What Is AWS IoT?

AWS IoT provides secure, bi-directional communication between Internet-connected things (devices such as sensors, actuators, embedded micro-controllers, or smart appliances) and the AWS Cloud. This enables you to collect telemetry data from multiple things, and store and analyze the data. You can also create applications that enable your users to control these devices from their phones or tablets.

AWS IoT Components

AWS IoT consists of the following components:

**Device gateway**
- Enables devices to securely and efficiently communicate with AWS IoT.

**Message broker**
- Provides a secure mechanism for things and AWS IoT applications to publish and receive messages from each other. You can use either the MQTT protocol directly or MQTT over WebSocket to publish and subscribe. You can use the HTTP REST interface to publish.

**Rules engine**
- Provides message processing and integration with other AWS services. You can use an SQL-based language to select data from message payloads, and then process and send the data to other services, such as Amazon S3, Amazon DynamoDB, and AWS Lambda. You can also use the message broker to republish messages to other subscribers.

**Security and Identity service**
- Provides shared responsibility for security in the AWS Cloud. Your things must keep their credentials safe in order to securely send data to the message broker. The message broker and rules engine use AWS security features to send data securely to devices or other AWS services.

**Thing registry**
- Sometimes referred to as the device registry. Organizes the resources associated with each thing. You register your things and associate up to three custom attributes with each thing. You can also associate certificates and MQTT client IDs with each thing to improve your ability to manage and troubleshoot your things.

**Group registry**
- Thing groups allow you to manage several things at once by categorizing them into groups. Groups can also contain groups—you can build a hierarchy of groups. Any action you perform on a parent group will apply to its child groups, and to all the things in it and in all of its child groups as well. Permissions given to a group will apply to all things in the group and in all of its child groups.

**Thing shadow**
- Sometimes referred to as a device shadow. A JSON document used to store and retrieve current state information for a thing (device, app, and so on).

**Thing Shadows service**
- Provides persistent representations of your things in the AWS Cloud. You can publish updated state information to a thing shadow, and your thing can synchronize its state when it connects. Your things can also publish their current state to a thing shadow for use by applications or devices.

**Device Provisioning service**
- Allows you to provision devices using a template that describes the resources required for your device: a thing, a certificate, and one or more policies. A thing is an entry in the device registry that
contains attributes that describe a device. Devices use certificates to authenticate with AWS IoT. Policies determine which operations a device can perform in AWS IoT.

The templates contain variables that are replaced by values in a dictionary (map). You can use the same template to provision multiple devices just by passing in different values for the template variables in the dictionary.

**Custom Authentication service**

You can define custom authorizers that allow you to manage your own authentication and authorization strategy using a custom authentication service and a Lambda function. Custom authorizers allow AWS IoT to authenticate your devices and authorize operations using bearer token authentication and authorization strategies.

Custom authorizers can implement various authentication strategies (for example: JWT verification, OAuth provider call out, and so on) and must return policy documents which are used by the device gateway to authorize MQTT operations.

**Jobs Service**

Allows you to define a set of remote operations that are sent to and executed on one or more devices connected to AWS IoT. For example, you can define a job that instructs a set of things to download and install application or firmware updates, reboot, rotate certificates, or perform remote troubleshooting operations.

To create a job, you specify a description of the remote operations to be performed and a list of targets that should perform them. The targets can be individual things, thing groups or both.

For information about AWS IoT limits, see [AWS IoT Limits](#).

## How to Get Started with AWS IoT

- To learn more about AWS IoT, see [How AWS IoT Works](#) (p. 3).
- To learn how to connect a thing to AWS IoT, see [Getting Started with AWS IoT](#) (p. 5).

## Accessing AWS IoT

AWS IoT provides the following interfaces to create and interact with your things:

- **AWS Command Line Interface (AWS CLI)**—Run commands for AWS IoT on Windows, macOS, and Linux. These commands allow you to create and manage things, certificates, rules, and policies. To get started, see the [AWS Command Line Interface User Guide](#). For more information about the commands for AWS IoT, see `iot` in the [AWS Command Line Interface Reference](#).
- **AWS IoT API**—Build your IoT applications using HTTP or HTTPS requests. These API actions allow you to programmatically create and manage things, certificates, rules, and policies. For more information about the API actions for AWS IoT, see `iot` in the [AWS IoT API Reference](#).
- **AWS SDKs**—Build your IoT applications using language-specific APIs. These SDKs wrap the HTTP/HTTPS API and allow you to program in any of the supported languages. For more information, see [AWS SDKs and Tools](#).
- **AWS IoT Device SDKs**—Build applications that run on devices that send messages to and receive messages from AWS IoT. For more information see, [AWS IoT SDKs](#).
Related Services

AWS IoT integrates directly with the following AWS services:

- **Amazon Simple Storage Service**—Provides scalable storage in the AWS Cloud. For more information, see Amazon S3.
- **Amazon DynamoDB**—Provides managed NoSQL databases. For more information, see Amazon DynamoDB.
- **Amazon Kinesis**—Enables real-time processing of streaming data at a massive scale. For more information, see Amazon Kinesis.
- **AWS Lambda**—Runs your code on virtual servers from Amazon EC2 in response to events. For more information, see AWS Lambda.
- **Amazon Simple Notification Service**—Sends or receives notifications. For more information, see Amazon SNS.
- **Amazon Simple Queue Service**—Stores data in a queue to be retrieved by applications. For more information, see Amazon SQS.

How AWS IoT Works

AWS IoT enables Internet-connected things to connect to the AWS Cloud and lets applications in the cloud interact with Internet-connected things. Common IoT applications either collect and process telemetry from devices or enable users to control a device remotely.

Things report their state by publishing messages, in JSON format, on MQTT topics. Each MQTT topic has a hierarchical name that identifies the thing whose state is being updated. When a message is published on an MQTT topic, the message is sent to the AWS IoT MQTT message broker, which is responsible for sending all messages published on an MQTT topic to all clients subscribed to that topic.

Communication between a thing and AWS IoT is protected through the use of X.509 certificates. AWS IoT can generate a certificate for you or you can use your own. In either case, the certificate must be registered and activated with AWS IoT, and then copied onto your thing. When your thing communicates with AWS IoT, it presents the certificate to AWS IoT as a credential.

We recommend that all things that connect to AWS IoT have an entry in the thing registry. The thing registry stores information about a thing and the certificates that are used by the thing to secure communication with AWS IoT.

You can create rules that define one or more actions to perform based on the data in a message. For example, you can insert, update, or query a DynamoDB table or invoke a Lambda function. Rules use expressions to filter messages. When a rule matches a message, the rules engine invokes the action using the selected properties. Rules also contain an IAM role that grants AWS IoT permission to the AWS resources used to perform the action.
Each thing has a thing shadow that stores and retrieves state information. Each item in the state information has two entries: the state last reported by the thing and the desired state requested by an application. An application can request the current state information for a thing. The shadow responds to the request by providing a JSON document with the state information (both reported and desired), metadata, and a version number. An application can control a thing by requesting a change in its state. The shadow accepts the state change request, updates its state information, and sends a message to indicate the state information has been updated. The thing receives the message, changes its state, and then reports its new state.
Getting Started with AWS IoT

This tutorial shows you how to create resources required to send, receive, and process MQTT messages from devices using AWS IoT.

You need the following to complete this tutorial:

- A computer with Wi-Fi access.
- If you have an AWS IoT button (pictured here), you can use it to complete this tutorial.
- If you do not have a button, you can purchase one [here](https://aws.amazon.com/button/) or you can use the MQTT client in the AWS IoT console to emulate a device.

For more information about AWS IoT, see What Is AWS IoT (p. 1).

Sign in to the AWS IoT Console

If you do not have an AWS account, create one.

**To create an AWS account:**

1. Open the [AWS home page](https://aws.amazon.com/) and choose Create an AWS Account.
2. Follow the online instructions. Part of the sign-up procedure involves receiving a phone call and entering a PIN using your phone's keypad.
3. Sign in to the AWS Management Console and open the [AWS IoT console](https://aws.amazon.com/iot/).
4. On the Welcome page, choose Get started.
Register a Device in the Thing Registry

Devices connected to AWS IoT are represented by things in the thing registry. The thing registry allows you to keep a record of all of the devices that are connected to your AWS IoT account.

The fastest way to start using your AWS IoT Button is to download the mobile app for iOS or Android. The mobile app creates the required AWS IoT resources for you, and adds an event source to your button that uses a Lambda blueprint to invoke a new AWS Lambda function of your choice. Blueprints are preconfigured Lambda functions that allow you to quickly connect the click of a button to the functions that fit you best, such as sending automated emails or text messages or deploying other AWS services. You can download the mobile apps from The Apple App Store or Google Play.

If you are unable to use the mobile apps, follow these instructions.

To register your device in the thing registry:

1. On the Welcome to the AWS IoT Console page, in the left navigation pane, choose Registry to expand the choices, and then choose Things.
2. On the page that says **You don't have any things yet**, choose **Register a thing**.

3. On the **Register a thing** page, in the **Name** field, type a name for your device, such as **MyIoTButton**. Choose **Create thing** to add your device to the thing registry.
Create and Activate a Device Certificate

Communication between your device and AWS IoT is protected through the use of X.509 certificates. AWS IoT can generate a certificate for you or you can use your own X.509 certificate. In this tutorial, AWS IoT generates the X.509 certificate for you. Certificates must be activated prior to use.

1. In the left navigation pane, choose Secure, Certificates (as necessary), and then Create a certificate.
2. On the **Create a certificate** page, choose **Create certificate**.

3. On the **Certificate created!** page, choose **Download** for the certificate, private key, and the root CA for AWS IoT (the public key need not be downloaded). Save each of them to your computer, and then choose **Activate** to continue.
Create an AWS IoT Policy

X.509 certificates are used to authenticate your device with AWS IoT. AWS IoT policies are used to authorize your device to perform AWS IoT operations, such as subscribing or publishing to MQTT topics. Your device will present its certificate when sending messages to AWS IoT. To allow your device to perform AWS IoT operations, you must create an AWS IoT policy and attach it to your device certificate.

To create an AWS IoT policy:

1. In the left navigation pane, choose Secure, and then Policies. On the You don't have a policy yet page, choose Create a policy.

Create an AWS IoT Policy

X.509 certificates are used to authenticate your device with AWS IoT. AWS IoT policies are used to authorize your device to perform AWS IoT operations, such as subscribing or publishing to MQTT topics. Your device will present its certificate when sending messages to AWS IoT. To allow your device to perform AWS IoT operations, you must create an AWS IoT policy and attach it to your device certificate.

To create an AWS IoT policy:

1. In the left navigation pane, choose Secure, and then Policies. On the You don't have a policy yet page, choose Create a policy.
2. On the Create a policy page, in the Name field, type a name for the policy (for example, MyIoTButtonPolicy). In the Action field, type iot:Connect. In the Resource ARN field, type *.
Select the Allow checkbox. This allows all clients to connect to AWS IoT.

---

**Create a policy**

Create a policy to define a set of authorized actions. You can authorize actions on one or more resources (things, topics, topic filters).

**Name**

MyIoTButtonPolicy

---

**Add statements**

Policy statements define the types of actions that can be performed by a resource.

**Action**

iot:Connect

**Resource ARN**

*

**Effect**

Allow

---

**Note**

You can restrict which clients (devices) are able to connect by specifying a client ARN as the resource. The client ARNs follow this format:

Select the **Add Statement** button to add another policy statement. In the **Action** field, type `iot:Publish`. In the **Resource ARN** field, type the ARN of the topic to which your device will publish.

**Note**
The topic ARN follows this format:

```
arn:aws:iot:your-region:your-aws-account:topic/iotbutton/your-button-serial-number
```

For example:

```
arn:aws:iot:us-east-1:123456789012:topic/iotbutton/G030JF055364XVRB
```

You can find the serial number on the bottom of your button.

If you are not using an AWS IoT button, after `topic/` in the ARN, place the topic your device publishes to. For example:

```
arn:aws:iot:us-east-1:123456789012:topic/my/topic/here
```

Finally, select the **Allow** check box. This allows your device to publish messages to the specified topic.

3. After you have entered the information for your policy, choose **Create**.

For more information, see [Managing AWS IoT Policies](#).
Attach an AWS IoT Policy to a Device Certificate

Now that you have created a policy, you must attach it to your device certificate. Attaching an AWS IoT policy to a certificate gives the device the permissions specified in the policy.

1. In the left navigation pane, choose Secure, and then Certificates.

2. In the box for the certificate you created, choose ... to open a drop-down menu, and then choose Attach policy.
3. In the **Attach policies to certificate(s)** dialog box, select the check box next to the policy you created in the previous step, and then choose **Attach**.

---

**Attach a Certificate to a Thing**

A device must have a certificate, private key and root CA certificate to authenticate with AWS IoT. We recommend that you also attach the device certificate to the thing that represents your device in AWS IoT. This allows you to create AWS IoT policies that grant permissions based on certificates attached to your things. For more information, see *Thing Policy Variables* (p. 127)

**To attach a certificate to the thing representing your device in the thing registry:**

1. In the box for the certificate you created, choose ... to open a drop-down menu, and then choose **Attach thing**.
2. In the **Attach things to certificate(s)** dialog box, select the check box next to the thing you registered, and then choose **Attach**.

3. To verify the thing is attached, select the box representing the certificate.
4. On the **Details** page for the certificate, in the left navigation pane, choose **Things**.

5. To verify the policy is attached, on the **Details** page for the certificate, in the left navigation pane, choose **Policies**.
Configure Your Device

Configuring your device allows it to connect to your Wi-Fi network. Your device must be connected to your Wi-Fi network to install required files and send messages to AWS IoT. All devices must install a device certificate, private key, and root CA certificate in order to communicate with AWS IoT.

Note
Pressing the AWS IoT button for 15 seconds will reset it and you will have to reconfigure your Wi-Fi and device certificate.

Configure an AWS IoT Button

The easiest way to configure your AWS IoT button is to use the AWS IoT button smart phone app. You can download it from the Apple App Store or the Google Play Store. If you are unable to use the smart phone app, follow these directions to configure your button.

Turn on your device

1. Remove the AWS IoT button from its packaging, and then press and hold the button until a blue blinking light appears. (This should take no longer than 15 seconds.)
2. The button acts as a Wi-Fi access point, so when your computer searches for Wi-Fi networks, it will find one called Button ConfigureMe - XXX where XXX is a three-character string generated by the button. Use your computer to connect to the button’s Wi-Fi access point.

Note
When the blue light stops blinking, the button ceases presenting itself as a Wi-Fi access point. Therefore, if you can't complete the following procedure soon enough, you may need to invoke the blue blinking light a few times to do so. Once configured, the device does not need to present itself as a Wi-Fi access point and communicates to the internet, just like any other computer, using your local Wi-Fi network.
3. The first time you connect to the button’s Wi-Fi access point, you will be prompted for the WPA2-PSK password. Type the last 8 characters of the device serial number (DSN). You'll find the DSN on the back of the device, as shown here:

Copy your device certificate and private key onto your AWS IoT button

To connect to AWS IoT, you must copy your device certificate and private key onto the AWS IoT button.

1. In a browser, navigate to http://192.168.0.1/index.html.
2. Complete the configuration form:
   - Type your Wi-Fi SSID and password.
   - Browse to and select your certificate and private key. For example, 2a540e2346-certificate.pem.crt.txt and 2a540e2346-private.pem.key, respectively.
   - Find your custom endpoint in the AWS IoT console. (From the dashboard, in the left navigation pane, choose Manage, and then choose Things. Select the box representing your button to show
Configure a Different Device

Consult your device’s documentation to connect to it and copy your device certificate, private key, and root CA certificate onto your device.

View Device MQTT Messages with the AWS IoT MQTT Client

You can use the AWS IoT MQTT client to better understand the MQTT messages sent by a device.

Devices publish MQTT messages on topics. You can use the AWS IoT MQTT client to subscribe to these topics to see these messages.

To view MQTT messages:

1. In the AWS IoT console, in the left navigation pane, choose Test.
2. Subscribe to the topic on which your thing publishes. In the case of the AWS IoT button, you can subscribe to `iotbutton/+` (note that `+` is the wildcard character). In **Subscribe to a topic**, in the **Subscription topic** field, type `iotbutton/+`, and then choose **Subscribe to topic**.

Choosing **Subscribe to topic** above, results in the topic `iotbutton/+` appearing in the **Subscriptions** column.
3. Press your AWS IoT button, and then view the resulting message in the AWS IoT MQTT client. If you do not have a button, you will simulate a button press in the next step.

Note
The AWS IoT Button FAQs contains useful button LED color pattern information.

4. To use the AWS IoT console to publish a message:

On the MQTT client page, in the Publish section, in the Specify a topic and a message to publish… field, type `iotbutton/ABCDEFG12345`. In the message payload section, type the following JSON:

```json
{
    "serialNumber": "ABCDEFG12345",
    "clickType": "SINGLE",
    "batteryVoltage": "2000 mV"
}
```

Choose Publish to topic. You should see the message in the AWS IoT MQTT client (choose `iotbutton/+` in the Subscription column to see the message).
Configure and Test Rules

The AWS IoT rules engine listens for incoming MQTT messages that match a rule. When a matching message is received, the rule takes some action with the data in the MQTT message (for example, writing data to an Amazon S3 bucket, invoking a Lambda function, or sending a message to an Amazon SNS topic). In this step, you will create and configure a rule to send the data received from a device to an Amazon SNS topic. Specifically, you will:

- Create an Amazon SNS topic.
- Subscribe to the Amazon SNS topic using a cell phone number.
- Create a rule that will send a message to the Amazon SNS topic when a message is received from your device.
- Test the rule using your AWS IoT button or an MQTT client.

In the upper-right corner of this page, there is a Filter View drop-down list. For instructions for testing your rule by using the AWS IoT button, choose AWS IoT Button. For instructions for testing your rule by using the AWS IoT MQTT client, choose MQTT Client.

Create an SNS Topic

Use the Amazon SNS console to create an Amazon SNS topic.

**Note**

Amazon SNS is not available in all AWS regions.

1. Open the Amazon SNS console.
2. On the left pane, choose Topics.
3. Choose **Create new topic**.

4. Type a topic name and a display name, and then choose **Create topic**.
5. Make a note of the ARN for the topic you just created.

Subscribe to an Amazon SNS Topic

To receive SMS messages on your cell phone, subscribe to the Amazon SNS topic.

1. In the Amazon SNS console, select the check box next to the topic you just created. From the Actions menu, choose Subscribe to topic.

2. On Create subscription, from the Protocol drop-down list, choose SMS. In the Endpoint field, type the phone number of an SMS-enabled cell phone, and then choose Create subscription.
Note
Enter the phone number using numbers and dashes only.

Create a Rule

AWS IoT rules consist of a topic filter, a rule action, and, in most cases, an IAM role. Messages published on topics that match the topic filter trigger the rule. The rule action defines which action to take when the rule is triggered. The IAM role contains one or more IAM policies that determine which AWS services the rule can access. You can create multiple rules that listen on a single topic. Likewise, you can create a single rule that is triggered by multiple topics. The AWS IoT rules engine continuously processes messages published on topics that match the topic filters defined in the rules.

In this example, you will create a rule that uses Amazon SNS to send an SMS notification to a cell phone number.

1. In the AWS IoT console, in the left navigation pane, choose Act.

2. On the Act page, choose Create a rule.
3. On the Create a rule page, in the Name field, type a name for your rule. In the Description field, type a description for the rule.

4. Scroll down to Message source. Choose the latest version from the Using SQL version drop-down list. In the Attribute field, type *. This specifies that you want to send the entire MQTT message that triggered the rule.
5. The rules engine uses the topic filter to determine which rules to trigger when an MQTT message is received. In the Topic filter field, type `iotbutton/your-button-DSN`. If you are not using an AWS IoT button, type `my/topic` or the topic used in the rule.

**Note**
You can find the DSN on the bottom of the button.

Leave Condition blank.

6. In Set one or more actions, choose Add action.
7. On the **Select an action** page, select **Send a message as an SNS push notification**, and then choose **Configure action**.

8. On the **Configure action** page, from the **SNS target** drop-down list, choose the Amazon SNS topic you created earlier.
9. Now give AWS IoT permission to publish to the Amazon SNS topic on your behalf when the rule is triggered. Choose **Create a new role**. Enter a name for your new role in the **IAM role name** field. After you have entered the name, choose **Create a new role** again. Select the newly created role from the **IAM role name** drop-down list.

10. Choose **Update role** to apply the permissions to the newly created role, and then choose **Add action**.
11. On the Create a Rule page, choose Create rule.

For more information about creating rules, see AWS IoT Rules.

Test the Amazon SNS Rule

You can test your rule by using an AWS IoT button or the AWS IoT MQTT client.

AWS IoT Button

Press your button. You should receive an SMS text that shows the current battery charge level on your device (among other things). Try a long press (about 2 seconds) and a fast double pressing, and note the resulting messages.
AWS IoT MQTT Client

To test your rule with the AWS IoT MQTT client:

1. In the AWS IoT console, in the left navigation pane, choose Test.
2. On the MQTT client page, in the Publish section, in the Specify a topic and a message to publish… field, type `my/topic` or the topic you used in the rule. In the message payload section, type the following JSON:

   ```json
   {
     "message": "Hello, from AWS IoT console"
   }
   ```

   **Note**
   If you are using a button, type `iotbutton/your-button-DSN` instead of `my/topic` in the Specify a topic and a message to publish… field.

3. Choose Publish to topic. You should receive an Amazon SNS message on your cell phone.

Congratulations! You have successfully created and configured a rule that sends data received from a device to an Amazon SNS topic.

Next Steps

For more information about AWS IoT rules, see AWS IoT Rule Tutorials (p. 46) and AWS IoT Rules (p. 162).
AWS IoT Button Quickstarts

The two quickstarts in this section show you how to configure and use the AWS IoT button. You can use the AWS IoT button wizard in the AWS Lambda console to easily and quickly configure your AWS IoT button. The AWS Lambda console contains a blueprint that automates the process of setting up your AWS IoT button by:

• Creating and activating an X.509 certificate and private key for authenticating with AWS IoT.
• Walking you through the configuration of your AWS IoT button in order to connect to your Wi-Fi network.
• Walking you through the copying of your certificate and private key to your AWS IoT button.
• Creating and attaching to the certificate an AWS IoT policy that gives the button permission to make calls to AWS IoT.
• Creating an AWS IoT rule that invokes a Lambda function when your AWS IoT button is pressed.
• Creating an IAM role and policy that allows the Lambda function to send email messages using Amazon SNS.
• Creating a Lambda function that sends an email message to the address specified in the Lambda function code.

The second quickstart shows you how to use an AWS CloudFormation template to configure the AWS IoT resources required to process the MQTT messages that are sent when the AWS IoT button is pressed.

If you do not have a button, you can purchase one here. For more information about AWS IoT, see What Is AWS IoT (p. 1).

Topics
• AWS IoT Button Wizard Quickstart (p. 31)
• AWS IoT Button AWS CloudFormation Quickstart (p. 40)
• Next Steps (p. 45)

AWS IoT Button Wizard Quickstart

The AWS IoT button wizard is a Lambda blueprint, so you must sign in to the AWS Lambda console in order to use it. If you do not have an AWS account, you can create one by following these steps.

To create an AWS account
1. Open the AWS home page and choose Create an AWS Account.
2. Follow the online instructions. Part of the sign-up procedure involves receiving a phone call and entering a PIN using your phone's keypad.

To configure the AWS IoT Button

1. Sign in to the AWS Management Console and open the AWS Lambda console.
2. If this is your first time in the AWS Lambda console, you see the following page. Choose the Get Started Now button.

3. On the Select blueprint page, from the Runtime drop-down menu, choose Node.js 4.3. In the filter text box, type button. To choose the iot-button-email blueprint, double-click it or choose the Next button.
4. On the **Configure triggers** page, from the **IoT Type** drop-down menu, choose **IoT Button**.

Type the serial number for your device. The device serial number (DSN) appears on the back of the button.

Choose **Generate certificate and keys**.

**Note**

You only need to generate a certificate and private key once. Then you can navigate to http://192.168.0.1/index.html in a browser to configure your button.
Use the links on the page to download the device certificate and the private key.
The page also includes instructions for configuring your AWS IoT button. On step 3, you choose a link to open a web page that allows you to connect the AWS IoT button to your network. Under **Wi-Fi Configuration**, type the network ID (SSID) and network password for your Wi-Fi network. Under **AWS IoT Configuration**, choose the certificate and private key you downloaded earlier. This copies your certificate and private key to your AWS IoT button. Select the check box to agree to the AWS IoT button terms and conditions, and then choose the **Configure** button.
Button ConfigureMe

Enter the value for any field that you wish to change for device:...

Wi-Fi Configuration:
SSID
Guest
Security
☐ Open Network(No Password)
Password
None (unsecured)

AWS IoT Configuration:
Certificate
Browse...
certificate.pem
Private Key
Browse...
private.key
Endpoint Subdomain
AST2RRXSNT910
Endpoint Region
us-west-2
Final Endpoint
.iot.us-west-2.amazonaws.com

☐ By clicking this box, you agree to the AWS IoT Button Terms and Conditions.

Configure

A configuration confirmation page is displayed.

Button ConfigureMe Setup

Thank you for configuring your device.

If you are unable to use your device, please enter configuration mode and try again.

5. Close the Configure tab and go back to the AWS Lambda console page. Choose Enable trigger, and then choose Next.

On the Configure function page, type a name for your function. The description, runtime, and Lambda function code is entered for you.
In the Lambda function code, replace the example email address with your own email address.
In the **Lambda function handler and role** section, from the **Role** drop-down menu, choose **Create new role from template(s)**. Type a unique name for the role.

At the bottom of the page, choose **Next**.

Review the settings for the Lambda function, and then choose **Create function**.
You should see a page that confirms your Lambda function has been created:
6. To test your Lambda function, choose the Test button. After about a minute, you should receive an email message with AWS Notification - Subscription Confirmation in the subject line. Choose the link in the email message to confirm the subscription to an SNS topic created by the Lambda function. When AWS IoT receives a message from your button, it sends a message to Amazon SNS. The Lambda function created a subscription to the Amazon SNS topic using the email address you added in the code. When Amazon SNS receives a message on this Amazon SNS topic, it forwards the message to your subscribed email address.

Press your button to send a message to AWS IoT. The message causes your Lambda rule to be triggered, and then your Lambda function is invoked. The Lambda function checks if your SNS topic exists. The Lambda function then sends the contents of the message to the Amazon SNS topic. Amazon SNS then forwards the message to the email address you specified in the Lambda function code.

---

AWS IoT Button AWS CloudFormation Quickstart

When the AWS IoT button is pressed, it sends basic information about the button to an Amazon SNS topic. The topic then forwards that information to you in an email message. This quickstart shows you how to use an AWS CloudFormation template to configure your AWS IoT button.

You need an AWS account and an AWS IoT button to complete the steps in this quickstart.

1. Use the AWS IoT console to create an AWS IoT certificate:
   a. Open the AWS IoT console.
   b. If a Welcome page appears, choose Get started.

---

AWS IoT Button AWS CloudFormation Quickstart

When the AWS IoT button is pressed, it sends basic information about the button to an Amazon SNS topic. The topic then forwards that information to you in an email message. This quickstart shows you how to use an AWS CloudFormation template to configure your AWS IoT button.

You need an AWS account and an AWS IoT button to complete the steps in this quickstart.

1. Use the AWS IoT console to create an AWS IoT certificate:
   a. Open the AWS IoT console.
   b. If a Welcome page appears, choose Get started.

---

AWS IoT Button AWS CloudFormation Quickstart

When the AWS IoT button is pressed, it sends basic information about the button to an Amazon SNS topic. The topic then forwards that information to you in an email message. This quickstart shows you how to use an AWS CloudFormation template to configure your AWS IoT button.

You need an AWS account and an AWS IoT button to complete the steps in this quickstart.

1. Use the AWS IoT console to create an AWS IoT certificate:
   a. Open the AWS IoT console.
   b. If a Welcome page appears, choose Get started.

---

AWS IoT Button AWS CloudFormation Quickstart

When the AWS IoT button is pressed, it sends basic information about the button to an Amazon SNS topic. The topic then forwards that information to you in an email message. This quickstart shows you how to use an AWS CloudFormation template to configure your AWS IoT button.

You need an AWS account and an AWS IoT button to complete the steps in this quickstart.

1. Use the AWS IoT console to create an AWS IoT certificate:
   a. Open the AWS IoT console.
   b. If a Welcome page appears, choose Get started.

---

AWS IoT Button AWS CloudFormation Quickstart

When the AWS IoT button is pressed, it sends basic information about the button to an Amazon SNS topic. The topic then forwards that information to you in an email message. This quickstart shows you how to use an AWS CloudFormation template to configure your AWS IoT button.

You need an AWS account and an AWS IoT button to complete the steps in this quickstart.

1. Use the AWS IoT console to create an AWS IoT certificate:
   a. Open the AWS IoT console.
   b. If a Welcome page appears, choose Get started.
c. In the AWS region selector, choose the AWS region where you want to create the AWS IoT certificate (for example, US East (N. Virginia)). You will be creating all supporting AWS resources (additional AWS IoT resources and an Amazon SNS resource) in the same AWS region.

d. On the Dashboard, in the left navigation pane, choose Security, and then choose Certificates.

e. On the Certificates pane, choose Create.

f. Choose One-click certificate creation - Create certificate.

g. On the Certificate created page, choose Download for the certificate, private key, and root CA for AWS IoT, save each of them to your computer, and then choose Activate.

h. Choose Done.

i. On the Certificates page, choose the certificate you just created.

j. In the Details pane, make a note of the certificate ARN value (for example, arn:aws:iot:region-ID:account-ID:cert/random-ID). You need it later in this procedure.

2. Use the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation/ to create the AWS IoT resources, an Amazon SNS resource, and an IAM role:

a. Save the following AWS CloudFormation template file named AWSIoTButtonQuickStart.template to your computer.

Note
Check the DSN for your button. Make sure the beginning of the "AllowedPattern" string matches your DSN.

```json
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description": "Creates required AWS resources to allow an AWS IoT button to send information through an Amazon Simple Notification Service (Amazon SNS) topic to an email address."
}
"Parameters": {
  "IoTButtonDSN": {
    "Type": "String",
    "Description": "The device serial number (DSN) of the AWS IoT Button. This can be found on the back of the button. The DSN must match the pattern of 'G030[A-Z][A-Z][0-9][0-9][0-9][0-5][0-9][1-7][0-9A-HJ-NP-X][0-9A-HJ-NP-X][0-9A-HJ-NP-X]'."}

                        "Resource": {
                            "Fn::Join": [
                                "",
                                [
                                    "arn:aws:sns:",
                                    {
                                        "Ref": "AWS::Region" },
                                    "",
                                    {
                                        "Ref": "AWS::AccountId" },
                                    "",
                                    {
                                        "Ref": "SNSTopicName" }
                                ]
                            ]
                        }
                    }
                ]
            },
            "PolicyName": {
                "Ref": "SNSTopicRoleName"
            }
        }
    ]
},
"IoTTopicRule": {
    "Type": "AWS::IoT::TopicRule",
    "Properties": {
        "RuleName": {
            "Fn::Join": ["",
            ["",
            ]
        }
    }
}

c. Make sure the region where you created the AWS IoT certificate (for example, US East (N. Virginia)) is displayed on the AWS region selector.

d. Choose Create Stack.

e. On the Select Template page, choose Upload a template to Amazon S3, and then choose Browse.

f. Select the AWSIoTButtonQuickStart.template file you saved earlier, choose Open, and then choose Next.

h. For CertificateARN, type the Amazon Resource Name (ARN) of the AWS IoT certificate (the certificate ARN value) that you noted earlier.

k. You can leave SNSTopicName and SNSTopicRoleName at their defaults, or specify a different Amazon SNS topic name and associated IAM role name. For example, if you plan to set up more AWS IoT buttons, you might want to change these values. Choose Next.

m. On the Review page, select I acknowledge that AWS CloudFormation might create IAM resources, and then choose Create.
n. When CREATE_COMPLETE is displayed for MyAWSIoTButtonStack, check your email inbox for a message with a subject line of AWS IoT Button Press Notification. Choose the Confirm subscription link in the body of the email message.

3. Using the private key and certificate you created earlier, follow the steps in Configure Your Device to set up your AWS IoT button.

4. After you have set it up, press the button once. A white light should blink several times and then be followed by a steady green light for a few moments. Shortly afterward, you should receive an email message with AWS IoT Button Press Notification in the subject line. It contains information sent by the button in the body of the email message.

5. After you are finished experimenting, you can clean up the AWS resources created by the AWS CloudFormation template. To do this, return to the AWS CloudFormation console and delete MyAWSIoTButtonStack. After you delete MyAWSIoTButtonStack, delete the AWS IoT certificate as follows:
   a. Return to the AWS IoT console.
   b. In the list of resources, select the check box inside of the box that represents the AWS IoT certificate (the box with the handshake icon).
   c. For Actions, choose Deactivate, and then confirm.
   d. With the box that represents the AWS IoT certificate still selected, for Actions, choose Delete, and then confirm.
   e. The private key and certificate that you downloaded earlier are no longer valid, so you can now delete them from your computer.

**Next Steps**

To learn more about the Lambda blueprint used to set up your button, see Getting Started with AWS IoT. To learn how to use AWS CloudFormation with the AWS IoT button, see http://docs.aws.amazon.com/iot/latest/developerguide/iot-button-cloud-formation.html.
AWS IoT Rule Tutorials

This guide includes tutorials that walk you through the creation and testing of AWS IoT rules. If you have not completed the AWS IoT Getting Started Tutorial (p. 5), we recommend you do that first. It shows you how to create an AWS account and connect your device to AWS IoT.

An AWS IoT rule consists of a SQL SELECT statement, a topic filter, and a rule action. Devices send information to AWS IoT by publishing messages to MQTT topics. The SQL SELECT statement allows you to extract data from an incoming MQTT message. The topic filter of an AWS IoT rule specifies one or more MQTT topics. The rule is triggered when an MQTT message is received on a topic that matches the topic filter. Rule actions allow you to take the information extracted from an MQTT message and send it to another AWS service. Rule actions are defined for AWS services like Amazon DynamoDB, AWS Lambda, Amazon SNS, and Amazon S3. By using a Lambda rule, you can call other AWS or third-party web services. For a complete list of rule actions, see AWS IoT Rule Actions (p. 172).

In these tutorials we assume you are using the AWS IoT button and will use iotbutton/+ as the topic filter in the rules. If you do not have an AWS IoT button, you can buy one here.

Alternatively, you can emulate the AWS IoT button by using an MQTT client like the AWS IoT MQTT client in the AWS IoT console. To emulate the AWS IoT button, publish a similar message on the iotbutton/ABCDEFG12345 topic. The number after the / is arbitrary. It is used as the serial number for the button.

You can also use your own device, but you must know on which MQTT topic your device publishes so you can specify it as the topic filter in the rule. For more information, see AWS IoT Rules (p. 162).

The AWS IoT button sends a JSON payload that looks like this:

```json
{
    "serialNumber" : "ABCDEFG12345",
    "batteryVoltage" : "2000mV",
    "clickType" : "SINGLE"
}
```

Creating a DynamoDB Rule

DynamoDB rules allow you to take information from an incoming MQTT message and write it to a DynamoDB table.

To create a DynamoDB rule:

1. In the AWS IoT console, in the left navigation pane, choose Rules.

3. On the Create a rule page, in the Name field, type a name for your rule. In the Description field, type a description for the rule.
4. Scroll down to **Message source**. Choose the latest version from the **Using SQL version** drop-down list. In the **Attribute** field, type *. This specifies that you want to send the entire MQTT message that triggered the rule.

5. The rules engine uses the topic filter to determine which rules to trigger when an MQTT message is received. In the **Topic filter** field, type `iotbutton/your-button-DSN`. If you are not using an AWS IoT button, type `my/topic` or the topic used in the rule.

   **Note**
   You can find the DSN on the bottom of the button.

   Leave **Condition** blank.
6. In **Set one or more actions**, choose **Add action**.

7. On the **Select an action** page, select **Insert a message into a DynamoDB table**, and then choose **Configure action**.
8. On the **Configure action** page, choose **Create a new resource**.
9. On the Amazon DynamoDB page, choose Create table.

10. On the Create DynamoDB table page, type a name in the Table name field. In Partition key, type SerialNumber. Select the Add sort key check box, and then type ClickType in the Sort key field. Select String for both the partition and sort keys.
11. Choose **Create**. It takes a few seconds to create your DynamoDB table. Close the browser tab where the Amazon DynamoDB console is open. If you do not close the tab, your DynamoDB table will not be displayed in the **Table name** drop-down list on the AWS IoT **Configure action** page.

12. On the **Configure action** page, choose your new table from the **Table name** drop-down list. In **Hash key value**, type `#{serialNumber}`. This instructs the rule to take the value of the `serialNumber` attribute from the MQTT message and write it into the `SerialNumber` column in the DynamoDB table. In **Range key value**, type `#{clickType}`. This writes the value of the `clickType` attribute into the `ClickType` column. Leave **Write message data to this column** blank. By default, the entire message is written to a column in the table named Payload. Choose **Create a new role**.
13. Type a unique name in **IAM role name**, and then choose the **Create a new role** button again. Choose the role you just created, choose **Update role**, and then choose **Add action**.

14. Choose **Create rule** to create the rule.
15. A confirmation message shows the rule has been created. Choose the left arrow to return to the Rules page.

16. Test the rule by pressing your configured AWS IoT button or by using an MQTT client to publish a message on a topic that matches your rule's topic filter. Finally, return to the DynamoDB console and select the table you created to view the entry for your button press or message.
Creating a Lambda Rule

You can define a rule that calls a Lambda function, passing in data from the MQTT message that triggered the rule. This allows you to process the incoming message and then call another AWS or third-party service.

In this tutorial, we assume you have completed the AWS IoT Getting Started Tutorial (p. 5) in which you create and subscribe to an Amazon SNS topic using your cell phone number. You will create a Lambda function that publishes a message to the Amazon SNS topic you created in the AWS IoT Getting Started Tutorial (p. 5). You will also create a Lambda rule that calls the Lambda function, passing in some data from the MQTT message that triggered the rule.

In this tutorial, we also assume you are using an AWS IoT button to trigger the Lambda rule. If you do not have an AWS IoT button, you can buy one here or you can use an MQTT client to send an MQTT message that triggers the rule.

Create the Lambda Function

To create the Lambda function:

1. In the AWS Lambda console, choose Get Started Now or, if you have created a Lambda function before, choose Create a Lambda function.
2. On the Select blueprint page, in the Filter field, type **hello-world**, and then choose the **hello-world** blueprint.

3. On the Configure triggers page, select the box to the left of the Lambda icon, and select **AWS IoT** from the drop-down menu.
4. In the **Device Serial Number** field, type your button's device serial number (DSN). The DSN is printed on the back of your AWS IoT button. If you have not already generated a certificate and private key for your AWS IoT button, choose **Generate certificate and keys**. Otherwise, skip to step 6.
5. Choose the links to download your certificate PEM and private key. Save these files in a secure location on your computer.

Follow the online instructions to configure your AWS IoT button.

6. Make sure that the **Enable trigger** check box is selected, and then choose **Next**.
7. On the **Configure function** page, type a name and description for the Lambda function. In **Runtime**, choose **Node.js 6.10**.

8. Scroll down to the **Lambda function code** section of the page. Replace the existing code with the following:

```javascript
// Load the AWS SDK
var AWS = require("aws-sdk");

// Set up the code to call when the Lambda function is invoked
exports.handler = (event, context, callback) => {
    // Load the message passed into the Lambda function into a JSON object
    var eventText = JSON.stringify(event, null, 2);

    // Log a message to the console, you can view this text in the Monitoring tab in the Lambda console or in the CloudWatch Logs console
    console.log("Received event:", eventText);

    // Create a string extracting the click type and serial number from the message sent by the AWS IoT button
    var messageText = "Received " + event.clickType + " message from button ID: " + event.serialNumber;

    // Write the string to the console
    console.log("Message to send: " + messageText);

    // Create an SNS object
    var sns = new AWS.SNS();

    // Populate the parameters for the publish operation
    var params = {
        Message: messageText,
    };

    sns.publish(params, context.done);
};
```
**Note**
Replace the value of `TopicArn` with the ARN of the Amazon SNS topic you created previously.

9. Scroll down to the Lambda function handler and role section of the page. For Role, choose Create a custom role. The IAM console opens, allowing you to create an IAM role that Lambda can assume when executing the Lambda function.

**To edit the role's policy to give it permission to publish to your Amazon SNS topic:**

b. Choose Edit to edit the role's policy.
c. Replace the policy document with the following:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs::*::*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "sns:Publish"
            ],
            "Resource": "arn:aws:sns:us-east-1:123456789012:MyIoTButtonSNSTopic"
        }
    ]
}
```

This policy document adds permission to publish to your Amazon SNS topic.

**Note**
Replace the value of the second `Resource` with the ARN of the Amazon SNS topic you created previously.

10. Choose Allow.

11. Leave the settings on the **Advanced settings** page at their defaults, and choose Next.
12. On the Review page, choose **Create function**.
Test Your Lambda Function

To test the Lambda function:

1. From the Actions menu, choose Configure test event.

2. Copy and paste the following JSON into the Input test event page, and then choose Save and test.

```json
{
    "serialNumber": "ABCDEFG12345",
    "clickType": "SINGLE",
    "batteryVoltage": "2000 mV"
}
```
3. In the AWS Lambda console, scroll to the bottom of the page. The **Log output** section displays the output the Lambda function has written to the console.
Creating a Lambda Rule

Now that you have created a Lambda function, you can create a rule that invokes the Lambda function.

1. In the AWS IoT console, in the left navigation pane, choose Rules.

3. Type a name and description for the rule.

4. Enter the following settings for the rule:
5. In **Set one or more actions**, choose **Add action**.

6. On the **Select an action** page, select **Invoke a Lambda function passing the message data**, and then choose **Configure action**.
7. From the **Function name** drop-down list, choose your Lambda function name, then choose **Add action**.

8. Choose **Create rule** to create your Lambda function.

---

**Test Your Lambda Rule**

In this tutorial, we assume you have completed the [AWS IoT Getting Started Tutorial (p. 5)](#), which covers:
• Configuring an AWS IoT button.
• Creating and subscribing to an Amazon SNS topic with a cell phone number.

Now that your button is configured and connected to Wi-Fi and you have configured an Amazon SNS topic, you can press the button to test your Lambda rule. You should receive an SMS text message on your phone that contains:

• The serial number of your button.
• The type of button press (SINGLE or DOUBLE).
• The battery voltage.

The message should look like the following:

```
IOT BUTTON> {
    "serialNumber" : "ABCDEFG12345",
    "clickType" : "SINGLE",
    "batteryVoltage" : "2000 mV"
}
```

If you do not have a button, you can buy one here or you can use the AWS IoT MQTT client instead.

1. In the AWS IoT console, choose Test.

2. On the MQTT client page, in the Publish section, in Specify a topic, type iotbutton/ABCDEFG12345.

   In Payload, type the following JSON, and then choose Publish to topic.

```
{
    "serialNumber" : "ABCDEFG12345",
    "clickType" : "SINGLE",
    "batteryVoltage" : "2000 mV"
}
```
3. You should receive a message on your cell phone.

Creating an Amazon SNS Rule

You can define a rule that sends message data to an Amazon SNS topic. In this tutorial, you will create a rule that sends the name of the AWS IoT thing that triggered the rule to all subscribers of an Amazon SNS topic.

To create a rule with an SNS action:

1. In the AWS IoT console, in the left navigation pane, choose Rules.

3. Type a name for your rule.

4. Under Message source, for Attribute type *, topic(3). For Topic filter, type $aws/things/+\shadow/update/accepted. The topic filter specifies the topics that, when a message is published to them, trigger the rule's action. The + used in the topic filter is a wildcard character that matches any thing name. The attribute appends the thing name onto the message contents.
5. In the **Set one or more actions** section, choose **Add action**.

6. Under **Select an action**, select **Send a message as an SNS push notification**, and then choose **Configure action**. (This button is not shown in screenshot).
7. **Choose Create new topic.**

8. A new tab opens in your browser. Type a name and description for your SNS topic, and then choose **Create topic.**
9. Switch to the browser tab where the AWS IoT console is open. For **SNS target**, choose the SNS topic you just created. For **Message format**, choose **JSON**.

10. For **IAM role name**, choose **Create a new role**.
11. Type a name for the role, and then choose **Create a new role.**
12. Select the role you just created, and then choose Add action.
13. Choose Create rule.

You have now created the rule. To test the rule, add a subscription to the SNS topic you created, and update the thing shadow of any AWS IoT thing. You can use the AWS IoT console to find a thing, open its detail page, and change the thing's shadow. When the Thing Shadow service is notified of the change, it will publish a message on $aws/things/MySNSThing/shadow/update/accepted. Your rule is triggered and all subscribers to your SNS topic receive a message that contains your thing's name.
AWS IoT SDK Tutorials

The AWS IoT Device SDKs help you to easily and quickly connect your devices to AWS IoT. The AWS IoT Device SDKs include open-source libraries, developer guides with samples, and porting guides so that you can build innovative IoT products or solutions on your choice of hardware platforms.

This guide provides step-by-step instructions for connecting your Raspberry Pi to the AWS IoT platform and setting it up for use with the AWS IoT Embedded C SDK and Device SDK for Javascript. After following the steps in this guide, you are able to connect to the AWS IoT platform and run sample apps included with these AWS IoT SDKs.

Contents
- Connecting Your Raspberry Pi (p. 78)
- Using the AWS IoT Embedded C SDK (p. 87)
- Using the AWS IoT Device SDK for JavaScript (p. 89)

Connecting Your Raspberry Pi

Follow these steps to connect your Raspberry Pi to the AWS IoT platform.

Prerequisites

- A fully set up Raspberry Pi board with Internet access

  For information about setting up your Raspberry Pi, see Raspberry Pi Quickstart Guide.
- Chrome or Firefox (Iceweasel) browser

  For information about installing Iceweasel, see the instructions on the Embedded Linux wiki.

In this guide, the following hardware and software are used:

- Raspberry Pi 2 Model B
- Raspbian Wheezy
- Raspbian Jessie
- Iceweasel browser

Sign in to the AWS IoT Console

1. Turn on your Raspberry Pi and confirm you have an Internet connection.
3. If this is your first time using the AWS IoT console, you see the **Welcome to the AWS IoT Console** page. In the left navigation pane, choose **Registry** to expand the choices, and then choose **Things**.

4. On the page that says **You don't have any things yet**, choose **Register a thing**. (If you have created a thing before, choose **Create**.)
Create and Attach a Thing (Device)

A thing represents a device whose status or data is stored in the AWS Cloud. The Thing Shadows service maintains a thing shadow for each device connected to AWS IoT. Thing shadows allow you to access and modify thing state data.

1. Type a name for the thing, and then choose Create thing.

2. On the Details page, choose Interact.

4. Choose Create certificate. This generates an X.509 certificate and key pair.
5. Create a working directory called `deviceSDK` where your files will be stored. Choose the links to download your public and private keys, certificate, and root CA and save them in the `deviceSDK` directory. Choose **Activate** to activate the X.509 certificate, then choose **Attach a policy**.

6. Choose **Create new policy**.
7. On the Create a policy page, in the Name field, type a name for the policy. In the Action field, type `iot:*`. In the Resource ARN field, type `*`. Select the Allow check box. This allows your Raspberry Pi to publish messages to AWS IoT.

8. Choose Create.
9. Choose the left arrow to return to the Policies page.

10. In the left navigation pane, under Security, choose Certificates.
11. In the box for the certificate you created, choose ... to open a drop-down menu, and then choose Attach policy.

12. In the Attach policies to certificate(s) dialog box, select the check box next to the policy you created, and then choose Attach.
13. In the box for the certificate you created, choose ... to open a drop-down menu, and then choose Attach thing.

14. In the Attach things to certificate(s) dialog box, select the check box next to the thing you created to represent your Raspberry Pi, and then choose Attach.
Using the AWS IoT Embedded C SDK

Set Up the Runtime Environment for the AWS IoT Embedded C SDK

1. Download the AWS IoT Device SDK for C from the following GitHub repository:

   ```
   git clone https://github.com/aws/aws-iot-device-sdk-embedded-C.git -b release
   ```

2. Before you can use the AWS IoT Embedded C SDK, you must download all required third-party libraries from GitHub. You can find instructions for doing this in the `deviceSDK/external_libs` folder.

Sample App Configuration

The AWS IoT Embedded C SDK includes sample apps for you to try. For simplicity, we are going to run `subscribe_publish_sample`.

1. Copy your certificate, private key, and root CA certificate into the `deviceSDK/certs` directory.

   If you did not get a copy of the root CA certificate, you can download it [here]. Copy the root CA text from the browser, paste it into a file, and then copy it into the `deviceSDK/certs` directory.

   **Note**
   Device and root CA certificates are subject to expiration or revocation. If this should occur, you must copy a new CA certificate or private key and device certificate onto your device.

2. Navigate to the `deviceSDK/sample_apps/subscribe_publish_sample` directory. You must configure your personal endpoint, private key, and certificate. The personal endpoint is the REST API endpoint you noted earlier. If you don't remember the endpoint and you have access to a machine with the AWS CLI installed, you can use the `aws iot describe-endpoint` command to find your personal endpoint URL. Or, go to the AWS IoT console. Choose **Registry**, choose **Things**, and then choose the thing that represents your Raspberry Pi. On the **Details** page for the thing, in the left navigation pane, choose **Interact**. Copy everything, including ".com", from **REST API endpoint**.
3. Open the `aws_iot_config.h` file and, in the `//Get from console` section, update the values for the following:

   - AWS_IOT_MQTT_HOST
     
     Your personal endpoint.

   - AWS_IOT_MY_THING_NAME
     
     Your thing name.

   - AWS_IOT_ROOT_CA_FILENAME
     
     Your root CA certificate.

   - AWS_IOT_CERTIFICATE_FILENAME
     
     Your certificate.

   - AWS_IOT_PRIVATE_KEY_FILENAME
     
     Your private key.

   For example:

   ```
   // Get from console
   // =================================================
   #define AWS_IOT_MQTT_HOST              "a22j5sm6o3yzc5.iot.us-east-1.amazonaws.com"
   #define AWS_IOT_MQTT_PORT              8883
   #define AWS_IOT_MQTT_CLIENT_ID         "MyRaspberryPi"
   #define AWS_IOT_MY_THING_NAME          "MyRaspberryPi"
   #define AWS_IOT_ROOT_CA_FILENAME       "root-CA.crt"
   #define AWS_IOT_CERTIFICATE_FILENAME   "4bbdc778b9-certificate.pem.crt"
   #define AWS_IOT_PRIVATE_KEY_FILENAME   "4bbdc778b9-private.pem.key"
   // =================================================
   ```

**Run Sample Applications**

1. Compile the `subscribe_publish_sample_app` using the included makefile.
make -f Makefile

This generates an executable file.

2. Now run the subscribe_publish_sample_app. You should see output similar to the following:

Your Raspberry Pi is now connected to AWS IoT using the AWS IoT Device SDK for C.

Using the AWS IoT Device SDK for JavaScript

The easiest way to install the AWS IoT Device SDK for Node.js is to use npm. In this section we describe how to install Node and npm.
Set Up the Runtime Environment for the AWS IoT Device SDK for JavaScript

To use the AWS IoT Device SDK for JavaScript, install Node and the npm development tool on your Raspberry Pi. These packages are not installed by default.

**Note**
Before you continue, you might want to configure the keyboard mapping for your Raspberry Pi. For more information, see [Configure Raspberry Pi Keyboard Mapping](#).

1. To add the Node repository, open a terminal and run the following command:
   ```bash
curl -sL https://deb.nodesource.com/setup_8.x | sudo -E bash -
   ```

2. To install Node, run
   ```bash
   sudo apt-get install nodejs
   ```

3. Run `npm -v` to determine if npm is installed. If no version information is returned, install npm as follows:
   ```bash
   sudo apt-get install npm
   ```

   You should see output similar to the following:

   ![Command output](image)

4. To verify the installation of Node and npm, run the following:
   ```bash
   node -v
   ```
   and
   ```bash
   npm -v
   ```

   You should see output similar to the following:
Install the AWS IoT Device SDK for JavaScript

To install the AWS IoT Device SDK for JavaScript/Node.js on your Raspberry Pi, open a console window and from your ~/deviceSDK directory, use npm to install the SDK:

```
npm install aws-iot-device-sdk
```

After the installation is complete, you should find a node_modules directory in your ~/deviceSDK directory.

Prepare to Run the Sample Applications

The AWS IoT Device SDK for JavaScript includes sample apps for you to try. To run them, you must configure your certificates and private key.

Edit the file ~/deviceSDK/node_modules/aws-iot-device-sdk/examples/lib/cmdline.js to change the default names for the private key (privateKey), certificate (clientCert), and CA root certificate (caCert) used by the samples. For example:

```javascript
default: {
  region: 'us-east-1',
  clientId: clientIdDefault,
  privateKey: '4bbdc778b9-private.pem.key',
  clientCert: '4bbdc778b9-certificate.pem.crt',
  caCert: 'root-CA.crt',
  testMode: 1,
  reconnectPeriod: 3 * 1000, /* milliseconds */
  delay: 4 * 1000      /* milliseconds */
};
```

Run the Sample Applications

Run the examples using
node examples/<YourDesiredExample>.js -f <certs location>

Assuming you are in the directory `~/deviceSDK/node_modules/aws-iot-device-sdk/`, the certificates location should be `~/deviceSDK/certs/`. For more information about how you can use command line options to specify the certificates location and your own host address, see Certificates.

If you want to create a configuration file for use with the command line option `--configuration-file (-F)`, create a file (in JSON format) with the following properties. For example:

```json
{
  "host": "a22j5sm6o3yzc5.iot.us-east-1.amazonaws.com",
  "port": 8883,
  "clientId": "MyRaspberryPi",
  "thingName": "MyRaspberryPi",
  "caCert": "root-CA.crt",
  "clientCert": "4bbdc778b9-certificate.pem.crt",
  "privateKey": "4bbdc778b9-private.pem.key"
}
```

Your Raspberry Pi is now connected to AWS IoT using the AWS IoT SDK for JavaScript.
Managing Things with AWS IoT

AWS IoT provides a thing registry that helps you manage your things. A thing is a representation of a specific device or logical entity. It can be a physical device or sensor (for example, a light bulb or a switch on a wall). It can also be a logical entity like an instance of an application or physical entity that does not connect to AWS IoT but is related to other devices that do (for example, a car that has engine sensors or a control panel).

Information about a thing is stored in the thing registry as JSON data. Here is an example thing:

```json
{
    "version": 3,
    "thingName": "MyLightBulb",
    "defaultClientId": "MyLightBulb",
    "thingTypeName": "LightBulb",
    "attributes": {
        "model": "123",
        "wattage": "75"
    }
}
```

Things are identified by a name. Things can also have attributes, which are name-value pairs you can use to store information about the thing, such as its serial number or manufacturer.

A typical device use case involves the use of the thing name as the default MQTT client ID. Although we do not enforce a mapping between a thing’s registry name and its use of MQTT client IDs, certificates, or shadow state, we recommend you choose a thing name and use it as the MQTT client ID for both the thing registry and the Thing Shadows service. This provides organization and convenience to your IoT fleet without removing the flexibility of the underlying device certificate model or thing shadows.

You do not need to create a thing in the thing registry to connect it to AWS IoT. Adding your things in the thing registry allows you to manage and search for them more easily.

Managing Things with the Thing Registry

You use the AWS IoT console or the AWS CLI to interact with the registry. The following sections show how to use the CLI to work with the thing registry.

Create a thing

The following command shows how to use the AWS IoT CreateThing command from the CLI to create a thing:

```bash
$ aws iot create-thing --thing-name "MyLightBulb" --attribute-payload "{"attributes": {"wattage":75,"model":123}}"
```

The CreateThing command will display the name and ARN of your new thing:

```json
{
    "thingArn": "arn:aws:iot:us-east-1:123456789012:thing/MyLightBulb",
    "thingName": "MyLightBulb"
}
```
List things

You can use the ListThings command to list all things in your account:

```bash
$ aws iot list-things
{
    "things": [
    {
        "attributes": {
            "model": "123",
            "wattage": "75"
        },
        "version": 1,
        "thingName": "MyLightBulb"
    },
    {
        "attributes": {
            "numOfStates": "3"
        },
        "version": 11,
        "thingName": "MyWallSwitch"
    }
    ]
}
```

Search for things

You can use the DescribeThing command to list information about a thing:

```bash
$ aws iot describe-thing --thing-name "MyLightBulb"
{
    "version": 3,
    "thingName": "MyLightBulb",
    "thingArn": "arn:aws:iot:us-east-1:123456789012:thing/MyLightBulb",
    "thingId": "12345678abcdefgh12345678ijklmnop12345678",
    "defaultClientId": "MyLightBulb",
    "thingTypeName": "StopLight",
    "attributes": {
        "model": "123",
        "wattage": "75"
    }
}
```

You can use the ListThings command to search for all things associated with a thing type name:

```bash
$ aws iot list-things --thing-type-name "LightBulb"
{
    "things": [
    {
        "thingTypeName": "LightBulb",
        "attributes": {
            "model": "123",
            "wattage": "75"
        }
    }
    ]
}
```
You can use the `ListThings` command to search for all things that have an attribute with a specific value:

```bash
$ aws iot list-things --attribute-name "wattage" --attribute-value "75"
```

Update a thing

You can use the `UpdateThing` command to update a thing:

```bash
$ aws iot update-thing --thing-name "MyLightBulb" --attribute-payload "{"attributes": {"wattage": "150", \"model\": \"456\"}}"
```
The `UpdateThing` command does not produce output. You can use the ` DescribeThing` command to see the result:

```bash
$ aws iot describe-thing --thing-name "MyLightBulb"
{
    "attributes": {
        "model": "456",
        "wattage": "150"
    },
    "version": 2,
    "thingName": "MyLightBulb"
}
```

### Delete a thing

You can use the `DeleteThing` command to delete a thing:

```bash
$ aws iot delete-thing --thing-name "MyThing"
```

### Attach a principal to a thing

A physical device must have an X.509 certificate in order to communicate with AWS IoT. You can associate the certificate on your device with the thing in the thing registry that represents your device. To attach a certificate to your thing, use the `AttachThingPrincipal` command:

```bash
$ aws iot attach-thing-principal --thing-name "MyLightBulb" --principal "arn:aws:iot:us-east-1:123456789012:cert/a0c01f5835079de0a7514643d68ef8414ab739a1e94ee4162977b02b12842847"
```

The `AttachThingPrincipal` command does not produce any output.

### Detach a principal from a thing

You can use the `DetachThingPrincipal` command to detach a certificate from a thing:

```bash
$ aws iot detach-thing-principal --thing-name "MyLightBulb" --principal "arn:aws:iot:us-east-1:123456789012:cert/a0c01f5835079de0a7514643d68ef8414ab739a1e94ee4162977b02b12842847"
```

The `DetachThingPrincipal` command does not produce any output.

### Thing Types

Thing types allow you to store description and configuration information that is common to all things associated with the same thing type. This simplifies the management of things in the thing registry. For example, you can define a LightBulb thing type. All things associated with the LightBulb thing type share a set of attributes: serial number, manufacturer, and wattage. When you create a thing of type LightBulb (or change the type of an existing thing to LightBulb) you can specify values for each of the attributes defined in the LightBulb thing type.

Although thing types are optional, their use provides better discovery of things.

- Things with a thing type can have up to 50 attributes.
- Things without a thing type can have up to three attributes.
- A thing can only be associated with one thing type.
There is no limit on the number of thing types you can create in your account.

Thing types are immutable. You cannot change a thing type name after it has been created. You can deprecate a thing type at any time to prevent new things from being associated with it. You can also delete thing types that have no things associated with them.

Create a Thing Type

You can use the `create-thing-type` command to create a thing type:

```bash
$ aws iot create-thing-type
--thing-type-name "LightBulb" --thing-type-properties "thingTypeDescription=light bulb type, searchableAttributes=wattage,model"
```

The `create-thing-type` command returns a response that contains the thing type and its ARN:

```json
{
  "thingTypeName": "LightBulb",
  "thingTypeArn": "arn:aws:iot:us-west-2:123456789012:thingtype/LightBulb"
}
```

List thing types

You can use the `list-thing-types` command to list thing types:

```bash
$ aws iot list-thing-types
```

The `list-thing-types` command returns a list of the thing types defined in your AWS account:

```json
{
  "thingTypes": [ 
    { 
      "thingTypeName": "LightBulb",
      "thingTypeProperties": { 
        "searchableAttributes": [ 
          "wattage",
          "model"
        ],
        "thingTypeDescription": "light bulb type"
      },
      "thingTypeMetadata": { 
        "deprecated": false,
        "creationDate": 1468423800950
      }
    }
  ]
}
```

Describe a thing type

You can use the `describe-thing-type` command to get information about a thing type:

```bash
$ aws iot describe-thing-type --thing-type-name "LightBulb"
```
The DescribeThingType command responds with information about the specified type:

```json
{
    "thingTypeName": "LightBulb",
    "thingTypeProperties": {
        "searchableAttributes": [
            "wattage",
            "model"
        ],
        "thingTypeDescription": "light bulb type"
    },
    "thingTypeMetadata": {
        "deprecated": false,
        "creationDate": 1468423800950,
    }
}
```

**Associate a thing type with a thing**

You can use the CreateThing command to specify a thing type when you create a thing:

```
$ aws iot create-thing --thing-name "MySecondLightBulb" --thing-type-name "LightBulb" --attribute-payload "{\"attributes\": {\"wattage\":\"75\", \"model\":\"123\"}}"
```

You can use the UpdateThing command at any time to change the thing type associated with a thing:

```
$ aws iot update-thing --thing-name "MyLightBulb" --thing-type-name "StopLight" --attribute-payload "{"attributes": {\"wattage\":\"75\", \"model\":\"123\"}}"
```

You can also use the UpdateThing command to disassociate a thing from a thing type.

**Deprecate a thing type**

Thing types are immutable. They cannot be changed after they are defined. You can, however, deprecate a thing type to prevent users from associating any new things with it. All existing things associated with the thing type will be unchanged.

To deprecate a thing type, use the DeprecateThingType command:

```
$ aws iot deprecate-thing-type --thing-type-name "myThingType"
```

You can use the DescribeThingType command to see the result:

```
$ aws iot describe-thing-type --thing-type-name "StopLight":
```

```json
{
    "thingTypeName": "StopLight",
    "thingTypeProperties": {
        "searchableAttributes": [
            "wattage",
            "numOfLights",
            "model"
        ],
        "thingTypeDescription": "traffic light type",
    },
    "thingTypeMetadata": {
        "deprecated": true,
    }
}
```
Deprecating a thing type is a reversible operation. You can undo a deprecation by using the `--undo-deprecate` flag with the `DeprecateThingType` CLI command:

```
$ aws iot deprecate-thing-type --thing-type-name "myThingType" --undo-deprecate
```

You can use the `DescribeThingType` CLI command to see the result:

```
$ aws iot describe-thing-type --thing-type-name "StopLight":
```

```
{
  "thingTypeName": "StopLight",
  "thingTypeArn": "arn:aws:iot:us-east-1:123456789012:thingtype/StopLight",
  "thingTypeId": "12345678abcdefgh12345678ijklmnop12345678",
  "thingTypeProperties": {
    "searchableAttributes": [
      "wattage",
      "numOfLights",
      "model"
    ],
    "thingTypeDescription": "traffic light type"
  },
  "thingTypeMetadata": {
    "deprecated": false,
    "creationDate": 1468425854308,
  }
}
```

## Delete a thing type

You can delete thing types only after they have been deprecated. To delete a thing type, use the `DeleteThingType` command:

```
$ aws iot delete-thing-type --thing-type-name "StopLight"
```

**Note**

You must wait five minutes after you deprecate a thing type before you can delete it.

## Thing Groups

Thing groups allow you to manage several things at once by categorizing them into groups. Groups can also contain groups — you can build a hierarchy of groups. You can attach a policy to a parent group and it will be inherited by its child groups, and by all of the things in the group and in its child groups as well. This makes control of permissions easy for large numbers of things.

Here are the things you can do with thing groups:

- Create, describe or delete a group.
- Add a thing to a group, or to more than one group.
- Remove a thing from a group.
- List the groups you have created.
- List all child groups of a group (its direct and indirect descendants.)
- List the things in a group, including all the things in its child groups.
- List all ancestor groups of a group (its direct and indirect parents.)
- Add, delete or update the attributes of a group. (Attributes are name-value pairs you can use to store information about a group.)
- Attach or detach a policy to or from a group.
- List the policies attached to a group.
- List the policies inherited by a thing (by virtue of the policies attached to its group, or one of its parent groups.)
- Configure logging options for things in a group (see Configure AWS IoT Logging (p. 341).)
- Create jobs that will be sent to and executed on every thing in a group and its child groups (see Jobs (p. 263).)

Here are some limitations of thing groups:

- If a group will be a child of another group, this must be specified at the time it is created.
- You can't change a group's parent later. (So be sure to plan your group hierarchy and create a parent group before creating any child groups it will contain.
- You cannot add a thing to more than 10 groups.
- You cannot add a thing to more than one group in the same hierarchy. (In other words, you cannot add a thing to two groups which share a common parent.)
- You cannot rename a group.

Attaching and detaching policies to groups can enhance the security of your AWS IoT operations in a number of significant ways. The per device method of attaching a policy to a certificate, which is then attached to a thing, is time consuming and makes it difficult to quickly update or change policies across a fleet of devices. Having a policy attached to the thing's group saves steps when it is time to rotate the certificates on a thing. And policies are dynamically applied to things when they change group membership, so you aren't required to re-create a complex set of permissions each time a device changes membership in a group.

**Create a Thing Group**

You can use the `CreateThingGroup` command to create a thing group:

```
# aws iot create-thing-group --thing-group-name LightBulbs
```

The `CreateThingGroup` command returns a response that contains the thing group, its ID, and its ARN:

```json
{
  "thingGroupName": "LightBulbs",
  "thingGroupId": "abcdefgh12345678ijklmnop12345678qrstuvwx",
  "thingGroupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/LightBulbs"
}
```

Here is an example which specifies a parent of the thing group when it is created:

```
# aws iot create-thing-group --thing-group-name RedLights --parent-group-name LightBulbs
```

As before, the `CreateThingGroup` command returns a response that contains the thing group and its ID and ARN:
Important
Keep in mind the following limits when creating group hierarchies:

- A group can have at most one direct parent.
- A group may have no more than 100 direct child groups.
- The maximum depth of a group hierarchy is 7.
- A group can have up to 50 attributes. (Attributes are name-value pairs you can use to store information about a group.) Each attribute name can contain up to 128 characters and each value up to 800 characters.

Describe a thing group

You can use the DescribeThingGroup command to get information about a thing group:

```
$ aws iot describe-thing-group --thing-group-name RedLights
```

The DescribeThingGroup command responds with information about the specified group:

```
{
  "thingGroupName": "RedLights",
  "thingGroupId": "12345678abcdefgh12345678ijklmnop12345678",
  "version": 1,
  "thingGroupMetadata": {
    "creationDate": 1478299948.882,
    "parentGroupName": "Lights",
    "rootToParentThingGroups": [
      {
        "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/ShinyObjects",
        "groupName": "ShinyObjects"
      },
      {
        "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/LightBulbs",
        "groupName": "LightBulbs"
      }
    ]
  },
  "thingGroupProperties": {
    "attributePayload": {
      "attributes": {
        "brightness": "3400 lumens"
      }
    },
    "thingGroupDescription": "string"
  }
}
```

Add thing to thing group

You can use the AddThingToThingGroup command to add a thing to a group:
The `AddThingToThingGroup` command does not produce any output.

**Important**

You can add a thing to a maximum of 10 groups. But you cannot add a thing to more than one group in the same hierarchy. (In other words, you cannot add a thing to two groups which share a common parent.)

### Remove thing from thing group

You can use the `RemoveThingFromThingGroup` command to remove a thing from a group:

```
$ aws iot remove-thing-from-thing-group --thing-name MyLightBulb --thing-group-name RedLights
```

The `RemoveThingFromThingGroup` command does not produce any output.

### List things in thing group

You can use the `ListThingsInThingGroup` command to list the things belonging to a group:

```
$ aws iot list-things-in-thing-group --thing-group-name LightBulbs
```

The `ListThingsInThingGroup` command returns a list of the things in the given group:

```
{
   "things": ["TestThingA"
   ]
}
```

With the `--recursive` parameter, you can list things belonging to a group and those in any of its child groups as well:

```
$ aws iot list-things-in-thing-group --thing-group-name LightBulbs --recursive
```

```
{
   "things": [
   "TestThingA",
   "MyLightBulb"
   ]
}
```

**Note**

This operation is eventually consistent, in other words, changes to the thing group may not be reflected immediately.

### List thing groups

You can use the `ListThingGroups` command to list groups you have created:

```
$ aws iot list-thing-groups
```
The `ListThingGroups` command returns a list of the groups defined in your AWS account:

```json
{
  "thingGroups": [
    {
      "groupName": "LightBulbs",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/LightBulbs"
    },
    {
      "groupName": "RedLights",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/RedLights"
    },
    {
      "groupName": "RedLEDLights",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/RedLEDLights"
    },
    {
      "groupName": "RedIncandescentLights",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/RedIncandescentLights"
    },
    {
      "groupName": "ReplaceableObjects",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/ReplaceableObjects"
    }
  ]
}
```

Use the optional filters to list those groups that have a given group as parent (`--parent-group`) or groups whose name begins with a given prefix (`--name-prefix-filter`). The `--recursive` parameter allows you to list all children groups as well, not just direct child groups of a thing group:

```
$ aws iot list-thing-groups --parent-group LightBulbs
```

In this case, the `ListThingGroups` command returns a list of the direct child groups of the thing group defined in your AWS account:

```
{
  "childGroups": [
    {
      "groupName": "RedLights",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/RedLights"
    }
  ]
}
```

Use the `--recursive` parameter with the `ListThingGroups` command to list all child groups of a thing group, not just direct children:

```
$ aws iot list-thing-groups --parent-group LightBulbs --recursive
```

The `ListThingGroups` command returns a list of all child groups of the thing group:

```
{
  "childGroups": [
    {
      "groupName": "RedLights",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/RedLights"
    }
  ]
}
```
List groups for thing

You can use the `ListThingGroupsForThing` command to list the groups a thing belongs to, including any parent groups:

```bash
$ aws iot list-thing-groups-for-thing --thing-name MyLightBulb
```

The `ListThingGroupsForThing` command returns a list of the thing groups this thing belongs to, including any parent groups:

```json
{
  "thingGroups": [
    {
      "groupName": "LightBulbs",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/LightBulbs"
    },
    {
      "groupName": "RedLights",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/RedLights"
    },
    {
      "groupName": "ReplaceableObjects",
      "groupArn": "arn:aws:iot:us-west-2:123456789012:thinggroup/ReplaceableObjects"
    }
  ]
}
```

Update a Thing Group

You can use the `UpdateThingGroup` command to update the attributes of a thing group:

```bash
$ aws iot update-thing-group --thing-group-name "LightBulbs" --thing-group-properties "thingGroupDescription="this is a test group\", attributePayload="{"attributes "={"Owner"="150","modelNames"="456"}}"
```

The `UpdateThingGroup` command returns a response that contains the group's version number after the update:

```json
{
  "version": 4
}
```
Delete a thing group

To delete a thing group, use the `DeleteThingGroup` command:

```
$ aws iot delete-thing-group --thing-group-name "RedLights"
```

The `DeleteThingGroup` command does not produce any output.

**Important**

If you try to delete a thing group which has child thing groups, this will generate an error:

```
A client error (InvalidRequestException) occurred when calling the DeleteThingGroup operation: Cannot delete thing group : RedLights when there are still child groups attached to it.
```

You must delete any child groups first before deleting the group.

You can delete a group that has child things, but any permissions granted to the things by membership in the group will no longer apply. Before deleting a group that has a policy attached, check carefully that removing those permissions would not stop the things in the group from being able to function properly. Also, note that commands that show which groups a thing belongs to (for example, `ListGroupsForThing`) may continue to show the group while records in the cloud are being updated.

Attach a policy to a thing group

You can use the `AttachPolicy` command to attach a policy to a thing group and so, by extension, to all things in that group and things in any of its child groups:

```
$ aws iot attach-policy \
--target "arn:aws:iot:us-west-2:123456789012:thinggroup/LightBulbs" \
--policy-name "myLightBulbPolicy"
```

The `AttachPolicy` command does not produce any output.

**Important**

The maximum number of policies that can be attached to a group is 2.

The `--target` can also be a certificate ARN or an Amazon Cognito Identity. See Security and Identity for AWS IoT (p. 109) for more information about policies, certificates and authentication.

Detach a policy from a thing group

You can use the `DetachPolicy` command to detach a policy from a group and so, by extension, to all things in that group and things in any of its child groups:

```
$ aws iot detach-policy --target "LightBulbs" --policy-name "myLightBulbPolicy"
```

The `DetachPolicy` command does not produce any output.

List the policies attached to a thing group

You can use the `ListAttachedPolicies` command to list the policies attached to a group:
List the groups for a policy

You can use the `ListAttachedPolicies` command to list policies attached to a group:

$ aws iot list-attached-policies --target "RedLights"

The `--target` parameter can also be a certificate ARN or Amazon Cognito Identity.

Add the optional `--recursive` parameter to include all policies attached to the group's parent groups as well.

The `ListAttachedPolicies` command returns a list of policies:

```json
{
   "policies": [
      "MyLightBulbPolicy"
   ]
}
```

### List the groups for a policy

You can use the `ListTargetsForPolicy` command to list the targets, including any groups, that a policy is attached to:

$ aws iot list-targets-for-policy --policy-name "MyLightBulbPolicy"

Add the optional `--page-size number` parameter to specify the maximum number of results to be returned for each query, and the `--marker string` parameter on subsequent calls to retrieve the next set of results, if any.

The `ListTargetsForPolicy` command returns a list of targets and the token to use to retrieve more results:

```json
{
   "nextMarker": "string",
   "targets": [ "string" ... ]
}
```

### Get effective policies for a thing

You can use the `GetEffectivePolicies` command to list the policies in effect for a thing, including the policies attached to any groups the thing belongs to (whether the group is a direct parent or indirect ancestor):

$ aws iot get-effective-policies \
   --thing-name "MyLightBulb" \
   --principal "arn:aws:iot:us-east-1:123456789012:cert/a0c01f5835079de0a7514643d68ef8414ab739a1e94ee4162977b02b12842847"

Use the `--principal` parameter to specify the ARN of the certificate attached to the thing. If you are using Amazon Cognito Identity authentication, use the `--cognito-identity-pool-id` parameter and, optionally, add the `--principal` parameter to specify a specific Cognito Identity. (If you specify only the `--cognito-identity-pool-id` then the policies associated with that identity pool's role for unauthenticated users are returned. If you use both, the policies associated with that identity pool's role for authenticated users are returned.

The `--thing-name` parameter is optional and may be used instead of the `--principal` parameter. When used, the policies attached to any group the thing belongs to, and the policies attached to any parent groups of these groups (up to the root group in the hierarchy) will be returned.
The `GetEffectivePolicies` command returns a list of policies:

```json
{
  "effectivePolicies": [
    {
      "policyArn": "string",
      "policyDocument": "string",
      "policyName": "string"
    }
    ...
  ]
}
```

## Test authorization for MQTT actions

You can use the `TestAuthorization` command to test whether an MQTT action is allowed for a thing:

```bash
$ aws iot test-authorization --principal "arn:aws:iot:us-east-1:123456789012:cert/a0c01f5835079de0a7514643d68ef8414ab739a1e94ee4162977b02b12842847" --auth-infos "[ "actionType": "PUBLISH", "resources": [ "arn:aws:iot:us-east-1:123456789012:topic/iotButton/G030JF053216F1BS" ] ]"
```

Use the `--principal` parameter to specify the ARN of the certificate attached to the thing. If using Amazon Cognito Identity authentication, specify a Cognito Identity as the `--principal` or use the `--cognito-identity-pool-id` parameter, or both. (If you specify only the `--cognito-identity-pool-id` then the policies associated with that identity pool's role for unauthenticated users are considered. If you use both, the policies associated with that identity pool's role for authenticated users are considered.

Specify one or more MQTT actions you want to test by listing sets of resources and action types following the `--auth-infos` parameter. The `actionType` field should contain "PUBLISH", "SUBSCRIBE", "RECEIVE", or "CONNECT". The `resources` field should contain a list of resource ARNs. See AWS IoT Policies (p. 122) for more information.

You can test the effects of adding policies by specifying them with the `--policy-names-to-add` parameter. Or you can test the effects of removing policies by them with the `--policy-names-to-skip` parameter.

You can use the optional `--client-id` parameter to further refine your results.

The `TestAuthorization` command returns details on actions which were allowed or denied for each set of `--auth-infos` queries you specified:

```json
{
  "authResults": [
    {
      "allowed": {
        "matchedStatements": [
          {
            "endPosition": {
              "column": number,
              "line": number
            },
            "policy": {
              "policyArn": "string",
              "policyName": "string"
            },
            "startPosition": {
```
Security and Identity for AWS IoT

Each connected device must have a credential to access the message broker or the Thing Shadows service. All traffic to and from AWS IoT must be encrypted over Transport Layer Security (TLS). Device credentials must be kept safe in order to send data securely to the message broker. AWS Cloud security mechanisms protect data as it moves between AWS IoT and other devices or AWS services.

- You are responsible for managing device credentials (X.509 certificates, AWS credentials) on your devices and policies in AWS IoT. You are responsible for assigning unique identities to each device and managing the permissions for a device or group of devices.
- Devices connect using your choice of identity (X.509 certificates, IAM users and groups, Amazon Cognito identities, or custom authentication tokens) over a secure connection according to the AWS IoT connection model.
- When using AWS IoT authentication, the message broker authenticates and authorizes all actions in your account. The message broker is responsible for authenticating your devices, securely ingesting device data, and adhering to the access permissions you place on devices using policies.
- When using custom authentication, a custom authorizer is responsible for authenticating your devices and providing an AWS IoT/IAM policy to authorize actions in your account.
- The AWS IoT rules engine forwards device data to other devices and other AWS services according to rules you define. It uses AWS access management systems to securely transfer data to its final destination.

AWS IoT Authentication

AWS IoT supports four types of identity principals for authentication:

- X.509 certificates
- IAM users, groups, and roles
- Amazon Cognito identities
- Federated identities

These identities can be used with mobile applications, web applications, or desktop applications. They can even be used by a user typing AWS IoT CLI commands. Typically, AWS IoT devices use X.509 certificates.
certificates, while mobile applications use Amazon Cognito identities. Web and desktop applications use IAM or federated identities. CLI commands use IAM.

X.509 Certificates

X.509 certificates are digital certificates that use the X.509 public key infrastructure standard to associate a public key with an identity contained in a certificate. X.509 certificates are issued by a trusted entity called a certification authority (CA). The CA maintains one or more special certificates called CA certificates that it uses to issue X.509 certificates. Only the certification authority has access to CA certificates.

Note
We recommend that each device be given a unique certificate to enable fine-grained management including certificate revocation. Devices must support rotation and replacement of certificates in order to ensure smooth operation as certificates expire.

AWS IoT supports the following certificate-signing algorithms:

- SHA256WITHRSA
- SHA384WITHRSA
- SHA384WITHRSA
- SHA512WITHRSA
- RSASSAPSS
- DSA_WITH_SHA256
- ECDSA-WITH-SHA256
- ECDSA-WITH-SHA384
- ECDSA-WITH-SHA512

Certificates provide several benefits over other identification and authentication mechanisms. Certificates enable asymmetric keys to be used with devices. This means you can burn private keys into secure storage on a device. This way, sensitive cryptographic material never leaves the device. Certificates provide stronger client authentication over other schemes, such as user name and password or bearer tokens, because the secret key never leaves the device.

AWS IoT authenticates certificates using the TLS protocol's client authentication mode. TLS is available in many programming languages and operating systems and is commonly used for encrypting data. In TLS client authentication, AWS IoT requests a client X.509 certificate and validates the certificate's status and AWS account against a registry of certificates. It then challenges the client for proof of ownership of the private key that corresponds to the public key contained in the certificate.

To use AWS IoT certificates, clients must support all of the following in their TLS implementation:

- TLS 1.2.
- SHA-256 RSA certificate signature validation.
- One of the cipher suites from the TLS cipher suite support section.

X.509 Certificates and AWS IoT

AWS IoT can use AWS IoT-generated certificates or certificates signed by a CA certificate for device authentication. Certificates generated by AWS IoT do not expire. The expiry date and time for certificates signed by a CA certificate are set when the certificate is created.
Note
We recommend that each device be given a unique certificate to enable fine-grained management including certificate revocation. Devices must support rotation and replacement of certificates in order to ensure smooth operation as certificates expire.

To use a certificate that is not created by AWS IoT, you must register a CA certificate. All device certificates must be signed by the CA certificate you register.

You can use the AWS IoT console or CLI to perform the following operations:

- Create and register an AWS IoT certificate.
- Register a CA certificate.
- Register a device certificate.
- Activate or deactivate a device certificate.
- Revoke a device certificate.
- Transfer a device certificate to another AWS account.
- List all CA certificates registered to your AWS account.
- List all device certificates registered to your AWS account.

For more information about the CLI commands to use to perform these operations, see AWS IoT CLI Reference.

For more information about using the AWS IoT console to create certificates, see Create and Activate a Device Certificate.

Server Authentication

Server certificates allow your devices to verify that they're communicating with AWS IoT and not another server impersonating AWS IoT. AWS IoT server certificates are signed by one of the following CA certificates:

- RSA 2048 bit key: VeriSign Class 3 Public Primary G5 root CA certificate
- RSA 2048 bit key: Amazon Root CA 1
- RSA 4096 bit key: Amazon Root CA 2
- ECC 256 bit key: Amazon Root CA 3
- ECC 384 bit key: Amazon Root CA 4

In order for your devices to validate the AWS IoT server certificate we recommend installing all of the CA certificates listed above on your devices.

Storing all of these certificates on your device can take up valuable memory space. If your devices implement RSA-based validation, you can omit the Amazon Root CA 3 and Amazon Root CA 4 ECC certificates. If your devices implement ECC-based certificate validation, you can omit the Amazon Root CA 1 and Amazon Root CA 2 RSA certificates.

You will need to include the VeriSign Class 3 Public Primary G5 root CA certificate regardless of the type of certificate validation your devices use.

Note
CA certificates have an expiration date after which they cannot be used to validate a server's certificate. CA certificates may need to be replaced prior to their expiration date. You should
ensure that you can update the root CA certificates on all of your devices to ensure ongoing connectivity and to keep up to date with security best practices.

Reference the CA root certificate in your device code when you connect to AWS IoT. For more information, see the AWS IoT Device SDKs (p. 325).

Create and Register an AWS IoT Device Certificate

You can use the AWS IoT console or the AWS IoT CLI to create an AWS IoT certificate.

To create a certificate (console)

1. Sign in to the AWS Management Console and open the AWS IoT console at https://console.aws.amazon.com/iot.
2. In the left navigation pane, choose Security to expand the choices, and then choose Certificates. Choose Create.
3. Choose One-click certificate creation - Create certificate. Alternatively, to generate a certificate with a certificate signing request (CSR), choose Create with CSR.
4. Use the links to the public key, private key, and certificate to download each to a secure location.
5. Choose Activate.

To create a certificate (CLI)

The AWS IoT CLI provides two commands to create certificates:

- create-keys-and-certificate
  The CreateKeysAndCertificate API creates a private key, public key, and X.509 certificate.
- create-certificate-from-csr
  The CreateCertificateFromCSR API creates a certificate given a CSR.

Use Your Own Certificate

To use your own X.509 certificates, you must register a CA certificate with AWS IoT. The CA certificate can then be used to sign device certificates. You can register up to 10 CA certificates with the same subject field per AWS account per region. This allows you to have more than one CA sign your device certificates.

Note
Device certificates must be signed by the registered CA certificate. It is common for a CA certificate to be used to create an intermediate CA certificate. If you are using an intermediate certificate to sign your device certificates, you must register the intermediate CA certificate. Use the AWS IoT root CA certificate when you connect to AWS IoT even if you register your own root CA certificate. The AWS IoT root CA certificate is used by a device to verify the identity of the AWS IoT servers.

Contents

- Registering Your CA Certificate (p. 113)
- Creating a Device Certificate Using Your CA Certificate (p. 114)
- Registering a Device Certificate (p. 115)
- Registering Device Certificates Manually (p. 115)
- Using Automatic/Just-in-Time Registration for Device Certificates (p. 115)
- Deactivate the CA Certificate (p. 116)
• **Revoke the Device Certificate** (p. 116)

If you do not have a CA certificate, you can use **OpenSSL** tools to create one.

**To create a CA certificate**

1. Generate a key pair.

   ```bash
   openssl genrsa -out rootCA.key 2048
   ```

2. Use the private key from the key pair to generate a CA certificate.

   ```bash
   openssl req -x509 -new -nodes -key rootCA.key -sha256 -days 1024 -out rootCA.pem
   ```

**Registering Your CA Certificate**

To register your CA certificate, you must:

- Get a registration code from AWS IoT.
- Sign a private key verification certificate with your CA certificate.
- Pass your CA certificate and a private key verification certificate to the `register-ca-certificate` CLI command.

The **Common Name** field in the private key verification certificate must be set to the registration code generated by the `get-registration-code` CLI command. A single registration code is generated per AWS account. You can use the `register-ca-certificate` command or the AWS IoT console to register CA certificates.

**To register a CA certificate**

1. Get a registration code from AWS IoT. This code will be used as the **Common Name** of the private key verification certificate.

   ```bash
   aws iot get-registration-code
   ```

2. Generate a key pair for the private key verification certificate.

   ```bash
   openssl genrsa -out verificationCert.key 2048
   ```

3. Create a CSR for the private key verification certificate. Set the **Common Name** field of the certificate to your registration code.

   ```bash
   openssl req -new -key verificationCert.key -out verificationCert.csr
   ```
   You will be prompted for some information, including the **Common Name**, for the certificate.

   ```
   Country Name (2 letter code) [AU]:
   State or Province Name (full name) []:
   Locality Name (for example, city) []:
   Organization Name (for example, company) []:
   Organizational Unit Name (for example, section) []:
   Common Name (e.g. server FQDN or YOUR name) []:XXXXXXXXXXXXMYREGISTRATIONCODEXXXXXX
   Email Address []:
   ```

4. Use the CSR to create a private key verification certificate.
5. Register the CA certificate with AWS IoT. Pass in the CA certificate and the private key verification certificate to the `register-ca-certificate` CLI command.

```
aws iot register-ca-certificate --ca-certificate file://rootCA.pem --verification-cert file://verificationCert.pem
```

6. Use the `update-certificate` CLI command to activate the CA certificate.

```
aws iot update-ca-certificate --certificate-id xxxxxxxxxxx --new-status ACTIVE
```

### Creating a Device Certificate Using Your CA Certificate

You can use a CA certificate registered with AWS IoT to create a device certificate. The device certificate must be registered with AWS IoT before use.

**To create a device certificate**

1. Generate a key pair.

```
openssl genrsa -out deviceCert.key 2048
```

2. Create a CSR for the device certificate.

```
openssl req -new -key deviceCert.key -out deviceCert.csr
```

You will be prompted for some information, as shown here.

```
Country Name (2 letter code) [AU]:
State or Province Name (full name) []:
Locality Name (for example, city) []:
Organization Name (for example, company) []:
Organizational Unit Name (for example, section) []:
Common Name (e.g. server FQDN or YOUR name) []:
Email Address []:
```

3. Create a device certificate from the CSR.

```
openssl x509 -req -in deviceCert.csr -CA rootCA.pem -CAkey rootCA.key -CAcreateserial -out deviceCert.pem -days 500 -sha256
```

**Note**

You must use the CA certificate registered with AWS IoT to create device certificates. If you have more than one CA certificate (with the same subject field and public key) registered in your AWS account, you must specify the CA certificate used to create the device certificate when you register your device certificate.

4. Register a device certificate.

```
```

5. Use the `update-certificate` CLI command to activate the device certificate.
Registering a Device Certificate

You must use the CA certificate registered with AWS IoT to sign device certificates. If you have more than one CA certificate (with the same subject field and public key) registered in your AWS account, you must specify the CA certificate used to sign the device certificate when you register your device certificate. You can register each device certificate manually, or you can use automatic registration, which allows devices to register their certificate when they connect to AWS IoT for the first time.

Registering Device Certificates Manually

Use the following CLI command to register a device certificate:

```
aws iot register-certificate --certificate-pem file://deviceCert.crt --ca-certificate-pem file://caCert.crt
```

Using Automatic/Just-in-Time Registration for Device Certificates

To register device certificates automatically when devices first connect to AWS IoT, you must enable automatic registration for your CA certificate. This will register any device certificate signed by your CA certificate when it connects to AWS IoT.

Enable Automatic Registration

Use the `update-ca-certificate` API to set the `auto-registration-status` of the CA certificate to `ENABLE`:

```
$ aws iot update-ca-certificate --cert-id caCertificateId --new-auto-registration-status ENABLE
```

You can also set the `auto-registration-status` to `ENABLE` when you use the `register-ca-certificate` API to register your CA certificate:

```
aws iot register-ca-certificate --ca-certificate file://rootCA.pem --verification-cert file://privateKeyVerificationCert.crt --allow-auto-registration
```

When a device first attempts to connect to AWS IoT, as part of the TLS handshake, it must present a registered CA certificate and a device certificate. AWS IoT recognizes the CA certificate as a registered CA certificate and automatically registers the device certificate and sets its status to `PENDING_ACTIVATION`. This means the device certificate was automatically registered and is awaiting activation. A certificate must be in the `ACTIVE` state before it can be used to connect to AWS IoT. When AWS IoT automatically registers a certificate or when a certificate in `PENDING_ACTIVATION` status connects, AWS IoT publishes a message to the following MQTT topic:

```
/aws/events/certificates/registered/caCertificateID
```

Where `caCertificateID` is the ID of the CA certificate that issued the device certificate.

The message published to this topic has the following structure:

```
{
    "certificateId": "certificateID",
    "caCertificateId": "caCertificateId",
    "timestamp": timestamp,

```
You can create a rule that listens on this topic and performs some actions. We recommend that you create a Lambda rule that verifies the device certificate is not on a certificate revocation list (CRL), activates the certificate, and creates and attaches a policy to the certificate. The policy determines which resources the device is able to access. For more information about how to create a Lambda rule that listens on the $aws/events/certificates/registered/caCertificateID topic and performs these actions, see Just-in-Time Registration.

Deactivate the CA Certificate

When you register a device certificate, AWS will check if the associated CA certificate is ACTIVE. If the CA certificate is INACTIVE, AWS IoT does not allow the device certificate to be registered. By marking the CA certificate as INACTIVE, you prevent any new device certificates issued by the compromised CA to be registered in your account. You can use the update-ca-certificate API to deactivate the CA certificate:

```bash
$ aws iot update-ca-certificate --cert-id certificateId --new-status INACTIVE
```

Note

Any registered device certificates that were signed by the compromised CA certificate will continue to work until you explicitly revoke them.

Use the ListCertificatesByCA API to get a list of all registered device certificates that were signed by the compromised CA. For each device certificate signed by the compromised CA certificate, use the UpdateCertificate API to revoke the device certificate to prevent it from being used.

Revoke the Device Certificate

If you detect suspicious activity on a registered device certificate, you can use the update-certificate API to revoke it:

```bash
$ aws iot update-certificate --cert-id certificateId --new-status REVOKED
```

If any error or exception occurs during the auto-registration of the device certificates, AWS IoT sends events or messages to your logs in CloudWatch Logs. For more information about setting up the logs for your account, see the Amazon CloudWatch documentation.

IAM Users, Groups, and Roles

IAM users, groups, and roles are the standard mechanisms for managing identity and authentication in AWS. You can use them to connect to AWS IoT HTTP interfaces using the AWS SDK and CLI.

IAM roles also allow AWS IoT to access other AWS resources in your account on your behalf. For example, if you want to have a device publish its state to a DynamoDB table, IAM roles allow AWS IoT to interact with Amazon DynamoDB. For more information, see IAM Roles.

For message broker connections over HTTP, AWS IoT authenticates IAM users, groups, and roles using the Signature Version 4 signing process. For information, see Signing AWS API Requests.

When using AWS Signature Version 4 with AWS IoT, clients must support the following in their TLS implementation:

- TLS 1.2, TLS 1.1, TLS 1.0.
• SHA-256 RSA certificate signature validation.
• One of the cipher suites from the TLS cipher suite support section.

For information, see the IAM User Guide.

Amazon Cognito Identities

Amazon Cognito Identity allows you to use your own identity provider or other popular identity providers, such as Login with Amazon, Facebook, or Google. You exchange a token from your identity provider for AWS security credentials. The credentials represent an IAM role and can be used with AWS IoT.

AWS IoT extends Amazon Cognito and allows policy attachment to Amazon Cognito identities. You can attach a policy to an Amazon Cognito identity and give fine-grained permissions to an individual user of your AWS IoT application. In this way, you can assign permissions between specific customers and their devices. For more information, see Amazon Cognito Identity.

Custom Authentication

AWS IoT allows you to define custom authorizers that allow you to manage your own authentication and authorization strategy using a custom authentication service and a Lambda function. Custom authorizers allow AWS IoT to authenticate your devices and authorize operations using bearer token authentication and authorization strategies.

When an HTTP connection is established (and optionally upgraded to a WebSocket connection) and SigV4 headers are not present, the AWS IoT device gateway checks if a custom authorizer is configured for the endpoint, and if so, it is used to authenticate the connection and authorize the device. Custom authorizers can implement various authentication strategies (for example: JWT verification, OAuth provider call out, and so on) and must return policy documents which are used by the device gateway to authorize MQTT operations.

Custom Authorizers

Custom authorizers consist of:

A name

A unique arbitrary string that identifies the authorizer.
A Lambda function ARN

An ARN of a Lambda function that implements the authentication logic and returns authorization policies.

A public key

The public key from a key pair that is used to prevent unauthorized calls to the authorizer's Lambda function.

Use the following command to generate a key pair:

```
openssl genrsa -out myKeyPair.pem 2048
```

Use the following command to extract the public key from the key pair:

```
openssl rsa -in myKeyPair.pem -pubout > mykey.pub
```

Token key name

The key name used to extract tokens from the WebSocket connection headers.

The logic that performs the authentication is implemented in a Lambda function.

**Note**

AWS Lambda usage is billed. For more information about Lambda, see [AWS Lambda Developer Guide](https://docs.aws.amazon.com/lambda/latest/dg/).

This function takes a token presented by a device, authenticates the device, and returns the following information:

- **isAuthenticated**
  - A Boolean value that indicates whether the token was authenticated. If this is false, the rest of the response fields should be ignored.
- **policy**
  - A list of policies that specifies which operations the token bearer can perform.
- **DisconnectAfterInSecs**
  - The length of time, in seconds, to keep the WebSocket connection open.
- **RefreshAfterInSecs**
  - The length of time, in seconds, after which the Lambda function is invoked to refresh the policies.
- **Context**
  - Additional information derived after validating the token. This information is made available in AWS IoT rules engine SQL statements and IAM/AWS IoT policy variables.

You must grant permission to the AWS IoT service principal to invoke the Lambda function that implements the custom authentication/authorization logic. You can do this with the following CLI command:

```
```

For more information about granting permission to call Lambda functions, see [AWS Lambda Permissions](https://docs.aws.amazon.com/lambda/latest/dg/permissions.html).
You can set a default authorizer that is used when authorizer information is not included in a connection request:

```
aws iot set-default-authorizer --authorizer-name <my-authorizer>
  --region <your-aws-region>
  --endpoint <your-iot-endpoint>
```

The `--source-arn` parameter ensures your Lambda function can only be invoked by the intended custom authorizer.

**Configure a Custom Authorizer**

1. Create a Lambda function that implements your authentication/authorization logic.
2. Register a custom authorizer with AWS IoT using the `Create-Authorizer` API.

```
aws iot create-authorizer --authorizer-name MyAuthorizer
  --token-key-name MyAuthorizerToken // Key used to extract token from headers
  --token-signing-public-keys FIRST_KEY=
  "-----BEGIN PUBLIC KEY-----
  [...]insert your public key here...]
  "-----END PUBLIC KEY-----"
  --status ACTIVE // Authorizer status - must be ACTIVE
  --region us-west-2 // AWS region
  --endpoint https://us-west-2.iot.amazonaws.com // IoT endpoint
```

**Custom Authorizer Workflow**

For a device to authenticate with the AWS IoT device gateway using a custom authorizer, it needs both a token and a signature used by AWS to validate the tokens before invoking the authorizer.

When a device attempts to connect to AWS IoT, it sends the following information in HTTP headers:

- A token generated by your authentication service.
- The signature generated by your authentication service.
- The authorizer used to authenticate the token. If omitted, the default authorizer is used.

The following is an example HTTP request to connect to AWS IoT over the WebSocket protocol.

```
GET /mqtt HTTP/1.1
Host: <your-iot-endpoint>
Upgrade: WebSocket
Connection: Upgrade
x-amz-customauthorizer-name = <authorizer-name>
x-amz-customauthorizer-signature = <token-signature>
<token-key-name> = <some-token>
```

In this example, the `x-amz-customauthorizer-name` header specifies the custom authorizer to use, the `x-amz-customauthorizer-signature` header contains the digital signature used to verify the
token, and the token-key-name is the token key name specified by the --token-key-name passed to the create-authorizer API.

The AWS IoT device gateway validates the digital signature and if valid, calls the specified authorizer. The following is an example payload AWS IoT sends to the custom authenticator’s Lambda function.

```
{
  "type":"TOKEN",
  "authorizationToken": "<caller-supplied-token>",
  "authorizerId": "<authorizer-id>",
  "endpoint": "<your-iot-endpoint>"
}
```

The authorizer validates the token and returns a principal ID, its associated AWS IoT/IAM policy, time-to-live (TTL) information for the connection, and any additional context generated by the authorizer.

The following is an example of the response from a custom authorizer.

```
{
  "isAuthenticated":true,
  "principalId": "xxxxxxxx",
  "policyDocument": {
    "Version": "2012-10-17",
    "Statement": [
      {
        "Action": "...",
        "Effect": "Allow|Deny",
        "Resource": "...
      }
    ],
    "connectionTtl": 300,
    "context": {
      "username": "foo",
      "city": "Seattle",
      "country": "USA"
    }
  }
}
```

The AWS IoT device gateway then establishes the WebSocket connection. AWS IoT caches the policies associated with the principal so subsequent calls can be authorized without having to reauthenticate the device. Any failure that occurs during custom authentication results in authentication failure and connection termination.

Authorization

Policies determine what an authenticated identity can do. An authenticated identity is used by devices, mobile applications, web applications, and desktop applications. An authenticated identity can even be a user typing AWS IoT CLI commands. The identity can execute AWS IoT operations only if it has a policy that grants it permission.

Both AWS IoT policies and IAM policies are used with AWS IoT to control the operations an identity (also called a principal) can perform. The policy type you use depends on the type of identity you are using to authenticate with AWS IoT. The following table shows the identity types, the protocols they use, and the policy types that can be used for authorization.

AWS IoT operations are divided into two groups:
• Control plane API allows you to perform administrative tasks like creating or updating certificates, things, rules, and so on.
• Data plane API allows you send data to and receive data from AWS IoT.

The type of policy you use depends on whether you are using control plane or data plane API.

**AWS IoT Data Plane API and Policy Types**

<table>
<thead>
<tr>
<th>Protocol and Authentication Mechanism</th>

<td>Amazon Cognito, IAM, or federated identity</td>
<td>AWS IoT policy for Amazon Cognito identities</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>IAM policy for other identities</td>
</tr>
</tbody>
</table>

AWS IoT policies are attached to X.509 certificates or Amazon Cognito identities. IAM policies are attached to an IAM user, group, or role. If you use the AWS IoT console or the AWS IoT CLI to attach the policy (to a certificate or Amazon Cognito Identity), you use an AWS IoT policy. Otherwise, you use an IAM policy.
Policy-based authorization is a powerful tool. It gives you complete control over what a device, user, or application can do in AWS IoT. For example, consider a device connecting to AWS IoT with a certificate. You can allow the device to access all MQTT topics, or you can restrict its access to a single topic. In another example, consider a user typing CLI commands at the command line. By using a policy, you can allow or deny access to any command or AWS IoT resource for the user. You can also control an application's access to AWS IoT resources.

AWS IoT Policies

AWS IoT policies are JSON documents. They follow the same conventions as IAM policies. AWS IoT supports named policies so many identities can reference the same policy document. Named policies are versioned so they can be easily rolled back.

AWS IoT defines a set of policy actions that describe the operations and resources to which you can grant or deny access. For example:

- `iot:Connect` represents permission to connect to the AWS IoT message broker.
- `iot:Subscribe` represents permission to subscribe to an MQTT topic or topic filter.
- `iot:GetThingShadow` represents permission to get a thing shadow.

AWS IoT policies allow you to control access to the AWS IoT data plane. The AWS IoT data plane consists of operations that allow you to connect to the AWS IoT message broker, send and receive MQTT messages, and get or update thing shadows. For more information, see AWS IoT Policy Actions (p. 122).

An AWS IoT policy is a JSON document that contains one or more policy statements. Each statement contains an Effect, an Action, and a Resource. The Effect specifies whether the action will be allowed or denied. The Action specifies the action the policy is allowing or denying. The Resource specifies the resource or resources on which the action is allowed or denied. The following policy grants all devices permission to connect to the AWS IoT message broker, but restricts the device to publishing on a specific MQTT topic:

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["iot:Publish"],
    "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/foo/bar"]
  },
  {
    "Effect": "Allow",
    "Action": ["iot:Connect"],
    "Resource": ["*"]
  }
}
```

AWS IoT Policy Actions

The following policy actions are defined by AWS IoT:

**MQTT Policy Actions**

- `iot:Connect`

  Represents the permission to connect to the AWS IoT message broker. The `iot:Connect` permission is checked every time a `CONNECT` request is sent to the broker. The message broker does not allow two clients with the same client ID to stay connected at the same time. After the second client connects, the broker detects this case and disconnects one of the clients. The `iot:Connect` permission can be used to ensure only authorized clients can connect using a specific client ID.
iot:Publish

Represents the permission to publish on an MQTT topic. This permission is checked every time a
PUBLISH request is sent to the broker. This can be used to allow clients to publish to specific topic
patterns.

**Note**
You must also grant iot:Connect permission to grant iot:Publish permission.

iot:Receive

Represents the permission to receive a message from AWS IoT. The iot:Receive permission is
checked every time a message is delivered to a client. Because this permission is checked on every
delivery, it can be used to revoke permissions to clients that are currently subscribed to a topic.

iot:Subscribe

Represents the permission to subscribe to a topic filter. This permission is checked every time a
SUBSCRIBE request is sent to the broker. This can be used to allow clients to subscribe to topics that
match specific topic patterns.

**Note**
You must also grant iot:Connect permission to grant iot:Subscribe permission.

**Thing Shadow Policy Actions**

iot:DeleteThingShadow

Represents the permission to delete a thing shadow. The iot:DeleteThingShadow permission is
checked every time a request is made to delete the thing shadow document.

iot:GetThingShadow

Represents the permission to retrieve a thing shadow. The iot:GetThingShadow permission is
checked every time a request is made to retrieve a thing shadow document.

iot:UpdateThingShadow

Represents the permission to update a thing shadow. The iot:UpdateThingShadow permission is
checked every time a request is made to update the state of a thing shadow document.

**Action Resources**

To specify a resource for an AWS IoT policy action, you must use the ARN of the resource. All resource
ARNs are of the following form:

```
arn:aws:iot:region:AWS account ID:resource type/resource name
```

The following table shows the resource to specify for each action type:

<table>
<thead>
<tr>
<th>Action</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>iot:DeleteThingShadow</td>
<td>A thing ARN - arn:aws:iot:us-east-1:123456789012:thing/thingOne</td>
</tr>
<tr>
<td>iot:Connect</td>
<td>A client ID ARN - arn:aws:iot:us-east-1:123456789012:client/myClientId</td>
</tr>
<tr>
<td>Action</td>
<td>Resource</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>iot:UpdateThingShadow</td>
<td>A thing ARN - arn:aws:iot:us-east-1:123456789012:thing/thingOne</td>
</tr>
<tr>
<td>iot:GetThingShadow</td>
<td>A thing ARN - arn:aws:iot:us-east-1:123456789012:thing/thingOne</td>
</tr>
</tbody>
</table>

**AWS IoT Policy Variables**

AWS IoT defines policy variables that can be used in AWS IoT policies within the resource or condition block. When a policy is evaluated, the policy variables are replaced by actual values. For example, if a device connected to the AWS IoT message broker with a client ID of "100-234-3456", the iot:ClientId policy variable would be replaced in the policy document by "100-234-3456". For more information about policy variables, see [IAM Policy Variables](https://docs.aws.amazon.com/IAM/latest/userguide/policy-variables.html) and [Multi-Value Conditions](https://docs.aws.amazon.com/IAM/latest/userguide/policy-conditions.html).

### Basic Policy Variables

AWS IoT defines the following basic policy variables:

- **iot:ClientId**: The client ID used to connect to the AWS IoT message broker.
- **aws:SourceIp**: The IP address of the client connected to the AWS IoT message broker.

The following AWS IoT policy shows the use of policy variables:

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": ["iot:Connect"],
        "Resource": [
            "arn:aws:iot:us-east-1:123451234510:client/${iot:ClientId}"
        ]
    },
    {
        "Effect": "Allow",
        "Action": ["iot:Publish"],
        "Resource": [
            "arn:aws:iot:us-east-1:123451234510:topic/foo/bar/${iot:ClientId}"
        ]
    }
}
```

In these examples, `${iot:ClientId}` is replaced by the ID of the client connected to the AWS IoT message broker when the policy is evaluated. When you use policy variables like `${iot:ClientId}`, you can inadvertently open access to unintended topics. For example, if you use a policy that uses `${iot:ClientId}` to specify a topic filter:

```json
{
    "Effect": "Allow",
    "Action": ["iot:Subscribe"],
    "Resource": "arn:aws:iot:us-east-1:123456789012:topic/myTopicName/$({iot:ClientId})"
}
```
A client can connect using + as the client ID. This would allow the user to subscribe to any topic matching the topic filter `foo/+/bar`. To protect against such security gaps, use the `iot:Connect` policy action to control which client IDs are able to connect. For example, this policy allows only clients whose client ID is `clientId1` to connect:

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["iot:Connect"],
    "Resource": ["arn:aws:iot:us-east-1:123456789012:client/clientid1"
  ]
}
}
```

**X.509 Certificate Policy Variables**

X.509 certificate policy variables allow you to write AWS IoT policies that grant permissions based on X.509 certificate attributes. The following sections describe how you can use these certificate policy variables.

**Issuer Attributes**

The following AWS IoT policy variables allow you to allow or deny permissions based on certificate attributes set by the certificate issuer.

- `iot:Certificate.Issuer.DistinguishedNameQualifier`
- `iot:Certificate.Issuer.Organization`
- `iot:Certificate.Issuer.OrganizationalUnit`
- `iot:Certificate.Issuer.State`
- `iot:Certificate.Issuer/CommonName`
- `iot:Certificate.Issuer.SerialNumber`
- `iot:Certificate.Issuer.Title`
- `iot:Certificate.Issuer.Surname`
- `iot:Certificate.Issuer.GivenName`
- `iot:Certificate.Issuer.Initials`
- `iot:Certificate.Issuer.Pseudonym`
- `iot:Certificate.Issuer.GenerationQualifier`

**Subject Attributes**

The following AWS IoT policy variables allow you to grant or deny permissions based on certificate subject attributes set by the certificate issuer.

- `iot:Certificate.Subject.DistinguishedNameQualifier`
- `iot:Certificate.Subject.Country`
- `iot:Certificate.Subject.Organization`
- `iot:Certificate.Subject.OrganizationalUnit`
X.509 certificates allow these attributes to contain one or more values. By default, the policy variables for each multi-value attribute return the first value. For example, the Certificate.Subject.Country attribute might contain a list of country names. When evaluated in a policy, \texttt{iot:Certificate.Subject.Country} is replaced by the first country name. You can request a specific attribute value using a zero-based index. For example, \texttt{iot:Certificate.Subject.Country#1} is replaced by the second country name in the Certificate.Subject.Country attribute. If you specify an attribute value that does not exist (for example, if you ask for a third value when there are only two values assigned to the attribute), no substitution is made and authorization fails. You can use the \texttt{.List} suffix on the policy variable name to specify all values of the attribute. The following example policy allows any client to connect to AWS IoT, but restricts publishing rights to those clients with certificates whose Certificate.Subject.Organization attribute is set to "Example Corp" or "AnyCompany".

This is done through the use of a "Condition" attribute that specifies a condition for the preceding action. The condition in this case is that the Certificate.Subject.Organization attribute of the certificate must include one of the listed values.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action": ["iot:Connect"],
            "Resource": ["*"]
        },
        {
            "Effect":"Allow",
            "Action": ["iot:Publish"],
            "Resource": ["*"]
        }
    ],
    "Condition": {
        "ForAllValues:StringEquals": {
            "iot:Certificate.Subject.Organization.List": [
                "Example Corp",
                "AnyCompany"
            ]
        }
    }
}
```
Issuer Alternate Name Attributes

The following AWS IoT policy variables allow you to grant or deny permissions based on issuer alternate name attributes set by the certificate issuer.

- `iot:Certificate.Issuer.AlternativeName.RFC822Name`
- `iot:Certificate.Issuer.AlternativeName.DNSName`
- `iot:Certificate.Issuer.AlternativeName.DirectoryName`
- `iot:Certificate.Issuer.AlternativeName.IPAddress`

Subject Alternate Name Attributes

The following AWS IoT policy variables allow you to grant or deny permissions based on subject alternate name attributes set by the certificate issuer.

- `iot:Certificate.Subject.AlternativeName.RFC822Name`
- `iot:Certificate.Subject.AlternativeName.DNSName`
- `iot:Certificate.Subject.AlternativeName.DirectoryName`
- `iot:Certificate.Subject.AlternativeName.UniformResourceIdentifier`
- `iot:Certificate.Subject.AlternativeName.IPAddress`

Other Attributes

You can use `iot:Certificate.SerialNumber` to allow or deny access to AWS IoT resources based on the serial number of a certificate. The `iot:Certificate.AvailableKeys` policy variable contains the name of all certificate policy variables that contain values.

X.509 Certificate Policy Variable Limitations

The following limitations apply to X.509 certificate policy variables:

Wildcards

If wildcard characters are present in certificate attributes, the policy variable is not replaced by the certificate attribute value, leaving the `${policy-variable}` text in the policy document. This might cause authorization failure.

Array fields

Certificate attributes that contain arrays are limited to five items. Additional items are ignored.

String length

All string values are limited to 1024 characters. If a certificate attribute contains a string longer than 1024 characters, the policy variable is not replaced by the certificate attribute value, leaving the `${policy-variable}` in the policy document. This might cause authorization failure.

Thing Policy Variables

Thing policy variables allow you to write AWS IoT policies that grant or deny permissions based on thing properties like thing names, thing types, and thing attribute values. The thing name is obtained from the client ID in the MQTT `Connect` message sent when a thing connects to AWS IoT. The thing policy variables are replaced when a thing connects to AWS IoT over MQTT using TLS mutual authentication or MQTT over the WebSocket protocol using authenticated Amazon Cognito identities. Thing policy variables are also replaced when a certificate or authenticated Amazon Cognito identity is attached to a
thing. You can use the AttachThingPrincipal API to attach certificates and authenticated Amazon Cognito identities to a thing.

The following thing policy variables are available:

- `iot:Connection.Thing.ThingName`
- `iot:Connection.Thing.ThingTypeName`
- `iot:Connection.Thing.Attributes[attributeName]`
- `iot:Connection.Thing.IsAttached`

**`iot:Connection.Thing.ThingName`**

This resolves to the name of the thing for which the policy is being evaluated. The thing name is set to the client ID of the MQTT/WebSocket connection. This policy variable is available only when connecting over MQTT or MQTT over the WebSocket protocol.

**`iot:Connection.Thing.ThingTypeName`**

This resolves to the thing type associated with the thing for which the policy is being evaluated. The thing name is set to the client ID of the MQTT/WebSocket connection. The thing type name is obtained by a call to the DescribeThing API. This policy variable is available only when connecting over MQTT or MQTT over the WebSocket protocol.

**`iot:Connection.Thing.Attributes[attributeName]`**

This resolves to the value of the specified attribute associated with the thing for which the policy is being evaluated. A thing can have up to 50 attributes. Each attribute is available as a policy variable: `iot:Connection.Thing.Attributes[attributeName]` where `attributeName` is the name of the attribute. The thing name is set to the client ID of the MQTT/WebSocket connection. This policy variable is only available when connecting over MQTT or MQTT over the WebSocket protocol.

**`iot:Connection.Thing.IsAttached`**

This resolves to `true` if the thing for which the policy is being evaluated has a certificate or Amazon Cognito identity attached.

**Example Policies**

AWS IoT policies are specified in a JSON document. These are the components of an AWS IoT policy:

**Version**

Must be set to "2012-10-17".

**Effect**

Must be set to "Allow" or "Deny".

**Action**

Must be set to "iot:operation-name" where `operation-name` is one of the following:

- "iot:Connect": Connect to AWS IoT
- "iot:Receive": Receive messages from AWS IoT
- "iot:Publish": MQTT publish.
- "iot:Subscribe": MQTT subscribe.
- "iot:UpdateThingShadow": Update a thing shadow.
- "iot:GetThingShadow": Retrieve a thing shadow.
"iot:DeleteThingShadow": Delete a thing shadow.

**Resource**

Must be set to one of the following:

### Connect Policy Examples

The following policy allows a set of client IDs to connect:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": [
        "arn:aws:iot:us-east-1:123456789012:client/clientid2",
        "arn:aws:iot:us-east-1:123456789012:client/clientid3"
      ]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Publish", "iot:Subscribe", "iot:Receive"],
      "Resource": [
        "*
      ]
    }
  ]
}
```

The following policy prevents a set of client IDs from connecting:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": ["iot:Connect"],
      "Resource": [
        "arn:aws:iot:us-east-1:123456789012:client/clientid2"
      ]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Publish", "iot:Subscribe", "iot:Receive"],
      "Resource": [
        "*
      ]
    }
  ]
}
```
Publish/Subscribe Policy Examples

The policy you use depends on how you are connecting to AWS IoT. You can connect to AWS IoT using an MQTT client, HTTP, or WebSocket. When you connect with an MQTT client, you are authenticating with an X.509 certificate. When you connect over HTTP or the WebSocket protocol, you are authenticating with Signature Version 4 and Amazon Cognito.

Policies for MQTT Clients

When you specify topic filters in AWS IoT policies for MQTT clients, MQTT wildcard characters "+" and "#" are treated as literal characters. Their use might result in unexpected behavior. For example, the following policy allows a client to subscribe to the topic filter `foo/*`:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["iot:Connect"],
            "Resource": ["*"]
        },
        {
            "Effect": "Allow",
            "Action": ["iot:Subscribe"],
            "Resource": ["arn:aws:iot:us-east-1:123456789012:topicfilter/foo/*"]
        }
    ]
}
```
"Action": [  "iot:Subscribe"  
],
]  
}
}

**Note**

The MQTT wildcard character '+' is not treated as a wildcard within a policy. Attempts to subscribe to topic filters that match the pattern `foo/+/bar` like `foo/baz/bar` or `foo/goo/bar` fails and causes the client to disconnect.

You can use "*" as a wildcard in the resource attribute of the policy. For example, the following policy allows the certificate holder to publish to all topics and subscribe to all topic filters in the AWS account:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iot:*"
      ],
      "Resource": [  "*"  
      ]
    }
  ]
}
```

The following policy allows the certificate holder to publish to all topics in the AWS account:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [  "iot:Publish", "iot:Connect"  
    ],
      "Resource": [  "*"  
    ]
    }
  ]
}
```

You can also use the "*" wildcard at the end of a topic filter. For example, the following policy allows the certificate holder to subscribe to a topic filter matching the pattern `foo/bar/*`:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [  "iot:Connect"  
    ],
  ]
}
```
The following policy allows the certificate holder to publish to the foo/bar and foo/baz topics:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [ "iot:Connect" ],
            "Resource": [ "*" ]
        },
        {
            "Effect": "Allow",
            "Action": [ "iot:Publish" ],
            "Resource": [
                "arn:aws:iot:us-east-1:123456789012:topic/foo/baz"
            ]
        }
    ]
}
```

The following policy prevents the certificate holder from publishing to the foo/bar topic:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [ "iot:Connect" ],
            "Resource": [ "*" ]
        },
        {
            "Effect": "Deny",
            "Action": [ "iot:Publish" ],
        }
    ]
}
```
The following policy allows the certificate holder to publish on topic foo and prevents the certificate holder from publishing to topic bar:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": ["*"]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Publish"],
      "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/foo"]
    },
    {
      "Effect": "Deny",
      "Action": ["iot:Publish"],
      "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/bar"]
    }
  ]
}
```

The following policy allows the certificate holder to subscribe to topic filter foo/bar:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": ["*"]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Subscribe"],
      "Resource": ["arn:aws:iot:us-east-1:123456789012:topicfilter/foo/bar"]
    }
  ]
}
```
The following policy allows the certificate holder to publish on the arn:aws:iot:us-east-1:123456789012:topic/iotmonitor/provisioning/8050373158915119971 topic and allows the certificate holder to subscribe to the topic filter arn:aws:iot:us-east-1:123456789012:topicfilter/iotmonitor/provisioning/8050373158915119971:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": ["*"]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Publish", "iot:Receive"],
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Subscribe"],
      "Resource": ["arn:aws:iot:us-east-1:123456789012:topicfilter/iotmonitor/provisioning/8050373158915119971"]
    }
  ]
}
```

**Policies for HTTP and WebSocket Clients**

For the following operations, AWS IoT uses AWS IoT policies attached to Amazon Cognito identities (through the AttachPolicy API) to scope down the permissions attached to the Amazon Cognito identity pool with authenticated identities. That means an Amazon Cognito identity needs permission from the IAM role policy attached to the pool and the AWS IoT policy attached to the Amazon Cognito identity through the AWS IoT AttachPolicy API.

- `iot:Connect`
- `iot:Publish`
- `iot:Subscribe`
- `iot:Receive`
- `iot:GetThingShadow`
- `iot:UpdateThingShadow`
- `iot:DeleteThingShadow`
**Note**
For other AWS IoT operations or for unauthenticated identities, AWS IoT does not scope down the permissions attached to the Amazon Cognito identity pool role. For both authenticated and unauthenticated identities, this is the most permissive policy that we recommend attaching to the Amazon Cognito pool role.

To allow unauthenticated Amazon Cognito identities to publish messages over HTTP on any topic, attach the following policy to the Amazon Cognito identity pool role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "iot:Connect",
            "iot:Publish",
            "iot:Subscribe",
            "iot:Receive",
            "iot:GetThingShadow",
            "iot:UpdateThingShadow",
            "iot:DeleteThingShadow"
         ],
         "Resource": ["*"
      }
   ]
}
```

To allow unauthenticated Amazon Cognito identities to publish MQTT messages over HTTP on any topic in your account, attach the following policy to the Amazon Cognito identity pool role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
         "Resource": ["*"
      }
   ]
}
```

**Note**
This example is for illustration only. Unless your service absolutely requires it, we recommend the use of a more restrictive policy, one that does not allow unauthenticated Amazon Cognito identities to publish on any topic.

To allow unauthenticated Amazon Cognito identities to publish MQTT messages over HTTP on topic1 in your account, attach the following policy to your Amazon Cognito identity pool role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
         "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/topic1"
      }
   ]
}
```

For an authenticated Amazon Cognito identity to publish MQTT messages over HTTP on topic1 in your AWS account, you must specify two policies, as outlined here. The first policy must be attached to an Amazon Cognito identity pool role. It allows identities from that pool to make a publish call. The second policy must be attached to an Amazon Cognito user using the AWS IoT AttachPolicy API. It allows the specified Amazon Cognito user access to the topic1 topic.
Amazon Cognito identity pool policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
         "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/topic1"]
      }
   ]
}
```

Amazon Cognito user policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
         "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/topic1"]
      }
   ]
}
```

Similarly, the following example policy allows the Amazon Cognito user to publish MQTT messages over HTTP on the `topic1` and `topic2` topics. Two policies are required. The first policy gives the Amazon Cognito identity pool role the ability to make the publish call. The second policy gives the Amazon Cognito user access to the `topic1` and `topic2` topics.

Amazon Cognito identity pool policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
         "Resource": ["*"]
      }
   ]
}
```

Amazon Cognito user policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
                      "arn:aws:iot:us-east-1:123456789012:topic/topic2"
         ]
      }
   ]
}
```

The following policies allow multiple Amazon Cognito users to publish to a topic. Two policies per Amazon Cognito identity are required. The first policy gives the Amazon Cognito identity pool role the ability to make the publish call. The second and third policies give the Amazon Cognito users access to the topics `topic1` and `topic2`, respectively.

Amazon Cognito identity pool policy:

```json
{
}
```
Amazon Cognito user1 policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["iot:Publish"],
    "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/topic1"]
  }]
}
```

Amazon Cognito user2 policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["iot:Publish"],
    "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/topic2"]
  }]
}
```

Receive Policy Examples

The following policy prevents the certificate holder using any client ID from receiving messages from a topic:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": ["iot:Receive"],
    },
    {
      "Effect": "Allow",
      "Action": ["iot:*"],
      "Resource": ["*"]
    }
  ]
}
```

The following policy allows the certificate holder using any client ID to subscribe and receive messages on one topic:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:*"],
      "Resource": ["*"]
    }
  ]
}
```
Certificate Policy Examples

The following policy allows a device to publish on a topic whose name is equal to the certificateId of the certificate with which the device authenticated itself:

```json
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": ["iot:Publish"],
      ]
   }]
}
```

The following policy allows a device to publish on a topic whose name is equal to the subject's common name field of the certificate with which the device authenticated itself:

```json
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": ["iot:Publish"],
   }]
}
```
The following policy allows a device to publish on a topic that is prefixed with "admin/" when the certificate used to authenticate the device has its `Subject.CommonName.2` field set to "Administrator":

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": ["*"],
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Publish"],
      "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/admin/*"],
      "Condition": {
        "StringEquals": {
          "iot:Certificate.Subject.CommonName.2": "Administrator"
        }
      }
    }
  ]
}
```

The following policy allows a device to publish on a topic that is prefixed with "admin/" when the certificate used to authenticate the device has any one of its `Subject.CommonName` fields set to "Administrator":

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": ["*"],
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Publish"],
      "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/admin/*"],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "iot:Certificate.Subject.CommonName.List": "Administrator"
        }
      }
    }
  ]
}
```

**Thing Policy Examples**

The following policy allows a thing to publish on a specific topic that contains the thing type name and thing name:

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["iot:Publish"],
    "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/admin/\{\{\{\"thingType\}\}\}_{\{\{\"thing\}\}\}}"]
  }]
}
```
The following policy allows the device to connect if the certificate used to authenticate with AWS IoT is attached to the thing for which the policy is being evaluated.

```
{
"Version": "2012-10-17",
"Statement": [{
  "Effect": "Allow",
  "Action": ["iot:Connect"],
  "Resource": ["*"]
}]
}
```

The following policy allows a device to publish on a set of topics (/foo/bar and /foo/baz) if:

- The thing associated with the device has an attribute called "Manufacturer" with a value of "foo", "bar", or "baz".
- The thing associated with the device exists in the thing registry and is attached to the certificate used to connect to AWS IoT.

```
{
"Version": "2012-10-17",
"Statement": [{
  "Effect": "Allow",
  "Action": ["iot:Publish"],
  "Resource": [
    "arn:aws:iot:us-east-1:123456789012:topic/foo/baz"
  ],
  "Condition": {
    "ForAnyValue:StringLike": {
      "iot:Connection.Thing.Attributes[Manufacturer]": [
        "foo",
        "bar",
        "baz"
      ]
    }
  }
}]
}
```

The following policy allows a device to publish to a topic if:

- The topic is composed of the thing type name, a "/", and the thing name.
- The thing exists in the thing registry.
- The thing is attached to the certificate used to connect to AWS IoT.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["iot:Publish"],
    "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/${iot:Connection.Thing.ThingTypeName}/${iot:Connection.Thing.ThingName}"],
    "Condition": {
      "Bool": {
        "iot:Connection.Thing.IsAttached": ["true"]
      }
    }
  }]
}
```
The following policy allows a device to publish only on its own thing shadow topic, if the thing exists in the thing registry.

```
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": ["iot:Publish"],
      "Resource": [
         "arn:aws:iot:us-east-1:123456789012:topic/${iot:Connection.Thing.ThingTypeName}/${iot:Connection.Thing.ThingName}"
      ]
   }]
}
```

IAM IoT Policies

AWS Identity and Access Management defines a policy action for each operation defined by AWS IoT, including control plane and data plane APIs.

AWS IoT API Permissions

The following table lists the AWS IoT API, the IAM permissions required, and the resource the API manipulates.

<table>
<thead>
<tr>
<th>API</th>
<th>Required Permission (Policy Actions)</th>
<th>Resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>AddLoggingRole</td>
<td>iot:AddLoggingRole</td>
<td>none</td>
</tr>
<tr>
<td>AddThingToThingGroup</td>
<td>iot:AddThingToThingGroup</td>
<td><code>arn:aws:iot:region:account-id:thinggroup/thing-group-name</code></td>
</tr>
<tr>
<td>AssociateTargetsWithJob</td>
<td>iot:AssociateTargetsWithJob</td>
<td><code>arn:aws:iot:region:account-id:thing/thing-name</code></td>
</tr>
<tr>
<td>AttachPolicy</td>
<td>iot:AttachPolicy</td>
<td><code>arn:aws:iot:region:account-id:thinggroup/thing-group-name</code> or</td>
</tr>
</tbody>
</table>

Note
The AWS account specified in the ARN must be the account to which the certificate is being transferred.
### API | Required Permission (Policy Actions) | Resources
--- | --- | ---
AttachThingPrincipal | iot:AttachThingPrincipal | `arn:aws:iot:region:account-id:cert/cert-id`
      | **Note** | The AWS account specified in the ARN must be the account to which the certificate is being transferred.
ClearDefaultAuthorizer | iot:ClearDefaultAuthorizer | None
CreateAuthorizer | iot:CreateAuthorizer | `arn:aws:iot:region:account-id:authorizer/authorizer-function-name`
CreateCertificateFromCsr | iot:CreateCertificateFromCsr | None
CreateKeysAndCertificate | iot:CreateKeysAndCertificate | None
CreateMessageSchema | iot:CreateMessageSchema | None
CreatePolicy | iot:CreatePolicy | `*`
      | **Note** | This must be an AWS IoT policy, not an IAM policy.
CreateRoleAlias | iot:CreateRoleAlias | (parameter: roleAlias)
      | | `arn:aws:iot:region:account-id:rolealias/role-alias-name`
CreateThing | iot:CreateThing | `arn:aws:iot:region:account-id:thing/thing-name`
CreateThingGroup | iot:CreateThingGroup | `arn:aws:iot:region:account-id:thinggroup/thing-group-name`
      | for group being created and for parent group, if used
CreateThingType | iot:CreateThingType | `arn:aws:iot:region:account-id:thingtype/thing-type-name`

Authorizing Direct Calls to AWS Services

Devices may use X.509 certificates to connect to AWS IoT using TLS mutual authentication protocols. Other AWS services do not support certificate-based authentication, but they can be called using AWS credentials in Signature Version 4 format. After authenticating a device with a certificate, AWS IoT can assume a role on behalf of the device and request temporary credentials from IAM. The device can then use that credential to call other AWS services.

Requests for temporary credentials can be made with an HTTP GET on port 443, for example:

https://<your-aws-account-id>.credentials.iot.region.amazonaws.com:443/role-aliases/<your-role-alias>/credentials

**Note**
To find your endpoint, use the describe-endpoint CLI command specifying `iot:CredentialProvider` as the endpoint type.
To make sure your device is communicating with AWS IoT (and not a service impersonating it), copy the Amazon Root CA 1 for RSA, and the VeriSign Class 3 Public Primary G5 root CA certificate to your device.

When making a request for temporary credentials, you can optionally provide a thing name in a request header called x-amzn-iot-thingname. In order to use thingName in a request header you must attach the thing to a device certificate using the AttachThingPrincipal API. When a device requests credentials by passing the thingName, AWS IoT checks that the thingName is attached to the certificate presented during the TLS handshake and will not provide temporary credentials unless it is.

Passing the thing name in the request allows you to use thingName and thingType as policy variables in the role’s access policy for fine-grained access. For more information, see AWS IoT Policy Variables (p. 124). You cannot use thing variables in policies unless a thing name is passed in the request header.

The policy attached to the device certificate must grant the device permission to assume the role. You do this by granting permission for the iot:AssumeRoleWithCertificate action on the ARN of the role alias, for example arn:aws:iot:<your-region>:<your-aws-account-id>:rolealias/<role-alias-name>

You grant privileges to the temporary credentials by creating an IAM role and attaching policies to it. You can have fine-grained control over the privileges granted to this role by using policy variables thingName, thingType and certificateId. For more information, see AWS IoT Policy Variables (p. 124).

The device which is going to make direct calls to AWS Services must know what role ARN to use when connecting to AWS IoT. But hard-coding the role ARN is not a good solution because you would have to update the device anytime the role ARN changes. A better solution is to create a role alias that points to the role ARN and use that on your device. If the role ARN changes, you can update the role alias and no change is required on the device. Role aliases are created using the CreateRoleAlias API. This API takes the following parameters:

credentialDurationInSeconds
    How long (in seconds) the credential is valid.

roleAlias
    An arbitrary string identifying the role alias. Must be 1-128 characters and must include only A-Za-z0-9=,@- characters.

roleArn
    The ARN of the role to which the role alias refers.

Note that the entity which performs the CreateRoleAlias must have sufficient privileges of its own to do so. Specifically, it must have an attached policy that allows the iam:PassRole action on the ARN of the created IAM role which is to be aliased.

You can pass a thing name in a request header when requesting temporary credentials. If the thing name is present, you can use thing policy variables to scope-down the credential returned by AWS IoT.

ThingName is an optional request parameter, which can be passed through an HTTP request header called x-amzn-iot-thingname.

Requests to AWS IoT for temporary credentials are made to port 443 over HTTP with TLS mutual authentication. This request must be an HTTP GET request. The URL is similar to:

```
```
Cross Account Access

AWS IoT allows you to enable a principal to publish or subscribe to a topic that is defined in an AWS account not owned by the principal. You configure cross account access by creating an IAM policy and IAM role and then attaching the policy to the role.

First, create an IAM policy just like you would for other users and certificates in your AWS account. For example, the following policy grants permissions to connect and publish to the /foo/bar topic.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Connect"],
         "Resource": ["*"]
      },
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
         "Resource": ["arn:aws:iot:us-east-1:123456789012:topic/foo/bar"]
      }
   ]
}
```

Next, follow the steps in Creating a Role for an IAM User. Enter the AWS account ID of the AWS account with which you want to share access. Then, in the final step, attach the policy you just created to the role. If, at a later time, you need to modify the AWS account ID to which you are granting access, you can use the following trust policy format to do so.

```json
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Principal": {
         "AWS": "arn:aws:iam:us-east-1:111111111111:user/MyUser"
      },
      "Action": "sts:AssumeRole"
   }]
}
```

Transport Security

The AWS IoT message broker and Thing Shadows service encrypt all communication with TLS. TLS is used to ensure the confidentiality of the application protocols (MQTT, HTTP) supported by AWS IoT. TLS is available in a number of programming languages and operating systems.

For MQTT, TLS encrypts the connection between the device and the broker. TLS client authentication is used by AWS IoT to identify devices. For HTTP, TLS encrypts the connection between the device and the broker. Authentication is delegated to AWS Signature Version 4.
TLS Cipher Suite Support

AWS IoT supports the following cipher suites:

- ECDHE-ECDSA-AES128-GCM-SHA256 (recommended)
- ECDHE-RSA-AES128-GCM-SHA256 (recommended)
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- ECDHE-ECDSA-AES128-SHA
- ECDHE-RSA-AES128-SHA
- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES256-SHA
- ECDHE-RSA-AES256-SHA
- AES128-GCM-SHA256
- AES128-SHA256
- AES128-SHA
- AES256-GCM-SHA384
- AES256-SHA256
- AES256-SHA
Message Broker for AWS IoT

The AWS IoT message broker is a publish/subscribe broker service that enables the sending and receiving of messages to and from AWS IoT. When communicating with AWS IoT, a client sends a message addressed to a topic like `Sensor/temp/room1`. The message broker, in turn, sends the message to all clients that have registered to receive messages for that topic. The act of sending the message is referred to as publishing. The act of registering to receive messages for a topic filter is referred to as subscribing.

The topic namespace is isolated for each AWS account and region pair. For example, the `Sensor/temp/room1` topic for an AWS account is independent from the `Sensor/temp/room1` topic for another AWS account. This is true of regions, too. The `Sensor/temp/room1` topic in the same AWS account in us-east-1 is independent from the same topic in us-east-2. AWS IoT does not support sending and receiving messages across AWS accounts and regions.

The message broker maintains a list of all client sessions and the subscriptions for each session. When a message is published on a topic, the broker checks for sessions with subscriptions that map to the topic. The broker then forwards the publish message to all sessions that have a currently connected client.

Protocols

The message broker supports the use of the MQTT protocol to publish and subscribe and the HTTPS protocol to publish. Both protocols are supported through IP version 4 and IP version 6. The message broker also supports MQTT over the WebSocket protocol.

Protocol/Port Mappings

The following table shows each protocol supported by AWS IoT, the authentication method, and port used for each protocol.

<table>
<thead>
<tr>
<th>Protocol, Authentication, and Port Mappings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol</td>
</tr>
<tr>
<td>----------</td>
</tr>
<tr>
<td>MQTT</td>
</tr>
<tr>
<td>HTTP</td>
</tr>
<tr>
<td>HTTP</td>
</tr>
<tr>
<td>MQTT + WebSocket</td>
</tr>
</tbody>
</table>

MQTT

MQTT is a widely adopted lightweight messaging protocol designed for constrained devices. For more information, see MQTT.

Although the AWS IoT message broker implementation is based on MQTT version 3.1.1, it deviates from the specification as follows:
• In AWS IoT, subscribing to a topic with Quality of Service (QoS) 0 means a message will be delivered zero or more times. A message might be delivered more than once. Messages delivered more than once might be sent with a different packet ID. In these cases, the DUP flag is not set.

• AWS IoT does not support publishing and subscribing with QoS 2. The AWS IoT message broker does not send a PUBACK or SUBACK when QoS 2 is requested.

• The QoS levels for publishing and subscribing to a topic have no relation to each other. One client can subscribe to a topic using QoS 1 while another client can publish to the same topic using QoS 0.

• When responding to a connection request, the message broker sends a CONNACK message. This message contains a flag to indicate if the connection is resuming a previous session. The value of this flag might be incorrect if two MQTT clients connect with the same client ID simultaneously.

• When a client subscribes to a topic, there might be a delay between the time the message broker sends a SUBACK and the time the client starts receiving new matching messages.

• The MQTT specification provides a provision for the publisher to request that the broker retain the last message sent to a topic and send it to all future topic subscribers. AWS IoT does not support retained messages. If a request is made to retain messages, the connection is disconnected.

• The message broker uses the client ID to identify each client. The client ID is passed in from the client to the message broker as part of the MQTT payload. Two clients with the same client ID are not allowed to be connected concurrently to the message broker. When a client connects to the message broker using a client ID that another client is using, a CONNACK message will be sent to both clients and the currently connected client will be disconnected.

• The message broker does not support persistent sessions (connections made with the cleanSession flag set to false). The AWS IoT message broker assumes all sessions are clean sessions and messages are not stored across sessions. If an MQTT client attempts to connect to the AWS IoT message broker with the cleanSession set to false, the client will be disconnected.

• On rare occasions, the message broker might resend the same logical PUBLISH message with a different packet ID.

• The message broker does not guarantee the order in which messages and ACK are received.

HTTP

The message broker supports clients connecting with the HTTP protocol using a REST API. Clients can publish by sending a POST message to `<AWS IoT Endpoint>/url_encoded_topic_name?qos=1".

For example, you can use curl to emulate a button press. If you followed the tutorial in Getting Started with AWS IoT (p. 5), rather than using the AWS IoT MQTT client to publish a message as you did in AWS IoT MQTT Client (p. 29), use something like the following command:

curl --tlsv1.2 --cacert root-CA.crt --cert 4b7828d2e5-certificate.pem.crt --key 4b7828d2e5-private.pem.key -X POST -d "{"serialNumber": "G030JF053216F1BS", "clickType": "SINGLE", "batteryVoltage": "2000mV" }" "https://a1pn10j0v8htwv.iot.us-east-1.amazonaws.com:8443/topics/iotbutton/virtualButton?qos=1"

--tlsv1.2

Use TLSv1.2 (SSL). curl must be installed with OpenSSL and you must use version 1.2 of TLS.

--cacert <filename>

The filename of the CA certificate to verify the peer.

--cert <filename>

The client certificate filename.
--key <filename>

The private key filename.

-X POST

The type of request, in this case, POST.

-d <data>

The HTTP POST data you want to publish. In this case, we emulate the data sent by a single button press.

"https://..."

The URL. In this case the REST API endpoint for the thing. (To find the endpoint for a thing, from the AWS IoT console choose Registry to expand your choices. Choose Things, choose the thing, and then choose Interact.) After the endpoint add the port (:8443) followed by the topic and, finally, specify the quality of service in a query string (?qos=1).

**MQTT Over the WebSocket Protocol**

AWS IoT supports MQTT over the WebSocket protocol to enable browser-based and remote applications to send and receive data from AWS IoT-connected devices using AWS credentials. AWS credentials are specified using AWS Signature Version 4. WebSocket support is available on TCP port 443, which allows messages to pass through most firewalls and web proxies.

A WebSocket connection is initiated on a client by sending an HTTP GET request. The URL you use is of the following form:

```
wss://<endpoint>.iot.<region>.amazonaws.com/mqtt
```

- **wss**
  
  Specifies the WebSocket protocol.

- **endpoint**
  
  Your AWS account-specific AWS IoT endpoint. You can use the AWS IoT CLI `describe-endpoint` command to find this endpoint.

- **region**
  
  The AWS region of your AWS account.

- **mqtt**
  
  Specifies you will be sending MQTT messages over the WebSocket protocol.

When the server responds, the client sends an upgrade request to indicate to the server it will communicate using the WebSocket protocol. After the server acknowledges the upgrade request, all communication is performed using the WebSocket protocol. The WebSocket implementation you use acts as a transport protocol. The data you send over the WebSocket protocol are MQTT messages.

**Using the WebSocket Protocol in a Web Application**

The WebSocket implementation provided by most web browsers does not allow the modification of HTTP headers, so you must add the Signature Version 4 information to the query string. For more information, see Adding Signing Information to the Query String.
AWS IoT Developer Guide
MQTT Over the WebSocket Protocol

The following JavaScript deﬁnes some utility functions used in generating a Signature Version 4 request.
/**
* utilities to do sigv4
* @class SigV4Utils
*/
function SigV4Utils() {}
SigV4Utils.getSignatureKey = function (key, date, region, service) {
var kDate = AWS.util.crypto.hmac('AWS4' + key, date, 'buffer');
var kRegion = AWS.util.crypto.hmac(kDate, region, 'buffer');
var kService = AWS.util.crypto.hmac(kRegion, service, 'buffer');
var kCredentials = AWS.util.crypto.hmac(kService, 'aws4_request', 'buffer');
return kCredentials;
};
SigV4Utils.getSignedUrl = function(host, region, credentials) {
var datetime = AWS.util.date.iso8601(new Date()).replace(/[:\-]|\.\d{3}/g, '');
var date = datetime.substr(0, 8);
var
var
var
var
var

method = 'GET';
protocol = 'wss';
uri = '/mqtt';
service = 'iotdevicegateway';
algorithm = 'AWS4-HMAC-SHA256';

var credentialScope = date + '/' + region + '/' + service + '/' + 'aws4_request';
var canonicalQuerystring = 'X-Amz-Algorithm=' + algorithm;
canonicalQuerystring += '&X-Amz-Credential=' +
encodeURIComponent(credentials.accessKeyId + '/' + credentialScope);
canonicalQuerystring += '&X-Amz-Date=' + datetime;
canonicalQuerystring += '&X-Amz-SignedHeaders=host';
var canonicalHeaders = 'host:' + host + '\n';
var payloadHash = AWS.util.crypto.sha256('', 'hex')
var canonicalRequest = method + '\n' + uri + '\n' + canonicalQuerystring + '\n' +
canonicalHeaders + '\nhost\n' + payloadHash;
var stringToSign = algorithm + '\n' + datetime + '\n' + credentialScope + '\n' +
AWS.util.crypto.sha256(canonicalRequest, 'hex');
var signingKey = SigV4Utils.getSignatureKey(credentials.secretAccessKey, date, region,
service);
var signature = AWS.util.crypto.hmac(signingKey, stringToSign, 'hex');
canonicalQuerystring += '&X-Amz-Signature=' + signature;
if (credentials.sessionToken) {
canonicalQuerystring += '&X-Amz-Security-Token=' +
encodeURIComponent(credentials.sessionToken);
}

};

var requestUrl = protocol + '://' + host + uri + '?' + canonicalQuerystring;
return requestUrl;

To create a Signature Version 4 request
1.

Create a canonical request for Signature Version 4.
The following JavaScript code creates a canonical request:
var datetime = AWS.util.date.iso8601(new Date()).replace(/[:\-]|\.\d{3}/g, '');
var date = datetime.substr(0, 8);

154


var method = 'GET';
var protocol = 'wss';
var uri = '/mqtt';
var service = 'iotdevicegateway';
var algorithm = 'AWS4-HMAC-SHA256';

var credentialScope = date + '/' + region + '/' + service + '/' + 'aws4_request';
var canonicalQuerystring = 'X-Amz-Algorithm=' + algorithm + '
encodeURIComponent(credentia.als.accessKeyId + '/\' + credentialScope);
canonicalQuerystring += '&X-Amz-Credential=' +
encodeURIComponent(credentials.accessKeyId + '/' + credentialScope);
canonicalQuerystring += '&X-Amz-Date=' + datetime;
canonicalQuerystring += '&X-Amz-SignedHeaders=host';

var canonicalHeaders = 'host:' + host + '\n';
var payloadHash = AWS.util.crypto.sha256('', 'hex')
var canonicalRequest = method + '\n' + uri + '\n' + canonicalQuerystring + '\n' +
canonicalHeaders + '\nhost\n' + payloadHash;

2. Create a string to sign, generate a signing key, and sign the string.

Take the canonical URL you created in the previous step and assemble it into a string to sign. You
do this by creating a string composed of the hashing algorithm, the date, the credential scope, and
the SHA of the canonical request. Next, generate the signing key and sign the string, as shown in the
following JavaScript code.

```javascript
var stringToSign = algorithm + '\n' + datetime + '\n' + credentialScope + '\n' +
AWS.util.crypto.sha256(canonicalRequest, 'hex');
var signingKey = SigV4Utils.getSignatureKey(credentials.secretAccessKey, date, region,
service);
var signature = AWS.util.crypto.hmac(signingKey, stringToSign, 'hex');
```

3. Add the signing information to the request.

The following JavaScript code shows how to add the signing information to the query string.

```javascript
canonicalQuerystring += '&X-Amz-Signature=' + signature;
```

4. If you have session credentials (from an STS server, AssumeRole, or Amazon Cognito), append the
session token to the end of the URL string after signing:

```javascript
canonicalQuerystring += '&X-Amz-Security-Token=' +
encodeURIComponent(credentials.sessionToken);
```

5. Prepend the protocol, host, and URI to the canonicalQuerystring:

```javascript
var requestUrl = protocol + '://host' + uri + '?' + canonicalQuerystring;
```

6. Open the WebSocket.

The following JavaScript code shows how to create a Paho MQTT client and call CONNECT to
AWS IoT. The endpoint argument is your AWS account-specific endpoint. The clientId is a text
identifier that is unique among all clients simultaneously connected in your AWS account.

```javascript
var client = new Paho.MQTT.Client(requestUrl, clientId);
```
var connectOptions = {
    onSuccess: function(){
        // connect succeeded
    },
    useSSL: true,
    timeout: 3,
    mqttVersion: 4,
    onFailure: function() {
        // connect failed
    }
};
client.connect(connectOptions);

Using the WebSocket Protocol in a Mobile Application

We recommend using one of the AWS IoT Device SDKs to connect your device to AWS IoT when making a WebSocket connection. The following AWS IoT Device SDKs support WebSocket-based MQTT connections to AWS IoT:

- Node.js
- iOS
- Android

For a reference implementation for connecting a web application to AWS IoT using MQTT over the WebSocket protocol, see AWS Labs WebSocket sample.

If you are using a programming or scripting language that is not currently supported, any existing WebSocket library can be used as long as the initial WebSocket upgrade request (HTTP POST) is signed using AWS Signature Version 4. Some MQTT clients, such as Eclipse Paho for JavaScript, support the WebSocket protocol natively.

Topics

The message broker uses topics to route messages from publishing clients to subscribing clients. The forward slash (/) is used to separate topic hierarchy. The following table lists the wildcards that can be used in the topic filter when you subscribe.

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>Must be the last character in the topic to which you are subscribing. Works as a wildcard by matching the current tree and all subtrees. For example, a subscription to Sensor/# will receive messages published to Sensor/, Sensor/temp, Sensor/temp/room1, but not the messages published to Sensor.</td>
</tr>
<tr>
<td>+</td>
<td>Matches exactly one item in the topic hierarchy. For example, a subscription to Sensor/+/room1 will receive messages published to Sensor/temp/room1, Sensor/moisture/room1, and so on.</td>
</tr>
</tbody>
</table>
Reserved Topics

Any topics beginning with $ are considered reserved and are not supported for publishing and subscribing except for those topics listed below. Any other attempts to publish or subscribe on topics beginning with $ will result in a terminated connection.

<table>
<thead>
<tr>
<th>Topic</th>
<th>Allowed Operations</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$aws/events/presence/connected/clientId</td>
<td>Subscribe</td>
<td>AWS IoT publishes to this topic when an MQTT client with the specified client ID connects to AWS IoT. For more information, see Connect/Disconnect Events (p. 160).</td>
</tr>
<tr>
<td>$aws/events/presence/disconnected/clientId</td>
<td>Subscribe</td>
<td>AWS IoT publishes to this topic when an MQTT client with the specified client ID disconnects to AWS IoT. For more information, see Connect/Disconnect Events (p. 160).</td>
</tr>
<tr>
<td>$aws/events/subscriptions/subscribed/clientId</td>
<td>Subscribe</td>
<td>AWS IoT publishes to this topic when an MQTT client with the specified client ID subscribes to an MQTT topic. For more information, see Subscribe/Unsubscribe Events (p. 160).</td>
</tr>
<tr>
<td>$aws/events/subscriptions/unsubscribed/clientId</td>
<td>Subscribe</td>
<td>AWS IoT publishes to this topic when an MQTT client with the specified client ID unsubscribes to an MQTT topic. For more information, see Subscribe/Unsubscribe Events (p. 160).</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/delete</td>
<td>Publish/Subscribe</td>
<td>A thing or an application publishes to this topic to delete a thing shadow. For more information see <a href="http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#delete-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#delete-pub-sub-topic</a>.</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/delete/accepted</td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when a thing shadow is deleted. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide/">http://docs.aws.amazon.com/iot/latest/developerguide/</a></td>
</tr>
<tr>
<td>Topic</td>
<td>Allowed Operations</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/delete/rejected</td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when a request to delete a thing shadow is rejected. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#delete-rejected-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#delete-rejected-pub-sub-topic</a>.</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/get</td>
<td>Publish/Subscribe</td>
<td>An application or a thing publishes an empty message to this topic to get a thing shadow. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html">http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html</a>.</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/get/accepted</td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when a request for a thing shadow is made successfully. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#get-accepted-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#get-accepted-pub-sub-topic</a>.</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/get/rejected</td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when a request for a thing shadow is rejected. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#get-rejected-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#get-rejected-pub-sub-topic</a>.</td>
</tr>
<tr>
<td>$aws/things/thingName/shadow/update</td>
<td>Publish/Subscribe</td>
<td>A thing or application publishes to this topic to update a thing shadow. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#update-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide//thing-shadow-mqtt.html#update-pub-sub-topic</a>.</td>
</tr>
</tbody>
</table>
## Lifecycle Events

AWS IoT publishes lifecycle events on the MQTT topics discussed in the following sections. These messages allow you to be notified of lifecycle events from the message broker.

<table>
<thead>
<tr>
<th>Topic</th>
<th>Allowed Operations</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$aws/things/thingName/shadow/update/accepted</code></td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when an update is successfully made to a thing shadow. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-accepted-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-accepted-pub-sub-topic</a>.</td>
</tr>
<tr>
<td><code>$aws/things/thingName/shadow/update/rejected</code></td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when an update to a thing shadow is rejected. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-rejected-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-rejected-pub-sub-topic</a>.</td>
</tr>
<tr>
<td><code>$aws/things/thingName/shadow/update/delta</code></td>
<td>Subscribe</td>
<td>The Thing Shadows service sends messages to this topic when a difference is detected between the reported and desired sections of a thing shadow. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-delta-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-delta-pub-sub-topic</a>.</td>
</tr>
<tr>
<td><code>$aws/things/thingName/shadow/update/documents</code></td>
<td>Subscribe</td>
<td>AWS IoT publishes a state document to this topic whenever an update to the shadow is successfully performed. For more information, see <a href="http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-documents-pub-sub-topic">http://docs.aws.amazon.com/iot/latest/developerguide/thing-shadow-mqtt.html#update-documents-pub-sub-topic</a>.</td>
</tr>
</tbody>
</table>
Connect/Disconnect Events

AWS IoT publishes a message to the following MQTT topics when a client connects or disconnects:

```plaintext
/aws/events/presence/connected/clientId
```
or

```plaintext
/aws/events/presence/disconnected/clientId
```

Where `clientId` is the MQTT client ID that connects to or disconnects from the AWS IoT message broker.

The message published to this topic has the following structure:

```json
{
   "clientId": "a1b2c3d4e5f6a7b8c9d0ef2a3b4c5d6",
   "timestamp": 1460065214626,
   "eventType": "connected",
   "sessionIdentifier": "00000000-0000-0000-0000-000000000000",
   "principalIdentifier": "000000000000/ABCDEFGHIJKLMNOPQRSTU:some-user/ABCDEFGHIJKLMNOPQRSTU:some-user"
}
```

The following is a list of JSON elements that are contained in the connection/disconnection messages published to the `$aws/events/presence/connected/clientId` topic.

- **clientId**
  The client ID of the connecting or disconnecting client.

  **Note**
  Client IDs that contain # or + do not receive lifecycle events.

- **eventType**
  The type of event. Valid values are `connected` or `disconnected`.

- **principalIdentifier**
  The credential used to authenticate. For TLS mutual authentication certificates, this is the certificate ID. For other connections, this is IAM credentials.

- **sessionIdentifier**
  A globally unique identifier in AWS IoT that exists for the life of the session.

- **timestamp**
  An approximation of when the event occurred, expressed in milliseconds since the Unix epoch. The accuracy of the timestamp is +/- 2 minutes.

Subscribe/Unsubscribe Events

AWS IoT publishes a message to the following MQTT topic when a client subscribes or unsubscribes to an MQTT topic:
$aws/events/subscriptions/subscribed/clientId

or

$aws/events/subscriptions/unsubscribed/clientId

Where clientId is the MQTT client ID that connects to the AWS IoT message broker.

The message published to this topic has the following structure:

```
{
  "clientId": "186b5",
  "timestamp": 1460065214626,
  "eventType": "subscribed" | "unsubscribed",
  "sessionIdentifier": "00000000-0000-0000-0000-000000000000",
  "principalIdentifier": "000000000000/ABCDEFGHIJKLMNOPQRSTU:some-user/ABCDEFGHIJKLMNOPQRSTU:some-user"
  "topics" : ["foo/bar","device/data","dog/cat"]
}
```

The following is a list of JSON elements that are contained in the subscribed and unsubscribed messages published to the $aws/events/subscriptions/subscribed/clientId and $aws/events/subscriptions/unsubscribed/clientId topics.

**clientId**

The client ID of the subscribing or unsubscribing client.

**Note**

Client IDs that contain # or + do not receive lifecycle events.

**eventType**

The type of event. Valid values are subscribed or unsubscribed.

**principalIdentifier**

The credential used to authenticate. For TLS mutual authentication certificates, this is the certificate ID. For other connections, this is IAM credentials.

**sessionIdentifier**

A globally unique identifier in AWS IoT that exists for the life of the session.

**timestamp**

An approximation of when the event occurred, expressed in milliseconds since the Unix epoch. The accuracy of the timestamp is +/- 2 minutes.

**topics**

An array of the MQTT topics to which the client has subscribed.

**Note**

Lifecycle messages might be sent out of order. You might receive duplicate messages.
Rules for AWS IoT

Rules give your devices the ability to interact with AWS services. Rules are analyzed and actions are performed based on the MQTT topic stream. You can use rules to support tasks like these:

- Augment or filter data received from a device.
- Write data received from a device to an Amazon DynamoDB database.
- Save a file to Amazon S3.
- Send a push notification to all users using Amazon SNS.
- Publish data to an Amazon SQS queue.
- Invoke a Lambda function to extract data.
- Process messages from a large number of devices using Amazon Kinesis.
- Send data to the Amazon Elasticsearch Service.
- Capture a CloudWatch metric.
- Change a CloudWatch alarm.
- Send the data from an MQTT message to Amazon Machine Learning to make predictions based on an Amazon ML model.
- Send a message to a Salesforce IoT Input Stream.

Before AWS IoT can perform these actions, you must grant it permission to access your AWS resources on your behalf. When the actions are performed, you incur the standard charges for the AWS services you use.

Contents

- Rule Error Handling (p. 170)
- Deleting a Rule (p. 172)
- AWS IoT Rule Actions (p. 172)
- AWS IoT SQL Reference (p. 182)

Granting AWS IoT the Required Access

You use IAM roles to control the AWS resources to which each rule has access. Before you create a rule, you must create an IAM role with a policy that allows access to the required AWS resources. AWS IoT assumes this role when executing a rule.

To create an IAM role (AWS CLI)

1. Save the following trust policy document, which grants AWS IoT permission to assume the role, to a file called iot-role-trust.json:
Use the `create-role` command to create an IAM role specifying the `iot-role-trust.json` file:

```bash
aws iam create-role --role-name my-iot-role --assume-role-policy-document file://iot-role-trust.json
```

The output of this command looks like the following:

```json
{
    "Role": {
        "AssumeRolePolicyDocument": "url-encoded-json",
        "RoleId": "AKIAIOSFODNN7EXAMPLE",
        "CreateDate": "2015-09-30T18:43:32.821Z",
        "RoleName": "my-iot-role",
        "Path": "/",
        "Arn": "arn:aws:iam::123456789012:role/my-iot-role"
    }
}
```

2. Save the following JSON into a file named `iot-policy.json`.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "dynamodb:*",
        "Resource": "*"
    }]
}
```

This JSON is an example policy document that grants AWS IoT administrator access to DynamoDB.

Use the `create-policy` command to grant AWS IoT access to your AWS resources upon assuming the role, passing in the `iot-policy.json` file:

```bash
aws iam create-policy --policy-name my-iot-policy --policy-document file://my-iot-policy-document.json
```

For more information about how to grant access to AWS services in policies for AWS IoT, see Creating an AWS IoT Rule (p. 164).

The output of the `create-policy` command contains the ARN of the policy. You need to attach the policy to a role.

```json
{
    "Policy": {
        "PolicyName": "my-iot-policy",
        "CreateDate": "2015-09-30T19:31:18.620Z",
        "Arn": "arn:aws:iam::123456789012:policy/my-iot-policy"
    }
}
```
"AttachmentCount": 0,
"IsAttachable": true,
"PolicyId": "ZXR6A36LTYANPAI7NJ5UV",
"DefaultVersionId": "v1",
"Path": "/",
"Arn": "arn:aws:iam::123456789012:policy/my-iot-policy",
"UpdateDate": "2015-09-30T19:31:18.620Z"
}
}

3. Use the `attach-role-policy` command to attach your policy to your role:

```bash
aws iam attach-role-policy --role-name my-iot-role --policy-arn "arn:aws:iam::123456789012:policy/my-iot-policy"
```

# Pass Role Permissions

Part of a rule definition is an IAM role that grants permission to access resources specified in the rule’s action. The rules engine assumes that role when the rule’s action is triggered. The role must be defined in the same AWS account as the rule.

When creating or replacing a rule you are, in effect, passing a role to the rules engine. The user performing this operation requires the `iam:PassRole` permission. To ensure you have this permission, create a policy that grants the `iam:PassRole` permission and attach it to your IAM user. The following policy shows how to allow `iam:PassRole` permission for a role.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1",
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::123456789012:role/myRole"
      ]
    }
  ]
}
```

In this policy example, the `iam:PassRole` permission is granted for the role `myRole`. The role is specified using the role's ARN. You must attach this policy to your IAM user or role to which your user belongs. For more information, see [Working with Managed Policies](#).

**Note**

Lambda functions use resource-based policy, where the policy is attached directly to the Lambda function itself. When creating a rule that invokes a Lambda function, you do not pass a role, so the user creating the rule does not need the `iam:PassRole` permission. For more information about Lambda function authorization, see [Granting Permissions Using a Resource Policy](#).

# Creating an AWS IoT Rule

You configure rules to route data from your connected things. Rules consist of the following:
Rule name

The name of the rule.

Optional description

A textual description of the rule.

SQL statement

A simplified SQL syntax to filter messages received on an MQTT topic and push the data elsewhere.
For more information, see AWS IoT SQL Reference (p. 182).

SQL version

The version of the SQL rules engine to use when evaluating the rule. Although this property is optional, we strongly recommend that you specify the SQL version. If this property is not set, the default, 2015-10-08, is used.

One or more actions

The actions AWS IoT performs when executing the rule. For example, you can insert data into a DynamoDB table, write data to an Amazon S3 bucket, publish to an Amazon SNS topic, or invoke a Lambda function.

An error action

The action AWS IoT performs when it is unable to perform a rule's action.

When you create a rule, be aware of how much data you are publishing on topics. If you create rules that include a wildcard topic pattern, they might match a large percentage of your messages, and you might need to increase the capacity of the AWS resources used by the target actions. Also, if you create a republish rule that includes a wildcard topic pattern, you can end up with a circular rule that causes an infinite loop.

Note

Creating and updating rules are administrator-level actions. Any user who has permission to create or update rules is able to access data processed by the rules.

To create a rule (AWS CLI)

Use the create-topic-rule command to create a rule:

```
aws iot create-topic-rule --rule-name my-rule --topic-rule-payload file://my-rule.json
```

The following is an example payload file with a rule that inserts all messages sent to the iot/test topic into the specified DynamoDB table. The SQL statement filters the messages and the role ARN grants AWS IoT permission to write to the DynamoDB table.

```json
{
    "sql": "SELECT * FROM 'iot/test'",
    "ruleDisabled": false,
    "awsIotSqlVersion": "2016-03-23",
    "actions": [{
        "dynamoDB": {
            "tableName": "my-dynamodb-table",
            "roleArn": "arn:aws:iam::123456789012:role/my-iot-role",
            "hashKeyField": "topic",
            "hashKeyValue": "${topic(2)}",
            "rangeKeyField": "timestamp",
            "rangeKeyValue": "${timestamp()}"
        }
    }
}
```
The following is an example payload file with a rule that inserts all messages sent to the `iot/test` topic into the specified S3 bucket. The SQL statement filters the messages, and the role ARN grants AWS IoT permission to write to the Amazon S3 bucket.

```json
{
    "awsIotSqlVersion": "2016-03-23",
    "sql": "SELECT * FROM 'iot/test'",
    "ruleDisabled": false,
    "actions": [
        {
            "s3": {
                "roleArn": "arn:aws:iam::123456789012:role/aws_iot_s3",
                "bucketName": "my-bucket",
                "key": "myS3Key"
            }
        }
    ]
}
```

The following is an example payload file with a rule that pushes data to Amazon ES:

```json
{
    "sql": "SELECT *, timestamp() as timestamp FROM 'iot/test'",
    "ruleDisabled": false,
    "awsIotSqlVersion": "2016-03-23",
    "actions": [
        {
            "elasticsearch": {
                "roleArn": "arn:aws:iam::123456789012:role/aws_iot_es",
                "endpoint": "https://my-endpoint",
                "index": "my-index",
                "type": "my-type",
                "id": "${newuuid()}"
            }
        }
    ]
}
```

The following is an example payload file with a rule that invokes a Lambda function:

```json
{
    "sql": "expression",
    "ruleDisabled": false,
    "awsIotSqlVersion": "2016-03-23",
    "actions": [
        {
            "lambda": {
                "functionArn": "arn:aws:lambda:us-west-2:123456789012:function:my-lambda-function"
            }
        }
    ]
}
```

The following is an example payload file with a rule that publishes to an Amazon SNS topic:

```json
{
    "sql": "expression",
    "ruleDisabled": false,
    "awsIotSqlVersion": "2016-03-23",
    "actions": [
```
The following is an example payload file with a rule that republishes on a different MQTT topic:

```json
{
  "sql": "expression",
  "ruleDisabled": false,
  "awsIotSqlVersion": "2016-03-23",
  "actions": [{
    "republish": {
      "topic": "my-mqtt-topic",
      "roleArn": "arn:aws:iam::123456789012:role/my-iot-role"
    }
  }]
}
```

The following is an example payload file with a rule that pushes data to an Amazon Kinesis Data Firehose stream:

```json
{
  "sql": "SELECT * FROM 'my-topic'",
  "ruleDisabled": false,
  "awsIotSqlVersion": "2016-03-23",
  "actions": [{
    "firehose": {
      "roleArn": "arn:aws:iam::123456789012:role/my-iot-role",
      "deliveryStreamName": "my-stream-name"
    }
  }]
}
```

The following is an example payload file with a rule that uses the Amazon Machine Learning machinelearning_predict function to republish to a topic if the data in the MQTT payload is classified as a 1.

```json
{
  "sql": "SELECT * FROM 'iot/test' where machinelearning_predict('my-model', 'arn:aws:iam::123456789012:role/my-iot-aml-role', *).predictedLabel=1",
  "ruleDisabled": false,
  "awsIotSqlVersion": "2016-03-23",
  "actions": [{
    "republish": {
      "roleArn": "arn:aws:iam::123456789012:role/my-iot-role",
      "topic": "my-mqtt-topic"
    }
  }]
}
```

The following is an example payload file with a rule that publishes messages to a Salesforce IoT Cloud input stream.

```json
{
  "sql": "expression",
```
Viewing Your Rules

Use the `list-topic-rules` command to list your rules:

```bash
aws iot list-topic-rules
```

Use the `get-topic-rule` command to get information about a rule:

```bash
aws iot get-topic-rule --rule-name my-rule
```

SQL Versions

The AWS IoT rules engine uses an SQL-like syntax to select data from MQTT messages. The SQL statements are interpreted based on an SQL version specified with the `awsIotSqlVersion` property in a JSON document that describes the rule. For more information about the structure of JSON rule documents, see Creating a Rule (p. 164). The `awsIotSqlVersion` property allows you to specify which version of the AWS IoT SQL rules engine you want to use. When a new version is deployed, you can continue to use an older version or change your rule to use the new version. Your current rules continue to use the version with which they were created.

The following JSON example shows how to specify the SQL version using the `awsIotSqlVersion` property:

```json
{
    "sql": "expression",
    "ruleDisabled": false,
    "awsIotSqlVersion": "2016-03-23",
    "actions": [{
        "republish": {
            "topic": "my-mqtt-topic",
            "roleArn": "arn:aws:iam::123456789012:role/my-iot-role"
        }
    }]
}
```

Current supported versions are:

- 2015-10-08, the original SQL version built on 2015-10-08.
- 2016-03-23, the SQL version built on 2016-03-23.
- beta, the most recent beta SQL version. The use of this version might introduce breaking changes to your rules.
What's New in the 2016-03-23 SQL Rules Engine Version

- Fixes for selecting nested JSON objects.
- Fixes for array queries.
- Inter-object query support.
- Support to output an array as a top-level object.
- Adds the encode (value, encodingScheme) function, which can be applied on both JSON and non-JSON format data.

Inter-Object Queries

This feature allows you to query for an attribute in a JSON object. For example, given the following MQTT message:

```json
{
    "e": [
        { "n": "temperature", "u": "Cel", "t": 1234, "v": 22.5 },
        { "n": "light", "u": "lm", "t": 1235, "v": 135 },
        { "n": "acidity", "u": "pH", "t": 1235, "v": 7 }
    ]
}
```

And the following rule:

```
SELECT (SELECT v FROM e WHERE n = 'temperature') as temperature FROM 'my/topic'
```

The rule generates the following output:

```json
{"temperature": [{"v":22.5}]}
```

Using the same MQTT message, given a slightly more complicated rule such as:

```
SELECT get((SELECT v FROM e WHERE n = 'temperature'),1).v as temperature FROM 'topic'
```

The rule generates the following output:

```json
{"temperature":22.5}
```

Output an Array as a Top-Level Object

This feature allows a rule to return an array as a top-level object. For example, given the following MQTT message:

```json
{
    "a": { "b": "c" },
    "arr": [1,2,3,4]
}
```

And the following rule:
Troubleshooting a Rule

If you are having an issue with your rules, you should enable CloudWatch Logs. By analyzing your logs, you can determine whether the issue is authorization or whether, for example, a WHERE clause condition did not match. For more information about using Amazon CloudWatch Logs, see Setting Up CloudWatchLogs.

Rule Error Handling

When AWS IoT receives a message from a device, the Rules Engine checks to see if the message matches a rule. If so, the rule's SQL statement is evaluated and the rule's actions are invoked, passing the SQL statement's result.

If a problem occurs when invoking an action, the Rules Engine will invoke an error action, if one is specified for the rule. This may happen when, for example:

- A rule doesn't have permission to access an Amazon S3 bucket.
- A user error causes DynamoDB provisioned throughput to be exceeded.

Error Action Message Format

A single message is generated per rule and message. For example, if two rule actions in the same rule fail, the error action will receive one message containing both errors.

The error action message will look like this:

```
{
  "ruleName": "TestAction",
  "topic": "testme/action",
  "cloudwatchTraceId": "7e146a2c-95b5-6cafa-98b9-50e3969734c7",
  "clientId": "iotconsole-1511213971966-0",
  "base64OriginalPayload": "ewogICJtZXNzYWdlIjogIkhlbGxvIHZyb20gQVdTIElvVCBjb25zb2xlIgp9",
  "failures": [
    {
      "failedAction": "S3Action",
      "failedResource": "us-east-1-s3-verify-user",
      "errorMessage": "Failed to put S3 object. The error received was The specified bucket does not exist (Service: Amazon S3; Status Code: 404; Error Code: NoSuchBucket; Request ID: 9DF5416B947B9AF; S3 Extended Request ID: yMah1cwPhqTH267QLPhTKeVPKJB8B05ndBHxOMWtxLTM6uAwwYYuqieAKy6qRPTxPltHXC0r4Y=)."
    }
  ]
}
```
Message arrived on: error/action, Action: s3, Bucket: us-east-1-s3-verify-user, Key: "aaa". Value of x-amz-id-2: yMahlcwPhqTH267QLPkTeVPkOB5ndBh20mWtxLTM6uAvwYYuqieAKyb6qRPTxP1tHXCoR4Y="

```
{}
```

**ruleName**

The name of the rule that triggered the error action.

**topic**

The topic on which the original message was received.

**cloudwatchTraceId**

A unique identity referring to the error logs in CloudWatch.

**clientId**

The client ID of the message publisher.

**base64OriginalPayload**

The original message payload base64 encoded.

**failures**

**failedAction**

The name of the action that failed to complete, for example "S3Action".

**failedResource**

The name of the resource, for example the name of an S3 bucket.

**errorMessage**

The description and explanation of the error.

## Error Action Example

Here is an example of a rule with an added error action. The following rule has an action that writes message data to a DynamoDB table and an error action that writes data to an Amazon S3 bucket:

```
{
  "sql" : "SELECT * FROM ...",
  "actions" : [{
    "dynamoDB" : {
      "table" : "PoorlyConfiguredTable",
      "hashKeyField" : "AConstantString",
      "hashKeyValue" : "AHashKey"
    }
  }],
  "errorAction" : {
    "s3" : {
      "roleArn": "arn:aws:iam::123456789012:role/aws_iot_s3",
      "bucket" : "message-processing-errors",
      "key" : "${replace(topic(), '/', '-') + '-' + timestamp() + '-' + newuuid()}
    }
  }
}
```

You can use any function or substitution in an error action's SQL statement, except for external functions (for example, get_thing_shadow, aws_lambda, and machinelearning_predict.)
For more information about rules and how to specify an error action, see Creating an AWS IoT Rule.

For more information on using CloudWatch to monitor the success or failure of rules, see AWS IoT Metrics and Dimensions (p. 330).

Deleting a Rule

When you are finished with a rule, you can delete it.

To delete a rule (AWS CLI)

Use the delete-topic-rule command to delete a rule:

```bash
aws iot delete-topic-rule --rule-name my-rule
```

AWS IoT Rule Actions

AWS IoT rule actions are used to specify what to do when a rule is triggered. You can define actions to write data to a DynamoDB database or a Kinesis stream or to invoke a Lambda function, and more. The following actions are supported:

- `cloudwatchAlarm` to change a CloudWatch alarm.
- `cloudwatchMetric` to capture a CloudWatch metric.
- `dynamodb` to write data to a DynamoDB database.
- `dynamodbv2` to write data to a DynamoDB database.
- `elasticsearch` to write data to an Amazon Elasticsearch Service domain.
- `firehose` to write data to an Amazon Kinesis Data Firehose stream.
- `kinesis` to write data to a Kinesis stream.
- `lambda` to invoke a Lambda function.
- `s3` to write data to an Amazon S3 bucket.
- `sns` to write data as a push notification.
- `sqs` to write data to an SQS queue.
- `republish` to republish the message on another MQTT topic.
- `salesforce` to write a message to a Salesforce IoT input stream.

**Note**

The AWS IoT rules engine does not currently retry delivery for messages that fail to be published to another service.

The following sections discuss each action in detail.

CloudWatch Alarm Action

The CloudWatch alarm action allows you to change CloudWatch alarm state. You can specify the state change reason and value in this call. When creating an AWS IoT rule with a CloudWatch alarm action, you must specify the following information:

- `roleArn`

  The IAM role that allows access to the CloudWatch alarm.
alarmName

  The CloudWatch alarm name.
stateReason

  Reason for the alarm change.
stateValue

  The value of the alarm state. Acceptable values are OK, ALARM, INSUFFICIENT_DATA.

Note

  Ensure the role associated with the rule has a policy that grants the cloudwatch:SetAlarmState permission.

The following JSON example shows how to define a CloudWatch alarm action in an AWS IoT rule:

```json
{
    "rule": {
        "sql": "SELECT * FROM 'some/topic'",
        "ruleDisabled": false,
        "actions": [{
            "cloudwatchAlarm": {
                "roleArn": "arn:aws:iam::123456789012:role/aws_iot_cw",
                "alarmName": "IotAlarm",
                "stateReason": "Temperature stabilized.",
                "stateValue": "OK"
            }
        }]
    }
}
```

For more information, see CloudWatch Alarms.

### CloudWatch Metric Action

The CloudWatch metric action allows you to capture a CloudWatch metric. You can specify the metric namespace, name, value, unit, and timestamp. When creating an AWS IoT rule with a CloudWatch metric action, you must specify the following information:

roleArn

  The IAM role that allows access to the CloudWatch metric.
metricNamespace

  CloudWatch metric namespace name.
metricName

  The CloudWatch metric name.
metricValue

  The CloudWatch metric value.
metricUnit

  The metric unit supported by CloudWatch.
metricTimestamp

  An optional Unix timestamp.
Note
Ensure the role associated with the rule has a policy granting the cloudwatch:PutMetricData permission.

The following JSON example shows how to define a CloudWatch metric action in an AWS IoT rule:

```json
{
    "rule": {
        "sql": "SELECT * FROM 'some/topic'",
        "ruleDisabled": false,
        "actions": [
            {
                "cloudwatchMetric": {
                    "roleArn": "arn:aws:iam::123456789012:role/aws_iot_cw",
                    "metricNamespace": "IotNamespace",
                    "metricName": "IotMetric",
                    "metricValue": "1",
                    "metricUnit": "Count",
                    "metricTimestamp": "1456821314"
                }
            }
        ]
    }
}
```

For more information, see CloudWatch Metrics.

**DynamoDB Action**

The `dynamodb` action allows you to write all or part of an MQTT message to a DynamoDB table. When creating a DynamoDB rule, you must specify the following information:

hashKeyType
The data type of the hash key (also called the partition key). Valid values are: "STRING" or "NUMBER".

hashKeyField
The name of the hash key (also called the partition key).

hashKeyValue
The value of the hash key.

rangeKeyType
Optional. The data type of the range key (also called the sort key). Valid values are: "STRING" or "NUMBER".

rangeKeyField
Optional. The name of the range key (also called the sort key).

rangeKeyValue
Optional. The value of the range key.

operation
Optional. The type of operation to be performed. This follows the substitution template, so it can be `#{operation}`, but the substitution must result in one of the following: INSERT, UPDATE, or DELETE.

payloadField
Optional. The name of the field where the payload is written. If this value is omitted, the payload is written to the `payload` field.
**DynamoDBv2 Action**

The `dynamodbv2` action allows you to write all or part of an MQTT message to a DynamoDB table. Each attribute in the payload is written to a separate column in the DynamoDB database. When creating a DynamoDB rule, you must specify the following information:

- **roleARN**
  - The IAM role that allows access to the DynamoDB table. At a minimum, the role must allow the `dynamodb:PutItem` IAM action.

- **tableName**
  - The name of the DynamoDB table.

**Note**

The MQTT message payload must contain a root-level key that matches the table's primary partition key and a root-level key that matches the table's primary sort key, if one is defined.
The data written to the DynamoDB table is the result from the SQL statement of the rule.

**Note**
Ensure the role associated with the rule has a policy granting the `dynamodb:PutItem` permission.

The following JSON example shows how to define a `dynamodb` action in an AWS IoT rule:

```json
{
    "rule": {
        "ruleDisabled": false,
        "sql": "SELECT * AS message FROM 'some/topic'",
        "description": "A test DynamoDBv2 rule",
        "actions": [{
            "dynamodbv2": {
                "roleArn": "arn:aws:iam::123456789012:role/aws_iot_dynamoDBv2",
                "putItem": {
                    "tableName": "my_ddb_table"
                }
            }
        }]
    }
}
```

For more information, see the Amazon DynamoDB Getting Started Guide.

### Amazon ES Action

The `elasticsearch` action allows you to write data from MQTT messages to an Amazon Elasticsearch Service domain. Data in Amazon ES can then be queried and visualized by using tools like Kibana. When you create an AWS IoT rule with an `elasticsearch` action, you must specify the following information:

- **endpoint**
  - The endpoint of your Amazon ES domain.
- **index**
  - The Amazon ES index where you want to store your data.
- **type**
  - The type of document you are storing.
- **id**
  - The unique identifier for each document.

**Note**
Ensure the role associated with the rule has a policy granting the `es:ESHttpPut` permission.

The following JSON example shows how to define an `elasticsearch` action in an AWS IoT rule:

```json
{
    
    "sql":"SELECT *, timestamp() as timestamp FROM 'iot/test'",
    "ruleDisabled":false,
    "actions":[
        {
            "elasticsearch":{
                "roleArn":"arn:aws:iam::123456789012:role/aws_iot_es",
            }
        }
    ]
}
```
Firehose Action

A firehose action sends data from an MQTT message that triggered the rule to a Kinesis Data Firehose stream. When creating a rule with a firehose action, you must specify the following information:

deliveryStreamName
The Kinesis Data Firehose stream to which to write the message data.

roleArn
The IAM role that allows access to Kinesis Data Firehose.

separator
A character separator that is used to separate records written to the Firehose stream. Valid values are: ‘\n’ (newline), ‘\t’ (tab), ‘\r\n’ (Windows newline), ‘,’ (comma).

**Note**
Make sure the role associated with the rule has a policy that grants the firehose:PutRecord permission.

The following JSON example shows how to create an AWS IoT rule with a firehose action:

```json
{
   "rule": {
      "sql": "SELECT * FROM 'some/topic'",
      "ruleDisabled": false,
      "actions": [{
         "firehose": {
            "roleArn": "arn:aws:iam::123456789012:role/aws_iot_firehose",
            "deliveryStreamName": "my_firehose_stream"
         }
      }]
   }
}
```

For more information, see the Kinesis Data Firehose Developer Guide.

Kinesis Action

The kinesis action allows you to write data from MQTT messages into a Kinesis stream. When creating an AWS IoT rule with a kinesis action, you must specify the following information:

stream
The Kinesis stream to which to write data.
partitionKey

The partition key used to determine to which shard the data is written. The partition key is usually composed of an expression (for example, "${topic()}") or "${timestamp()}"").

Note

Ensure that the policy associated with the rule has the `kinesis:PutRecord` permission.

The following JSON example shows how to define a `kinesis` action in an AWS IoT rule:

```json
{
  "rule": {
    "sql": "SELECT * FROM 'some/topic'",
    "ruleDisabled": false,
    "actions": [{
      "kinesis": {
        "roleArn": "arn:aws:iam::123456789012:role/aws_iot_kinesis",
        "streamName": "my_kinesis_stream",
        "partitionKey": "${topic()}",
      }
    }],
  }
}
```

For more information, see the [Kinesis Developer Guide](#).

Lambda Action

A lambda action calls a Lambda function, passing in the MQTT message that triggered the rule. In order for AWS IoT to call a Lambda function, you must configure a policy granting the `lambda:InvokeFunction` permission to AWS IoT. Lambda functions use resource-based policies, so you must attach the policy to the Lambda function itself. Use the following CLI command to attach a policy granting `lambda:InvokeFunction` permission:

```bash
aws lambda add-permission --function-name "function_name" --region "region" --principal iot.amazonaws.com --source-arn arn:aws:iot:us-east-2:account_id:rule/rule_name --source-account "account_id" --statement-id "unique_id" --action "lambda:InvokeFunction"
```

The following are the arguments for the `add-permission` command:

--function-name

Name of the Lambda function whose resource policy you are updating by adding a new permission.

--region

The AWS region of your account.

--principal

The principal who is getting the permission. This should be `iot.amazonaws.com` to allow AWS IoT permission to call a Lambda function.

--source-arn

The ARN of the rule. You can use the `get-topic-rule` CLI command to get the ARN of a rule.

--source-account

The AWS account where the rule is defined.
--statement-id

A unique statement identifier.

--action

The Lambda action you want to allow in this statement. In this case, we want to allow AWS IoT to invoke a Lambda function, so we specify `lambda:InvokeFunction`.

**Note**

If you add a permission for an AWS IoT principal without providing the source ARN, any AWS account that creates a rule with your Lambda action can trigger rules to invoke your Lambda function from AWS IoT.

For more information, see [Lambda Permission Model](https://docs.aws.amazon.com/iot/latest/developerguide/lamda-permission-model.html).

When creating a rule with a `lambda` action, you must specify the Lambda function to invoke when the rule is triggered.

The following JSON example shows a rule that calls a Lambda function:

```json
{  
  "rule": {  
    "sql": "SELECT * FROM 'some/topic'",
    "ruleDisabled": false,
    "actions": [{
      "lambda": {
        "functionArn": "arn:aws:lambda:us-east-2:123456789012:function:myLambdaFunction"
      }
    }
  }
}
```

For more information, see the [AWS Lambda Developer Guide](https://docs.aws.amazon.com/lambda/latest/dg/lambda-intro.html).

## Republish Action

The `republish` action allows you to republish the message that triggered the role to another MQTT topic. When creating a rule with a `republish` action, you must specify the following information:

- **topic**
  
  The MQTT topic to which to republish the message.

- **roleArn**
  
  The IAM role that allows publishing to the MQTT topic.

**Note**

Make sure the role associated with the rule has a policy granting the `iot:Publish` permission.

```json
{  
  "rule": {  
    "sql": "SELECT * FROM 'some/topic'",
    "ruleDisabled": false,
    "actions": [{
      "republish": {
        "topic": "another/topic",
        "roleArn": "arn:aws:iam::123456789012:role/aws_iot_republish"
      }
    }
  }
}
```
S3 Action

A `s3` action writes the data from the MQTT message that triggered the rule to an Amazon S3 bucket. When creating an AWS IoT rule with an `s3` action, you must specify the following information:

- **bucket**
  The Amazon S3 bucket to which to write data.

- **cannedacl**
  The Amazon S3 canned ACL that controls access to the object identified by the object key. For more information, see S3 Canned ACLs.

- **key**
  The path to the file where the data is written. For example, if the value of this argument is `${topic()}/${timestamp()}`, the topic the message was sent to is "this/is/my/topic," and the current timestamp is 1460685389, the data is written to a file called "1460685389" in the "this/is/my/topic" folder on Amazon S3.

  **Note**
  Using a static key results in a single file in Amazon S3 being overwritten for each invocation of the rule. More common use cases are to use the message timestamp or another unique message identifier, so that a new file is saved in Amazon S3 for each message received.

- **roleArn**
  The IAM role that allows access to the Amazon S3 bucket.

  **Note**
  Make sure the role associated with the rule has a policy granting the `s3:PutObject` permission.

The following JSON example shows how to define an `s3` action in an AWS IoT rule:

```json
{
  "rule": {
    "sql": "SELECT * FROM 'some/topic'",
    "ruleDisabled": false,
    "actions": [ {
      "s3": {
        "roleArn": "arn:aws:iam::123456789012:role/aws_iot_s3",
        "bucketName": "my-bucket",
        "key": "${topic()}/${timestamp()}"
      }
    } ]
  }
}
```

For more information, see the Amazon S3 Developer Guide.

SNS Action

A `sns` action sends the data from the MQTT message that triggered the rule as an SNS push notification. When creating a rule with an `sns` action, you must specify the following information:
messageFormat

The message format. Accepted values are "JSON" and "RAW." The default value of the attribute is "RAW." SNS uses this setting to determine if the payload should be parsed and relevant platform-specific parts of the payload should be extracted.

roleArn

The IAM role that allows access to SNS.

targetArn

The SNS topic or individual device to which the push notification is sent.

Note
Make sure the policy associated with the rule has the `sns:Publish` permission.

The following JSON example shows how to define an `sns` action in an AWS IoT rule:

```json
{
  "rule": {
    "sql": "SELECT * FROM 'some/topic'",
    "ruleDisabled": false,
    "actions": [
      {
        "sns": {
          "roleArn": "arn:aws:iam::123456789012:role/aws_iot_sns"
        }
      }
    ]
  }
}
```

For more information, see the Amazon SNS Developer Guide.

**SQS Action**

A `sqs` action sends data from the MQTT message that triggered the rule to an SQS queue. When creating a rule with an `sqs` action, you must specify the following information:

queueUrl

The URL of the SQS queue to which to write the data.

useBase64

Set to `true` if you want the MQTT message data to be Base64-encoded before writing to the SQS queue. Otherwise, set to `false`.

roleArn

The IAM role that allows access to the SQS queue.

Note
Make sure the role associated with the rule has a policy granting the `sqs:SendMessage` permission.

The following JSON example shows how to create an AWS IoT rule with an `sqs` action:

```json
{
  "rule": {
```

181
"sql": "SELECT * FROM 'some/topic'",
"ruleDisabled": false,
"actions": [{
  "sqs": {
    "queueUrl": "https://sqs.us-east-2.amazonaws.com/123456789012/my_sqs_queue",
    "roleArn": "arn:aws:iam::123456789012:role/aws_iot_sqs",
    "useBase64": false
  }
}]
}

For more information, see the Amazon SQS Developer Guide.

Salesforce Action

A salesforce action sends data from the MQTT message that triggered the rule to a Salesforce IoT Input Stream. When creating a rule with a salesforce action, you must specify the following information:

url

The URL exposed by the Salesforce IoT Input Stream. The URL is available from the Salesforce IoT Platform when you create an Input Stream. Refer to the Salesforce IoT documentation to learn more.

token

The token used to authenticate access to the specified Salesforce IoT Input Stream. The token is available from the Salesforce IoT Platform when you create an Input Stream. Refer to the Salesforce IoT documentation to learn more.

Note

These parameters do not support substitution.

The following JSON example shows how to create an AWS IoT rule with a salesforce action:

```
{
  "sql": "expression",
  "ruleDisabled": false,
  "awsIotSqlVersion": "2016-03-23",
  "actions": [{
    "salesforce": {
      "token": "ABCDEFGHI123456789abcdefghi123456789",
      "url": "https://ingestion-cluster-id.my-env.sfdcnow.com/streams/stream-id/connection-id/my-event"
    }
  }]
}
```

For more information, refer to the Salesforce IoT documentation.

AWS IoT SQL Reference

In AWS IoT, rules are defined using an SQL-like syntax. SQL statements are composed of three types of clauses:
**SELECT**

Required. Extracts information from the incoming payload and performs transformations.

**FROM**

Required. The MQTT topic filter from which the rule receives messages.

**WHERE**

Optional. Adds conditional logic that determines if a rule is evaluated and its actions are executed.

An example SQL statement looks like this:

```sql
SELECT color AS rgb FROM 'a/b' WHERE temperature > 50
```

An example MQTT message (also called an incoming payload) looks like this:

```json
{
    "color":"red",
    "temperature":100
}
```

If this message is published on the ‘a/b’ topic, the rule is triggered and the SQL statement is evaluated. The SQL statement extracts the value of the rgb property if the "temperature" property is greater than 50. The WHERE clause specifies the condition \textit{temperature} > 50. The AS keyword renames the "color" property to "rgb". The result (also called an outgoing payload) looks like this:

```json
{
    "rgb":"red"
}
```

This data is then forwarded to the rule's action, which sends the data for more processing. For more information about rule actions, see \textit{AWS IoT Rule Actions (p. 172)}.

## Data Types

The AWS IoT rules engine supports all JSON data types.

**Supported Data Types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>A discrete Int. 34 digits maximum.</td>
</tr>
<tr>
<td>Decimal</td>
<td>A Decimal with a precision of 34 digits, with a minimum non-zero magnitude of 1E-999 and a maximum magnitude 9.999...E999.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Some functions return Decimals with double precision rather than 34-digit precision.</td>
</tr>
<tr>
<td>Boolean</td>
<td>True or False.</td>
</tr>
<tr>
<td>String</td>
<td>A UTF-8 string.</td>
</tr>
<tr>
<td>Array</td>
<td>A series of values that don't have to have the same type.</td>
</tr>
</tbody>
</table>
## Data Types

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A JSON value consisting of a key and a value. Keys must be strings. Values can be any type.</td>
</tr>
<tr>
<td>Null</td>
<td>Null as defined by JSON. It's an actual value that represents the absence of a value. You can explicitly create a Null value by using the Null keyword in your SQL statement. For example: &quot;SELECT NULL AS n FROM 'a/b'&quot;</td>
</tr>
<tr>
<td>Undefined</td>
<td>Not a value. This isn't explicitly representable in JSON except by omitting the value. For example, in the object (&quot;\text{&quot;foo&quot;: null}), the key &quot;foo&quot; returns NULL, but the key &quot;bar&quot; returns Undefined. Internally, the SQL language treats Undefined as a value, but it isn't representable in JSON, so when serialized to JSON, the results are Undefined.</td>
</tr>
</tbody>
</table>

```json
{"foo":null, "bar":undefined}
```

is serialized to JSON as:

```json
{"foo":null}
```

Similarly, Undefined is converted to an empty string when serialized by itself. Functions called with invalid arguments (for example, wrong types, wrong number of arguments, and so on) returns Undefined.

### Conversions

The following table lists the results when a value of one type is converted to another type (when a value of the incorrect type is given to a function). For example, if the absolute value function "abs" (which expects an Int or Decimal) is given a String, it attempts to convert the String to a Decimal, following these rules. In this case, 'abs("-5.123")' is treated as 'abs(-5.123)'.

**Note**

There are no attempted conversions to Array, Object, Null, or Undefined.

### To Decimal

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>A Decimal with no decimal point.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The source value.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined. (You can explicitly use the cast function to transform true = 1.0, false = 0.0.)</td>
</tr>
<tr>
<td>String</td>
<td>The SQL engine tries to parse the string as a Decimal. AWS IoT attempts to parse strings matching the regular expression: ^-?\d+(.\d</td>
</tr>
</tbody>
</table>
### Data Types

#### Argument Type

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The source value.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The source value rounded to the nearest Int.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined. (You can explicitly use the cast function to transform true = 1.0, false = 0.0.)</td>
</tr>
<tr>
<td>String</td>
<td>The SQL engine will try to parse the string as a Decimal. We will attempt to parse strings matching the regular expression: `^-?\d+(.\d+)((?i)E-?\d+)?$. &quot;0&quot;, &quot;-1.2&quot;, &quot;5E-12&quot; are all examples of strings that would be automatically converted to Decimals. We will attempt to convert the String to a Decimal, and then truncate the decimal places of that Decimal to make an Int.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Null.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

#### To Int

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The source value.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The source value rounded to the nearest Int.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined. (You can explicitly use the cast function to transform true = 1.0, false = 0.0.)</td>
</tr>
<tr>
<td>String</td>
<td>The SQL engine will try to parse the string as a Decimal. We will attempt to parse strings matching the regular expression: `^-?\d+(.\d+)((?i)E-?\d+)?$. &quot;0&quot;, &quot;-1.2&quot;, &quot;5E-12&quot; are all examples of strings that would be automatically converted to Decimals. We will attempt to convert the String to a Decimal, and then truncate the decimal places of that Decimal to make an Int.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Null.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

#### To Boolean

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Undefined. (You can explicitly use the cast function to transform 0 = False, any_nonzero_value = True.)</td>
</tr>
<tr>
<td>Decimal</td>
<td>Undefined. (You can explicitly use the cast function to transform 0 = False, any_nonzero_value = True.)</td>
</tr>
<tr>
<td>Boolean</td>
<td>The original value.</td>
</tr>
<tr>
<td>String</td>
<td>&quot;true&quot;=True and &quot;false&quot;=False (case-insensitive). Other string values will be Undefined.</td>
</tr>
</tbody>
</table>
Operator Syntax

### Argument Type | Result
--- | ---
Array | Undefined.
Object | Undefined.
Null | Undefined.
Undefined | Undefined.

### To String

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>A string representation of the Int in standard notation.</td>
</tr>
<tr>
<td>Decimal</td>
<td>A string representing the Decimal value, possibly in scientific notation.</td>
</tr>
<tr>
<td>Boolean</td>
<td>&quot;true&quot; or &quot;false&quot;. All lowercase.</td>
</tr>
<tr>
<td>String</td>
<td>The original value.</td>
</tr>
<tr>
<td>Array</td>
<td>The Array serialized to JSON. The resultant string will be a comma-separated list, enclosed in square brackets. Strings will be quoted. Decimals, Ints, Booleans and Null will not.</td>
</tr>
<tr>
<td>Object</td>
<td>The object serialized to JSON. The resultant string will be a comma-separated list of key-value pairs and will begin and end with curly braces. Strings will be quoted. Decimals, Ints, Booleans and Null will not.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

Operators

The following operators can be used in SELECT, FROM, and WHERE clauses.

**AND operator**

Returns a Boolean result. Performs a logical AND operation. Returns true if left and right operands are true. Otherwise, returns false. Boolean operands or case-insensitive "true" or "false" string operands are required.

**Syntax:** `expression AND expression`.

**AND Operator**

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Boolean</td>
<td>Boolean. True if both operands are true. Otherwise, false.</td>
</tr>
</tbody>
</table>
### OR operator

Returns a Boolean result. Performs a logical OR operation. Returns true if either the left or the right operands are true. Otherwise, returns false. Boolean operands or case-insensitive "true" or "false" string operands are required.

**Syntax:** `expression OR expression`.

#### OR Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>String/Boolean</td>
<td>String/Boolean</td>
<td>If all strings are &quot;true&quot; or &quot;false&quot; (case-insensitive), they are converted to Boolean and processed normally as boolean AND boolean.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### NOT operator

Returns a Boolean result. Performs a logical NOT operation. Returns true if the operand is false. Otherwise, returns true. A boolean operand or case-insensitive "true" or "false" string operand is required.

**Syntax:** `NOT expression`.

#### NOT Operator

<table>
<thead>
<tr>
<th>Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Boolean. True if operand is false. Otherwise, true.</td>
</tr>
<tr>
<td>String</td>
<td>If string is &quot;true&quot; or &quot;false&quot; (case-insensitive), it is converted to the corresponding boolean value, and the opposite value is returned.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### > operator

Returns a Boolean result. Returns true if the left operand is greater than the right operand. Both operands are converted to a Decimal, and then compared.

**Syntax:** `expression > expression`.
> Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Boolean. True if the left operand is greater than the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings can be converted to Decimal, then Boolean. Returns true if the left operand is greater than the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

>= operator

Returns a Boolean result. Returns true if the left operand is greater than or equal to the right operand. Both operands are converted to a Decimal, and then compared.

Syntax: `expression >= expression`.

>= Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Boolean. True if the left operand is greater than or equal to the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings can be converted to Decimal, then Boolean. Returns true if the left operand is greater than or equal to the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

< operator

Returns a Boolean result. Returns true if the left operand is less than the right operand. Both operands are converted to a Decimal, and then compared.

Syntax: `expression < expression`.

< Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Boolean. True if the left operand is less than the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings can be converted to Decimal, then Boolean. Returns true if the left operand is less than the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

<= operator

Returns a Boolean result. Returns true if the left operand is less than or equal to the right operand. Both operands are converted to a Decimal, and then compared.
Operators

Syntax: expression <= expression.

>= Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Boolean. True if the left operand is less than or equal to the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings can be converted to Decimal, then Boolean. Returns true if the left operand is less than or equal to the right operand. Otherwise, false.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined</td>
<td>Undefined</td>
</tr>
</tbody>
</table>

<> operator

Returns a Boolean result. Returns true if both left and right operands are not equal. Otherwise, returns false.

Syntax: expression <> expression.

> Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>True if left operand is not equal to right operand. Otherwise, false.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal</td>
<td>True if left operand is not equal to right operand. Otherwise, false. Int is converted to Decimal before being compared.</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
<td>True if left operand is not equal to right operand. Otherwise, false.</td>
</tr>
<tr>
<td>Array</td>
<td>Array</td>
<td>True if the items in each operand are not equal and not in the same order. Otherwise, false</td>
</tr>
<tr>
<td>Object</td>
<td>Object</td>
<td>True if the keys and values of each operand are not equal. Otherwise, false. The order of keys/values is unimportant.</td>
</tr>
<tr>
<td>Null</td>
<td>Null</td>
<td>False.</td>
</tr>
<tr>
<td>Any Value</td>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Any Value</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Mismatched Type</td>
<td>Mismatched Type</td>
<td>True.</td>
</tr>
</tbody>
</table>

= operator

Returns a Boolean result. Returns true if both left and right operands are equal. Otherwise, returns false.

Syntax: expression = expression.
### = Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>True if left operand is equal to right operand. Otherwise, false.</td>
</tr>

<tr>
<td>Undefined</td>
<td>Any Value</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Mismatched Type</td>
<td>Mismatched Type</td>
<td>False.</td>
</tr>
</tbody>
</table>

### + operator

The "+" is an overloaded operator. It can be used for string concatenation or addition.

**Syntax:** `expression + expression`.

### + Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Any Value</td>
<td>Converts the right operand to a string and concatenates it to the end of the left operand.</td>
</tr>
<tr>
<td>Any Value</td>
<td>String</td>
<td>Converts the left operand to a string and concatenates the right operand to the end of the converted left operand.</td>
</tr>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int value. Adds operands together.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Decimal value. Adds operands together.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### - operator

Subtracts the right operand from the left operand.

**Syntax:** `expression - expression`.

### - Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int value. Subtracts right operand from left operand.</td>
</tr>
<tr>
<td>Left Operand</td>
<td>Right Operand</td>
<td>Output</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Decimal value. Subtracts right operand from left operand.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings convert to Decimals correctly, a Decimal value is returned. Subtracts right operand from left operand. Otherwise, returns Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other value</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**/* operator**

Multiplies the left operand by the right operand.

* Syntax: `expression * expression`.

**/ Operator**

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int value. Multiplies the left operand by the right operand.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Decimal value. Multiplies the left operand by the right operand.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings convert to Decimals correctly, a Decimal value is returned. Multiplies the left operand by the right operand. Otherwise, returns Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**/ operator**

Divides the left operand by the right operand.

* Syntax: `expression / expression`.

**/ Operator**

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int value. Divides the left operand by the right operand.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Decimal value. Divides the left operand by the right operand.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings convert to Decimals correctly, a Decimal value is returned. Divides the left operand by the right operand. Otherwise, returns Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**% operator**

Returns the remainder from dividing the left operand by the right operand.
% Operator

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int value. Returns the remainder from dividing the left operand by the right operand.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all Strings convert to Decimals correctly, a Decimal value is returned. Returns the remainder from dividing the left operand by the right operand. Otherwise, Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

Functions

You can use the following built-in functions in the SELECT or WHERE clauses of your SQL expressions.

abs(Decimal)

Returns the absolute value of a number. Supported by SQL version 2015-10-8 and later.

Example: abs(-5) returns 5.

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int, the absolute value of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal, the absolute value of the argument.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal. The result is the absolute value of the argument. If the string cannot be converted, the result is Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

accountid()

Returns the ID of the account that owns this rule as a String. Supported by SQL version 2015-10-8 and later.

Example:

accountid() = "123456789012"
acos(Decimal)

Returns the inverse cosine of a number in radians. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \text{acos}(0) = 1.5707963267948966 \)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the inverse cosine of the argument. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the inverse cosine of the argument. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal, the inverse cosine of the argument. If the string cannot be converted, the result is Undefined. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

asin(Decimal)

Returns the inverse sine of a number in radians. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \text{asin}(0) = 0.0 \)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the inverse sine of the argument. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the inverse sine of the argument. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the inverse sine of the argument. If the string cannot be converted, the result is Undefined. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>
### atan(Decimal)

Returns the inverse tangent of a number in radians. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: `atan(0) = 0.0`

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### atan2(Decimal, Decimal)

Returns the angle, in radians, between the positive x-axis and the (x, y) point defined in the two arguments. The angle is positive for counter-clockwise angles (upper half-plane, y > 0), and negative for clockwise angles (lower half-plane, y < 0). Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: `atan2(1, 0) = 1.5707963267948966`

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Decimal (with double precision), the angle between the x-axis and the specified (x,y) point.</td>
</tr>
<tr>
<td>Int/Decimal/String</td>
<td>Int/Decimal/String</td>
<td>Decimal, the inverse tangent of the point described. If a string cannot be converted, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>
aws_lambda(functionArn, inputJson)

Calls the specified Lambda function passing inputJson to the Lambda function and returns the JSON generated by the Lambda function.

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>functionArn</td>
<td>The ARN of the Lambda function to call. The Lambda function must return JSON data.</td>
</tr>
<tr>
<td>inputJson</td>
<td>The JSON input passed to the Lambda function.</td>
</tr>
</tbody>
</table>

You must grant AWS IoT lambda:invokeFunction permissions to invoke the specified Lambda function. The following example shows how to grant the lambda:invokeFunction permission using the AWS CLI:

```bash
aws lambda add-permission --function-name "function_name"
--region "region"
--principal iot.amazonaws.com
--source-arn arn:aws:iot:us-east-1:account_id:rule/rule_name
--source-account "account_id"
--statement-id "unique_id"
--action "lambda:InvokeFunction"
```

The following are the arguments for the add-permission command:

--function-name

Name of the Lambda function whose resource policy you are updating by adding a new permission.

--region

The AWS region of your account.

--principal

The principal who is getting the permission. This should be iot.amazonaws.com to allow AWS IoT permission to call a Lambda function.

--source-arn

The ARN of the rule. You can use the get-topic-rule CLI command to get the ARN of a rule.

--source-account

The AWS account where the rule is defined.

--statement-id

A unique statement identifier.

--action

The Lambda action you want to allow in this statement. In this case, we want to allow AWS IoT to invoke a Lambda function, so we specify lambda:InvokeFunction.

**Note**

If you add a permission for a AWS IoT principal without providing the source ARN, any AWS account that creates a rule with your Lambda action can trigger rules to invoke your Lambda function from AWS IoT.
For more information, see Lambda Permission Model.

The following rule shows how to call the aws_lambda function:

```
SELECT aws_lambda("arn:aws:lambda:us-east-1:account_id:function:lambda_function",
payload.inner.element).some.value as output FROM 'a/b'
```

payload.inner.element selects data from message published on topic 'a/b'.

some.value selects data from the output that is generated by the Lambda function.

**Note**
Rules Engine limits the execution duration of Lambda Functions. Lambda function calls from rules should be completed within 2000ms.

**bitand(Int, Int)**

Performs a bitwise AND on the bit representations of the two Int(-converted) arguments. Supported by SQL version 2015-10-8 and later.

Example: \( \text{bitand}(13, 5) = 5 \)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int, a bitwise AND of the two arguments.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Int, a bitwise AND of the two arguments. If any of the arguments cannot be converted to Int, the result is Undefined.</td>
</tr>
<tr>
<td>Int/Decimal/String</td>
<td>Int/Decimal/String</td>
<td>Int, the bitwise AND of the two arguments. All strings are converted to Decimals and rounded down to the nearest Int. If the conversion fails, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**bitor(Int, Int)**

Performs a bitwise OR of the bit representations of the two arguments. Supported by SQL version 2015-10-8 and later.

Example: \( \text{bitor}(8, 5) = 13 \)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int, the bitwise OR of the two arguments.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Int, the bitwise OR of the two arguments. If any of the arguments cannot be converted to Int, the result is Undefined.</td>
</tr>
<tr>
<td>Int/Decimal/String</td>
<td>Int/Decimal/String</td>
<td>Int, the bitwise OR of the two arguments. All strings are converted to Decimals and rounded down to the nearest Int. If the conversion fails, the result is Undefined.</td>
</tr>
</tbody>
</table>
### Argument Type | Argument Type | Result
---|---|---
Other Value | Other Value | Undefined.

**bitxor(Int, Int)**

Performs a bitwise XOR on the bit representations of the two Int(-converted) arguments. Supported by SQL version 2015-10-8 and later.

**Example:** `bitxor(13, 5) = 8`

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int, a bitwise XOR of the two arguments.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Int, a bitwise XOR of the two numbers.</td>
</tr>
<tr>
<td>Int/Decimal/String</td>
<td>Int/Decimal/String</td>
<td>Int, a bitwise XOR of the two arguments.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**bitnot(Int)**

Performs a bitwise NOT on the bit representations of the Int(-converted) argument. Supported by SQL version 2015-10-8 and later.

**Example:** `bitnot(13) = 2`

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int, a bitwise NOT of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Int, a bitwise NOT of the argument. The Decimal value is rounded down to the nearest Int.</td>
</tr>
<tr>
<td>String</td>
<td>Int, a bitwise NOT of the argument. Strings are converted to Decimals and rounded down to the nearest Int. If any conversion fails, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other value.</td>
</tr>
</tbody>
</table>

**cast()**

Converts a value from one data type to another. Cast behaves mostly like the standard conversions, with the addition of the ability to cast numbers to/from Booleans. If AWS IoT cannot determine how to cast one type to another, the result is **Undefined**. Supported by SQL version 2015-10-8 and later. Format: `cast(value as type)`.

**Example:**

`cast(true as Decimal) = 1.0`
The following keywords may appear after "as" when calling `cast`:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal</td>
<td>Casts value to Decimal.</td>
</tr>
<tr>
<td>Bool</td>
<td>Casts value to Boolean.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Casts value to Boolean.</td>
</tr>
<tr>
<td>String</td>
<td>Casts value to String.</td>
</tr>
<tr>
<td>Nvarchar</td>
<td>Casts value to String.</td>
</tr>
<tr>
<td>Text</td>
<td>Casts value to String.</td>
</tr>
<tr>
<td>Ntext</td>
<td>Casts value to String.</td>
</tr>
<tr>
<td>varchar</td>
<td>Casts value to String.</td>
</tr>
<tr>
<td>Int</td>
<td>Casts value to Int.</td>
</tr>
</tbody>
</table>

**Casting rules:**

**Cast to Decimal**

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>A Decimal with no decimal point.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The source value.</td>
</tr>
<tr>
<td>Boolean</td>
<td>true = 1.0, false = 0.0.</td>
</tr>
<tr>
<td>String</td>
<td>Will try to parse the string as a Decimal. We will attempt to parse strings matching the regex: ^-?\d+(\d+)?(?!E-? \d+)?$.&quot;0&quot;, &quot;-1.2&quot;, &quot;5E-12&quot; are all examples of Strings that would be converted automatically to Decimals.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**Cast to Int**

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The source value.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The source value, rounded down to the nearest Int.</td>
</tr>
<tr>
<td>Boolean</td>
<td>true = 1.0, false = 0.0.</td>
</tr>
</tbody>
</table>
### Argument Type

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Will try to parse the string as a Decimal. We will attempt to parse strings matching the regex: ^-?\d+(\d+)((?!E-? \d+)?$ &quot;0&quot;, &quot;-1.2&quot;, &quot;5E-12&quot; are all examples of strings that would be converted automatically to Decimals. Will attempt to convert the string to a Decimal and round down to the nearest Int.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

#### Cast to Boolean

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>0 = False, any_nonzero_value = True.</td>
</tr>
<tr>
<td>Decimal</td>
<td>0 = False, any_nonzero_value = True.</td>
</tr>
<tr>
<td>Boolean</td>
<td>The source value.</td>
</tr>
<tr>
<td>String</td>
<td>&quot;true&quot; = True and &quot;false&quot; = False (case-insensitive). Other string values = Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

#### Cast to String

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>A string representation of the Int, in standard notation.</td>
</tr>
<tr>
<td>Decimal</td>
<td>A string representing the Decimal value, possibly in scientific notation.</td>
</tr>
<tr>
<td>Boolean</td>
<td>&quot;true&quot; or &quot;false&quot;, all lowercase.</td>
</tr>
<tr>
<td>String</td>
<td>&quot;true&quot;=True and &quot;false&quot;=False (case-insensitive). Other string values = Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>The array serialized to JSON. The result string will be a comma-separated list enclosed in square brackets. Strings are quoted. Decimals, Ints, Booleans are not.</td>
</tr>
<tr>
<td>Object</td>
<td>The object serialized to JSON. The JSON string will be a comma-separated list of key-value pairs and will</td>
</tr>
<tr>
<td>Argument Type</td>
<td>Result</td>
</tr>
<tr>
<td>---------------</td>
<td>--------</td>
</tr>
<tr>
<td></td>
<td>begin and end with curly braces. Strings are quoted. Decimals, Ints, Booleans and Null are not.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### ceil(Decimal)

Rounds the given Decimal up to the nearest Int. Supported by SQL version 2015-10-8 and later.

Examples:

\[
\text{ceil}(1.2) = 2\\
\text{ceil}(11.2) = 11
\]

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int, the argument value.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Int, the Decimal value rounded up to the nearest Int.</td>
</tr>
<tr>
<td>String</td>
<td>Int. The string is converted to Decimal and rounded up to the nearest Int. If the string cannot be converted to a Decimal, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### chr(String)

Returns the ASCII character that corresponds to the given Int argument. Supported by SQL version 2015-10-8 and later.

Examples:

\[
\text{chr}(65) = "A".\\
\text{chr}(49) = "1".
\]

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The character corresponding to the specified ASCII value. If the argument is not a valid ASCII value, the result is Undefined.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The character corresponding to the specified ASCII value. The Decimal argument is rounded down to the nearest Int. If the argument is not a valid ASCII value, the result is Undefined.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>
### Argument Type | Result
--- | ---
String | If the String can be converted to a Decimal, it is rounded down to the nearest Int. If the argument is not a valid ASCII value, the result is Undefined.
Array | Undefined.
Object | Undefined.
Null | Undefined.
Other Value | Undefined.

#### clientid()

Returns the ID of the MQTT client sending the message, or n/a if the message wasn't sent over MQTT. Supported by SQL version 2015-10-8 and later.

Example:
```
clientid() = "123456789012"
```

#### concat()

Concatenates arrays or strings. This function accepts any number of arguments and returns a String or an Array. Supported by SQL version 2015-10-8 and later.

Examples:
```
cat() = Undefined.
cat(1) = "1".
cat([1, 2, 3], 4) = [1, 2, 3, 4].
cat([1, 2, 3], "hello") = [1, 2, 3,"hello"]
cat("con", "cat") = "concat"
cat(1, "hello") = "1hello"
cat("he","is","man") = "heisman"
cat([1, 2, 3], "hello", [4, 5, 6]) = [1, 2, 3,"hello", 4, 5, 6]
```

#### Number of Arguments | Result
--- | ---
0 | Undefined.
1 | The argument is returned unmodified.
2+ | If any argument is an Array, the result is a single array containing all of the arguments. If no arguments are Arrays, and at least one argument is a String, the result is the concatenation of the String representations of all the arguments. Arguments will be converted to Strings using the standard conversions listed above.
cos(Decimal)

Returns the cosine of a number in radians. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example:

\[
\cos(0) = 1.
\]

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the cosine of the argument. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the cosine of the argument. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the cosine of the argument. If the string cannot be converted to a Decimal, the result is Undefined. Imaginary results are returned as Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

cosh(Decimal)

Returns the hyperbolic cosine of a number in radians. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \cosh(2.3) = 5.037220649268761 \).
### encode(value, encodingScheme)

Use the `encode` function to encode the payload, which potentially might be non-JSON data, into its string representation based on the encoding scheme. Supported by SQL version 2016-03-23 and later.

**value**
- Any of the valid expressions, as defined in [AWS IoT SQL Reference (p. 182)](#). In addition, you can specify `*` to encode the entire payload, regardless of whether it's in JSON format. If you supply an expression, the result of the evaluation will first be converted to a string before it is encoded.

**encodingScheme**
- A literal string representing the encoding scheme you want to use. Currently, only ‘base64’ is supported.

### endswith(String, String)

Returns a Boolean indicating whether the first String argument ends with the second String argument. If either argument is Null or Undefined, the result is Undefined. Supported by SQL version 2015-10-8 and later.

**Example:** `endswith("cat","at") = true`.

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>String</td>
<td>True if the first argument ends in the second argument. Otherwise, false.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Both arguments are converted to strings using the standard conversion rules. True if the first argument ends in the second argument. Otherwise, false. If either argument is Null or Undefined, the result is Undefined.</td>
</tr>
</tbody>
</table>

### exp(Decimal)

Returns e raised to the Decimal argument. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

**Example:** `exp(1) = e`.

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), e ^ argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), e ^ argument.</td>
</tr>
<tr>
<td>Argument Type</td>
<td>Result</td>
</tr>
<tr>
<td>---------------</td>
<td>--------</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), e^ argument. If the String cannot be converted to a Decimal, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**get**

Extracts a value from a collection-like type (Array, String, Object). No conversion will be applied to the first argument. Conversion applies as documented in the table to the second argument. Supported by SQL version 2015-10-8 and later.

Examples:

get(["a", "b", "c"], 1) = "b"
get({"a":"b"}, "a") = "b"
get("abc", 1) = "b"

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Any Type (converted to Int)</td>
<td>The item at the 0-based index of the Array provided by the second argument (converted to Int). If the conversion is unsuccessful, the result is Undefined. If the index is outside the bounds of the Array (negative or &gt;= array.length), the result is Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Any Type (converted to Int)</td>
<td>The character at the 0-based index of the string provided by the second argument (converted to Int). If the conversion is unsuccessful, the result is Undefined. If the index is outside the bounds of the string (negative or &gt;= string.length), the result is Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>String (no conversion is applied)</td>
<td>The value stored in the object corresponding to the string key provided as the second argument.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Any Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**get_thing_shadow(thingName, roleARN)**

Returns the shadow of the specified thing. Supported by SQL version 2016-03-23 and later.

**thingName**

String: The name of the thing whose shadow you want to retrieve.

**roleArn**

String: A role ARN with `iot:GetThingShadow` permission.

Example:
SELECT * from 'a/b'
WHERE get_thing_shadow("MyThing","arn:aws:iam::123456789012:role/AllowsThingShadowAccess") .state.reported.alarm = 'ON'

Hashing Functions

AWS IoT provides the following hashing functions:

- md2
- md5
- sha1
- sha224
- sha256
- sha384
- sha512

All hash functions expect one string argument. The result is the hashed value of that string. Standard string conversions apply to non-string arguments. All hash functions are supported by SQL version 2015-10-8 and later.

Examples:

md2("hello") = "a9046c73e00331af68917d3804f70655"
md5("hello") = "5d41402abc4b2a76b9719d911017c592"

indexOf(String, String)

Returns the first index (0-based) of the second argument as a substring in the first argument. Both arguments are expected as strings. Arguments that are not strings are subjected to standard string conversion rules. This function does not apply to arrays, only to strings. Supported by SQL version 2015-10-8 and later.

Examples:

indexOf("abcd", "bc") = 1

isNull()

Returns whether the argument is the Null value. Supported by SQL version 2015-10-8 and later.

Examples:

isNull(5) = false.
isNull(Null) = true.

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>false</td>
</tr>
<tr>
<td>Decimal</td>
<td>false</td>
</tr>
<tr>
<td>Boolean</td>
<td>false</td>
</tr>
<tr>
<td>Argument Type</td>
<td>Result</td>
</tr>
<tr>
<td>---------------</td>
<td>--------</td>
</tr>
<tr>
<td>String</td>
<td>false</td>
</tr>
<tr>
<td>Array</td>
<td>false</td>
</tr>
<tr>
<td>Object</td>
<td>false</td>
</tr>
<tr>
<td>Null</td>
<td>true</td>
</tr>
<tr>
<td>Undefined</td>
<td>false</td>
</tr>
</tbody>
</table>

**isUndefined()**

Returns whether the argument is `Undefined`. Supported by SQL version 2015-10-8 and later.

Examples:

- `isUndefined(5) = false`.
- `isNull(floor([1,2,3])) = true`.

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>false</td>
</tr>
<tr>
<td>Decimal</td>
<td>false</td>
</tr>
<tr>
<td>Boolean</td>
<td>false</td>
</tr>
<tr>
<td>String</td>
<td>false</td>
</tr>
<tr>
<td>Array</td>
<td>false</td>
</tr>
<tr>
<td>Object</td>
<td>false</td>
</tr>
<tr>
<td>Null</td>
<td>false</td>
</tr>
<tr>
<td>Undefined</td>
<td>true</td>
</tr>
</tbody>
</table>

**length(String)**

Returns the number of characters in the provided string. Standard conversion rules apply to non-String arguments. Supported by SQL version 2015-10-8 and later.

Examples:

- `length("hi") = 2`
- `length(false) = 5`

**ln(Decimal)**

Returns the natural logarithm of the argument. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: `ln(e) = 1`. 
<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the natural log of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the natural log of the argument.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the natural log of the argument. If the string cannot be converted to a Decimal the result is Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**log(Decimal)**

Returns the base 10 logarithm of the argument. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \log(100) = 2.0 \).

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the base 10 log of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the base 10 log of the argument.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the base 10 log of the argument. If the String cannot be converted to a Decimal the result is Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**lower(String)**

Returns the lowercase version of the given String. Non-string arguments are converted to Strings using the standard conversion rules. Supported by SQL version 2015-10-8 and later.

Examples:
lower("HELLO") = "hello".
lower(['HELLO']) = ['hello'].

**lpad(String, Int)**

Returns the String argument, padded on the left side with the number of spaces specified by the second argument. The Int argument must be between 0 and 1000. If the provided value is outside of this valid range, the argument will be set to the nearest valid value (0 or 1000). Supported by SQL version 2015-10-8 and later.

Examples:

lpad("hello", 2) = " hello".
lpad(1, 3) = " 1"

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Int</td>
<td>String, the provided String with a number of spaces specified by Int</td>
</tr>
<tr>
<td>String</td>
<td>Decimal</td>
<td>The Decimal argument will be rounded down to the nearest Int and the String is padded on the left with the specified number of spaces.</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
<td>The second argument will be converted to a Decimal, which is rounded down to the nearest Int, and the String is padded with the specified number of spaces on the left. If the second argument cannot be converted to an Int, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Int/Decimal/String</td>
<td>The first value will be converted to a String using standard conversions, and then the LPAD function will be applied on that String. If it cannot be converted, the result is Undefined.</td>
</tr>
<tr>
<td>Any Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**ltrim(String)**

Removes all leading whitespace (tabs and spaces) from the provided String. Supported by SQL version 2015-10-8 and later.

Example:

ltrim(" h i ") = "hi".

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The String representation of the Int with all leading whitespace removed.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The String representation of the Decimal with all leading whitespace removed.</td>
</tr>
<tr>
<td>Argument Type</td>
<td>Result</td>
</tr>
<tr>
<td>---------------</td>
<td>--------</td>
</tr>
<tr>
<td>Boolean</td>
<td>The String representation of the boolean (&quot;true&quot; or &quot;false&quot;) with all leading whitespace removed.</td>
</tr>
<tr>
<td>String</td>
<td>The argument with all leading whitespace removed.</td>
</tr>
<tr>
<td>Array</td>
<td>The String representation of the Array (using standard conversion rules) with all leading whitespace removed.</td>
</tr>
<tr>
<td>Object</td>
<td>The String representation of the Object (using standard conversion rules) with all leading whitespace removed.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**machinelearning_predict(modelId)**

Use the `machinelearning_predict` function to make predictions using the data from an MQTT message based on an Amazon Machine Learning (Amazon ML) model. Supported by SQL version 2015-10-8 and later. The arguments for the `machinelearning_predict` function are:

**modelId**

The ID of the model against which to run the prediction. The real-time endpoint of the model must be enabled.

**roleArn**

The IAM role that has a policy with `machinelearning:Predict` and `machinelearning:GetMLModel` permissions and allows access to the model against which the prediction is run.

**record**

The data to be passed into the Amazon ML Predict API. This should be represented as a single layer JSON object. If the record is a multi-level JSON object, the record will be flattened by serializing its values. For example, the following JSON:

```json
{ "key1": {"innerKey1": "value1"}, "key2": 0 }
```

would become:

```json
{ "key1": "{"innerKey1": "value1"}", "key2": 0 }
```

The function returns a JSON object with the following fields:

**predictedLabel**

The classification of the input based on the model.

**details**

Contains the following attributes:

- **PredictiveModelType**
  
  The model type. Valid values are REGRESSION, BINARY, MULTICLASS.
Algorithm

The algorithm used by Amazon ML to make predictions. The value must be SGD.

predictedScores

Contains the raw classification score corresponding to each label.

predictedValue

The value predicted by Amazon ML.

**mod(Decimal, Decimal)**

Returns the remainder of the division of the first argument by the second argument. Supported by SQL version 2015-10-8 and later. You can also use "%" as an infix operator for the same modulo functionality. Supported by SQL version 2015-10-8 and later.

Example: \( \text{mod}(8, 3) = 2 \).

<table>
<thead>
<tr>
<th>Left Operand</th>
<th>Right Operand</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>Int, the first argument.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>Decimal, the first argument.</td>
</tr>
<tr>
<td>String/Int/Decimal</td>
<td>String/Int/Decimal</td>
<td>If all strings convert to Float, argument modulo the second operand. Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**nanvl(AnyValue, AnyValue)**

Returns the first argument if it is a valid Decimal. Otherwise, the second argument is returned. Supported by SQL version 2015-10-8 and later.

Example: \( \text{nanvl}(8, 3) = 8 \).

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>Any Value</td>
<td>The second argument.</td>
</tr>
<tr>
<td>Null</td>
<td>Any Value</td>
<td>The second argument.</td>
</tr>
<tr>
<td>Decimal (NaN)</td>
<td>Any Value</td>
<td>The second argument.</td>
</tr>
<tr>
<td>Decimal (not NaN)</td>
<td>Any Value</td>
<td>The first argument.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Any Value</td>
<td>The first argument.</td>
</tr>
</tbody>
</table>

**newuuid()**

Returns a random 16-byte UUID. Supported by SQL version 2015-10-8 and later.

Example: \( \text{newuuid}() = 123a4567-b89c-12d3-e456-789012345000 \)
numbytes(String)

Returns the number of bytes in the UTF-8 encoding of the provided string. Standard conversion rules apply to non-String arguments. Supported by SQL version 2015-10-8 and later.

Examples:

numbytes("hi") = 2
numbytes("€") = 3

principal()

Returns the X.509 certificate fingerprint or thing name, depending on which endpoint, MQTT or HTTP, received the request. Supported by SQL version 2015-10-8 and later.

Example:

principal() = "ba67293af50bf2506f5f93469686da660c7c844e7b3950bff16813e0d31e9373"

parse_time(String, Long, [String])

Use the parse_time function to format a timestamp into a human-readable date/time format. Supported by SQL version 2016-03-23 and later. The arguments for the parse_time function are:

- pattern
  - (String) A date/time pattern which conforms to the ISO 8601 standard format. (Specifically, the function supports Joda-Time formats.)
- timestamp
  - (Long) The time to be formatted in milliseconds since Unix epoch. See function timestamp() (p. 223).
- timezone
  - (String) [Optional] The time zone of the formatted date/time. The default is "UTC". The function supports Joda-Time time zones

Examples:

When this message is published to the topic 'A/B', the payload{"ts": "1970.01.01 AD at 21:46:40 CST"} will be sent to the S3 bucket:

```json
{
"rule": {
  "awsIotSqlVersion": "2016-03-23",
  "sql": "SELECT parse_time(yyyy.MM.dd G 'at' HH:mm:ss z", 100000000, "America/Belize" ) as ts FROM 'A/B'",
  "ruleDisabled": false,
  "actions": [
    {
      "s3": {
        "roleArn": "arn:aws:iam::ACCOUNT_ID:role/ROLE_NAME",
        "bucketName": "BUCKET_NAME",
        "key": "KEY_NAME"
      }
    }
  ]
},
"ruleName": "RULE_NAME"
```
When this message is published to the topic 'A/B', a payload similar to {"ts": "2017.06.09 AD at 17:19:46 UTC"} (but with the current date/time) will be sent to the S3 bucket:

```json
{
   "rule": {
      "awsIotSqlVersion": "2016-03-23",
      "sql": "SELECT parse_time("yyyy.MM.dd G 'at' HH:mm:ss z", timestamp()) as ts FROM 'A/B'",
      "ruleDisabled": false,
      "actions": [
         {
            "s3": {
               "roleArn": "arn:aws:iam::ACCOUNT_ID:rule:role/ROLE_NAME",
               "bucketName": "BUCKET_NAME",
               "key": "KEY_NAME"
            }
         }
      ],
      "ruleName": "RULE_NAME"
   }
}
```

`parse_time()` can also be used as a substitution template. For example, when this message is published to the topic 'A/B', the payload will be sent to the S3 bucket with key = "2017":

```json
{
   "rule": {
      "awsIotSqlVersion": "2016-03-23",
      "sql": "SELECT * FROM 'A/B'",
      "ruleDisabled": false,
      "actions": [
         {
            "s3": {
               "roleArn": "arn:aws:iam::ACCOUNT_ID:rule:role/ROLE_NAME",
               "bucketName": "BUCKET_NAME",
               "key": "${parse_time("yyyy", timestamp(), "UTC")}" 
            }
         }
      ],
      "ruleName": "RULE_NAME"
   }
}
```

### power(Decimal, Decimal)

Returns the first argument raised to the second argument. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later. Supported by SQL version 2015-10-8 and later.

Example: `power(2, 5) = 32.0`.

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>A Decimal (with double precision raised to the second argument)</td>
</tr>
</tbody>
</table>
## Functions

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int/Decimal/String</td>
<td>Int/Decimal/String</td>
<td>A Decimal (with double precision) raised to the second argument’s power. Any strings are converted to Decimals. If any String fails to be converted to Decimal, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### rand()

Returns a pseudorandom, uniformly distributed double between 0.0 and 1.0. Supported by SQL version 2015-10-8 and later.

Example:

`rand() = 0.8231909191640703`

### regexp_matches(String, String)

Returns whether the first argument contains a match for the second argument (regex).

Example:

`Regexp_matches("aaaa", "a\{2,\}) = true.`

`Regexp_matches("aaaa", "b") = false.`

#### First argument:

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The String representation of the Int.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The String representation of the Decimal.</td>
</tr>
<tr>
<td>Boolean</td>
<td>The String representation of the boolean (&quot;true&quot; or &quot;false&quot;).</td>
</tr>
<tr>
<td>String</td>
<td>The String.</td>
</tr>
<tr>
<td>Array</td>
<td>The String representation of the Array (using standard conversion rules).</td>
</tr>
<tr>
<td>Object</td>
<td>The String representation of the Object (using standard conversion rules).</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

#### Second argument:

Must be a valid regex expression. Non-string types are converted to String using the standard conversion rules. Depending on the type, the resultant string may or may not be a valid regular expression. If the (converted) argument is not valid regex, the result is Undefined.

#### Third argument:
Must be a valid regex replacement string. (Can reference capture groups.) Non-string types will be converted to String using the standard conversion rules. If the (converted) argument is not a valid regex replacement string, the result is Undefined.

**regexp_replace(String, String, String)**

Replaces all occurrences of the second argument (regular expression) in the first argument with the third argument. Reference capture groups with "\$". Supported by SQL version 2015-10-8 and later.

Example:

Regexp_replace("abcd", "bc", "x") = "axd".

Regexp_replace("abcd", "b(.*)d", "$1") = "ac".

**First argument:**

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The String representation of the Int.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The String representation of the Decimal.</td>
</tr>
<tr>
<td>Boolean</td>
<td>The String representation of the boolean (&quot;true&quot; or &quot;false&quot;).</td>
</tr>
<tr>
<td>String</td>
<td>The source value.</td>
</tr>
<tr>
<td>Array</td>
<td>The String representation of the Array (using standard conversion rules).</td>
</tr>
<tr>
<td>Object</td>
<td>The String representation of the Object (using standard conversion rules).</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**Second argument:**

Must be a valid regex expression. Non-string types are converted to Strings using the standard conversion rules. Depending on the type, the resultant string may or may not be a valid regular expression. If the (converted) argument is not a valid regex expression, the result is Undefined.

**Third argument:**

Must be a valid regex replacement string. (Can reference capture groups.) Non-string types will be converted to Strings using the standard conversion rules. If the (converted) argument is not a valid regex replacement string, the result is Undefined.

**regexp_substr(String, String)**

Finds the first match of the 2nd parameter (regex) in the first parameter. Reference capture groups with "\$". Supported by SQL version 2015-10-8 and later.

Example:

regexp_substr("hihihello", "hi") => "hi"

regexp_substr("hihihello", "(hi)*") => "hihi".
**First argument:**

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The String representation of the Int.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The String representation of the Decimal.</td>
</tr>
<tr>
<td>Boolean</td>
<td>The String representation of the boolean (&quot;true&quot; or &quot;false&quot;).</td>
</tr>
<tr>
<td>String</td>
<td>The String argument.</td>
</tr>
<tr>
<td>Array</td>
<td>The String representation of the Array (using standard conversion rules).</td>
</tr>
<tr>
<td>Object</td>
<td>The String representation of the Object (using standard conversion rules).</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**Second argument:**

Must be a valid regex expression. Non-string types are converted to Strings using the standard conversion rules. Depending on the type, the resultant string may or may not be a valid regular expression. If the (converted) argument is not a valid regex expression, the result is Undefined.

**Third argument:**

Must be a valid regex replacement string. (Can reference capture groups.) Non-string types will be converted to String using the standard conversion rules. If the argument is not a valid regex replacement string, the result is Undefined.

**rpad(String, Int)**

Returns the string argument, padded on the right side with the number of spaces specified in the second argument. The Int argument must be between 0 and 1000. If the provided value is outside of this valid range, the argument will be set to the nearest valid value (0 or 1000). Supported by SQL version 2015-10-8 and later.

Examples:

rpad("hello", 2) = "hello ".

rpad(1, 3) = "1 ".

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Int</td>
<td>The String is padded on the right side with a number</td>
</tr>
<tr>
<td>argument Type 1</td>
<td>argument Type 2</td>
<td>Result</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------</td>
<td>--------</td>
</tr>
<tr>
<td>String</td>
<td>Decimal</td>
<td>The Decimal argument will be rounded down to the nearest Int and the string is padded on the right side with a number of spaces equal to the provided Int.</td>
</tr>
<tr>
<td>argument Type 1</td>
<td>argument Type 2</td>
<td>Result</td>
</tr>
<tr>
<td>----------------</td>
<td>----------------</td>
<td>--------</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

The second argument will be converted to a Decimal, which is rounded down to the nearest Int. The String is padded on the right side with a number of spaces equal to the Int value.
### round(Decimal)

Rounds the given Decimal to the nearest Int. If the Decimal is equidistant from two Int values (for example, 0.5), the Decimal is rounded up. Supported by SQL version 2015-10-8 and later.

**Example:**
- \(\text{Round}(1.2) = 1.\)
- \(\text{Round}(1.5) = 2.\)
- \(\text{Round}(1.7) = 2.\)
- \(\text{Round}(-1.1) = -1.\)
- \(\text{Round}(-1.5) = -2.\)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal is rounded down to the nearest Int.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal is rounded down to the nearest Int. If the string cannot be converted to a Decimal, the result is Undefined.</td>
</tr>
</tbody>
</table>

### Other Value

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other Value</td>
<td>Int/Decimal/String</td>
<td>The first value will be converted to a String using the standard conversions, and the rpad function will be applied on that String. If it cannot be converted, the result is Undefined.</td>
</tr>
</tbody>
</table>

<p>| Any Value       | Other Value     | Undefined. |</p>
<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**rtrim(String)**

Removes all trailing whitespace (tabs and spaces) from the provided String. Supported by SQL version 2015-10-8 and later.

Examples:

```
rtrim(" h i ") = " h i"
```

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The String representation of the Int.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The String representation of the Decimal.</td>
</tr>
<tr>
<td>Boolean</td>
<td>The String representation of the boolean (&quot;true&quot; or &quot;false&quot;).</td>
</tr>
<tr>
<td>Array</td>
<td>The String representation of the Array (using standard conversion rules).</td>
</tr>
<tr>
<td>Object</td>
<td>The String representation of the Object (using standard conversion rules).</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**sign(Decimal)**

Returns the sign of the given number. When the sign of the argument is positive, 1 is returned. When the sign of the argument is negative, -1 is returned. If the argument is 0, 0 is returned. Supported by SQL version 2015-10-8 and later.

Examples:

```
sign(-7) = -1.
sign(0) = 0.
sign(13) = 1.
```

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int, the sign of the Int value.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Int, the sign of the Decimal value.</td>
</tr>
<tr>
<td>String</td>
<td>Int, the sign of the Decimal value. The string is converted to a Decimal value, and the sign of the Decimal value is returned. If the String cannot be converted to a Decimal, the result is Undefined. Supported by SQL version 2015-10-8 and later.</td>
</tr>
<tr>
<td>Argument Type</td>
<td>Result</td>
</tr>
<tr>
<td>---------------</td>
<td>--------</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### sin(Decimal)

Returns the sine of a number in radians. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \sin(0) = 0.0 \)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the sine of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the sine of the argument.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the sine of the argument. If the string cannot be converted to a Decimal, the result is Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### sinh(Decimal)

Returns the hyperbolic sine of a number. Decimal values are rounded to double precision before function application. The result is a Decimal value of double precision. Supported by SQL version 2015-10-8 and later.

Example: \( \sinh(2.3) = 4.936961805545957 \)
Argument Type | Result
--- | ---
Object | Undefined.
Null | Undefined.
Undefined | Undefined.

**substring(String, Int [, Int])**

Expects a String followed by one or two Int values. For a String and a single Int argument, this function returns the substring of the provided String from the provided Int index (0-based, inclusive) to the end of the String. For a String and two Int arguments, this function returns the substring of the provided String from the first Int index argument (0-based, inclusive) to the second Int index argument (0-based, exclusive). Indices that are less than zero will be set to zero. Indices that are greater than the String length will be set to the String length. For the three argument version, if the first index is greater than (or equal to) the second index, the result is the empty String.

If the arguments provided are not (String, Int), or (String, Int, Int), the standard conversions will be applied to the arguments to attempt to convert them into the correct types. If the types cannot be converted, the result of the function is Undefined. Supported by SQL version 2015-10-8 and later.

Examples:

substring("012345", 0) = "012345".
substring("012345", 2) = "2345".
substring("012345", 2.745) = "2345".
substring(123, 2) = "3".
substring("012345", -1) = "012345".
substring(true, 1.2) = "rue".
substring(false, -2.411E247) = "false".
substring("012345", 1, 3) = "12".
substring("012345", -50, 50) = "012345".
substring("012345", 3, 1) = ".

**sqrt(Decimal)**

Returns the square root of a number. Decimal arguments are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \text{sqrt}(9) = 3.0 \).
### startswith(String, String)

Returns Boolean, whether the first string argument starts with the second string argument. If either argument is Null or Undefined, the result is Undefined. Supported by SQL version 2015-10-8 and later.

**Example:**

```sql
startswith("ranger", "ran") = true
```

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>String</td>
<td>Whether the first string starts with the second string. Both arguments will be converted to Strings using the standard conversion rules. Returns whether the first string starts with the second string. If either argument is Null or Undefined, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Other Value</td>
<td></td>
</tr>
</tbody>
</table>

### tan(Decimal)

Returns the tangent of a number in radians. Decimal values are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

**Example:**

```sql
tan(3) = -0.1425465430742778
```

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the tangent of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the tangent of the argument.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the tangent of the argument. If the string cannot be converted to a Decimal, the result is Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Argument Type</td>
<td>Result</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**tanh(Decimal)**

Returns the hyperbolic tangent of a number in radians. Decimal values are rounded to double precision before function application. Supported by SQL version 2015-10-8 and later.

Example: \( \text{tanh}(2.3) = 0.9800963962661914 \)

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Decimal (with double precision), the hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal (with double precision), the hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Undefined.</td>
</tr>
<tr>
<td>String</td>
<td>Decimal (with double precision), the hyperbolic tangent of the argument. If the string cannot be converted to a Decimal, the result is Undefined.</td>
</tr>
<tr>
<td>Array</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Object</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

**timestamp()**

Returns the current timestamp in milliseconds from 00:00:00 Coordinated Universal Time (UTC), Thursday, 1 January 1970, as observed by the AWS IoT rules engine. Supported by SQL version 2015-10-8 and later.

Example: \( \text{timestamp()} = 1481825251155 \)

**topic(Decimal)**

Returns the topic to which the message that triggered the rule was sent. If no parameter is specified, the entire topic is returned. The Decimal parameter is used to specify a specific, one-based topic segment. For the topic `foo/bar/baz`, topic(1) will return `foo`, topic(2) will return `bar`, and so on. Supported by SQL version 2015-10-8 and later.

Examples:

```
topic() = "things/myThings/thingOne"
topic(1) = "things"
```
**traceid()**

Returns the trace ID (UUID) of the MQTT message, or Undefined if the message wasn’t sent over MQTT. Supported by SQL version 2015-10-8 and later.

Example:

```sql
traceid() = "12345678-1234-1234-1234-123456789012"
```

**trunc(Decimal, Int)**

Truncates the first argument to the number of Decimal places specified by the second argument. If the second argument is less than zero, it will be set to zero. If the second argument is greater than 34, it will be set to 34. Trailing zeroes are stripped from the result. Supported by SQL version 2015-10-8 and later.

Examples:

```sql
trunc(2.3, 0) = 2.
trunc(2.3123, 2) = 2.31.
trunc(2.888, 2) = 2.88.
(2.00, 5) = 2.
```

<table>
<thead>
<tr>
<th>argument Type 1</th>
<th>argument Type 2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>Int</td>
<td>The source value.</td>
</tr>
<tr>
<td>Int/Decimal</td>
<td>Int/Decimal</td>
<td>The first argument is truncated to the length described by the second argument. The second argument, if not an Int, will be rounded down to the nearest Int. Strings are converted to Decimal values. If the string conversion fails, the result is Undefined.</td>
</tr>
<tr>
<td>Int/Decimal/String</td>
<td>Int/Decimal/String</td>
<td>The first argument is truncated to the length described by the second argument. The second argument, if not an Int, will be rounded down to the nearest Int. Strings are converted to Decimal values. If the string conversion fails, the result is Undefined.</td>
</tr>
<tr>
<td>Other Value</td>
<td>Undefined</td>
<td></td>
</tr>
</tbody>
</table>

**trim(String)**

Removes all leading and trailing whitespace from the provided String. Supported by SQL version 2015-10-8 and later.

Example:

```sql
Trim( " hi " ) = "hi"
```

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
<td>The String representation of the Int with all leading and trailing whitespace removed.</td>
</tr>
<tr>
<td>Decimal</td>
<td>The String representation of the Decimal with all leading and trailing whitespace removed.</td>
</tr>
</tbody>
</table>
### Argument Type

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>The String representation of the Boolean (&quot;true&quot; or &quot;false&quot;) with all leading and trailing whitespace removed.</td>
</tr>
<tr>
<td>String</td>
<td>The String with all leading and trailing whitespace removed.</td>
</tr>
<tr>
<td>Array</td>
<td>The String representation of the Array using standard conversion rules.</td>
</tr>
<tr>
<td>Object</td>
<td>The String representation of the Object using standard conversion rules.</td>
</tr>
<tr>
<td>Null</td>
<td>Undefined.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined.</td>
</tr>
</tbody>
</table>

### upper(String)

Returns the uppercase version of the given String. Non-String arguments are converted to String using the standard conversion rules. Supported by SQL version 2015-10-8 and later.

#### Examples:

- `upper("hello") = "HELLO"
- `upper(["hello"]) = ["HELLO"]`

### SELECT Clause

The AWS IoT SELECT clause is essentially the same as the ANSI SQL SELECT clause, with some minor differences.

You can use the SELECT clause to extract information from incoming MQTT messages. `SELECT *` can be used to retrieve the entire incoming message payload. For example:

```
Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL statement: SELECT * FROM 'a/b'
Outgoing payload: {"color":"red", "temperature":50}
```

If the payload is a JSON object, you can reference keys in the object. Your outgoing payload will contain the key-value pair. For example:

```
Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL statement: SELECT color FROM 'a/b'
Outgoing payload: {"color":"red"}
```

You can use the AS keyword to rename keys. For example:

```
Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL:SELECT color AS my_color FROM 'a/b'
Outgoing payload: {"my_color":"red"}
```

You can select multiple items by separating them with a comma. For example:
Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL: SELECT color as my_color, temperature as farenheit FROM 'a/b'
Outgoing payload: {"my_color":"red","farenheit":50}

You can select multiple items including '*' to add items to the incoming payload. For example:

Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL: SELECT *, 15 as speed FROM 'a/b'
Outgoing payload: {"color":"red", "temperature":50, speed:15}"

You can use the "VALUE" keyword to produce outgoing payloads that are not JSON objects. You may only select one item. For example:

Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL: SELECT VALUE color FROM 'a/b'
Outgoing payload: "red"

You can use '.' syntax to drill into nested JSON objects in the incoming payload. For example:

Incoming payload published on topic 'a/b': {"color":{"red":255,"green":0,"blue":0}, "temperature":50}
SQL: SELECT color.red as red_value FROM 'a/b'
Outgoing payload: {"red_value":255}

You can use functions (see Functions (p. 192)) to transform the incoming payload. Parentheses can be used for grouping. For example:

Incoming payload published on topic 'a/b': {"color":"red", "temperature":50}
SQL: SELECT (temperature – 32) * 5 / 9 AS celsius, upper(color) as my_color FROM 'a/b'
Outgoing payload: {"celsius":10,"my_color":"RED"}

Working with Binary Payloads

When the message payload should be handled as raw binary data (rather than a JSON object), you can use the * operator to refer to it in a SELECT clause.

These rules must be followed to use * to refer to the message payload as raw binary data:
1. The SQL statement and templates must not refer to JSON names, other than *.
2. The SELECT statement must have * as the only item, or must have only functions, for example:

```
SELECT * FROM 'a/b'
```

```
SELECT encode(*, 'base64') AS data, timestamp() AS ts FROM 'a/b'
```

Binary Payload Examples

The following SELECT clause can be used with binary payloads because it doesn't refer to any JSON names.

```
SELECT * FROM 'a/b'
```
The following `SELECT` can not be used with binary payloads because it refers to `device_type` in the `WHERE` clause.

```
SELECT * FROM 'a/b' WHERE device_type = 'thermostat'
```

The following `SELECT` can not be used with binary payloads because it violates rule #2.

```
SELECT *, timestamp() AS timestamp FROM 'a/b'
```

The following `SELECT` can be used with binary payloads because it doesn't violate either rule #1 or #2.

```
SELECT * FROM 'a/b' WHERE timestamp() % 12 = 0
```

The following AWS IoT rule can not be used with payloads because it violates rule #1.

```
{
  "sql": "SELECT * FROM 'a/b'"
  "actions": [{
    "republish": {
      "topic": "device/${device_id}"
    }
  ]
}
```

FROM Clause

The FROM clause subscribes your rule to a topic or topic filter. A topic filter allows you to subscribe to a group of similar topics.

Example:

Incoming payload published on topic 'a/b': {temperature: 50}

Incoming payload published on topic 'a/c': {temperature: 50}

SQL: "SELECT temperature AS t FROM 'a/b".

The rule is subscribed to 'a/b', so the incoming payload is passed to the rule, and the outgoing payload (passed to the rule actions) is: {t: 50}. The rule is not subscribed to 'a/c', so the rule is not triggered for the message published on 'a/c'.

You can use the # wildcard character to match any subpath in a topic filter:

Example:

Incoming payload published on topic 'a/b': {temperature: 50}.

Incoming payload published on topic 'a/c': {temperature: 60}.

Incoming payload published on topic 'a/e/f': {temperature: 70}.

Incoming payload published on topic 'b/x': {temperature: 80}.

SQL: "SELECT temperature AS t FROM 'a/#".

The rule is subscribed to any topic beginning with 'a', so it is executed three times, sending outgoing payloads of {t: 50} (for a/b), {t: 60} (for a/c), and {t: 70} (for a/e/f) to its actions. It is not subscribed to 'b/x', so the rule will not be triggered for the {temperature: 80} message.
You can use the '+' character to match any one particular path element:

Example:

Incoming payload published on topic 'a/b': {temperature: 50}.
Incoming payload published on topic 'a/c': {temperature: 60}.
Incoming payload published on topic 'a/e/f': {temperature: 70}.
Incoming payload published on topic 'b/x': {temperature: 80}.

SQL: "SELECT temperature AS t FROM 'a/+'."

The rule is subscribed to all topics with two path elements where the first element is 'a'. The rule is executed for the messages sent to 'a/b' and 'a/c', but not 'a/e/f' or 'b/x'.

You can use functions and operators in the WHERE clause. In the WHERE clause, you cannot reference any aliases created with the AS keyword in the SELECT. (The WHERE clause is evaluated first, to determine if the SELECT clause is evaluated.)

**WHERE Clause**

The WHERE clause determines if a rule is evaluated for a message sent to an MQTT topic to which the rule is subscribed. If the WHERE clause evaluates to true, the rule is evaluated. Otherwise, the rule is not evaluated.

Example:

Incoming payload published on a/b: {"color":"red", "temperature":40}.

SQL: SELECT color AS my_color FROM 'a/b' WHERE temperature > 50 AND color <> 'red'.

In this case, the rule would not be evaluated; there would be no outgoing payload; and rules actions would not be triggered.

You can use functions and operators in the WHERE clause. However, you cannot reference any aliases created with the AS keyword in the SELECT. (The WHERE clause is evaluated first, to determine if SELECT is evaluated.)

**Literals**

You can directly specify literal objects in the SELECT and WHERE clauses of your rule SQL, which can be useful for passing information.

**Note**

Literals are only available when using SQL Version 2016-03-23 or newer.

JSON object syntax is used (key-value pairs, comma-separated, where keys are strings and values are JSON values, wrapped in curly brackets {}). For example:

Incoming payload published on topic a/b: "{lat_long: [47.606,-122.332]}"

SQL statement: SELECT {'latitude': get(lat_long, 0),'longitude':get(lat_long, 1)} as lat_long FROM 'a/b'

The resulting outgoing payload would be: {'latitude':47.606, 'longitude':-122.332}. 
You can also directly specify arrays in the SELECT and WHERE clauses of your rule SQL, which allows you to group information. JSON syntax is used (wrap comma-separated items in square brackets [] to create an array literal). For example:

Incoming payload published on topic a/b: {lat: 47.696, long: -122.332}

SQL statement: SELECT [lat,long] as lat_long FROM 'a/b'

The resulting output payload would be: {"lat_long": [47.606,-122.332]}

**Case Statements**

Case statements can be used for branching execution, like a switch statement, or if/else statements.

**Syntax:**

```
CASE v WHEN t[1] THEN r[1]
    WHEN t[2] THEN r[2] ...
    WHEN t[n] THEN r[n]
    ELSE r[e] END
```

The expression v is evaluated and matched for equality against each t[i] expression. If a match is found, the corresponding r[i] expression becomes the result of the case statement. If there is more than one possible match, the first match is selected. If there are no matches, the else statement's re is used as the result. If there is no match and no else statement, the result of the case statement is Undefined. For example:

Incoming payload published on topic a/b: {"color":"yellow"}

SQL statement: SELECT CASE color WHEN 'green' THEN 'go' WHEN 'yellow' THEN 'caution' WHEN 'red' THEN 'stop' ELSE 'you are not at a stop light' END AS instructions FROM 'a/b'

The resulting output payload would be: {"instructions":"caution"}.

Case statements require at least one WHEN clause. An ELSE clause is not required.

**Note**

If v is Undefined, the result of the case statement is Undefined.

**JSON Extensions**

You can use the following extensions to ANSI SQL syntax to make it easier to work with nested JSON objects.

**."" Operator**

This operator accesses members in embedded JSON objects and functions identically to ANSI SQL and JavaScript. For example:

```
SELECT foo.bar AS bar.baz FROM 'a/b'
```

**"*" Operator**

This functions in the same way as the * wildcard in ANSI SQL. It's used in the SELECT clause only and creates a new JSON object containing the message data. If the message payload is not in JSON format, * returns the entire message payload as raw bytes. For example:
Applying a Function to an Attribute Value

The following is an example JSON payload that could be published by a device:

```json
{
    "deviceid" : "iot123",
    "temp" : 54.98,
    "humidity" : 32.43,
    "coords" : {
        "latitude" : 47.615694,
        "longitude" : -122.3359976
    }
}
```

The following example applies a function to an attribute value in a JSON payload:

```sql
SELECT temp, md5(deviceid) AS hashed_id FROM topic/#
```

The result of this query is the following JSON object:

```json
{
    "temp": 54.98,
    "hashed_id": "e37f81fb397e595c4aeb5645b8cbbbd1"
}
```

Substitution Templates

You can use a substitution template to augment the JSON data returned when a rule is triggered and AWS IoT performs an action. The syntax for a substitution template is `${expression}`, where `expression` can be any expression supported by AWS IoT in SELECT or WHERE clauses. For more information about supported expressions, see AWS IoT SQL Reference (p. 182).

Substitution templates appear in the SELECT clause within a rule:

```json
{
    "sql": "SELECT *, topic() AS topic FROM 'my/iot/topic'",
    "ruleDisabled": false,
    "actions": [{
        "republish": {
            "topic": "${topic()}/republish",
            "roleArn": "arn:aws:iam::123456789012:role/my-iot-role"
        }
    }]
}
```

If this rule is triggered by the following JSON:

```json
{
    "deviceid" : "iot123",
    "temp" : 54.98,
    "humidity" : 32.43,
    "coords" : {
        "latitude" : 47.615694,
        "longitude" : -122.3359976
    }
}
```
Here is the output of the rule:

```json
{
    "coords":{
        "longitude":-122.3359976,
        "latitude":47.615694
    },
    "humidity":32.43,
    "temp":54.98,
    "deviceid":"iot123",
    "topic":"my/iot/topic"
}
```
Thing Shadows for AWS IoT

A thing shadow (sometimes referred to as a device shadow) is a JSON document that is used to store and retrieve current state information for a thing (device, app, and so on). The Thing Shadows service maintains a thing shadow for each thing you connect to AWS IoT. You can use thing shadows to get and set the state of a thing over MQTT or HTTP, regardless of whether the thing is connected to the Internet. Each thing shadow is uniquely identified by its name.

- Thing Shadow Document Syntax (p. 260)
- Thing Shadow Error Messages (p. 262)

Thing Shadows Data Flow

The Thing Shadows service acts as an intermediary, allowing devices and applications to retrieve and update thing shadows.

To illustrate how devices and applications communicate with the Thing Shadows service, this section walks you through the use of the AWS IoT MQTT client and the AWS CLI to simulate communication between an internet-connected light bulb, an application, and the Thing Shadows service.

The Thing Shadows service uses MQTT topics to facilitate communication between applications and devices. To see how this works, use the AWS IoT MQTT client to subscribe to the following MQTT topics with QoS 1:

$aws/things/myLightBulb/shadow/update/accepted

The Thing Shadows service sends messages to this topic when an update is successfully made to the thing shadow.

$aws/things/myLightBulb/shadow/update/rejected

The Thing Shadows service sends messages to this topic when an update to the thing shadow is rejected.

$aws/things/myLightBulb/shadow/update/delta

The Thing Shadows service sends messages to this topic when a difference is detected between the reported and desired sections of the thing shadow. For more information, see /update/delta (p. 256).

$aws/things/myLightBulb/shadow/get/accepted

The Thing Shadows service sends messages to this topic when a request for the thing shadow is made successfully.

$aws/things/myLightBulb/shadow/get/rejected

The Thing Shadows service sends messages to this topic when a request for the thing shadow is rejected.
$aws/things/myLightBulb/shadow/delete/accepted

The Thing Shadows service sends messages to this topic when the thing shadow is deleted.

$aws/things/myLightBulb/shadow/delete/rejected

The Thing Shadows service sends messages to this topic when a request to delete the thing shadow is rejected.

$aws/things/myLightBulb/shadow/update/documents

The Thing Shadows service publishes a state document to this topic whenever an update to the thing shadow is successfully performed.

To learn more about all of the MQTT topics used by the Thing Shadows service, see Thing Shadow MQTT Topics (p. 253).

Note

We recommend that you subscribe to the .../rejected topics to see any errors sent by the Thing Shadows service.

When the light bulb comes online, it sends its current state to the Thing Shadows service by sending an MQTT message to the $aws/things/myLightBulb/shadow/update topic.

To simulate this, use the AWS IoT MQTT client to publish the following message to the $aws/things/myLightbulb/shadow/update topic:

```json
{
   "state": {
      "reported": {
         "color": "red"
      }
   }
}
```

This message sets the color of the light bulb to "red."

The Thing Shadows service responds by sending the following message to the $aws/things/myLightBulb/shadow/update/accepted topic:

```json
{
   "messageNumber": 4,
   "payload": {
      "state": {
         "reported": {
            "color": "red"
         }
      },
      "metadata": {
         "reported": {
            "color": {
            "timestamp": 1469564492
            }
         }
      },
      "version": 1,
      "timestamp": 1469564492
   },
   "qos": 0,
   "timestamp": 1469564492848,
   "topic": "$aws/things/myLightBulb/shadow/update/accepted"
}
```
This message indicates the Thing Shadows service received the UPDATE request and updated the thing shadow. If the thing shadow doesn't exist, it is created. Otherwise, the thing shadow is updated with the data in the message. If you don’t see a message published to $aws/things/myLightBulb/shadow/update/accepted, check the subscription to $aws/things/myLightBulb/shadow/update/rejected to see any error messages.

In addition, the Thing Shadows service publishes the following message to the $aws/things/myLightBulb/shadow/update/documents topic.

```
{
    "previous":null,
    "current":{
        "state":{
            "reported":{
                "color":"red"
            }
        },
        "metadata":{
            "reported":{
                "color":{
                    "timestamp":1483467764
                }
            }
        },
        "version":1
    },
    "timestamp":1483467764
}
```

Messages are published to the /update/documents topic whenever an update to the thing shadow is successfully performed. For more information of the contents of messages published to this topic, see Thing Shadow MQTT Topics (p. 253).

An application that interacts with the light bulb comes online and requests the light bulb's current state. The application sends an empty message to the $aws/things/myLightBulb/shadow/get topic. To simulate this, use the AWS IoT MQTT client to publish an empty message ("") to the $aws/things/myLightBulb/shadow/get topic.

The Thing Shadows service responds by publishing the requested thing shadow to the $aws/things/myLightBulb/shadow/get/accepted topic:

```
{
    "messageNumber": 1,
    "payload": {
        "state": {
            "reported": {
                "color": "red"
            }
        },
        "metadata": {
            "reported": {
                "color": {
                    "timestamp": 1469564492
                }
            }
        },
        "version": 1,
        "timestamp": 1469564571
    },
    "qos": 0,
    "timestamp": 1469564571533,
    "topic": "$aws/things/myLightBulb/shadow/get/accepted"
}
```
If you don't see a message on the $aws/things/myLightBulb/shadow/get/accepted topic, check the $aws/things/myLightBulb/shadow/get/rejected topic for any error messages.

The application displays this information to the user, and the user requests a change to the light bulb's color (from red to green). To do this, the application publishes a message on the $aws/things/myLightBulb/shadow/update topic:

```json
{
  "state": {
    "desired": {
      "color": "green"
    }
  }
}
```

To simulate this, use the AWS IoT MQTT client to publish the preceding message to the $aws/things/myLightBulb/shadow/update topic.

The Thing Shadows service responds by sending a message to the $aws/things/myLightBulb/shadow/update/accepted topic:

```json
{
  "messageNumber": 5,
  "payload": {
    "state": {
      "desired": {
        "color": "green"
      }
    },
    "metadata": {
      "desired": {
        "color": {
          "timestamp": 1469564658
        }
      }
    },
    "version": 2,
    "timestamp": 1469564658
  },
  "qos": 0,
  "timestamp": 1469564658286,
  "topic": "$aws/things/myLightBulb/shadow/update/accepted"
}
```

and to the $aws/things/myLightBulb/shadow/update/delta topic:

```json
{
  "messageNumber": 1,
  "payload": {
    "version": 2,
    "timestamp": 1469564658,
    "state": {
      "color": "green"
    },
    "metadata": {
      "color": {
        "timestamp": 1469564658
      }
    }
  }
}
```
The Thing Shadow service publishes a message to this topic when it accepts a thing shadow update and the resulting thing shadow contains different values for desired and reported states.

The Thing Shadow service also publishes a message to the $aws/things/myLightBulb/shadow/update/documents topic:

```
{
  "previous":{
    "state":{
      "reported":{
        "color":"red"
      }
    },
    "metadata":{
      "reported":{
        "color":{
          "timestamp":1483467764
        }
      }
    },
    "version":1
  },
  "current":{
    "state":{
      "desired":{
        "color":"green"
      },
      "reported":{
        "color":"red"
      }
    },
    "metadata":{
      "desired":{
        "color":{
          "timestamp":1483468612
        }
      },
      "reported":{
        "color":{
          "timestamp":1483467764
        }
      }
    },
    "version":2
  },
  "timestamp":1483468612
}
```

The light bulb is subscribed to the $aws/things/myLightBulb/shadow/update/delta topic, so it receives the message, changes its color, and publishes its new state. To simulate this, use the AWS IoT MQTT client to publish the following message to the $aws/things/myLightbulb/shadow/update/topic to update the shadow state:

```
{
  "state":{
    "reported":{
      "color":"green"
    }
  },
  "version":1
}
```
In response, the Thing Shadows service sends a message to the $aws/things/myLightBulb/shadow/update/accepted topic:

```
{
  "messageNumber": 6,
  "payload": {
    "state": {
      "reported": {
        "color": "green"
      },
      "desired": null
    },
    "metadata": {
      "reported": {
        "color": {
          "timestamp": 1469564801
        }
      },
      "desired": {
        "timestamp": 1469564801
      }
    },
    "version": 3,
    "timestamp": 1469564801
  },
  "qos": 0,
  "timestamp": 1469564801673,
  "topic": "$aws/things/myLightBulb/shadow/update/accepted"
}
```

and to the $aws/things/myLightBulb/shadow/update/documents topic:

```
{
  "previous":{
    "state":{
      "reported":{
        "color":"red"
      }
    },
    "metadata":{
      "reported":{
        "color":{
          "timestamp":1483470355
        }
      }
    },
    "version":3
  },
  "current":{
    "state":{
      "reported":{
        "color":"green"
      }
    },
    "metadata":{
      "reported":{
        "color":{
          "timestamp":1483470364
        }
      }
    },
    "version":6
  }
}
```
The app requests the current state from the Thing Shadows service and displays the most recent state data. To simulate this, run the following command:

```bash
aws iot-data get-thing-shadow --thing-name "myLightBulb" "output.txt" && cat "output.txt"
```

**Note**

On Windows, omit the `&& cat "output.txt"`, which displays the contents of output.txt to the console. You can open the file in Notepad or any text editor to see the contents of the thing shadow.

The Thing Shadows service returns the thing shadow document:

```json
{
  "state": {
    "reported": {
      "color": "green"
    }
  },
  "metadata": {
    "reported": {
      "color": {
        "timestamp": 1469564801
      }
    }
  },
  "version": 3,
  "timestamp": 1469564864
}
```

To delete the thing shadow, publish an empty message to the `$aws/things/myLightBulb/shadow/delete` topic. AWS IoT responds by publishing a message to the `$aws/things/myLightBulb/shadow/delete/accepted` topic:

```json
{
  "version": 1,
  "timestamp": 1488565234
}
```

## Detecting a Thing Is Connected

To determine if a device is currently connected, include a connected setting in the thing shadow and use an MQTT Last Will and Testament (LWT) message that sets the connected setting to `false` if a device is disconnected due to error.

**Note**

Currently, LWT messages sent to AWS IoT reserved topics (topics that begin with `$`) are ignored by the AWS IoT Shadows service, but are still processed by subscribed clients and by the AWS IoT rules engine. If you want the AWS IoT Shadows service to receive LWT messages, register an LWT message to a non-reserved topic and create a rule that republishes the message on the reserved topic. The following example shows how to create a republish rule that listens for messages from the `my/things/myLightBulb/update` topic and republishes it to `$aws/things/myLightBulb/shadow/update`. 

---

238
When a device connects, it registers an LWT that sets the connected setting to **false**:

```json
{
    "state": {
        "reported": {
            "connected": "false"
        }
    }
}
```

It also publishes a message on its update topic ($aws/things/myLightBulb/shadow/update), setting its connected state to **true**:

```json
{
    "state": {
        "reported": {
            "connected": "true"
        }
    }
}
```

When the device disconnects gracefully, it publishes a message on its update topic and sets its connected state to **false**:

```json
{
    "state": {
        "reported": {
            "connected": "false"
        }
    }
}
```

If the device disconnects due to an error, its LWT message is posted automatically to the update topic.

## Thing Shadows Documents

The Thing Shadows service respects all rules of the JSON specification. Values, objects, and arrays are stored in the thing shadow document.

### Contents
- Document Properties (p. 240)
Document Properties

A thing shadow document has the following properties:

- **state**
  - **desired**
    - The desired state of the thing. Applications can write to this portion of the document to update the state of a thing without having to directly connect to a thing.
  - **reported**
    - The reported state of the thing. Things write to this portion of the document to report their new state. Applications read this portion of the document to determine the state of a thing.

- **metadata**
  - Information about the data stored in the `state` section of the document. This includes timestamps, in Epoch time, for each attribute in the `state` section, which enables you to determine when they were updated.

- **timestamp**
  - Indicates when the message was transmitted by AWS IoT. By using the timestamp in the message and the timestamps for individual attributes in the `desired` or `reported` section, a thing can determine how old an updated item is, even if it doesn't feature an internal clock.

- **clientToken**
  - A string unique to the device that enables you to associate responses with requests in an MQTT environment.

- **version**
  - The document version. Every time the document is updated, this version number is incremented. Used to ensure the version of the document being updated is the most recent.

For more information, see [Thing Shadow Document Syntax](p. 260).

Versioning of a Thing Shadow

The Thing Shadows service supports versioning on every update message (both request and response), which means that with every update of a thing shadow, the version of the JSON document is incremented. This ensures two things:

- A client can receive an error if it attempts to overwrite a shadow using an older version number. The client is informed it must resync before it can update a thing shadow.
- A client can decide not to act on a received message if the message has a lower version than the version stored by the client.

In some cases, a client might bypass version matching by not submitting a version.
Client Token

You can use a client token with MQTT-based messaging to verify the same client token is contained in a request and request response. This ensures the response and request are associated.

Example Document

Here is an example thing shadow document:

```json
{
  "state": {
    "desired": {
      "color": "RED",
      "sequence": ["RED", "GREEN", "BLUE"]
    },
    "reported": {
      "color": "GREEN"
    }
  },
  "metadata": {
    "desired": {
      "color": {
        "timestamp": 12345
      },
      "sequence": {
        "timestamp": 12345
      }
    },
    "reported": {
      "color": {
        "timestamp": 12345
      }
    }
  },
  "version": 10,
  "clientToken": "UniqueClientToken",
  "timestamp": 123456789
}
```

Empty Sections

A thing shadow document contains a desired section only if it has a desired state. For example, the following is a valid state document with no desired section:

```
{
  "reported": { "temp": 55 }
}
```

The reported section can also be empty:

```
{
  "desired": { "color": "RED" }
}
```

If an update causes the desired or reported sections to become null, the section is removed from the document. To remove the desired section from a document (in response, for example, to a device updating its state), set the desired section to null:
It is also possible a thing shadow document will not contain desired or reported sections. In that case, the shadow document is empty. For example, this is a valid document:

```
{
}
```

## Arrays

Thing shadows support arrays, but treat them as normal values in that an update to an array replaces the whole array. It is not possible to update part of an array.

**Initial state:**

```
{
  "desired": { "colors": ["RED", "GREEN", "BLUE"] }
}
```

**Update:**

```
{
  "desired": { "colors": ["RED"] }
}
```

**Final state:**

```
{
  "desired": { "colors": ["RED"] }
}
```

Arrays can't have null values. For example, the following array is not valid and will be rejected.

```
{
  "desired": {
    "colors": [ null, "RED", "GREEN"]
  }
}
```

## Using Thing Shadows

AWS IoT provides three methods for working with thing shadows:

**UPDATE**

Creates a thing shadow if it doesn't exist, or updates the content of a thing shadow with the data provided in the request. The data is stored with timestamp information to indicate when it was last
updated. Messages are sent to all subscribers with the difference between desired or reported state (delta). Things or apps that receive a message can perform an action based on the difference between desired or reported states. For example, a device can update its state to the desired state, or an app can update its UI to show the change in the device's state.

GET

Retrieves the latest state stored in the thing shadow (for example, during start-up of a device to retrieve configuration and the last state of operation). This method returns the full JSON document, including metadata.

DELETE

Deletes a thing shadow, including all of its content. This removes the JSON document from the data store. You can’t restore a thing shadow you deleted, but you can create a new thing shadow with the same name.

Protocol Support

These methods are supported through both MQTT and a RESTful API over HTTPS. Because MQTT is a publish/subscribe communication model, AWS IoT implements a set of reserved topics. Things or applications subscribe to these topics before publishing on a request topic in order to implement a request–response behavior. For more information, see Thing Shadow MQTT Topics (p. 253) and Thing Shadow RESTful API (p. 251).

Updating a Thing Shadow

You can update a thing shadow by using the UpdateThingShadow (p. 252) RESTful API or by publishing to the /update (p. 254) topic. Updates affect only the fields specified in the request.

Initial state:

```json
{  
  "state": { 
    "reported": { 
      "color": { "r": 255, "g": 255, "b": 0 } 
    } 
  } 
}
```

An update message is sent:

```json
{  
  "state": { 
    "desired": { 
      "color": { "r": 10 }, 
      "engine": "ON" 
    } 
  } 
}
```

The device receives the desired state on the /update/delta topic that is triggered by the previous /update message and then executes the desired changes. When finished, the device should confirm its updated state through the reported section in the thing shadow JSON document.

Final state:

```json
{  
}
```
Retrieving a Thing Shadow Document

You can retrieve a thing shadow by using the GetThingShadow (p. 251) RESTful API or by subscribing and publishing to the /get (p. 257) topic. This retrieves the entire document plus the delta between the desired or reported states.

Example document:

```json
{
    "state": {
        "desired": {
            "lights": {
                "color": "RED",
                "engine": "ON"
            },
        },
        "reported": {
            "lights": {
                "color": "GREEN",
                "engine": "ON"
            }
        }
    },
    "metadata": {
        "desired": {
            "lights": {
                "color": {
                    "timestamp": 123456
                },
                "engine": {
                    "timestamp": 123456
                }
            }
        },
        "reported": {
            "lights": {
                "color": {
                    "timestamp": 789012
                }
            },
            "engine": {
                "timestamp": 789012
            }
        },
        "version": 10,
        "timestamp": 123456789
    }
}
```

Response:

```json
{
    "state": {
        "desired": {
```
"lights": {  
  "color": "RED"
},
  "engine": "ON"
},
"reported": {  
  "lights": {  
    "color": "GREEN"
  },
  "engine": "ON"
},
"delta": {  
  "lights": {  
    "color": "RED"
  }
},
"metadata": {  
  "desired": {  
    "lights": {  
      "color": {  
        "timestamp": 123456
      },
      "engine": {  
        "timestamp": 123456
      }
    },
    "engine": {  
      "timestamp": 123456
    }
  },
  "reported": {  
    "lights": {  
      "color": {  
        "timestamp": 789012
      },
      "engine": {  
        "timestamp": 789012
      }
    },
    "delta": {  
      "lights": {  
        "color": {  
          "timestamp": 123456
        }
      }
    }
  },
  "version": 10,
  "timestamp": 123456789
}

Optimistic Locking

You can use the state document version to ensure you are updating the most recent version of a thing shadow document. When you supply a version with an update request, the service rejects the request with an HTTP 409 conflict response code if the current version of the state document does not match the version supplied.

For example:

Initial document:

```json
{
  "state": {
```
Deleting Data

You can delete data from a thing shadow by publishing to the `/update` (p. 254) topic, setting the fields to be deleted to null. Any field with a value of null is removed from the document.

Initial state:

```json
{  
  "state": {  
    "desired": {  
      "lights": { "color": "RED" },  
      "colors": [  
        "RED",  
        "GREEN",  
        "BLUE"  
      ]  
    },  
    "version": 10  
  }  
}
```

Update: (version doesn't match; request will be rejected)

```json
{  
  "state": {  
    "desired": {  
      "colors": [  
        "BLUE"  
      ]  
    },  
    "version": 9  
  }  
}
```

Result:

```
409 Conflict
```

Update: (version matches; this request will be accepted)

```json
{  
  "state": {  
    "desired": {  
      "colors": [  
        "BLUE"  
      ]  
    },  
    "version": 10  
  }  
}
```

Final state:

```json
{  
  "state": {  
    "desired": {  
      "colors": [  
        "BLUE"  
      ]  
    },  
    "version": 11  
  }  
}
```
"engine": "ON",
},
"reported": {
    "lights": { "color": "GREEN" },
    "engine": "OFF"
}
}

An update message is sent:

{
    "state": {
        "desired": null,
        "reported": {
            "engine": null
        }
    }
}

Final state:

{
    "state": {
        "reported": {
            "lights": { "color": "GREEN" }
        }
    }
}

You can delete all data from a thing shadow by setting its state to null. For example, sending the following message deletes all of the state data, but the thing shadow remains.

{
    "state": null
}

The thing shadow still exists even if its state is null. The version of the thing shadow is incremented when the next update occurs.

Deleting a Thing Shadow

You can delete a thing shadow document by using the DeleteThingShadow (p. 253) RESTful API or by publishing to the /delete (p. 258) topic.

Note
Deleting a thing shadow does not delete the thing. Deleting a thing does not delete the thing shadow.

Initial state:

{
    "state": {
        "desired": {
            "lights": { "color": "RED" },
            "engine": "ON"
        },
        "reported": {
            "lights": { "color": "GREEN" },
            "engine": "OFF"
        }
    }
}
An empty message is published to the /delete topic.

Final state:

HTTP 404 - resource not found

Delta State

Delta state is a virtual type of state that contains the difference between the desired and reported states. Fields in the desired section that are not in the reported section are included in the delta. Fields that are in the reported section and not in the desired section are not included in the delta. The delta contains metadata, and its values are equal to the metadata in the desired field. For example:

```
{
    "state": {
        "desired": {
            "color": "RED",
            "state": "STOP"
        },
        "reported": {
            "color": "GREEN",
            "engine": "ON"
        },
        "delta": {
            "color": "RED",
            "state": "STOP"
        }
    },
    "metadata": {
        "desired": {
            "color": {
                "timestamp": 12345
            },
            "state": {
                "timestamp": 12345
            },
        "reported": {
            "color": {
                "timestamp": 12345
            },
            "engine": {
                "timestamp": 12345
            }
        },
        "delta": {
            "color": {
                "timestamp": 12345
            },
            "state": {
                "timestamp": 12345
            }
        }
    },
    "version": 17,
    "timestamp": 123456789
}
```
When nested objects differ, the delta contains the path all the way to the root.

```
{
    "state": {
        "desired": {
            "lights": {
                "color": {
                    "r": 255,
                    "g": 255,
                    "b": 255
                }
            }
        },
        "reported": {
            "lights": {
                "color": {
                    "r": 255,
                    "g": 0,
                    "b": 255
                }
            }
        },
        "delta": {
            "lights": {
                "color": {
                    "g": 255
                }
            }
        },
        "version": 18,
        "timestamp": 123456789
    }
```

The Thing Shadows service calculates the delta by iterating through each field in the desired state and comparing it to the reported state.

Arrays are treated like values. If an array in the desired section doesn't match the array in the reported section, then the entire desired array is copied into the delta.

### Observing State Changes

When a thing shadow is updated, messages are published on two MQTT topics:

- `$aws/things/thing-name/shadow/update/accepted`
- `$aws/things/thing-name/shadow/update/delta`

The message sent to the update/delta topic is intended for the thing whose state is being updated. This message contains only the difference between the desired and reported sections of the thing shadow document. Upon receiving this message, the thing decides whether to make the requested change. If the thing's state is changed, it publishes its new current state to the $aws/things/thing-name/shadow/update topic.

Devices and applications can subscribe to either of these topics to be notified when the state of the document has changed.

Here is an example of that flow:

1. Device reports state.
2. The system updates the state document in its persistent data store.
3. The system publishes a delta message, which contains only the delta and is targeted at the subscribed devices. Devices should subscribe to this topic to receive updates.
4. The thing shadow publishes an accepted message, which contains the entire received document, including metadata. Applications should subscribe to this topic to receive updates.

Message Order

There is no guarantee that messages from the AWS IoT service will arrive at the device in any specific order.

Initial state document:

```json
{
    "state": {
        "reported": { "color": "blue" }
    },
    "version": 10,
    "timestamp": 123456777
}
```

Update 1:

```json
{
    "state": { "desired": { "color": "RED" } },
    "version": 10,
    "timestamp": 123456777
}
```

Update 2:

```json
{
    "state": { "desired": { "color": "GREEN" } },
    "version": 11,
    "timestamp": 123456778
}
```

Final state document:

```json
{
    "state": {
        "reported": { "color": "GREEN" }
    },
    "version": 12,
    "timestamp": 123456779
}
```

This results in two delta messages:

```json
{
    "state": {
        "color": "RED"
    },
    "version": 11,
    "timestamp": 123456778
}
```

```json
{
    "state": {
        "color": "GREEN"
    },
    "version": 12,
    "timestamp": 123456779
}
```
The device might receive these messages out of order. Because the state in these messages is cumulative, a device can safely discard any messages that contain a version number older than the one it is tracking. If the device receives the delta for version 12 before version 11, it can safely discard the version 11 message.

### Trim Thing Shadow Messages

To reduce the size of thing shadow messages sent to your device, define a rule that selects only the fields your device needs and republishes the message on an MQTT topic to which your device is listening.

The rule is specified in JSON and should look like the following:

```json
{
    "sql": "SELECT state, version FROM 'aws/things/+/shadow/update/delta'",
    "ruleDisabled": false,
    "actions": [{
        "republish": {
            "topic": "#{topic(2)}/delta",
            "roleArn": "arn:aws:iam::123456789012:role/my-iot-role"
        }
    }]
}
```

The SELECT statement determines which fields from the message will be republished to the specified topic. A "+" wild card is used to match all thing shadow names. The rule specifies that all matching messages should be republished to the specified topic. In this case, the "topic()" function is used to specify the topic on which to republish. `topic(2)` evaluates to the thing name in the original topic. For more information about creating rules, see Rules.

### Thing Shadow RESTful API

A thing shadow exposes the following URI for updating state information:

```
https://endpoint/things/thingName/shadow
```

The endpoint is specific to your AWS account. To retrieve your endpoint, use the `describe-endpoint` command. The format of the endpoint is as follows:

```
identifier.iot.region.amazonaws.com
```

#### API Actions

- GetThingShadow (p. 251)
- UpdateThingShadow (p. 252)
- DeleteThingShadow (p. 253)

#### GetThingShadow

Gets the thing shadow for the specified thing.
The response state document includes the delta between the desired and reported states.

**Request**

The request includes the standard HTTP headers plus the following URI:

```
HTTP GET https://endpoint/things/thingName/shadow
```

**Response**

Upon success, the response includes the standard HTTP headers plus the following code and body:

```
HTTP 200
BODY: response state document
```

For more information, see Example Response State Document (p. 260).

**Authorization**

Retrieving a thing shadow requires a policy that allows the caller to perform the `iot:GetThingShadow` action. The Thing Shadows service accepts two forms of authentication: Signature Version 4 with IAM credentials or TLS mutual authentication with a client certificate.

The following is an example policy that allows a caller to retrieve a thing shadow:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iot:GetThingShadow",
      "Resource": ["arn:aws:iot:region:account:thing/thing"]
    }
  ]
}
```

**UpdateThingShadow**

Updates the thing shadow for the specified thing.

Updates affect only the fields specified in the request state document. Any field with a value of null is removed from the thing shadow.

**Request**

The request includes the standard HTTP headers plus the following URI and body:

```
HTTP POST https://endpoint/things/thingName/shadow
BODY: request state document
```

For more information, see Example Request State Document (p. 260).

**Response**

Upon success, the response includes the standard HTTP headers plus the following code and body:

```
HTTP 200
BODY: response state document
```

For more information, see Example Response State Document (p. 260).
## Authorization

Updating a thing shadow requires a policy that allows the caller to perform the `iot:UpdateThingShadow` action. The Thing Shadows service accepts two forms of authentication: Signature Version 4 with IAM credentials or TLS mutual authentication with a client certificate.

The following is an example policy that allows a caller to update a thing shadow:

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "iot:UpdateThingShadow",
        "Resource": ["arn:aws:iot:region:account:thing/thing"]
    }]
}
```

## DeleteThingShadow

Deletes the thing shadow for the specified thing.

### Request

The request includes the standard HTTP headers plus the following URI:

HTTP DELETE https://endpoint/things/thingName/shadow

### Response

Upon success, the response includes the standard HTTP headers plus the following code and body:

HTTP 200
BODY: Empty response state document

### Authorization

Deleting a thing shadow requires a policy that allows the caller to perform the `iot:DeleteThingShadow` action. The Thing Shadows service accepts two forms of authentication: Signature Version 4 with IAM credentials or TLS mutual authentication with a client certificate.

The following is an example policy that allows a caller to delete a thing shadow:

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "iot:DeleteThingShadow",
        "Resource": ["arn:aws:iot:region:account:thing/thing"]
    }]
}
```

## Thing Shadow MQTT Topics

The Thing Shadows service uses reserved MQTT topics to enable applications and things to get, update, or delete the state information for a thing (thing shadow). The names of these topics start with `$aws/`
things/thingName/shadow. Publishing and subscribing on thing shadow topics requires topic-based authorization. AWS IoT reserves the right to add new topics to the existing topic structure. For this reason, we recommend that you avoid wild card subscriptions to shadow topics. For example, avoid subscribing to topic filters like $aws/things/thingName/shadow/# because the number of topics that match this topic filter might increase as AWS IoT introduces new shadow topics. For examples of the messages published on these topics see Thing Shadows Data Flow (p. 232).

The following are the MQTT topics used for interacting with thing shadows.

**Topics**
- /update (p. 254)
- /update/accepted (p. 255)
- /update/documents (p. 255)
- /update/rejected (p. 256)
- /update/delta (p. 256)
- /get (p. 257)
- /get/accepted (p. 257)
- /get/rejected (p. 258)
- /delete (p. 258)
- /delete/accepted (p. 259)
- /delete/rejected (p. 259)

**/update**

Publish a request state document to this topic to update the thing shadow:

```sql
$aws/things/thingName/shadow/update
```

A client attempting to update the state of a thing would send a JSON request state document like this:

```json
{
    "state" : {
        "desired" : {
            "color" : "red",
            "power" : "on"
        }
    }
}
```

A thing updating its thing shadow would send a JSON request state document like this:

```json
{
    "state" : {
        "reported" : {
            "color" : "red",
            "power" : "on"
        }
    }
}
```

AWS IoT responds by publishing to either /update/accepted (p. 255) or /update/rejected (p. 256).

For more information, see Request State Documents (p. 260).
Example Policy

The following is an example of the required policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Publish"],
      ]
   ]
}
```

/update/accepted

AWS IoT publishes a response state document to this topic when it accepts a change for the thing shadow:

```
/aws/things/thingName/shadow/update/accepted
```

For more information, see Response State Documents (p. 260).

Example Policy

The following is an example of the required policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["iot:Subscribe", "iot:Receive"],
         "Resource": ["arn:aws:iot:region:account:topicfilter/${aws/things/thingName/shadow/update/accepted}"
      ]
   ]
}
```

/update/documents

AWS IoT publishes a state document to this topic whenever an update to the shadow is successfully performed:

```
/aws/things/thingName/shadow/update/documents
```

The JSON document will contain two primary nodes: previous and current. The previous node will contain the contents of the full shadow document before the update was performed while current will contain the full shadow document after the update is successfully applied. When the thing shadow is updated (created) for the first time, the previous node will contain null.

Example Policy

The following is an example of the required policy:
AWS IoT publishes an error response document to this topic when it rejects a change for the thing shadow:

```
/aws/things/thingName/shadow/update/rejected
```

For more information, see Error Response Documents (p. 261).

### Example Policy

The following is an example of the required policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": ["iot:Subscribe", "iot:Receive"],
    }]
}
```

AWS IoT publishes a response state document to this topic when it accepts a change for the thing shadow and the request state document contains different values for desired and reported states:

```
/aws/things/thingName/shadow/update/delta
```

For more information, see Response State Documents (p. 260).

### Publishing Details

- A message published on `update/delta` includes only the desired attributes that differ between the desired and reported sections. It contains all of these attributes, regardless of whether these attributes were contained in the current update message or were already stored in AWS IoT. Attributes that do not differ between the desired and reported sections are not included.
- If an attribute is in the reported section but has no equivalent in the desired section, it is not included.
• If an attribute is in the desired section but has no equivalent in the reported section, it is included.
• If an attribute is deleted from the reported section but still exists in the desired section, it is included.

Example Policy

The following is an example of the required policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "iot:Subscribe",
            "iot:Receive"
        ],
    }]
}
```

/get

Publish an empty message to this topic to get the thing shadow:

```
/aws/things/thingName/shadow/get
```

AWS IoT responds by publishing to either /get/accepted (p. 257) or /get/rejected (p. 258).

Example Policy

The following is an example of the required policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "iot:Publish"
        ],
    }]
}
```

/get/accepted

AWS IoT publishes a response state document to this topic when returning the thing shadow:

```
/aws/things/thingName/shadow/get/accepted
```

For more information, see Response State Documents (p. 260).

Example Policy

The following is an example of the required policy:
AWS IoT publishes an error response document to this topic when it can't return the thing shadow:

```
/aws/things/thingName/shadow/get/rejected
```

For more information, see Error Response Documents (p. 261).

**Example Policy**

The following is an example of the required policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "iot:Subscribe",
            "iot:Receive"
        ],
        "Resource": ["arn:aws:iot:region:account:topicfilter/$aws/things/thingName/shadow/get/accepted"]
    }]
}
```

### /delete

To delete a thing shadow, publish an empty message to the delete topic:

```
/aws/things/thingName/shadow/delete
```

The content of the message is ignored.

AWS IoT responds by publishing to either /delete/accepted (p. 259) or /delete/rejected (p. 259).

**Example Policy**

The following is an example of the required policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "iot:Subscribe",
            "iot:Receive"
        ],
        "Resource": ["arn:aws:iot:region:account:topicfilter/$aws/things/thingName/shadow/get/accepted"]
    }]
}
```

### /delete/accepted

AWS IoT publishes a message to this topic when a thing shadow is deleted:

`#aws/things/thingName/shadow/delete/accepted`

#### Example Policy

The following is an example of the required policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [  "iot:Subscribe",  "iot:Receive"
    ],
  }]
}
```

### /delete/rejected

AWS IoT publishes an error response document to this topic when it can't delete the thing shadow:

`#aws/things/thingName/shadow/delete/rejected`

For more information, see Error Response Documents (p. 261).

#### Example Policy

The following is an example of the required policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [  "iot:Subscribe",  "iot:Receive"
    ],
  }]
}
```
Thing Shadow Document Syntax

The Thing Shadows service uses the following documents in UPDATE, GET, and DELETE operations using the RESTful API (p. 251) or MQTT Pub/Sub Messages (p. 253). For more information, see Thing Shadows Documents (p. 239).

Examples
- Request State Documents (p. 260)
- Response State Documents (p. 260)
- Error Response Documents (p. 261)

Request State Documents

Request state documents have the following format:

```json
{
  "state": {
    "desired": {
      "attribute1": integer2,
      "attribute2": "string2",
      ...
      "attributeN": boolean2
    },
    "reported": {
      "attribute1": integer1,
      "attribute2": "string1",
      ...
      "attributeN": boolean1
    }
  }
  "clientToken": "token",
  "version": version
}
```

- **state** — Updates affect only the fields specified.
- **clientToken** — If used, you can verify that the request and response contain the same client token.
- **version** — If used, the Thing Shadows service processes the update only if the specified version matches the latest version it has.

Response State Documents

Response state documents have the following format:

```json
{
  "state": {
    "desired": {
      "attribute1": integer2,
      "attribute2": "string2",
      ...
      "attributeN": boolean2
    },
    "reported": {
      "attribute1": integer1,
      "attribute2": "string1",
      ...
      "attributeN": boolean1
    }
  }
}
```
Error Response Documents

Error response documents have the following format:

```json
{
    "code": "error-code",
    "message": "error-message",
    "timestamp": "timestamp",
    "clientToken": "token",
    "version": "version"
}
```

- **state**
  - **reported** — Only present if a thing reported any data in the `reported` section and contains only fields that were in the request state document.
  - **desired** — Only present if a thing reported any data in the `desired` section and contains only fields that were in the request state document.
  - **metadata** — Contains the timestamps for each attribute in the `desired` and `reported` sections so that you can determine when the state was updated.
  - **timestamp** — The Epoch date and time the response was generated by AWS IoT.
  - **clientToken** — Present only if a client token was used when publishing valid JSON to the `/update` topic.
  - **version** — The current version of the document for the thing shadow shared in AWS IoT. It is increased by one over the previous version of the document.
"clientToken": "token"
}

- **code** — An HTTP response code that indicates the type of error.
- **message** — A text message that provides additional information.
- **timestamp** — The date and time the response was generated by AWS IoT.
- **clientToken** — Present only if a client token was used when publishing valid JSON to the /update topic.

For more information, see Thing Shadow Error Messages (p. 262).

## Thing Shadow Error Messages

The Thing Shadows service publishes a message on the error topic (over MQTT) when an attempt to change the state document fails. This message is only emitted as a response to a publish request on one of the reserved $aws topics. If the client updates the document using the REST API, then it receives the HTTP error code as part of its response, and no MQTT error messages are emitted.

<table>
<thead>
<tr>
<th>HTTP Error Code</th>
<th>Error Messages</th>
</tr>
</thead>
</table>
| 400 (Bad Request) | - Invalid JSON  
- Missing required node: state  
- State node must be an object  
- Desired node must be an object  
- Reported node must be an object  
- Invalid version  
- Invalid clientToken  
- JSON contains too many levels of nesting; maximum is 6  
- State contains an invalid node |
| 401 (Unauthorized)| - Unauthorized                                                                 |
| 403 (Forbidden)  | - Forbidden                                                                    |
| 404 (Not Found)  | - Thing not found                                                              |
| 409 (Conflict)   | - Version conflict                                                            |
| 413 (Payload Too Large) | - The payload exceeds the maximum size allowed                               |
| 415 (Unsupported Media Type) | - Unsupported documented encoding; supported encoding is UTF-8 |
| 429 (Too Many Requests) | - The Thing Shadow service will generate this error message when there are more than 10 in-flight requests. |
| 500 (Internal Server Error) | - Internal service failure                                                      |
Jobs

AWS IoT Jobs is a service that allows you to define a set of jobs — remote operations that are sent to and executed on one or more devices connected to AWS IoT. For example, you can define a job that instructs a set of devices to download and install application or firmware updates, reboot, rotate certificates, or perform remote troubleshooting operations.

To create a job, you make a job document which is a description of the remote operations to be performed, and you specify a list of targets that should perform the operations. The targets can be individual things, thing groups (p. 99) or both.

AWS IoT Jobs sends a message to inform the targets that a job is available. The target starts the execution of the job by downloading the job document, performing the operations it specifies, and reporting its progress to AWS IoT. The Jobs service provides commands to track the progress of a job on a specific target and for all the targets of the job.

Managing Jobs

Jobs are created and managed using the Jobs HTTPS API. For more information, see Job Management and Control API (p. 277).

Continuous Jobs

By default, a job is sent to all targets that you specify when you create the job. After those targets complete the job (or report that they are unable to do so), the job is complete. However, you can make a job continuous by setting an optional parameter when you create the job. A continuous job is one that continues to run and is executed when a change is detected in a target. For example, a job will run on a device when the thing representing the device is added to a target group, even after the job was completed by all things originally in the group. A continuous job can be used to onboard or upgrade devices as they are added to a group.

Configuring Rollouts

When you create a job you can specify how quickly targets are notified of a pending job execution. This allows you to create a staged rollout to better manage updates, reboots, and other operations.

The following field can be added to the CreateJob request:

```
"jobExecutionRolloutConfig": {
    "maximumPerMinute": "integer"
}
```

Job Documents

Job documents are UTF-8 encoded JSON documents that contain the information your devices need to perform a job. A job document will most likely contain one or more URLs where the device can
download an update or some other data. The job document itself can be stored in an Amazon S3
bucket, or be included inline with the command that creates the job.

To allow a device secure, time-limited access to data beyond that included in the job document itself,
you can use presigned Amazon S3 URLs. You can place your data in an Amazon S3 bucket and add
a placeholder link to the data in the job document. When the Jobs service receives a request for the
job document, it parses the job document looking for placeholder links and it replaces them with
presigned Amazon S3 URLs.

The placeholder link is of the following form:

```
${aws:iot:s3-presigned-url:https://s3.amazonaws.com/bucket/key}
```

where `bucket` is your bucket name and `key` is the object in the bucket to which you are linking.

When creating a job that uses presigned Amazon S3 URLs, you must provide an IAM role ARN that
grants permission to download files from the Amazon S3 bucket where the data or updates are
stored. The role must also grant permission for AWS IoT to assume the role.

**To grant Jobs permission to assume your role:**

1. Sign in to the AWS Management Console and open the IAM console at https://
   console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. Search for your role and choose it.
4. Choose the Trust Relationships tab.
5. Choose the Edit Trust Relationship button.
6. On the Edit Trust Relationship page, replace the policy document with the following JSON:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": { 
        "Service": [
          "iot.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
7. Choose Update Trust Policy

You can optionally specify a timeout for the presigned URL. For more information, see
CreateJob (p. 284).
Create Jobs

CreateJob

You use the CreateJob command to create a job. The job is queued for execution on the targets (things or thing groups) that you specify. To create a job, you need a job document that can be included in the body of the request or as a link to an Amazon S3 document. If the job includes downloading files using presigned Amazon S3 URLs, you need an IAM role ARN that has permission to download the file and grants permission to AWS IoT to assume the role.

If you have a file called job-document.json stored in an Amazon S3 bucket called jobBucket and the role with permission to download files from Amazon S3 is called S3DownloadRole, the CLI command to create a job would look like this:

```bash
aws iot create-job \
  --job-id 010 \
  --targets arn:aws:iot:us-east-1:123456789012:thing/thingOne \
  --presigned-url-config "{\"roleArn\":"arn:aws:iam::123456789012:role/S3DownloadRole", \"expiresInSec\":3600}"
```

If you want to specify the job document inline, use the `--document` parameter instead of the `--document-source` parameter.

A job is sent to and executed on targets in the order they appear in the `--targets` list. For example, if the targets list is:

```
[ arn:aws:iot:us-east-1:123456789012:thing/thingOne, 
  arn:aws:iot:us-east-1:123456789012:thinggroup/thinggroupOne, 
  arn:aws:iot:us-east-1:123456789012:thing/thingTwo, 
  arn:aws:iot:us-east-1:123456789012:thinggroup/thinggroupTwo ]
```

then the job will be executed on thingOne, followed by the things in thinggroupOne then thingTwo and finally by the things in thinggroupTwo.

**Note**

Job documents that are specified as Amazon S3 files are retrieved at the time you create the job. Changing the contents of the Amazon S3 file you used as the source of your job document after you have created the job does not change what is sent to the targets of the job.

Cancel a Job

CancelJob

You use the the CancelJob command to cancel a job. Cancelling a job will stop AWS IoT rolling out any new job executions for the job. It will also cancel any job executions that have already been QUEUED. IoT will leave any job executions in an IN_PROGRESS or terminal status untouched because the device is already executing the job or has already completed it.

The command displays no output.
Job executions that are QUEUED will be canceled. Job executions that are IN_PROGRESS or in a terminal state are not canceled. The status of a canceled job or of one of its job execution is eventually consistent — IoT will stop scheduling new job executions and not present QUEUED job executions for that job to devices as soon as possible. But changing the status of a job execution to CANCELED may take some time depending on the number of devices and other factors.

Get a Job Document

GetJobDocument

You use the GetJobDocument command to retrieve a job document for a job.

more info (5)

aws iot get-job-document --job-id 010

The command returns the job document for the specified job:

```
{
}
```

Note
When you retrieve a job document using this command, any placeholder URLs are not replaced by presigned Amazon S3 URLs. The placeholder URLs are replaced by presigned Amazon S3 URLs in the job document that is returned when a device calls the GetPendingJobExecutions (p. 294) MQTT API.

Tracking Jobs

List Jobs

ListJobs

You use the ListJobs command to get a list of all jobs in your AWS account. Note that job data and job execution data will be purged after 90 days.

more info (6)

aws iot list-jobs

The command lists all jobs in your account sorted by the job status:

```
{
  "jobs": [
    {
      "status": "IN_PROGRESS",
      "lastUpdatedAt": 1486687079.743,
      "jobArn": "arn:aws:iot:us-east-1:123456789012:job/013",
      "createdAt": 1486687079.743,
      "targetSelection": "SNAPSHOT",
```
Describe a Job

DescribeJob

You use the DescribeJob command to get the status of a specific job.

more info (7)

```bash
$ aws iot describe-job --job-id 010
```

The command returns the status of the specified job:

```json
{
    "job": {
        "status": "IN_PROGRESS",
        "jobArn": "arn:aws:iot:us-east-1:123456789012:job/010",
        "targets": [
            "arn:aws:iot:us-east-1:123456789012:thing/myThing"
        ],
        "jobProcessDetails": {
            "numberOfCanceledThings": 0,
            "numberOfFailedThings": 0,
            "numberOfInProgressThings": 0,
            "numberOfQueuedThings": 0,
            "numberOfRejectedThings": 0,
            "numberOfRemovedThings": 0,
            "numberOfSucceededThings": 0,
            "processingTargets": [
                "arn:aws:iot:us-east-1:123456789012:thing/thingOne",
                "arn:aws:iot:us-east-1:123456789012:thinggroup/thinggroupOne",
                "arn:aws:iot:us-east-1:123456789012:thing/thingTwo",
                "arn:aws:iot:us-east-1:123456789012:thinggroup/thinggroupTwo"
            ]
        },
        "presignedUrlConfig": {
            "expiresInSec": 60,
            "roleArn": "arn:aws:iam::123456789012:role/S3DownloadRole"
        },
        "jobId": "010",
        "createdAt": 1486668586.444,
        "lastUpdatedAt": 1486668586.444,
        "targetSelection": "SNAPSHOT",
        "jobArn": "arn:aws:iot:us-east-1:123456789012:job/010",
        "createdAt": 1486668586.444,
        "completedAt": 1486668789.690,
        "targetSelection": "SNAPSHOT",
        "jobId": "012"
    },
    "status": "COMPLETED",
    "lastUpdatedAt": 1486668586.444,
    "jobArn": "arn:aws:iot:us-east-1:123456789012:job/012",
    "createdAt": 1486668586.444,
    "completedAt": 1486668789.690,
    "targetSelection": "SNAPSHOT",
    "jobId": "012"
},
{
    "status": "CANCELED",
    "lastUpdatedAt": 1486668586.444,
    "jobArn": "arn:aws:iot:us-east-1:123456789012:job/011",
    "createdAt": 1486668586.444,
    "completedAt": 1486668789.690,
    "targetSelection": "SNAPSHOT",
    "jobId": "011"
}
}``
List Executions for a Job

ListJobExecutionsForJob

A job running on a specific device is represented by a job execution object. You use the ListJobExecutionsForJob command to list all job executions for a job.

```
aws iot list-job-executions-for-job --job-id 010
```

The command returns a list of job executions:

```
{
  "executionSummaries": [
    {
      "thingArn": "arn:aws:iot:us-east-1:123456789012:thing/thingOne",
      "jobExecutionSummary": {
        "status": "QUEUED",
        "lastUpdatedAt": 1486593196.378,
        "queuedAt": 1486593196.378,
        "executionNumber": 1234567890
      }
    },
    {
      "thingArn": "arn:aws:iot:us-east-1:123456789012:thing/thingTwo",
      "jobExecutionSummary": {
        "status": "IN_PROGRESS",
        "lastUpdatedAt": 1486593345.659,
        "queuedAt": 1486593196.378,
        "startedAt": 1486593345.659,
        "executionNumber": 4567890123
      }
    }
  ]
}
```

List Job Executions for a Thing

ListJobExecutionsForThing

You use the ListJobExecutionsForThing command to list all job executions running on a thing.

```
aws iot list-job-executions-for-thing --thing-name thingOne
```

The command returns a list of job executions that are running or have run on the specified thing:

```
{
  "executionSummaries": [
```
Describe Job Execution

DescribeJobExecution

You use the DescribeJobExecution command to get the status of a specific job execution. You specify a job ID and thing name (and, optionally, an execution number) to identify the job execution.

The job's execution status must be QUEUED or IN_PROGRESS.

more info (10)

aws iot describe-job-execution --job-id 017 --thing-name thingOne

The command returns the JobExecution (p. 280):

```json
{
  "execution": {
    "jobId": "017",
    "executionNumber": 4516820379,
  }
}
```
Jobs Events

Jobs also publishes to reserved topics on the MQTT protocol when jobs are pending, completed, or canceled, and when a device reports success or failure when executing a job. Devices or management and monitoring applications can keep track of the status of jobs by subscribing to these topics.

For more information about publishing and subscribing to MQTT topics, see Message Broker for AWS IoT (p. 151)

job pending

AWS IoT Jobs publishes a message on an MQTT topic when a job is added to or removed from the list of pending job executions for a thing, or there is a change to the order to the jobs on the list:

• $aws/things/thingName/jobs/notify
• $aws/things/thingName/jobs/notify-next

The messages contain the following example payloads:

$aws/things/thingName/jobs/notify:

```json
{
  "jobs": {
    "JobExecutionState": [ JobExecutionSummary (p. 281) ... ],
  },
  "timestamp": timestamp,
}
```

$aws/things/thingName/jobs/notify-next:

```json
{
  "execution": JobExecutionData (p. 290),
  "timestamp": timestamp,
}
```

job completed/canceled

AWS IoT Jobs publishes a message on an MQTT topic when a job is completed or canceled:

• $aws/events/job/jobID/completed
The message contains the following example payload:

```
{
  "eventType": "job",
  "eventId": "UUID",
  "timestamp": timestamp,
  "operation": "completed|canceled",
  "jobId": "043",
  "status": "COMPLETED|CANCELED",
  "targets": [    
    "arn:aws:iot:us-west-2:123456789012:thing/zzzzzz"
  ],
  "description": "sample description",
  "completedAt": "14889914167084",
  "createdAt": "14889025672199",
  "lastUpdatedAt": "14889734904359",
  "jobProcessDetails": {
    "numberOfCanceledThings": 1,
    "numberOfSucceededThings": 1,
    "numberOfRejectedThings": 0,
    "numberOfFailedThings": 1,
    "numberOfInProgressThings": 0,
    "numberOfRemovedThings": 0,
    "processingTargets": [
      "arn:aws:iot:us-east-1:123456789012:thing/thingOne",
      "arn:aws:iot:us-east-1:123456789012:thing/thingTwo",
      "arn:aws:iot:us-east-1:123456789012:thinggroup/thingThree"
    ]
  }
}
```

The message contains the following example payload:

```
{
  "eventType": "jobExecution",
  "eventId": "UUID",
  "timestamp": "14889025672199",
  "operation": "succeeded|failed|rejected|canceled",
  "jobId": "031",
  "status": "SUCCESS|FAILED|REJECTED|CANCELED",
  "thingName": "myThing",
}
```
Devices and Jobs

device communication with Jobs

Devices can communicate with Jobs through the use of MQTT messages. Each device must subscribe to the appropriate topics to receive messages from Jobs. Each device has its own MQTT topic. Devices can also use an HTTPS API to communicate with Jobs. This section describes how to use MQTT messages to program a device to work with Jobs. The HTTPS API commands are similar and are described in Using the AWS IoT Jobs APIs (p. 276).

using the MQTT protocol

Communication between the Jobs service and your devices can occur over the MQTT protocol. Devices subscribe to MQTT topics to be notified of new jobs and receive responses from the Jobs service. Devices publish on MQTT topics to query or update the state of a job execution.

MQTT topic overview

For more information about publishing and subscribing to MQTT topics, see Message Broker for AWS IoT (p. 151)

Devices can:

• Be notified whenever a job execution is added or removed from the list of pending job executions for a device by subscribing to the $aws/things/thing-name/jobs/notify MQTT topic, where thing-name is the name of the thing associated with the device.
• Be notified when the next pending job execution has changed by subscribing to the $aws/things/thing-name/jobs/notify-next MQTT topic, where thing-name is the name of the thing associated with the device.
• Update the status of a job execution by calling the UpdateJobExecution (p. 299) API.
• Query the status of a job execution by calling the DescribeJobExecution (p. 297) API.
• Retrieve a list of pending job executions by calling the GetPendingJobExecutions (p. 294) API.
• Retrieve the next pending job execution by calling the DescribeJobExecution (p. 297) API with jobId $next.
• Get and start the next pending job execution by calling the StartNextPendingJobExecution (p. 295) API.

The Jobs service publishes success and failure messages on an MQTT topic formed by appending accepted or rejected to the topic used to make the request. For example, if a request message is published on the $aws/things/myThing/jobs/get topic, the Jobs service publishes success messages on the $aws/things/myThing/jobs/get/accepted topic and publishes rejected messages on the $aws/things/myThing/jobs/get/rejected topic.

more info (14)

In this section, a device called MyThing should subscribe to the following MQTT topics:

• $aws/things/MyThing/jobs/notify (or $aws/things/MyThing/jobs/notify-next)
• $aws/things/MyThing/jobs/get/accepted
• $aws/things/MyThing/jobs/get/rejected
• $aws/things/MyThing/jobs/jobId/get/accepted
• $aws/things/MyThing/jobs/jobId/get/rejected
Programming Devices to Work with Jobs

Device Workflow

In general, there are two ways a device can handle the jobs it is given to execute.

Option A: Get the next job

1. When a device first comes online, it should subscribe to the device's notify-next topic.
2. Call the DescribeJobExecution (p. 297) MQTT API with jobId $next to get the next job, its job document, and other details, including any state saved in statusDetails.
3. Call the UpdateJobExecution (p. 299) MQTT API to update the job status. Or, to combine this and the previous step in one call, the device can call StartNextPendingJobExecution (p. 295).
4. Perform the actions specified by the job document using the UpdateJobExecution (p. 299) MQTT API to report on the progress of the job.
5. Call the UpdateJobExecution (p. 299) MQTT API again to update the job status and report success or failure.
6. Because this job's execution status has been changed to a terminal status, the next job available for execution (if any) will change. The device is notified that the next pending job execution has changed. At this point, the device should continue as described in step 2.

If the device remains online, it will continue to receive notifications of the next pending job execution, including its JobExecutionData, whenever it completes a job or when a new pending job execution is added. When this occurs, the device continues as described in step 2.

Option B: Pick from available jobs

1. When a device first comes online, it should subscribe to the thing's notify topic.
2. Call the GetPendingJobExecutions (p. 294) MQTT API to get a list of pending job executions.
3. If the list contains one or more job executions, pick one.
4. Call the DescribeJobExecution (p. 297) MQTT API to get the job document and other details, including any state saved in statusDetails.
5. Call the UpdateJobExecution (p. 299) MQTT API to update the job status. If the includeJobDocument field is set to true in this command, the device can skip the previous step and retrieve the job document at this point.
6. Perform the actions specified by the job document using the UpdateJobExecution (p. 299) MQTT API to report on the progress of the job.
7. Call the UpdateJobExecution (p. 299) MQTT API again to update the job status and report success or failure.

If the device remains online, it will be notified of all pending job executions whenever a new pending job execution becomes available. When this occurs, the device can continue as described in step 2.

If the device is unable to execute the job, it should call the UpdateJobExecution (p. 299) MQTT API to update the job status to REJECTED.

Starting a New Job

new job notification

When a new job is created, Jobs publishes a message on the $aws/things/thing-name/jobs/notify topic for each target device.
more info (15)

The message contains the following information:

```
{
  "timestamp":1476214217017,
  "jobs":{
    "QUEUED":[
      {
        "jobId":"0001",
        "queuedAt":1476214216981,
        "lastUpdatedAt":1476214216981,
        "versionNumber": 1
      }
    ]
  }
}
```

The device receives this message on the `$aws/things/thingName/jobs/notify` topic when the job execution is queued.

get job information

To get more information about a job execution, the device calls the DescribeJobExecution (p. 297) MQTT API with the `includeJobDocument` field set to true.

more info (16)

If the request is successful, Jobs publishes a message on the `$aws/things/MyThing/jobs/0023/get/accepted` topic:

```
{
  "clientToken" : "client-001",
  "timestamp" : 1489097434407,
  "execution" : {
    "jobId" : "023",
    "status" : "QUEUED",
    "queuedAt" : 1489097374841,
    "lastUpdatedAt" : 1489097374841,
    "versionNumber" : 1,
    "jobDocument" : {
      < contents of job document >
    }
  }
}
```

**Note**

If the request fails, Jobs publishes a message on the `$aws/things/MyThing/jobs/0023/get/rejected` topic.

The device now has the job document, which it can interpret to perform the remote operations for the job. If the job document contains an Amazon S3 presigned URL, the device can use that URL to download any required files for the job.

The device can call the StartNextPendingJobExecution (p. 295) MQTT API to request more information and start any pending job execution, in one step.
Report Job Execution Status

update execution status

As the device is executing the job, it can call the `UpdateJobExecution (p. 299)` MQTT API to update the status of the job execution.

For example, a device can update the job execution status to `IN_PROGRESS` by publishing the following message on the `$aws/things/MyThing/jobs/0023/update` topic:

```json
{
    "status":"IN_PROGRESS",
    "statusDetails": {
        "progress":"50%"
    },
    "expectedVersion":"1",
    "clientToken":"client001"
}
```

Jobs responds by publishing a message to the `$aws/things/MyThing/jobs/0023/update/accepted` or `$aws/things/MyThing/jobs/0023/update/rejected` topic:

```json
{
    "clientToken":"client001",
    "timestamp":1476289222841
}
```

The device can combine the two previous requests by calling `StartNextPendingJobExecution (p. 295)`, which gets and starts the next pending job execution and allows the device to update the job execution status. This request also returns the job document when there is a job execution pending.

The `status` field can be set to `QUEUED`, `IN_PROGRESS`, `SUCCESS`, `FAILED`, `REJECTED`, `REMOVED`, or `CANCELED`. You cannot update the status of a job execution that is already in a terminal state.

report execution completed

When the device is finished executing the job, it calls the `UpdateJobExecution (p. 299)` MQTT API. If the job was successful, set `status` to `SUCCESS` and, in `statusDetails` in the message payload, add other information about the job as name/value pairs.

For example:

```json
{
    "status":"SUCCESS",
    "statusDetails": {
        "progress":"100%"
    },
    "expectedVersion":"2",
    "clientToken":"client-001"
}
```

If the job was not successful, set `status` to `FAILED` and, in `statusDetails`, add information about the error that occurred:

```json
{
```

275
"status": "FAILED",
"statusDetails": {
  "errorCode": "101",
  "errorMsg": "Unable to install update"
},
"expectedVersion": "2",
"clientToken": "client-001"

**Note**
The `statusDetails` attribute can contain any number of name/value pairs.

When Jobs receives this update, it publishes a message on the `$aws/things/MyThing/jobs/notify` topic to indicate the job execution is complete:

```json
{
  "timestamp": 1476290692776,
  "jobs": {}
}
```

### Additional Jobs

#### additional jobs

If there are other job executions pending for the device, they are included in the message published to `$aws/things/MyThing/jobs/notify`.

For example:

```json
{
  "timestamp": 1476290692776,
  "jobs": {
    "QUEUED": [{
      "jobId": "0002",
      "queuedAt": 1476290646230,
      "lastUpdatedAt": 1476290646230
    }],
    "IN_PROCESS": [{
      "jobId": "0003",
      "queuedAt": 1476290646230,
      "lastUpdatedAt": 1476290646230
    }]
  }
}
```

### Using the AWS IoT Jobs APIs

There are two categories of API used in AWS IoT Jobs:

- Those used for management and control of jobs.
- Those used by the devices executing those jobs.

In general, job management and control uses an HTTPS protocol API. Devices can use either an MQTT or an HTTPS protocol API. (The HTTPS API is designed for a low volume of calls typical when creating and
tracking jobs. It usually opens a connection for a single request, and then closes the connection after the response is received. The MQTT API allows long polling. It is designed for large amounts of traffic that can scale to millions of devices.)

**Note**
Each Jobs HTTPS API has a corresponding command that allows you to call the API from the AWS CLI. The commands are lowercase, with hyphens between the words that make up the name of the API. For example, you can invoke the `CreateJob` API on the CLI by typing:

```
aws iot create-job ...
```

---

## Job Management and Control API

### Job Management and Control Data Types

The following data types are used by management and control applications to communicate with Jobs.

#### Job

**Job data type**

The Job object contains details about a job.

**Syntax**

```json
{
  "jobArn": "string",
  "jobId": "string",
  "status": "IN_PROGRESS|CANCELED|COMPLETED",
  "targetSelection": "CONTINUOUS|SNAPSHOT",
  "comment": "string",
  "targets": ["string"],
  "description": "string",
  "createdAt": timestamp,
  "lastUpdatedAt": timestamp,
  "completedAt": timestamp,
  "jobProcessDetails": {
    "processingTargets": ["string"],
    "numberOfCanceledThings": "long",
    "numberOfSucceededThings": "long",
    "numberOfFailedThings": "long",
    "numberOfRejectedThings": "long",
    "numberOfQueuedThings": "long",
    "numberOfInProgressThings": "long",
    "numberOfRemovedThings": "long",
  },
  "presignedUrlConfig": {
    "expiresInSec": number,
    "roleArn": "string"
  },
  "jobExecutionRolloutConfig": {
    "maximumPerMinute": "integer"
  }
}
```

**Description**

- **jobArn**
  
  An ARN identifying the job with the format "arn:aws:iot:region:account:job/jobId".
jobId

The unique identifier you assigned to this job when it was created.

status

The status of the job, one of IN_PROGRESS, CANCELED, or COMPLETED.

targetSelection

Specifies whether the job continues to run (CONTINUOUS) or is complete after those things specified as targets have completed the job (SNAPSHOT). If CONTINUOUS, the job might also be run on a thing when a change is detected in a target. For example, a job runs on a thing when the thing is added to a target group, even after the job was completed by all things originally in the group.

comment

If the job was updated, describes the reason for the update.

targets

A list of AWS IoT things and thing groups to which the job should be sent.

description

A short text description of the job.

createdAt

The time, in milliseconds since the epoch, when the job was created.

lastUpdatedAt

The time, in milliseconds since the epoch, when the job was last updated.

completedAt

The time, in milliseconds since the epoch, when the job was completed.

jobProcessDetails

Details about the job process:

processingTargets

A list of AWS IoT things and thing groups that are currently executing the job.

numberOfCanceledThings

The number of AWS IoT things that canceled the job.

numberOfSucceededThings

The number of AWS IoT things that successfully completed the job.

numberOfFailedThings

The number of AWS IoT things that failed to complete the job.

numberOfRejectedThings

The number of AWS IoT things that rejected the job.

numberOfQueuedThings

The number of AWS IoT things that are awaiting execution of the job.

numberOfInProgressThings

The number of AWS IoT things that are currently executing the job.
numberOfRemovedThings

The number of AWS IoT things that are no longer scheduled to execute the job because they have been deleted or removed from the group that was a target of the job.

presignedUrlConfig

Configuration information for presigned Amazon S3 URLs.

expiresInSec

How long (in seconds) presigned URLs are valid. Valid values are 60 - 3600. The default value is 3600 seconds. Presigned URLs are generated when Jobs receives an MQTT request for the job document.

roleArn

The ARN of an IAM role that grants permission to download files from an Amazon S3 bucket. The role must also grant permission for AWS IoT to download the files. For more information about how to create and configure the role, see Job Documents (p. 263).

jobExecutionRolloutConfig

Allows you to create a staged rollout of a job.

maximumPerMinute

The maximum number of things (devices) to which the job will be sent for execution, per minute.

JobSummary

JobSummary data type

The JobSummary object contains a job summary.

**syntax (2)**

```json
{
  "jobArn": "string",
  "jobId": "string",
  "status": "IN_PROGRESS|CANCELED|COMPLETED",
  "description": "string",
  "targetSelection": "CONTINUOUS|SNAPSHOT",
  "thingGroupId": "string",
  "createdAt": timestamp,
  "lastUpdatedAt": timestamp,
  "completedAt": timestamp
}
```

description (2)

**jobArn**

An ARN that identifies the job.

**jobId**

The unique identifier you assigned to this job when it was created.

**status**

The job status. Can be one of IN_PROGRESS, CANCELED, or COMPLETED.
targetSelection

Specifies whether the job continues to run (CONTINUOUS) or is complete after all those things specified as targets have completed the job (SNAPSHOT). If CONTINUOUS, the job might also be run on a thing when a change is detected in a target. For example, a job runs on a thing when the thing is added to a target group, even after the job was completed by all things originally in the group.

thingGroupId

The ID of the thing group.

createdAt

The UNIX timestamp for when the job was created.

lastUpdatedAt

The UNIX timestamp for when the job was last updated.

completedAt

The UNIX timestamp for when the job was completed.

**JobExecution**

JobExection data type

The JobExecution object represents the execution of a job on a particular device.

**syntax**

```json
{
   "jobId": "string",
   "executionNumber": 1234567890,
   "thingArn": "string",
   "queuedAt": timestamp,
   "lastUpdatedAt": timestamp,
   "startedAt": timestamp,
   "status": "QUEUED|IN_PROGRESS|FAILED|SUCCESS|CANCELED|REJECTED|REMOVED",
   "statusDetails": {
      "detailsMap": {
         "string": "string" ...
      },
      "status": "string"
   }
}
```

**description**

**jobId**

The unique identifier you assigned to this job when it was created.

**executionNumber**

A number that identifies this job execution on this particular device. It can be used later in commands that return or update job execution information.

**thingArn**

The AWS IoT thing ARN.

**queuedAt**

The time, in milliseconds since the epoch, when the job execution was queued.
lastUpdatedAt

The time, in milliseconds since the epoch, when the job execution was last updated.

startedAt

The time, in milliseconds since the epoch, when the job execution was started.

status

The status of the job execution. Can be one of "QUEUED", "IN_PROGRESS", "FAILED", "SUCCESS", "CANCELED", "REJECTED", or "REMOVED".

statusDetails

A collection of name/value pairs that describe the status of the job execution.

JobExecutionSummary

JobExecutionSummary data type

The JobExecutionSummary object contains job execution summary information:

```json
{
  "executionNumber": 1234567890,
  "queuedAt": timestamp,
  "lastUpdatedAt": timestamp,
  "startedAt": timestamp,
  "status": "QUEUED|IN_PROGRESS|FAILED|SUCCESS|CANCELED|REJECTED|REMOVED"
}
```

description (4)

executionNumber

A number that identifies a particular job execution on a particular device. It can be used later in commands that return or update job execution information.

queuedAt

The time, in milliseconds since the epoch, when the job execution was queued.

lastUpdatedAt

The time, in milliseconds since the epoch, when the job execution was last updated.

startAt

The time, in milliseconds since the epoch, when the job execution was started.

status

The status of the job execution: QUEUED, IN_PROGRESS, FAILED, SUCCESS, CANCELED, REJECTED, or REMOVED.

JobExecutionSummaryForJob

JobExecutionSummaryForJob data type

The JobExecutionSummaryForJob object contains a summary of information about job executions for a specific job.
{  
  "executionSummary": [  
    {  
      "thingArn": "string",  
      "jobExecutionSummary": { JobExecutionSummary }  
    }  
  ]  
}

description (5)

thingArn

The AWS IoT thing ARN.

jobExecutionSummary

An JobExecutionSummary (p. 281) object.

JobExecutionSummaryForThing

JobExecutionSummaryForThing data type

The JobExecutionSummaryForThing object contains a summary of information about a job execution on a specific thing.

syntax (6)

{  
  "jobId": "string",  
  "jobExecutionSummary": { JobExecutionSummary }  
}

description (6)

jobId

The unique identifier you assigned to this job when it was created.

jobExecutionSummary

A JobExecutionSummary (p. 281) object.

Job Management and Control HTTPS Commands

The following commands are available for management and control applications over the HTTPS protocol.

AssociateTargetsWithJob

AssociateTargetsWithJob command

Associates a group with a continuous job. For more information, see CreateJob (p. 284). The following criteria must be met:

- The job must have been created with the targetSelection field set to "CONTINUOUS".
- The job status must currently be "IN_PROGRESS".
• The total number of targets associated with a job must not exceed 100.

HTTPS (1)

Request:

```plaintext
POST /jobs/jobId/targets
{
    "targets": [ "string" ],
    "comment": "string"
}
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
<tr>
<td>targets</td>
<td>A list of thing group ARNs that define the targets of the job.</td>
</tr>
<tr>
<td>comment</td>
<td>Optional. A comment string that describes why the job was associated with the targets.</td>
</tr>
</tbody>
</table>

Response:

```plaintext
{
    "jobArn": "string",
    "jobId": "string",
    "description": "string"
}
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobArn</td>
<td>An ARN identifying the job.</td>
</tr>
<tr>
<td>jobId</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
<tr>
<td>description</td>
<td>A short text description of the job.</td>
</tr>
</tbody>
</table>

MQTT (1)

Not available.

**CancelJob**

CancelJob command

Cancels a job.

HTTPS (2)

Request:

```plaintext
PUT /jobs/jobId/cancel
```

MQTT (1)

Not available.
jobId

The unique identifier you assigned to this job when it was created.

comment

[Optional] A comment string describing why the job was canceled.

Response:

{
   "jobArn": "string",
   "jobId": "string",
   "description": "string"
}

jobArn

The job ARN.

jobId

The unique identifier you assigned to this job when it was created.

description

A short text description of the job.

MQTT (2)

Not available.

CreateJob

CreateJob command

Creates a job. You can provide the job document as a link to a file in an Amazon S3 bucket (documentSource parameter) or in the body of the request (document parameter).

A job can be made continuous by setting the optional targetSelection parameter to "CONTINUOUS". (The default is "SNAPSHOT"). A continuous job can be used to onboard or upgrade devices as they are added to a group because it continues to run and is executed on newly added things, even after the things in the group at the time the job was created have completed the job.

The following validations are performed on arguments to the CreateJob API:

- The targets argument must be a list of valid thing or thing group ARNs. All things and thing groups must be in your AWS account.
- The documentSource argument must be a valid Amazon S3 URL to a job document. Amazon S3 URLs are of the form: https://s3.amazonaws.com/bucketName/objectName.
- The document stored in the URL specified by the documentSource argument must be a UTF-8 encoded JSON document.
- The size of a job document is limited to 32 KB due to the limit on the size of an MQTT message (128 KB) and encryption.
- The jobId must be unique within your AWS account.
HTTPS (3)

Request:

```
PUT /jobs/jobId
{
   "targets": [ "string" ],
   "document": "string",
   "documentSource": "string",
   "description": "string",
   "presignedUrlConfigData": {
      "roleArn": "string",
      "expiresInSec": "integer"
   },
   "targetSelection": "CONTINUOUS|SNAPSHOT",
   "jobExecutionsRolloutConfig": {
      "maximumPerMinute": "integer"
   }
}
```

**jobId**

A job identifier, which must be unique for your AWS account. We recommend using a UUID. Alpha-numeric characters, ",", and "," can be used here.

**targets**

A list of thing or thing group ARNs that defines the targets of the job.

**document**

Optional. The job document.

**documentSource**

Optional. An Amazon S3 link to the job document.

**description**

**presignedUrlConfigData**

Optional. Configuration information for presigned Amazon S3 URLs.

**roleArn**

The ARN of the IAM role that contains permissions to access the Amazon S3 bucket. This is the bucket that contains the data that devices download with the presigned Amazon S3 URLs. This role must also grant AWS IoT permission to assume the role. For more information, see Job Documents (p. 263).

**expiresInSec**

How long (in seconds) presigned URLs are valid. Valid values are 60 - 3600. The default value is 3600 seconds. Presigned URLs are generated when Jobs receives an MQTT request for the job document.

**targetSelection**

Optional. Specifies whether the job continues to run (CONTINUOUS) or is complete after all those things specified as targets have completed the job (SNAPSHOT). If CONTINUOUS, the job might also be scheduled to run on a thing when a change is detected in a target. For example, a job is scheduled to run on a thing when the thing is added to a target group, even after the job was completed by all things originally in the group.
JobManagement and Control API

jobExecutionRolloutConfig

Optional. Allows you to create a staged rollout of a job.

maximumPerMinute

The maximum number of things on which the job is sent for execution, per minute. Valid values are 1 to 1000. If not specified, the default is 1000. The actual number of things that receive the job might be less during any particular minute interval (due to system latency), but will not be more than the specified value.

Response:

```json
{
    "jobArn": "string",
    "jobId": "string",
    "description": "string"
}
```

jobArn

The ARN of the job.

jobId

The unique identifier you assigned to this job.

description

An optional short text description of the job.

MQTT (3)

Not available.

DescribeJob

DescribeJob command

Gets the details of the specified job.

HTTPS (4)

Request:

```plaintext
GET /jobs/jobId
```

jobId

The unique identifier you assigned to this job when it was created.

Response:

```json
{
    "documentSource": "string",
    "job": Job
}
```
documentSource
An Amazon S3 link to the job document.

job
A Job (p. 277) object.

MQTT (4)
Not available.

DescribeJobExecution
DescribeJobExecution command
Gets details of a job execution. The job's execution status must be SUCCEEDED or FAILED.

HTTPS (5)
Request:

GET /things/thingName/jobs/jobId?executionNumber=executionNumber

jobId
The unique identifier you assigned to this job when it was created.

thingName
The thing name associated with the device the job execution is running on.

executionNumber
Optional. A number that is used to specify a particular job execution on a particular device. (See JobExecution (p. 280).) If not specified, the latest job execution is returned.

Response:

{  "execution": { JobExecution } }

execution
A JobExecution (p. 280) object.

MQTT (5)
Not available.

GetJobDocument
GetJobDocument command
Gets the job document for a job.

Note
Placeholder URLs are not replaced with presigned Amazon S3 URLs in the document returned. Presigned URLs are generated only when Jobs receives a request over MQTT.
HTTPS (6)

Request:

GET /jobs/jobId/job-document

jobId

The unique identifier you assigned to this job when it was created.

Response:

```json
{
   "document": "string"
}
```

document

The job document content.

MQTT (6)

Not available.

**ListJobExecutionsForJob**

ListExecutionsForJob command

Gets a list of job executions for a job.

HTTPS (7)

Request:

GET /jobs/jobId/things?status=status&maxResults=maxResults&nextToken=nextToken

jobId

The unique identifier you assigned to this job when it was created.

status

Optional. A filter that lets you search for jobs that have the specified status: QUEUED, IN_PROGRESS, SUCCESS, FAILED, REJECTED, REMOVED, or CANCELED.

maxResults

Optional. The maximum number of results to be returned per request.

nextToken

Optional. The token to retrieve the next set of results.

Response:

```json
{
   "executionSummaries": [ JobExecutionSummary ... ]
}
```
executionSummaries

A list of JobExecutionSummary (p. 281) objects associated with the specified job ID.

MQTT (7)

Not available.

**ListJobExecutionsForThing**

ListJobExecutionsForThing command

Gets a list of job executions for a thing.

HTTPS (8)

Request:

```
GET /things/thingName/jobs?status=status&maxResults=maxResults&nextToken=nextToken
```

thingName

The name of the thing for which JobExecutions will be listed.

status

An optional filter that lets you search for jobs that have the specified status: QUEUED, IN_PROGRESS, SUCCESS, FAILED, REJECTED, REMOVED, or CANCELED.

maxResults

The maximum number of results to be returned per request.

nextToken

The token for the next set of results, or null if there are no additional results.

Response:

```
{
  "executionSummaries": [ JobExecutionSummary ... ]
}
```

executionSummaries

A list of the JobExecutionSummary (p. 281) objects for the job executions associated with the specified thing.

MQTT (8)

Not available.

**ListJobs**

ListJobs command

Gets a list of the jobs in your AWS account.
HTTPS (9)

Request:

GET /jobs?
status=status&targetSelection=targetSelection&thingGroupName=thingGroupName&thingGroupId=thingGroupId&maxResults=maxResults&nextToken=nextToken

status

Optional. A filter that lets you search for jobs that have the specified status: IN_PROGRESS, CANCELED, or COMPLETED.

targetSelection

Optional. A filter that lets you search for jobs that have the specified targetSelection value: CONTINUOUS or SNAPSHOT.

thingGroupName

Optional. A filter that lets you search for jobs that have the specified thing group name as a target.

thingGroupId

Optional. A filter that lets you search for jobs that have the specified thing group ID as a target.

maxResults

Optional. The maximum number of results to be returned per request.

nextToken

Optional. The token to retrieve the next set of results.

Response:

{
   "jobs": [ JobSummary ... ],
}

jobs

A list of JobSummary (p. 279) objects, one for each job in your AWS account that matches the specified filtering criteria.

MQTT (9)

Not available.

Jobs Device MQTT and HTTPS APIs

Device MQTT and HTTPS Data Types

The following data types are used to communicate with Jobs over the MQTT and HTTPS protocols.

JobExecution

JobExecution data type

Contains data about a job execution.
```json
{
    "jobId": "string",
    "thingName": "string",
    "jobDocument": "string",
    "status": "QUEUED|IN_PROGRESS|FAILED|SUCCESS|CANCELED|REJECTED|REMOVED",
    "statusDetails": {
        "string": "string"
    }
    "queuedAt": "timestamp",
    "startedAt": "timestamp",
    "lastUpdatedAt": "timestamp",
    "versionNumber": "number",
    "executionNumber": "long"
}
```

**JobExecutionState**

**JobExecutionState data type**

Contains data about the state of a job execution.

**Job Execution State**

**JobExecutionState data type**

Contains data about the state of a job execution.
syntax (8)

```
{
    "status": "QUEUED|IN_PROGRESS|FAILED|SUCCESS|CANCELED|REJECTED|REMOVED",
    "statusDetails": {
        "string": "string"
    }
    "versionNumber": "number"
}
```

description (8)

**status**

The status of the job execution. Can be one of: "QUEUED", "IN_PROGRESS", "FAILED", "SUCCESS", "CANCELED", "REJECTED", or "REMOVED".

**statusDetails**

A collection of name/value pairs that describe the status of the job execution.

**versionNumber**

The version of the job execution. Job execution versions are incremented each time they are updated by a device.

### JobExecutionSummary

JobExecutionSummary data type

Contains a subset of information about a job execution.

syntax (9)

```
{
    "jobId": "string",
    "queuedAt": timestamp,
    "startedAt": timestamp,
    "lastUpdatedAt": timestamp,
    "versionNumber": "number",
    "executionNumber": "long"
}
```

description (9)

**jobId**

The unique identifier you assigned to this job when it was created.

**queuedAt**

The time, in milliseconds since the epoch, when the job execution was enqueued.

**startedAt**

The time, in milliseconds since the epoch, when the job execution started.

**lastUpdatedAt**

The time, in milliseconds since the epoch, when the job execution was last updated.

**versionNumber**

The version of the job execution. Job execution versions are incremented each time AWS IoT Jobs receives an update from a device.
executionNumber

A number that identifies a particular job execution on a particular device.

**ErrorResponse**

ErrorRepsonse data type

Contains information about an error that occurred during a Jobs operation.

**syntax (10)**

```
{
  "code": "ErrorCode",
  "message": "string",
  "clientToken": "string",
  "timestamp": timestamp,
  "executionState": JobExecutionState
}
```

**description (10)**

**code**

ErrorCode can be set to:

**InvalidTopic**

The request was sent to a topic in the Jobs namespace that does not map to any API.

**InvalidJson**

The contents of the request could not be interpreted as valid UTF-8-encoded JSON.

**InvalidRequest**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

**InvalidStateTransition**

An update attempted to change the job execution to a state that is invalid because of the job execution's current state (for example, an attempt to change a request in state SUCCESS to state IN_PROGRESS). In this case, the body of the error message also contains the executionState field.

**ResourceNotFound**

The JobExecution specified by the request topic does not exist.

**VersionMismatch**

The expected version specified in the request does not match the version of the job execution in Jobs. In this case, the body of the error message also contains the executionState field.

**InternalError**

There was an internal error processing the request.

**RequestThrottled**

The request was throttled.

**TerminalStateReached**

Occurs when a command to describe a job is performed on a job that is in a terminal state.
message

An error message string.

clientToken

An arbitrary string used to correlate a request with its reply.

timestamp

The time, in milliseconds since the epoch.

executionState

A JobExecutionState (p. 291) object. This field is included only when the code field has the value InvalidStateTransition or VersionMismatch. This makes it unnecessary in these cases to perform a separate DescribeJobExecution request to obtain the current job execution status data.

Device Commands

The following commands are available over the MQTT and HTTPS protocols.

GetPendingJobExecutions

GetPendingJobExecutions command

Gets the list of all jobs for a thing that are not in a terminal status.

MQTT (11)

To invoke this API, publish a message on $aws/things/thingName/jobs/get.

Request:

```json
{ "clientToken": "string" }
```

clientToken

Optional. A client token used to correlate requests and responses. Enter an arbitrary value here and it will be reflected in the response.

Response:

```json
{
  "inProgressJobs" : [ JobExecutionSummary ... ],
  "queuedJobs" : [ JobExecutionSummary ... ],
  "timestamp" : 1489096425069,
  "clientToken" : "client-001"
}
```

inProgressJobs

A list of JobExecutionSummary (p. 292) objects with status IN_PROGRESS.

queuedJobs

A list of JobExecutionSummary (p. 292) objects with status QUEUED.

clientToken

A client token used to correlate requests and responses.
timestamp

The time, in milliseconds since the epoch, when the message was sent.

HTTPS (11)

Request:

```
GET /things/thingName/jobs
```

thingName

The name of the thing associated with the device.

Response:

```
{
    "inProgressJobs" : [ JobExecutionSummary ... ],
    "queuedJobs" : [ JobExecutionSummary ... ]
}
```

inProgressJobs

A list of JobExecutionSummary (p. 292) objects.

queuedJobs

A list of JobExecutionSummary (p. 292) objects.

**StartNextPendingJobExecution**

StartNextPendingJobExecution command

Gets and starts the next pending (status IN_PROGRESS or QUEUED) job execution for a thing.

- Any job executions with status IN_PROGRESS are returned first.
- Job executions are returned in the order in which they were created.
- If the next pending job execution is QUEUED, its state is changed to IN_PROGRESS and the job execution's status details are set as specified.
- If the next pending job execution is already IN_PROGRESS, its status details are not changed.
- If no job executions are pending, the response does not include the execution field.

MQTT (13)

To invoke this API, publish a message on: $aws/things/thingName/jobs/start-next.

Request:

```
{
    "statusDetails": {
        "string": "job-execution-state"
        ...
    },
    "clientToken": "string"
}
```
statusDetails

A collection of name/value pairs that describe the status of the job execution. If not specified, the statusDetails are unchanged.

clientToken

A client token used to correlate requests and responses. Enter an arbitrary value here and it will be reflected in the response.

Response:

```
{  
  "execution" : JobExecutionData,  
  "timestamp" : timestamp,  
  "clientToken" : "string"
}
```

execution

A JobExecution (p. 290) object. For example:

```
{  
  "execution" : {  
    "jobId" : "022",  
    "thingName" : "MyThing",  
    "jobDocument" : "< contents of job document >",  
    "status" : "IN_PROGRESS",  
    "queuedAt" : 1489096123309,  
    "lastUpdatedAt" : 1489096123309,  
    "versionNumber" : 1,  
    "executionNumber" : 1234567890  
  },  
  "clientToken" : "client-1",  
  "timestamp" : 1489088524284,
}
```

timestamp

The time, in milliseconds since the epoch, when the message was sent to the device.

clientToken

A client token used to correlate requests and responses.

HTTPS (13)

Request:

```
PUT /things/thingName/jobs/$next
{
  "statusDetails": {
    "string": "string"
    ...
  }
}
```

thingName

The name of the thing associated with the device.
statusDetails

A collection of name/value pairs that describe the status of the job execution. If not specified, the statusDetails are unchanged.

Response:

```json
{
    "execution" : JobExecution
}
```

execution

A JobExecution (p. 290) object. For example:

```json
{
    "execution" : {
        "jobId" : "022",
        "thingName" : "MyThing",
        "jobDocument" : "< contents of job document >",
        "status" : "IN_PROGRESS",
        "queuedAt" : 1489096123309,
        "lastUpdatedAt" : 1489096123309,
        "versionNumber" : 1,
        "executionNumber" : 1234567890
    },
    "clientToken" : "client-1",
    "timestamp" : 1489088524284,
}
```

DescribeJobExecution

DescribeJobExecution command

Gets detailed information about a job execution.

MQTT (14)

To invoke this API, publish a message on $aws/things/thingName/jobs/jobId/get.

Request:

```json
{
    "executionNumber": "long",
    "includeJobDocument": "boolean",
    "clientToken": "string"
}
```

thingName

The name of the thing associated with the device.

jobId

The unique identifier assigned to this job when it was created.

Or use $next to return the next pending (status IN_PROGRESS or QUEUED) job execution for a thing. In this case, any job executions with status IN_PROGRESS are returned first. Job executions are returned in the order in which they were created.
executionNumber

Optional. A number that identifies a particular job execution on a particular device. If not specified, the latest job execution is returned.

includeJobDocument

Optional. When set to true, the response contains the job document. The default is true.

clientToken

A client token used to correlate requests and responses. Enter an arbitrary value here and it will be reflected in the response.

Response:

```
{
  "execution" : JobExecutionData,
  "timestamp": "timestamp",
  "clientToken": "string"
}
```

execution

A JobExecution (p. 290) object.

timestamp

The time, in milliseconds since the epoch, when the message was sent.

clientToken

A client token used to correlate requests and responses.

HTTPS (14)

The job's execution status must be QUEUED or IN_PROGRESS.

Request:

```
GET /things/thingName/jobs/jobId?
executionNumber=executionNumber&includeJobDocument=includeJobDocument
```

thingName

The name of the thing associated with the device.

jobId

The unique identifier assigned to this job when it was created.

Or use $next to return the next pending (status IN_PROGRESS or QUEUED) job execution for a thing. In this case, any job executions with status IN_PROGRESS are returned first. Job executions are returned in the order in which they were created.

includeJobDocument

Optional. When set to true, the response contains the job document. The default is false.

executionNumber

Optional. A number that identifies a particular job execution on a particular device. If not specified, the latest job execution is returned.
Response:

```json
{
  "execution": JobExecution,
}
```

A `JobExecution` (p. 290) object.

**UpdateJobExecution**

UpdateJobExecution command

Updates the status of a job execution.

MQTT (15)

To invoke this API, publish a message on `$aws/things/thingName/jobs/jobId/update`.

Request:

```json
{
  "status": "job-execution-state",
  "statusDetails": {
    "string": "string"
    ...
  },
  "expectedVersion": "number",
  "executionNumber": "long",
  "includeJobExecutionState": "boolean",
  "includeJobDocument": "boolean",
  "clientToken": "string"
}
```

status

The new status for the job execution (IN_PROGRESS, FAILED, SUCCEEDED, or REJECTED). This must be specified on every update.

statusDetails

A collection of name/value pairs that describe the status of the job execution. If not specified, the statusDetails are unchanged.

expectedVersion

The expected current version of the job execution. Each time you update the job execution, its version is incremented. If the version of the job execution stored in Jobs does not match, the update is rejected with a VersionMismatch error, and an ErrorResponse (p. 293) that contains the current job execution status data is returned. (This makes it unnecessary to perform a separate DescribeJobExecution request in order to obtain the job execution status data.)

executionNumber

Optional. A number that identifies a particular job execution on a particular device. If not specified, the latest job execution is used.

includeJobExecutionState

Optional. When included and set to true, the response contains the JobExecutionState field. The default is false.
includeJobDocument

Optional. When included and set to true, the response contains the JobDocument. The default is false.

clientToken

A client token used to correlate requests and responses. Enter an arbitrary value here and it will be reflected in the response.

Response:

```
{
   "executionState": JobExecutionState,
   "jobDocument": "string",
   "timestamp": timestamp,
   "clientToken": "string"
}
```

executionState

A JobExecutionState (p. 291) object.

jobDocument

A Job Documents (p. 263) object.

timestamp

The time, in milliseconds since the epoch, when the message was sent.

clientToken

A client token used to correlate requests and responses.

HTTPS (15)

Request:

```
POST /things/thingName/jobs/jobId
{
   "status": "job-execution-state",
   "statusDetails": {
      "string": "string"
   },
   "expectedVersion": "number",
   "includeJobExecutionState": "boolean",
   "includeJobDocument": "boolean",
   "executionNumber": "long"
}
```

tthingName

The name of the thing associated with the device.

jobId

The unique identifier assigned to this job when it was created.

status

The new status for the job execution (IN_PROGRESS, FAILED, SUCCEEDED, or REJECTED). This must be specified on every update.
statusDetails

Optional. A collection of name/value pairs that describe the status of the job execution. If not specified, the statusDetails are unchanged.

expectedVersion

Optional. The expected current version of the job execution. Each time you update the job execution, its version is incremented. If the version of the job execution stored in Jobs does not match, the update is rejected with a VersionMismatch error, and an ErrorResponse (p. 293) that contains the current job execution status data is returned. (This makes it unnecessary to perform a separate DescribeJobExecution request in order to obtain the job execution status data.)

includeJobExecutionState

Optional. When included and set to true, the response contains the JobExecutionState data. The default is false.

includeJobDocument

Optional. When set to true, the response contains the job document. The default is false.

executionNumber

Optional. A number that identifies a particular job execution on a particular device.

Response:

```
{
  "executionState": JobExecutionState,
  "jobDocument": "string"
}
```

executionState

A JobExecutionState (p. 291) object.

jobDocument

The contents of the Job Documents (p. 263).

The following updates are available over the MQTT protocol only.

**JobExecutionsChanged**

JobExecutionsChanged message

Sent whenever a job execution is added to or removed from the list of pending job executions for a thing.

MQTT (16)

**Topic:** $aws/things/thingName/jobs/notify

**Message payload:**

```
{
  "jobs": {
    "JobExecutionState": [ JobExecutionSummary (p. 281) ... ]
  },
  "timestamp": timestamp,
```
NextJobExecutionChanged

NextJobExecutionChanged message

Sent whenever there is a change to which job execution is next on the list of pending job executions for a thing, as defined for DescribeJobExecution (p. 297) with job id \$next. This message is not sent when the next job's execution details change, only when the next job that would be returned by DescribeJobExecution with job id \$next has changed. Consider job executions J1 and J2 with state QUEUED. J1 is next on the list of pending job executions. If the state of J2 is changed to IN_PROGRESS while the state of J1 remains unchanged, then this notification is sent and contains details of J2.

MQTT (17)

Topic: \$aws/things/thingName/jobs/notify-next

Message payload:

```json
{
    "execution" : JobExecutionData (p. 290),
    "timestamp": timestamp,
}
```

HTTPS (17)

Not available.
Device Provisioning

To provision a device, create a template that describes the resources required for your device. Devices require a thing, a certificate, and one or more policies. A thing is an entry in the device registry that contains attributes that describe a device. Devices use certificates to authenticate with AWS IoT. Policies determine which operations a device can perform in AWS IoT.

Templates contain variables that are replaced when the template is used to provision a device. A dictionary (map) is used to provide values for the variables used in a template. You can use the same template to provision multiple devices. You simply pass in different values for the template variables in the dictionary.

Provisioning Templates

A provision template is a JSON document that uses parameters to describe the resources your device must use to interact with AWS IoT. A template contains two sections: Parameters and Resources.

Parameters Section

The Parameters section declares the parameters used within the Resources section. Each parameter declares a name, a type, and an optional default value. The default value is used when the dictionary passed in with the template does not contain a value for the parameter. The Parameters section of a template document looks like the following:

```
"Parameters" : {
    "ThingName" : {
        "Type" : "String",
    },
    "SerialNumber" : {
        "Type" : "String",
    },
    "Location" : {
        "Type" : "String",
        "Default" : "WA",
    },
    "CSR" : {
        "Type" : "String",
    }
}
```

This template snippet declares four parameters: ThingName, SerialNumber, Location, and CSR. All of these parameters are of type String. The Location parameter declares a default value of "WA".

Resources Section

The Resources section of the template declares the resources required for your device to communicate with AWS IoT: a thing, a certificate, and one or more policies. Each resource specifies a logical name, a type, and a set of properties.
A logical name allows you to refer to a resource elsewhere in the template.

The type specifies the kind of resource you are declaring. Valid types are:

- `AWS::IoT::Thing`
- `AWS::IoT::Certificate`
- `AWS::IoT::Policy`

The properties you specify depend on the type of resource you are declaring.

**Thing Resources**

Thing resources are declared using the following properties:

- **ThingName**: String.
- **AttributePayload**: A list of name/value pairs.
- **ThingType**: Optional. String for an associated thing type for the thing.
- **ThingGroups**: Optional. A list of groups to which the thing belongs.

**Certificate Resources**

Certificates can be specified in one of the following ways:

- A certificate signing request (CSR).
- A certificate ID of an existing device certificate.
- A device certificate created with a CA certificate registered with AWS IoT. If you have more than one CA certificate registered with the same subject field, you must also pass in the CA certificate used to sign the device certificate.

**Note**

When you declare a certificate in a template, use only one of the preceding methods. If you use a CSR, you cannot also specify a certificate ID or a device certificate.

For more information about certificates and AWS IoT see [AWS IoT and Certificates](#).

Certificate resources are declared using the following properties:

- **CertificateSigningRequest**: String.
- **CACertificatePem**: String.
- **Status**: Optional. String that can be one of: ACTIVE, INACTIVE, PENDING_ACTIVATION. Defaults to ACTIVE.

**Policy Resources**

Policy resources are declared using one the following properties:

- **PolicyName**: Optional. String. Defaults to a hash of the policy document.
- **PolicyDocument**: a stringified JSON object. Optional. If PolicyDocument is not provided, the policy must already be created.
Note

If a Policy section is present, PolicyName or PolicyDocument, but not both, must be specified.

Override Settings

If a template specifies a resource that already exists, the OverrideSettings section allows you to specify the action to take:

DO NOTHING

Leave the resource as is.

REPLACE

Replace the resource with the resource specified in the template.

FAIL

Cause the request to fail with a ResourceConflictsException.

Resource Example

The following template snippet declares a thing, a certificate, and a policy:

```
"Resources" : {
    "thing" : {
        "Type" : "AWS::IoT::Thing",
        "Properties" : {
            "ThingName" : {"Ref" : "ThingName"},
            "AttributePayload" : { "version" : "v1", "serialNumber" : {"Ref" : "SerialNumber"}},
            "ThingTypeName" : "lightBulb-versionA",
            "ThingGroups" : ["v1-lightbulbs", {"Ref" : "Location"}]
        }
    },
    "certificate" : {
        "Type" : "AWS::IoT::Certificate",
        "Properties" : {
            "CertificateSigningRequest": {"Ref" : "CSR"},
            "Status" : "ACTIVE"
        }
    }
    "policy" : { 
        "Type" : "AWS::IoT::Policy",
        "Properties" : {
        }
    }
}
```

The thing is declared with:

- The logical name "thing".
- The type AWS::IoT::Thing.
- A set of thing properties.
The thing properties include the thing name, a set of attributes, an optional thing type name, and an optional list of thing groups to which the thing will belong.

Parameters are referenced by "Ref": "<parameter-name>". When the template is evaluated, the parameters are replaced with the parameter's value from the dictionary passed in with the template.

The certificate is declared with:

- The logical name "certificate".
- The type AWS::IoT::Certificate.
- A set of properties.

The properties include the CSR for the certificate, and setting the status to ACTIVE. The CSR text is passed as a parameter in the dictionary passed with the template.

The policy is declared with:

- The logical name "policy".
- The type AWS::IoT::Policy.
- Either the name of an existing policy or a policy document.

Template Example

The following JSON file is an example of a complete provisioning template:

(Note that the PolicyDocument field value must be a stringified JSON object.)

```json
{
"Parameters" : {
  "ThingName" : {
    "Type" : "String"
  },
  "SerialNumber" : {
    "Type" : "String"
  },
  "Location" : {
    "Type" : "String",
    "Default" : "WA"
  },
  "CSR" : {
    "Type" : "String"
  }
},
"Resources" : {
  "thing" : {
    "Type" : "AWS::IoT::Thing",
    "Properties" : {
      "ThingName" : {"Ref" : "ThingName"},
      "AttributePayload" : { "version" : "v1", "serialNumber" : {"Ref" : "SerialNumber"}},
      "ThingTypeName" : "lightBulb-versionA",
      "ThingGroups" : ["v1-lightbulbs", {"Ref" : "Location"}]
    }
  }
}
```
Programmatic Provisioning

To provision a thing, use the `RegisterThing` API or the `register-thing` CLI command. The `register-thing` CLI command takes the following arguments:

--template-body

The provisioning template.

--parameters

A list of name/value pairs for the parameters used in the provisioning template, in JSON format. For example:

```
{"ThingName" : "MyProvisionedThing", "CSR" : "<csr-text>"}
```

See Template Example (p. 306).

`RegisterThing` or `register-thing` returns the ARNs for the resources and the text of the certificate it created:

```
{
    "certificatePem": "<certificate-text>",
    "resourceArns": {
        "certificate": "arn:aws:iot:us-west-2:123456789012:cert/cd82bb924d4c6cbb14986dcbb4f40f30d892cc6b3ce7ad5008ed6542eaa2b049",
        "thing": "arn:aws:iot:us-west-2:123456789012:thing/MyProvisionedThing"
    }
}
```

If a parameter is omitted from the dictionary, the default value is used. If no default value is specified, the parameter is not replaced with a value.

Just-in-Time Provisioning

You can have your devices provisioned when they first attempt to connect to AWS IoT. Just-in-time provisioning (JITP) settings are made on CA certificates. You must enable automatic registration and
associate a provisioning template with the CA certificate used to sign the device certificate you are using to provision the device.

You can make these settings when registering a new CA certificate with the RegisterCACertificate API or the register-ca-certificate CLI command:

```bash
aws iot register-ca-certificate --ca-certificate <your-ca-cert> --verification-cert <your-verification-cert> --set-as-active --allow-auto-registration --provisioning-config <your-template>
```

For more information, see Registering a CA certificate.

You can also use the UpdateCACertificate API or the update-ca-certificate CLI command to update the settings for a CA certificate:

```bash
$ aws iot update-ca-certificate --cert-id <caCertificateId> --new-auto-registration-status ENABLE --provisioning-config <your-template>
```

When a device attempts to connect to AWS IoT by using a certificate signed by a registered CA certificate, AWS IoT loads the template from the CA certificate and calls RegisterThing using the template.

AWS IoT defines the following parameters that you can declare and reference within provisioning templates:

- AWS::IoT::Certificate::Country
- AWS::IoT::Certificate::Organization
- AWS::IoT::Certificate::OrganizationalUnit
- AWS::IoT::Certificate::DistinguishedNameQualifier
- AWS::IoT::Certificate::StateName
- AWS::IoT::Certificate::CommonName
- AWS::IoT::Certificate::SerialNumber
- AWS::IoT::Certificate::Id

The values for these provisioning template parameters are extracted from the certificate of the device being provisioned.

**Bulk Provisioning**

You can use the start-thing-registration-task command to provision things in bulk. This command takes a provisioning template, an Amazon S3 bucket name, a key name, and a role ARN that allows access to the file in the Amazon S3 bucket. The file in the Amazon S3 bucket contains the values used to replace the parameters in the template. The file must be a newline-delimited JSON file. Each line contains all of the parameter values for provisioning a single device. For example:

```json
{"ThingName": "foo", "SerialNumber": "123", "CSR": "csr1"}
{"ThingName": "bar", "SerialNumber": "456", "CSR": "csr2"}
```

Use the ListThingRegistrationTasks API to list the your current bulk thing provisioning tasks. To get information about a specific bulk thing provisioning task, use the DescribeThingRegistrationTask. Use the StopThingRegistrationTask to stop a bulk thing provisioning task.
Note
Only one bulk provisioning operation task can run at a time.
Fleet Indexing Service

Fleet Indexing is a managed service that allows you to index and search your thing registry and thing shadow data in the cloud. After your fleet index is set up, the service manages the indexing of all your thing registry and shadow updates. You can use a simple query language based on the popular open source search engine, Apache Lucene, to search across this data.

To get started, enable indexing and AWS IoT creates the index for your things. After it is active, you can run queries on your index. AWS IoT keeps it continuously updated with your latest data.

You can use the [AWS IoT console](https://aws.amazon.com/iot/) to manage indexing configuration and run your search queries. If you prefer programmatic access, you can use the AWS SDKs or the AWS CLI.

Please note that there are additional costs for using this service, beyond the standard charges for AWS IoT services, which are outlined in [AWS IoT Device Management Pricing](https://aws.amazon.com/iot/pricing/).

Managing Indexing

AWS_Things is the index created for all of your things. You can control whether you want to index only thing registry data or both thing registry and shadow data.

Enabling Indexing

You can create the AWS_Things index and control its configuration by using the `thing-indexing-configuration` setting in the `UpdateIndexingConfiguration` API. You can retrieve the current indexing configuration by using the `GetIndexingConfiguration` API.

The following command shows how to use the `get-indexing-configuration` CLI command to retrieve the current thing-indexing configuration:

```bash
aws iot get-indexing-configuration
{
   "thingIndexing": "OFF"
}
```

The following command shows how to use the `aws iot update-indexing-configuration` CLI command to update the thing-indexing configuration:

```bash
aws iot update-indexing-configuration --thing-indexing-configuration
thingIndexingMode=REGISTRY_AND_SHADOW
```

Valid values for `thing-indexing-configuration` are:

- **OFF**
  - No indexing/delete index.
- **REGISTRY**
  - Create or configure the AWS_Things index to index thing registry data only.
- **REGISTRY_AND_SHADOW**
  - Create or configure the AWS_Things index to index thing registry and shadow data.
Note
Normally, thing shadows are encrypted. However, if you decide to include thing shadows in the `AWS_Things` index, the data will be decrypted in order to index it.

Describing Indexes

The following command shows you how to use the `describe-index` CLI command to retrieve the current status of the index:

```bash
aws iot describe-index --index-name "AWS_Things"
{
    "indexName": "AWS_Things",
    "indexStatus": "BUILDING",
    "schema": "REGISTRY_AND_SHADOW"
}
```

The first time you enable indexing, AWS IoT builds your index. You cannot query the index if the `indexStatus` is `BUILDING`. The schema indicates which type of data, REGISTRY or REGISTRY_AND_SHADOW, is indexed.

Changing the configuration for your index causes the index to be rebuilt. The `indexStatus` during this process is `REBUILDING`. You can execute queries on the existing data while a rebuild is in progress. For example, if you change the index configuration from REGISTRY to REGISTRY_AND_SHADOW, while the index is being rebuilt, you can query registry data, including the latest updates, but you cannot query the shadow data until the rebuild is complete. The amount of time it takes to build or rebuild the index depends on the amount of data.

Querying an Index

The following command shows how to use the `search-index` CLI command to query data in the index:

```bash
aws iot search-index --index-name "AWS_Things" --query-string "thingName:mything*"
{
    "things":[
    {
        "thingName":"mything1",
        "thingGroupNames":[
            "mygroup1"
        ],
        "thingId":"a4b9f759-b0f2-4857-8a4b-967745ed9f4e",
        "attributes":{
            "attribute1":"abc"
        }
    },
    {
        "thingName":"mything2",
        "thingTypeName":"MyThingType",
        "thingGroupNames":[
            "mygroup1",
            "mygroup2"
        ],
        "thingId":"01014ef9-e97e-44c6-985a-d0b06924f2af",
        "attributes":{
            "model":"1.2",
            "country":"usa"
        },
        "shadow":{
            "desired":{
                "location":"new york",
                "myvalues":[3, 4, 5]
            }
        }
    }
    ]
}
```
Query Syntax

Queries are specified using a Lucene-like query syntax. For more information, see Lucene query syntax overview on the Apache website.

The following features of Lucene query syntax are supported:

- Terms and phrases
- Searching fields
- Prefix search
- Range search
- Boolean operators AND, OR, NOT and –
- Grouping
- Field grouping
- Escaping special characters

The following features of Lucene query syntax are NOT supported:

- Leading wildcard search (such as **xyz”), but searching for "*" will match all things
- Regular expressions
- Boosting
Example Queries

Queries are specified in a query string using a Lucene-like query syntax and passed to the SearchIndex API. The following table lists some example query strings:

<table>
<thead>
<tr>
<th>Query String</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;abc&quot;</td>
<td>Queries for &quot;abc&quot; in any registry or thing shadow field.</td>
</tr>
<tr>
<td>&quot;thingName:myThingName&quot;</td>
<td>Queries for a thing with name &quot;myThingName&quot;.</td>
</tr>
<tr>
<td>&quot;thingName:my*&quot;</td>
<td>Queries for things with names that begin with &quot;my&quot;.</td>
</tr>
<tr>
<td>&quot;thingName:ab?&quot;</td>
<td>Queries for things with names that have &quot;ab&quot; plus one additional character, for example: &quot;aba&quot;, &quot;abb&quot;, &quot;abc&quot; etc.</td>
</tr>
<tr>
<td>&quot;attributes.myAttribute:75&quot;</td>
<td>Queries for things with an attribute called &quot;MyAttribute&quot; that has the value 75.</td>
</tr>
<tr>
<td>&quot;attributes.myAttribute:[75 TO 80]&quot;</td>
<td>Queries for things with an attribute called &quot;MyAttribute&quot; whose value falls within a numeric range (75 - 80, inclusive).</td>
</tr>
<tr>
<td>&quot;attributes.myAttribute:{75 TO 80}&quot;</td>
<td>Queries for things with an attribute called &quot;MyAttribute&quot; whose value falls within the numeric range (&gt;75 and &lt;=80).</td>
</tr>
<tr>
<td>'attributes.serialNumber['abcd&quot; TO &quot;abcf&quot;]'</td>
<td>Queries for things with an attribute called &quot;serialNumber&quot; whose value is within an alphanumeric string range. This query will return things with a &quot;serialNumber&quot; attribute with values &quot;abcd&quot;, &quot;abce&quot;, or &quot;abcf&quot;.</td>
</tr>
<tr>
<td>Query String</td>
<td>Result</td>
</tr>
<tr>
<td>--------------</td>
<td>--------</td>
</tr>
<tr>
<td>&quot;attributes.myAttribute:i*t&quot;</td>
<td>Queries for things with an attribute called &quot;MyAttribute&quot; whose value is 'i', followed by any number of characters, followed by 't'.</td>
</tr>
<tr>
<td>&quot;attributes.attr1:abc AND attributes.attr2&lt;5 NOT attributes.attr3&gt;10&quot;</td>
<td>Queries for things that combine terms using Boolean expressions. This query will return things that have an attribute named &quot;attr1&quot; with a value &quot;abc&quot;, an attribute named &quot;attr2&quot; that is less than 5, and an attribute named &quot;attr3&quot; that is not greater than 10.</td>
</tr>
<tr>
<td>&quot;shadow.hasDelta:true&quot;</td>
<td>Queries for things whose shadow has a delta element.</td>
</tr>
<tr>
<td>&quot;-attributes.model:legacy&quot;</td>
<td>Queries for things where the attribute model is not &quot;legacy&quot;.</td>
</tr>
</tbody>
</table>
| "shadow.reported.stats.battery:(>70 AND <100) (v2 | v3) -attributes.model:legacy" | Queries for things with the following:  
  - The thing's shadow stats.battery attribute has a value between 70 and 100.  
  - The text "v2" or "v3" occurs in a thing's name, type name, or attribute values.  
  - The thing's model attribute is not set to "legacy". |
| "shadow.reported.myvalues:2" | Queries for things where the myvalues array in the thing shadow's reported section contains a value of 2. |
| "shadow.reported.location:* NOT shadow.desired.stats.battery:*" | Queries for things with the following:  
  - The location attribute exists in the thing shadow's reported section.  
  - The stats.battery attribute does not exist in the thing shadow's desired section. |

### Authorization

You can specify the things index as a resource ARN in an AWS IoT policy action:

<table>
<thead>
<tr>
<th>Action</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>iot:SearchIndex</td>
<td>An index ARN (for example, arn:aws:iot:&lt;your-aws-region&gt;:index/AWS_Things).</td>
</tr>
<tr>
<td>iot:DescribeIndex</td>
<td>An index ARN (for example, arn:aws:iot:&lt;your-aws-region&gt;:index/AWS_Things).</td>
</tr>
</tbody>
</table>
AWS IoT Events

AWS IoT publishes event messages when certain events occur. Events are generated by the AWS IoT thing registry when things are added, updated, or deleted. Each event causes a single event message to be sent. Event messages are published over MQTT with a JSON payload. The content of the payload depends on the type of event.

You control which event types are published by calling the UpdateEventConfigurations API.

You can get the current event configuration by calling the DescribeEventConfigurations API.

In order to receive event messages your device must use an appropriate policy that allows it to connect to the AWS IoT device gateway and subscribe to MQTT event topics. You must also subscribe to the appropriate topic filters.

Policy Required for Receiving AWS IoT Events

The following is an example of the policy required for receiving lifecycle events:

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Effect":"Allow",
            "Action":[
                "iot:Subscribe",
                "iot:Receive"
            ],
            "Resource":[
                "arn:aws:iot:region:account:/$aws/events/*"
            ]
        }]
}
```

Registry Events

The AWS IoT device registry publishes event messages when things, thing types, and thing groups are created, updated, or deleted. The AWS IoT registry currently supports the following event types:

thingEvent

Sent when a thing is created, updated, or deleted.

thingTypeEvent

Sent when a thing type is created, deprecated, undeprecated, or deleted.

thingTypeAssociationMessage

Sent when a thing type is associated or disassociated with a thing.

thingGroupEvent

Sent when a thing group is created, updated, or deleted.

thingGroupMembershipEvent

Sent when a thing is added to or removed from a thing group.
thingGroupHierarchyEvent

Sent when adding or removing a thing group to or from its thing group parent.

Registry event messages are published using the following MQTT topics:

$aws/events/thing/<thingName>/[ created | updated | deleted ]

Topics where thing events are published.

$aws/events/thingGroup/<groupName>/[ created | updated | deleted ]

Topics where thingGroup events are published.

$aws/events/thingType/<thingTypeName>/[ created | updated | deleted ]

Topics where thingType events are published.

$aws/events/thingTypeAssociation/thing/<thingName>/<typeName>

Topic where thingTypeAssociation events are published.

$aws/events/thingGroupMembership/thingGroup/<thingGroupName>/thing/<thingName>/[ added | removed ]

Topics where thingGroupMembership events are published.

$aws/events/thingGroupHierarchy/thingGroup/<parentThingGroupName>/childThingGroup/<childThingGroupName>[ added | removed ]

Topics where thingGroupHierarchyEvent events are published.

Note
Event messages are guaranteed to be published once. It is possible for them to be published more than once. The ordering of event messages is not guaranteed.

Thing Events

The payload for a thingEvent contains the following attributes:

eventType

Set to "thingEvent" for thingEvent events.

eventId

A unique event ID (string).

timestamp

The UNIX timestamp of when the event occurred.

operation

The operation that triggered the event. Valid values are:

- CREATED
- UPDATED
- Deleted

accountId

Your AWS account ID.
thingId
The ID of the thing being created, updated, or deleted.

thingName
The name of the thing being created, updated, or deleted.

versionNumber
The version of the thing being created, updated, or deleted. This value is set to 1 when a thing is created. It is incremented by 1 each time the thing is updated.

thingTypeName
The thing type associated with the thing, if one exists. Otherwise, null.

attributes
A collection of name-value pairs associated with the thing.

The following is an example of a payload that is published when a thing has been created.

```
{  
  "eventType" : "thingEvent",  
  "eventId" : "f5ae9b94-8b8e-4d8e-8c8f-b3266dd89853",  
  "timestamp" : 1502210967087,  
  "operation" : "CREATED",  
  "accountId" : "123456789012",  
  "thingId" : "b604f69c-aa9a-4d4a-829e-c480e958a0b5",  
  "thingName" : "MyThing",  
  "versionNumber" : 1,  
  "thingTypeName" : null,  
  "attributes": {  
    "attribute3": "value3",  
    "attribute1": "value1",  
    "attribute2": "value2"  
  }  
}
```

The following is an example of a payload that is published when a thing has been updated.

```
{  
  "eventType" : "thingEvent",  
  "eventId" : "b930023e-2348-4f9a-8b75-ba519742bd8a",  
  "timestamp" : 1502211188141,  
  "operation" : "UPDATED",  
  "accountId" : "123456789012",  
  "thingId" : "b604f69c-aa9a-4d4a-829e-c480e958a0b5",  
  "thingName" : "MyThing",  
  "versionNumber" : 2,  
  "thingTypeName" : null,  
  "attributes": {  
    "attribute3": "value3",  
    "attribute1": "value1",  
    "attribute2": "value2"  
  }  
}
```

The following is an example of a payload that is published when a thing has been deleted.

```
{  
  "eventType" : "thingEvent",  
  "eventId" : "46b0b159-cd50-4b6d-afe7-8b737d997471",  
  "timestamp" : 1502211188141,  
  "operation" : "DELETED",  
  "accountId" : "123456789012",  
  "thingId" : "b604f69c-aa9a-4d4a-829e-c480e958a0b5",  
  "thingName" : "MyThing",  
  "versionNumber" : 3,  
  "thingTypeName" : null,  
  "attributes": {  
    "attribute3": "value3",  
    "attribute1": "value1",  
    "attribute2": "value2"  
  }  
}
```
Thing Type Events

The payload for a thingTypeEvent event contains the following attributes:

eventType

Set to "thingTypeEvent" for thingTypeEvent events.

eventId

A unique event ID (string).

timestamp

The UNIX timestamp of when the event occurred.

operation

The operation that triggered the event. Valid values are:

- CREATED
- DEPRECATED
- DELETED

accountId

Your AWS account ID.

thingTypeId

The ID of the thing type being created, deprecated, or deleted.

thingTypeName

The name of the thing type being created, deprecated, or deleted.

isDeprecated

true if the thing type is deprecated. Otherwise, false.

deprecationDate

The UNIX timestamp for when the thing type was deprecated.

searchableAttributes

A collection of name-value pairs associated with the thing type that can be used for searching.

description

A description of the thing type.

The following is an example of a payload that is published when a thing type is created.
The payload for a thingGroupEvent event contains the following attributes:

**eventType**
Set to "thingGroupEvent" for thingGroupEvent events.

**eventId**
A unique event ID (string).

**timestamp**
The UNIX timestamp of when the event occurred.

---

**Thing Group Events**

The following is an example of a payload that is published when a thing type is deprecated.

```
{
  "eventType" : "thingTypeEvent",
  "eventId" : "8827376c-4b05-49a3-9b3b-733729df7ed5",
  "timestamp" : 1502140154962,
  "operation" : "UPDATED",
  "accountId" : "123456789012",
  "thingTypeId" : "c530ae83-32aa-4592-94d3-da29879d1aac",
  "thingTypeName" : "MyThingType",
  "isDeprecated" : true,
  "deprecationDate" : 1502212522970,
  "searchableAttributes" : [ "attribute1", "attribute2", "attribute3" ],
  "description" : "My thing type"
}
```

The following is an example of a payload that is published when a thing type is deleted.

```
{
  "eventType" : "thingTypeEvent",
  "eventId" : "8827376c-4b05-49a3-9b3b-733729df7ed5",
  "timestamp" : 1502216007699,
  "operation" : "DELETED",
  "accountId" : "123456789012",
  "thingTypeId" : "c530ae83-32aa-4592-94d3-da29879d1aac",
  "thingTypeName" : "MyThingType",
  "isDeprecated" : true,
  "deprecationDate" : 1502212522970,
  "searchableAttributes" : [ "attribute1", "attribute2", "attribute3" ],
  "description" : "My thing type"
}
```
operation

The operation that triggered the event. Valid values are:

- CREATED
- UPDATED
- DELETED

accountId

Your AWS account ID.

thingGroupId

The ID of the thing group being created, updated, or deleted.

thingGroupName

The name of the thing group being created, updated, or deleted.

versionNumber

The version of the thing group. This value is set to 1 when a thing group is created. It is incremented by 1 each time the thing group is updated.

parentGroupName

The name of the parent thing group (if one exists).

parentGroupId

The ID of the parent thing group (if one exists).

description

A description of the thing group.

rootToParentThingGroups

An array of information about the parent thing group. There is one entry for each parent thing group, starting with the parent of the current thing group and continuing until the root thing group has been reached. Each entry contains the thing group name and the thing group ARN.

attributes

A collection of name-value pairs associated with the thing group.

The following is an example of a payload that is published when a thing group is created.

```json
{
  "eventType" : "thingGroupEvent",
  "eventId" : "87f8e095-531c-47b3-aab5-5171364d138d",
  "timestamp" : 1502141209886,
  "operation" : "CREATED",
  "accountId" : "0123456789012",
  "thingGroupId" : "8f82a106-6b1d-4331-8984-a84db5f6f8cb",
  "thingGroupName" : "MyRootThingGroup",
  "versionNumber" : 1,
  "parentGroupName" : null,
  "parentGroupId" : null,
  "description" : "My root thing group",
  "rootToParentThingGroups" : null,
  "attributes" : {
    "attribute1" : "value1",
    "attribute3" : "value3",
    "attribute2" : "value2"
  }
}
```
The following is an example of a payload that is published when a thing group is updated.

```json
{
  "eventType" : "thingGroupEvent",
  "eventId" : "63609e4c-2720-466c-8cfe-aa1d897c7f03",
  "timestamp" : 1502141982675,
  "operation" : "UPDATED",
  "accountId" : "123456789012",
  "thingGroupId" : "98e8d404-b093-45e9-97f4-fb02aa2ac733",
  "thingGroupName" : "MyChildThingGroup",
  "versionNumber" : 2,
  "parentGroupName" : null,
  "parentGroupId" : null,
  "description" : "Myupdated child thing group",
  "rootToParentThingGroups" : null,
  "attributes" : {
    "attribute1" : "newValue1",
    "attribute3" : "value3",
    "attribute2" : "value2"
  }
}
```

The following is an example of a payload that is published when a thing group is deleted.

```json
{
  "eventType" : "thingGroupEvent",
  "eventId" : "c05cd030-5337-42de-a3a3-9e408f26c628",
  "timestamp" : 1502141623543,
  "operation" : "DELETED",
  "accountId" : "123456789012",
  "thingGroupId" : "06838589-373f-4312-b1f2-53f2192291c4",
  "thingGroupName" : "MyChildThingGroup",
  "versionNumber" : 2,
  "parentGroupName" : "MyParentThingGroup",
  "parentGroupId" : "8f82a106-6b1d-4331-8984-a84db5f6f8cb",
  "description" : "My child thing group",
  "rootToParentThingGroups" : null,
  "attributes" : {
    "attribute1" : "newValue1",
    "attribute3" : "value3",
    "attribute2" : "value2"
  }
}
```

**Thing Group Membership Events**

The payload for a `thingGroupMembershipEvent` event contains the following attributes:

- **eventType**
  - Set to "thingGroupMembershipEvent" for `thingGroupMembershipEvent` events.

- **eventId**
  - The event ID.

- **timestamp**
  - The UNIX timestamp for when the event occurred.
operation

**ADDED** when a thing is added to a thing group. **REMOVED** when a thing is removed from a thing group.

`accountId`

Your AWS account ID.

`groupArn`

The ARN of the thing group.

`groupId`

The ID of the group.

`thingArn`

The ARN of the thing that was added or removed from the thing group.

`thingId`

The ID of the thing that was added or removed from the thing group.

`membershipId`

An ID that represents the relationship between the thing and the thing group. This value is generated when you add a thing to a thing group.

The following is an example of a payload that is published when a thing is added to a thing group.

```json
{
    "eventType" : "thingGroupMembershipEvent",
    "eventId" : "d684bd5f-6f6e-48e1-950c-766ac7f02fd1",
    "timestamp" : 1502141492627,
    "operation" : "ADDED",
    "accountId" : "123456789012",
    "groupId" : "06838589-373f-4312-b1f2-53f2192291c4",
    "thingId" : "b604f69c-aa9a-4d4a-829e-c480e958a0b5",
    "membershipId" : "8505ebf8-4d32-4286-80e9-c23a4a16bbd8"
}
```

The following is an example of a payload that is published when a thing is removed from a thing group.

```json
{
    "eventType" : "thingGroupMembershipEvent",
    "eventId" : "8749197f-7412-453f-8fcd-8ba18661d3bd",
    "timestamp" : 1502141575159,
    "operation" : "REMOVED",
    "accountId" : "123456789012",
    "groupId" : "06838589-373f-4312-b1f2-53f2192291c4",
    "thingId" : "b604f69c-aa9a-4d4a-829e-c480e958a0b5",
    "membershipId" : "8505ebf8-4d32-4286-80e9-c23a4a16bbd8"
}
```

**Thing Group Hierarchy Events**

The `thingGroupHierarchyEvent` event occurs when a thing group is added as a child of another thing group. The payload for a `thingGroupHierarchyEvent` event contains the following attributes:
**eventType**

Set to "thingGroupHierarchyEvent" for thingGroupHierarchyEvent events.

**eventId**

The event ID.

**timestamp**

The UNIX timestamp for when the event occurred.

**operation**

*ADDED* when a thing is added to a thing group. *REMOVED* when a thing is removed from a thing group.

**accountId**

Your AWS account ID.

**thingGroupId**

The ID of the parent thing group.

**thingGroupName**

The name of the parent thing group.

**childGroupId**

The ID of the child thing group.

**childGroupName**

The name of the child thing group.

The following is an example of a payload that is published when a thing group is added as a child of another thing group.

```json
{
    "eventType" : "thingGroupHierarchyEvent",
    "eventId" : "264192c7-b573-46ef-ab7b-489fcd47da41",
    "timestamp" : 1502141354583,
    "operation" : "ADDED",
    "accountId" : "123456789012",
    "thingGroupId" : "8f82a106-6b1d-4331-8984-a84db5f6f8cb",
    "thingGroupName" : "MyRootThingGroup",
    "childGroupId" : "06838589-373f-4312-b1f2-53f2192291c4",
    "childGroupName" : "MyChildThingGroup"
}
```

The following is an example of a payload that is published when a thing group is removed as child of another thing group.

```json
{
    "eventType" : "thingGroupMembershipEvent",
    "eventId" : "8749197f-7412-453f-8fcd-8ba1861d3bda",
    "timestamp" : 1502141575159,
    "operation" : "REMOVED",
    "accountId" : "123456789012",
    "groupId" : "06838589-373f-4312-b1f2-53f2192291c4",
    "thingId" : "b604f69c-aa9a-4d4a-829e-c480e958a0b5",
    "membershipId" : "8505ebf8-4d32-4286-80e9-c23a4a16bbd8"
}
```
The AWS IoT Device SDKs help you to easily and quickly connect your devices to AWS IoT. The AWS IoT Device SDKs include open-source libraries, developer guides with samples, and porting guides so that you can build innovative IoT products or solutions on your choice of hardware platforms.

**AWS Mobile SDK for Android**

The AWS SDK for Android contains a library, samples, and documentation for developers to build connected mobile applications using AWS. This SDK also includes support for calling AWS IoT APIs. For more information, see the following:

- AWS Mobile SDK for Android on GitHub
- AWS Mobile SDK for Android Readme
- AWS Mobile SDK for Android Samples

**Arduino Yún SDK**

The AWS IoT Arduino Yún SDK makes it possible for developers to connect their Arduino Yún-compatible boards to AWS IoT. By connecting a device to AWS IoT, users can securely work with the message broker, rules, and thing shadows provided by AWS IoT and with other AWS services like AWS Lambda, Kinesis, and Amazon S3. For more information, see the following:

- Arduino Yún SDK on GitHub
- Arduino Yún SDK Readme

**AWS IoT Device SDK for Embedded C**

The AWS IoT Device SDK for Embedded C is a collection of C source files that can be used in embedded applications to securely connect to the AWS IoT platform. It includes transport clients, TLS implementations, and examples for their use. It also supports AWS IoT-specific features such as an API to access the Thing Shadows service. It is distributed as source code and is intended to be built into
customer firmware along with application code, other libraries, and RTOS. For more information, see the following:

- AWS IoT Device SDK for Embedded C GitHub
- AWS IoT Device SDK for Embedded C Readme
- AWS IoT Device SDK for Embedded C Porting Guide

AWS IoT C++ Device SDK

The AWS IoT C++ Device SDK allows developers to build connected applications using AWS and the AWS IoT APIs. Specifically, this SDK was designed for devices that are not resource constrained and required advanced features such as message queuing, multi-threading support, and the latest language features. For more information, see the following:

- AWS IoT C++ Device SDK GitHub
- AWS IoT C++ Device SDK Readme

AWS Mobile SDK for iOS

The AWS SDK for iOS is an open-source software development kit, distributed under an Apache Open Source license. The SDK for iOS provides a library, code samples, and documentation to help developers build connected mobile applications using AWS. This SDK also includes support for calling the AWS IoT API.

- AWS SDK for iOS on GitHub
- AWS SDK for iOS Readme
- AWS SDK for iOS Samples

AWS IoT Device SDK for Java

The AWS IoT Device SDK for Java makes it possible for Java developers to access the AWS IoT platform through MQTT or MQTT over the WebSocket protocol. The SDK is built with AWS IoT thing shadow support. You can access thing shadows by using HTTP methods, including GET, UPDATE, and DELETE. The SDK also supports a simplified thing shadow access model, which allows developers to exchange data with thing shadows by just using getter and setter methods, without having to serialize or deserialize any JSON documents. For more information, see the following:

- AWS IoT Device SDK for Java on GitHub
- AWS IoT Device SDK for Java readme

AWS IoT Device SDK for JavaScript

The aws-iot-device-sdk.js package makes it possible for developers to write JavaScript applications that access AWS IoT using MQTT or MQTT over the WebSocket protocol. It can be used in Node.js environments and browser applications. For more information, see the following:

- AWS IoT Device SDK for JavaScript on GitHub
- AWS IoT Device SDK for JavaScript readme
AWS IoT Device SDK for Python

The AWS IoT Device SDK for Python makes it possible for developers to write Python scripts to use their devices to access the AWS IoT platform through MQTT or MQTT over the WebSocket protocol. By connecting their devices to AWS IoT, users can securely work with the message broker, rules, and thing shadows provided by AWS IoT and with other AWS services like AWS Lambda, Kinesis, and Amazon S3, and more.

- AWS IoT Device SDK for Python on GitHub
- AWS IoT Device SDK for Python readme
Monitoring AWS IoT

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS IoT and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring AWS IoT, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

The next step is to establish a baseline for normal AWS IoT performance in your environment, by measuring performance at various times and under different load conditions. As you monitor AWS IoT, store historical monitoring data so that you can compare it with current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

For example, if you're using Amazon EC2, you can monitor CPU utilization, disk I/O, and network utilization for your instances. When performance falls outside your established baseline, you might need to reconfigure or optimize the instance to reduce CPU utilization, improve disk I/O, or reduce network traffic.

To establish a baseline you should, at a minimum, monitor the following items:

- PublishIn.Success
- PublishOut.Success
- Subscribe.Success
- Ping.Success
- Connect.Success
- GetThingShadow.Accepted
- UpdateThingShadow.Accepted
- DeleteThingShadow.Accepted
- RulesExecuted

Topics

- Monitoring Tools (p. 328)
- Monitoring with Amazon CloudWatch (p. 329)
- Logging AWS IoT API Calls with AWS CloudTrail (p. 336)

Monitoring Tools

AWS provides various tools that you can use to monitor AWS IoT. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.
Automated Monitoring Tools

You can use the following automated monitoring tools to watch AWS IoT and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring with Amazon CloudWatch (p. 329).

- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see Monitoring Log Files in the Amazon CloudWatch User Guide.

- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see What is Amazon CloudWatch Events in the Amazon CloudWatch User Guide.

- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Working with CloudTrail Log Files in the AWS CloudTrail User Guide.

Manual Monitoring Tools

Another important part of monitoring AWS IoT involves manually monitoring those items that the CloudWatch alarms don’t cover. The AWS IoT, CloudWatch, and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on AWS IoT.

- **AWS IoT dashboard shows:**
  - CA certificates
  - Certificates
  - Policies
  - Rules
  - Things
- **CloudWatch home page shows:**
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:
- Create customized dashboards to monitor the services you care about
- Graph metric data to troubleshoot issues and discover trends
- Search and browse all your AWS resource metrics
- Create and edit alarms to be notified of problems

Monitoring with Amazon CloudWatch

You can monitor AWS IoT using CloudWatch, which collects and processes raw data from AWS IoT into readable, near real-time metrics. These statistics are recorded for a period of two weeks, so that you can access historical information and gain a better perspective on how your web application or service is...
performing. By default, AWS IoT metric data is automatically sent to CloudWatch in 1 minute periods. For more information, see What Are Amazon CloudWatch, Amazon CloudWatch Events, and Amazon CloudWatch Logs? in the Amazon CloudWatch User Guide.

**AWS IoT Metrics and Dimensions**

When you interact with AWS IoT, it sends the following metrics and dimensions to CloudWatch every minute. You can use the following procedures to view the metrics for AWS IoT.

**To view metrics using the CloudWatch console**

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

2. In the navigation pane, choose Metrics.
3. In the CloudWatch Metrics by Category pane, under the metrics category for AWS IoT, select a metrics category, and then in the upper pane, scroll down to view the full list of metrics.

**To view metrics using the AWS CLI**

- At a command prompt, use the following command:

```bash
aws cloudwatch list-metrics --namespace "AWS/IoT"
```

CloudWatch displays the following metrics for AWS IoT:

**AWS IoT Metrics**

AWS IoT sends the following metrics to CloudWatch once per received request.

**IoT Metrics**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RulesExecuted</td>
<td>The number of AWS IoT rules executed.</td>
</tr>
</tbody>
</table>

**Rule Metrics**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TopicMatch</td>
<td>The number of incoming messages published on a topic on which a rule is listening. The RuleName dimension contains the name of the rule.</td>
</tr>
<tr>
<td>ParseError</td>
<td>The number of JSON parse errors that occurred in messages published on a topic on which a rule is</td>
</tr>
</tbody>
</table>
### Metric

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Listening</td>
<td>The <code>RuleName</code> dimension contains the name of the rule.</td>
</tr>
</tbody>
</table>

### Rule Action Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Success</td>
<td>The number of successful rule action invocations. The <code>RuleName</code> dimension contains the name of the rule that specifies the action. The <code>ActionType</code> dimension contains the type of action that was invoked.</td>
</tr>
<tr>
<td>Failure</td>
<td>The number of failed rule action invocations. The <code>RuleName</code> dimension contains the name of the rule that specifies the action. The <code>RuleName</code> dimension contains the name of the rule that specifies the action. The <code>ActionType</code> dimension contains the type of action that was invoked.</td>
</tr>
</tbody>
</table>

### Message Broker Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect.AuthError</td>
<td>The number of connection requests that could not be authorized by the message broker. The <code>Protocol</code> dimension contains the protocol used to send the CONNECT. message.</td>
</tr>
<tr>
<td>Connect.ClientError</td>
<td>The number of connection requests rejected because the MQTT message did not meet the requirements defined in AWS IoT Limits. The <code>Protocol</code> dimension contains the protocol used to send the CONNECT. message.</td>
</tr>
<tr>
<td>Connect.ServerError</td>
<td>The number of connection requests that failed because an internal error occurred. The <code>Protocol</code> dimension contains the protocol used to send the CONNECT message.</td>
</tr>
<tr>
<td>Connect.Success</td>
<td>The number of successful connections to the message broker. The <code>Protocol</code> dimension contains the protocol used to send the CONNECT message.</td>
</tr>
<tr>
<td>Connect.Throttle</td>
<td>The number of connection requests that were throttled because the client exceeded the allowed connect request rate. The <code>Protocol</code> dimension contains the protocol used to send the CONNECT message.</td>
</tr>
<tr>
<td>Ping.Success</td>
<td>The number of ping messages received by the message broker. The <code>Protocol</code> dimension contains the protocol used to send the ping message.</td>
</tr>
<tr>
<td>PublishIn.AuthError</td>
<td>The number of publish requests the message broker was unable to authorize. The <code>Protocol</code> dimension contains the protocol used to publish the message.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PublishIn.ClientError</td>
<td>The number of publish requests rejected by the message broker because the message did not meet the requirements defined in AWS IoT Limits. The Protocol dimension contains the protocol used to publish the message.</td>
</tr>
<tr>
<td>PublishIn.ServerError</td>
<td>The number of publish requests the message broker failed to process because an internal error occurred. The Protocol dimension contains the protocol used to send the PUBLISH message.</td>
</tr>
<tr>
<td>PublishIn.Success</td>
<td>The number of publish requests successfully processed by the message broker. The Protocol dimension contains the protocol used to send the PUBLISH message.</td>
</tr>
<tr>
<td>PublishIn.Throttle</td>
<td>The number of publish request that were throttled because the client exceeded the allowed inbound message rate. The Protocol dimension contains the protocol used to send the PUBLISH message.</td>
</tr>
<tr>
<td>PublishOut.AuthError</td>
<td>The number of publish requests made by the message broker that could not be authorized by AWS IoT. The Protocol dimension contains the protocol used to send the PUBLISH message.</td>
</tr>
<tr>
<td>PublishOut.ClientError</td>
<td>The number of publish requests made by the message broker that were rejected because the message did not meet the requirements defined in AWS IoT Limits. The Protocol dimension contains the protocol used to send the PUBLISH message.</td>
</tr>
<tr>
<td>PublishOut.Success</td>
<td>The number of publish requests successfully made by the message broker. The Protocol dimension contains the protocol used to send the PUBLISH message.</td>
</tr>
<tr>
<td>Subscribe.AuthError</td>
<td>The number of subscription requests made by a client that could not be authorized. The Protocol dimension contains the protocol used to send the SUBSCRIBE message.</td>
</tr>
<tr>
<td>Subscribe.ClientError</td>
<td>The number of subscribe requests that were rejected because the SUBSCRIBE message did not meet the requirements defined in AWS IoT Limits. The Protocol dimension contains the protocol used to send the SUBSCRIBE message.</td>
</tr>
<tr>
<td>Subscribe.ServerError</td>
<td>The number of subscribe requests that were rejected because an internal error occurred. The Protocol dimension contains the protocol used to send the SUBSCRIBE message.</td>
</tr>
<tr>
<td>Subscribe.Success</td>
<td>The number of subscribe requests that were successfully processed by the message broker. The Protocol dimension contains the protocol used to send the SUBSCRIBE message.</td>
</tr>
</tbody>
</table>
### Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subscribe.Throttle</td>
<td>The number of subscribe requests that were throttled because the client exceeded the allowed subscribe request rate. The Protocol dimension contains the protocol used to send the SUBSCRIBE message.</td>
</tr>
<tr>
<td>Unsubscribe.ClientError</td>
<td>The number of unsubscribe requests that were rejected because the UNSUBSCRIBE message did not meet the requirements defined in AWS IoT Limits. The Protocol dimension contains the protocol used to send the UNSUBSCRIBE message.</td>
</tr>
<tr>
<td>Unsubscribe.ServerError</td>
<td>The number of unsubscribe requests that were rejected because an internal error occurred. The Protocol dimension contains the protocol used to send the UNSUBSCRIBE message.</td>
</tr>
<tr>
<td>Unsubscribe.Success</td>
<td>The number of unsubscribe requests that were successfully processed by the message broker. The Protocol dimension contains the protocol used to send the UNSUBSCRIBE message.</td>
</tr>
<tr>
<td>Unsubscribe.Throttle</td>
<td>The number of unsubscribe requests that were rejected because the client exceeded the allowed unsubscribe request rate. The Protocol dimension contains the protocol used to send the UNSUBSCRIBE message.</td>
</tr>
</tbody>
</table>

**Note**
The message broker metrics are displayed in the AWS IoT console under Protocol Metrics.

### Thing Shadow Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeleteThingShadow.Accepted</td>
<td>The number of DeleteThingShadow requests processed successfully. The Protocol dimension contains the protocol used to make the request.</td>
</tr>
<tr>
<td>GetThingShadow.Accepted</td>
<td>The number of GetThingShadow requests processed successfully. The Protocol dimension contains the protocol used to make the request.</td>
</tr>
<tr>
<td>UpdateThingShadow.Accepted</td>
<td>The number of UpdateThingShadow requests processed successfully. The Protocol dimension contains the protocol used to make the request.</td>
</tr>
</tbody>
</table>

**Note**
The thing shadow metrics are displayed in the AWS IoT console under Protocol Metrics.

### Dimensions for Metrics

Metrics use the namespace and provide metrics for the following dimension(s):
### How Do I Use AWS IoT Metrics?

The metrics reported by AWS IoT provide information that you can analyze in different ways. The following use cases are based on a scenario where you have ten things that connect to the internet once a day. Each day:

- Ten things connect to AWS IoT at roughly the same time.
- Each thing subscribes to a topic filter, and then waits for an hour before disconnecting. During this period, things communicate with one another and learn more about the state of the world.
- Each thing publishes some perception it has based on its newly found data using `UpdateThingShadow`.
- Each thing disconnects from AWS IoT.

These are suggestions to get you started, not a comprehensive list.

- How can I be notified if my things do not connect successfully each day? (p. 334)
- How can I be notified if my things are not publishing data each day? (p. 335)
- How can I be notified if my thing’s shadow updates are being rejected each day? (p. 336)

### Creating CloudWatch Alarms to Monitor AWS IoT

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period you specify and performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods.

**How can I be notified if my things do not connect successfully each day?**

   
   For more information, see Set Up Amazon Simple Notification Service.

2. Create the alarm.

   ```bash
   Prompt> aws cloudwatch put-metric-alarm \
   --alarm-name ConnectSuccessAlarm \
   --alarm-description "Alarm when my Things don't connect successfully" \
   ```
Creating CloudWatch Alarms

```
--namespace AWS/IoT
--metric-name Connect.Success
--dimensions Name=Protocol,Value=MQTT
--statistic Sum
--threshold 10
--comparison-operator LessThanThreshold
--period 86400
--unit Count
--evaluation-periods 1
```

Prompt>`aws cloudwatch put-metric-alarm
--alarm-name ConnectSuccessAlarm
--alarm-description "Alarm when my Things don't connect successfully"
--namespace AWS/IoT
--metric-name Connect.Success
--dimensions Name=Protocol,Value=MQTT
--statistic Sum
--threshold 10
--comparison-operator LessThanThreshold
--period 86400
--unit Count
--evaluation-periods 1

3. Test the alarm.

Prompt>`aws cloudwatch set-alarm-state --alarm-name ConnectSuccessAlarm --state-reason "initializing" --state-value OK

Prompt>`aws cloudwatch set-alarm-state --alarm-name ConnectSuccessAlarm --state-reason "initializing" --state-value ALARM

How can I be notified if my things are not publishing data each day?

   
   For more information, see Set Up Amazon Simple Notification Service.

2. Create the alarm.

```
Prompt>`aws cloudwatch put-metric-alarm
--alarm-name PublishInSuccessAlarm
--alarm-description "Alarm when my Things don't publish their data"
--namespace AWS/IoT
--metric-name PublishIn.Success
--dimensions Name=Protocol,Value=MQTT
--statistic Sum
--threshold 10
--comparison-operator LessThanThreshold
--period 86400
--unit Count
--evaluation-periods 1
```

3. Test the alarm.
How can I be notified if my thing’s shadow updates are being rejected each day?

2. Create the alarm.

```bash
Prompt>aws cloudwatch put-metric-alarm
  --alarm-name UpdateThingShadowSuccessAlarm
  --alarm-description "Alarm when my Things Shadow updates are getting rejected"
  --namespace AWS/IoT
  --metric-name UpdateThingShadow.Success
  --dimensions Name=Protocol,Value=MQTT
  --statistic Sum
  --threshold 10
  --comparison-operator LessThanThreshold
  --period 86400
  --unit Count
  --evaluation-periods 1
```

3. Test the alarm.

```bash
Prompt>aws cloudwatch set-alarm-state --alarm-name UpdateThingShadowSuccessAlarm --state-reason "initializing" --state-value OK

Prompt>aws cloudwatch set-alarm-state --alarm-name UpdateThingShadowSuccessAlarm --state-reason "initializing" --state-value ALARM
```

Logging AWS IoT API Calls with AWS CloudTrail

AWS IoT is integrated with CloudTrail, a service that captures all of the AWS IoT API calls and delivers the log files to an Amazon S3 bucket that you specify. CloudTrail captures API calls from the AWS IoT console or from your code to the AWS IoT APIs. Using the information collected by CloudTrail, you can determine the request that was made to AWS IoT, the source IP address from which the request was made, who made the request, when it was made, and so on.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

AWS IoT Information in CloudTrail

When CloudTrail logging is enabled in your AWS account, API calls made to AWS IoT actions are tracked in CloudTrail log files where they are written with other AWS service records. CloudTrail determines when to create and write to a new file based on a time period and file size.
All AWS IoT actions are logged by CloudTrail and are documented in the AWS IoT API Reference. For example, calls to the `CreateThing`, `ListThings`, and `ListTopicRules` sections generate entries in the CloudTrail log files.

Every log entry contains information about who generated the request. The user identity information in the log entry helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail `userIdentity` Element.

You can store your log files in your Amazon S3 bucket for as long as you want, but you can also define Amazon S3 lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted with Amazon S3 server-side encryption (SSE).

If you want to be notified upon log file delivery, you can configure CloudTrail to publish Amazon SNS notifications when new log files are delivered. For more information, see Configuring Amazon SNS Notifications for CloudTrail.

You can also aggregate AWS IoT log files from multiple AWS regions and multiple AWS accounts into a single Amazon S3 bucket.

For more information, see Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts.

### Understanding AWS IoT Log File Entries

CloudTrail log files can contain one or more log entries. Each entry lists multiple JSON-formatted events. A log entry represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Log entries are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `AttachPolicy` action.

```json
{
    "timestamp":"1460159496",
    "AdditionalEventData":"",
    "Annotation":"",
    "ApiVersion":"",
    "ErrorCode":"",
    "ErrorMessage":"",
    "EventID":"8bff4fed-c229-4d2d-8264-4ab28a487505",
    "EventName":"AttachPolicy",
    "EventTime":"2016-04-08T23:51:36Z",
    "EventType":"AwsApiCall",
    "ReadOnly":"",
    "RecipientAccountList":"",
    "RequestID":"d4875df2-fee4-11e5-b829-23bf9b56bcd",
    "RequestParamers":{
        "principal":"arn:aws:iot:us-east-1:123456789012:cert/528ce3ee8047fe6a75ee51ab7beddb4eb268ad41d2ea881a10b67e8e76924d894",
        "policyName":"ExamplePolicyForIoT"
    },
    "Resources":"
```
"UserAgent":"aws-internal/3",

Troubleshooting AWS IoT

The following information might help you troubleshoot common issues in AWS IoT.

Tasks

- Diagnosing Connectivity Issues (p. 339)
- Setting Up CloudWatch Logs with AWS IoT (p. 339)
- Diagnosing Problems with Thing Shadows (p. 357)
- Diagnosing Salesforce IoT Input Stream Action Issues (p. 358)
- AWS IoT Errors (p. 359)

Diagnosing Connectivity Issues

Authentication

How do my devices authenticate AWS IoT endpoints?

Add the AWS IoT CA certificate to your client's trust store. You can download the CA certificate from here.

How can I validate a correctly configured certificate?

Use the OpenSSL `s_client` command to test a connection to the AWS IoT endpoint:

```bash
openssl s_client -connect custom_endpoint.iot.us-east-1.amazonaws.com:8443 -CAfile CA.pem -cert cert.pem -key privateKey.pem
```

Authorization

I received a PUBNACK or SUBNACK response from the broker. What do I do?

Make sure that there is a policy attached to the certificate you are using to call AWS IoT. All publish/subscribe operations are denied by default.

Setting Up CloudWatch Logs with AWS IoT

AWS IoT sends progress events about each message as it passes from your devices through the message broker and the rules engine. To view these logs, you must configure AWS IoT to generate the logs used by CloudWatch.

For more information about CloudWatch Logs, see CloudWatch Logs.

To enable AWS IoT logging, you must create an IAM role, register the role with AWS IoT, and then configure AWS IoT logging.
Note
Before you enable AWS IoT logging, make sure you understand the CloudWatch Logs access permissions. Users with access to CloudWatch Logs can see debugging information from your devices. For more information see Authentication and Access Control for Amazon CloudWatch Logs.

Create a Logging Role

Use the IAM console to create a logging role.

1. From the navigation pane, choose Roles, and then choose Create new role.
2. Choose AWS Service Role and for service role type, choose AWS IoT.
3. Choose the AWSIoTLogging role, and then choose Next Step.
4. Type a name and description for the role, and then choose Create role.

Logging Role Policy

The following policy documents provide the role policy and trust policy that allow AWS IoT to submit logs to CloudWatch on your behalf.

Note
These documents were created for you when you created the logging role.

Role policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:PutMetricFilter",
                "logs:PutRetentionPolicy"
            ],
            "Resource": ["*"]
        }
    ]
}
```

Trust policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": "iot.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```
Log Level

The log level specifies which types of logs are generated.

ERROR
- Any error that causes an operation to fail.
- Logs include ERROR information only.

WARN
- Anything that can potentially cause inconsistencies in the system, but might not cause the operation to fail.
- Logs include ERROR and WARN information.

INFO
- High-level information about the flow of things.
- Logs include INFO, ERROR, and WARN information.

DEBUG
- Information that might be helpful when debugging a problem.
- Logs include DEBUG, INFO, ERROR, and WARN information.

DISABLED
- All logging is disabled.

Configure AWS IoT Logging

You can configure logging in two ways, global logging and fine grained logging. Global logging sets one logging level for all logs no matter what resource triggered the logs. Fine-grained logging allows you to set a logging level for a specific resource or set of resources. Currently only thing groups are supported.

Global Logging

Use the `set-logging-options` CLI command to set the logging options for your account. `set-logging-options` takes two arguments:

- **roleArn**
  - Your logging role ARN. The logging role grants AWS IoT permission to write to your CloudWatch Logs.

- **logLevel**
  - The log level to use. Valid values are: ERROR, WARN, INFO, DEBUG, or DISABLED

For example:

```
aws iot set-logging-options
  --logging-options-payload
    roleArn="arn:aws:iam::<your-aws-account-num>:role/<IoTLoggingRole>",logLevel="INFO"
```
You can use the `get-logging-options` CLI command to get the current logging options.

**Fine-Grained Logging**

Fine-grained logging allows you to specify a logging level for a target. A target is defined by a resource type and a resource name. Currently, AWS IoT supports thing groups as targets. Fine-grained logging allows you to set a logging level for a specific thing group. Say we have a thing group called "Phones" that contains things that represent different kinds of phones. We then create another thing group called "MobilePhones" and make it a child of the "Phones" thing group. Fine-grained logging allows you to configure one logging level for all things in the "Phones" group (and any child groups) and another logging level for things in the "MobilePhones" group. In this example, we have assigned two different logging levels to things in the "MobilePhones" group — one from the logging level for the "Phones" thing group and another from the "MobilePhones" thing group — but the logging level specified for the child thing group will override the logging level specified for the parent thing group.

Use the `set-v2-logging-options` CLI command to enable fine-grained logging and set the default logging level. It takes the following optional arguments:

```
--role-arn
An IAM role that allows AWS IoT to write to your CloudWatch Logs. If not specified, AWS IoT uses the logging role associated with your account. The logging role is associated with your account when it is created. For more information, see Create a Logging Role (p. 340)
```

```
--default-log-level
The logging level used if not specified. Valid values are: DEBUG, INFO, ERROR, WARN, and DISABLED
```

```
--disable-all-logging
If set to true, all logging is disabled.
```

The `get-v2-logging-options` CLI command returns the configured IAM logging role, the default logging level, and the `disableAllLogs` value.

Use the `set-v2-logging-level` CLI command to configure fine-grained logging for a target. It takes the following arguments:

```
--log-target
A JSON document that contains the resource type and name of the entity for which you are configuring logging. AWS IoT currently supports `THING_GROUP` for resource type. You can configure up to 10 logging targets.
```

```
--log-level
The logging level used when generating logs for the specified resource. Valid values are: DEBUG, INFO, ERROR, WARN, and DISABLED
```

Use the `list-v2-logging-levels` CLI command to get a list of the currently configured fine-grained logging levels. Call the `delete-v2-logging-level` CLI command to delete a logging level. Use the `delete-v2-logging-level` command to delete a fine-grained logging level.

**CloudWatch Log Entry Format**

Each component of AWS IoT generates its own logs. Each log entry has an `eventType` that indicates which operation caused the log to be generated. This section describes the logs generated by the following AWS IoT components:

- Message Broker (p. 343)
AWS IoT Developer Guide
CloudWatch Log Entry Format

• Thing Shadows (p. 347)
• Rules Engine (p. 349)
• Jobs (p. 352)

All CloudWatch Logs have the following common attributes:

timestamp
The UNIX timestamp of when the client connected to the AWS IoT message broker.

logLevel
The log level being used. For more information, see the section called “Log Level” (p. 341).

traceId
A randomly generated identifier that can be used to correlate all logs for a specific request.

accountId
Your AWS account ID.

status
The status of the request.

eventType
The event type for which the log was generated. The value of the event type for each event is listed in the following sections.

Message Broker Logs

The AWS IoT message broker generates logs for the following events:

Connect Log
The AWS IoT message broker generates a Connect log when an MQTT client connects.

For example:

```json
{
    "timestamp": "2017-08-10 15:37:23.476",
    "logLevel": "INFO",
    "traceId": "20b23f3f-d7f1-feeae-169f-82263394f6db",
    "accountId": "123456789012",
    "status": "Success",
    "eventType": "Connect",
    "protocol": "MQTT",
    "clientId": "abf27092886e49a8a5c1922749736453",
    "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eaf5a932167",
    "sourceIp": "205.251.233.181",
    "sourcePort": 13490
}
```

In addition to the attributes common to all CloudWatch Logs, Connect log entries contain the following attributes:

eventType
Connect for connection logs.

343
protocol

The protocol used when making the request. Valid values are MQTT or HTTP.

clientId

The ID of the client making the request.

principalId

The ID of the principal making the request.

sourceIp

The IP address where the request originated.

sourcePort

The port where the request originated.

Subscribe Log

The AWS IoT message broker generates a Subscribe log when an MQTT client subscribes to a topic.

For example:

```json
{
  "timestamp": "2017-08-10 15:39:04.413",
  "logLevel": "INFO",
  "traceId": "7aa5c38d-1b49-3753-15dc-513ce4ab9fa6",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "Subscribe",
  "protocol": "MQTT",
  "topicName": "$aws/things/MyThing/shadow/#",
  "clientId": "abf2709286e49a8a5c1922749736453",
  "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eeafc5a932167",
  "sourceIp": "205.251.233.181",
  "sourcePort": 13490
}
```

In addition to the attributes common to all CloudWatch Logs, Subscribe log entries contain the following attributes:

**eventType**

Subscribe for subscription logs.

**protocol**

The protocol used when making the request. Valid values are MQTT or HTTP.

**topicName**

The name of the subscribed topic.

**clientId**

The ID of the client making the request.

**principalId**

The ID of the principal making the request.
sourceIp

The IP address where the request originated.

sourcePort

The port where the request originated.

Publish-In Log

The AWS IoT message broker generates a Publish-In log when the AWS IoT message broker receives an MQTT message.

For example:

```json
{
  "timestamp": "2017-08-10 15:39:30.961",
  "logLevel": "INFO",
  "traceId": "672ec480-31ce-fd8b-b5fb-22e3ac420699",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "Publish-In",
  "protocol": "MQTT",
  "topicName": "$aws/things/MyThing/shadow/get",
  "clientId": "abf27092886e49a8a5c1922749736453",
  "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eeafc5a932167",
  "sourceIp": "205.251.233.181",
  "sourcePort": 13490
}
```

In addition to the attributes common to all CloudWatch Logs, Publish-In log entries contain the following attributes:

eventType

Publish-In when the message broker receives a message.

status

The status of the request.

protocol

The protocol used when making the request. Valid values are MQTT or HTTP.

topicName

The name of the subscribed topic.

clientId

The ID of the client making the request.

principalId

The ID of the principal making the request.

sourceIp

The IP address where the request originated.

sourcePort

The port where the request originated.
Publish-Out Log

The AWS IoT message broker generates a Publish-Out log when the message broker publishes an MQTT message.

For example:

```
{
    "timestamp": "2017-08-10 15:39:30.961",
    "logLevel": "INFO",
    "traceId": "672ec480-31ce-fd8b-b5fb-22e3ac420699",
    "accountId": "123456789012",
    "status": "Success",
    "eventType": "Publish-Out",
    "protocol": "MQTT",
    "topicName": "$aws/things/MyThing/shadow/get",
    "clientId": "abf27092886e49a8a5c1922749736453",
    "principalId": "145179c40e2219e18a909d896a5340b74cf97a93641beec2fc3eafcc5a932167",
    "sourceIp": "205.251.233.181",
    "sourcePort": 13490
}
```

In addition to the attributes common to all CloudWatch Logs, Publish-Out log entries contain the following attributes:

- **eventType**: Publish-Out when the message broker publishes a message.
- **status**: The status of the request.
- **protocol**: The protocol used when making the request. Valid values are MQTT or HTTP.
- **topicName**: The name of the subscribed topic.
- **clientId**: The ID of the client making the request.
- **principalId**: The ID of the principal making the request.
- **sourceIp**: The IP address where the request originated.
- **sourcePort**: The port where the request originated.

Disconnect Log

The AWS IoT message broker generates a Disconnect log when an MQTT client disconnects.

For example:
In addition to the attributes common to all CloudWatch Logs, Disconnect log entries contain the following attributes:

**eventType**
- Disconnect for connection logs.

**protocol**
- The protocol used when making the request. Valid values are MQTT or HTTP.

**clientId**
- The ID of the client making the request.

**principalId**
- The ID of the principal making the request.

**sourceIp**
- The IP address where the request originated.

**sourcePort**
- The port where the request originated.

### Thing Shadow Logs

The AWS IoT Thing Shadow service generates logs for the following events:

**GetThingShadow Logs**

The Thing Shadow service generates a GetThingShadow log when a get request for a thing shadow is received.

For example:

```json
{
  "timestamp": "2017-08-09 17:56:30.941",
  "logLevel": "INFO",
  "traceId": "b575f19a-97a2-cf72-0ed0-c64a783a2504",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "GetThingShadow",
  "protocol": "MQTT",
  "deviceShadowName": "MyThing",
  "topicName": "$aws/things/MyThing/shadow/get"
}
```
In addition to the attributes common to all CloudWatch Logs, GetThingShadow log entries contain the following attributes:

**eventType**
- GetThingShadow for GetThingShadow logs.

**protocol**
- The protocol used when making the request. Valid values are MQTT or HTTP.

**deviceShadowName**
- The name of the requested thing shadow.

**topicName**
- The name of the topic on which the request was published.

**UpdateThingShadow Logs**

The Thing Shadow service generates an UpdateThingShadow log when a request to update a thing shadow is received.

For example:

```
{
  "timestamp": "2017-08-07 18:43:59.436",
  "logLevel": "INFO",
  "traceId": "d0074ba8-0c4b-a400-69df-76326d414c28",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "UpdateThingShadow",
  "protocol": "MQTT",
  "deviceShadowName": "Jack",
  "topicName": "$aws/things/Jack/shadow/update"
}
```

In addition to the attributes common to all CloudWatch Logs, UpdateThingShadow log entries contain the following attributes:

**eventType**
- UpdateThingShadow for update shadow logs.

**protocol**
- The protocol used when making the request. Valid values are MQTT or HTTP.

**deviceShadowName**
- The name of the thing shadow to update.

**topicName**
- The name of the topic on which the request was published.

**DeleteThingShadow Logs**

The Thing Shadow service generates a DeleteThingShadow log when a request to delete a thing shadow is received.
For example:

```json
{
  "timestamp": "2017-08-07 18:47:56.664",
  "logLevel": "INFO",
  "traceId": "1a60d02e-15b9-605b-7096-a9f584a6ad3f",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "DeleteThingShadow",
  "protocol": "MQTT",
  "deviceShadowName": "Jack",
  "topicName": "/aws/things/Jack/shadow/delete"
}
```

In addition to the attributes common to all CloudWatch Logs, `DeleteThingShadow` log entries contain the following attributes:

- **eventType**: `DeleteThingShadow` for `DeleteThingShadow` logs.
- **protocol**: The protocol used when making the request. Valid values are `MQTT` or `HTTP`.
- **deviceShadowName**: The name of the thing shadow to update.
- **topicName**: The name of the topic on which the request was published.

### Rules Engine Logs

The AWS IoT Rules Engine service generates logs for the following events:

#### Rule Match Logs

The AWS IoT rules engine generates a `RuleMatch` log when the message broker receives a message that matches a rule.

For example:

```json
{
  "timestamp": "2017-08-10 16:32:46.002",
  "logLevel": "INFO",
  "traceId": "30aa7ccc-1d23-0b97-aa7b-76196d83537e",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "RuleMatch",
  "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eeafcc5a932167"
}
```

In addition to the attributes common to all CloudWatch Logs, `RuleMatch` log entries contain the following attributes:
AWS IoT Developer Guide
CloudWatch Log Entry Format

**eventType**

RuleMatch for rule match logs.

**clientId**

The ID of the client making the request.

**topicName**

The name of the subscribed topic.

**ruleName**

The name of the matching rule.

**principalId**

The ID of the principal making the request.

### Function Execution Logs

The rules engine generates a FunctionExecution log when a rule's SQL query calls an external function. An external function is called when a rule's action makes an HTTP request to AWS IoT or another web service (for example, calling `get_thing_shadow` or `machinelearning_predict`).

More info (10)

A FunctionExecution log will look like the following:

```
{
  "timestamp": "2017-07-13 18:33:51.903",
  "logLevel": "DEBUG",
  "traceId": "180532b7-0cc7-057b-687a-5ca1824838f5",
  "status": "Success",
  "eventType": "FunctionExecution",
  "clientId": "N/A",
  "topicName": "rules/test",
  "ruleName": "ruleTestPredict",
  "ruleAction": "MachinelearningPredict",
  "resources": {
    "ModelId": "predict-model"
  },
  "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eeafc5a932167"
}
```

In addition to the attributes common to all CloudWatch Logs, FunctionExecution log entries contain the following attributes:

**eventType**

FunctionExecution for rule match logs.

**clientId**

N/A for FunctionExecution logs.

**topicName**

The name of the subscribed topic.

**ruleName**

The name of the matching rule.

**resources**

A collection of resources used by the rule's actions.
principalId

The ID of the principal making the request.

Starting Execution Logs

The AWS IoT rules engine generates a StartingExecution log when the rules engine starts to invoke a rule's action.

For example:

```
{
  "timestamp": "2017-08-10 16:32:46.002",
  "logLevel": "DEBUG",
  "traceId": "30aa7ccc-1d23-0b97-aa7b-76196d83537e",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "StartingRuleExecution",
  "clientId": "abf27092886e49a8a5c1922749736453",
  "topicName": "rules/test",
  "ruleName": "JSONLogsRule",
  "ruleAction": "RepublishAction",
  "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eeafc5a932167"
}
```

In addition to the attributes common to all CloudWatch Logs, StartingExecution log entries contain the following attributes:

- **eventType**
  - StartingRuleExecution for starting rule execution logs.

- **clientId**
  - The ID of the client making the request.

- **topicName**
  - The name of the subscribed topic.

- **ruleName**
  - The name of the matching rule.

- **ruleAction**
  - The name of the invoked action.

- **principalId**
  - The ID of the principal making the request.

Rule Execution Logs

The AWS IoT rules engine generates a RuleExecution log when the rules engine invokes a rule's action.

For example:

```
{
```

351
In addition to the attributes common to all CloudWatch Logs, RuleExecution log entries contain the following attributes:

**eventType**

RuleExecution for rule execution logs.

**clientId**

The ID of the client making the request.

**topicName**

The name of the subscribed topic.

**ruleName**

The name of the matching rule.

**ruleAction**

The name of the invoked action.

**resources**

A collection of resources used by the rule's actions.

**principalId**

The ID of the principal making the request.

---

**Job Logs**

The AWS IoT Job service generates logs for the following events:

**Get Job Execution Logs**

The AWS IoT rules engine generates a GetJobExecution log when the Job service receives a request for a job execution.

For example:

```json
{
  "timestamp": "2017-08-10 19:08:05.813",
  "logLevel": "DEBUG",
  "accountId": "123456789012",
  "principalId": "145179c40e2219e18a909d896a5340b74cf97a39641beec2fc3eeac5a932167"
}
```
"status": "Success",
"eventType": "GetJobExecution",
"protocol": "MQTT",
"clientId": "thingOne",
"topicName": "$aws/things/thingOne/jobs/get",
"details": "The request status is SUCCESS."
}

In addition to the attributes common to all CloudWatch Logs, GetJobExecution log entries contain the following attributes:

**eventType**

GetJobExecution for get job execution logs.

**protocol**

The protocol used when making the request. Valid values are MQTT or HTTP.

**clientId**

The ID of the client making the request.

**topicName**

The name of the subscribed topic.

**details**

Additional information from the Jobs service.

Describe Job Execution Logs

The AWS IoT rules engine generates a DescribeJobExecution log when the Jobs service receives a request to describe a job execution.

For example:

```
{
  "timestamp": "2017-08-10 19:13:22.841",
  "logLevel": "DEBUG",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "DescribeJobExecution",
  "protocol": "MQTT",
  "clientId": "thingOne",
  "jobId": "002",
  "topicName": "$aws/things/thingOne/jobs/002/get",
  "clientToken": "myToken",
  "details": "The request status is SUCCESS."
}
```

In addition to the attributes common to all CloudWatch Logs, GetJobExecution log entries contain the following attributes:

**eventType**

DescribeJobExecution for describe job execution logs.

**protocol**

The protocol used when making the request. Valid values are MQTT or HTTP.
Update Job Execution Logs

The AWS IoT rules engine generates an UpdateJobExecution log when the Jobs service receives a request to update a job execution.

For example:

```
{
  "timestamp": "2017-08-10 19:25:14.758",
  "logLevel": "DEBUG",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "UpdateJobExecution",
  "protocol": "MQTT",
  "clientId": "thingOne",
  "jobId": "002",
  "topicName": "/aws/things/thingOne/jobs/002/update",
  "clientToken": "myClientToken",
  "versionNumber": "1",
  "details": "The destination status is IN_PROGRESS. The request status is SUCCESS."
}
```

In addition to the attributes common to all CloudWatch Logs, UpdateJobExecution log entries contain the following attributes:

- **eventType**
  - UpdateJobExecution for update job execution logs.
- **protocol**
  - The protocol used when making the request. Valid values are MQTT or HTTP.
- **clientId**
  - The ID of the client making the request.
- **jobId**
  - The job ID for the job execution.
- **topicName**
  - The topic used to make the request.
clientToken
The client token.

versionNumber
The version of the job execution.

details
Additional information from the Jobs service.

Report Final Job Execution Count
The AWS IoT Jobs service generates a ReportFinalJobExecutionCount log when a job is completed.

For example:

```json
{
  "timestamp": "2017-08-10 19:44:16.776",
  "logLevel": "INFO",
  "accountId": "123456789012",
  "status": "Success",
  "eventType": "ReportFinalJobExecutionCount",
  "protocol": "MQTT",
  "jobId": "002",
  "details": "Job 002 completed. QUEUED job execution count: 0 IN_PROGRESS job execution count: 0 FAILED job execution count: 0 SUCCESS job execution count: 1 CANCELED job execution count: 0 REJECTED job execution count: 0 REMOVED job execution count: 0"
}
```

In addition to the attributes common to all CloudWatch Logs, ReportFinalJobExecutionCount log entries contain the following attributes:

**eventType**
ReportFinalJobExecutionCount for report final job execution count logs.

**protocol**
The protocol used when making the request. Valid values are MQTT or HTTP.

**jobId**
The job ID for the job execution.

**details**
Additional information from the Jobs service.

### Viewing Logs

**To view your logs**

2. In the Filter text box, type `AWSIoTLogsV2`, and press Enter.
3. Double-click the `AWSIoTLogsV2` log group.
4. Choose Search Log Group. A complete list of the AWS IoT logs generated for your account is displayed.
5. Choose the expand icon to look at an individual stream.

You can also type a query in the Filter events text box. Here are some interesting queries to try:

- `{ $.logLevel = "INFO" }`
  Find all logs that have a log level of INFO.
- `{ $.status = "Success" }`
  Find all logs that have a status of Success.
- `{ $.status = "Success" && $.eventType = "GetThingShadow" }`
  Find all logs that have a status of Success and an event type of GetThingShadow.

For more information about creating filter expressions, see CloudWatch Logs Queries.

Diagnosing Rules Issues

CloudWatch Logs is the best place to debug issues you are having with rules. When you enable CloudWatch Logs for AWS IoT, you can see which rules are triggered and their success or failure. You also get information about whether WHERE clause conditions match.

The most common rules issue is authorization. The logs show if your role is not authorized to perform AssumeRole on the resource. Here is an example log generated by fine-grained logging (p. 342):

```
{
  "timestamp": "2017-12-09 22:49:17.954",
  "logLevel": "ERROR",
  "traceId": "ff563525-6469-506a-e141-78d40375fc4e",
  "accountId": "123456789012",
  "status": "Failure",
  "eventType": "RuleExecution",
  "clientId": "iotconsole-123456789012-3",
  "topicName": "test-topic",
  "ruleName": "rule1",
  "ruleAction": "DynamoAction",
  "resources": {
    "ItemHashKeyField": "id",
    "Table": "trashbin",
    "Operation": "Insert",
    "ItemHashKeyValue": "id",
    "IsPayloadJSON": "true"
  },
  "principalId": "ABCDEFG1234567ABCD890:outis",
  "details": "User: arn:aws:sts::123456789012:assumed-role/dynamo-testbin/5aUMInJH is not authorized to perform: dynamodb:PutItem on resource: arn:aws:dynamodb:us-east-1:123456789012:table/testbin (Service: AmazonDynamoDBv2; Status Code: 400; Error Code: AccessDeniedException; Request ID: AKQJ987654321AKQJ123456789AKQJ987654321AKQJ987654321)"
}
```

Here is a similar example log generated by global logging (p. 341):

```
2017-12-09 22:49:17.954 TRACEID:ff562535-6964-506a-e141-78d40375fc4e
PRINCIPALID:ABCDEFG1234567ABCD890:outis [ERROR] EVENT:DynamoActionFailure
TOPICNAME:test-topic CLIENTID:iotconsole-123456789012-3
MESSAGE:Dynamo Insert record failed. The error received was User: arn:aws:sts::123456789012:assumed-role/dynamo-testbin/5aUMInJH is not authorized to perform: dynamodb:PutItem on resource: arn:aws:dynamodb:us-east-1:123456789012:table/testbin
```

356
For more information, see the section called “Viewing Logs” (p. 355).

External services are controlled by the end user. Before rule execution, make sure external services are set up with enough throughput and capacity units.

## Diagnosing Problems with Thing Shadows

### Diagnosing Thing Shadows

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>A thing shadow document is rejected with &quot;Invalid JSON document.&quot;</td>
<td>If you are unfamiliar with JSON, modify the examples provided in this guide for your own use. For more information, see Thing Shadow Document Syntax.</td>
</tr>
<tr>
<td>I submitted correct JSON, but none or only parts of it are stored in the thing shadow document.</td>
<td>Be sure you are following the JSON formatting guidelines. Only JSON fields in the desired and reported sections are stored. JSON content (even if formally correct) outside of those sections is ignored.</td>
</tr>
<tr>
<td>I received an error that the thing shadow exceeds the allowed size.</td>
<td>The thing shadow supports 8 KB of data only. Try shortening field names inside of your JSON document or simply create more thing shadows. A device can have an unlimited number of thing shadows. The only requirement is that the thing name is unique in your account.</td>
</tr>
<tr>
<td>When I receive a thing shadow, it is larger than 8 KB. How can this happen?</td>
<td>Upon receipt, the AWS IoT service adds metadata to the thing shadow. The service includes this data in its response, but it does not count toward the limit of 8 KB. Only the data for desired and reported state inside the state document sent to the thing shadow counts toward the limit.</td>
</tr>
<tr>
<td>My request has been rejected due to incorrect version. What should I do?</td>
<td>Perform a GET operation to sync to the latest state document version. When using MQTT, subscribe to the ./update/accepted topic to be notified about state changes and receive the latest version of the JSON document.</td>
</tr>
<tr>
<td>The timestamp is off by several seconds.</td>
<td>The timestamp for individual fields and the whole JSON document is updated when the document is received by the AWS IoT service or when the state document is published onto the ./update/accepted and ./update/delta message. Messages can be delayed over the network, which can cause the timestamp to be off by a few seconds.</td>
</tr>
</tbody>
</table>
Diagnosing Salesforce Action Issues

Troubleshooting Guidelines

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>My device can publish and subscribe on the corresponding thing shadow topics, but when I attempt to update the thing shadow document over the HTTP REST API, I get HTTP 403.</td>
<td>Be sure you have created policies in IAM to allow access to these topics and for the corresponding action (UPDATE/GET/DELETE) for the credentials you are using. IAM policies and certificate policies are independent.</td>
</tr>
<tr>
<td>Other issues.</td>
<td>The Thing Shadows service logs errors to CloudWatch Logs. To identify device and configuration issues, enable CloudWatch Logs and view the logs for debug information.</td>
</tr>
</tbody>
</table>

### Execution Trace

How do I see the execution trace of a Salesforce action?

If CloudWatch Logs are not set up, see the Setting Up CloudWatch Logs with AWS IoT (p. 339) section. After you have activated the logs, you are able to see the execution trace of the Salesforce action.

### Action Success and Failure

How do I check that messages have been sent successfully to a Salesforce IoT input stream?

View the logs generated by execution of the Salesforce action in CloudWatch Logs. If you see "Action executed successfully," then it means that the AWS IoT rules engine received confirmation from the Salesforce IoT that the message was successfully pushed to the targeted input stream.

If you are experiencing problems with the Salesforce IoT platform, contact Salesforce IoT support.

What do I do if messages have not been sent successfully to a Salesforce IoT input stream?

View the logs generated by execution of the Salesforce action in CloudWatch Logs. Depending on the log entry, you can try the following actions:

- Failed to locate the host
  - Check that the url parameter of the action is correct and that your Salesforce IoT input stream exists.
- Received Internal Server Error from Salesforce
  - Retry. If the problem persists, contact Salesforce IoT Support.
- Received Bad Request Exception from Salesforce
  - Check the payload you are sending for errors.
- Received Unsupported Media Type Exception from Salesforce
  - Salesforce IoT does not support a binary payload at this time. Check that you are sending a JSON payload.
Received Unauthorized Exception from Salesforce

Check that the token parameter of the action is correct and that your token is still valid.

Received Not Found Exception from Salesforce

Check that the url parameter of the action is correct and that your Salesforce IoT input stream exists.

If you receive an error that is not listed here, contact AWS Support.

AWS IoT Errors

This section lists the error codes sent by AWS IoT.

Message Broker Error Codes

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Description</th>

IoT Commands

This chapter contains the following sections:

- AcceptCertificateTransfer (p. 362)
- AddThingToThingGroup (p. 364)
- AssociateTargetsWithJob (p. 366)
- AttachPolicy (p. 369)
- AttachPrincipalPolicy (p. 371)
- AttachThingPrincipal (p. 372)
- CancelCertificateTransfer (p. 374)
- CancelJob (p. 376)
- ClearDefaultAuthorizer (p. 378)
- CreateAuthorizer (p. 379)
- CreateCertificateFromCsr (p. 382)
- CreateJob (p. 385)
- CreateKeysAndCertificate (p. 391)
- CreatePolicy (p. 393)
- CreatePolicyVersion (p. 396)
- CreateRoleAlias (p. 399)
- CreateThing (p. 402)
- CreateThingGroup (p. 406)
- CreateThingType (p. 409)
- CreateTopicRule (p. 412)
- DeleteAuthorizer (p. 428)
- DeleteCACertificate (p. 429)
- DeleteCertificate (p. 431)
- DeletePolicy (p. 433)
- DeletePolicyVersion (p. 435)
- DeleteRegistrationCode (p. 436)
- DeleteRoleAlias (p. 437)
- DeleteThing (p. 439)
- DeleteThingGroup (p. 441)
- DeleteThingShadow (p. 442)
- DeleteThingType (p. 444)
- DeleteTopicRule (p. 446)
- DeleteV2LoggingLevel (p. 447)
- DeprecateThingType (p. 449)
- DescribeAuthorizer (p. 450)
- DescribeCACertificate (p. 453)
- DescribeCertificate (p. 456)
- DescribeDefaultAuthorizer (p. 460)
- DescribeEndpoint (p. 463)
- DescribeEventConfigurations (p. 464)
• DescribeIndex (p. 466)
• DescribeJob (p. 469)
• DescribeJobExecution (p. 474)
• DescribeJobExecution (p. 478)
• DescribeRoleAlias (p. 482)
• DescribeThing (p. 485)
• DescribeThingGroup (p. 488)
• DescribeThingRegistrationTask (p. 492)
• DescribeThingType (p. 495)
• DetachPolicy (p. 499)
• DetachPrincipalPolicy (p. 501)
• DetachThingPrincipal (p. 503)
• DisableTopicRule (p. 504)
• EnableTopicRule (p. 505)
• GetEffectivePolicies (p. 507)
• GetIndexingConfiguration (p. 509)
• GetJobDocument (p. 511)
• GetLoggingOptions (p. 513)
• GetPendingJobExecutions (p. 514)
• GetPolicy (p. 518)
• GetPolicyVersion (p. 520)
• GetRegistrationCode (p. 523)
• GetThingShadow (p. 524)
• GetTopicRule (p. 526)
• GetV2LoggingOptions (p. 542)
• ListAttachedPolicies (p. 544)

• ListPolicies (p. 576)
• ListPolicyPrincipals (p. 579)
• ListPolicyVersions (p. 581)
• ListPrincipalPolicies (p. 584)
• ListPrincipalThings (p. 587)
• ListRoleAliases (p. 589)
• ListTargetsForPolicy (p. 592)
• ListThingGroups (p. 594)
• ListThingGroupsForThing (p. 597)
• ListThingPrincipals (p. 600)
• ListThingRegistrationTaskReports (p. 602)
AcceptCertificateTransfer

Accepts a pending certificate transfer. The default state of the certificate is INACTIVE.

To check for pending certificate transfers, call ListCertificates to enumerate your certificates.

Request syntax:

```
PATCH /accept-certificate-transfer/certificateId?setAsActive=setAsActive
```
### URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>yes</td>
<td>The ID of the certificate.</td>
</tr>
<tr>
<td>setAsActive</td>
<td>SetAsActive</td>
<td>no</td>
<td>Specifies whether the certificate is active.</td>
</tr>
</tbody>
</table>

### Errors:

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404
- **TransferAlreadyCompletedException**
  - You can't revert the certificate transfer because the transfer is already complete.
  - HTTP response code: 410
- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400
- **ThrottlingException**
  - The rate exceeds the limit.
  - HTTP response code: 429
- **UnauthorizedException**
  - You are not authorized to perform this operation.
  - HTTP response code: 401
- **ServiceUnavailableException**
  - The service is temporarily unavailable.
  - HTTP response code: 503
- **InternalFailureException**
  - An unexpected error has occurred.
  - HTTP response code: 500

### CLI

**Synopsis:**

```
aws iot accept-certificate-transfer \
  --certificate-id <value> \
  [--set-as-active | --no-set-as-active] \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```
cli-input-json format:

```json
{
  "certificateId": "string",
  "setAsActive": "boolean"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>string</td>
<td>The ID of the certificate.</td>
</tr>
<tr>
<td></td>
<td>length max:64 min:64</td>
<td></td>
</tr>
<tr>
<td></td>
<td>pattern: (0x)?[a-fA-F0-9]+</td>
<td></td>
</tr>
<tr>
<td>setAsActive</td>
<td>boolean</td>
<td>Specifies whether the certificate is active.</td>
</tr>
</tbody>
</table>

Output:

None

**AddThingToThingGroup**

Adds a thing to a thing group.

**Request syntax:**

```
PUT /thing-groups/addThingToThingGroup
Content-type: application/json

{
  "thingGroupName": "string",
  "thingGroupArn": "string",
  "thingName": "string",
  "thingArn": "string"
}
```

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingGroupName</td>
<td>ThingGroupName</td>
<td>no</td>
<td>The name of the group to which you are adding a thing.</td>
</tr>
<tr>
<td>thingGroupArn</td>
<td>ThingGroupArn</td>
<td>no</td>
<td>The ARN of the group to which you are adding a thing.</td>
</tr>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>no</td>
<td>The name of the thing to add to a group.</td>
</tr>
<tr>
<td>thingArn</td>
<td>ThingArn</td>
<td>no</td>
<td>The ARN of the thing to add to a group.</td>
</tr>
</tbody>
</table>
Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

CLI

Synopsis:

```
aws iot add-thing-to-thing-group \
    [--thing-group-name <value>] \
    [--thing-group-arn <value>] \
    [--thing-name <value>] \
    [--thing-arn <value>] \
    [--cli-input-json <value>] \
    [--generate-cli-skeleton]
```

cli-input-json format:

```
{
    "thingGroupName": "string",
    "thingGroupArn": "string",
    "thingName": "string",
    "thingArn": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingGroupName</td>
<td>string</td>
<td>The name of the group to which you are adding a thing.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>pattern: [a-zA-Z0-9:_-]+</td>
<td></td>
</tr>
</tbody>
</table>
### AssociateTargetsWithJob

Associates a group with a continuous job. The following criteria must be met:

- The job must have been created with the `targetSelection` field set to "CONTINUOUS".
- The job status must currently be "IN_PROGRESS".
- The total number of targets associated with a job must not exceed 100.

**Request syntax:**

```plaintext
POST /jobs/jobId/targets
Content-type: application/json

{
  "targets": [
    "string"
  ],
  "comment": "string"
}
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>yes</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
</tbody>
</table>

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targets</td>
<td>JobTargets</td>
<td>yes</td>
<td>A list of thing group ARNs that define the targets of the job.</td>
</tr>
</tbody>
</table>
### AssociateTargetsWithJob

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comment</td>
<td>Comment</td>
<td>no</td>
<td>An optional comment string describing why the job was associated with the targets.</td>
</tr>
</tbody>
</table>

**Response syntax:**

```json
Content-type: application/json
{
    "jobArn": "string",
    "jobId": "string",
    "description": "string"
}
```

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobArn</td>
<td>JobArn</td>
<td>no</td>
<td>An ARN identifying the job.</td>
</tr>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>no</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
<tr>
<td>description</td>
<td>JobDescription</td>
<td>no</td>
<td>A short text description of the job.</td>
</tr>
</tbody>
</table>

**Errors:**

- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
    - HTTP response code: 400

- **ResourceNotFoundException**
  - The specified resource does not exist.
    - HTTP response code: 404

- **LimitExceededException**
  - The number of attached entities exceeds the limit.
    - HTTP response code: 410

- **ThrottlingException**
  - The rate exceeds the limit.
    - HTTP response code: 429
ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

CLI

Synopsis:

```
aws iot associate-targets-with-job \
  --targets <value> \
  --job-id <value> \
  [--comment <value>] \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "targets": [
    "string"
  ],
  "jobId": "string",
  "comment": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>string</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
<tr>
<td>description</td>
<td>string</td>
<td>A short text description of the job.</td>
</tr>
</tbody>
</table>

### AttachPolicy

Attaches a policy to the specified target.

**Request syntax:**

```
PUT /target-policies/policyName
Content-type: application/json

{
  "target": "string"
}
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>PolicyName</td>
<td>yes</td>
<td>The name of the policy to attach.</td>
</tr>
</tbody>
</table>

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>PolicyTarget</td>
<td>yes</td>
<td>The identity to which the policy is attached.</td>
</tr>
</tbody>
</table>

**Errors:**

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404
- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
HTTP response code: 400
ThrottlingException
The rate exceeds the limit.

HTTP response code: 429
UnauthorizedException
You are not authorized to perform this operation.

HTTP response code: 401
ServiceUnavailableException
The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException
An unexpected error has occurred.

HTTP response code: 500
LimitExceededException
The number of attached entities exceeds the limit.

HTTP response code: 410

**CLI**

**Synopsis:**

```bash
aws iot attach-policy \
  --policy-name <value> \
  --target <value> \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

cli-input-json format:

```json
{
  "policyName": "string",
  "target": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>string</td>
<td>The name of the policy to attach.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1 pattern: [w+,.@-]+</td>
<td></td>
</tr>
<tr>
<td>target</td>
<td>string</td>
<td>The identity to which the policy is attached.</td>
</tr>
</tbody>
</table>
AttachPrincipalPolicy

Attaches the specified policy to the specified principal (certificate or other credential).

**Note:** This API is deprecated. Please use AttachPolicy instead.

**Request syntax:**

```
PUT /principal-policies/policyName
x-amzn-iot-principal: principal
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>PolicyName</td>
<td>yes</td>
<td>The policy name.</td>
</tr>
<tr>
<td>principal</td>
<td>Principal</td>
<td>yes</td>
<td>The principal, which can be a certificate ARN (as returned from the CreateCertificate operation) or an Amazon Cognito ID.</td>
</tr>
</tbody>
</table>

**Errors:**

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404

- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400

- **ThrottlingException**
  - The rate exceeds the limit.
  - HTTP response code: 429

- **UnauthorizedException**
  - You are not authorized to perform this operation.
  - HTTP response code: 401

- **ServiceUnavailableException**
  - The service is temporarily unavailable.
  - HTTP response code: 503
InternalFailureException
An unexpected error has occurred.
HTTP response code: 500

LimitExceededException
The number of attached entities exceeds the limit.
HTTP response code: 410

CLI

Synopsis:

```
aws iot attach-principal-policy \
  --policy-name <value> \
  --principal <value> \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "policyName": "string",
  "principal": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>principal</td>
<td>string</td>
<td>The principal, which can be a certificate ARN (as returned from the CreateCertificate operation) or an Amazon Cognito ID.</td>
</tr>
</tbody>
</table>

Output:
None

AttachThingPrincipal

Attaches the specified principal to the specified thing.

Request syntax:

```
PUT /things/thingName/principals
```
x-amzn-principal: principal

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing.</td>
</tr>
<tr>
<td>principal</td>
<td>Principal</td>
<td>yes</td>
<td>The principal, such as a certificate or other credential.</td>
</tr>
</tbody>
</table>

**Errors:**

**ResourceNotFoundException**

The specified resource does not exist.

HTTP response code: 404

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**UnauthorizedException**

You are not authorized to perform this operation.

HTTP response code: 401

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

**InternalFailureException**

An unexpected error has occurred.

HTTP response code: 500

**CLI**

**Synopsis:**

```bash
aws iot attach-thing-principal \  
  --thing-name <value> \  
  --principal <value>  \  
  [--cli-input-json <value>] \  
  [--generate-cli-skeleton]
```
cli-input-json format:

```
{
  "thingName": "string",
  "principal": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>string</td>
<td>The name of the thing.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>length max:128 min:1 pattern: [a-zA-Z0-9-_:-]+</td>
</tr>
<tr>
<td>principal</td>
<td>string</td>
<td>The principal, such as a certificate or other credential.</td>
</tr>
</tbody>
</table>

Output:
None

## CancelCertificateTransfer

Cancels a pending transfer for the specified certificate.

**Note** Only the transfer source account can use this operation to cancel a transfer. (Transfer destinations can use RejectCertificateTransfer instead.) After transfer, AWS IoT returns the certificate to the source account in the INACTIVE state. After the destination account has accepted the transfer, the transfer cannot be cancelled.

After a certificate transfer is cancelled, the status of the certificate changes from PENDING_TRANSFER to INACTIVE.

### Request syntax:

```
PATCH /cancel-certificate-transfer/certificateId
```

### URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>Certificateld</td>
<td>yes</td>
<td>The ID of the certificate.</td>
</tr>
</tbody>
</table>

### Errors:

- **ResourceNotFoundException**
  
  The specified resource does not exist.
  
  HTTP response code: 404

- **TransferAlreadyCompletedException**
  
  You can't revert the certificate transfer because the transfer is already complete.
HTTP response code: 410
InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400
ThrottlingException

The rate exceeds the limit.

HTTP response code: 429
UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401
ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

## CLI

### Synopsis:

```bash
aws iot cancel-certificate-transfer \
   --certificate-id <value> \
   [- --cli-input-json <value>] \
   [---generate-cli-skeleton]
```

### cli-input-json format:

```json
{
   "certificateId": "string"
}
```

### cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>

<table>
<thead>
<tr>
<th>length max:64 min:64</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern: (0x)?[a-fA-F0-9]+</td>
</tr>
</tbody>
</table>

Output:

375
CancelJob

Cancels a job.

**Request syntax:**

```
PUT /jobs/jobId/cancel
Content-type: application/json
{
  "comment": "string"
}
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>yes</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
</tbody>
</table>

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comment</td>
<td>Comment</td>
<td>no</td>
<td>An optional comment string describing why the job was canceled.</td>
</tr>
</tbody>
</table>

**Response syntax:**

```
Content-type: application/json
{
  "jobArn": "string",
  "jobId": "string",
  "description": "string"
}
```

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobArn</td>
<td>JobArn</td>
<td>no</td>
<td>The job ARN.</td>
</tr>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>no</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
<tr>
<td>description</td>
<td>JobDescription</td>
<td>no</td>
<td>A short text description of the job.</td>
</tr>
</tbody>
</table>
Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

<td>string</td>
<td>length max:2028 pattern: [^\p{C}]+ An optional comment string describing why the job was canceled.</td>
</tr>
</tbody>
</table>
ClearDefaultAuthorizer

Clears the default authorizer.

**Request syntax:**

```
DELETE /default-authorizer
```

**Errors:**

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404

- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400

- **ThrottlingException**
  - The rate exceeds the limit.
  - HTTP response code: 429

- **UnauthorizedException**
  - You are not authorized to perform this operation.
HTTP response code: 401
ServiceUnavailableException
The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException
An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:

```
aws iot clear-default-authorizer \n[--cli-input-json <value>] \n[--generate-cli-skeleton]
```

cli-input-json format:

```
{
}
```

Output:
None

CreateAuthorizer

Creates an authorizer.

Request syntax:

```
POST /authorizer/authorizerName
Content-type: application/json

{
    "authorizerFunctionArn": "string",
    "tokenKeyName": "string",
    "tokenSigningPublicKeys": {
        "string": "string"
    },
    "status": "string"
}
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>AuthorizerName</td>
<td>yes</td>
<td>The authorizer name.</td>

</tr>
</tbody>
</table>
### CreateCertificateFromCsr

Creates an X.509 certificate using the specified certificate signing request.

**Note:** The CSR must include a public key that is either an RSA key with a length of at least 2048 bits or an ECC key from NIST P-256 or NIST P-384 curves.

**Note:** Reusing the same certificate signing request (CSR) results in a distinct certificate.

#### Input:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tokenKeyName</td>
<td>string</td>
<td>The name of the token key used to extract the token from the HTTP headers.</td>
</tr>
<tr>
<td>length max:128 min:1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pattern: [a-zA-Z0-9_-]+</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tokenSigningPublicKeys</td>
<td>map</td>
<td>The public keys used to verify the digital signature returned by your custom authentication service.</td>
</tr>
<tr>
<td>key: KeyName</td>
<td></td>
<td></td>
</tr>
<tr>
<td>value: KeyValue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>KeyName</td>
<td>string</td>
<td>The public keys used to verify the digital signature returned by your custom authentication service.</td>
</tr>
<tr>
<td>length max:128 min:1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pattern: [a-zA-Z0-9_-]+</td>
<td></td>
<td></td>
</tr>
<tr>
<td>KeyValue</td>
<td>string</td>
<td>The status of the create authorizer request.</td>
</tr>
<tr>
<td>length max:5120</td>
<td></td>
<td></td>
</tr>
<tr>
<td>status</td>
<td>string</td>
<td>The status of the create authorizer request.</td>
</tr>
<tr>
<td>enum: ACTIVE</td>
<td>INACTIVE</td>
<td>The status of the create authorizer request.</td>
</tr>
<tr>
<td>java class:</td>
<td></td>
<td>iot.identity.service.AuthorizerStatus</td>
</tr>
</tbody>
</table>

Output:

```
{
  "authorizerName": "string",
  "authorizerArn": "string"
}
```

**cli output fields:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>string</td>
<td>The authorizer's name.</td>
</tr>
<tr>
<td>length max:128 min:1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pattern: [w=,@-]+</td>
<td></td>
<td></td>
</tr>
<tr>
<td>authorizerArn</td>
<td>string</td>
<td>The authorizer ARN.</td>
</tr>
</tbody>
</table>

---

382
You can create multiple certificates in a batch by creating a directory, copying multiple .csr files into that directory, and then specifying that directory on the command line. The following commands show how to create a batch of certificates given a batch of CSRs.

Assuming a set of CSRs are located inside of the directory my-csr-directory:

On Linux and OS X, the command is:

```
$ ls my-csr-directory/ | xargs -I  aws iot create-certificate-from-csr --certificate-signing-request file://my-csr-directory/
```

This command lists all of the CSRs in my-csr-directory and pipes each CSR file name to the aws iot create-certificate-from-csr AWS CLI command to create a certificate for the corresponding CSR.

The aws iot create-certificate-from-csr part of the command can also be run in parallel to speed up the certificate creation process:

```
$ ls my-csr-directory/ | xargs -P 10 -I  aws iot create-certificate-from-csr --certificate-signing-request file://my-csr-directory/
```

On Windows PowerShell, the command to create certificates for all CSRs in my-csr-directory is:

```
> ls -Name my-csr-directory | % aws iot create-certificate-from-csr --certificate-signing-request file://my-csr-directory/$_
```

On a Windows command prompt, the command to create certificates for all CSRs in my-csr-directory is:

```
> forfiles /p my-csr-directory /c "cmd /c aws iot create-certificate-from-csr --certificate-signing-request file://@path"
```

### Request syntax:

```json
POST /certificates?setAsActive=setAsActive
Content-type: application/json

{
   "certificateSigningRequest": "string"
}
```

### URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setAsActive</td>
<td>SetAsActive</td>
<td>no</td>
<td>Specifies whether the certificate is active.</td>
</tr>
</tbody>
</table>

### Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateSigningRequest</td>
<td>CertificateSigningRequest</td>
<td>yes</td>
<td>The certificate signing request (CSR).</td>
</tr>
</tbody>
</table>

### Response syntax:

```json
Content-type: application/json

{

```
"certificateArn": "string",
"certificateId": "string",
"certificatePem": "string"
}

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateArn</td>
<td>CertificateArn</td>
<td>no</td>
<td>The Amazon Resource Name (ARN) of the certificate. You can use the ARN as a principal for policy operations.</td>
</tr>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>no</td>
<td>The ID of the certificate. Certificate management operations only take a certificateId.</td>
</tr>
<tr>
<td>certificatePem</td>
<td>CertificatePem</td>
<td>no</td>
<td>The certificate data, in PEM format.</td>
</tr>
</tbody>
</table>

Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

<td>string</td>
<td>The job description.</td>
</tr>
<tr>
<td></td>
<td>length max:2028</td>
<td></td>
</tr>
</tbody>
</table>
CreateKeysAndCertificate

Creates a 2048-bit RSA key pair and issues an X.509 certificate using the issued public key.

**Note** This is the only time AWS IoT issues the private key for this certificate, so it is important to keep it in a secure location.

**Request syntax:**

```plaintext
POST /keys-and-certificate?setAsActive=setAsActive
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setAsActive</td>
<td>SetAsActive</td>
<td>no</td>
<td>Specifies whether the certificate is active.</td>
</tr>
</tbody>
</table>

**Response syntax:**

```json
Content-type: application/json

{
  "certificateArn": "string",
  "certificateId": "string",
  "certificatePem": "string",
  "keyPair": {
    "PublicKey": "string",
    "PrivateKey": "string"
  }
}
```

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateArn</td>
<td>CertificateArn</td>
<td>no</td>
<td>The ARN of the certificate.</td>
</tr>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>no</td>
<td>The ID of the certificate. AWS IoT issues a default subject name for the certificate (for example, AWS IoT Certificate).</td>
</tr>
<tr>
<td>certificatePem</td>
<td>CertificatePem</td>
<td>no</td>
<td>The certificate data, in PEM format.</td>
</tr>
<tr>
<td>keyPair</td>
<td>KeyPair</td>
<td>no</td>
<td>The generated key pair.</td>
</tr>
</tbody>
</table>
Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:

```bash
aws iot create-keys-and-certificate \
    [--set-as-active | --no-set-as-active] \ 
    [--cli-input-json <value>] \ 
    [--generate-cli-skeleton]

<tr>
<td>policyDocument</td>
<td>string</td>
<td>The JSON document that describes the policy. &lt;br&gt;<strong>policyDocument</strong> must have a minimum length of 1, with a maximum length of 2048, excluding whitespace.</td>
</tr>
</tbody>
</table>

**Output:**

```
{
}
```
CreatePolicyVersion

Creates a new version of the specified AWS IoT policy. To update a policy, create a new policy version. A managed policy can have up to five versions. If the policy has five versions, you must use DeletePolicyVersion to delete an existing version before you create a new one.

Optionally, you can set the new version as the policy's default version. The default version is the operative version (that is, the version that is in effect for the certificates to which the policy is attached).

Request syntax:

```
POST /policies/policyName/version?setAsDefault=setAsDefault
Content-type: application/json

{
  "policyDocument": "string"
}
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>PolicyName</td>
<td>yes</td>
<td>The policy name.</td>
</tr>
<tr>
<td>setAsDefault</td>
<td>SetAsDefault</td>
<td>no</td>
<td>Specifies whether the policy version is set as the default. When this parameter is true, the new policy version becomes the operative version (that is, the version that is in effect for the certificates to which the policy is attached).</td>
</tr>
</tbody>
</table>

**CLI**

**Synopsis:**

```
aws iot create-thing-type \
  --thing-type-name <value> \
  [--thing-type-properties <value>] \
  [--cli-input-json <value>] \n  [--generate-cli-skeleton]
```

**cli-input-json format:**

```json
{
  "thingTypeName": "string",
  "thingTypeProperties": {
    "thingTypeDescription": "string",
    "searchableAttributes": ["string"
  ]
}
}
```

**cli-input-json fields:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingTypeName</td>
<td>string</td>
<td>The name of the thing type.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1 pattern: [a-zA-Z0-9:_-]+</td>
<td></td>
</tr>
<tr>
<td>thingTypeProperties</td>
<td>ThingTypeProperties</td>
<td>The ThingTypeProperties for the thing type to create. It contains information about the new thing</td>
</tr>
</tbody>
</table>
Create Topic Rule

Creates a rule. Creating rules is an administrator-level action. Any user who has permission to create rules will be able to access data processed by the rule.

Request syntax:

```
POST /rules/ruleName
Content-type: application/json
```
{  
"topicRulePayload": {  
"sql": "string",  
"description": "string",  
"actions": [  
{  
"dynamoDB": {  
"tableName": "string",  
"roleArn": "string",  
"operation": "string",  
"hashKeyField": "string",  
"hashKeyValue": "string",  
"hashKeyType": "string",  
"rangeKeyField": "string",  
"rangeKeyValue": "string",  
"rangeKeyType": "string",  
"payloadField": "string"  
},  
"dynamoDBv2": {  
"roleArn": "string",  
"putItem": {  
"tableName": "string"  
}  
},

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ruleName</td>
<td>RuleName</td>
<td>yes</td>
<td>The name of the rule.</td>
</tr>
</tbody>
</table>

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>topicRulePayload</td>
<td>TopicRulePayload</td>
<td>yes</td>
<td>The rule payload.</td>
</tr>
</tbody>
</table>

Errors:

SqlParseException

The Rule-SQL expression can't be parsed correctly.

HTTP response code: 400

InternalException

An unexpected error has occurred.

HTTP response code: 500
InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ResourceAlreadyExistsException

The resource already exists.

HTTP response code: 409

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

CLI

Synopsis:

```bash
aws iot create-topic-rule
   --rule-name <value> \\
   --topic-rule-payload <value> \\
   [--cli-input-json <value>] \\
   [--generate-cli-skeleton]
```

cli-input-json format:

DeleteAuthorizer

Deletes an authorizer.

Request syntax:

```
DELETE /authorizer/authorizerName
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>AuthorizerName</td>
<td>yes</td>
<td>The name of the authorizer to delete.</td>
</tr>
</tbody>
</table>

Errors:

DeleteConflictException

You can't delete the resource because it is attached to one or more resources.

HTTP response code: 409

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
HTTP response code: 400
ThrottlingException
The rate exceeds the limit.

HTTP response code: 429
UnauthorizedException
You are not authorized to perform this operation.

HTTP response code: 401
ServiceUnavailableException
The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException
An unexpected error has occurred.

HTTP response code: 500

**CLI**

**Synopsis:**

```
aws iot delete-authorizer \
  --authorizer-name <value>  \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "authorizerName": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>string</td>
<td>The name of the authorizer to delete.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1 pattern: [w=,@-]+</td>
<td></td>
</tr>
</tbody>
</table>

Output:

None

**DeleteCACertificate**

Deletes a registered CA certificate.
Request syntax:

```
DELETE /cacertificate/caCertificateId
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>yes</td>
<td>The ID of the certificate to delete.</td>
</tr>
</tbody>
</table>

**Errors:**

- **InvalidRequestException**
  
  The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

  
  HTTP response code: 400

- **CertificateStateException**

  The certificate operation is not allowed.

  HTTP response code: 406

- **ThrottlingException**

  The rate exceeds the limit.

  HTTP response code: 429

- **UnauthorizedException**

  You are not authorized to perform this operation.

  HTTP response code: 401

- **ServiceUnavailableException**

  The service is temporarily unavailable.

  HTTP response code: 503

- **InternalFailureException**

  An unexpected error has occurred.

  HTTP response code: 500

- **ResourceNotFoundException**

  The specified resource does not exist.

  HTTP response code: 404

**CLI**

**Synopsis:**
DeleteCertificate

Deletes the specified certificate.

A certificate cannot be deleted if it has a policy attached to it or if its status is set to ACTIVE. To delete a certificate, first use the DetachPrincipalPolicy API to detach all policies. Next, use the UpdateCertificate API to set the certificate to the INACTIVE status.

Request syntax:

```
DELETE /certificates/certificateId?forceDelete=forceDelete
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>yes</td>
<td>The ID of the certificate.</td>
</tr>
<tr>
<td>forceDelete</td>
<td>ForceDelete</td>
<td>no</td>
<td>Forces a certificate request to be deleted.</td>
</tr>
</tbody>
</table>

Errors:

CertificateStateException

The certificate operation is not allowed.

HTTP response code: 406
DeleteConflictException

You can't delete the resource because it is attached to one or more resources.

HTTP response code: 409

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

## CLI

### Synopsis:

```
aws iot  delete-certificate  
   --certificate-id <value>  
   [--force-delete | --no-force-delete]  
   [--cli-input-json <value>]  
   [--generate-cli-skeleton]
```

cli-input-json format:

```json
{
   "certificateId": "string",
   "forceDelete": "boolean"
}
```
DeletePolicy

Deletes the specified policy.

A policy cannot be deleted if it has non-default versions or it is attached to any certificate.

To delete a policy, use the DeletePolicyVersion API to delete all non-default versions of the policy; use the DetachPrincipalPolicy API to detach the policy from any certificate; and then use the DeletePolicy API to delete the policy.

When a policy is deleted using DeletePolicy, its default version is deleted with it.

Request syntax:

DELETE /policies/policyName

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>PolicyName</td>
<td>yes</td>
<td>The name of the policy to delete.</td>
</tr>
</tbody>
</table>

Errors:

DeleteConflictException

You can't delete the resource because it is attached to one or more resources.

HTTP response code: 409

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404
InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:

```
aws iot delete-policy \
   --policy-name <value> \
   [--cli-input-json <value>] \
   [--generate-cli-skeleton]
```

cli-input-json format:

```
{
   "policyName": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>string</td>
<td>The name of the policy to delete.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1 pattern: [w+,.@-]+</td>
<td></td>
</tr>
</tbody>
</table>

Output:
DeletePolicyVersion

Deletes the specified version of the specified policy. You cannot delete the default version of a policy using this API. To delete the default version of a policy, use DeletePolicy. To find out which version of a policy is marked as the default version, use ListPolicyVersions.

Request syntax:

```
DELETE /policies/policyName/version/policyVersionId
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>PolicyName</td>
<td>yes</td>
<td>The name of the policy.</td>
</tr>
<tr>
<td>policyVersionId</td>
<td>PolicyVersionId</td>
<td>yes</td>
<td>The policy version ID.</td>
</tr>
</tbody>
</table>

Errors:

DeleteConflictException

You can't delete the resource because it is attached to one or more resources.

HTTP response code: 409

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException

An unexpected error has occurred.
HTTP response code: 500

CLI

Synopsis:

```
aws iot delete-policy-version
  --policy-name <value>
  --policy-version-id <value>
  [--cli-input-json <value>]
  [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "policyName": "string",
  "policyVersionId": "string"

<tbody>
<tr>
<td>roleAlias</td>
<td>string</td>
<td>The role alias to delete.</td>
</tr>
</tbody>
</table>

Output:
None

DeleteThing

Deletes the specified thing.

Request syntax:

```sh
DELETE /things/thingName?expectedVersion=expectedVersion
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing to delete.</td>
</tr>
<tr>
<td>expectedVersion</td>
<td>OptionalVersion</td>
<td>no</td>
<td>The expected version of the thing record in the registry. If the version of the record in the registry does not match the expected version specified in the request, the DeleteThing request is rejected with a VersionConflictException.</td>
</tr>
</tbody>
</table>

Errors:

- **ResourceNotFoundException**
  The specified resource does not exist.
  
  HTTP response code: 404

- **VersionConflictException**
  An exception thrown when the version of a thing passed to a command is different than the version specified with the --version parameter.

  HTTP response code: 409
InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

</table>

DeleteThingType

Deletes the specified thing type. You cannot delete a thing type if it has things associated with it. To delete a thing type, first mark it as deprecated by calling DeprecateThingType, then remove any associated things by calling UpdateThing to change the thing type on any associated thing, and finally use DeleteThingType to delete the thing type.

Request syntax:
DELETE /thing-types/thingTypeName

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingTypeName</td>
<td>ThingTypeName</td>
<td>yes</td>
<td>The name of the thing type.</td>

Errors:

InternalException

An unexpected error has occurred.

HTTP response code: 500

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

CLI

Synopsis:

```
aws iot  delete-v2-logging-level \
   --target-type <value> \
   --target-name <value> \
   [--cli-input-json <value>] \
   [--generate-cli-skeleton]
```

cli-input-json format:

```
{
   "targetType": "string",
   "targetName": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetType</td>
<td>string, enum: DEFAULT</td>
<td>THING_GROUP</td>
</tr>
<tr>
<td></td>
<td>[java class: iot.goldeneye.service.LogTargetType]</td>
<td></td>
</tr>
<tr>
<td>targetName</td>
<td>string</td>
<td>The name of the resource for which you are configuring logging.</td>
</tr>
</tbody>
</table>

Output:

None
DeprecateThingType

Deprecates a thing type. You can not associate new things with deprecated thing type.

Request syntax:

```
POST /thing-types/{thingTypeName}/deprecate
Content-type: application/json
{
  "undoDeprecate": "boolean"
}
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingTypeName</td>
<td>ThingTypeName</td>
<td>yes</td>
<td>The name of the thing type to deprecate.</td>
</tr>
</tbody>
</table>

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>undoDeprecate</td>
<td>UndoDeprecate</td>
<td>no</td>
<td>Whether to undeprecate a deprecated thing type. If true, the thing type will not be deprecated anymore and you can associate it with things.</td>
</tr>
</tbody>
</table>

Errors:

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404
- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400
- **ThrottlingException**
  - The rate exceeds the limit.
  - HTTP response code: 429
- **UnauthorizedException**
  - You are not authorized to perform this operation.
HTTP response code: 401
ServiceUnavailableException
The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException
An unexpected error has occurred.

HTTP response code: 500

**CLI**

**Synopsis:**

```bash
aws iot deprecate-thing-type \
    --thing-type-name <value> \
    [--undo-deprecate | --no-undo-deprecate] \
    [--cli-input-json <value>] \

CLI

Synopsis:

aws iot describe-index
   --index-name <value>  
   [--cli-input-json <value>] 
   [--generate-cli-skeleton]

cli-input-json format:

{  
   "indexName": "string"
}

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexName</td>
<td>string</td>
<td>The index name.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>pattern: [a-zA-Z0-9:_-]+</td>
<td></td>
</tr>
</tbody>
</table>

Output:

{  
   "indexName": "string",
   "indexStatus": "string",
   "schema": "string"
}

cli output fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexName</td>
<td>string</td>
<td>The index name.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>pattern: [a-zA-Z0-9:_-]+</td>
<td></td>
</tr>
<tr>
<td>indexStatus</td>
<td>string</td>
<td>The index status.</td>
</tr>
<tr>
<td></td>
<td>enum: ACTIVE</td>
<td>BUILDING</td>
</tr>
<tr>
<td></td>
<td>java class: com.amazonaws.iot.indexing.IndexStatus</td>
<td></td>
</tr>
</tbody>
</table>
DescribeJob

Describes a job.

Request syntax:

GET /jobs/jobId

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>yes</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
</tbody>
</table>

Response syntax:

Content-type: application/json

{
  "documentSource": "string",
  "job": {
    "jobArn": "string",
    "jobId": "string",
    "targetSelection": "string",
    "status": "string",
    "comment": "string",
    "targets": ["string"],
    "description": "string",
    "presignedUrlConfig": {
      "roleArn": "string",
      "expiresInSec": "long"
    },
    "jobExecutionsRolloutConfig": {
      "maximumPerMinute": "integer"
    },
    "createdAt": "timestamp",
    "lastUpdatedAt": "timestamp",
    "completedAt": "timestamp",
    "jobProcessDetails": {
      "schema": "string",
      "type": "string",  
      "description": "Contains a value that specifies the type of indexing performed. Valid values are:
1. REGISTRY – Your thing index will contain only registry data.
2. REGISTRY_AND_SHADOW - Your thing index will contain registry and shadow data."}
  }
}
Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>documentSource</td>
<td>JobDocumentSource</td>
<td>no</td>
<td>An S3 link to the job document.</td>
</tr>
<tr>
<td>job</td>
<td>Job</td>
<td>no</td>
<td>Information about the job.</td>
</tr>
</tbody>
</table>

Errors:

- **InvalidRequestException**
  
  The contents of the request were invalid. For example, this code is returned when an 
  UpdateJobExecution request contains invalid status details. The message contains details about the 
  error.

  HTTP response code: 400

- **ResourceNotFoundException**

  The specified resource does not exist.

  HTTP response code: 404

- **ThrottlingException**

  The rate exceeds the limit.

  HTTP response code: 429

- **ServiceUnavailableException**

  The service is temporarily unavailable.

  HTTP response code: 503

### DescribeJobExecution

Describes a job execution.

#### Request syntax:

```
GET /things/thingName/jobs/jobId?executionNumber=executionNumber
```
URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>yes</td>
<td>The unique identifier you assigned to this job when it was created.</td>
</tr>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing on which the job execution is running.</td>
</tr>
<tr>
<td>executionNumber</td>
<td>ExecutionNumber</td>
<td>no</td>
<td>A string (consisting of the digits &quot;0&quot; through &quot;9&quot;) which is used to specify a particular job execution on a particular device.</td>
</tr>
</tbody>
</table>

Response syntax:

Content-type: application/json

```
{   "execution": {       "jobId": "string",       "status": "string",       "statusDetails": {         "detailsMap": {             "string": "string"         }       },       "thingArn": "string",       "queuedAt": "timestamp",       "startedAt": "timestamp",       "lastUpdatedAt": "timestamp",       "executionNumber": "long"   } }
```

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>execution</td>
<td>JobExecution</td>
<td>no</td>
<td>Information about the job execution.</td>
</tr>
</tbody>
</table>

Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

<tr>
<td></td>
<td>range- max:3600 min:900</td>
<td></td>
</tr>
</tbody>
</table>
DescribeThing

Gets information about the specified thing.

Request syntax:

```
GET /things/thingName
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing.</td>
</tr>
</tbody>
</table>

Response syntax:

```
Content-type: application/json

{
  "defaultClientId": "string",
  "thingName": "string",
  "thingId": "string",
  "thingArn": "string",
  "thingTypeName": "string",
  "attributes": {
    "string": "string"
  },
  "version": "long"
}
```

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultClientId</td>
<td>ClientId</td>
<td>no</td>
<td>The default client ID.</td>
</tr>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>no</td>
<td>The name of the thing.</td>
</tr>
<tr>
<td>thingId</td>
<td>ThingId</td>
<td>no</td>
<td>The ID of the thing to describe.</td>
</tr>
<tr>
<td>thingArn</td>
<td>ThingArn</td>
<td>no</td>
<td>The ARN of the thing to describe.</td>
</tr>
<tr>
<td>thingTypeName</td>
<td>ThingTypeName</td>
<td>no</td>
<td>The thing type name.</td>
</tr>
<tr>
<td>attributes</td>
<td>Attributes</td>
<td>no</td>
<td>The thing attributes.</td>
</tr>
</tbody>
</table>
DescribeThing

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>Version</td>
<td>no</td>
<td>The current version of the thing record in the registry.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>To avoid unintentional changes to the information in the registry, you can</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>pass the version information in the expectedVersion parameter of the Update</td>
</tr>
<tr>

**Output:**

```
{
  "policyArn": "string",
  "policyName": "string",
  "policyDocument": "string",
  "policyVersion": "string",
  "isDefaultVersion": "boolean"
}
```
GetRegistrationCode

Gets a registration code used to register a CA certificate with AWS IoT.

Request syntax:

GET /registrationcode

Response syntax:

Content-type: application/json

```
{
  "registrationCode": "string"
}
```

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>registrationCode</td>
<td>RegistrationCode</td>
<td>no</td>
<td>The CA certificate registration code.</td>
</tr>
</tbody>
</table>

Errors:

- ThrottlingException
  - The rate exceeds the limit.
  - HTTP response code: 429
- UnauthorizedException
  - You are not authorized to perform this operation.
HTTP response code: 401
ServiceUnavailableException
  The service is temporarily unavailable.
HTTP response code: 503
InternalFailureException
  An unexpected error has occurred.
HTTP response code: 500
InvalidRequestException
  The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
HTTP response code: 400

**CLI**

**Synopsis:**

```bash
aws iot get-registration-code \\
  [--cli-input-json <value>] \\
  [--generate-cli-skeleton]
```

**cli-input-json format:**

```json
{}
```

**Output:**

```json
{
  "registrationCode": "string"
}
```

**cli output fields:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>registrationCode</td>
<td>string</td>
<td>The CA certificate registration code.</td>
</tr>
<tr>
<td></td>
<td>length max:64 min:64</td>
<td>pattern: (0x)?[a-fA-F0-9]+</td>
</tr>
</tbody>
</table>

**GetThingShadow**

Gets the thing shadow for the specified thing.

For more information, see `GetThingShadow` in the AWS IoT Developer Guide.

**Request syntax:**
GET /things/thingName/shadow

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing.</td>
</tr>
</tbody>
</table>

**Response syntax:**

```json
Content-type: application/json

{
  "payload": "blob"
}
```

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>JsonDocument</td>
<td>no</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

**Errors:**

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**ResourceNotFoundException**

The specified resource does not exist.

HTTP response code: 404

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**UnauthorizedException**

You are not authorized to perform this operation.

HTTP response code: 401

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

**InternalFailureException**

An unexpected error has occurred.
HTTP response code: 500
MethodNotAllowedException

The specified combination of HTTP verb and URI is not supported.

HTTP response code: 405
UnsupportedDocumentEncodingException

The encoding is not supported.

HTTP response code: 415

CLI

Synopsis:

```bash
aws iot-data get-thing-shadow \
  --thing-name <value> \ 
  [--cli-input-json <value>] \ 
  [--generate-cli-skeleton]
```

cli-input-json format:

```json
{
  "thingName": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>string</td>
<td>The name of the thing.</td>
</tr>
</tbody>
</table>

Output:

```json
{
  "payload": "blob"
}
```

cli output fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>blob</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

GetTopicRule

Gets information about the rule.
Request syntax:

GET /rules/ruleName

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ruleName</td>
<td>RuleName</td>
<td>yes</td>
<td>The name of the rule.</td>
</tr>
</tbody>
</table>

Response syntax:

```
Content-type: application/json

</tbody>
</table>
GetV2LoggingOptions

Gets the fine grained logging options.

Request syntax:

```
GET /v2LoggingOptions
```

Response syntax:

```
Content-type: application/json
```
Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleArn</td>
<td>AwsArn</td>
<td>no</td>
<td>The IAM role ARN AWS IoT uses to write to your CloudWatch logs.</td>
</tr>
<tr>
<td>defaultLogLevel</td>
<td>LogLevel</td>
<td>no</td>
<td>The default log level.</td>
</tr>
<tr>
<td>disableAllLogs</td>
<td>DisableAllLogs</td>
<td>no</td>
<td>Disables all logs.</td>
</tr>
</tbody>
</table>

Errors:

InternalException
An unexpected error has occurred.
HTTP response code: 500

InvalidRequestException
The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
HTTP response code: 400

ServiceUnavailableException
The service is temporarily unavailable.
HTTP response code: 503

CLI

Synopsis:

```
aws iot get-v2-logging-options  
[-cli-input-json <value>]  
[-generate-cli-skeleton]
```

cli-input-json format:

```
{
}
```

Output:

```
{
  "roleArn": "string",
  "defaultLogLevel": "string",
  "disableAllLogs": "boolean"
}
```
cli output fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleArn</td>
<td>string</td>
<td>The IAM role ARN AWS IoT uses to write to your CloudWatch logs.</td>
</tr>
<tr>
<td>defaultLogLevel</td>
<td>string</td>
<td>The default log level.</td>
</tr>
<tr>
<td></td>
<td>enum: DEBUG</td>
<td>INFO</td>
</tr>
<tr>
<td>disableAllLogs</td>
<td>boolean</td>
<td>Disables all logs.</td>
</tr>
</tbody>
</table>

ListAttachedPolicies

Lists the policies attached to the specified thing group.

Request syntax:

POST /attached-policies/target?recursive=recursive&pageSize=pageSize&marker=marker

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>PolicyTarget</td>
<td>yes</td>
<td>The group for which the policies will be listed.</td>
</tr>
<tr>
<td>recursive</td>
<td>Recursive</td>
<td>no</td>
<td>When true, recursively list attached policies.</td>
</tr>
<tr>
<td>marker</td>
<td>Marker</td>
<td>no</td>
<td>The token to retrieve the next set of results.</td>
</tr>
<tr>
<td>pageSize</td>
<td>PageSize</td>
<td>no</td>
<td>The maximum number of results to be returned per request.</td>
</tr>
</tbody>
</table>

Response syntax:

Content-type: application/json

```json
{
  "policies": [
    {
      "policyName": "string",
      "policyArn": "string"
    }
  ],
}
"nextMarker": "string"
}

### Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policies</td>
<td>Policies</td>
<td>no</td>
<td>The policies.</td>
</tr>
<tr>
<td>nextMarker</td>
<td>Marker</td>
<td>no</td>
<td>The token to retrieve the next set of results, or null if there are no more results.</td>
</tr>
</tbody>
</table>

### Errors:

- **ResourceNotFoundException**
  
  The specified resource does not exist.
  
  HTTP response code: 404

- **InvalidRequestException**
  
  The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  
  HTTP response code: 400

- **ThrottlingException**
  
  The rate exceeds the limit.
  
  HTTP response code: 429

- **UnauthorizedException**
  
  You are not authorized to perform this operation.
  
  HTTP response code: 401

- **ServiceUnavailableException**
  
  The service is temporarily unavailable.
  
  HTTP response code: 503

- **InternalFailureException**
  
  An unexpected error has occurred.
  
  HTTP response code: 500

- **LimitExceededException**
  
  The number of attached entities exceeds the limit.
  
  HTTP response code: 410

### CLI

**Synopsis:**
aws iot list-attached-policies \ 
  --target <value> \ 
  [--recursive | --no-recursive] \ 
  [--marker <value>] \ 
  [--page-size <value>] \ 
  [--cli-input-json <value>] \ 
  [--generate-cli-skeleton]

cli-input-json format:

{  
  "target": "string",  
  "recursive": "boolean",  
  "marker": "string",  
  "pageSize": "integer"  
}

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>string</td>
<td>The group for which the policies will be listed.</td>
</tr>
<tr>
<td>recursive</td>
<td>boolean</td>
<td>When true, recursively list attached policies.</td>
</tr>
<tr>
<td>marker</td>
<td>string</td>
<td>The token to retrieve the next set of results.</td>
</tr>
<tr>
<td>pageSize</td>
<td>integer</td>
<td>The maximum number of results to be returned per request.</td>
</tr>
</tbody>
</table>

Output:

{  
  "policies": [  
    {  
      "policyName": "string",  
      "policyArn": "string"  
    }  
  ],  
  "nextMarker": "string"  
}

cli output fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policies</td>
<td>list</td>
<td>The policies.</td>
</tr>
<tr>
<td></td>
<td>member: Policy</td>
<td></td>
</tr>
<tr>
<td></td>
<td>java class: java.util.List</td>
<td></td>
</tr>
</tbody>
</table>
ListAuthorizers

Lists the authorizers registered in your account.

Request syntax:

```
GET /authorizers/?
pageSize=pageSize&marker=marker&isAscendingOrder=ascendingOrder&status=status
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageSize</td>
<td>PageSize</td>
<td>no</td>
<td>The maximum number of results to return at one time.</td>
</tr>
<tr>
<td>marker</td>
<td>Marker</td>
<td>no</td>
<td>A marker used to get the next set of results.</td>
</tr>
<tr>
<td>ascendingOrder</td>
<td>AscendingOrder</td>
<td>no</td>
<td>Return the list of authorizers in ascending alphabetical order.</td>
</tr>
<tr>
<td>status</td>
<td>AuthorizerStatus</td>
<td>no</td>
<td>The status of the list authorizers request.</td>
</tr>
</tbody>
</table>

Response syntax:

```
Content-type: application/json

{
    "authorizers": [
        {
            "authorizerName": "string",
            "authorizerArn": "string"
        }
    ],
    "nextMarker": "string"
}
```
Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizers</td>
<td>Authorizers</td>
<td>no</td>
<td>The authorizers.</td>
</tr>
<tr>
<td>nextMarker</td>
<td>Marker</td>
<td>no</td>
<td>A marker used to get the next set of results.</td>
</tr>
</tbody>
</table>

Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:

```bash
aws iot list-authorizers
    [--page-size <value>]
    [--marker <value>]
    [--ascending-order | --no-ascending-order]
    [--status <value>]
    [--cli-input-json <value>]
    [--generate-cli-skeleton]
```

cli-input-json format:

```json
{}
```

### Publish

Publishes state information.

For more information, see HTTP Protocol in the AWS IoT Developer Guide.

**Request syntax:**

```
POST /topics/topic?qos=qos
Content-type: application/json

{
  "payload": "blob"
}
```

#### URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>topic</td>
<td>Topic</td>
<td>no</td>
<td>The name of the MQTT topic.</td>
</tr>
<tr>
<td>qos</td>
<td>Qos</td>
<td>no</td>
<td>The Quality of Service (QoS) level.</td>
</tr>
</tbody>
</table>

#### Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>Payload</td>
<td>no</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

#### Errors:

- **InternalFailureException**
  
  An unexpected error has occurred.

  HTTP response code: 500
InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

MethodNotAllowedException

The specified combination of HTTP verb and URI is not supported.

HTTP response code: 405

CLI

Synopsis:

```bash
aws iot-data publish \
    [--topic <value>] \

<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

Output:

None
RegisterCACertificate

Registers a CA certificate with AWS IoT. This CA certificate can then be used to sign device certificates, which can be then registered with AWS IoT. You can register up to 10 CA certificates per AWS account that have the same subject field. This enables you to have up to 10 certificate authorities sign your device certificates. If you have more than one CA certificate registered, make sure you pass the CA certificate when you register your device certificates with the RegisterCertificate API.

Request syntax:

```
POST /cacertificate?setAsActive=setAsActive&allowAutoRegistration=allowAutoRegistration
Content-type: application/json

{  
  "caCertificate": "string",
  "verificationCertificate": "string",
  "registrationConfig": {
    "templateBody": "string",
    "roleArn": "string"
  }
}
```

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setAsActive</td>
<td>SetAsActive</td>
<td>no</td>
<td>A boolean value that specifies if the CA certificate is set to active.</td>
</tr>
<tr>
<td>allowAutoRegistration</td>
<td>AllowAutoRegistration</td>
<td>no</td>
<td>Allows this CA certificate to be used for auto registration of device certificates.</td>
</tr>
</tbody>
</table>

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>registrationConfig</td>
<td>RegistrationConfig</td>
<td>no</td>
<td>Information about the registration configuration.</td>
</tr>
</tbody>
</table>

Response syntax:

```
Content-type: application/json

{
  "certificateArn": "string",
}
```
"certificateId": "string"
}

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateArn</td>
<td>CertificateArn</td>
<td>no</td>
<td>The CA certificate ARN.</td>
</tr>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>no</td>
<td>The CA certificate identifier.</td>
</tr>
</tbody>
</table>

**Errors:**

**ResourceAlreadyExistsException**

The resource already exists.

HTTP response code: 409

**RegistrationCodeValidationException**

The registration code is invalid.

HTTP response code: 400

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**CertificateValidationException**

The certificate is invalid.

HTTP response code: 400

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**LimitExceededException**

The number of attached entities exceeds the limit.

HTTP response code: 410

**UnauthorizedException**

You are not authorized to perform this operation.

HTTP response code: 401

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException
An unexpected error has occurred.
HTTP response code: 500

<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>no</td>
<td>The certificate identifier.</td>
</tr>
</tbody>
</table>

Errors:

- **ResourceAlreadyExistsException**
  - The resource already exists.
  - HTTP response code: 409

- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400

- **CertificateValidationException**
  - The certificate is invalid.
  - HTTP response code: 400

- **CertificateStateException**
  - The certificate operation is not allowed.
  - HTTP response code: 406

- **CertificateConflictException**
  - Unable to verify the CA certificate used to sign the device certificate you are attempting to register. This is happens when you have registered more than one CA certificate that has the same subject field and public key.
  - HTTP response code: 409
ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:

```
aws iot register-certificate \
   --certificate-pem <value> \ 
   [--ca-certificate-pem <value>] \ 
   [--set-as-active | --no-set-as-active] \ 
   [--status <value>] \
   [--cli-input-json <value>] \ 
   [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "certificatePem": "string",
  "caCertificatePem": "string",
  "status": "string"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificatePem</td>
<td>string, length max:65536 min:1</td>
<td>The certificate data, in PEM format.</td>
</tr>
<tr>
<td>caCertificatePem</td>
<td>string, length max:65536 min:1</td>
<td>The CA certificate used to sign the device certificate being registered.</td>
</tr>
<tr>
<td>status</td>
<td>string, enum: ACTIVE</td>
<td>The status of the register certificate request.</td>
</tr>
</tbody>
</table>
RegisterThing

Provisions a thing.

Request syntax:

POST /things
Content-type: application/json

{
   "templateBody": "string",
   "parameters": {
      "string": "string"
   }
}

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>templateBody</td>
<td>TemplateBody</td>
<td>yes</td>
<td>The provisioning template.</td>
</tr>
<tr>
<td>parameters</td>
<td>Parameters</td>
<td>no</td>
<td>The parameters for provisioning a thing.</td>
</tr>
</tbody>
</table>

Response syntax:
Content-type: application/json
{
  "certificatePem": "string",
  "resourceArns": {
    "string": "string"
  }
}

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificatePem</td>
<td>CertificatePem</td>
<td>no</td>
<td>ARNs for the generated resources.</td>
</tr>
<tr>
<td>resourceArns</td>
<td>ResourceArns</td>
<td>no</td>
<td>ARNs for the generated resources.</td>
</tr>
</tbody>
</table>

**Errors:**

**InternalFailureException**

An unexpected error has occurred.

HTTP response code: 500

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**UnauthorizedException**

You are not authorized to perform this operation.

HTTP response code: 401

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**ConflictingResourceUpdateException**

A conflicting resource update exception. This exception is thrown when two pending updates cause a conflict.

HTTP response code: 409

**ResourceRegistrationFailureException**

The resource registration failed.

HTTP response code: 400
CLI

Synopsis:

```
aws iot register-thing \
  --template-body <value> \
  [--parameters <value>] \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "templateBody": "string",
  "parameters": {
    "string": "string"
  }
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>templateBody</td>
<td>string</td>
<td>The provisioning template.</td>

<td>ARNs for the generated resources.</td>
</tr>
<tr>
<td></td>
<td>key: ResourceLogicalId</td>
<td></td>
</tr>
<tr>
<td></td>
<td>value: ResourceArn</td>
<td></td>
</tr>
</tbody>
</table>
RejectCertificateTransfer

Rejects a pending certificate transfer. After AWS IoT rejects a certificate transfer, the certificate status changes from PENDING_TRANSFER to INACTIVE.

To check for pending certificate transfers, call ListCertificates to enumerate your certificates.

This operation can only be called by the transfer destination. After it is called, the certificate will be returned to the source’s account in the INACTIVE state.

Request syntax:

PATCH /reject-certificate-transfer/certificateId
Content-type: application/json

{  "rejectReason": "string"
}

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>yes</td>
<td>The ID of the certificate.</td>
</tr>
</tbody>
</table>

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rejectReason</td>
<td>Message</td>
<td>no</td>
<td>The reason the certificate transfer was rejected.</td>
</tr>
</tbody>
</table>

Errors:

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

TransferAlreadyCompletedException

You can’t revert the certificate transfer because the transfer is already complete.

HTTP response code: 410

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
HTTP response code: 400
ThrottlingException
The rate exceeds the limit.

HTTP response code: 429
UnauthorizedException
You are not authorized to perform this operation.

HTTP response code: 401
ServiceUnavailableException
The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException
An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:

```
aws iot reject-certificate-transfer \
   --certificate-id <value> \
   [--reject-reason <value>] \
   [--cli-input-json <value>] \
   [--generate-cli-skeleton]
```

cli-input-json format:

```
{
    "certificateId": "string",
    "rejectReason": "string"
}
```

cli-input-json fields:

<tr>
<td></td>
<td>length max:128</td>
<td></td>
</tr>
</tbody>
</table>

Output:
RemoveThingFromThingGroup

Remove the specified thing from the specified group.

Request syntax:

```
PUT /thing-groups/removeThingFromThingGroup
Content-type: application/json

{
  "thingGroupName": "string",
  "thingGroupArn": "string",
  "thingName": "string",
  "thingArn": "string"
}
```

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingGroupName</td>
<td>ThingGroupName</td>
<td>no</td>
<td>The group name.</td>
</tr>
<tr>
<td>thingGroupArn</td>
<td>ThingGroupArn</td>
<td>no</td>
<td>The group ARN.</td>
</tr>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>no</td>
<td>The name of the thing to remove from the group.</td>

Output:
None

**SearchIndex**

The query search index.

**Request syntax:**

```
POST /indices/search
Content-type: application/json

{
  "indexName": "string",
  "queryString": "string",
  "nextToken": "string",
  "maxResults": "integer",
  "queryVersion": "string"
}
```

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexName</td>
<td>IndexName</td>
<td>no</td>
<td>The search index name.</td>
</tr>
<tr>
<td>queryString</td>
<td>QueryString</td>
<td>yes</td>
<td>The search query string.</td>
</tr>
<tr>
<td>nextToken</td>
<td>NextToken</td>
<td>no</td>
<td>The token used to get the next set of results, or null if there are no additional results.</td>
</tr>
<tr>
<td>maxResults</td>
<td>QueryMaxResults</td>
<td>no</td>
<td>The maximum number of results to return at one time.</td>
</tr>
<tr>
<td>queryVersion</td>
<td>QueryVersion</td>
<td>no</td>
<td>The query version.</td>
</tr>
</tbody>
</table>
Response syntax:

```
Content-type: application/json

{
   "nextToken": "string",
   "things": [
      {
         "thingName": "string",
         "thingId": "string",
         "thingTypeName": "string",
         "thingGroupNames": [
            "string"
         ],
         "attributes": {
            "string": "string"

<td>no</td>
<td>The things that match the search query.</td>
</tr>
</tbody>
</table>

Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503
InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

InvalidQueryException

The query is invalid.

HTTP response code: 400

IndexNotReadyException

The index is not ready.

HTTP response code: 400

**CLI**

**Synopsis:**

```
aws iot search-index
    [--index-name <value>]

</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>AuthorizerName</td>
<td>yes</td>
<td>The authorizer name.</td>
</tr>
</tbody>
</table>

Response syntax:
Content-type: application/json

{
  "authorizerName": "string",
  "authorizerArn": "string"
}

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>AuthorizerName</td>
<td>no</td>
<td>The authorizer name.</td>

<tr>
<td>authorizerArn</td>
<td>AuthorizerArn</td>
<td>no</td>
<td>The authorizer ARN.</td>
</tr>
</tbody>
</table>

Errors:

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404

- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400

- **ThrottlingException**
  - The rate exceeds the limit.
  - HTTP response code: 429

- **UnauthorizedException**
  - You are not authorized to perform this operation.
  - HTTP response code: 401

- **ServiceUnavailableException**
  - The service is temporarily unavailable.
  - HTTP response code: 503

- **InternalFailureException**
  - An unexpected error has occurred.
  - HTTP response code: 500

**CLI**

Synopsis:

aws iot set-default-authorizer \
**SetDefaultPolicyVersion**

Sets the specified version of the specified policy as the policy’s default (operative) version. This action affects all certificates to which the policy is attached. To list the principals the policy is attached to, use the ListPrincipalPolicy API.

**Request syntax:**

```
PATCH /policies/policyName/version/policyVersionId
```

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policyName</td>
<td>PolicyName</td>
<td>yes</td>
<td>The policy name.</td>
</tr>
</tbody>
</table>

**cli-input-json format:**

```
{
  "authorizerName": "string"
}
```

**cli-input-json fields:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>string</td>
<td>The authorizer name.</td>
</tr>
</tbody>
</table>

**Output:**

```
{
  "authorizerName": "string",
  "authorizerArn": "string"
}
```

**cli output fields:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>string</td>
<td>The authorizer name.</td>
</tr>
<tr>
<td>authorizerArn</td>
<td>string</td>
<td>The authorizer ARN.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Req?</td>
</tr>
<tr>
<td>---------------</td>
<td>------------</td>
<td>------</td>
</tr>
<tr>
<td>policyVersionId</td>
<td>PolicyVersionId</td>
<td>yes</td>
</tr>
</tbody>
</table>

**Errors:**

**ResourceNotFoundException**

The specified resource does not exist.

HTTP response code: 404

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an `UpdateJobExecution` request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**UnauthorizedException**

You are not authorized to perform this operation.

HTTP response code: 401

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

**InternalFailureException**

An unexpected error has occurred.

HTTP response code: 500

**CLI**

**Synopsis:**

```bash
aws iot set-default-policy-version \
  --policy-name <value> \
  --policy-version-id <value> \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

**cli-input-json format:**

```json
{
  "policyName": "string",
  "policyVersionId": "string"
}
```
SetLoggingOptions

Sets the logging options.

Request syntax:

```plaintext
POST /loggingOptions
Content-type: application/json

{
    "loggingOptionsPayload": {
        "roleArn": "string",
        "logLevel": "string"
    }
}
```

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loggingOptionsPayload</td>
<td>LoggingOptionsPayload</td>
<td>yes</td>
<td>The logging options payload.</td>
</tr>
</tbody>
</table>

Errors:

<tr>
<td>logLevel</td>
<td>string</td>
<td>The log level.</td>
</tr>
</tbody>
</table>

Output:

None

SetV2LoggingLevel

Sets the logging level.

Request syntax:

```
POST /v2LoggingLevel
```
Content-type: application/json

{
  "logTarget": {
    "targetType": "string",
    "targetName": "string"
  },
  "logLevel": "string"
}

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logTarget</td>
<td>LogTarget</td>
<td>yes</td>
<td>The log target.</td>
</tr>
<tr>
<td>logLevel</td>
<td>LogLevel</td>
<td>yes</td>
<td>The log level.</td>
</tr>
</tbody>
</table>

Errors:

InternalException

An unexpected error has occurred.

HTTP response code: 500

NotConfiguredException

The resource is not configured.

Output:
None

**SetV2LoggingOptions**

Sets the logging options for the V2 logging service.

**Request syntax:**

POST /v2LoggingOptions
Content-type: application/json

```
{
    "roleArn": "string",
    "defaultLogLevel": "string",
    "disableAllLogs": "boolean"
}
```

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleArn</td>
<td>AwsArn</td>
<td>no</td>
<td>The role ARN that allows IoT to write to Cloudwatch logs.</td>
</tr>
</tbody>
</table>
### Name | Type | Req? | Description
---|---|---|---
defaultLogLevel | LogLevel | no | The default logging level.
disableAllLogs | DisableAllLogs | no | Set to true to disable all logs, otherwise set to false.

### Errors:

**InternalException**

An unexpected error has occurred.

HTTP response code: 500

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

### CLI

**Synopsis:**

```bash
aws iot set-v2-logging-options 
    [--role-arn <value>] 
    [--default-log-level <value>] 
    [--disable-all-logs | --no-disable-all-logs] 
    [--cli-input-json <value>] 
    [--generate-cli-skeleton]
```

**cli-input-json format:**

```json
{
  "roleArn": "string",
  "defaultLogLevel": "string",
  "disableAllLogs": "boolean"
}
```

**cli-input-json fields:**

<table>
<thead>

StartThingRegistrationTask

Creates a bulk thing provisioning task.

Request syntax:

```
POST /thing-registration-tasks
Content-type: application/json
{
  "templateBody": "string",
  "inputFileBucket": "string",
  "inputFileKey": "string",
  "roleArn": "string"
}
```

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>templateBody</td>
<td>TemplateBody</td>
<td>yes</td>
<td>The provisioning template.</td>
</tr>
<tr>
<td>inputFileBucket</td>
<td>RegistryS3BucketName</td>
<td>yes</td>
<td>The S3 bucket that contains the input file.</td>
</tr>
<tr>
<td>inputFileKey</td>
<td>RegistryS3KeyName</td>
<td>yes</td>
<td>The name of input file within the S3 bucket. This file contains a newline delimited JSON file. Each line contains the parameter values to provision one device (thing).</td>
</tr>
<tr>
<td>roleArn</td>
<td>RoleArn</td>
<td>yes</td>
<td>The IAM role ARN that grants permission the input file.</td>
</tr>
</tbody>
</table>

Response syntax:
Content-type: application/json
{
  "taskId": "string"
}

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>taskId</td>
<td>TaskId</td>
<td>no</td>
<td>The bulk thing provisioning task ID.</td>
</tr>
</tbody>
</table>

Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

LimitExceededException

The number of attached entities exceeds the limit.

HTTP response code: 410

CLI

Synopsis:

```
aws iot test-authorization \
  [--principal <value>] \ 
  [--cognito-identity-pool-id <value>] \ 
  --auth-infos <value> \ 
  [--client-id <value>] \ 
  [--policy-names-to-add <value>] \ 
  [--policy-names-to-skip <value>] \ 
  [--cli-input-json <value>] \
```
cli-input-json format:

```json
{
    "principal": "string",
    "cognitoIdentityPoolId": "string",
    "authInfos": [
        {
            "actionType": "string",
            "resources": [
                "string"
            ]
        }
    ],
    "clientId": "string",
    "policyNamesToAdd": [
        "string"
    ],
    "policyNamesToSkip": [
        "string"
    ]
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>principal</td>
<td>string</td>
<td>The principal.</td>
</tr>
<tr>
<td>cognitoIdentityPoolId</td>
<td>string</td>
<td>The Cognito identity pool ID.</td>
</tr>
<tr>
<td>authInfos</td>
<td>list</td>
<td>A list of authorization info objects. Simulating authorization will create a response for each authInfo object in the list.</td>

</table>
## TestInvokeAuthorizer

Invoke the specified custom authorizer for testing purposes.

### Request syntax:

```bash
POST /authorizer/authorizerName/test
Content-type: application/json

{
```
"token": "string",
"tokenSignature": "string"
}

**URI Request Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizerName</td>
<td>AuthorizerName</td>
<td>yes</td>
<td>The custom authorizer name.</td>
</tr>
</tbody>
</table>

**Request Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>token</td>
<td>Token</td>
<td>yes</td>
<td>The token returned by your custom authentication service.</td>
</tr>
<tr>
<td>tokenSignature</td>
<td>TokenSignature</td>
<td>yes</td>
<td>The signature made with the token and your custom authentication service's private key.</td>
</tr>
</tbody>
</table>

**Response syntax:**

```json
Content-type: application/json
{
  "isAuthenticated": "boolean",
  "principalId": "string",
  "policyDocuments": [
    "string"
  ],
  "refreshAfterInSeconds": "integer",
  "disconnectAfterInSeconds": "integer"
}
```

**Response Body Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isAuthenticated</td>
<td>IsAuthenticated</td>
<td>no</td>
<td>True if the token is authenticated, otherwise false.</td>
</tr>
<tr>
<td>principalId</td>
<td>PrincipalId</td>
<td>no</td>
<td>The principal ID.</td>
</tr>
<tr>
<td>policyDocuments</td>
<td>PolicyDocuments</td>
<td>no</td>
<td>IAM policy documents.</td>
</tr>
<tr>
<td>refreshAfterInSeconds</td>
<td>Seconds</td>
<td>no</td>
<td>The number of seconds after which the temporary credentials are refreshed.</td>
</tr>
<tr>
<td>disconnectAfterInSeconds</td>
<td>Seconds</td>
<td>no</td>
<td>The number of seconds after which</td>
</tr>
</tbody>
</table>
### Errors:

**ResourceNotFoundException**

The specified resource does not exist.

HTTP response code: 404

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**UnauthorizedException**

You are not authorized to perform this operation.

HTTP response code: 401

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

**InternalFailureException**

An unexpected error has occurred.

HTTP response code: 500

**InvalidResponseException**

The response is invalid.

HTTP response code: 400

### CLI

**Synopsis:**

```bash
aws iot test-invoke-authorizer \

</tbody>
</table>
TransferCertificate

Transfers the specified certificate to the specified AWS account.

You can cancel the transfer until it is acknowledged by the recipient.

No notification is sent to the transfer destination's account. It is up to the caller to notify the transfer target.

The certificate being transferred must not be in the ACTIVE state. You can use the UpdateCertificate API to deactivate it.

The certificate must not have any policies attached to it. You can use the DetachPrincipalPolicy API to detach them.

Request syntax:

PATCH /transfer-certificate/certificateId?targetAwsAccount=targetAwsAccount
Content-type: application/json

{   "transferMessage": "string"
}

URI Request Parameters:

Name | Type | Req? | Description
--- | --- | --- | ---
certificateId | CertificateId | yes | The ID of the certificate.
targetAwsAccount | AwsAccountId | yes | The AWS account.

Request Body Parameters:

Name | Type | Req? | Description
--- | --- | --- | ---
transferMessage | Message | no | The transfer message.

Response syntax:

Content-type: application/json

{   "transferredCertificateArn": "string"}
Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transferredCertificateArn</td>
<td>CertificateArn</td>
<td>no</td>
<td>The ARN of the certificate.</td>
</tr>
</tbody>
</table>

Errors:

InvalidRequestException

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

ResourceNotFoundException

The specified resource does not exist.

HTTP response code: 404

CertificateStateException

The certificate operation is not allowed.

HTTP response code: 406

TransferConflictException

You can't transfer the certificate because authorization policies are still attached.

HTTP response code: 409

ThrottlingException

The rate exceeds the limit.

HTTP response code: 429

UnauthorizedException

You are not authorized to perform this operation.

HTTP response code: 401

ServiceUnavailableException

The service is temporarily unavailable.

HTTP response code: 503

InternalFailureException

An unexpected error has occurred.

HTTP response code: 500

CLI

Synopsis:
aws iot transfer-certificate
  --certificate-id <value> \
  --target-aws-account <value> \
  [--transfer-message <value>] \
  [--cli-input-json <value>] \

An unexpected error has occurred.
HTTP response code: 500

CLI

Synopsis:

```
aws iot update-ca-certificate \
  --certificate-id <value> \
  [--new-status <value>] \
  [--new-auto-registration-status <value>] \
  [--registration-config <value>] \
  [--remove-auto-registration | --no-remove-auto-registration] \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]
```

cli-input-json format:

```
{
  "certificateId": "string",
  "newStatus": "string",
  "newAutoRegistrationStatus": "string",
  "registrationConfig": {
    "templateBody": "string",
    "roleArn": "string"
  }
}
```
### UpdateCertificate

Updates the status of the specified certificate. This operation is idempotent.

Moving a certificate from the ACTIVE state (including REVOKE) will not disconnect currently connected devices, but these devices will be unable to reconnect.

The ACTIVE state is required to authenticate devices connecting to AWS IoT using a certificate.

**Request syntax:**

```
PUT /certificates/certificateId?newStatus=newStatus
```
URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>certificateId</td>
<td>CertificateId</td>
<td>yes</td>
<td>The ID of the certificate.</td>
</tr>
<tr>
<td>newStatus</td>
<td>CertificateStatus</td>
<td>yes</td>
<td>The new status.</td>
</tr>
</tbody>
</table>

**Note:** Setting the status to PENDING_TRANSFER will result in an exception being thrown. PENDING_TRANSFER is a status used internally by AWS IoT. It is not intended for developer use.

**Note:** The status value REGISTER_INACTIVE is deprecated and should not be used.

Errors:

- **ResourceNotFoundException**
  - The specified resource does not exist.
  - HTTP response code: 404

- **CertificateStateException**
  - The certificate operation is not allowed.
  - HTTP response code: 406

- **InvalidRequestException**
  - The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
  - HTTP response code: 400

- **ThrottlingException**
  - The rate exceeds the limit.
  - HTTP response code: 429

- **UnauthorizedException**
  - You are not authorized to perform this operation.
  - HTTP response code: 401

- **ServiceUnavailableException**
  - The service is temporarily unavailable.
  - HTTP response code: 503
**InternalFailureException**

An unexpected error has occurred.

HTTP response code: 500

**CLI**

**Synopsis:**

```
aws iot update-certificate \
   --certificate-id <value> \
   --new-status <value> \
   [--cli-input-json <value>] \
   [--generate-cli-skeleton]
```

**cli-input-json format:**

```json
{
   "certificateId": "string",
   "newStatus": "string"
}
```

**cli-input-json fields:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>

</tr>
</tbody>
</table>

**Note:** Setting the status to PENDING_TRANSFER will result in an exception being thrown. PENDING_TRANSFER is a status used internally by AWS IoT. It is not intended for developer use.

**Note:** The status value REGISTER_INACTIVE is deprecated and should not be used.

**Output:**

None

**UpdateEventConfigurations**

Updates the event configurations.
Request syntax:

```patch
PATCH /event-configurations
Content-type: application/json

{
    "eventConfigurations": {
        "string": {
            "Enabled": "boolean"
        }
    }
}
```

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventConfigurations</td>
<td>EventConfigurations</td>
<td>no</td>
<td>The new event configuration values.</td>
</tr>
</tbody>
</table>

Errors:

AWS IoT Developer Guide

UpdateJobExecution

Updates the status of a job execution.

Request syntax:

POST /things/thingName/jobs/jobId
Content-type: application/json

{  
  "status": "string",
  "statusDetails": {
    "string": "string"
  },
  "expectedVersion": "long",
  "includeJobExecutionState": "boolean",
  "includeJobDocument": "boolean",
  "executionNumber": "long"
}

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>JobId</td>
<td>yes</td>
<td>The unique identifier assigned to this job when it was created.</td>
</tr>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing associated with the device.</td>
</tr>
</tbody>
</table>

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>JobExecutionStatus</td>
<td>yes</td>
<td>The new status for the job execution (IN_PROGRESS, FAILED, SUCCESS, or REJECTED). This must be specified on every update.</td>
</tr>
<tr>
<td>statusDetails</td>
<td>DetailsMap</td>
<td>no</td>
<td>Optional. A collection of name/value pairs</td>
</tr>
</tbody>
</table>
### UpdateJobExecution

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expectedVersion</td>
<td>ExpectedVersion</td>
<td>no</td>
<td>Optional. The expected current version of the job execution. Each time you update the job execution, its version is incremented. If the version of the job execution stored in Jobs does not match, the update is rejected with a VersionMismatch error, and an ErrorResponse that contains the current job execution status data is returned. (This makes it unnecessary to perform a separate DescribeJobExecution request in order to obtain the job execution status data.)</td>
</tr>
<tr>
<td>includeJobExecutionState</td>
<td>IncludeExecutionState</td>
<td>no</td>
<td>Optional. When included and set to true, the response contains the JobExecutionState data. The default is false.</td>
</tr>
<tr>
<td>includeJobDocument</td>
<td>IncludeJobDocument</td>
<td>no</td>
<td>Optional. When set to true, the response contains the job document. The default is false.</td>
</tr>
<tr>
<td>executionNumber</td>
<td>ExecutionNumber</td>
<td>no</td>
<td>Optional. A number that identifies a particular job execution on a particular device.</td>
</tr>
</tbody>
</table>

### Response syntax:

```json
Content-type: application/json

{
  "executionState": {
    "status": "string",
    "statusDetails": {
```

699
"string": "string",
"versionNumber": "long",
"jobDocument": "string"}

### Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>executionState</td>
<td>JobExecutionState</td>
<td>no</td>
<td>A JobExecutionState object.</td>
</tr>
<tr>
<td>jobDocument</td>
<td>JobDocument</td>
<td>no</td>
<td>The contents of the Job Documents.</td>
</tr>
</tbody>
</table>

### Errors:

**InvalidRequestException**

The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.

HTTP response code: 400

**ResourceNotFoundException**

The specified resource does not exist.

HTTP response code: 404

**ThrottlingException**

The rate exceeds the limit.

HTTP response code: 429

**ServiceUnavailableException**

The service is temporarily unavailable.

HTTP response code: 503

**CertificateValidationException**

The certificate is invalid.

HTTP response code: 400

**InvalidStateTransitionException**

An update attempted to change the job execution to a state that is invalid because of the job execution's current state (for example, an attempt to change a request in state SUCCESS to state IN_PROGRESS). In this case, the body of the error message also contains the executionState field.

HTTP response code: 409

### CLI

#### Synopsis:
aws iot update-job-execution \
  --job-id <value> \
  --thing-name <value> \
  --status <value> \
  [--status-details <value>] \
  [--expected-version <value>] \
  [--include-job-execution-state | --no-include-job-execution-state] \
  [--include-job-document | --no-include-job-document] \
  [--execution-number <value>] \
  [--cli-input-json <value>] \
  [--generate-cli-skeleton]

cli-input-json format:

{
  "jobId": "string",
  "thingName": "string",
  "status": "string",
  "statusDetails": {
    "string": "string"
  },
  "expectedVersion": "long",
  "includeJobExecutionState": "boolean",
  "includeJobDocument": "boolean",
  "executionNumber": "long"
}

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobId</td>
<td>string</td>
<td>The unique identifier assigned to this job when it was created.</td>

</tbody>
</table>
### Name | Type | Description
---|---|---
DetailsValue | string | length max:1024 min:1
pattern: [^\p{C}]*+ | 
expectedVersion | long | java class: java.lang.Long
Optional. The expected current version of the job execution. Each time you update the job execution, its version is incremented. If the version of the job execution stored in Jobs does not match, the update is rejected with a VersionMismatch error, and an ErrorResponse that contains the current job execution status data is returned. (This makes it unnecessary to perform a separate DescribeJobExecution request in order to obtain the job execution status data.)
includeJobExecutionState | boolean | java class: java.lang.Boolean
Optional. When included and set to true, the response contains the JobExecutionState data. The default is false.
includeJobDocument | boolean | java class: java.lang.Boolean
Optional. When set to true, the response contains the job document. The default is false.
executionNumber | long | java class: java.lang.Long
Optional. A number that identifies a particular job execution on a particular device.

**Output:**

```json
{
  "executionState": {
    "status": "string",
    "statusDetails": {
      "string": "string"
    },
    "versionNumber": "long"
  },

UpdateThingShadow

Updates the thing shadow for the specified thing.

For more information, see UpdateThingShadow in the AWS IoT Developer Guide.

Request syntax:

POST /things/{thingName}/shadow
Content-type: application/json

{
  "payload": "blob"
}

URI Request Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>ThingName</td>
<td>yes</td>
<td>The name of the thing.</td>
</tr>
</tbody>
</table>

Request Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>JsonDocument</td>
<td>yes</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

Response syntax:

Content-type: application/json
{  
  "payload": "blob"
}

Response Body Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Req?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>JsonDocument</td>
<td>no</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

Errors:

ConflictException
The specified version does not match the version of the document.
HTTP response code: 409

RequestEntityTooLargeException
The payload exceeds the maximum size allowed.
HTTP response code: 413

InvalidRequestException
The contents of the request were invalid. For example, this code is returned when an UpdateJobExecution request contains invalid status details. The message contains details about the error.
HTTP response code: 400

ThrottlingException
The rate exceeds the limit.
HTTP response code: 429

UnauthorizedException
You are not authorized to perform this operation.
HTTP response code: 401

ServiceUnavailableException
The service is temporarily unavailable.
HTTP response code: 503

InternalFailureException
An unexpected error has occurred.
HTTP response code: 500

MethodNotAllowedException
The specified combination of HTTP verb and URI is not supported.
HTTP response code: 405

UnsupportedDocumentEncodingException
The encoding is not supported.
CLI

Synopsis:

```
aws iot-data update-thing-shadow
   --thing-name <value> \
   --payload <value> \
   [--cli-input-json <value>] \n   [--generate-cli-skeleton]
```

cli-input-json format:

```json
{
   "thingName": "string",
   "payload": "blob"
}
```

cli-input-json fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thingName</td>
<td>string</td>
<td>The name of the thing.</td>
</tr>
<tr>
<td></td>
<td>length max:128 min:1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>pattern: [a-zA-Z0-9:_-]+</td>
<td></td>
</tr>
<tr>
<td>payload</td>
<td>blob</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>

Output:

```json
{
   "payload": "blob"
}
```

cli output fields:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>blob</td>
<td>The state information, in JSON format.</td>
</tr>
</tbody>
</table>
