyPi").getOrCreate() as spark:
        hits = (
            spark.sparkContext.parallelize(range(tries), partitions)
            .map(calculate_hit)
            .reduce(add)
        )
        pi = 4.0 * hits / tries
        logger.info("%s tries and %s hits gives pi estimate of %s.", tries, hits, pi)
        if output_uri is not None:
            df = spark.createDataFrame([(tries, hits, pi)], ["tries", "hits", "pi"])
            df.write.mode("overwrite").json(output_uri)

if __name__ == "__main__":
    parser = argparse.ArgumentParser()
    parser.add_argument(
        "--partitions",
        default=2,
        type=int,
        help="The number of parallel partitions to use when calculating pi.",
    )
    parser.add_argument(
        "--output_uri", help="The URI where output is saved, typically an S3 bucket."
    )
    args = parser.parse_args()

    calculate_pi(args.partitions, args.output_uri)
```

Improve Spark performance with Amazon S3

Amazon EMR offers features to help optimize performance when using Spark to query, read and write data saved in Amazon S3.

S3 Select can improve query performance for CSV and JSON files in some applications by "pushing down" processing to Amazon S3.

The EMRFS S3-optimized committer is an alternative to the OutputCommitter class, which uses the multipart uploads feature of EMRFS to improve performance when writing Parquet files to Amazon S3 using Spark SQL, DataFrames, and Datasets.

Topics

Use S3 Select with Spark to improve query performance

With Amazon EMR release 5.17.0 and later, you can use S3 Select with Spark on Amazon EMR . *S3 Select* allows applications to retrieve only a subset of data from an object. For Amazon EMR , the computational work of filtering large data sets for processing is "pushed down" from the cluster to Amazon S3, which can improve performance in some applications and reduces the amount of data transferred between Amazon EMR and Amazon S3.

S3 Select is supported with CSV and JSON files using `s3selectCSV` and `s3selectJSON` values to specify the data format. For more information and examples, see Specify S3 Select in your code.

Is S3 Select right for my application?

We recommend that you benchmark your applications with and without S3 Select to see if using it may be suitable for your application.

Use the following guidelines to determine if your application is a candidate for using S3 Select:

- Your query filters out more than half of the original data set.
- Your network connection between Amazon S3 and the Amazon EMR cluster has good transfer speed and available bandwidth. Amazon S3 does not compress HTTP responses, so the response size is likely to increase for compressed input files.

Considerations and limitations

- Amazon S3 server-side encryption with customer-provided encryption keys (SSE-C) and client-side encryption are not supported.
- The `AllowQuotedRecordDelimiters` property is not supported. If this property is specified, the query fails.
- Only CSV and JSON files in UTF-8 format are supported. Multi-line CSVs are not supported.
- Only uncompressed or gzip files are supported.
- Spark CSV and JSON options such as `nanValue`, `positiveInf`, `negativeInf`, and options related to corrupt records (for example, failfast and dropmalformed mode) are not supported.
- Using commas (,) within decimals is not supported. For example, `10,000` is not supported and `10000` is.
- Comment characters in the last line are not supported.
- Empty lines at the end of a file are not processed.
- The following filters are not pushed down to Amazon S3:
  - Aggregate functions such as `COUNT()` and `SUM()`.
  - Filters that `CAST()` an attribute. For example, `CAST(stringColumn as INT) = 1`.
  - Filters with an attribute that is an object or is complex. For example, `intArray[1] = 1, objectColumn.objectNumber = 1`.
  - Filters for which the value is not a literal value. For example, `intColumn1 = intColumn2`
  - Only S3 Select supported data types are supported with the documented limitations.

Specify S3 Select in your code

The following examples demonstrate how to specify S3 Select for CSV using Scala, SQL, R, and PySpark. You can use S3 Select for JSON in the same way. For a listing of options, their default values, and limitations, see Options.

PySpark

```
spark
  .read
  .format("s3selectCSV") // "s3selectJson" for Json
  .schema(...) // optional, but recommended
  .options(...) // optional
  .load("s3://path/to/my/datafiles")
```

R

```
read.df("s3://path/to/my/datafiles", "s3selectCSV", schema, header = "true",
 delimiter = "\t")
```

Scala

```
spark
  .read
  .format("s3selectCSV") // "s3selectJson" for Json
  .schema(...) // optional, but recommended
  .options(...) // optional. Examples:
  // .options(Map("quote" -> "\'", "header" -> "true")) or
  // .option("quote", "\'").option("header", "true")
  .load("s3://path/to/my/datafiles")
```

SQL

```
CREATE TEMPORARY VIEW MyView (number INT, name STRING) USING s3selectCSV OPTIONS
 (path "s3://path/to/my/datafiles", header "true", delimiter "\t")
```

Options

The following options are available when using `s3selectCSV` and `s3selectJSON`. If not specified, default values are used.

Options with S3selectCSV

Option	Default	Usage
`compression`	`"none"`	Indicates whether compressi on is used. `"gzip"` is the only setting supported besides `"none"`.
`delimiter`	`","`	Specifies the field delimiter.
`quote`	`'\"'`	Specifies the quote character . Specifying an empty string is not supported and results in a malformed XML error.
`escape`	`'\\'`	Specifies the escape character .
`header`	`"false"`	`"false"` specifies that there is no header. `"true"` specifies that a header is in the first line. Only headers in the first line are supported, and empty lines before a header are not supported.
comment	`"#"`	Specifies the comment character. The comment indicator cannot be disabled. In other words, a value of `\u0000` is not supported.
`nullValue`	""	

Options with S3selectJSON

Option	Default	Usage
`compression`	`"none"`	Indicates whether compression is used. `"gzip"` is the only setting supported besides `"none"`.
`multiline`	"false"	`"false"` specifies that the JSON is in S3 Select `LINES` format, meaning that each line in the input data contains a single JSON object. `"true"` specifies that the JSON is in S3 Select `DOCUMENT` format, meaning that a JSON object can span multiple lines in the input data.

Use the EMRFS S3-optimized committer

The EMRFS S3-optimized committer is an alternative OutputCommitter implementation that is optimized for writing files to Amazon S3 when using EMRFS. The EMRFS S3-optimized committer improves application performance by avoiding list and rename operations done in Amazon S3 during job and task commit phases. The committer is available with Amazon EMR release 5.19.0 and later, and is enabled by default with Amazon EMR 5.20.0 and later. The committer is used for Spark jobs that use Spark SQL, DataFrames, or Datasets. Starting with Amazon EMR 6.4.0, this committer can be used for all common formats including parquet, ORC, and text-based formats (including CSV and JSON). For releases prior to Amazon EMR 6.4.0, only the Parquet format is supported. There are circumstances under which the committer is not used. For more information, see Requirements for the EMRFS S3-optimized committer.

Topics

- Job tuning considerations
- Enable the EMRFS S3-optimized committer for Amazon EMR 5.19.0

Requirements for the EMRFS S3-optimized committer

The EMRFS S3-optimized committer is used when the following conditions are met:

- You run Spark jobs that use Spark SQL, DataFrames, or Datasets to write files to Amazon S3. Starting with Amazon EMR 6.4.0, this committer can be used for all common formats including parquet, ORC, and text-based formats (including CSV and JSON). For releases prior to Amazon EMR 6.4.0, only the Parquet format is supported.
- Multipart uploads are enabled in Amazon EMR . This is the default. For more information, see The EMRFS S3-optimized committer and multipart uploads.
- Spark's built-in file format support is used. The built-in file format support is used in the following circumstances:
  - For Hive metastore tables, when `spark.sql.hive.convertMetastoreParquet` is set to `true` for Parquet tables, or `spark.sql.hive.convertMetastoreOrc` is set to `true` for Orc tables with Amazon EMR 6.4.0 or above. These are the default settings.
  - When jobs write to file format data sources or tables—for example, the target table is created with the `USING parquet` clause.
  - When jobs write to non-partitioned Hive metastore Parquet tables. Spark's built-in Parquet support does not support partitioned Hive tables, which is a known limitation. For more information, see Hive metastore Parquet table conversion in the Apache Spark SQL, DataFrames and Datasets Guide.
- Spark job operations that write to a default partition location—for example, `${table_location}/k1=v1/k2=v2/`—use the committer. The committer is not used if a job operation writes to a custom partition location—for example, if a custom partition location is set using the `ALTER TABLE SQL` command.
- The following values for Spark must be used:
  - The `spark.sql.parquet.fs.optimized.committer.optimization-enabled` property must be set to `true`. This is the default setting with Amazon EMR 5.20.0 and later. With Amazon EMR 5.19.0, the default value is `false`. For information about configuring this value, see Enable the EMRFS S3-optimized committer for Amazon EMR 5.19.0.
  - If writing to non-partitioned Hive metastore tables, only Parquet and Orc file formats are supported. `spark.sql.hive.convertMetastoreParquet` must be set to `true` if writing to

non-partitioned Parquet Hive metastore tables. `spark.sql.hive.convertMetastoreOrc` must be set to `true` if writing to non-partitioned Orc Hive metastore tables. These are the default settings.

- `spark.sql.parquet.output.committer.class` must be set to `com.amazon.emr.committer.EmrOptimizedSparkSqlParquetOutputCommitter`. This is the default setting.
- `spark.sql.sources.commitProtocolClass` must be set to `org.apache.spark.sql.execution.datasources.SQLEmrOptimizedCommitProtocol` or `org.apache.spark.sql.execution.datasources.SQLHadoopMapReduceCommitProtocol`. `org.apache.spark.sql.execution.datasources.SQLEmrOptimizedCommitProtocol` is the default setting for the Amazon EMR 5.x series version 5.30.0 and higher, and for the Amazon EMR 6.x series version 6.2.0 and higher. `org.apache.spark.sql.execution.datasources.SQLHadoopMapReduceCommitProtocol` is the default setting for previous Amazon EMR versions.
- If Spark jobs overwrite partitioned Parquet datasets with dynamic partition columns, then the `partitionOverwriteMode` write option and `spark.sql.sources.partitionOverwriteMode` must be set to `static`. This is the default setting.

> **Note**
>
> The `partitionOverwriteMode` write option was introduced in Spark 2.4.0. For Spark version 2.3.2, included with Amazon EMR release 5.19.0, set the `spark.sql.sources.partitionOverwriteMode` property.

Occasions when EMRFS S3-optimized committer is not used

Generally, the EMRFS S3-optimized committer isn't used in the following situations.

Situation	Why the committer is not used
When you write to HDFS	The committer only supports writing to Amazon S3 using EMRFS.
When you use the S3A file system	The committer only supports EMRFS.

Situation	Why the committer is not used
When you use MapReduce or Spark's RDD API	The committer only supports using SparkSQL, DataFrame, or Dataset APIs.

The following Scala examples demonstrate some additional situations that prevent the EMRFS S3-optimized committer from being used in whole (the first example) and in part (the second example).

Example – Dynamic partition overwrite mode

The following Scala example instructs Spark to use a different commit algorithm, which prevents use of the EMRFS S3-optimized committer altogether. The code sets the `partitionOverwriteMode` property to `dynamic` to overwrite only those partitions to which you're writing data. Then, dynamic partition columns are specified by `partitionBy`, and the write mode is set to `overwrite`.

```
val dataset = spark.range(0, 10)
  .withColumn("dt", expr("date_sub(current_date(), id)"))

dataset.write.mode("overwrite")
  .option("partitionOverwriteMode", "dynamic")
  .partitionBy("dt")
  .parquet("s3://EXAMPLE-DOC-BUCKET/output")
```

You must configure all three settings to avoid using the EMRFS S3-optimized committer. When you do so, Spark executes a different commit algorithm that's specified in Spark's commit protocol. For Amazon EMR 5.x releases earlier than 5.30.0 and for Amazon EMR 6.x releases earlier than 6.2.0, the commit protocol uses Spark's staging directory, which is a temporary directory created under the output location that starts with `.spark-staging`. The algorithm sequentially renames partition directories, which can negatively impact performance. For more information about Amazon EMR releases 5.30.0 and later and 6.2.0 and later, see Use the EMRFS S3-optimized commit protocol.

The algorithm in Spark 2.4.0 follows these steps:

1. Task attempts write their output to partition directories under Spark's staging directory—for example, `${outputLocation}/spark-staging-${jobID}/k1=v1/k2=v2/`.

2. For each partition written, the task attempt keeps track of relative partition paths—for example, `k1=v1/k2=v2`.
3. When a task completes successfully, it provides the driver with all relative partition paths that it tracked.
4. After all tasks complete, the job commit phase collects all the partition directories that successful task attempts wrote under Spark's staging directory. Spark sequentially renames each of these directories to its final output location using directory tree rename operations.
5. The staging directory is deleted before the job commit phase completes.

Example – Custom partition location

In this example, the Scala code inserts into two partitions. One partition has a custom partition location. The other partition uses the default partition location. The EMRFS S3-optimized committer is only used for writing task output to the partition that uses the default partition location.

```
val table = "dataset"
val location = "s3://bucket/table"

spark.sql(s"""
  CREATE TABLE $table (id bigint, dt date)
  USING PARQUET PARTITIONED BY (dt)
  LOCATION '$location'
""")

// Add a partition using a custom location
val customPartitionLocation = "s3://bucket/custom"
spark.sql(s"""
  ALTER TABLE $table ADD PARTITION (dt='2019-01-28')
  LOCATION '$customPartitionLocation'
""")

// Add another partition using default location
spark.sql(s"ALTER TABLE $table ADD PARTITION (dt='2019-01-29')")

def asDate(text: String) = lit(text).cast("date")

spark.range(0, 10)
  .withColumn("dt",
```

```
    when($"id" > 4, asDate("2019-01-28")).otherwise(asDate("2019-01-29")))
  .write.insertInto(table)
```

The Scala code creates the following Amazon S3 objects:

```
custom/part-00001-035a2a9c-4a09-4917-8819-e77134342402.c000.snappy.parquet
custom_$folder$
table/_SUCCESS
table/dt=2019-01-29/part-00000-035a2a9c-4a09-4917-8819-e77134342402.c000.snappy.parquet
table/dt=2019-01-29_$folder$
table_$folder$
```

When writing to partitions at custom locations, Spark uses a commit algorithm similar to the previous example, which is outlined below. As with the earlier example, the algorithm results in sequential renames, which may negatively impact performance.

1. When writing output to a partition at a custom location, tasks write to a file under Spark's staging directory, which is created under the final output location. The name of the file includes a random UUID to protect against file collisions. The task attempt keeps track of each file along with the final desired output path.
2. When a task completes successfully, it provides the driver with the files and their final desired output paths.
3. After all tasks complete, the job commit phase sequentially renames all files that were written for partitions at custom locations to their final output paths.
4. The staging directory is deleted before the job commit phase completes.

The EMRFS S3-optimized committer and multipart uploads

To use the EMRFS S3-optimized committer, you must enable multipart uploads for Amazon EMR . Multipart uploads are enabled by default. You can re-enable it if required. For more information, see Configure multipart upload for Amazon S3 in the *Amazon EMR Management Guide*.

The EMRFS S3-optimized committer uses the transaction-like characteristics of multipart uploads to ensure files written by task attempts only appear in the job's output location upon task commit. By using multipart uploads in this way, the committer improves task commit performance over the default FileOutputCommitter algorithm version 2. When using the EMRFS S3-optimized committer, there are some key differences from traditional multipart upload behavior to consider:

- Multipart uploads are always performed regardless of the file size. This differs from the default behavior of EMRFS, where the `fs.s3n.multipart.uploads.split.size` property controls the file size at which multipart uploads are triggered.
- Multipart uploads are left in an incomplete state for a longer period of time until the task commits or aborts. This differs from the default behavior of EMRFS where a multipart upload completes when a task finishes writing a given file.

Because of these differences, if a Spark Executor JVM crashes or is killed while tasks are running and writing data to Amazon S3, incomplete multipart uploads are more likely to be left behind. For this reason, when you use the EMRFS S3-optimized committer, be sure to follow the best practices for managing failed multipart uploads. For more information, see Best practices for working with Amazon S3 buckets in the *Amazon EMR Management Guide*.

Job tuning considerations

The EMRFS S3-optimized committer consumes a small amount of memory for each file written by a task attempt until the task gets committed or aborted. In most jobs, the amount of memory consumed is negligible. For jobs that have long-running tasks that write a large number of files, the memory that the committer consumes may be noticeable and require adjustments to the memory allocated for Spark executors. You can tune executor memory using the `spark.executor.memory` property. As a guideline, a single task writing 100,000 files would typically require an additional 100MB of memory. For more information, see Application properties in the Apache Spark Configuration documentation.

Enable the EMRFS S3-optimized committer for Amazon EMR 5.19.0

If you are using Amazon EMR 5.19.0 , you can manually set the `spark.sql.parquet.fs.optimized.committer.optimization-enabled` property to `true` when you create a cluster or from within Spark if you are using Amazon EMR .

Enabling the EMRFS S3-optimized committer when creating a cluster

Use the `spark-defaults` configuration classification to set the `spark.sql.parquet.fs.optimized.committer.optimization-enabled` property to `true`. For more information, see Configure applications.

Enabling the EMRFS S3-optimized committer from Spark

You can set `spark.sql.parquet.fs.optimized.committer.optimization-enabled` to `true` by hard-coding it in a `SparkConf`, passing it as a `--conf` parameter in the Spark shell or `spark-submit` and `spark-sql` tools, or in `conf/spark-defaults.conf`. For more information, see Spark configuration in Apache Spark documentation.

The following example shows how to enable the committer while running a spark-sql command.

```
spark-sql \
  --conf spark.sql.parquet.fs.optimized.committer.optimization-enabled=true \
  -e "INSERT OVERWRITE TABLE target_table SELECT * FROM source_table;"
```

Use the EMRFS S3-optimized commit protocol

The EMRFS S3-optimized commit protocol is an alternative FileCommitProtocol implementation that is optimized for writing files with Spark dynamic partition overwrite to Amazon S3 when using EMRFS. The protocol improves application performance by avoiding rename operations in Amazon S3 during the Spark dynamic partition overwrite job commit phase.

Note that the Use the EMRFS S3-optimized committer also improves performance by avoiding rename operations. However, it doesn't work for dynamic partition overwrite cases, while the commit protocol's improvements only target dynamic partition overwrite cases.

The commit protocol is available with Amazon EMR release 5.30.0 and later and 6.2.0 and later and is enabled by default. Amazon EMR added a parallelism improvement starting with release 5.31.0. The protocol is used for Spark jobs that use Spark SQL, DataFrames, or Datasets. There are circumstances under which the commit protocol is not used. For more information, see Requirements for the EMRFS S3-optimized commit protocol.

Topics

Requirements for the EMRFS S3-optimized commit protocol

The EMRFS S3-optimized commit protocol is used when the following conditions are met:

- You run Spark jobs that use Spark SQL, DataFrames, or Datasets to overwrite partitioned tables.
- You run Spark jobs whose partition overwrite mode is `dynamic`.
- Multipart uploads are enabled in Amazon EMR . This is the default. For more information, see The EMRFS S3-optimized commit protocol and multipart uploads.
- The filesystem cache for EMRFS is enabled. This is the default. Check that the setting `fs.s3.impl.disable.cache` is set to `false`.
- Spark's built-in data source support is used. Built-in data source support is used in the following circumstances:
  - When jobs write to built-in data sources or tables.
  - When jobs write to the Hive metastore Parquet table. This happens when `spark.sql.hive.convertInsertingPartitionedTable` and `spark.sql.hive.convertMetastoreParquet` are both set to true. These are the default settings.
  - When jobs write to the Hive metastore ORC table. This happens when `spark.sql.hive.convertInsertingPartitionedTable` and `spark.sql.hive.convertMetastoreOrc` are both set to `true`. These are the default settings.
- Spark job operations that write to a default partition location – for example, `${table_location}/k1=v1/k2=v2/` – use the commit protocol. The protocol is not used if a job operation writes to a custom partition location – for example, if a custom partition location is set using the `ALTER TABLE SQL` command.
- The following values for Spark must be used:
  - `spark.sql.sources.commitProtocolClass` must be set to `org.apache.spark.sql.execution.datasources.SQLEmrOptimizedCommitProtocol`. This is the default setting for Amazon EMR releases 5.30.0 and higher, and 6.2.0 and higher.
  - The `partitionOverwriteMode` write option or `spark.sql.sources.partitionOverwriteMode` must be set to `dynamic`. The default setting is `static`.

> **Note**
>
> The `partitionOverwriteMode` write option was introduced in Spark 2.4.0. For Spark version 2.3.2, included with Amazon EMR release 5.19.0, set the `spark.sql.sources.partitionOverwriteMode` property.

- If Spark jobs overwrite to the Hive metastore Parquet table, `spark.sql.hive.convertMetastoreParquet`, `spark.sql.hive.convertInsertingPartitionedTable`, and `spark.sql.hive.convertMetastore.partitionOverwriteMode` must be set to `true`. There are the default settings.
- If Spark jobs overwrite to the Hive metastore ORC table, `spark.sql.hive.convertMetastoreOrc`, `spark.sql.hive.convertInsertingPartitionedTable`, and `spark.sql.hive.convertMetastore.partitionOverwriteMode` must be set to `true`. There are the default settings.

Example – Dynamic partition overwrite mode

In this Scala example, optimization is triggered. First, you set the `partitionOverwriteMode` property to `dynamic`. This only overwrites those partitions to which you're writing data. Then, you specify dynamic partition columns with `partitionBy` and set the write mode to `overwrite`.

```
val dataset = spark.range(0, 10)
  .withColumn("dt", expr("date_sub(current_date(), id)"))

dataset.write.mode("overwrite")                       // "overwrite" instead of "insert"
  .option("partitionOverwriteMode", "dynamic")  // "dynamic" instead of "static"
  .partitionBy("dt")                            // partitioned data instead of
 unpartitioned data
  .parquet("s3://EXAMPLE-DOC-BUCKET/output")    // "s3://" to use Amazon EMR file
 system, instead of "s3a://" or "hdfs://"
```

When the EMRFS S3-optimized commit protocol is not used

Generally, the EMRFS S3-optimized commit protocol works the same as open source default Spark SQL commit protocol, `org.apache.spark.sql.execution.datasources.SQLHadoopMapReduceCommitProtocol`. Optimization won't occur in the following situations.

Situation	Why the commit protocol is not used
When you write to HDFS	The commit protocol only supports writing to Amazon S3 using EMRFS.

Situation	Why the commit protocol is not used
When you use the S3A file system	The commit protocol only supports EMRFS.
When you use MapReduce or Spark's RDD API	The commit protocol only supports using SparkSQL, DataFrame, or Dataset APIs.
When the dynamic partition overwrite isn't triggered	The commit protocol only optimizes dynamic partition overwrite cases. For other cases, see Use the EMRFS S3-optimized committer.

The following Scala examples demonstrate some additional situations that the EMRFS S3-optimized commit protocol delegates to `SQLHadoopMapReduceCommitProtocol`.

Example – Dynamic partition overwrite mode with custom partition location

In this example, the Scala programs overwrites two partitions in dynamic partition overwrite mode. One partition has a custom partition location. The other partition uses the default partition location. The EMRFS S3-optimized commit protocol only improves the partition that uses the default partition location.

```
val table = "dataset"
val inputView = "tempView"
val location = "s3://bucket/table"

spark.sql(s"""
  CREATE TABLE $table (id bigint, dt date)
  USING PARQUET PARTITIONED BY (dt)
  LOCATION '$location'
""")

// Add a partition using a custom location
val customPartitionLocation = "s3://bucket/custom"
spark.sql(s"""
  ALTER TABLE $table ADD PARTITION (dt='2019-01-28')
  LOCATION '$customPartitionLocation'
""")

// Add another partition using default location
spark.sql(s"ALTER TABLE $table ADD PARTITION (dt='2019-01-29')")
```

```
def asDate(text: String) = lit(text).cast("date")

spark.range(0, 10)
  .withColumn("dt",
    when($"id" > 4, asDate("2019-01-28")).otherwise(asDate("2019-01-29")))
  .createTempView(inputView)

// Set partition overwrite mode to 'dynamic'
spark.sql(s"SET spark.sql.sources.partitionOverwriteMode=dynamic")

spark.sql(s"INSERT OVERWRITE TABLE $table SELECT * FROM $inputView")
```

The Scala code creates the following Amazon S3 objects:

```
custom/part-00001-035a2a9c-4a09-4917-8819-e77134342402.c000.snappy.parquet
custom_$folder$
table/_SUCCESS
table/dt=2019-01-29/part-00000-035a2a9c-4a09-4917-8819-e77134342402.c000.snappy.parquet
table/dt=2019-01-29_$folder$
table_$folder$
```

Note

Writing to custom partition locations in earlier Spark versions may result in data loss. In this example, partition `dt='2019-01-28'` would be lost. For more details, see SPARK-35106. This is fixed in Amazon EMR release 5.33.0 and later, excluding 6.0.x and 6.1.x.

When writing to partitions at custom locations, Spark uses a commit algorithm similar to the previous example, which is outlined below. As with the earlier example, the algorithm results in sequential renames, which may negatively impact performance.

The algorithm in Spark 2.4.0 follows these steps:

1. When writing output to a partition at a custom location, tasks write to a file under Spark's staging directory, which is created under the final output location. The name of the file includes a random UUID to protect against file collisions. The task attempt keeps track of each file along with the final desired output path.
2. When a task completes successfully, it provides the driver with the files and their final desired output paths.

3. After all tasks complete, the job commit phase sequentially renames all files that were written for partitions at custom locations to their final output paths.
4. The staging directory is deleted before the job commit phase completes.

The EMRFS S3-optimized commit protocol and multipart uploads

To use make use of the optimization for dynamic partition overwrite in the EMRFS S3-optimized commit protocol, multipart uploads must be enabled in Amazon EMR . Multipart uploads are enabled by default. You can re-enable it if required. For more information, see Configure multipart upload for Amazon S3 in the *Amazon EMR Management Guide*.

During dynamic partition overwrite, the EMRFS S3-optimized commit protocol uses the transaction-like characteristics of multipart uploads to ensure files written by task attempts only appear in the job's output location upon job commit. By using multipart uploads in this way, the commit protocol improves job commit performance over the default `SQLHadoopMapReduceCommitProtocol`. When using the EMRFS S3-optimized commit protocol, there are some key differences from traditional multipart upload behavior to consider:

- Multipart uploads are always performed regardless of the file size. This differs from the default behavior of EMRFS, where the `fs.s3n.multipart.uploads.split.size` property controls the file size at which multipart uploads are triggered.
- Multipart uploads are left in an incomplete state for a longer period of time until the task commits or aborts. This differs from the default behavior of EMRFS where a multipart upload completes when a task finishes writing a given file.

Because of these differences, if a Spark Executor JVM crashes or is killed while tasks are running and writing data to Amazon S3, or a Spark Driver JVM crashes or is killed while a job is running, incomplete multipart uploads are more likely to be left behind. For this reason, when you use the EMRFS S3-optimized commit protocol, be sure to follow the best practices for managing failed multipart uploads. For more information, see Best practices for working with Amazon S3 buckets in the *Amazon EMR Management Guide*.

Job tuning considerations

On Spark executors, the EMRFS S3-optimized commit protocol consumes a small amount of memory for each file written by a task attempt until the task gets committed or aborted. In most jobs, the amount of memory consumed is negligible.

On Spark drivers, the EMRFS S3-optimized commit protocol requires memory to store metadata info of each committed file until the job gets committed or aborted. In most jobs, default Spark driver memory setting is negligible.

For jobs that have long-running tasks that write a large number of files, the memory that the commit protocol consumes may be noticeable and require adjustments to the memory allocated for Spark, especially for Spark executors. You can tune memory using the `spark.driver.memory` property for Spark drivers, and the `spark.executor.memory` property for Spark executors. As a guideline, a single task writing 100,000 files would typically require an additional 100MB of memory. For more information, see [Application properties] in the Apache Spark Configuration documentation.

Retry Amazon S3 requests with EMRFS

This topic provides information about the retry strategies that you can use when making requests to Amazon S3 with EMRFS. When your request rate increases, S3 tries to scale to support the new rate. During this process S3 can throttle requests and return a `503 Slow Down` error. To improve the success rate of your S3 requests, you can adjust your retry strategy by configuring properties in your `emrfs-site` configuration.

You can adjust your retry strategy in the following ways.

- Increase the maximum retry limit for the default exponential backoff retry strategy.
- Enable and configure the additive-increase/multiplicative-decrease (AIMD) retry strategy. AIMD is supported for Amazon EMR releases 6.4.0 and later.

Use the default exponential backoff strategy

By default, EMRFS uses an exponential backoff strategy to retry Amazon S3 requests. The default EMRFS retry limit is 15. To avoid an S3 `503 Slow Down` error, you can increase the retry limit when you create a new cluster, on a running cluster, or at application runtime.

To increase the retry limit, you must change the value for `fs.s3.maxRetries` in your `emrfs-site` configuration. The following example configuration sets `fs.s3.maxRetries` to a custom value of 30.

```
[
    {
      "Classification": "emrfs-site",
```

```
      "Properties": {
        "fs.s3.maxRetries": "30"
      }
    }
]
```

For more information about working with configuration objects, see Configure applications.

Use the AIMD retry strategy

With Amazon EMR release 6.4.0 and later, EMRFS supports an alternative retry strategy based on an additive-increase/multiplicative-decrease (AIMD) model. The AIMD retry strategy is especially useful when you work with large Amazon EMR clusters.

AIMD calculates a custom request rate using data about recent successful requests. This strategy decreases the number of throttled requests and the total attempts required per request.

To enable the AIMD retry strategy, you must set the `fs.s3.aimd.enabled` property to `true` in your `emrfs-site` configuration as in the following example.

```
[
    {
      "Classification": "emrfs-site",
      "Properties": {
        "fs.s3.aimd.enabled": "true"
      }
    }
]
```

For more information about working with configuration objects, see Configure applications.

Advanced AIMD retry settings

You can configure the properties listed in the following table to refine retry behavior when you use the AIMD retry strategy. For most use cases, we recommend that you use the default values.

Advanced AIMD retry strategy properties

Property	Default value	Description
`fs.s3.aimd.increaseIncrement`	0.1	Controls how quickly the request rate increases when

Property	Default value	Description
		consecutive requests are successful.
`fs.s3.aimd.reductionFactor`	2	Controls how quickly the request rate decreases when Amazon S3 returns a 503 response. The default factor of 2 cuts the request rate in half.
`fs.s3.aimd.minRate`	0.1	Sets the lower bound for the request rate when requests experience sustained throttling by S3.
`fs.s3.aimd.initialRate`	5500	Sets the initial request rate, which then changes according to the values that you specify for `fs.s3.aimd.increaseIncrement` and `fs.s3.aimd.reductionFactor` . The initial rate is also used for GET requests, and scaled proportionally (3500/5500) for PUT requests.
`fs.s3.aimd.adjustWindow`	2	Controls how frequently the request rate is adjusted, measured in number of responses.
`fs.s3.aimd.maxAttempts`	100	Sets the maximum number of attempts to try a request.

Add a Spark step

You can use Amazon EMR steps to submit work to the Spark framework installed on an EMR cluster. For more information, see Steps in the Amazon EMR Management Guide. In the console and CLI, you do this using a Spark application step, which runs the `spark-submit` script as a step on your behalf. With the API, you use a step to invoke `spark-submit` using `command-runner.jar`.

For more information about submitting applications to Spark, see the Submitting applications topic in the Apache Spark documentation.

To submit a Spark step using the console

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. In the **Cluster List**, choose the name of your cluster.
3. Scroll to the **Steps** section and expand it, then choose **Add step**.
4. In the **Add Step** dialog box:
   - For **Step type**, choose **Spark application**.
   - For **Name**, accept the default name (Spark application) or type a new name.
   - For **Deploy mode**, choose **Client** or **Cluster** mode. Client mode launches the driver program on the cluster's primary instance, while cluster mode launches your driver program on the cluster. For client mode, the driver's log output appears in the step logs, while for cluster mode, the driver's log output appears in the logs for the first YARN container. For more information, see Cluster mode overview in the Apache Spark documentation.
   - Specify the desired **Spark-submit options**. For more information about `spark-submit` options, see Launching applications with spark-submit.
   - For **Application location**, specify the local or S3 URI path of the application.
   - For **Arguments**, leave the field blank.
   - For **Action on failure**, accept the default option (**Continue**).
5. Choose **Add**. The step appears in the console with a status of Pending.
6. The status of the step changes from **Pending** to **Running** to **Completed** as the step runs. To update the status, choose the **Refresh** icon above the **Actions** column.

7. The results of the step are located in the Amazon EMR console Cluster Details page next to your step under **Log Files** if you have logging configured. You can optionally find step information in the log bucket you configured when you launched the cluster.

To submit work to Spark using the AWS CLI

Submit a step when you create the cluster or use the `aws emr add-steps` subcommand in an existing cluster.

1. Use `create-cluster` as shown in the following example.

   Note

   Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name "Add Spark Step Cluster" --release-label emr-7.2.0 --
applications Name=Spark \
--ec2-attributes KeyName=myKey --instance-type m5.xlarge --instance-count 3 \
--steps Type=Spark,Name="Spark Program",ActionOnFailure=CONTINUE,Args=[--
class,org.apache.spark.examples.SparkPi,/usr/lib/spark/examples/jars/spark-
examples.jar,10] --use-default-roles
```

   As an alternative, you can use `command-runner.jar` as shown in the following example.

```
aws emr create-cluster --name "Add Spark Step Cluster" --release-label emr-7.2.0 \
--applications Name=Spark --ec2-attributes KeyName=myKey --instance-type m5.xlarge
 --instance-count 3 \
--steps Type=CUSTOM_JAR,Name="Spark Program",Jar="command-
runner.jar",ActionOnFailure=CONTINUE,Args=[spark-example,SparkPi,10] --use-default-
roles
```

   Note

   Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

2. Alternatively, add steps to a cluster already running. Use `add-steps`.

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF --steps
 Type=Spark,Name="Spark Program",ActionOnFailure=CONTINUE,Args=[--
class,org.apache.spark.examples.SparkPi,/usr/lib/spark/examples/jars/spark-
examples.jar,10]
```

As an alternative, you can use `command-runner.jar` as shown in the following example.

```
aws emr add-steps --cluster-id j-2AXXXXXXGAPLF --steps Type=CUSTOM_JAR,Name="Spark
 Program",Jar="command-runner.jar",ActionOnFailure=CONTINUE,Args=[spark-
example,SparkPi,10]
```

To submit work to Spark using the SDK for Java

1. The following example shows how to add a step to a cluster with Spark using Java.

```
AWSCredentials credentials = new BasicAWSCredentials(accessKey, secretKey);
AmazonElasticMapReduce emr = new AmazonElasticMapReduceClient(credentials);

StepFactory stepFactory = new StepFactory();
AmazonElasticMapReduceClient emr = new AmazonElasticMapReduceClient(credentials);
AddJobFlowStepsRequest req = new AddJobFlowStepsRequest();
req.withJobFlowId("j-1K48XXXXXXHCB");

List<StepConfig> stepConfigs = new ArrayList<StepConfig>();

HadoopJarStepConfig sparkStepConf = new HadoopJarStepConfig()
   .withJar("command-runner.jar")
   .withArgs("spark-submit","--executor-memory","1g","--
class","org.apache.spark.examples.SparkPi","/usr/lib/spark/examples/jars/spark-
examples.jar","10");

StepConfig sparkStep = new StepConfig()
   .withName("Spark Step")
   .withActionOnFailure("CONTINUE")
   .withHadoopJarStep(sparkStepConf);

stepConfigs.add(sparkStep);
req.withSteps(stepConfigs);
AddJobFlowStepsResult result = emr.addJobFlowSteps(req);
```

2. View the results of the step by examining the logs for the step. You can do this in the AWS Management Console if you have enabled logging by choosing **Steps**, selecting your step, and then, for **Log files**, choosing either `stdout` or `stderr`. To see the logs available, choose **View Logs**.

Overriding Spark default configuration settings

You may want to override Spark default configuration values on a per-application basis. You can do this when you submit applications using a step, which essentially passes options to `spark-submit`. For example, you may wish to change the memory allocated to an executor process by changing `spark.executor.memory`. You would supply the `--executor-memory` switch with an argument like the following:

```
spark-submit --executor-memory 1g --class org.apache.spark.examples.SparkPi /usr/lib/spark/examples/jars/spark-examples.jar 10
```

Similarly, you can tune `--executor-cores` and `--driver-memory`. In a step, you would provide the following arguments to the step:

```
--executor-memory 1g --class org.apache.spark.examples.SparkPi /usr/lib/spark/examples/jars/spark-examples.jar 10
```

You can also tune settings that may not have a built-in switch using the `--conf` option. For more information about other settings that are tunable, see the [Dynamically loading Spark properties](#) topic in the Apache Spark documentation.

View Spark application history

You can view Spark, YARN application, and Tez UI details using the **Application user interfaces** tab of a cluster's detail page in the console. Amazon EMR application user interfaces (UI) make it easier for you to troubleshoot and analyze active jobs and job history.

For more information, see View application history in the *Amazon EMR Management Guide*.

Access the Spark web UIs

You can view the Spark web UIs by following the procedures to create an SSH tunnel or create a proxy in the section called Connect to the cluster in the Amazon EMR Management Guide and then navigating to the YARN ResourceManager for your cluster. Choose the link under **Tracking UI** for your application. If your application is running, you see **ApplicationMaster**. This takes you to the application master's web UI at port 20888 wherever the driver is located. The driver may be located on the cluster's primary node if you run in YARN client mode. If you are running an application in YARN cluster mode, the driver is located in the ApplicationMaster for the application on the cluster. If your application has finished, you see **History**, which takes you to the Spark HistoryServer UI port number at 18080 of the EMR cluster's primary node. This is for applications that have already completed. You can also navigate to the Spark HistoryServer UI directly at http://*master-public-dns-name*:18080/.

With Amazon EMR release 5.25.0 and later, you can access Spark history server UI from the console without setting up a web proxy through an SSH connection. For more information, see [View persistent application user interfaces](#).

Using the Spark structured streaming Amazon Kinesis Data Streams connector

Amazon EMR releases 7.1.0 and higher include a spark structured streaming Amazon Kinesis Data Streams connector in the release image. With this connector, you can use Spark on Amazon EMR to process data that's stored in Amazon Kinesis Data Streams. The connector supports both consumer types of `GetRecords` (shared throughput) and `SubscribeToShard` (enhanced fan-out). This integration is based on the `spark-sql-kinesis-connector`. For details about how to get started using the connector, see the README.

The following example demonstrates how to use the connector to launch a Spark application with Amazon EMR

```
spark-submit my_kinesis_streaming_script.py
```

Using Amazon Redshift integration for Apache Spark with Amazon EMR

With Amazon EMR release 6.4.0 and later, every release image includes a connector between Apache Spark and Amazon Redshift. With this connector, you can use Spark on Amazon EMR to process data stored in Amazon Redshift. For Amazon EMR releases 6.4.0 through 6.8.0, the integration is based on the `spark-redshift` open-source connector. For Amazon EMR releases 6.9.0 and later, the Amazon Redshift integration for Apache Spark has been migrated from the community version to a native integration.

Topics

Launching a Spark application using the Amazon Redshift integration for Apache Spark

For Amazon EMR releases 6.4 through 6.9, you must use the `--jars` or `--packages` option to specify which of the following JAR files you want to use. The `--jars` option specifies dependencies stored locally, in HDFS, or using HTTP/S. To see other file locations supported by the `--jars` option, see Advanced Dependency Management in the Spark documentation. The `--packages` option specifies dependencies stored in the public Maven repo.

- `spark-redshift.jar`
- `spark-avro.jar`
- `RedshiftJDBC.jar`
- `minimal-json.jar`

Amazon EMR releases 6.10.0 and higher don't require the `minimal-json.jar` dependency, and automatically install the other dependencies to each cluster by default. The following examples show how to launch a Spark application with the Amazon Redshift integration for Apache Spark.

Amazon EMR 6.10.0 +

The following example shows how to launch a Spark application with the `spark-redshift` connector with Amazon EMR releases 6.10 and higher.

```
spark-submit my_script.py
```

Amazon EMR 6.4.0 - 6.9.x

To launch a Spark application with the `spark-redshift` connector on Amazon EMR releases 6.4 through 6.9, you must use the `--jars` or `--packages` option, as the following example shows. Note that the paths listed with the `--jars` option are the default paths for the JAR files.

```
spark-submit \
  --jars /usr/share/aws/redshift/jdbc/RedshiftJDBC.jar,/usr/share/aws/redshift/
spark-redshift/lib/spark-redshift.jar,/usr/share/aws/redshift/spark-redshift/lib/
spark-avro.jar,/usr/share/aws/redshift/spark-redshift/lib/minimal-json.jar \
  my_script.py
```

Authenticating with Amazon Redshift integration for Apache Spark

Using AWS Secrets Manager to retrieve credentials and connect to Amazon Redshift

The following code sample shows how you can use AWS Secrets Manager to retrieve credentials to connect to an Amazon Redshift cluster with the PySpark interface for Apache Spark in Python.

```
from pyspark.sql import SQLContext
import boto3

sc = # existing SparkContext
sql_context = SQLContext(sc)

secretsmanager_client = boto3.client('secretsmanager')
secret_manager_response = secretsmanager_client.get_secret_value(
    SecretId='string',
    VersionId='string',
    VersionStage='string'
)
username = # get username from secret_manager_response
password = # get password from secret_manager_response
url = "jdbc:redshift://redshifthost:5439/database?user=" + username + "&password=" +
 password

# Read data from a table
df = sql_context.read \
    .format("io.github.spark_redshift_community.spark.redshift") \
    .option("url", url) \
```

```
    .option("dbtable", "my_table") \
    .option("tempdir", "s3://path/for/temp/data") \
    .load()
```

Using IAM to retrieve credentials and connect to Amazon Redshift

You can use the Amazon Redshift-provided JDBC version 2 driver to connect to Amazon Redshift with the Spark connector. To use AWS Identity and Access Management (IAM), configure your JDBC URL to use IAM authentication. To connect to a Redshift cluster from Amazon EMR, you must give your IAM role permission to retrieve temporary IAM credentials. Assign the following permissions to your IAM role so that it can retrieve credentials and run Amazon S3 operations.

- Redshift:GetClusterCredentials (for provisioned Amazon Redshift clusters)
- Redshift:DescribeClusters (for provisioned Amazon Redshift clusters)
- Redshift:GetWorkgroup (for Amazon Redshift Serverless workgroups)
- Redshift:GetCredentials (for Amazon Redshift Serverless workgroups)
- s3:GetBucket
- s3:GetBucketLocation
- s3:GetObject
- s3:PutObject
- s3:GetBucketLifecycleConfiguration

For more information about `GetClusterCredentials`, see Resource policies for `GetClusterCredentials`.

You also must make sure that Amazon Redshift can assume the IAM role during `COPY` and `UNLOAD` operations.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
```

```
    ]
}
```

The following example uses IAM authentication between Spark and Amazon Redshift:

```
from pyspark.sql import SQLContext
import boto3

sc = # existing SparkContext
sql_context = SQLContext(sc)

url = "jdbc:redshift:iam//redshift-host:redshift-port/db-name"
iam_role_arn = "arn:aws:iam::account-id:role/role-name"

# Read data from a table
df = sql_context.read \
    .format("io.github.spark_redshift_community.spark.redshift") \
    .option("url", url) \
    .option("aws_iam_role", iam_role_arn) \
    .option("dbtable", "my_table") \
    .option("tempdir", "s3a://path/for/temp/data") \
    .mode("error") \
    .load()
```

Reading and writing from and to Amazon Redshift

The following code examples use PySpark to read and write sample data from and to an Amazon Redshift database with data source API and using SparkSQL.

Data source API

Use PySpark to read and write sample data from and to an Amazon Redshift database with data source API.

```
import boto3
from pyspark.sql import SQLContext

sc = # existing SparkContext
sql_context = SQLContext(sc)

url = "jdbc:redshift:iam://redshifthost:5439/database"
aws_iam_role_arn = "arn:aws:iam::accountID:role/roleName"
```

```
df = sql_context.read \
    .format("io.github.spark_redshift_community.spark.redshift") \
    .option("url", url) \
    .option("dbtable", "tableName") \
    .option("tempdir", "s3://path/for/temp/data") \
    .option("aws_iam_role", "aws_iam_role_arn") \
    .load()

df.write \
    .format("io.github.spark_redshift_community.spark.redshift") \
    .option("url", url) \
    .option("dbtable", "tableName_copy") \
    .option("tempdir", "s3://path/for/temp/data") \
    .option("aws_iam_role", "aws_iam_role_arn") \
    .mode("error") \
    .save()
```

SparkSQL

Use PySpark to read and write sample data from and to an Amazon Redshift database with SparkSQL.

```
import boto3
import json
import sys
import os
from pyspark.sql import SparkSession

spark = SparkSession \
    .builder \
    .enableHiveSupport() \
    .getOrCreate()

url = "jdbc:redshift:iam://redshifthost:5439/database"
aws_iam_role_arn = "arn:aws:iam::accountID:role/roleName"

bucket = "s3://path/for/temp/data"
tableName = "tableName" # Redshift table name

s = f"""CREATE TABLE IF NOT EXISTS {tableName} (country string, data string)
    USING io.github.spark_redshift_community.spark.redshift
```

```
    OPTIONS (dbtable '{tableName}', tempdir '{bucket}', url '{url}', aws_iam_role
 '{aws_iam_role_arn}' ); """

spark.sql(s)

columns = ["country" ,"data"]
data = [("test-country","test-data")]
df = spark.sparkContext.parallelize(data).toDF(columns)

# Insert data into table
df.write.insertInto(tableName, overwrite=False)
df = spark.sql(f"SELECT * FROM {tableName}")
df.show()
```

Considerations and limitations when using the Spark connector

- We recommend that you turn on SSL for the JDBC connection from Spark on Amazon EMR to Amazon Redshift.
- We recommend that you manage the credentials for the Amazon Redshift cluster in AWS Secrets Manager as a best practice. See Using AWS Secrets Manager to retrieve credentials for connecting to Amazon Redshift for an example.
- We recommend that you pass an IAM role with the parameter `aws_iam_role` for the Amazon Redshift authentication parameter.
- The `tempdir` URI points to an Amazon S3 location. This temp directory isn't cleaned up automatically and therefore could add additional cost.
- Consider the following recommendations for Amazon Redshift:
  - We recommend that you block public access to the Amazon Redshift cluster.
  - We recommend that you turn on Amazon Redshift audit logging.
  - We recommend that you turn on Amazon Redshift at-rest encryption.
- Consider the following recommendations for Amazon S3:
  - We recommend that you block public access to Amazon S3 buckets.
  - We recommend that you use Amazon S3 server-side encryption to encrypt the Amazon S3 buckets used.
  - We recommend that you use Amazon S3 lifecycle policies to define the retention rules for the Amazon S3 bucket.

- Amazon EMR always verifies code imported from open-source into the image. For security, we don't support the following authentication methods from Spark to Amazon S3:
  - Setting AWS access keys in the `hadoop-env` configuration classification
  - Encoding AWS access keys in the `tempdir` URI

For more information on using the connector and its supported parameters, see the following resources:

- Amazon Redshift integration for Apache Spark in the *Amazon Redshift Management Guide*
- The `spark-redshift` community repository on Github

Spark release history

The following table lists the version of Spark included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

> **Important**
>
> Apache Spark version 2.3.1, available beginning with Amazon EMR release 5.16.0, addresses CVE-2018-8024 and CVE-2018-1334. We recommend that you migrate earlier versions of Spark to Spark version 2.3.1 or later.

Spark version information

Amazon EMR Release label	Spark Version	Components installed with Spark
emr-7.2.0	3.5.1	delta, emrfs, emr-goodies, emr-ddb, emr-s3-select, hadoop-client, hadoop-hd fs-datanode, hadoop-hdfs-library, hadoop-hdfs-nameno de, hadoop-httpfs-server, hadoop-kms-server, hadoop-

emr-4.1.0	1.5.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave

Amazon EMR Release label	Spark Version	Components installed with Spark
emr-4.0.0	1.4.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave

Apache Sqoop

Apache Sqoop is a tool for transferring data between Amazon S3, Hadoop, HDFS, and RDBMS databases. For more information, see the Apache Sqoop website. Sqoop is included in Amazon EMR releases 5.0.0 and later. Earlier releases include Sqoop as a sandbox application. For more information, see Amazon EMR 4.x release versions.

Topics

Sqoop version information

Sqoop version for 7.2.0

The following table lists the version of Sqoop included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Sqoop.

For the version of components installed with Sqoop in this release, see Release 7.2.0 Component Versions.

Sqoop version information for emr-7.2.0

Amazon EMR Release Label	Sqoop Version	Components Installed With Sqoop
emr-7.2.0	Sqoop 1.4.7	emrfs, emr-ddb, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-

Amazon EMR Release Label	Sqoop Version	Components Installed With Sqoop
		timeline-server, mariadb-server, sqoop-client

Sqoop version for 6.15.0

The following table lists the version of Sqoop included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Sqoop.

For the version of components installed with Sqoop in this release, see Release 6.15.0 Component Versions.

Sqoop version information for emr-6.15.0

Amazon EMR Release Label	Sqoop Version	Components Installed With Sqoop
emr-6.15.0	Sqoop 1.4.7	emrfs, emr-ddb, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mariadb-server, sqoop-client

Sqoop version for 5.36.2

The following table lists the version of Sqoop included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Sqoop.

For the version of components installed with Sqoop in this release, see Release 5.36.2 Component Versions.

Sqoop version information for emr-5.36.2

Amazon EMR Release Label	Sqoop Version	Components Installed With Sqoop
emr-5.36.2	Sqoop 1.4.7	emrfs, emr-ddb, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mariadb-server, sqoop-client

Considerations with Sqoop on Amazon EMR

Consider the following items when you run Sqoop on Amazon EMR.

Using Sqoop with HCatalog integration

Sqoop on Amazon EMR supports Sqoop-HCatalog integration. When you use Sqoop to write output to an HCatalog table in Amazon S3, disable Amazon EMR direct write by setting the `mapred.output.direct.NativeS3FileSystem` and `mapred.output.direct.EmrFileSystem` properties to `false`. For more information, see Using HCatalog. You can use the Hadoop `-D mapred.output.direct.NativeS3FileSystem=false` and `-D mapred.output.direct.EmrFileSystem=false` commands. If you don't disable direct write, no error occurs, but the table is created in Amazon S3 and no data is written.

Sqoop JDBC and database support

By default, Sqoop has a MariaDB and PostgreSQL driver installed. The PostgreSQL driver installed for Sqoop only works for PostgreSQL 8.4. To install an alternate set of JDBC connectors for Sqoop, connect to the cluster master node and install them in `/usr/lib/sqoop/lib`. The following are links for various JDBC connectors:

- MariaDB: About MariaDB Connector/J.
- PostgreSQL: PostgreSQL JDBC driver.
- SQLServer: Download Microsoft JDBC driver for SQL Server.
- MySQL: Download Connector/J
- Oracle: Get Oracle JDBC drivers and UCP from the Oracle Maven repository

The supported databases for Sqoop are listed at the following url, http://sqoop.apache.org/docs/*version*/SqoopUserGuide.html#_supported_databases, where *version* is the version of Sqoop you are using, for example 1.4.6. If the JDBC connect string does not match those in this list, you must specify a driver.

For example, you can export to an Amazon Redshift database table with the following command (for JDBC 4.1):

```
sqoop export --connect jdbc:redshift://$MYREDSHIFTHOST:5439/mydb --table mysqoopexport
 --export-dir s3://mybucket/myinputfiles/ --driver com.amazon.redshift.jdbc41.Driver --
username master --password Mymasterpass1
```

You can use both the MariaDB and MySQL connection strings but if you specify the MariaDB connection string, you need to specify the driver:

```
sqoop export --connect jdbc:mariadb://$HOSTNAME:3306/mydb --table mysqoopexport
 --export-dir s3://mybucket/myinputfiles/ --driver org.mariadb.jdbc.Driver --
username master --password Mymasterpass1
```

If you are using Secure Socket Layer encryption to access your database, you need to use a JDBC URI like in the following Sqoop export example:

```
sqoop export --connect jdbc:mariadb://$HOSTNAME:3306/mydb?
verifyServerCertificate=false&useSSL=true&requireSSL=true --table mysqoopexport
 --export-dir s3://mybucket/myinputfiles/ --driver org.mariadb.jdbc.Driver --
username master --password Mymasterpass1
```

For more information about SSL encryption in RDS, see Using SSL to encrypt a connection to a DB instance in the Amazon RDS User Guide.

For more information, see the Apache Sqoop documentation.

Securing your password

There are several methods that you might choose from to securely pass your password:

Java KeyStore

The preferred method encrypts the password with a Java KeyStore (JKS), eliminating the need to store the password in a readable format.

1. Create a password alias. On prompt, enter the password that you use to access the database.

```
hadoop credential create mydb.password.alias -provider jceks://hdfs/user/root/
mysql.password.jceks
```

2. Use the password alias to launch the Sqoop job:

```
sqoop export -Dhadoop.security.credential.provider.path=jceks://hdfs/user/
root/mysql.password.jceks --connect jdbc:mariadb://$HOSTNAME:3306/mydb
 --table mysqoopexport --export-dir s3://mybucket/myinputfiles/ --driver
 org.mariadb.jdbc.Driver --username master --password-alias mydb.password.alias
```

--password-file

You can use the `--password-file` command to pass the password through a file as shown in the following example:

1. Create a new file that contains the password:

```
echo -n 'Mymasterpass1' > /home/hadoop/mysql-pass.password
```

2. Use the file to launch the Sqoop job:

```
sqoop export --connect jdbc:mariadb://$HOSTNAME:3306/mydb --table mysqoopexport
 --export-dir s3://mybucket/myinputfiles/ --driver org.mariadb.jdbc.Driver --
username master --password-file /home/hadoop/mysql-pass.password
```

-P

You can use the -P command to enter the password through a prompt as shown in the following example:

```
sqoop export --connect jdbc:mariadb://$HOSTNAME:3306/mydb --table mysqoopexport --
export-dir s3://mybucket/myinputfiles/ --driver org.mariadb.jdbc.Driver --username
 master -P
```

Sqoop release history

The following table lists the version of Sqoop included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Sqoop version information

Amazon EMR Release label	Sqoop Version	Components installed with Sqoop
emr-7.2.0	1.4.7	emrfs, emr-ddb, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, mariadb-server, sqoop-client

emr-5.0.0	1.4.6	emrfs, emr-ddb, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, mysql-server, sqoop-client

TensorFlow

TensorFlow is an open-source symbolic math library for machine intelligence and deep learning applications. For more information, see the TensorFlow website. TensorFlow is available with Amazon EMR release version 5.17.0 and later.

The following table lists the version of TensorFlow included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with TensorFlow.

For the version of components installed with TensorFlow in this release, see Release 7.2.0 Component Versions.

TensorFlow version information for emr-7.2.0

Amazon EMR Release Label	TensorFlow Version	Components Installed With TensorFlow
emr-7.2.0	TensorFlow 2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow

The following table lists the version of TensorFlow included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with TensorFlow.

For the version of components installed with TensorFlow in this release, see Release 6.15.0 Component Versions.

TensorFlow version information for emr-6.15.0

Amazon EMR Release Label	TensorFlow Version	Components Installed With TensorFlow
emr-6.15.0	TensorFlow 2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow

The following table lists the version of TensorFlow included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with TensorFlow.

For the version of components installed with TensorFlow in this release, see Release 5.36.2 Component Versions.

TensorFlow version information for emr-5.36.2

Amazon EMR Release Label	TensorFlow Version	Components Installed With TensorFlow
emr-5.36.2	TensorFlow 2.4.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow

TensorFlow builds by Amazon EC2 instance type

Amazon EMR uses different builds of the TensorFlow library depending on the instance types that you choose for your cluster. The following table lists builds by instance type.

EC2 instance types	TensorFlow build
M5 and C5	Tensorflow 1.9.0 with Intel MKL optimization
P2	Tensorflow 1.9.0 with CUDA 9.2, cuDNN 7.1
P3	Tensorflow 1.9.0 with CUDA 9.2, cuDNN 7.1, NCCL 2.2.13 Nvidia NCCL is available only on P3 instances. **End User License Agreement (EULA)**: By using Nvidia components on Amazon EMR, you agree to the terms and conditions outlined in the product EULA.
All others	Tensorflow 1.9.0

Security

In addition to following the guidance in Using TensorFlow securely we recommend that you launch your cluster in a private subnet to help you limit access to trusted sources. For more information, see Amazon VPC options in the *Amazon EMR Management Guide*.

Using TensorBoard

TensorBoard is a suite of visualization tools for TensorFlow programs. For more information, see TensorBoard: Visualized learning on the Tensorflow website.

To use TensorBoard with Amazon EMR, you must start TensorBoard on the cluster master node.

To use tensorboard with Tensorflow on Amazon EMR

1. Connect to the master node of the cluster using SSH. For more information, see Connect to the master node using SSH in the *Amazon EMR Management Guide*.
2. Type the following command to start Tensorboard on the master node. Replace */my/log/directory* with a directory on the master node where you have generated and stored summary data using a summary writer.

   Amazon EMR 5.19.0 and later

   ```
   python3 -m tensorboard.main --logdir=/home/hadoop/tensor --bind_all
   ```

   Amazon EMR 5.18.1 and earlier

   ```
   python3 -m tensorboard.main --logdir=/my/log/dir
   ```

   By default, the master node hosts TensorBoard using port 6006 and the master public DNS name. After you start TensorBoard, the command line output presents the URL that can be used to connect to TensorBoard, as shown in the following example:

   ```
   TensorBoard 1.9.0 at http://master-public-dns-name:6006 (Press CTRL+C to quit)
   ```
3. Set up access to web interfaces on the master node from trusted clients. For more information, see View web interfaces hosted on Amazon EMR clusters in the *Amazon EMR Management Guide*.
4. Open TensorBoard at `http://master-public-dns-name:6006`.

TensorFlow release history

The following table lists the version of TensorFlow included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

TensorFlow version information

Amazon EMR Release label	TensorFlow Version	Components installed with TensorFlow
emr-7.2.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow
emr-5.36.2	2.4.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow
emr-7.1.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow

Amazon EMR Release label	TensorFlow Version	Components installed with TensorFlow
emr-7.0.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow
emr-6.15.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow
emr-6.14.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow

Amazon EMR Release label	TensorFlow Version	Components installed with TensorFlow
emr-6.13.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow
emr-6.12.0	2.11.0	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tensorflow

Apache Tez

Apache Tez is a framework that creates a complex directed acyclic graph (DAG) of tasks for processing data. You can use it as an alternative to Hadoop MapReduce for some use cases. For example, you can run Pig and Hive workflows with Hadoop MapReduce or you can use Tez as an execution engine. For more information, see https://tez.apache.org/. Amazon EMR releases 4.7.0 and higher include Tez.

The following table lists the version of Tez included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Tez.

For the version of components installed with Tez in this release, see Release 7.2.0 Component Versions.

Tez version information for emr-7.2.0

Amazon EMR Release Label	Tez Version	Components Installed With Tez
emr-7.2.0	Tez 0.10.2	emrfs, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tez-on-yarn, tez-on-worker

The following table lists the version of Tez included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Tez.

For the version of components installed with Tez in this release, see Release 6.15.0 Component Versions.

Tez version information for emr-6.15.0

Amazon EMR Release Label	Tez Version	Components Installed With Tez
emr-6.15.0	Tez 0.10.2	emrfs, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tez-on-yarn, tez-on-worker

The following table lists the version of Tez included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Tez.

For the version of components installed with Tez in this release, see Release 5.36.2 Component Versions.

Tez version information for emr-5.36.2

Amazon EMR Release Label	Tez Version	Components Installed With Tez
emr-5.36.2	Tez 0.9.2	emrfs, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tez-on-yarn

Topics

Creating a cluster with Tez

To install Tez, choose Apache Tez as an application when you create your cluster.

To create a cluster with Tez installed using the console

1. Navigate to the new Amazon EMR console and select **Switch to the old console** from the side navigation. For more information on what to expect when you switch to the old console, see Using the old console.
2. Choose **Create cluster**, **Go to advanced options**.
3. Under **Software Configuration**, select a **Release** of **emr-4.7.0** or higher.
4. Select **Tez** along with other applications you want Amazon EMR to install.
5. Select other options as necessary and then choose **Create cluster**.

To create a cluster with Tez using the AWS CLI

- Use the `create-cluster` command along with the `-- applications` option to specify **Tez**. The following example creates a cluster with Tez installed.

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --name "Cluster with Tez" --release-label emr-7.2.0 \
--applications Name=Tez --ec2-attributes KeyName=myKey \
--instance-type m5.xlarge --instance-count 3 --use-default-roles
```

Configuring Tez

You can customize Tez by setting values using the `tez-site` configuration classification, which configures settings in the `tez-site.xml` configuration file. For more information, see [TezConfiguration](#) in the Apache Tez documentation. To change Hive or Pig to use the Tez execution engine, use the `hive-site` and `pig-properties` configuration classifications as appropriate. Examples are shown below.

Example configuration

Example Example: Customizing the Tez root logging level and setting Tez as the execution engine for Hive and Pig

The example `create-cluster` command shown below creates a cluster with Tez, Hive, and Pig installed. The command references a file stored in Amazon S3, `myConfig.json`, which specifies properties for the `tez-site` classification that sets `tez.am.log.level` to DEBUG, and sets the execution engine to Tez for Hive and Pig using the `hive-site` and `pig-properties` configuration classifications.

> **Note**
>
> Linux line continuation characters (\) are included for readability. They can be removed or used in Linux commands. For Windows, remove them or replace with a caret (^).

```
aws emr create-cluster --release-label emr-7.2.0 \
--applications Name=Tez Name=Hive Name=Pig --ec2-attributes KeyName=myKey \
--instance-type m5.xlarge --instance-count 3 \
--configurations https://s3.amazonaws.com/mybucket/myfolder/myConfig.json --use-
default-roles
```

Example contents of `myConfig.json` are shown below.

```
[
    {
      "Classification": "tez-site",
      "Properties": {
        "tez.am.log.level": "DEBUG"
```

```
      }
    },
    {
      "Classification": "hive-site",
      "Properties": {
        "hive.execution.engine": "tez"
      }
    },
    {
      "Classification": "pig-properties",
      "Properties": {
        "exectype": "tez"
      }
    }
  ]
```

Note

With Amazon EMR version 5.21.0 and later, you can override cluster configurations and specify additional configuration classifications for each instance group in a running cluster. You do this by using the Amazon EMR console, the AWS Command Line Interface (AWS CLI), or the AWS SDK. For more information, see Supplying a Configuration for an Instance Group in a Running Cluster.

Tez asynchronous split opening

When there is a large number of small files in the table path, and a query attempts to read them all, each small file that corresponds to each individual split gets combined under one Tez *grouped split*. A single mapper then processes the single Tez grouped split. Since the execution is synchronous, each individual split under the grouped split gets processed one by one. This requires `RecordReader` objects to synchronously process the splits.

Name	Classification	Description
`tez.grouping.split.init.threads`	`tez-site`	Specifies the number of daemon threads that Tez uses to pre-initiate the `RecordReaders` and open

Name	Classification	Description
		splits. For ACID tables, the maximum supported value of `tez.grouping.split.init.threads` is 1.
`tez.grouping.split.init.recordreaders`	`tez-site`	Specifies the number of `RecordReaders` to keep pre-initialised by the daemon threads. This can help when Tez grouped split contains a large number of `InputSplits`. Initialization of `RecordReaders` to process those input splits can be done asynchronously with daemon threads instead of sequential processing.

Benchmarking for Tez asynchronous split opening

We used the following environments and configurations for benchmarking the Tez asynchronous split opening capability:

- **Benchmark environment** – Amazon EMR cluster with 1 primary node that uses m5.16xlarge, and 16 core nodes that use m5.16xlarge.
- **Benchmark configurations** – To simulate the scenario for benchmarking where a large number of input splits are in a single Tez grouped split, `tez.grouping.split-count` is set to 1.
- **Table used for benchmarking** – The table contains 200 partitions, with each partition containing a single file. The benchmark is done for when that table contains CSV files, and when that table contains parquet files. Hive query for benchmarking: `SELECT COUNT(*)` from the table ten times, and take the average runtime.
- **Configurations to enable Tez async split opening** – As follows:
  - `tez.grouping.split.init.threads` = 4
  - `tez.grouping.split.init.recordreaders` = 10

Dataset	Feature disabled (baseline)	Feature enabled	Improvement
CSV dataset	90.26 seconds	79.20 seconds	12.25%
Parquet dataset	54.67 seconds	42.23 seconds	22.75%

Tez web UI

Tez has its own web user interface. To view the web UI, see the following URL.

```
http://masterDNS:8080/tez-ui
```

To enable the Hive Queries tab on the Tez web UI, set the following configuration.

```
[
  {
    "Classification": "hive-site",
    "Properties": {
      "hive.exec.pre.hooks": "org.apache.hadoop.hive.ql.hooks.ATSHook",
      "hive.exec.post.hooks": "org.apache.hadoop.hive.ql.hooks.ATSHook",
      "hive.exec.failure.hooks": "org.apache.hadoop.hive.ql.hooks.ATSHook"
    }
  }
]
```

You can also view Tez, Spark, and YARN application UI details using links on the **Application user interfaces** tab of a cluster's detail page in the console. Amazon EMR application user interfaces (UI) are hosted off-cluster and are available after the cluster has terminated. They don't require you to set up a SSH connection or web proxy, making it easier for you to troubleshoot and analyze active jobs and job history.

For more information, see View application history in the *Amazon EMR Management Guide*.

Timeline Server

The YARN Timeline Server is configured to run when Tez is installed. To view jobs submitted through Tez or MapReduce execution engines using the Timeline Server, view the web UI using the

URL `http://master-public-DNS:8188`. For more information, see View web interfaces hosted on Amazon EMR clusters in the *Amazon EMR Management Guide*.

Tez release history

The following table lists the version of Tez included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Tez version information

Amazon EMR Release label	Tez Version	Components installed with Tez
emr-7.2.0	0.10.2	emrfs, emr-goodies, hadoop-client, hadoop-mapred, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, tez-on-yarn, tez-on-worker

Tez release notes by version

Topics

Amazon EMR 7.1.0 - Tez release notes

Amazon EMR 7.1.0 - Tez changes

Type	Description
Bug Fix	TEZ-4394 – Netty4 ShuffleHandler: should use 1 boss thread (#256)
Upgrade	Upgrades Netty to 4.1.100.Final.
Upgrade	Upgrades Jetty to 9.4.53.v20231009.

Amazon EMR 6.15.0 - Tez release notes

Amazon EMR 6.15.0 - Tez changes

Type	Description
Feature	TEZ-4397: Open Tez Input splits asynchron ously
Upgrade	TEZ-4493: Upgrade Apache Hadoop to 3.3.6

Amazon EMR 6.15.0 - Tez features

- **Tez asynchronous split opening** – Amazon EMR 6.15.0 introduces configurations that you can specify to asynchronously open the input splits in a Tez *grouped split*. The feature was initiated by TEZ-4397, but had regressions in OSS Hive. Amazon EMR Hive fixed the regressions and additional bugs in Hive ACID table. This improvement results in faster performance of read queries when there are a large number of input splits in a single Tez grouped split. For more information, see Tez asynchronous split opening.

Amazon EMR 6.14.0 - Tez release notes

Amazon EMR 6.14.0 - Tez changes

Type	Description
Improvement	Upgrade TLS version in Tez to 1.2

Amazon EMR 6.13.0 - Tez release notes

Amazon EMR 6.13.0 - Tez changes

Type	Description
Bug Fix	REVERT TEZ-4295: Could not decompress data. Buffer length is too small.
Bug Fix	REVERT TEZ-4302: `NullPointerException` in `CodecUtils` with `GzipCodec` .
Bug Fix	REVERT TEZ-4234: Compressor can cause `IllegalArgumentException` in `Buffer.limit` where limit exceeds capacity.
Bug Fix	REVERT TEZ-4135: Improve memory allocation when executing in-memory reads.

Amazon EMR 6.12.0 - Tez release notes

Amazon EMR 6.12.0 - Tez changes

Type	Description
Improvement	Added Support For JDK 11 and JDK 17 Runtime

Type	Description
Bug Fix	TEZ-4492: Update Bowerrc to use bower.herokuapp mirror to avoid Bower Registry CERT_EXPIRE issue (BOWER-2608)
Upgrade	Upgraded Surefire to 3.0.0-M7

Amazon EMR 6.11.0 - Tez release notes

Amazon EMR 6.11.0 - Tez changes

Type	Description
Bug	Fixed invalid vertex state transition during vertex level cleanup of shuffle data
Bug	Fixed DAG or vertex level cleanup of shuffle data not working
Improvement	Enable tez.am.dag.cleanup.on.completion by default for clearing shuffle data of completed DAGs

Amazon EMR 6.10.0 - Tez release notes

Amazon EMR 6.10.0 - Tez changes

Type	Description
Feature	Enable `tez.runtime.transfer.data-via-events.enabled` by default
Backport	TEZ-4450: Fix shuffle data fetch failure when shuffle data is transferred via data movement events

Type	Description
Backport	TEZ-4460: Fix read timeout error in fetching shuffle data from Tez Shuffle Handler
Backport	TEZ-4455: Add LoggingHandler in ShuffleHandler pipeline for better debuggability
Bug	Fix Tez task getting stuck intermittently when preemption of task is enabled

Amazon EMR 6.9.0 - Tez release notes

Amazon EMR 6.9.0 - Tez changes

Type	Description
Upgrade	Tez is upgraded to 0.10.2. For more information, see the change log for Apache Tez 0.10.2.
Upgrade	Upgrade Hadoop to 3.3.3.
Bug	Disable `tez.runtime.transfer.data-via-events.enabled` by default due to TEZ-4450.

Amazon EMR 6.8.0 - Tez release notes

Amazon EMR 6.8.0 - Tez changes

Type	Description
Backport	TEZ-3363: Delete intermediate data at the vertex level for Shuffle Handler
Backport	TEZ-4129: Delete intermediate attempt data for failed attempts for Shuffle Handler

Type	Description
Backport	TEZ-4430: Fixed tez.task.launch.cmd-opts property not working

Amazon EMR 6.7.0 - Tez release notes

Amazon EMR 6.7.0 - Tez changes

Type	Description
Backport	TEZ-4403: Upgrade SLF4J version to 1.7.36
Backport	TEZ-4405: Replace log4j 1.x with reload4j
Backport	TEZ-4411: Tez Build Failure: FileSaver.js not found

Amazon EMR 6.6.0 - Tez release notes

Amazon EMR 6.6.0 - Tez changes

Type	Description
Backport	TEZ-3918: Fixed tez.task.log.level property not working.
Backport	TEZ-4353: Update commons-io to 2.8.0.
Backport	TEZ-4114: Remove direct jetty dependency from tez.
Backport	TEZ-4323: Jetty jars were removed from dist package with TEZ-4114.

Apache Zeppelin

Use Apache Zeppelin as a notebook for interactive data exploration. For more information about Zeppelin, see https://zeppelin.apache.org/. Zeppelin is included in Amazon EMR releases 5.0.0 and later. Earlier releases include Zeppelin as a sandbox application. For more information, see Amazon EMR 4.x release versions.

To access the Zeppelin web interface, set up an SSH tunnel to the master node and a proxy connection. For more information, see View web interfaces hosted on EMR clusters.

The following table lists the version of Zeppelin included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with Zeppelin.

For the version of components installed with Zeppelin in this release, see Release 7.2.0 Component Versions.

Zeppelin version information for emr-7.2.0

Amazon EMR Release Label	Zeppelin Version	Components Installed With Zeppelin
emr-7.2.0	Zeppelin 0.10.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, livy-server, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, zeppelin-server

The following table lists the version of Zeppelin included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with Zeppelin.

For the version of components installed with Zeppelin in this release, see Release 6.15.0 Component Versions.

Zeppelin version information for emr-6.15.0

Amazon EMR Release Label	Zeppelin Version	Components Installed With Zeppelin
emr-6.15.0	Zeppelin 0.10.1	aws-sagemaker-spark-sdk, emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, livy-server, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, zeppelin-server

The following table lists the version of Zeppelin included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with Zeppelin.

For the version of components installed with Zeppelin in this release, see Release 5.36.2 Component Versions.

Zeppelin version information for emr-5.36.2

Amazon EMR Release Label	Zeppelin Version	Components Installed With Zeppelin
emr-5.36.2	Zeppelin 0.10.0	aws-sagemaker-spark-sdk, emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-nameno

Amazon EMR Release Label	Zeppelin Version	Components Installed With Zeppelin
		de, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server , hudi, hudi-spark, livy-server, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, zeppelin-server

Topics

- Considerations when using Zeppelin on Amazon EMR
- Zeppelin release history

Considerations when using Zeppelin on Amazon EMR

- Connect to Zeppelin using the same SSH tunneling method to connect to other web servers on the master node. Zeppelin server is found at port 8890.
- Zeppelin on Amazon EMR release versions 5.0.0 and later supports Shiro authentication.
- Zeppelin on Amazon EMR release versions 5.8.0 and later supports using AWS Glue Data Catalog as the metastore for Spark SQL. For more information, see Using AWS Glue Data Catalog as the metastore for Spark SQL.
- Zeppelin does not use some of the settings defined in your cluster's `spark-defaults.conf` configuration file, even though it instructs YARN to allocate executors dynamically if you have set `spark.dynamicAllocation.enabled` to `true`. You must set executor settings, such as memory and cores, using the Zeppelin **Interpreter** tab, and then restart the interpreter for them to be used.
- Amazon EMR releases 6.10.0 and higher support Apache Zeppelin integration with Apache Flink. See Working with Flink jobs from Zeppelin in Amazon EMR for more information.
- Zeppelin on Amazon EMR does not support the SparkR interpreter.

Zeppelin release history

The following table lists the version of Zeppelin included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

Zeppelin version information

Amazon EMR Release label	Zeppelin Version	Components installed with Zeppelin
emr-7.2.0	0.10.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, hudi, hudi-spark, livy-server, r, spark-client, spark-history-server, spark-on-yarn, spark-yarn-slave, zeppelin-server

Apache ZooKeeper

Apache ZooKeeper is a centralized service for maintaining configuration information, naming, providing distributed synchronization, and providing group services. For more information about ZooKeeper, see http://zookeeper.apache.org/.

The following table lists the version of ZooKeeper included in the latest release of the Amazon EMR 7.x series, along with the components that Amazon EMR installs with ZooKeeper.

For the version of components installed with ZooKeeper in this release, see Release 7.2.0 Component Versions.

ZooKeeper version information for emr-7.2.0

Amazon EMR Release Label	ZooKeeper Version	Components Installed With ZooKeeper
emr-7.2.0	ZooKeeper 3.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, zookeeper-client, zookeeper-server

The following table lists the version of ZooKeeper included in the latest release of the Amazon EMR 6.x series, along with the components that Amazon EMR installs with ZooKeeper.

For the version of components installed with ZooKeeper in this release, see Release 6.15.0 Component Versions.

ZooKeeper version information for emr-6.15.0

Amazon EMR Release Label	ZooKeeper Version	Components Installed With ZooKeeper
emr-6.15.0	ZooKeeper 3.5.10	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, zookeeper-client, zookeeper-server

The following table lists the version of ZooKeeper included in the latest release of the Amazon EMR 5.x series, along with the components that Amazon EMR installs with ZooKeeper.

For the version of components installed with ZooKeeper in this release, see Release 5.36.2 Component Versions.

ZooKeeper version information for emr-5.36.2

Amazon EMR Release Label	ZooKeeper Version	Components Installed With ZooKeeper
emr-5.36.2	ZooKeeper 3.4.14	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server,

Amazon EMR Release Label	ZooKeeper Version	Components Installed With ZooKeeper
		zookeeper-client, zookeeper-server

Topics

- ZooKeeper release history

ZooKeeper release history

The following table lists the version of ZooKeeper included in each release version of Amazon EMR, along with the components installed with the application. For component versions in each release, see the Component Version section for your release in Amazon EMR 7.x release versions, Amazon EMR 6.x release versions, or Amazon EMR 5.x release versions.

ZooKeeper version information

Amazon EMR Release label	ZooKeeper Version	Components installed with ZooKeeper
emr-7.2.0	3.9.1	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-namenode, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, zookeeper-client, zookeeper-server
emr-5.36.2	3.4.14	emrfs, emr-goodies, hadoop-client, hadoop-hdfs-datanode, hadoop-hdfs-library, hadoop-hdfs-nameno

Amazon EMR Release label	ZooKeeper Version	Components installed with ZooKeeper
		de, hadoop-httpfs-server, hadoop-kms-server, hadoop-yarn-nodemanager, hadoop-yarn-resourcemanager, hadoop-yarn-timeline-server, zookeeper-client, zookeeper-server

Connectors and utilities

Amazon EMR provides several connectors and utilities to access other AWS services as data sources. You can usually access data in these services within a program. For example, you can specify an Kinesis stream in a Hive query, Pig script, or MapReduce application and then operate on that data.

Topics

Export, import, query, and join tables in DynamoDB using Amazon EMR

> **Note**
>
> The Amazon EMR-DynamoDB Connector is open-sourced on GitHub. For more information, see https://github.com/awslabs/emr-dynamodb-connector.

DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. Developers can create a database table and grow its request traffic or storage without limit. DynamoDB automatically spreads the data and traffic for the table over a sufficient number of servers to handle the request capacity specified by the customer and the amount of data stored, while maintaining consistent, fast performance. Using Amazon EMR and Hive you can quickly and efficiently process large amounts of data, such as data stored in DynamoDB. For more information about DynamoDB, see Amazon DynamoDB Developer Guide.

Apache Hive is a software layer that you can use to query map reduce clusters using a simplified, SQL-like query language called HiveQL. It runs on top of the Hadoop architecture. For more information about Hive and HiveQL, go to the HiveQL language manual. For more information about Hive and Amazon EMR, see Apache Hive .

You can use Amazon EMR with a customized version of Hive that includes connectivity to DynamoDB to perform operations on data stored in DynamoDB:

- Loading DynamoDB data into the Hadoop Distributed File System (HDFS) and using it as input into an Amazon EMR cluster.
- Querying live DynamoDB data using SQL-like statements (HiveQL).
- Joining data stored in DynamoDB and exporting it or querying against the joined data.
- Exporting data stored in DynamoDB to Amazon S3.
- Importing data stored in Amazon S3 to DynamoDB.

> **Note**
>
> The Amazon EMR-DynamoDB Connector does not support clusters configured to use Kerberos authentication.

To perform each of the following tasks, you'll launch an Amazon EMR cluster, specify the location of the data in DynamoDB, and issue Hive commands to manipulate the data in DynamoDB.

There are several ways to launch an Amazon EMR cluster: you can use the Amazon EMR console, the command line interface (CLI), or you can program your cluster using an AWS SDK or the Amazon EMR API. You can also choose whether to run a Hive cluster interactively or from a script. In this section, we will show you how to launch an interactive Hive cluster from the Amazon EMR console and the CLI.

Using Hive interactively is a great way to test query performance and tune your application. After you have established a set of Hive commands that will run on a regular basis, consider creating a Hive script that Amazon EMR can run for you.

> **Warning**
>
> Amazon EMR read or write operations on an DynamoDB table count against your established provisioned throughput, potentially increasing the frequency of provisioned throughput exceptions. For large requests, Amazon EMR implements retries with exponential backoff to manage the request load on the DynamoDB table. Running Amazon EMR jobs concurrently with other traffic may cause you to exceed the allocated provisioned throughput level. You can monitor this by checking the **ThrottleRequests** metric in Amazon CloudWatch. If the request load is too high, you can relaunch the cluster and set the Read percent setting or Write percent setting to a lower value to throttle the Amazon

EMR operations. For information about DynamoDB throughput settings, see Provisioned throughput.
If a table is configured for On-Demand mode, you should change the table back to provisioned mode before running an export or import operation. Pipelines need a throughput ratio in order to calculate resources to use from a DynamoDBtable. On-demand mode removes provisioned throughput. To provision throughput capacity, you can use Amazon CloudWatch Events metrics to evaluate the aggregate throughput that a table has used.

Topics

Set up a Hive table to run Hive commands

Apache Hive is a data warehouse application you can use to query data contained in Amazon EMR clusters using a SQL-like language. For more information about Hive, see http://hive.apache.org/.

The following procedure assumes you have already created a cluster and specified an Amazon EC2 key pair. To learn how to get started creating clusters, see Getting started with Amazon EMR in the *Amazon EMR Management Guide*.

Configure Hive to use MapReduce

When you use Hive on Amazon EMR to query DynamoDB tables, errors can occur if Hive uses the default execution engine, Tez. For this reason, when you create a cluster with Hive that integrates with DynamoDB as described in this section, we recommend that you use a configuration classification that sets Hive to use MapReduce. For more information, see Configure applications.

The following snippet shows the configuration classification and property to use to set MapReduce as the execution engine for Hive:

```
[
                {
                    "Classification": "hive-site",
                    "Properties": {
```

```
                    "hive.execution.engine": "mr"
                }
            }
        ]
```

To run Hive commands interactively

1. Connect to the master node. For more information, see [Connect to the master node using SSH](#) in the *Amazon EMR Management Guide*.
2. At the command prompt for the current master node, type `hive`.

   You should see a hive prompt: `hive>`
3. Enter a Hive command that maps a table in the Hive application to the data in DynamoDB. This table acts as a reference to the data stored in Amazon DynamoDB; the data is not stored locally in Hive and any queries using this table run against the live data in DynamoDB, consuming the table's read or write capacity every time a command is run. If you expect to run multiple Hive commands against the same dataset, consider exporting it first.

   The following shows the syntax for mapping a Hive table to a DynamoDB table.

   ```
   CREATE EXTERNAL TABLE hive_tablename
    (hive_column1_name column1_datatype, hive_column2_name column2_datatype...)
   STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
   TBLPROPERTIES ("dynamodb.table.name" = "dynamodb_tablename",
   "dynamodb.column.mapping" =
    "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name..."
   ```

   When you create a table in Hive from DynamoDB, you must create it as an external table using the keyword `EXTERNAL`. The difference between external and internal tables is that the data in internal tables is deleted when an internal table is dropped. This is not the desired behavior when connected to Amazon DynamoDB, and thus only external tables are supported.

   For example, the following Hive command creates a table named *hivetable1* in Hive that references the DynamoDB table named *dynamodbtable1*. The DynamoDB table *dynamodbtable1* has a hash-and-range primary key schema. The hash key element is `name` (string type), the range key element is `year` (numeric type), and each item has an attribute value for `holidays` (string set type).

```
CREATE EXTERNAL TABLE hivetable1 (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");
```

Line 1 uses the HiveQL `CREATE EXTERNAL TABLE` statement. For *hivetable1*, you need to establish a column for each attribute name-value pair in the DynamoDB table, and provide the data type. These values are not case-sensitive, and you can give the columns any name (except reserved words).

Line 2 uses the `STORED BY` statement. The value of `STORED BY` is the name of the class that handles the connection between Hive and DynamoDB. It should be set to `'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'`.

Line 3 uses the `TBLPROPERTIES` statement to associate "hivetable1" with the correct table and schema in DynamoDB. Provide `TBLPROPERTIES` with values for the `dynamodb.table.name` parameter and `dynamodb.column.mapping` parameter. These values *are* case-sensitive.

Note

All DynamoDB attribute names for the table must have corresponding columns in the Hive table. Depending on your Amazon EMR version, the following scenarios occur if the one-to-one mapping does not exist:

- On Amazon EMR version 5.27.0 and later, the connector has validations that ensure a one-to-one mapping between DynamoDB attribute names and columns in the Hive table. An error will occur if the one-to-one mapping does not exist.
- On Amazon EMR version 5.26.0 and earlier, the Hive table won't contain the name-value pair from DynamoDB. If you do not map the DynamoDB primary key attributes, Hive generates an error. If you do not map a non-primary key attribute, no error is generated, but you won't see the data in the Hive table. If the data types do not match, the value is null.

Then you can start running Hive operations on *hivetable1*. Queries run against *hivetable1* are internally run against the DynamoDB table *dynamodbtable1* of your DynamoDB account, consuming read or write units with each execution.

When you run Hive queries against a DynamoDB table, you need to ensure that you have provisioned a sufficient amount of read capacity units.

For example, suppose that you have provisioned 100 units of read capacity for your DynamoDB table. This will let you perform 100 reads, or 409,600 bytes, per second. If that table contains 20GB of data (21,474,836,480 bytes), and your Hive query performs a full table scan, you can estimate how long the query will take to run:

21,474,836,480 / 409,600 = 52,429 seconds = 14.56 hours

The only way to decrease the time required would be to adjust the read capacity units on the source DynamoDB table. Adding more Amazon EMR nodes will not help.

In the Hive output, the completion percentage is updated when one or more mapper processes are finished. For a large DynamoDB table with a low provisioned read capacity setting, the completion percentage output might not be updated for a long time; in the case above, the job will appear to be 0% complete for several hours. For more detailed status on your job's progress, go to the Amazon EMR console; you will be able to view the individual mapper task status, and statistics for data reads. You can also log on to Hadoop interface on the master node and see the Hadoop statistics. This will show you the individual map task status and some data read statistics. For more information, see the following topics:

- Web interfaces hosted on the master node
- View the Hadoop web interfaces

For more information about sample HiveQL statements to perform tasks such as exporting or importing data from DynamoDB and joining tables, see Hive command examples for exporting, importing, and querying data in DynamoDB.

To cancel a Hive request

When you execute a Hive query, the initial response from the server includes the command to cancel the request. To cancel the request at any time in the process, use the **Kill Command** from the server response.

1. Enter `Ctrl+C` to exit the command line client.

2. At the shell prompt, enter the **Kill Command** from the initial server response to your request.

   Alternatively, you can run the following command from the command line of the master node to kill the Hadoop job, where *job-id* is the identifier of the Hadoop job and can be retrieved from the Hadoop user interface.

```
hadoop job -kill job-id
```

Data types for Hive and DynamoDB

The following table shows the available Hive data types, the default DynamoDB type that they correspond to, and the alternate DynamoDB types that they can also map to.

Hive type	Default DynamoDB type	Alternate DynamoDB type(s)
string	string (S)	
bigint or double	number (N)	
binary	binary (B)	
boolean	boolean (BOOL)	
array	list (L)	number set (NS), string set (SS), or binary set (BS)
map<string,string>	item	map (M)
map<string,?>	map (M)	
	null (NULL)	

If you want to write your Hive data as a corresponding alternate DynamoDB type, or if your DynamoDB data contains attribute values of an alternate DynamoDB type, you can specify the column and the DynamoDB type with the `dynamodb.type.mapping` parameter. The following example shows the syntax for specifying an alternate type mapping.

```
CREATE EXTERNAL TABLE hive_tablename (hive_column1_name column1_datatype,
 hive_column2_name column2_datatype...)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodb_tablename",
"dynamodb.column.mapping" =
 "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name...",
"dynamodb.type.mapping" = "hive_column1_name:dynamodb_attribute1_datatype");
```

The type mapping parameter is optional, and only has to be specified for the columns that use alternate types.

For example, the following Hive command creates a table named `hivetable2` that references the DynamoDB table `dynamodbtable2`. It is similar to `hivetable1`, except that it maps the `col3` column to the string set (SS) type.

```
CREATE EXTERNAL TABLE hivetable2 (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable2",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays",
"dynamodb.type.mapping" = "col3:SS");
```

In Hive, `hivetable1` and `hivetable2` are identical. However, when data from those tables are written to their corresponding DynamoDB tables, `dynamodbtable1` will contain lists, while `dynamodbtable2` will contain string sets.

If you want to write Hive `null` values as attributes of DynamoDB `null` type, you can do so with the `dynamodb.null.serialization` parameter. The following example shows the syntax for specifying `null` serialization.

```
CREATE EXTERNAL TABLE hive_tablename (hive_column1_name column1_datatype,
 hive_column2_name column2_datatype...)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodb_tablename",
"dynamodb.column.mapping" =
 "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name...",
```

```
"dynamodb.null.serialization" = "true");
```

The null serialization parameter is optional, and is set to `false` if not specified. Note that DynamoDB `null` attributes are read as `null` values in Hive regardless of the parameter setting. Hive collections with `null` values can be written to DynamoDB only if the null serialization parameter is specified as `true`. Otherwise, a Hive error occurs.

The bigint type in Hive is the same as the Java long type, and the Hive double type is the same as the Java double type in terms of precision. This means that if you have numeric data stored in DynamoDB that has precision higher than is available in the Hive datatypes, using Hive to export, import, or reference the DynamoDB data could lead to a loss in precision or a failure of the Hive query.

Exports of the binary type from DynamoDB to Amazon Simple Storage Service (Amazon S3) or HDFS are stored as a Base64-encoded string. If you are importing data from Amazon S3 or HDFS into the DynamoDB binary type, it should be encoded as a Base64 string.

Hive options

You can set the following Hive options to manage the transfer of data out of Amazon DynamoDB. These options only persist for the current Hive session. If you close the Hive command prompt and reopen it later on the cluster, these settings will have returned to the default values.

Hive options	Description
`dynamodb.throughput.read.percent`	Set the rate of read operations to keep your DynamoDB provisioned throughput rate in the allocated range for your table. The value is between `0.1` and `1.5`, inclusively. The value of 0.5 is the default read rate, which means that Hive will attempt to consume half of the read provisioned throughout resources in the table. Increasing this value above 0.5 increases the read request rate. Decreasing it below 0.5 decreases the read request rate. This read rate is approximate. The actual read rate will depend on factors such as whether there is a uniform distribution of keys in DynamoDB.

Hive options	Description
	If you find your provisioned throughput is frequently exceeded by the Hive operation, or if live read traffic is being throttled too much, then reduce this value below `0.5`. If you have enough capacity and want a faster Hive operation, set this value above `0.5`. You can also oversubscribe by setting it up to 1.5 if you believe there are unused input/output operations available.
`dynamodb.throughput.write.percent`	Set the rate of write operations to keep your DynamoDB provisioned throughput rate in the allocated range for your table. The value is between `0.1` and `1.5`, inclusively. The value of 0.5 is the default write rate, which means that Hive will attempt to consume half of the write provisioned throughout resources in the table. Increasing this value above 0.5 increases the write request rate. Decreasing it below 0.5 decreases the write request rate. This write rate is approximate. The actual write rate will depend on factors such as whether there is a uniform distribution of keys in DynamoDB If you find your provisioned throughput is frequently exceeded by the Hive operation, or if live write traffic is being throttled too much, then reduce this value below `0.5`. If you have enough capacity and want a faster Hive operation, set this value above `0.5`. You can also oversubscribe by setting it up to 1.5 if you believe there are unused input/output operations available or this is the initial data upload to the table and there is no live traffic yet.

Hive options	Description
dynamodb.endpoint	Specify the endpoint for the DynamoDB service. For more information about the available DynamoDB endpoints, see Regions and endpoints.
dynamodb.max.map.tasks	Specify the maximum number of map tasks when reading data from DynamoDB. This value must be equal to or greater than 1.
dynamodb.retry.duration	Specify the number of minutes to use as the timeout duration for retrying Hive commands. This value must be an integer equal to or greater than 0. The default timeout duration is two minutes.

These options are set using the SET command as shown in the following example.

```
SET dynamodb.throughput.read.percent=1.0;

INSERT OVERWRITE TABLE s3_export SELECT *
FROM hiveTableName;
```

Hive command examples for exporting, importing, and querying data in DynamoDB

The following examples use Hive commands to perform operations such as exporting data to Amazon S3 or HDFS, importing data to DynamoDB, joining tables, querying tables, and more.

Operations on a Hive table reference data stored in DynamoDB. Hive commands are subject to the DynamoDB table's provisioned throughput settings, and the data retrieved includes the data written to the DynamoDB table at the time the Hive operation request is processed by DynamoDB. If the data retrieval process takes a long time, some data returned by the Hive command may have been updated in DynamoDB since the Hive command began.

Hive commands `DROP TABLE` and `CREATE TABLE` only act on the local tables in Hive and do not create or drop tables in DynamoDB. If your Hive query references a table in DynamoDB, that table must already exist before you run the query. For more information about creating and deleting tables in DynamoDB, see Working with tables in DynamoDB in the *Amazon DynamoDB Developer Guide*.

> **Note**
>
> When you map a Hive table to a location in Amazon S3, do not map it to the root path of the bucket, s3://mybucket, as this may cause errors when Hive writes the data to Amazon S3. Instead map the table to a subpath of the bucket, s3://mybucket/mypath.

Exporting data from DynamoDB

You can use Hive to export data from DynamoDB.

To export a DynamoDB table to an Amazon S3 bucket

- Create a Hive table that references data stored in DynamoDB. Then you can call the INSERT OVERWRITE command to write the data to an external directory. In the following example, *s3://bucketname/path/subpath/* is a valid path in Amazon S3. Adjust the columns and datatypes in the CREATE command to match the values in your DynamoDB. You can use this to create an archive of your DynamoDB data in Amazon S3.

```
CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");

INSERT OVERWRITE DIRECTORY 's3://bucketname/path/subpath/' SELECT *
FROM hiveTableName;
```

To export a DynamoDB table to an Amazon S3 bucket using formatting

- Create an external table that references a location in Amazon S3. This is shown below as s3_export. During the CREATE call, specify row formatting for the table. Then, when you use INSERT OVERWRITE to export data from DynamoDB to s3_export, the data is written out in the specified format. In the following example, the data is written out as comma-separated values (CSV).

```
CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");

CREATE EXTERNAL TABLE s3_export(a_col string, b_col bigint, c_col array<string>)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3_export SELECT *
FROM hiveTableName;
```

To export a DynamoDB table to an Amazon S3 bucket without specifying a column mapping

- Create a Hive table that references data stored in DynamoDB. This is similar to the preceding example, except that you are not specifying a column mapping. The table must have exactly one column of type `map<string, string>`. If you then create an `EXTERNAL` table in Amazon S3 you can call the `INSERT OVERWRITE` command to write the data from DynamoDB to Amazon S3. You can use this to create an archive of your DynamoDB data in Amazon S3. Because there is no column mapping, you cannot query tables that are exported this way. Exporting data without specifying a column mapping is available in Hive 0.8.1.5 or later, which is supported on Amazon EMR AMI 2.2.*x* and later.

```
CREATE EXTERNAL TABLE hiveTableName (item map<string,string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1");

CREATE EXTERNAL TABLE s3TableName (item map<string, string>)
```

```
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3TableName SELECT *
FROM hiveTableName;
```

To export a DynamoDB table to an Amazon S3 bucket using data compression

- Hive provides several compression codecs you can set during your Hive session. Doing so causes the exported data to be compressed in the specified format. The following example compresses the exported files using the Lempel-Ziv-Oberhumer (LZO) algorithm.

```
SET hive.exec.compress.output=true;
SET io.seqfile.compression.type=BLOCK;
SET mapred.output.compression.codec = com.hadoop.compression.lzo.LzopCodec;

CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");

CREATE EXTERNAL TABLE lzo_compression_table (line STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE lzo_compression_table SELECT *
FROM hiveTableName;
```

The available compression codecs are:

- org.apache.hadoop.io.compress.GzipCodec
- org.apache.hadoop.io.compress.DefaultCodec
- com.hadoop.compression.lzo.LzoCodec
- com.hadoop.compression.lzo.LzopCodec
- org.apache.hadoop.io.compress.BZip2Codec

- org.apache.hadoop.io.compress.SnappyCodec

To export a DynamoDB table to HDFS

- Use the following Hive command, where *hdfs:///directoryName* is a valid HDFS path and *hiveTableName* is a table in Hive that references DynamoDB. This export operation is faster than exporting a DynamoDB table to Amazon S3 because Hive 0.7.1.1 uses HDFS as an intermediate step when exporting data to Amazon S3. The following example also shows how to set `dynamodb.throughput.read.percent` to 1.0 in order to increase the read request rate.

```
CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");

SET dynamodb.throughput.read.percent=1.0;

INSERT OVERWRITE DIRECTORY 'hdfs:///directoryName' SELECT * FROM hiveTableName;
```

  You can also export data to HDFS using formatting and compression as shown above for the export to Amazon S3. To do so, simply replace the Amazon S3 directory in the examples above with an HDFS directory.

To read non-printable UTF-8 character data in Hive

- You can read and write non-printable UTF-8 character data with Hive by using the `STORED AS SEQUENCEFILE` clause when you create the table. A SequenceFile is Hadoop binary file format; you need to use Hadoop to read this file. The following example shows how to export data from DynamoDB into Amazon S3. You can use this functionality to handle non-printable UTF-8 encoded characters.

```
CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
```

```
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");

CREATE EXTERNAL TABLE s3_export(a_col string, b_col bigint, c_col array<string>)
STORED AS SEQUENCEFILE
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3_export SELECT *
FROM hiveTableName;
```

Importing data to DynamoDB

When you write data to DynamoDB using Hive you should ensure that the number of write capacity units is greater than the number of mappers in the cluster. For example, clusters that run on m1.xlarge EC2 instances produce 8 mappers per instance. In the case of a cluster that has 10 instances, that would mean a total of 80 mappers. If your write capacity units are not greater than the number of mappers in the cluster, the Hive write operation may consume all of the write throughput, or attempt to consume more throughput than is provisioned. For more information about the number of mappers produced by each EC2 instance type, see Configure Hadoop.

The number of mappers in Hadoop are controlled by the input splits. If there are too few splits, your write command might not be able to consume all the write throughput available.

If an item with the same key exists in the target DynamoDB table, it is overwritten. If no item with the key exists in the target DynamoDB table, the item is inserted.

To import a table from Amazon S3 to DynamoDB

- You can use Amazon EMR (Amazon EMR) and Hive to write data from Amazon S3 to DynamoDB.

```
CREATE EXTERNAL TABLE s3_import(a_col string, b_col bigint, c_col array<string>)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
LOCATION 's3://bucketname/path/subpath/';

CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");
```

```
INSERT OVERWRITE TABLE hiveTableName SELECT * FROM s3_import;
```

To import a table from an Amazon S3 bucket to DynamoDB without specifying a column mapping

- Create an EXTERNAL table that references data stored in Amazon S3 that was previously exported from DynamoDB. Before importing, ensure that the table exists in DynamoDB and that it has the same key schema as the previously exported DynamoDB table. In addition, the table must have exactly one column of type `map<string, string>`. If you then create a Hive table that is linked to DynamoDB, you can call the `INSERT OVERWRITE` command to write the data from Amazon S3 to DynamoDB. Because there is no column mapping, you cannot query tables that are imported this way. Importing data without specifying a column mapping is available in Hive 0.8.1.5 or later, which is supported on Amazon EMR AMI 2.2.3 and later.

```
CREATE EXTERNAL TABLE s3TableName (item map<string, string>)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

CREATE EXTERNAL TABLE hiveTableName (item map<string,string>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1");

INSERT OVERWRITE TABLE hiveTableName SELECT *
FROM s3TableName;
```

To import a table from HDFS to DynamoDB

- You can use Amazon EMR and Hive to write data from HDFS to DynamoDB.

```
CREATE EXTERNAL TABLE hdfs_import(a_col string, b_col bigint, c_col array<string>)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
LOCATION 'hdfs:///directoryName';

CREATE EXTERNAL TABLE hiveTableName (col1 string, col2 bigint, col3 array<string>)
```

```
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodbtable1",
"dynamodb.column.mapping" = "col1:name,col2:year,col3:holidays");

INSERT OVERWRITE TABLE hiveTableName SELECT * FROM hdfs_import;
```

Querying data in DynamoDB

The following examples show the various ways you can use Amazon EMR to query data stored in DynamoDB.

To find the largest value for a mapped column (max)

- Use Hive commands like the following. In the first command, the CREATE statement creates a Hive table that references data stored in DynamoDB. The SELECT statement then uses that table to query data stored in DynamoDB. The following example finds the largest order placed by a given customer.

```
CREATE EXTERNAL TABLE hive_purchases(customerId bigint, total_cost double,
 items_purchased array<String>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Purchases",
"dynamodb.column.mapping" =
 "customerId:CustomerId,total_cost:Cost,items_purchased:Items");

SELECT max(total_cost) from hive_purchases where customerId = 717;
```

To aggregate data using the GROUP BY clause

- You can use the GROUP BY clause to collect data across multiple records. This is often used with an aggregate function such as sum, count, min, or max. The following example returns a list of the largest orders from customers who have placed more than three orders.

```
CREATE EXTERNAL TABLE hive_purchases(customerId bigint, total_cost double,
 items_purchased array<String>)
```

```
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Purchases",
"dynamodb.column.mapping" =
 "customerId:CustomerId,total_cost:Cost,items_purchased:Items");

SELECT customerId, max(total_cost) from hive_purchases GROUP BY customerId HAVING
 count(*) > 3;
```

To join two DynamoDB tables

- The following example maps two Hive tables to data stored in DynamoDB. It then calls a join across those two tables. The join is computed on the cluster and returned. The join does not take place in DynamoDB. This example returns a list of customers and their purchases for customers that have placed more than two orders.

```
CREATE EXTERNAL TABLE hive_purchases(customerId bigint, total_cost double,
 items_purchased array<String>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Purchases",
"dynamodb.column.mapping" =
 "customerId:CustomerId,total_cost:Cost,items_purchased:Items");

CREATE EXTERNAL TABLE hive_customers(customerId bigint, customerName string,
 customerAddress array<String>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Customers",
"dynamodb.column.mapping" =
 "customerId:CustomerId,customerName:Name,customerAddress:Address");

Select c.customerId, c.customerName, count(*) as count from hive_customers c
JOIN hive_purchases p ON c.customerId=p.customerId
GROUP BY c.customerId, c.customerName HAVING count > 2;
```

To join two tables from different sources

- In the following example, Customer_S3 is a Hive table that loads a CSV file stored in Amazon S3 and hive_purchases is a table that references data in DynamoDB. The following example joins together customer data stored as a CSV file in Amazon S3 with order data stored in DynamoDB to return a set of data that represents orders placed by customers who have "Miller" in their name.

```
CREATE EXTERNAL TABLE hive_purchases(customerId bigint, total_cost double,
 items_purchased array<String>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Purchases",
"dynamodb.column.mapping" =
 "customerId:CustomerId,total_cost:Cost,items_purchased:Items");

CREATE EXTERNAL TABLE Customer_S3(customerId bigint, customerName string,
 customerAddress array<String>)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
LOCATION 's3://bucketname/path/subpath/';

Select c.customerId, c.customerName, c.customerAddress from
Customer_S3 c
JOIN hive_purchases p
ON c.customerid=p.customerid
where c.customerName like '%Miller%';
```

Note

In the preceding examples, the CREATE TABLE statements were included in each example for clarity and completeness. When running multiple queries or export operations against a given Hive table, you only need to create the table one time, at the beginning of the Hive session.

Optimizing performance for Amazon EMR operations in DynamoDB

Amazon EMR operations on a DynamoDB table count as read operations, and are subject to the table's provisioned throughput settings. Amazon EMR implements its own logic to try to balance the load on your DynamoDB table to minimize the possibility of exceeding your provisioned throughput. At the end of each Hive query, Amazon EMR returns information about the cluster used to process the query, including how many times your provisioned throughput was exceeded.

You can use this information, as well as CloudWatch metrics about your DynamoDB throughput, to better manage the load on your DynamoDB table in subsequent requests.

The following factors influence Hive query performance when working with DynamoDB tables.

Provisioned read capacity units

When you run Hive queries against a DynamoDB table, you need to ensure that you have provisioned a sufficient amount of read capacity units.

For example, suppose that you have provisioned 100 units of Read Capacity for your DynamoDB table. This will let you perform 100 reads, or 409,600 bytes, per second. If that table contains 20GB of data (21,474,836,480 bytes), and your Hive query performs a full table scan, you can estimate how long the query will take to run:

21,474,836,480 / 409,600 = 52,429 seconds = 14.56 hours

The only way to decrease the time required would be to adjust the read capacity units on the source DynamoDB table. Adding more nodes to the Amazon EMR cluster will not help.

In the Hive output, the completion percentage is updated when one or more mapper processes are finished. For a large DynamoDB table with a low provisioned Read Capacity setting, the completion percentage output might not be updated for a long time; in the case above, the job will appear to be 0% complete for several hours. For more detailed status on your job's progress, go to the Amazon EMR console; you will be able to view the individual mapper task status, and statistics for data reads.

You can also log on to Hadoop interface on the master node and see the Hadoop statistics. This shows you the individual map task status and some data read statistics. For more information, see Web interfaces hosted on the master node in the *Amazon EMR Management Guide*.

Read percent setting

By default, Amazon EMR manages the request load against your DynamoDB table according to your current provisioned throughput. However, when Amazon EMR returns information about your job that includes a high number of provisioned throughput exceeded responses, you can adjust the default read rate using the `dynamodb.throughput.read.percent` parameter when you set up the Hive table. For more information about setting the read percent parameter, see Hive options.

Write percent setting

By default, Amazon EMR manages the request load against your DynamoDB table according to your current provisioned throughput. However, when Amazon EMR returns information about your job that includes a high number of provisioned throughput exceeded responses, you can adjust the default write rate using the `dynamodb.throughput.write.percent` parameter when you set up the Hive table. For more information about setting the write percent parameter, see Hive options.

Retry duration setting

By default, Amazon EMR re-runs a Hive query if it has not returned a result within two minutes, the default retry interval. You can adjust this interval by setting the `dynamodb.retry.duration` parameter when you run a Hive query. For more information about setting the write percent parameter, see Hive options.

Number of map tasks

The mapper daemons that Hadoop launches to process your requests to export and query data stored in DynamoDB are capped at a maximum read rate of 1 MiB per second to limit the read capacity used. If you have additional provisioned throughput available on DynamoDB, you can improve the performance of Hive export and query operations by increasing the number of mapper daemons. To do this, you can either increase the number of EC2 instances in your cluster *or* increase the number of mapper daemons running on each EC2 instance.

You can increase the number of EC2 instances in a cluster by stopping the current cluster and re-launching it with a larger number of EC2 instances. You specify the number of EC2 instances in the **Configure EC2 Instances** dialog box if you're launching the cluster from the Amazon EMR console, or with the `--num-instances` option if you're launching the cluster from the CLI.

The number of map tasks run on an instance depends on the EC2 instance type. For more information about the supported EC2 instance types and the number of mappers each one provides, see Task configuration. There, you will find a "Task Configuration" section for each of the supported configurations.

Another way to increase the number of mapper daemons is to change the `mapreduce.tasktracker.map.tasks.maximum` configuration parameter of Hadoop to a higher value. This has the advantage of giving you more mappers without increasing either the number or the size of EC2 instances, which saves you money. A disadvantage is that setting this value too high can cause the EC2 instances in your cluster to run out of memory. To set `mapreduce.tasktracker.map.tasks.maximum`, launch the cluster and specify a value for `mapreduce.tasktracker.map.tasks.maximum` as a property of the mapred-site configuration classification. This is shown in the following example. For more information, see [Configure applications](#).

```
{
    "configurations": [
    {
        "classification": "mapred-site",
        "properties": {
            "mapred.tasktracker.map.tasks.maximum": "10"
        }
    }
    ]
}
```

Parallel data requests

Multiple data requests, either from more than one user or more than one application to a single table may drain read provisioned throughput and slow performance.

Process duration

Data consistency in DynamoDB depends on the order of read and write operations on each node. While a Hive query is in progress, another application might load new data into the DynamoDB table or modify or delete existing data. In this case, the results of the Hive query might not reflect changes made to the data while the query was running.

Avoid exceeding throughput

When running Hive queries against DynamoDB, take care not to exceed your provisioned throughput, because this will deplete capacity needed for your application's calls to `DynamoDB::Get`. To ensure that this is not occurring, you should regularly monitor the read volume and throttling on application calls to `DynamoDB::Get` by checking logs and monitoring metrics in Amazon CloudWatch.

Request time

Scheduling Hive queries that access a DynamoDB table when there is lower demand on the DynamoDB table improves performance. For example, if most of your application's users live in

San Francisco, you might choose to export daily data at 4 a.m. PST, when the majority of users are asleep, and not updating records in your DynamoDB database.

Time-based tables

If the data is organized as a series of time-based DynamoDB tables, such as one table per day, you can export the data when the table becomes no longer active. You can use this technique to back up data to Amazon S3 on an ongoing fashion.

Archived data

If you plan to run many Hive queries against the data stored in DynamoDB and your application can tolerate archived data, you may want to export the data to HDFS or Amazon S3 and run the Hive queries against a copy of the data instead of DynamoDB. This conserves your read operations and provisioned throughput.

Kinesis

Amazon EMR clusters can read and process Amazon Kinesis streams directly, using familiar tools in the Hadoop ecosystem such as Hive, Pig, MapReduce, the Hadoop Streaming API, and Cascading. You can also join real-time data from Amazon Kinesis with existing data on Amazon S3, Amazon DynamoDB, and HDFS in a running cluster. You can directly load the data from Amazon EMR to Amazon S3 or DynamoDB for post-processing activities. For information about Amazon Kinesis service highlights and pricing, see the Amazon Kinesis page.

What can I do with Amazon EMR and Amazon Kinesis integration?

Integration between Amazon EMR and Amazon Kinesis makes certain scenarios much easier; for example:

- **Streaming log analysis**–You can analyze streaming web logs to generate a list of top 10 error types every few minutes by region, browser, and access domain.
- **Customer engagement**–You can write queries that join clickstream data from Amazon Kinesis with advertising campaign information stored in a DynamoDB table to identify the most effective categories of ads that are displayed on particular websites.
- **Ad-hoc interactive queries**–You can periodically load data from Amazon Kinesis streams into HDFS and make it available as a local Impala table for fast, interactive, analytic queries.

Checkpointed analysis of Amazon Kinesis streams

Users can run periodic, batched analysis of Amazon Kinesis streams in what are called *iterations*. Because Amazon Kinesis stream data records are retrieved by using a sequence number, iteration boundaries are defined by starting and ending sequence numbers that Amazon EMR stores in a DynamoDB table. For example, when `iteration0` ends, it stores the ending sequence number in DynamoDB so that when the `iteration1` job begins, it can retrieve subsequent data from the stream. This mapping of iterations in stream data is called *checkpointing*. For more information, see Kinesis connector.

If an iteration was checkpointed and the job failed processing an iteration, Amazon EMR attempts to reprocess the records in that iteration.

Checkpointing is a feature that allows you to:

- Start data processing after a sequence number processed by a previous query that ran on same stream and logical name
- Re-process the same batch of data from Kinesis that was processed by an earlier query

To enable checkpointing, set the `kinesis.checkpoint.enabled` parameter to `true` in your scripts. Also, configure the following parameters:

Configuration setting	Description
kinesis.checkpoint.metastore.table.name	DynamoDB table name where checkpoint information will be stored
kinesis.checkpoint.metastore.hash.key.name	Hash key name for the DynamoDB table
kinesis.checkpoint.metastore.hash.range.name	Range key name for the DynamoDB table
kinesis.checkpoint.logical.name	A logical name for current processing
kinesis.checkpoint.iteration.no	Iteration number for processing associated with the logical name

Configuration setting	Description
kinesis.rerun.iteration.without.wait	Boolean value that indicates if a failed iteration can be rerun without waiting for timeout; the default is `false`

Provisioned IOPS recommendations for Amazon DynamoDB tables

The Amazon EMR connector for Amazon Kinesis uses the DynamoDB database as its backing for checkpointing metadata. You must create a table in DynamoDB before consuming data in an Amazon Kinesis stream with an Amazon EMR cluster in checkpointed intervals. The table must be in the same region as your Amazon EMR cluster. The following are general recommendations for the number of IOPS you should provision for your DynamoDB tables; let `j` be the maximum number of Hadoop jobs (with different logical name+iteration number combination) that can run concurrently and `s` be the maximum number of shards that any job will process:

For **Read Capacity Units**: `j*s/5`

For **Write Capacity Units**: `j*s`

Performance considerations

Amazon Kinesis shard throughput is directly proportional to the instance size of nodes in Amazon EMR clusters and record size in the stream. We recommend that you use m5.xlarge or larger instances on master and core nodes.

Schedule Amazon Kinesis analysis with Amazon EMR

When you are analyzing data on an active Amazon Kinesis stream, limited by timeouts and a maximum duration for any iteration, it is important that you run the analysis frequently to gather periodic details from the stream. There are multiple ways to execute such scripts and queries at periodic intervals; we recommend using AWS Data Pipeline for recurrent tasks like these. For more information, see AWS Data Pipeline PigActivity and AWS Data Pipeline HiveActivity in the *AWS Data Pipeline Developer Guide*.

Migrating Spark Kinesis connector to SDK 2.x for Amazon EMR 7.0

The AWS SDK provides a rich set of APIs and libraries to interact with AWS cloud computing services, such as managing credentials, connecting to S3 and Kinesis services. The Spark

Kinesis connector is used to consume data from Kinesis Data Streams, and the received data is transformed and processed in Spark's execution engine. Currently this connector is built on top of 1.x of AWS SDK and Kinesis-client-library (KCL).

As part of the AWS SDK 2.x migration, the Spark Kinesis connector is also updated accordingly to run with the SDK 2.x. In the Amazon EMR 7.0 release, Spark contains the SDK 2.x upgrade that is not yet available in the community version of Apache Spark. If you use the Spark Kinesis connector from a release that's lower than 7.0, you must migrate your application codes to run on SDK 2.x before you can migrate to Amazon EMR 7.0.

Migration guides

This section describes the steps to migrate an application to the upgraded Spark Kinesis connector. It includes guides to migrate to the Kinesis Client Library (KCL) 2.x, AWS credential providers, and AWS service clients in AWS SDK 2.x. For reference, it also includes a sample WordCount program that uses the Kinesis connector.

Topics

Migrating KCL from 1.x to 2.x

- **Metrics level and dimensions in `KinesisInputDStream`**

  When you instantiate a `KinesisInputDStream`, you can control the metrics level and dimensions for the stream. The following example demonstrates how you might customize these parameters with KCL 1.x:

```
import
 com.amazonaws.services.kinesis.clientlibrary.lib.worker.KinesisClientLibConfiguration
import com.amazonaws.services.kinesis.metrics.interfaces.MetricsLevel

val kinesisStream = KinesisInputDStream.builder
  .streamingContext(ssc)
```

```
  .streamName(streamName)
  .endpointUrl(endpointUrl)
  .regionName(regionName)
  .initialPosition(new Latest())
  .checkpointAppName(appName)
  .checkpointInterval(kinesisCheckpointInterval)
  .storageLevel(StorageLevel.MEMORY_AND_DISK_2)
  .metricsLevel(MetricsLevel.DETAILED)

 .metricsEnabledDimensions(KinesisClientLibConfiguration.DEFAULT_METRICS_ENABLED_DIMENSIONS.a
  .build()
```

In KCL 2.x, these config settings have different package names. To migrate to 2.x:

1. Change the import statements for `com.amazonaws.services.kinesis.clientlibrary.lib.worker.KinesisClientLibCon` and `com.amazonaws.services.kinesis.metrics.interfaces.MetricsLevel` to `software.amazon.kinesis.metrics.MetricsLevel` and `software.amazon.kinesis.metrics.MetricsUtil` respectively.

   ```
   // import com.amazonaws.services.kinesis.metrics.interfaces.MetricsLevel
   import software.amazon.kinesis.metrics.MetricsLevel

   // import
    com.amazonaws.services.kinesis.clientlibrary.lib.worker.KinesisClientLibConfiguration
   import software.amazon.kinesis.metrics.MetricsUtil
   ```

2. Replace the line `metricsEnabledDimensionsKinesisClientLibConfiguration.DEFAULT_METRICS_ENABL` with `metricsEnabledDimensionsSet(MetricsUtil.OPERATION_DIMENSION_NAME, MetricsUtil.SHARD_ID_DIMENSION_NAME)`

Following is an updated version of the `KinesisInputDStream` with customized metrics level and metrics dimensions:

```
import software.amazon.kinesis.metrics.MetricsLevel
import software.amazon.kinesis.metrics.MetricsUtil

val kinesisStream = KinesisInputDStream.builder
  .streamingContext(ssc)
```

```
  .streamName(streamName)
  .endpointUrl(endpointUrl)
  .regionName(regionName)
  .initialPosition(new Latest())
  .checkpointAppName(appName)
  .checkpointInterval(kinesisCheckpointInterval)
  .storageLevel(StorageLevel.MEMORY_AND_DISK_2)
  .metricsLevel(MetricsLevel.DETAILED)
  .metricsEnabledDimensions(Set(MetricsUtil.OPERATION_DIMENSION_NAME, 
 MetricsUtil.SHARD_ID_DIMENSION_NAME))
  .build()
```

- Message handler function in `KinesisInputDStream`

  When instantiating a `KinesisInputDStream`, you may also provide a “message handler function” that takes a Kinesis Record and returns a generic object T, in case you would like to use other data included in a Record such as partition key.

  In KCL 1.x, the message handler function signature is: `Record => T`, where Record is `com.amazonaws.services.kinesis.model.Record`. In KCL 2.x, the handler’s signature is changed to: `KinesisClientRecord => T`, where KinesisClientRecord is `software.amazon.kinesis.retrieval.KinesisClientRecord`.

  Following is an example of providing a message handler in KCL 1.x:

```
import com.amazonaws.services.kinesis.model.Record

def addFive(r: Record): Int = JavaUtils.bytesToString(r.getData).toInt + 5
val stream = KinesisInputDStream.builder
  .streamingContext(ssc)
  .streamName(streamName)
  .endpointUrl(endpointUrl)
  .regionName(regionName)
  .initialPosition(new Latest())
  .checkpointAppName(appName)
  .checkpointInterval(Seconds(10))
  .storageLevel(StorageLevel.MEMORY_ONLY)
  .buildWithMessageHandler(addFive)
```

  To migrate the message handler:

1. Change the import statement for `com.amazonaws.services.kinesis.model.Record` to `software.amazon.kinesis.retrieval.KinesisClientRecord`.

```
// import com.amazonaws.services.kinesis.model.Record
import software.amazon.kinesis.retrieval.KinesisClientRecord
```

2. Update the the method signature of the message handler.

```
//def addFive(r: Record): Int = JavaUtils.bytesToString(r.getData).toInt + 5
def addFive = (r: KinesisClientRecord) => JavaUtils.bytesToString(r.data()).toInt
 + 5
```

Following is an updated example of providing the message handler in KCL 2.x:

```
import software.amazon.kinesis.retrieval.KinesisClientRecord

def addFive = (r: KinesisClientRecord) => JavaUtils.bytesToString(r.data()).toInt + 5
val stream = KinesisInputDStream.builder
  .streamingContext(ssc)
  .streamName(streamName)
  .endpointUrl(endpointUrl)
  .regionName(regionName)
  .initialPosition(new Latest())
  .checkpointAppName(appName)
  .checkpointInterval(Seconds(10))
  .storageLevel(StorageLevel.MEMORY_ONLY)
  .buildWithMessageHandler(addFive)
```

For more information about migrating from KCL 1.x to 2.x, see Migrating Consumers from KCL 1.x to KCL 2.x.

Migrating AWS credentials providers from AWS SDK 1.x to 2.x

Credentials providers are used to obtain AWS credentials for interactions with AWS. There are several interface and class changes related to the credentials providers in SDK 2.x, which can be found here. Spark Kinesis connector has defined an interface (`org.apache.spark.streaming.kinesis.SparkAWSCredentials`) and implementation classes that returns 1.x version of AWS credential providers. These credentials providers are needed when initializing Kinesis clients. For instance, if you are using the method `SparkAWSCredentials.provider` in the applications, you would need to update codes to consume 2.x version of AWS credential providers.

Following is an example of using the credential providers in AWS SDK 1.x:

```
import org.apache.spark.streaming.kinesis.SparkAWSCredentials
import com.amazonaws.auth.AWSCredentialsProvider

val basicSparkCredentials = SparkAWSCredentials.builder
    .basicCredentials("accessKey", "secretKey")
    .build()

val credentialProvider = basicSparkCredentials.provider
assert(credentialProvider.isInstanceOf[AWSCredentialsProvider], "Type should be
 AWSCredentialsProvider")
```

To migrate to SDK 2.x:

1. Change the import statement for `com.amazonaws.auth.AWSCredentialsProvider` to `software.amazon.awssdk.auth.credentials.AwsCredentialsProvider`

```
//import com.amazonaws.auth.AWSCredentialsProvider
import software.amazon.awssdk.auth.credentials.AwsCredentialsProvider
```

2. Update the remaining codes that use this class.

```
import org.apache.spark.streaming.kinesis.SparkAWSCredentials
import software.amazon.awssdk.auth.credentials.AwsCredentialsProvider

val basicSparkCredentials = SparkAWSCredentials.builder
    .basicCredentials("accessKey", "secretKey")
    .build()

val credentialProvider = basicSparkCredentials.provider
assert (credentialProvider.isInstanceOf[AwsCredentialsProvider], "Type should be
 AwsCredentialsProvider")
```

Migrating AWS service clients from AWS SDK 1.x to 2.x

AWS service clients have different package names in 2.x (i.e. `software.amazon.awssdk`). whereas the SDK 1.x uses `com.amazonaws`. For more information about the client changes, see here. If you are using these service clients in the codes, you would need to migrate the clients accordingly.

Following is an example of creating a client in SDK 1.x:

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClient
import com.amazonaws.services.dynamodbv2.document.DynamoDB

AmazonDynamoDB ddbClient = AmazonDynamoDBClientBuilder.defaultClient();
AmazonDynamoDBClient ddbClient = new AmazonDynamoDBClient();
```

To migrate to 2.x:

1. Change the import statements for service clients. Take DynamoDB clients as an example. You would need to change `com.amazonaws.services.dynamodbv2.AmazonDynamoDBClient` or `com.amazonaws.services.dynamodbv2.document.DynamoDB` to `software.amazon.awssdk.services.dynamodb.DynamoDbClient`.

```
// import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClient
// import com.amazonaws.services.dynamodbv2.document.DynamoDB
import software.amazon.awssdk.services.dynamodb.DynamoDbClient
```

2. Update the codes that initialize the clients

```
// AmazonDynamoDB ddbClient = AmazonDynamoDBClientBuilder.defaultClient();
// AmazonDynamoDBClient ddbClient = new AmazonDynamoDBClient();

DynamoDbClient ddbClient = DynamoDbClient.create();
DynamoDbClient ddbClient = DynamoDbClient.builder().build();
```

For more information about migrating AWS SDK from 1.x to 2.x, see What's different between the AWS SDK for Java 1.x and 2.x

Code examples for streaming applications

```
import java.net.URI
```

```
import software.amazon.awssdk.auth.credentials.DefaultCredentialsProvider
import software.amazon.awssdk.http.apache.ApacheHttpClient
import software.amazon.awssdk.services.kinesis.KinesisClient
import software.amazon.awssdk.services.kinesis.model.DescribeStreamRequest
import software.amazon.awssdk.regions.Region
import software.amazon.kinesis.metrics.{MetricsLevel, MetricsUtil}

import org.apache.spark.SparkConf
import org.apache.spark.storage.StorageLevel
import org.apache.spark.streaming.{Milliseconds, StreamingContext}
import org.apache.spark.streaming.dstream.DStream.toPairDStreamFunctions
import org.apache.spark.streaming.kinesis.KinesisInitialPositions.Latest
import org.apache.spark.streaming.kinesis.KinesisInputDStream

object KinesisWordCountASLSDKV2 {

  def main(args: Array[String]): Unit = {
    val appName = "demo-app"
    val streamName = "demo-kinesis-test"
    val endpointUrl = "https://kinesis.us-west-2.amazonaws.com"
    val regionName = "us-west-2"

    // Determine the number of shards from the stream using the low-level Kinesis
 Client
    // from the AWS Java SDK.
    val credentialsProvider = DefaultCredentialsProvider.create
    require(credentialsProvider.resolveCredentials() != null,
      "No AWS credentials found. Please specify credentials using one of the methods
 specified " +
        "in https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/
credentials.html")
    val kinesisClient = KinesisClient.builder()
      .credentialsProvider(credentialsProvider)
      .region(Region.US_WEST_2)
      .endpointOverride(URI.create(endpointUrl))
      .httpClientBuilder(ApacheHttpClient.builder())
      .build()
    val describeStreamRequest = DescribeStreamRequest.builder()
      .streamName(streamName)
      .build()
    val numShards = kinesisClient.describeStream(describeStreamRequest)
      .streamDescription
      .shards
```

```
      .size

    // In this example, we are going to create 1 Kinesis Receiver/input DStream for
 each shard.
    // This is not a necessity; if there are less receivers/DStreams than the number of
 shards,
    // then the shards will be automatically distributed among the receivers and each
 receiver
    // will receive data from multiple shards.
    val numStreams = numShards

    // Spark Streaming batch interval
    val batchInterval = Milliseconds(2000)

    // Kinesis checkpoint interval is the interval at which the DynamoDB is updated
 with information
    // on sequence number of records that have been received. Same as batchInterval for
 this
    // example.
    val kinesisCheckpointInterval = batchInterval

    // Setup the SparkConfig and StreamingContext
    val sparkConfig = new SparkConf().setAppName("KinesisWordCountASLSDKV2")
    val ssc = new StreamingContext(sparkConfig, batchInterval)

    // Create the Kinesis DStreams
    val kinesisStreams = (0 until numStreams).map { i =>
      KinesisInputDStream.builder
        .streamingContext(ssc)
        .streamName(streamName)
        .endpointUrl(endpointUrl)
        .regionName(regionName)
        .initialPosition(new Latest())
        .checkpointAppName(appName)
        .checkpointInterval(kinesisCheckpointInterval)
        .storageLevel(StorageLevel.MEMORY_AND_DISK_2)
        .metricsLevel(MetricsLevel.DETAILED)
        .metricsEnabledDimensions(Set(MetricsUtil.OPERATION_DIMENSION_NAME,
 MetricsUtil.SHARD_ID_DIMENSION_NAME))
        .build()
    }

    // Union all the streams
```

```
    val unionStreams = ssc.union(kinesisStreams)

    // Convert each line of Array[Byte] to String, and split into words
    val words = unionStreams.flatMap(byteArray => new String(byteArray).split(" "))

    // Map each word to a (word, 1) tuple so we can reduce by key to count the words
    val wordCounts = words.map(word => (word, 1)).reduceByKey(_ + _)

    // Print the first 10 wordCounts
    wordCounts.print()

    // Start the streaming context and await termination
    ssc.start()
    ssc.awaitTermination()
  }
}
```

Considerations when using the upgraded Spark Kinesis connector

- If your applications uses the `Kinesis-producer-library` with JDK version lower than 11, you may run into exceptions like `java.lang.NoClassDefFoundError: javax/xml/bind/DatatypeConverter`. This happens because EMR 7.0 comes with JDK 17 by default and J2EE modules have been removed from the standard libraries since Java 11+. This could be fixed by adding the following dependency in the pom file. Replace the library version with one as you see fit.

```
<dependency>
      <groupId>javax.xml.bind</groupId>
      <artifactId>jaxb-api</artifactId>
      <version>${jaxb-api.version}</version>
    </dependency>
```

- The Spark Kinesis connector jar can be found under this path after an EMR cluster is created: `/usr/lib/spark/connector/lib/`

S3DistCp (s3-dist-cp)

Apache DistCp is an open-source tool you can use to copy large amounts of data. *S3DistCp* is similar to DistCp, but optimized to work with AWS, particularly Amazon S3. The command for S3DistCp in Amazon EMR version 4.0 and later is `s3-dist-cp`, which you add as a step in a cluster or at the command line. Using S3DistCp, you can efficiently copy large amounts of data from Amazon S3 into HDFS where it can be processed by subsequent steps in your Amazon EMR cluster. You can also use S3DistCp to copy data between Amazon S3 buckets or from HDFS to Amazon S3. S3DistCp is more scalable and efficient for parallel copying large numbers of objects across buckets and across AWS accounts.

For specific commands that demonstrate the flexibility of S3DistCP in real-world scenarios, see Seven tips for using S3DistCp on the AWS Big Data blog.

Like DistCp, S3DistCp uses MapReduce to copy in a distributed manner. It shares the copy, error handling, recovery, and reporting tasks across several servers. For more information about the Apache DistCp open source project, see the DistCp guide in the Apache Hadoop documentation.

If S3DistCp is unable to copy some or all of the specified files, the cluster step fails and returns a non-zero error code. If this occurs, S3DistCp does not clean up partially copied files.

Important

S3DistCp does not support Amazon S3 bucket names that contain the underscore character.
S3DistCp does not support concatenation for Parquet files. Use PySpark instead. For more information, see Concatenating parquet files in Amazon EMR.
To avoid copy errors when using S3DistCP to copy a single file (instead of a directory) from S3 to HDFS, use Amazon EMR version 5.33.0 or later, or Amazon EMR version 6.3.0 or later.

S3DistCp options

Though similar to DistCp, S3DistCp supports a different set of options to change how it copies and compresses data.

When you call S3DistCp, you can specify the options described in the following table. The options are added to the step using the arguments list. Examples of the S3DistCp arguments are shown in the following table.

Option	Description	Required
`--src=LOCATION`	Location of the data to copy. This can be either an HDFS or Amazon S3 location.	Yes

Option	Description	Required
	Example: `--src=s3://amzn-s3-demo-bucket1/logs/j-3GYXXXXXX9IOJ/node` **Important** S3DistCp does not support Amazon S3 bucket names that contain the underscore character.	
`--dest=LOCATION`	Destination for the data. This can be either an HDFS or Amazon S3 location. Example: `--dest=hdfs:///output` **Important** S3DistCp does not support Amazon S3 bucket names that contain the underscore character.	Yes
`--srcPattern=PATTERN`	A regular expression that filters the copy operation to a subset of the data at `--src`. If neither `--srcPattern` nor `--groupBy` is specified, all data at `--src` is copied to `--dest`. If the regular expression argument contains special characters, such as an asterisk (*), either the regular expression or the entire `--args` string must be enclosed in single quotes ('). Example: `--srcPattern=.*daemons.*-hadoop-.*`	No

Option	Description	Required
--groupBy=PATTERN	A regular expression that causes S3DistCp to concatenate files that match the expression. For example, you could use this option to combine all of the log files written in one hour into a single file. The concatenated filename is the value matched by the regular expression for the grouping. Parentheses indicate how files should be grouped, with all of the items that match the parenthetical statement being combined into a single output file. If the regular expression does not include a parenthetical statement, the cluster fails on the S3DistCp step and return an error. If the regular expression argument contains special characters, such as an asterisk (*), either the regular expression or the entire `--args` string must be enclosed in single quotes ('). When `--groupBy` is specified, only files that match the specified pattern are copied. You do not need to specify `--groupBy` and `--srcPattern` at the same time. Example: `--groupBy=.*subnetid.*([0-9]+-[0-9]+-[0-9]+-[0-9]+).*`	No

Option	Description	Required
`--targetSize=SIZE`	The size, in mebibytes (MiB), of the files to create based on the `--groupBy` option. This value must be an integer. When `--targetSize` is set, S3DistCp attempts to match this size; the actual size of the copied files may be larger or smaller than this value. Jobs are aggregated based on the size of the data file, thus it is possible that the target file size will match the source data file size. If the files concatenated by `--groupBy` are larger than the value of `--targetSize`, they are broken up into part files, and named sequentially with a numeric value appended to the end. For example, a file concatenated into `myfile.gz` would be broken into parts as: `myfile0.gz`, `myfile1.gz`, etc. Example: `--targetSize=2`	No
`--appendToLastFile`	Specifies the behavior of S3DistCp when copying to files from Amazon S3 to HDFS which are already present. It appends new file data to existing files. If you use `--appendToLastFile` with `--groupBy`, new data is appended to files which match the same groups. This option also respects the `--targetSize` behavior when used with `--groupBy`.	No

Option	Description	Required
`--outputCodec=CODEC`	Specifies the compression codec to use for the copied files. This can take the values: `gzip`, `gz`, `lzo`, `snappy`, or `none`. You can use this option, for example, to convert input files compressed with Gzip into output files with LZO compression, or to uncompress the files as part of the copy operation. If you choose an output codec, the filename will be appended with the appropriate extension (e.g. for `gz` and `gzip`, the extension is `.gz`) If you do not specify a value for `--outputCodec` , the files are copied over with no change in their compression. Example: `--outputCodec=lzo`	No
`--s3ServerSideEncryption`	Ensures that the target data is transferred using SSL and automatically encrypted in Amazon S3 using an AWS service-side key. When retrieving data using S3DistCp, the objects are automatically unencrypted. If you attempt to copy an unencrypted object to an encryption-required Amazon S3 bucket, the operation fails. For more information, see Using data encryption. Example: `--s3ServerSideEncryption`	No
`--deleteOnSuccess`	If the copy operation is successful, this option causes S3DistCp to delete the copied files from the source location. This is useful if you are copying output files, such as log files, from one location to another as a scheduled task, and you don't want to copy the same files twice. Example: `--deleteOnSuccess`	No

Option	Description	Required
`--disableMultipartUpload`	Disables the use of multipart upload. Example: `--disableMultipartUpload`	No
`--multipartUploadChunkSize=SIZE`	The size, in MiB, of each part in an Amazon S3 multipart upload. S3DistCp uses multipart upload when it copies data larger than the `multipartUploadChunkSize` . To improve job performance, you can increase the size of each part. The default size is 128 MiB. Example: `--multipartUploadChunkSize=1000`	No
`--numberFiles`	Prepends output files with sequential numbers. The count starts at 0 unless a different value is specified by `--startingIndex` . Example: `--numberFiles`	No
`--startingIndex=INDEX`	Used with `--numberFiles` to specify the first number in the sequence. Example: `--startingIndex=1`	No
`--outputManifest=FILENAME`	Creates a text file, compressed with Gzip, that contains a list of all the files copied by S3DistCp. Example: `--outputManifest=manifest-1.gz`	No

Option	Description	Required
--previousManifest=PATH	Reads a manifest file that was created during a previous call to S3DistCp using the --outputManifest flag. When the --previousManifest flag is set, S3DistCp excludes the files listed in the manifest from the copy operation. If --outputManifest is specified along with --previousManifest , files listed in the previous manifest also appear in the new manifest file, although the files are not copied. Example: --previousManifest=/usr/bin/manifest-1.gz	No
--requirePreviousManifest	Requires a previous manifest created during a previous call to S3DistCp. If this is set to false, no error is generated when a previous manifest is not specified. The default is true.	No
--copyFromManifest	Reverses the behavior of --previousManifest to cause S3DistCp to use the specified manifest file as a list of files to copy, instead of a list of files to exclude from copying. Example: --copyFromManifest --previousManifest=/usr/bin/manifest-1.gz	No
--s3Endpoint=ENDPOINT	Specifies the Amazon S3 endpoint to use when uploading a file. This option sets the endpoint for both the source and destination. If not set, the default endpoint is s3.amazonaws.com . For a list of the Amazon S3 endpoints, see Regions and endpoints. Example: --s3Endpoint=s3.eu-west-1.amazonaws.com	No

Option	Description	Required
--storageClass=CLASS	The storage class to use when the destination is Amazon S3. Valid values are STANDARD and REDUCED_REDUNDANCY. If this option is not specified, S3DistCp tries to preserve the storage class. Example: `--storageClass=STANDARD`	No
--srcPrefixesFile=PATH	a text file in Amazon S3 (s3://), HDFS (hdfs:///) or local file system (file:/) that contains a list of `src` prefixes, one prefix per line. If `srcPrefixesFile` is provided, S3DistCp will not list the src path. Instead, it generates a source list as the combined result of listing all prefixes specified in this file. The relative path as compared to src path, instead of these prefixes, will be used to generate the destination paths. If `srcPattern` is also specified, it will be applied to the combined list results of the source prefixes to further filter the input. If `copyFromManifest` is used, objects in the manifest will be copied and `srcPrefixesFile` will be ignored. Example: `--srcPrefixesFile=PATH`	No

In addition to the options above, S3DistCp implements the Tool interface which means that it supports the generic options.

Adding S3DistCp as a step in a cluster

You can call S3DistCp by adding it as a step in your cluster. Steps can be added to a cluster at launch or to a running cluster using the console, CLI, or API. The following examples demonstrate adding an S3DistCp step to a running cluster. For more information on adding steps to a cluster, see Submit work to a cluster in the *Amazon EMR Management Guide*.

To add a S3DistCp step to a running cluster using the AWS CLI

For more information on using Amazon EMR commands in the AWS CLI, see the AWS CLI Command Reference.

- To add a step to a cluster that calls S3DistCp, pass the parameters that specify how S3DistCp should perform the copy operation as arguments.

  The following example copies daemon logs from Amazon S3 to `hdfs:///output`. In the following command:

  - `--cluster-id` specifies the cluster
  - `Jar` is the location of the S3DistCp JAR file. For an example of how to run a command on a cluster using command-runner.jar, see Submit a custom JAR step to run a script or command.
  - `Args` is a comma-separated list of the option name-value pairs to pass in to S3DistCp. For a complete list of the available options, see S3DistCp options.

  To add an S3DistCp copy step to a running cluster, put the following in a JSON file saved in Amazon S3 or your local file system as *`myStep.json`* for this example. Replace *`j-3GYXXXXXX9IOK`* with your cluster ID and replace *`mybucket`* with your Amazon S3 bucket name.

```
[
    {
        "Name":"S3DistCp step",
        "Args":["s3-dist-cp","--s3Endpoint=s3.amazonaws.com","--src=s3://mybucket/
logs/j-3GYXXXXXX9IOJ/node/","--dest=hdfs:///output","--srcPattern=.*[a-zA-Z,]+"],
        "ActionOnFailure":"CONTINUE",
        "Type":"CUSTOM_JAR",
        "Jar":"command-runner.jar"
    }
]
```

```
aws emr add-steps --cluster-id j-3GYXXXXXX9IOK --steps file://./myStep.json
```

Example Copy log files from Amazon S3 to HDFS

This example also illustrates how to copy log files stored in an Amazon S3 bucket into HDFS by adding a step to a running cluster. In this example the `--srcPattern` option is used to limit the data copied to the daemon logs.

To copy log files from Amazon S3 to HDFS using the `--srcPattern` option, put the following in a JSON file saved in Amazon S3 or your local file system as *`myStep.json`* for this example. Replace *`j-3GYXXXXXX9IOK`* with your cluster ID and replace *`mybucket`* with your Amazon S3 bucket name.

```
[
    {
        "Name":"S3DistCp step",
        "Args":["s3-dist-cp","--s3Endpoint=s3.amazonaws.com","--src=s3://mybucket/logs/
j-3GYXXXXXX9IOJ/node/","--dest=hdfs:///output","--srcPattern=.*daemons.*-hadoop-.*"],
        "ActionOnFailure":"CONTINUE",
        "Type":"CUSTOM_JAR",
        "Jar":"command-runner.jar"
    }
]
```

Cleaning up after failed S3DistCp jobs

If S3DistCp cannot copy some or all of the specified files, the command or cluster step fails and returns a non-zero error code. If this occurs, S3DistCp does not clean up partially copied files. You must delete them manually.

Partially copied files are saved to the HDFS `tmp` directory in sub-directories with the unique identifier of the S3DistCp job. You can find this ID in the standard output of the job.

For example, for an S3DistCp job with the ID `4b1c37bb-91af-4391-aaf8-46a6067085a6`, you can connect to the master node of the cluster and run the following command to view output files associated with the job.

```
hdfs dfs -ls /tmp/4b1c37bb-91af-4391-aaf8-46a6067085a6/output
```

The command returns a list of files similar to the following:

```
Found 8 items
```

```
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:03 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/_SUCCESS
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:02 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00000
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:02 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00001
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:02 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00002
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:03 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00003
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:03 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00004
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:03 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00005
-rw-r--r--   1 hadoop hadoop          0 2018-12-10 06:03 /tmp/4b1c37bb-91af-4391-
aaf8-46a6067085a6/output/part-r-00006
```

You can then run the following command to delete the directory and all contents.

```
hdfs dfs rm -rf /tmp/4b1c37bb-91af-4391-aaf8-46a6067085a6
```

Run commands and scripts on an Amazon EMR cluster

This topic covers how to run a command or a script as a step on your cluster. Running a command or script as a step is one of the many ways you can Submit work to a cluster and is useful in the following situations:

- When you don't have SSH access to your Amazon EMR cluster
- When you want to run a bash or shell command to troubleshoot your cluster

You can run a script either when you create a cluster or when your cluster is in the `WAITING` state. To run a script before step processing begins, you use a bootstrap action instead. For more information about bootstrap actions, see Create bootstrap actions to install additional software in the *Amazon EMR Management Guide*.

Amazon EMR provides the following tools to help you run scripts, commands, and other on-cluster programs. You can invoke both tools using the Amazon EMR management console or the AWS CLI.

`command-runner.jar`

Located on the Amazon EMR AMI for your cluster. You can use `command-runner.jar` to run commands on your cluster. You specify `command-runner.jar` without using its full path.

`script-runner.jar`

Hosted on Amazon S3 at `s3://`*`<region>`*`.elasticmapreduce/libs/script-runner/script-runner.jar` where *`<region>`* is the Region in which your Amazon EMR cluster resides. You can use `script-runner.jar` to run scripts saved locally or on Amazon S3 on your cluster. You must specify the full URI of `script-runner.jar` when you submit a step.

Submit a custom JAR step to run a script or command

The following AWS CLI examples illustrate some common use cases of `command-runner.jar` and `script-runner.jar` on Amazon EMR.

Example : Running a command on a cluster using `command-runner.jar`

When you use `command-runner.jar`, you specify commands, options, and values in your step's list of arguments.

The following AWS CLI example submits a step to a running cluster that invokes `command-runner.jar`. The specified command in the `Args` list downloads a script called *`my-script.sh`* from Amazon S3 into the hadoop user home directory. The command then modifies the script's permissions and runs *`my-script.sh`*.

When you use the AWS CLI, the items in your `Args` list should be comma separated with no whitespace between list elements. For example, `Args=[example-command,example-option,"example option value"]` instead of `Args=[example-command, example-option, "example option value"]`.

```
aws emr add-steps \
--cluster-id j-2AXXXXXXGAPLF \
--steps Type=CUSTOM_JAR,Name="Download a script from S3, change its permissions, and
 run it",ActionOnFailure=CONTINUE,Jar=command-runner.jar,Args=[bash,-c,"aws s3 cp s3://
EXAMPLE-DOC-BUCKET/my-script.sh /home/hadoop; chmod u+x /home/hadoop/my-script.sh; cd /
home/hadoop; ./my-script.sh"]
```

Example : Running a script on a cluster using `script-runner.jar`

When you use `script-runner.jar`, you specify the script that you want to run in your step's list of arguments.

The following AWS CLI example submits a step to a running cluster that invokes `script-runner.jar`. In this case, the script called *`my-script.sh`* is stored on Amazon S3. You can also specify local scripts that are stored on the master node of your cluster.

```
aws emr add-steps \
--cluster-id j-2AXXXXXXGAPLF \
--steps Type=CUSTOM_JAR,Name="Run a script from S3 with script-
runner.jar",ActionOnFailure=CONTINUE,Jar=s3://us-west-2.elasticmapreduce/libs/script-
runner/script-runner.jar,Args=[s3://EXAMPLE-DOC-BUCKET/my-script.sh]
```

Other ways to use `command-runner.jar`

You can also use `command-runner.jar` to submit work to a cluster with tools such as `spark-submit` or `hadoop-streaming`. When you launch an application using `command-runner.jar`, you specify `CUSTOM_JAR` as the step type instead of using a value like `SPARK`, `STREAMING`, or `PIG`. Tool availability varies depending on which applications you've installed on the cluster.

The following example command uses `command-runner.jar` to submit a step using `spark-submit`. The `Args` list specifies `spark-submit` as the command, followed by the Amazon S3 URI of the Spark application *my-app.py* with arguments and values.

```
aws emr add-steps \
--cluster-id j-2AXXXXXXGAPLF \
--steps Type=CUSTOM_JAR,Name="Run spark-submit using command-
runner.jar",ActionOnFailure=CONTINUE,Jar=command-runner.jar,Args=[spark-submit,S3://
DOC-EXAMPLE-BUCKET/my-app.py,ArgName1,ArgValue1,ArgName2,ArgValue2]
```

The following table identifies additional tools that you can run using `command-runner.jar`.

Tool name	Description
`hadoop-streaming`	Submits an Hadoop streaming program. In the console and some SDKs, this is a streaming step.
`hive-script`	Runs a Hive script. In the console and SDKs, this is a Hive step.
`pig-script`	Runs a Pig script. In the console and SDKs, this is a Pig step.
`spark-submit`	Runs a Spark application. In the console, this is a Spark step.
`hadoop-lzo`	Runs the Hadoop LZO indexer on a directory.
`s3-dist-cp`	Distributed copy large amounts of data from Amazon S3 into HDFS. For more information, see S3DistCp (s3-dist-cp).
