What Is Amazon Lex?

Amazon Lex is an AWS service for building conversational interfaces for any applications using voice and text. With Amazon Lex, the same conversational engine that powers Amazon Alexa is now available to any developer, enabling you to build sophisticated, natural language chatbots into your new and existing applications. Amazon Lex provides the deep functionality and flexibility of natural language understanding (NLU) and automatic speech recognition (ASR) so you can build highly engaging user experiences with lifelike, conversational interactions, and create new categories of products.

Amazon Lex enables any developer to build conversational chatbots quickly. With Amazon Lex, no deep learning expertise is necessary—to create a bot, you just specify the basic conversation flow in the Amazon Lex console. Amazon Lex manages the dialogue and dynamically adjusts the responses in the conversation. Using the console, you can build, test, and publish your text or voice chatbot. You can then add the conversational interfaces to bots on mobile devices, web applications, and chat platforms (for example, Facebook Messenger).

Amazon Lex provides pre-built integration with AWS Lambda, and you can easily integrate with many other services on the AWS platform, including Amazon Cognito, AWS Mobile Hub, Amazon CloudWatch, and Amazon DynamoDB. Integration with Lambda provides bots access to pre-built serverless enterprise connectors to link to data in SaaS applications, such as Salesforce, HubSpot, or Marketo.

Some of the benefits of using Amazon Lex include:

- **Simplicity** – Amazon Lex guides you through using the console to create your own chatbot in minutes. You supply just a few example phrases, and Amazon Lex builds a complete natural language model through which the bot can interact using voice and text to ask questions, get answers, and complete sophisticated tasks.

- **Democratized deep learning technologies** – Powered by the same technology as Alexa, Amazon Lex provides ASR and NLU technologies to create a Speech Language Understanding (SLU) system. Through SLU, Amazon Lex takes natural language speech and text input, understands the intent behind the input, and fulfills the user intent by invoking the appropriate business function.

Speech recognition and natural language understanding are some of the most challenging problems to solve in computer science, requiring sophisticated deep learning algorithms to be trained on massive amounts of data and infrastructure. Amazon Lex puts deep learning technologies within reach of all developers, powered by the same technology as Alexa. Amazon Lex chatbots convert incoming speech to text and understand the user intent to generate an intelligent response, so you can focus on building your bots with differentiated value-add for your customers, to define entirely new categories of products made possible through conversational interfaces.

- **Seamless deployment and scaling** – With Amazon Lex, you can build, test, and deploy your chatbots directly from the Amazon Lex console. Amazon Lex enables you to easily publish your voice or text chatbots for use on mobile devices, web apps, and chat services (for example, Facebook Messenger). Amazon Lex scales automatically so you don’t need to worry about provisioning hardware and managing infrastructure to power your bot experience.

- **Built-in integration with the AWS platform** – Amazon Lex has native interoperability with other AWS services, such as Amazon Cognito, AWS Lambda, Amazon CloudWatch, and AWS Mobile Hub. You
can take advantage of the power of the AWS platform for security, monitoring, user authentication, business logic, storage, and mobile app development.

- **Cost-effectiveness** – With Amazon Lex, there are no upfront costs or minimum fees. You are charged only for the text or speech requests that are made. The pay-as-you-go pricing and the low cost per request make the service a cost-effective way to build conversational interfaces. With the Amazon Lex free tier, you can easily try Amazon Lex without any initial investment.

### Are You a First-time User of Amazon Lex?

If you are a first-time user of Amazon Lex, we recommend that you read the following sections in order:

1. **Getting Started with Amazon Lex (p. 28)** – In this section, you set up your account and test Amazon Lex.
2. **API Reference (p. 194)** – This section provides additional examples that you can use to explore Amazon Lex.
Amazon Lex: How It Works

Amazon Lex enables you to build applications using a speech or text interface powered by the same technology that powers Amazon Alexa. Following are the typical steps you perform when working with Amazon Lex:

1. Create a bot and configure it with one or more intents that you want to support. You add the configuration so that the bot is able to understand the user's goal (intent), engage in conversation with the user to elicit information, and, after the user provides the necessary data, fulfill the user's intent.

2. Test the bot. You can use the test window client provided by the Amazon Lex console.

3. Publish a version and create an alias.

4. Deploy the bot. You can deploy the bot on platforms such as mobile applications or messaging platforms such as Facebook Messenger.

Before you get started, familiarize yourself with the following Amazon Lex core concepts and terminology:

- **Bot** – A bot performs automated tasks such as ordering a pizza, booking a hotel, ordering flowers, and so on. An Amazon Lex bot is powered by Automatic Speech Recognition (ASR) and Natural Language Understanding (NLU) capabilities, the same technology that powers Amazon Alexa.

- **Intent** – An intent represents an action that the user wants to perform. You create a bot to support one or more related intents. For example, you might create a bot that orders pizza and drinks. For each intent, you provide the following required information:
  - **Intent name**– A descriptive name for the intent. For example, OrderPizza.
  - **Sample utterances** – How a user might convey the intent. For example, a user might say "Can I order a pizza please" or "I want to order a pizza".
  - **How to fulfill the intent** – How you want to fulfill the intent after the user provides the necessary information (for example, place order with a local pizza shop). We recommend that you create a Lambda function to fulfill the intent.

You can optionally configure the intent so Amazon Lex simply returns the information back to the client application to do the necessary fulfillment.

In addition to custom intents such as ordering a pizza, Amazon Lex also provides built-in intents to quickly set up your bot. For more information, see Built-in Intents and Slot Types (p. 22).
• **Slot** – An intent can require zero or more slots or parameters. You add slots as part of the intent configuration. At runtime, Amazon Lex prompts the user for specific slot values. The user must provide values for all *required* slots before Amazon Lex can fulfill the intent.

For example, the `OrderPizza` intent requires slots such as pizza size, crust type, and number of pizzas. In the intent configuration, you add these slots. For each slot, you provide slot type and a prompt for Amazon Lex to send to the client to elicit data from the user. A user can reply with a slot value that includes additional words, such as "large pizza please" or "let's stick with small." Amazon Lex can still understand the intended slot value.

• **Slot type** – Each slot has a type. You can create your custom slot types or use built-in slot types. For example, you might create and use the following slot types for the `OrderPizza` intent:

  • **Size** – With enumeration values *Small*, *Medium*, and *Large*.
  • **Crust** – With enumeration values *Thick* and *Thin*.

Amazon Lex also provides built-in slot types. For example, `AMAZON.NUMBER` is a built-in slot type that you can use for the number of pizzas ordered. For more information, see *Built-in Intents and Slot Types* (p. 22).

The following topics provide additional information. We recommend that you review them in order and then explore the *Getting Started with Amazon Lex* (p. 28) exercises.

**Topics**

- **Programming Model** (p. 4)
- **Service Permissions** (p. 8)
- **Managing Messages (Prompts and Statements)** (p. 8)
- **Managing Conversation Context** (p. 17)
- **Bot Deployment Options** (p. 21)
- **Built-in Intents and Slot Types** (p. 22)
- **Custom Slot Types** (p. 26)

**Programming Model**

A bot is the primary resource type in Amazon Lex. The other resource types in Amazon Lex are *intent*, *slot type*, *alias*, and *bot channel association*.

You create a bot using the Amazon Lex console or the model building API. The console provides a graphical user interface that you use to build a production-ready bot for your application. If you prefer, you can use the model building API through the AWS CLI or your own custom program to create a bot.

After you create a bot, you deploy it on one of the supported platforms or integrate it into your own application. When a user interacts with the bot, the client application sends requests to the bot using the Amazon Lex runtime API. For example, when a user says "I want to order pizza," your client sends
the user input to Amazon Lex using one of the runtime API operations. Users can provide speech or text input.

You can also create Lambda functions and use them in an intent. Use these Lambda function code hooks to perform runtime activities such as initialization, validation of user input, and intent fulfillment. The following sections provide additional information.

Topics
- Model Building API Operations (p. 5)
- Runtime API Operations (p. 6)
- Lambda Functions as Code Hooks (p. 6)

Model Building API Operations

To programmatically create bots, intents, and slot types, use the model building API operations. You can also use the model building API to manage, update, and delete resources for your bot. The model building API operations include:

- **PutBot** (p. 285), **PutBotAlias** (p. 293), **PutIntent** (p. 297), and **PutSlotType** (p. 307) to create and update bots, bot aliases, intents, and slot types, respectively.
- **CreateBotVersion** (p. 197), **CreateIntentVersion** (p. 202), and **CreateSlotTypeVersion** (p. 208) to create and publish versions of your bots, intents, and slot types, respectively.
- **GetBot** (p. 230) and **GetBots** (p. 247) to get a specific bot or a list of bots that you have created, respectively.
- **GetIntent** (p. 262) and **GetIntents** (p. 267) to get a specific intent or a list of intents that you have created, respectively.
- **GetSlotType** (p. 273) and **GetSlotTypes** (p. 276) to get a specific slot type or a list of slot types that you have created, respectively.
- **GetBuiltinIntent** (p. 253), **GetBuiltinIntents** (p. 255), and **GetBuiltinSlotTypes** (p. 257) to get an Amazon Lex built-in intent, a list of Amazon Lex built-in intents, or a list of built-in slot types that you can use in your bot, respectively.
- **GetBotChannelAssociation** (p. 241) and **GetBotChannelAssociations** (p. 244) to get an association between your bot and a messaging platform or a list of the associations between your bot and messaging platforms, respectively.
- **DeleteBot** (p. 212), **DeleteBotAlias** (p. 214), **DeleteBotChannelAssociation** (p. 216), **DeleteIntent** (p. 220), and **DeleteSlotType** (p. 224) to remove unneeded resources in your account.

You can use the model building API to create custom tools to manage your Amazon Lex resources. For example, there is a limit of 100 versions each for bots, intents, and slot types. You could use the model building API to build a tool that automatically deletes old versions when your bot nears the limit.

To make sure that only one operation updates a resource at a time, Amazon Lex uses checksums. When you use a **Put** API operation—**PutBot** (p. 285), **PutBotAlias** (p. 293) **PutIntent** (p. 297), or **PutSlotType** (p. 307)—to update a resource, you must pass the current checksum of the resource in the request. If two tools try to update a resource at the same time, they both provide the same current checksum. The first request to reach Amazon Lex matches the current checksum of the resource. By the time that the second request arrives, the checksum is different. The second tool receives a **PreconditionFailedException** exception and the update terminates.

The **Get** operations—**GetBot** (p. 230), **GetIntent** (p. 262), and **GetSlotType** (p. 273)—are eventually consistent. If you use a **Get** operation immediately after you create or modify a resource with one of the **Put** operations, the changes might not be returned. After a **Get** operation returns the most recent...
update, it always returns that updated resource until the resource is modified again. You can determine if an updated resource has been returned by looking at the checksum.

Runtime API Operations

Client applications use the following runtime API operations to communicate with Amazon Lex:

- **PostContent (p. 312)** – Takes speech or text input and returns intent information and a text or speech message to convey to the user. Currently, Amazon Lex supports the following audio formats:

  **Input audio formats** – LPCM and Opus

  **Output audio formats** – MPEG, OGG, and PCM

  The `PostContent` operation supports audio input at 8kHz and 16kHz. Applications where the end user speaks with Amazon Lex over the telephone, such as an automated call center, can pass 8kHz audio directly.

- **PostText (p. 320)** – Takes text as input and returns intent information and a text message to convey to the user.

Your client application uses the runtime API to call a specific Amazon Lex bot to process utterances — user text or voice input. For example, suppose that a user says “I want pizza.” The client sends this user input to a bot using one of the Amazon Lex runtime API operations. From the user input, Amazon Lex recognizes that the user request is for the `OrderPizza` intent defined in the bot. Amazon Lex engages the user in a conversation to gather the required information, or slot data, such as pizza size, toppings, and number of pizzas. After the user provides all of the necessary slot data, Amazon Lex either invokes the Lambda function code hook to fulfill the intent, or returns the intent data to the client, according to the intent configuration.

Use the `PostContent (p. 312)` operation when your bot uses speech input. For example, an automated call center application can send speech to a Amazon Lex bot to address customer enquiries without needing to talk to an agent. You can use the 8kHz audio format to send audio directly from the telephone to Amazon Lex.

The test window in the Amazon Lex console uses the `PostContent (p. 312)` API to send text and speech requests to Amazon Lex. You use this test window in the *Getting Started with Amazon Lex (p. 28)* exercises.

Lambda Functions as Code Hooks

You can configure your Amazon Lex bot to invoke a Lambda function as a code hook. The code hook can serve multiple purposes:

- **Customize user interaction** – For example, when Joe asks for available pizza toppings, you can use prior knowledge of Joe’s choices to display a subset of toppings.

- **Validate the user’s input** – Suppose that Jen wants to pick up flowers after hours. You can validate the time that Jen input and send an appropriate response.

- **Fulfill the user’s intent** – After Joe provides all of the information for his pizza order, Amazon Lex can invoke a Lambda function to place the order with a local pizzeria.
When you configure an intent, you specify Lambda functions as code hooks in the following places:

- Dialog code hook for initialization and validation – This Lambda function is invoked on each user input, assuming Amazon Lex understood the user intent.
- Fulfillment code hook – This Lambda function is invoked after the user provides all of the slot data required to fulfill the intent.

You choose the intent and set the code hooks in the Amazon Lex console, as shown in the following screen shot:

You can also set the code hooks using the `dialogCodeHook` and `fulfillmentActivity` fields in the `PutIntent` operation.

One Lambda function can do initialization, validation, and fulfillment. The event data that the Lambda function receives has a field that identifies the caller as either a dialog or fulfillment code hook. You can use this information to execute the appropriate portion of your code.

You can use a Lambda function to build a bot that can navigate complex dialogs. You use the `dialogAction` field in the Lambda function response to direct Amazon Lex to take specific actions. For example, you can use the `ElicitSlot` dialog action to tell Amazon Lex to ask the user for a slot value that isn't required. You can use the `ElicitIntent` dialog action to elicit a new intent when the user is finished with the previous one.
Service Permissions

Amazon Lex uses AWS Identity and Access Management (IAM) service-linked roles. Amazon Lex assumes these roles to call AWS services on behalf of your bots and bot channels. The roles exist within your account, but are linked to Amazon Lex use cases and have predefined permissions. Only Amazon Lex can assume these roles, and you can't modify their permissions. You can delete them after deleting their related resources using IAM. This protects your Amazon Lex resources because you can't inadvertently remove necessary permissions.

Amazon Lex uses two IAM service-linked roles:

- **AWSServiceRoleForLexBots** — Amazon Lex uses this service-linked role to invoke Amazon Polly to synthesize speech responses for your bot.
- **AWSServiceRoleForLexChannels** — Amazon Lex uses this service-linked role to post text to your bot when managing channels.

You don't need to manually create either of these roles. When you create your first bot using the console, Amazon Lex creates the **AWSServiceRoleForLexBots** role for you. When you first associate a bot with a messaging channel, Amazon Lex creates the **AWSServiceRoleForLexChannels** role for you.

Creating Resource-Based Policies for AWS Lambda

When invoking Lambda functions, Amazon Lex uses resource-based policies. A resource-based policy is attached to a resource; it lets you specify who has access to the resource and which actions they can perform on it. This enables you to narrowly scope permissions between Lambda functions and the intents that you have created. It also allows you to see those permissions in a single policy when you manage Lambda functions that have many event sources.

For more information, see Using Resource-Based Polices for AWS Lambda (Lambda Function Policies) in the AWS Lambda Developer Guide.

To create resource-based policies for intents that you associate with a Lambda function, you can use the Amazon Lex console. Or, you can use the AWS command line interface (AWS CLI). In the AWS CLI, use the Lambda AddPermission API with the Principal field set to lex.amazonaws.com and the SourceArn set to the ARN of the intent that is allowed to invoke the function.

Deleting Service-Linked Roles

You can use the IAM console, the IAM CLI, or the IAM API to delete the **AWSServiceRoleForLexBots** and **AWSServiceRoleForLexChannels** service-linked roles. For more information, see Deleting a Service-Linked Role in the IAM User Guide.
You configure messages that you want a bot to send when you create the bot. Consider the following examples:

- You can configure your bot with the following clarification prompt:

  I don't understand. What would you like to do?

  Amazon Lex sends this message to the client if it doesn't understand the user's intent.

- Suppose that you create a bot to support an intent called OrderPizza. For a pizza order, you want users to provide information such as pizza size, toppings, and crust type. For example, you can configure prompts such as the following:

  What size pizza you want?
  What toppings you want on the pizza?
  Do you want thick or thin crust?

  After Amazon Lex determines the user's intent to order pizza, it sends these messages to the client to elicit data from the user.

This section explains designing user interactions in your bot configuration.

**Types of Messages**

You can classify messages as follows:

- Prompt – A prompt expects a user response, typically a question.
- Statement – A statement does not expect a response.

The messages you configure can have dynamic components:

- Messages can use the following syntax to refer to slot values of the intent that Amazon Lex is currently aware of:

  `{SlotName}`

- Messages can use the following syntax to refer to session attributes:

  `[AttributeName]`

You can have messages that include both slots and session attributes.

At runtime, Amazon Lex substitutes these references with actual values. For example, suppose that you configure the following message in the OrderPizza intent of your bot:

"Hey [FirstName], your {PizzaTopping} pizza will arrive in [DeliveryTime] minutes"
This message refers to both slot (PizzaTopping) and session attributes (FirstName and DeliveryTime). At runtime, Amazon Lex replaces these placeholders with values and returns the following message to the client:

"Hey John, your cheese pizza will arrive in 30 minutes"

For information about session attributes, see the runtime API operations PostText (p. 320), and PostContent (p. 312). For an example, see Example Bot: BookTrip (p. 140).

If you add code hooks using Lambda functions in your intent configuration, you can create messages dynamically. Lambda functions can generate messages and return them to Amazon Lex to send to the user. By providing the messages while configuring your bot, you can eliminate the need to construct a prompt in code hooks.

**Contexts for Configuring Messages**

You can add messages in the following contexts. Use the Amazon Lex console or build-time API to configure your bot:

- **Bot-level messages** – You can configure your bot with clarification prompts and hang-up messages. At runtime, Amazon Lex uses the clarification prompts if it does not understand the user's intent. You can also configure the number of times that Amazon Lex requests clarification before hanging up with a hang-up message. You configure these bot-level messages with the PutBot (p. 285) operation, or in the **Error Handling** section in the Amazon Lex console, as shown in the following screen shot:

  ![Amazon Lex Console](image)

  **Note**
  - If you have a Lambda function configured as a code hook for an intent, the Lambda function might return a response directing Amazon Lex to elicit user intent. If the Lambda function does not provide a message to convey to the user, then Amazon Lex uses the clarification prompt you configured.

  - Amazon Lex uses the hang-up statement whenever the user doesn't respond with an appropriate answer for a prompt within the maximum permissible attempts. This includes responses to intent elicitations, slot elicitations, follow-up prompts, and intent confirmations. To configure the maximum permissible attempts, use the PutBot (p. 285) operation, or, in the console, specify it in the **Error Handling** section.
• Intent-level messages – You can configure the intent-level messages such as confirmation prompts, cancel statements, goodbye message, and prompts that Amazon Lex can use to elicit slot values, as shown in the following screenshot:

![Image of Amazon Lex UI](image)

• Confirmation prompts and cancel statements – After a user provides all of the required data, Amazon Lex asks the user for confirmation using the specified message before fulfilling the intent. If the user replies "No" to a confirmation prompt, Amazon Lex returns the cancel statement to the client.

• Goodbye message or follow-up prompts – If you add a Lambda function as a code hook to fulfill the intent, you can configure one of these messages as backup messages. If the Lambda function succeeds but does not provide a message to send to the user, Amazon Lex sends the message that you configured.

• The following is an example of a goodbye message. The example assumes that the application maintains the DeliveryTime session attribute.

"I have placed your order for pizza. It will arrive in [DeliveryTime] minutes."

• The following is an example of a follow-up prompt:
"I have placed your order for pizza. Do you want me to do anything else?".

If you configure a follow-up prompt, you must also configure a cancel statement. If the user's reply to a follow-up prompt is a "Yes," Amazon Lex recognizes the user's confirmation and also recognizes the user's intent (OrderDrink), and then follows up accordingly. For example:

"Yes, I also want to order a drink."

If the user says "No," Amazon Lex sends the cancel statement. For example:

"Alright. Let me know if you need anything else."

- Prompts to elicit value slot values – You must specify at least one prompt message for each of the required slots in an intent. At runtime, Amazon Lex uses one of these messages to prompt the user to provide value for this slot. For example, for a cityName slot, the following is a valid prompt:

"Which city would you like to fly to?"

**Note**
In a Lambda function that is a code hook for an intent, you can override any of the messages that you configured at build time.

You can configure more than one message for a specific context. At runtime, Amazon Lex picks the message with the maximum possible substitutions. For example, to elicit a value for crust type in the OrderPizza intent, you can configure multiple messages, as follows:

Hey [FirstName], what topping would you like for your {PizzaSize} pizza?
Hey [FirstName], what topping would you like for your pizza?
What topping would you like?
Tell me the topping you would like on your pizza.

Then, Amazon Lex uses the following order of selection:

- If both the FirstName session attribute and the PizzaSize slot value are available, Amazon Lex uses the first prompt.
- If the FirstName session attribute is available, but the PizzaSize slot value isn't, Amazon Lex uses the second prompt.
- If both the session attribute and the slot value aren't available, Amazon Lex randomly chooses the third or fourth prompt.

At runtime, Amazon Lex disregards messages with references to unresolved slot values. If all of the messages for a given context have unresolved references, Amazon Lex throws a BadRequestException error. We recommend that you have at least one message without references.

**Supported Message Formats**

Amazon Lex supports messages in the following formats: plain text and Speech Synthesis Markup Language (SSML).

If the output mode is text, such as when a client sends requests using the PostText API operation or the PostContent API operation with the Accept HTTP header set to text/plain; charset=utf-8, Amazon Lex selects only plain text messages. It disregards SSML messages.
Note

- If you configure your bot with only SSML messages and a text client communicates with your bot, Amazon Lex returns a BadRequestException error. We recommend that you provide at least one PlainText message for each context.
- If outputDialogMode in the incoming event is text, you must return a PlainText message from your AWS Lambda function. For more information, see Lambda Function Input Event and Response Format (p. 98).

Amazon Lex also supports synthesizing audio from SSML. For more information, see Using SSML in the Amazon Polly Developer Guide.

Response Cards

Use response cards to simplify interactions for your users and increase your bot's accuracy by reducing typographical errors in text interactions. A response card contains a set of appropriate responses that a user can select to respond to a prompt. You can send a response card for each prompt that Amazon Lex sends to your client application. You can use response cards with Facebook Messenger, Slack, and Twilio as well as your own client applications.

For example, in a taxi application, you can configure an option in the response card for "Home" and set the value to the user's home address. When the user selects this option, Amazon Lex receives the entire address as the input text.

You can define a response card for the following prompts:

- Conclusion statement
- Confirmation prompt
- Follow-up prompt
- Rejection statement
- Slot type utterances

You can define only one response card for each prompt.

You configure response cards when you create an intent. You can define a static response card at build time using the console or the PutIntent (p. 297) operation. Or you can define a dynamic response card at runtime in a Lambda function. If you define both static and dynamic response cards, the dynamic response card takes precedence.

Amazon Lex sends response cards in the format that the client understands. It transforms response cards for Facebook Messenger, Slack, and Twilio. For other clients, Amazon Lex sends a JSON structure in the
PostText (p. 320) response. For example, if the client is Facebook Messenger, Amazon Lex transforms the response card to a generic template. For more information about Facebook Messenger generic templates, see Generic Template on the Facebook website. For an example of the JSON structure, see Generating Response Cards Dynamically (p. 16).

You can use response cards only with the PostText (p. 320) operation. You can't use response cards with the PostContent (p. 312) operation.

Defining Static Response Cards

Define static response cards with the PutBot (p. 285) operation or the Amazon Lex console when you create an intent. A static response card is defined at the same time as the intent. Use a static response card when the responses are fixed. Suppose that you are creating a bot with an intent that has a slot for flavor. When defining the flavor slot, you specify prompts, as shown in the following console screenshot:

![Console Screenshot]

When defining prompts, you can optionally associate a response card and define details with the PutBot (p. 285) operation, or, in the Amazon Lex console, as shown in the following example:
Now suppose that you've integrated your bot with Facebook Messenger. The user can click the buttons to choose a flavor, as shown in the following illustration:
To customize the content of a response card, you can refer to session attributes. At runtime, Amazon Lex substitutes these references with appropriate values from the session attributes. For more information, see Setting Session Attributes (p. 17). For an example, see Example: Using a Response Card (p. 162).

Generating Response Cards Dynamically

To generate response cards dynamically at runtime, use the initialization and validation Lambda function for the intent. Use a dynamic response card when the responses are determined at runtime in the Lambda function. In response to user input, the Lambda function generates a response card and returns the it in the dialogAction section of the response. For more information, see Response Format (p. 101).

The following is a partial response from a Lambda function that shows the responseCard element. It generates a user experience similar to the one shown in the preceding section.

```json
responseCard: {
  "version": 1,
  "contentType": "application/vnd.amazonaws.card.generic",
  "genericAttachments": [
    {
      "title": "What Flavor?",
      "subtitle": "What flavor do you want?",
      "imageUrl": "Link to image",
      "attachmentLinkUrl": "Link to attachment",
    }
  ]
}
```
Managing Conversation Context

Conversation context is the information that a user, your application, or a Lambda function provides to an Amazon Lex bot to fulfill an intent. Conversation context includes slot data that the user provides, request attributes set by the client application, and session attributes that the client application and Lambda functions create.

Topics
- Setting Session Attributes (p. 17)
- Setting Request Attributes (p. 18)
- Setting the Session Timeout (p. 20)
- Sharing Information Between Intents (p. 20)
- Setting Complex Attributes (p. 20)

Setting Session Attributes

Session attributes contain application-specific information that is passed between a bot and a client application during a session. Amazon Lex passes session attributes to all Lambda functions configured for a bot. If a Lambda function adds or updates session attributes, Amazon Lex passes the new information back to the client application. For example:

- In Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30), the example bot uses the price session attribute to maintain the price of flowers. The Lambda function sets this attribute based on the type of flowers that was ordered. For more information, see Step 5 (Optional): Review the Details of the Information Flow (Console) (p. 45).
- In Example Bot: BookTrip (p. 140), the example bot uses the currentReservation session attribute to maintain a copy of the slot type data during the conversation to book a hotel or to book a rental car. For more information, see Details of the Information Flow (p. 148).

Use session attributes in your Lambda functions to initialize a bot and to customize prompts and response cards. For example:

- Initialization — In a pizza ordering bot, the client application passes the user’s location as a session attribute in the first call to the PostContent (p. 312) or PostText (p. 320) operation. For example,
"Location": "111 Maple Street". The Lambda function uses this information to find the closest pizzeria to place the order.

- Personalize prompts — Configure prompts and response cards to refer to session attributes. For example, "Hey [FirstName], what toppings would you like?" If you pass the user's first name as a session attribute ("FirstName": "Jo"), Amazon Lex substitutes the name for the placeholder. It then sends a personalized prompt to the user, "Hey Jo, which toppings would you like?"

Session attributes persist for the duration of the session. Amazon Lex stores them in an encrypted data store until the session ends. The client can create session attributes in a request by calling either the PostContent (p. 312) or the PostText (p. 320) operation with the `sessionAttributes` field set to a value. A Lambda function can create a session attribute in a response. After the client or a Lambda function creates a session attribute, the stored attribute value is used any time that the client application doesn't include `sessionAttributes` field in a request to Amazon Lex.

For example, suppose you have two session attributes, ("x": 1, "y": 2). If the client calls the PostContent or PostText operation without specifying the `sessionAttributes` field, Amazon Lex calls the Lambda function with the stored session attributes ("x": 1, "y": 2). If the Lambda function doesn't return session attributes, Amazon Lex returns the stored session attributes to the client application.

If either the client application or a Lambda function passes session attributes, Amazon Lex updates the stored session attributes. Passing an existing value, such as  ("x": 2), updates the stored value. When an empty map, {}, is passed, stored values are erased.

To send session attributes to Amazon Lex, you create a string-to-string map of the attributes. The following shows how to map session attributes:

```json
{
  "attributeName": "attributeValue",
  "attributeName": "attributeValue"
}
```

For the PostText operation you insert the map into the body of the request using the `sessionAttributes` field, as follows:

```json
"sessionAttributes": {
  "attributeName": "attributeValue",
  "attributeName": "attributeValue"
}
```

For the PostContent operation, you base64 encode the map, and then send it as the `x-amz-lex-session-attributes` header.

If you are sending binary or structured data in a session attribute, you must first transform the data to a simple string. For more information, see Setting Complex Attributes (p. 20).

**Setting Request Attributes**

*Request attributes* contain request-specific information and apply only to the current request. A client application sends this information to Amazon Lex. Use request attributes to pass information that doesn't need to persist for the entire session. You can create your own request attributes or you can use predefined attributes. To send request attributes, use the `x-amz-lex-request-attributes` header in a the section called “PostContent” (p. 312) or the `requestAttributes` field in a the section called “PostText” (p. 320) request. Because request attributes don't persist across requests like session attributes do, they are not returned in PostContent or PostText responses.

**Note**

To send information that persists across requests, use session attributes.
The namespace `x-amz-lex:` is reserved for the predefined request attributes. Don't create request attributes with the prefix `x-amz-lex:`.

**Setting Predefined Request Attributes**

Amazon Lex provides predefined request attributes for managing the way that it processes information sent to your bot. The attributes are not persisted in the session, you must send the predefined attributes in each request. All predefined attributes are in the `x-amz-lex:` namespace.

In addition to the following predefined attributes, Amazon Lex provides predefined attributes for messaging platforms. For a list of those attributes, see Deploying an Amazon Lex Bot on a Messaging Platform (p. 106).

**Setting the Preferred Time Zone**

To set the time zone used to resolve dates so that it is relative to the user's time zone, use the `x-amz-lex:time-zone` request attribute. If you do not specify a time zone in the `x-amz-lex:time-zone` attribute, the default depends on the region that you are using for your bot.

<table>
<thead>
<tr>
<th>Region</th>
<th>Default time zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>America/New York</td>
</tr>
<tr>
<td>EU (Ireland)</td>
<td>Europe/Dublin</td>
</tr>
</tbody>
</table>

For example, if the user responds tomorrow in response to the prompt "Which day would you like your package delivered?" the actual date that the package is delivered depends on the user's time zone. For example, when it is 01:00 September 16 in New York, it is 22:00 September 15 in Los Angeles. If a person in Los Angeles orders a package to be delivered "tomorrow" using the default time zone, the package would be delivered on the 17th, not the 16th, as expected. However, if you set the `x-amz-lex:time-zone` request attribute to `America/Los_Angeles`, the package would be delivered on the 16th.

You can set the attribute to any of the Internet Assigned Number Authority (IANA) time zone names. For more information, see Time Zone Database on the IANA website.

**Setting User-Defined Request Attributes**

A **user-defined request attribute** is data that you send to your bot in each request. You send the information in the `amz-lex-request-attributes` header of a `PostContent` request or in the `requestAttributes` field of a `PostText` request.

To send request attributes to Amazon Lex, you create a string-to-string map of the attributes. The following shows how to map request attributes:

```json
{
    "attributeName": "attributeValue",
    "attributeName": "attributeValue"
}
```

For the `PostText` operation you insert the map into the body of the request using the `requestAttributes` field, as follows:

```json
"requestAttributes": {
    "attributeName": "attributeValue",
    "attributeName": "attributeValue"
}
```
For the `PostContent` operation, you base64 encode the map, and then send it as the `x-amz-lex-request-attributes` header.

If you are sending binary or structured data in a request attribute, you must first transform the data to a simple string. For more information, see Setting Complex Attributes (p. 20).

### Setting the Session Timeout

Amazon Lex retains context information—slot data and session attributes—until a conversation session ends. To control how long a session lasts for a bot, set the session timeout. By default, session duration is 5 minutes, but you can specify any duration between 0 and 1,440 minutes (24 hours).

For example, suppose that you create a `ShoeOrdering` bot that supports intents such as `OrderShoes` and `GetOrderStatus`. When Amazon Lex detects that the user's intent is to order shoes, it asks for slot data. For example, it asks for shoe size, color, brand, etc. If the user provides some of the slot data but doesn't complete the shoe purchase, Amazon Lex remembers all of the slot data and session attributes for the duration of the session. If the user returns to the session before it expires, he or she can provide the remaining slot data, and complete the purchase.

In the Amazon Lex console, you set the session timeout when you create a bot. With the AWS command line interface (AWS CLI) or API, you set the timeout when you create or update a bot with the `PutBot` (p. 285) operation by setting the `idleSessionTTLInSeconds` field.

### Sharing Information Between Intents

Amazon Lex supports sharing information between intents. To share between intents, use session attributes.

For example, a user of the `ShoeOrdering` bot starts by ordering shoes. The bot engages in a conversation with the user, gathering slot data, such as shoe size, color, and brand. When the user places an order, the Lambda function that fulfills the order sets the `orderNumber` session attribute, which contains the order number. To get the status of the order, the user uses the `GetOrderStatus` intent. The bot can ask the user for slot data, such as order number and order date. When the bot has the required information, it returns the status of the order.

If you think that your users might switch intents during the same session, you can design your bot to return the status of the latest order. Instead of asking the user for order information again, you use the `orderNumber` session attribute to share information across intents and fulfill the `GetOrderStatus` intent. The bot does this by returning the status of the last order that the user placed.

For an example of cross-intent information sharing, see Example Bot: BookTrip (p. 140).

### Setting Complex Attributes

Session and request attributes are string-to-string maps of attributes and values. In many cases, you can use the string map to transfer attribute values between your client application and a bot. In some cases, however, you might need to transfer binary data or a complex structure that can't be easily converted to a string map. For example, the following JSON object represents an array of the three most populous cities in the United States:

```json
{
    "cities": [
        {
            "city": {
                "name": "New York",
                "state": "New York",
                "pop": "8537673"
            }
        },
        
```
This array of data doesn't translate well to a string-to-string map. In such a case, you can transform an object to a simple string so that you can send it to your bot with the PostContent (p. 312) and PostText (p. 320) operations.

For example, if you are using JavaScript, you can use the JSON.stringify operation to convert an object to JSON, and the JSON.parse operation to convert JSON text to a JavaScript object:

```javascript
// To convert an object to a string.
var jsonString = JSON.stringify(object, null, 2);
// To convert a string to an object.
var obj = JSON.parse(JSON string);
```

To send session attributes with the PostContent operation, you must base64 encode the attributes before you add them to the request header, as shown in the following JavaScript code:

```javascript
var encodedAttributes = new Buffer(attributeString).toString("base64");
```

You can send binary data to the PostContent and PostText operations by first converting the data to a base64-encoded string, and then sending the string as the value in the session attributes:

```json
"sessionAttributes" : {
  "binaryData": "base64 encoded data"
}
```

Bot Deployment Options

Currently, Amazon Lex provides the following bot deployment options:

- **AWS Mobile SDK** – You can build mobile applications that communicate with Amazon Lex using the AWS Mobile SDKs.
- **Facebook Messenger** – You can integrate your Facebook Messenger page with your Amazon Lex bot so that end users on Facebook can communicate with the bot. In the current implementation, this integration supports only text input messages.
- **Slack** – You can integrate your Amazon Lex bot with a Slack messaging application.
- **Twilio** – You can integrate your Amazon Lex bot with the Twilio Simple Messaging Service (SMS).

For examples, see Deploying and Exporting Amazon Lex Bots (p. 106).
Built-in Intents and Slot Types

To make it easier to create your bots, Amazon Lex allows you to use standard Alexa built-in intents and slot types.

Topics
- Built-in Intents (p. 22)
- Built-in Slot Types (p. 22)

Built-in Intents

For common actions, you can use the Alexa standard built-in intents library. To create an intent from a built-in intent, choose a built-intent in the console, and give it a new name. The new intent has the configuration of base intent, such as the sample utterances and slots.

For a list of built-in intents, see Standard Built-in Intents in the Alexa Skills Kit.

Note
Amazon Lex doesn't support the following intents:
- AMAZON.YesIntent
- AMAZON.NoIntent
- The intents in the Built-in Intent Library in the Alexa Skills Kit

In the current implementation, you can't do the following:
- Add or remove sample utterances or slots from the base intent
- Configure slots for build-in intents

Built-in Slot Types

Amazon Lex supports built-in slot types from the Alexa Skills Kit. You can create slots of these types in your intents. This eliminates the need to create enumeration values for commonly used slot data such as date, time, and location. Built-in slot types do not have versions.

For a list of available built-in slot types, see Slot Type Reference in the Alexa Skills Kit documentation.

Note
Amazon Lex doesn't support the AMAZON.LITERAL built-in slot type.

Amazon Lex supports the following built-in slot types. Slot types marked "Developer Preview" are in preview and might change.

<table>
<thead>
<tr>
<th>Slot Type</th>
<th>Short Description</th>
<th>Supported Languages</th>
<th>Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMAZON.EmailAddress (p. 23)</td>
<td>Converts words that represent an email address into a standard email address</td>
<td>English (US)</td>
<td>Developer Preview</td>
</tr>
<tr>
<td>AMAZON.Percentage (p. 24)</td>
<td>Converts words that represent a percentage to a number and a percent sign (%)</td>
<td>English (US)</td>
<td>Developer Preview</td>
</tr>
</tbody>
</table>
When used with Amazon Lex, the following slot types extend the Alexa Skill Kit slot type.

<table>
<thead>
<tr>
<th>Slot Type</th>
<th>Short Description</th>
<th>Supported Languages</th>
<th>Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMAZON.PhoneNumber</td>
<td>Converts words that represent a phone number into a numeric string</td>
<td>English (US)</td>
<td>Developer Preview</td>
</tr>
<tr>
<td>AMAZON.SpeedUnit</td>
<td>Converts words that represent a speed unit into a standard abbreviation</td>
<td>English (US)</td>
<td>Developer Preview</td>
</tr>
<tr>
<td>AMAZON.WeightUnit</td>
<td>Converts words that represent a weight unit into a standard abbreviation</td>
<td>English (US)</td>
<td>Developer Preview</td>
</tr>
</tbody>
</table>

The built-in slot types are described in detail in the following sections.

### Alexa Skills Kit Slot Types

You can use any of the slot types from the Alexa Skills Kit in your Amazon Lex bots. To use one of the slot types, specify the slot type name in the console or in a call to the `PutIntent` operation. For a list of available built-in slot types, see Slot Type Reference in the Alexa Skills Kit.

**Note**
Amazon Lex doesn't support the AMAZON.LITERAL built-in slot type.

### AMAZON.EmailAddress

This slot type is in preview release for Amazon Lex and is subject to change.

Recognizes words that represent an email address provided as username@domain. Addresses can include the following special characters in a user name: underscore (_), hyphen (-), period (.), and the plus sign (+).

### AMAZON.NUMBER

This slot type is in preview release for Amazon Lex and is subject to change.
Converts numeric words into digits.

Amazon Lex extends the AMAZON.NUMBER slot type to convert words or numbers that express a number into digits, including decimal numbers. The following table shows how the AMAZON.NUMBER slot type captures numeric words.

<table>
<thead>
<tr>
<th>Input</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>one hundred twenty three point four five</td>
<td>123.45</td>
</tr>
<tr>
<td>one hundred twenty three dot four five</td>
<td>123.45</td>
</tr>
<tr>
<td>point four two</td>
<td>0.42</td>
</tr>
<tr>
<td>point forty two</td>
<td>0.42</td>
</tr>
<tr>
<td>232.998</td>
<td>232.998</td>
</tr>
<tr>
<td>50</td>
<td>50</td>
</tr>
</tbody>
</table>

**AMAZON.Percentage**

This slot type is in preview release for Amazon Lex and is subject to change.

Converts words and symbols that represent a percentage into a numeric value with a percent sign (%). If the user enters a number without a percent sign or the word "percent," the slot value is set to the number. The following table shows how the AMAZON.Percentage slot type captures percentages.

<table>
<thead>
<tr>
<th>Input</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>50 percent</td>
<td>50%</td>
</tr>
<tr>
<td>0.4 percent</td>
<td>0.4%</td>
</tr>
<tr>
<td>23.5%</td>
<td>23.5%</td>
</tr>
<tr>
<td>25</td>
<td>25</td>
</tr>
</tbody>
</table>

**AMAZON.PhoneNumber**

This slot type is in preview release for Amazon Lex and is subject to change.

Converts the numbers or words that represent a phone number into a string format without punctuation as follows.

**Note**

Only U.S. phone numbers are supported.
### Built-in Slot Types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Input</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>International number with leading plus (+) sign</td>
<td>11-digit number with leading plus sign.</td>
<td>+1 509 555-1212</td>
<td>+15095551212</td>
</tr>
<tr>
<td>International number without leading plus (+) sign</td>
<td>11-digit number without leading plus sign</td>
<td>1 (509) 555-1212</td>
<td>15095551212</td>
</tr>
<tr>
<td>National number</td>
<td>10-digit number without international code</td>
<td>(509) 555-1212</td>
<td>5095551212</td>
</tr>
<tr>
<td>Local number</td>
<td>7-digit phone number without and international code or an area code</td>
<td>555-1212</td>
<td>5551212</td>
</tr>
</tbody>
</table>

#### AMAZON.SpeedUnit

This slot type is in preview release for Amazon Lex and is subject to change.

Converts words that represent speed units into the corresponding abbreviation.

For example, "miles per hour" is converted to mph.

The following examples show how the AMAZON.SpeedUnit slot type captures speed units.

<table>
<thead>
<tr>
<th>Speed unit</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>miles per hour, mph, MPH, m/h</td>
<td>mph</td>
</tr>
<tr>
<td>kilometers per hour, km per hour, kmph, KMPH, km/h</td>
<td>kmph</td>
</tr>
<tr>
<td>meters per second, mps, MPS, m/s</td>
<td>mps</td>
</tr>
<tr>
<td>nautical miles per hour, knots, knot</td>
<td>knot</td>
</tr>
</tbody>
</table>

#### AMAZON.TIME

Converts words that represent times into time values.

Amazon Lex extends the AMAZON.TIME slot type to include resolutions for ambiguous times. When a user enters an ambiguous time, Amazon Lex uses the slotDetails attribute of a Lambda event to pass resolutions for the ambiguous times to your Lambda function. For example, if your bot prompts the user for a delivery time, the user can respond by saying "10 o'clock." This time is ambiguous. It means either 10:00 AM or 10:00 PM. In this case, the value in the slots map is null, and the slotDetails entity contains the two possible resolutions of the time. Amazon Lex inputs the following into the Lambda function:

```json
"slots": {
```
When the user responds with an unambiguous time, Amazon Lex sends the time to your Lambda function in the `slots` attribute of the Lambda event and the `slotDetails` attribute is empty. For example, if your user responds to the prompt for a delivery time with "10:00 PM," Amazon Lex inputs the following into the Lambda function:

```
"slots": {
  "deliveryTime": "22:00"
}
```

For more information about the data sent from Amazon Lex to a Lambda function, see Input Event Format (p. 98).

**AMAZON.WeightUnit**

This slot type is in preview release for Amazon Lex and is subject to change.

Converts words that represent a weight unit into the corresponding abbreviation. For example, "kilogram" is converted to kg.

The following examples show how the `AMAZON.WeightUnit` slot type captures weight units:

<table>
<thead>
<tr>
<th>Weight unit</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>kilograms, kilos, kgs, KGS</td>
<td>kg</td>
</tr>
<tr>
<td>grams, gms, gm, GMS, g</td>
<td>g</td>
</tr>
<tr>
<td>milligrams, mg, mgs</td>
<td>mg</td>
</tr>
<tr>
<td>pounds, lbs, LBS</td>
<td>lbs</td>
</tr>
<tr>
<td>ounces, oz, OZ</td>
<td>oz</td>
</tr>
<tr>
<td>tonne, ton, t</td>
<td>t</td>
</tr>
<tr>
<td>kiloton, kt</td>
<td>kt</td>
</tr>
</tbody>
</table>

**Custom Slot Types**

For each intent, you can specify parameters that indicate the information that the intent needs to fulfill the user's request. These parameters, or slots, have a type. A slot type is a list of values that Amazon Lex
uses to train the machine learning model to recognize values for a slot. For example, you can define a slot type called "Genres." Each value in the slot type is the name of a genre, "comedy," "adventure," "documentary," etc. You can define a synonym for a slot type value. For example, you can define the synonyms "funny" and "humorous" for the value "comedy."

You can configure the slot type to restrict resolution to the slot values. The slot values will be used as an enumeration and the value entered by the user will be resolved to the slot value only if it is the same as one of the slot values or a synonym. A synonym is resolved to the corresponding slot value. For example, if the user enters "funny" it will resolve to the slot value "comedy."

Alternately, you can configure the slot type to expand the values. Slot values will be used as training data and the slot is resolved to the value provided by the user if it is similar to the slot values and synonyms. This is the default behavior.

Amazon Lex maintains a list of possible resolutions for a slot. Each entry in the list provides a resolution value that Amazon Lex recognized as additional possibilities for the slot. A resolution value is the best effort to match the slot value. The list contains up to five values.

When the value entered by the user is a synonym, the first entry in the list of resolution values is the slot type value. For example, if the user enters "funny," the slots field contains "funny" and the first entry in the slotDetails field is "comedy." You can configure the valueSelectionStrategy when you create or update a slot type with the PutSlotType (p. 307) operation so that the slot value is filled with the first value in the resolution list.

If you are using a Lambda function, the input event to the function includes a resolution list called slotDetails. The following example shows the slot and slot details section of the input to a Lambda function:

```json
"slots": {  
  "MovieGenre": "funny";
},  
"slotDetails": {  
  "Movie": {  
    "resolutions": [  
      "value": "comedy"
    ]
  }
}
```

For each slot type, you can define a maximum of 10,000 values and synonyms. Each bot can have a total number of 50,000 slot type values and synonyms.
Getting Started with Amazon Lex

Amazon Lex provides API operations that you can integrate with your existing applications. For a list of supported operations, see the API Reference (p. 194). You can use any of the following options:

- AWS SDK — When using the SDKs your requests to Amazon Lex are automatically signed and authenticated using the credentials that you provide. This is the recommended choice for building your applications.
- AWS CLI — You can use the AWS CLI to access any Amazon Lex feature without having to write any code.
- AWS Console — The console is the easiest way to get started testing and using Amazon Lex.

If you are new to Amazon Lex, we recommend that you read Amazon Lex: How It Works (p. 3). first.

Topics
- Step 1: Set Up an AWS Account and Create an Administrator User (p. 28)
- Step 2: Set Up the AWS Command Line Interface (p. 29)
- Step 3: Getting Started (Console) (p. 30)
- Step 4: Getting Started (AWS CLI) (p. 69)

Step 1: Set Up an AWS Account and Create an Administrator User

Before you use Amazon Lex for the first time, complete the following tasks:

1. Sign Up for AWS (p. 28)
2. Create an IAM User (p. 29)

Sign Up for AWS

If you already have an AWS account, skip this task.

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including Amazon Lex. You are charged only for the services that you use.

With Amazon Lex, you pay only for the resources that you use. If you are a new AWS customer, you can get started with Amazon Lex for free. For more information, see AWS Free Usage Tier.

If you already have an AWS account, skip to the next task. If you don’t have an AWS account, use the following procedure to create one.

To create an AWS account

1. Open https://aws.amazon.com/, and then choose Create an AWS Account.
   
   **Note**
   
   This might be unavailable in your browser if you previously signed into the AWS Management Console. In that case, choose Sign in to a different account, and then choose Create a new AWS account.

2. Follow the online instructions.
Part of the sign-up procedure involves receiving a phone call and entering a PIN using the phone keypad.

Write down your AWS account ID because you'll need it for the next task.

Create an IAM User

Services in AWS, such as Amazon Lex, require that you provide credentials when you access them so that the service can determine whether you have permissions to access the resources owned by that service. The console requires your password. You can create access keys for your AWS account to access the AWS CLI or API.

However, we don't recommend that you access AWS using the credentials for your AWS account. Instead, we recommend that you:

- Use AWS Identity and Access Management (IAM) to create an IAM user
- Add the user to an IAM group with administrative permissions
- Grant administrative permissions to the IAM user that you created.

You can then access AWS using a special URL and the IAM user's credentials.

The Getting Started exercises in this guide assume that you have a user (adminuser) with administrator privileges. Follow the procedure to create adminuser in your account.

To create an administrator user and sign in to the console

1. Create an administrator user called adminuser in your AWS account. For instructions, see Creating Your First IAM User and Administrators Group in the IAM User Guide.
2. As a user, you can sign in to the AWS Management Console using a special URL. For more information, How Users Sign In to Your Account in the IAM User Guide.

For more information about IAM, see the following:

- AWS Identity and Access Management (IAM)
- Getting Started
- IAM User Guide

Next Step

Step 2: Set Up the AWS Command Line Interface (p. 29)

Step 2: Set Up the AWS Command Line Interface

If you prefer to use Amazon Lex with the AWS Command Line Interface (AWS CLI), download and configure it.

**Important**

You don't need the AWS CLI to perform the steps in the Getting Started exercises. However, some of the later exercises in this guide use the AWS CLI. If you prefer to start by using the console, skip this step and go to Step 3: Getting Started (Console) (p. 30). Later, when you need the AWS CLI, return here to set it up.
To set up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:
   - Getting Set Up with the AWS Command Line Interface
   - Configuring the AWS Command Line Interface

2. Add a named profile for the administrator user to the end of the AWS CLI config file. You use this profile when executing AWS CLI commands. For more information about named profiles, see Named Profiles in the AWS Command Line Interface User Guide.

   `[profile adminuser]
   aws_access_key_id = adminuser access key ID
   aws_secret_access_key = adminuser secret access key
   region = aws-region`

   For a list of available AWS Regions, see Regions and Endpoints in the Amazon Web Services General Reference.

3. Verify the setup by typing the Help command at the command prompt:

   `aws help`

Step 3: Getting Started (Console) (p. 30)

Step 3: Getting Started (Console)

The easiest way to learn how to use Amazon Lex is by using the console. To get you started, we created the following exercises, all of which use the console:

- Exercise 1 — Create an Amazon Lex bot using a blueprint, a predefined bot that provides all of the necessary bot configuration. You do only a minimum of work to test the end-to-end setup.
  
  In addition, you use the Lambda function blueprint, provided by AWS Lambda, to create a Lambda function. The function is a code hook that uses predefined code that is compatible with your bot.

- Exercise 2 — Create a custom bot by manually creating and configuring a bot. You also create a Lambda function as a code hook. Sample code is provided.

- Exercise 3 — Publish a bot, and then create a new version of it. As part of this exercise you create an alias that points to the bot version.

Topics
- Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30)
- Exercise 2: Create a Custom Amazon Lex Bot (p. 57)
- Exercise 3: Publish a Version and Create an Alias (p. 68)

Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console)

In this exercise, you do the following:
Create your first Amazon Lex bot, and test it in the Amazon Lex console.

For this exercise, you use the OrderFlowers blueprint. For information about blueprints, see Amazon Lex and AWS Lambda Blueprints (p. 105).

Create an AWS Lambda function and test it in the Lambda console. While processing a request, your bot calls this Lambda function. For this exercise, you use a Lambda blueprint (lex-order-flowers-python) provided in the AWS Lambda console to create your Lambda function. The blueprint code illustrates how you can use the same Lambda function to perform initialization and validation, and to fulfill the OrderFlowers intent.

Update the bot to add the Lambda function as the code hook to fulfill the intent. Test the end-to-end experience.

The following sections explain what the blueprints do.

**Amazon Lex Bot: Blueprint Overview**

You use the OrderFlowers blueprint to create an Amazon Lex bot. For more information about the structure of a bot, see Amazon Lex: How It Works (p. 3). The bot is preconfigured as follows:

- **Intent** – OrderFlowers
- **Slot types** – One custom slot type called FlowerTypes with enumeration values: roses, lilies, and tulips.
- **Slots** – The intent requires the following information (that is, slots) before the bot can fulfill the intent.
  - PickupTime (AMAZON.TIME built-in type)
  - FlowerType (FlowerTypes custom type)
  - PickupDate (AMAZON.DATE built-in type)
- **Utterance** – The following sample utterances indicate the user's intent:
  - "I would like to pick up flowers."
  - "I would like to order some flowers."
- **Prompts** – After the bot identifies the intent, it uses the following prompts to fill the slots:
  - Prompt for the FlowerType slot – "What type of flowers would you like to order?"
  - Prompt for the PickupDate slot – "What day do you want the {FlowerType} to be picked up?"
  - Prompt for the PickupTime slot – "At what time do you want the {FlowerType} to be picked up?"
  - Confirmation statement – "Okay, your {FlowerType} will be ready for pickup by {PickupTime} on {PickupDate}. Does this sound okay?"

**AWS Lambda Function: Blueprint Summary**

The Lambda function in this exercise performs both initialization and validation and fulfillment tasks. Therefore, after creating the Lambda function, you update the intent configuration by specifying the same Lambda function as a code hook to handle both the initialization and validation and fulfillment tasks.

- As an initialization and validation code hook, the Lambda function performs basic validation. For example, if the user provides a time for pickup that is outside of normal business hours, the Lambda function directs Amazon Lex to re-prompt the user for the time.
- As part of the fulfillment code hook, the Lambda function returns a summary message indicating that the flower order has been placed (that is, the intent is fulfilled).
Next Step

Step 1: Create an Amazon Lex Bot (Console) (p. 32)

Step 1: Create an Amazon Lex Bot (Console)

For this exercise, create a bot for ordering flowers, called OrderFlowersBot.

To create an Amazon Lex bot (console)

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. On the Bots page, choose Create.
3. On the Create your Lex bot page, provide the following information, and then choose Create.
   - Choose the OrderFlowers blueprint.
   - Leave the default bot name (OrderFlowers).
4. Choose Create. The console makes the necessary requests to Amazon Lex to save the configuration. The console then displays the bot editor window.
5. To build the bot, choose Build twice.
6. Test the bot.

   Note
   You can test the bot by typing text into the test window, or, for compatible browsers, by choosing the microphone button in the test window and speaking.

Use the following example text to engage in conversation with the bot to order flowers:
From this input, the bot infers the `OrderFlowers` intent and prompts for slot data. When you provide all of the required slot data, the bot fulfills the intent (`OrderFlowers`) by returning all of the information to the client application (in this case, the console). The console shows the information in the test window.

Specifically:

- In the statement "What day do you want the roses to be picked up?," the term "roses" appears because the prompt for the `pickupDate` slot is configured using substitutions, `{FlowerType}`. Verify this in the console.
- The "Okay, your roses will be ready..." statement is the confirmation prompt that you configured.
- The last statement ("{FlowerType}: roses...") is just the slot data that is returned to the client, in this case, in the test window. In the next exercise, you use a Lambda function to fulfill the intent, in which case you get a message indicating that the order is fulfilled.

Next Step

Step 2 (Optional): Review the Details of Information Flow (Console) (p. 34)
Step 2 (Optional): Review the Details of Information Flow (Console)

This section explains the flow of information between a client and Amazon Lex for each user input in our example conversation.

To see the flow of information for spoken or typed content, choose the appropriate topic.

Topics
- Step 2a (Optional): Review the Details of the Spoken Information Flow (Console)  (p. 34)
- Step 2b (Optional): Review the Details of the Typed Information Flow (Console) (p. 38)

Step 2a (Optional): Review the Details of the Spoken Information Flow (Console)

This section explains the flow of information between the client and Amazon Lex when the client uses speech to send requests. For more information, see PostContent (p. 312).

1. The user says: I would like to order some flowers.
   a. The client (console) sends the following PostContent (p. 312) request to Amazon Lex:

   ```
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/content HTTP/1.1
   x-amz-lex-session-attributes: "e30="
   Content-Type: "audio/x-l16; sample-rate=16000; channel-count=1"
   Accept: "audio/mpeg"
   Request body
   input stream
   ```

   Both the request URI and the body provide information to Amazon Lex:
   - Request URI – Provides the bot name (OrderFlowers), bot alias ($LATEST), and the user name (a random string that identifies the user). content indicates that this is a PostContent API request (not a PostText request).
   - Request headers
     - x-amz-lex-session-attributes – The base64-encoded value represents "[]". When the client makes the first request, there are no session attributes.
     - Content-Type – Reflects the audio format.
     - Request body – The user input audio stream ("I would like to order some flowers.").

   Note
   If the user chooses to send text ("I would like to order some flowers") to the PostContent API instead of speaking, the request body is the user input. The Content-Type header is set accordingly:

   ```
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/content HTTP/1.1
   x-amz-lex-session-attributes: "e30="
   Content-Type: "text/plain; charset=utf-8"
   Accept: accept
   Request body
   input stream
   ```
b. From the input stream, Amazon Lex detects the intent (OrderFlowers). It then chooses one of the intent’s slots (in this case, the FlowerType) and one of its value elicitation prompts, and then sends a response with the following headers:

```
x-amz-lex-dialog-state:ElicitSlot
x-amz-lex-input-transcript:I would like to order some flowers.
x-amz-lex-intent-name:OrderFlowers
x-amz-lex-message:What type of flowers would you like to order?
x-amz-lex-session-attributes:e30=
x-amz-lex-slot-to-elicit:FlowerType
x-amz-lex-slots:eyJQaWNrdXBUaW1lIjpudWxsLCJGbG93ZXJUeXBlIjpudWxsLCJQaWNrdXBEYXRlIjpudWxsLQ==
```

The header values provide the following information:

- **x-amz-lex-input-transcript** – Provides the transcript of the audio (user input) from the request
- **x-amz-lex-message** – Provides the transcript of the audio Amazon Lex returned in the response
- **x-amz-lex-slots** – The base64 encoded version of the slots and values:

  ```
  {"PickupTime":null,"FlowerType":null,"PickupDate":null}
  ```

- **x-amz-lex-session-attributes** – The base64-encoded version of the session attributes ({}).

The client plays the audio in the response body.

2. The user says: roses

   a. The client (console) sends the following PostContent request to Amazon Lex:

```
POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/content HTTP/1.1
x-amz-lex-session-attributes: "e30="
Content-Type: "audio/x-l16; sample-rate=16000; channel-count=1"
Accept: "audio/mpeg"

Request body
input stream ("roses")
```

The request body is the user input audio stream (roses). The sessionAttributes remains empty.

b. Amazon Lex interprets the input stream in the context of the current intent (it remembers that it had asked this user for information pertaining to the FlowerType slot). Amazon Lex first updates the slot value for the current intent. It then chooses another slot (PickupDate), along with one of its prompt messages (When do you want to pick up the roses?), and returns a response with the following headers:

```
x-amz-lex-dialog-state:ElicitSlot
x-amz-lex-input-transcript:roses
x-amz-lex-intent-name:OrderFlowers
x-amz-lex-message:When do you want to pick up the roses?
x-amz-lex-session-attributes:e30=
x-amz-lex-slot-to-elicit:PickupDate
x-amz-lex-slots:eyJQaWNrdXBUaW1lIjpudWxsLCJGbG93ZXJUeXBlIjpudWxsLCJQaWNrdXBEYXRlIjpudWxsLQ==
```

The client plays the audio in the response body.
Exercise 1: Create a Bot Using a Blueprint

The header values provide the following information:

- **x-amz-lex-slots** – The base64-encoded version of the slots and values:
  ```json
  {"PickupTime":null,"FlowerType":"roses","PickupDate":null}
  ```

- **x-amz-lex-session-attributes** – The base64-encoded version of the session attributes
  ```json
  {}
  ```

The client plays the audio in the response body.

3. The user says: tomorrow

   a. The client (console) sends the following PostContent (p. 312) request to Amazon Lex:

   ```
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wWdhx6nlheferh6a73fujd3118f5w/content HTTP/1.1
   x-amz-lex-session-attributes: "e30="
   Content-Type: "audio/x-l16; sample-rate=16000; channel-count=1"
   Accept: "audio/mpeg"
   
   Request body
   input stream ("tomorrow")
   ```

   The request body is the user input audio stream ("tomorrow"). The sessionAttributes remains empty.

   b. Amazon Lex interprets the input stream in the context of the current intent (it remembers that it had asked this user for information pertaining to the PickupDate slot). Amazon Lex updates the slot (PickupDate) value for the current intent. It then chooses another slot to elicit value for (PickupTime) and one of the value elicitation prompts (When do you want to pick up the roses on 2017-03-18?), and returns a response with the following headers:

   ```
   x-amz-lex-dialog-state:ElicitSlot
   x-amz-lex-input-transcript:tomorrow
   x-amz-lex-intent-name:OrderFlowers
   x-amz-lex-message:When do you want to pick up the roses on 2017-03-18?
   x-amz-lex-session-attributes:e30=
   x-amz-lex-slot-to-elicit:PickupTime
   x-amz-lex-slots:eyQaWNrdXBv61IjpuGWsLCJGbG93ZXJUeXB1Ijoicm9zaDzIiwiaXNjYW1lbl93aWxmdWxhdGlvbiBwcm92aWNlcm5hZ2UifQ==
   x-amzn-RequestId:3a205b70-0b69-11e7-b447-eb69face3e6f
   ```

   The header values provide the following information:

   - **x-amz-lex-slots** – The base64-encoded version of the slots and values:
     ```json
     {"PickupTime":null,"FlowerType":"roses","PickupDate":"2017-03-18"}
     ```

   - **x-amz-lex-session-attributes** – The base64-encoded version of the session attributes
     ```json
     {}
     ```

   The client plays the audio in the response body.

4. The user says: 6 pm
a. The client (console) sends the following PostContent (p. 312) request to Amazon Lex:

```plaintext
POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/content HTTP/1.1
x-amz-lex-session-attributes: "e30="
Content-Type: "text/plain; charset=utf-8"
Accept: "audio/mpeg"

Request body
input stream ("6 pm")
```

The request body is the user input audio stream ("6 pm"). The sessionAttributes remains empty.

b. Amazon Lex interprets the input stream in the context of the current intent (it remembers that it had asked this user for information pertaining to the PickupTime slot). It first updates the slot value for the current intent.

Now Amazon Lex detects that it has information for all of the slots. However, the OrderFlowers intent is configured with a confirmation message. Therefore, Amazon Lex needs an explicit confirmation from the user before it can proceed to fulfill the intent. It sends a response with the following headers requesting confirmation before ordering the flowers:

```plaintext
x-amz-lex-dialog-state:ConfirmIntent
x-amz-lex-input-transcript:six p. m.
x-amz-lex-intent-name:OrderFlowers
x-amz-lex-message:Okay, your roses will be ready for pickup by 18:00 on 2017-03-18. Does this sound okay?
x-amz-lex-session-attributes:e30=
x-amz-lex-slots:eyJQaWNrdXBUaW1lIjoiMTg6MDAiLCJGbG93ZXJUeXBlIjoiZmdsIiwibGxvZyJdIiwibGxvZyJdIiwicmFuZ1NpdW0iOiJvYmplY3RzIiwiaHR0cHM6Ly93d3cuZm9sZS9pZC5naXZlL2kxMjMwNjAxMjIvNjUyNy5odG1sIiwiaHR0cHM6Ly93d3cuZm9sZS9pZC5naXZlL2kxMjMwNjAxMjIvNjUyNy5odG1sIiwicm9zaXplIjoiZmFsc2VzU2FyZyIsIyI6Ijc0MzI1NzQyNzoiLCJ1c2VyX2lkIjoiNjRiYTM0YjYyZTM3ZDE2M2M5ZmE1MmFjYmE2ZjIyZbzCI0Q=='
x-amzn-RequestId:083ca360-0b6a-11e7-b447-eb69face3e6f
```

The header values provide the following information:

- x-amz-lex-slots – The base64-encoded version of the slots and values:

  ```plaintext
  {"PickupTime":"18:00","FlowerType":"roses","PickupDate":"2017-03-18"}
  ```

- x-amz-lex-session-attributes – The base64-encoded version of the session attributes ({}).

The client plays the audio in the response body.

5. The user says: Yes

a. The client (console) sends the following PostContent (p. 312) request to Amazon Lex:

```plaintext
POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/content HTTP/1.1
x-amz-lex-session-attributes: "e30="
Content-Type: "audio/x-l16; sample-rate=16000; channel-count=1"
Accept: "audio/mpeg"

Request body
input stream ("Yes")
```
Exercise 1: Create a Bot Using a Blueprint

The request body is the user input audio stream ("Yes"). The sessionAttributes remains empty.

b. Amazon Lex interprets the input stream and understands that the user want to proceed with the order. The OrderFlowers intent is configured with ReturnIntent as the fulfillment activity. This directs Amazon Lex to return all of the intent data to the client. Amazon Lex returns a response with following:

- x-amz-lex-dialog-state: ReadyForFulfillment
- x-amz-lex-input-transcript: yes
- x-amz-lex-intent-name: OrderFlowers
- x-amz-lex-session-attributes: e30=
- x-amz-lex-slots:eyJQaWNrdXBUaW1lIjoiMTg6MDAiLCJGbG93ZXJUeXBlIjoicm9zaSaSDszIiwiaG4zaSU3VwRGF0ZSI6IjIjIiwMTctMDMtMiwK

The x-amz-lex-dialog-state response header is set to ReadyForFulfillment. The client can then fulfill the intent.

6. Now, retest the bot. To establish a new (user) context, choose the Clear link in the console. Provide data for the OrderFlowers intent, and include some invalid data. For example:

- Jasmine as the flower type (it is not one of the supported flower types)
- Yesterday as the day when you want to pick up the flowers

Notice that the bot accepts these values because you don't have any code to initialize and validate the user data. In the next section, you add a Lambda function to do this. Note the following about the Lambda function:

- It validates slot data after every user input. It fulfills the intent at the end. That is, the bot processes the flower order and returns a message to the user instead of simply returning slot data to the client. For more information, see Using Lambda Functions (p. 98).
- It also sets the session attributes. For more information about session attributes, see PostText (p. 320).

After you complete the Getting Started section, you can do the additional exercises (Additional Examples: Creating Amazon Lex Bots (p. 122)). Example Bot: BookTrip (p. 140) uses session attributes to share cross-intent information to engage in a dynamic conversation with the user.

Next Step

Step 3: Create a Lambda Function (Console) (p. 42)

Step 2b (Optional): Review the Details of the Typed Information Flow (Console)

This section explains flow of information between client and Amazon Lex in which the client uses the PostText API to send requests. For more information, see PostText (p. 320).

1. User types: I would like to order some flowers

   a. The client (console) sends the following PostText (p. 320) request to Amazon Lex:

   ```
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhex6nlheferh6073fujd3118f5w/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   {
     "inputText": "I would like to order some flowers",
     "sessionAttributes": {}
   }
   ```
Both the request URI and the body provide information to Amazon Lex:

- Request URI – Provides bot name (`OrderFlowers`), bot alias (`$LATEST`), and user name (a random string identifying the user). The trailing `text` indicates that it is a `PostText` API request (and not `PostContent`).

- Request body – Includes the user input (`inputText`) and empty `sessionAttributes`. When the client makes the first request, there are no session attributes. The Lambda function initiates them later.

b. From the `inputText`, Amazon Lex detects the intent (`OrderFlowers`). This intent does not have any code hooks (that is, the Lambda functions) for initialization and validation of user input or fulfillment.

Amazon Lex chooses one of the intent’s slots (`FlowerType`) to elicit the value. It also selects one of the value-elicitation prompts for the slot (all part of the intent configuration), and then sends the following response back to the client. The console displays the message in the response.

The client displays the message in the response.

2. User types: roses

a. The client (console) sends the following `PostText` request to Amazon Lex:

```json
POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/text
"Content-Type":"application/json"
"Content-Encoding":"amz-1.0"

{  
  "inputText": "roses",
  "sessionAttributes": {}
}
```

The `inputText` in the request body provides user input. The `sessionAttributes` remains empty.

b. Amazon Lex first interprets the `inputText` in the context of the current intent—the service remembers that it had asked the specific user for information about the `FlowerType` slot. Amazon Lex first updates the slot value for the current intent and chooses another slot
(PickupDate) along with one of its prompt messages—What day do you want the roses to be picked up?—for the slot.

Then, Amazon Lex returns the following response:

![JSON response](image)

The client displays the message in the response.

3. User types: tomorrow
   a. The client (console) sends the following PostText (p. 320) request to Amazon Lex:

   ```
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6a73fujd3118f5w/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   {
     "inputText": "tomorrow",
     "sessionAttributes": {}
   }
   ```

   The inputText in the request body provides user input. The sessionAttributes remains empty.

   b. Amazon Lex first interprets the inputText in the context of the current intent—the service remembers that it had asked the specific user for information about the PickupDate slot. Amazon Lex updates the slot (PickupDate) value for the current intent. It chooses another slot to elicit value for (PickupTime). It returns one of the value-elicitation prompts—Deliver the roses at what time on 2017-01-01?—to the client.

   Amazon Lex then returns the following response:

   ![JSON response](image)
The client displays the message in the response.

4. User types: 6 pm
   a. The client (console) sends the following PostText (p. 320) request to Amazon Lex:

   ```json
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6o73fujd3118f5w/text
   "Content-Type" : "application/json"
   "Content-Encoding" : "amz-1.0"
   {
     "inputText" : "6 pm",
     "sessionAttributes" : {}
   }
   ``

   The `inputText` in the request body provides user input. The `sessionAttributes` remains empty.
   
   b. Amazon Lex first interprets the `inputText` in the context of the current intent—the service remembers that it had asked the specific user for information about the `PickupTime` slot. Amazon Lex first updates the slot value for the current intent. Now Amazon Lex detects that it has information for all the slots.

   The `OrderFlowers` intent is configured with a confirmation message. Therefore, Amazon Lex needs an explicit confirmation from the user before it can proceed to fulfill the intent. Amazon Lex sends the following message to the client requesting confirmation before ordering the flowers:

   ![Image showing the response message]

   The client displays the message in the response.

5. User types: Yes
   a. The client (console) sends the following PostText (p. 320) request to Amazon Lex:

   ```json
   POST /bot/OrderFlowers/alias/$LATEST/user/4o9wwdhx6nlheferh6o73fujd3118f5w/text
   "Content-Type" : "application/json"
   "Content-Encoding" : "amz-1.0"
   {
     "inputText" : "Yes",
     "sessionAttributes" : {}
   }
   ``

   The `inputText` in the request body provides user input. The `sessionAttributes` remains empty.
b. Amazon Lex interprets the inputText in the context of confirming the current intent. It understands that the user want to proceed with the order. The OrderFlowers intent is configured with ReturnIntent as the fulfillment activity (there is no Lambda function to fulfill the intent). Therefore, Amazon Lex returns the slot data to the client.

Amazon Lex set the dialogState to ReadyForFulfillment. The client can then fulfill the intent.

6. Now test the bot again. To do that, you must choose the Clear link in the console to establish a new (user) context. Now as you provide data for the order flowers intent, try to provide invalid data. For example:

- Jasmine as the flower type (it is not one of the supported flower types).
- Yesterday as the day when you want to pick up the flowers.

Notice that the bot accepts these values because you don't have any code to initialize/validate user data. In the next section, you add a Lambda function to do this. Note the following about the Lambda function:

- The Lambda function validates slot data after every user input. It fulfills the intent at the end. That is, the bot processes the flowers order and returns a message to the user instead of simply returning slot data to the client. For more information, see Using Lambda Functions (p. 98).
- The Lambda function also sets the session attributes. For more information about session attributes, see PostText (p. 320).

After you complete the Getting Started section, you can do the additional exercises (Additional Examples: Creating Amazon Lex Bots (p. 122)). Example Bot: BookTrip (p. 140) uses session attributes to share cross-intent information to engage in a dynamic conversation with the user.

Next Step

Step 3: Create a Lambda Function (Console) (p. 42)

**Step 3: Create a Lambda Function (Console)**

Create a Lambda function (using the lex-order-flowers-python blueprint) and perform test invocation using sample event data in the AWS Lambda console.

You return to the Amazon Lex console and add the Lambda function as the code hook to fulfill the OrderFlowers intent in the OrderFlowersBot that you created in the preceding section.
To create the Lambda function (console)

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create function.
3. On the Create function page, choose Blueprints. Type lex- in the filter text box to find the blueprint, choose the lex-order-flowers-python blueprint.

Lambda function blueprints are provided in both Node.js and Python. For this exercise, use the Python-based blueprint.
4. On the Basic information page, do the following, and then choose Create function.
   - Type a Lambda function name (OrderFlowersCodeHook).
   - For the IAM role, choose Create a new role from template(s).
   - Type a role name (LexOrderFlowersRole).
   - Leave the other default values.
5. Choose Create function.
6. Test the Lambda function.
   a. Choose Select a test events, Configure test event.
   b. Choose Lex-Order Flowers from the Event template list. This sample event matches the Amazon Lex request/response model (see Using Lambda Functions (p. 98)). Give the test event a name (LexOrderFlowersTest).
   c. Choose Create.
   d. Verify that the Lambda function successfully executed. The response in this case matches the Amazon Lex response model.

Next Step

Step 4: Add the Lambda Function as Code Hook (Console) (p. 43)

Step 4: Add the Lambda Function as Code Hook (Console)

In this section, you update the configuration of the OrderFlowers intent to use the Lambda function as follows:

- First use the Lambda function as a code hook to perform fulfillment of the OrderFlowers intent. You test the bot and verify that you received a fulfillment message from the Lambda function. Amazon Lex invokes the Lambda function only after you provide data for all the required slots for ordering flowers.
- Configure the same Lambda function as a code hook to perform initialization and validation. You test and verify that the Lambda function performs validation (as you provide slot data).

To add a Lambda function as a code hook (console)

1. In the Amazon Lex console, select the OrderFlowers bot. The console shows the OrderFlowers intent. Make sure that the intent version is set to $LATEST because this is the only version that we can modify.
2. Add the Lambda function as the fulfillment code hook and test it.
   a. In the Editor, choose AWS Lambda function as Fulfillment, and select the Lambda function that you created in the preceding step (OrderFlowersCodeHook). Choose OK to give Amazon Lex permission to invoke the Lambda function.
You are configuring this Lambda function as a code hook to fulfill the intent. Amazon Lex invokes this function only after it has all the necessary slot data from the user to fulfill the intent.

b. Specify a **Goodbye message**.

c. **Choose Build**.

d. Test the bot using the previous conversation.

The last statement "Thanks, your order for roses....." is a response from the Lambda function that you configured as a code hook. In the preceding section, there was no Lambda function. Now you are using a Lambda function to actually fulfill the **OrderFlowers** intent.

3. Add the Lambda function as an initialization and validation code hook, and test.

   The sample Lambda function code that you are using can both perform user input validation and fulfillment. The input event the Lambda function receives has a field (**invocationSource**) that the code uses to determine what portion of the code to execute. For more information, see Lambda Function Input Event and Response Format (p. 98).

   a. Select the **$LATEST** version of the **OrderFlowers** intent. That's is the only version that you can update.

   b. In the Editor, choose **Initialization and validation** in Options.

   c. Again, select the same Lambda function.

   d. **Choose Build**.

   e. Test the bot.

      You are now ready to converse with Amazon Lex as follows. To test the validation portion, choose time 6 PM, and your Lambda function returns a response ("Our business hours are from 10 AM to 5 PM."), and prompts you again. After you provide all the valid slot data, the Lambda function fulfills the order.
Exercise 1: Create a Bot Using a Blueprint

Step 5 (Optional): Review the Details of the Information Flow (Console) (p. 45)

Step 5 (Optional): Review the Details of the Information Flow (Console)

This section explains the flow of information between the client and Amazon Lex for each user input, including the integration of the Lambda function.

Note
The section assumes that the client sends requests to Amazon Lex using the PostText runtime API and shows request and response details accordingly. For an example of the information flow between the client and Amazon Lex in which client uses the PostContent API, see Step 2a (Optional): Review the Details of the Spoken Information Flow (Console) (p. 34).
For more information about the PostText runtime API and additional details on the requests and responses shown in the following steps, see PostText (p. 320).

1. User: I would like to order some flowers.
   
a. The client (console) sends the following PostText (p. 320) request to Amazon Lex:

   ```
   POST /bot/OrderFlowers/alias/$LATEST/user/ignw84y6seypre4xly5rimopuri2xwnd/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   {
       "inputText": "I would like to order some flowers",
       "sessionAttributes": {}
   }
   ```

   Both the request URI and the body provide information to Amazon Lex:
   
   - Request URI – Provides bot name (OrderFlowers), bot alias ($LATEST), and user name (a random string identifying the user). The trailing text indicates that it is a PostText API request (and not PostContent).
   - Request body – Includes the user input (inputText) and empty sessionAttributes. When the client makes the first request, there are no session attributes. The Lambda function initiates them later.

   b. From the inputText, Amazon Lex detects the intent (OrderFlowers). This intent is configured with a Lambda function as a code hook for user data initialization and validation. Therefore, Amazon Lex invokes that Lambda function by passing the following information as event data:

   ```
   {
       "messageVersion": "1.0",
       "invocationSource": "DialogCodeHook",
       "userId": "ignw84y6seypre4xly5rimopuri2xwnd",
       "sessionAttributes": {},
       "bot": {
           "name": "OrderFlowers",
           "alias": null,
           "version": "$LATEST"
       },
       "outputDialogMode": "Text",
       "currentIntent": {
           "name": "OrderFlowers",
           "slots": {
               "PickupTime": null,
               "FlowerType": null,
               "PickupDate": null
           },
           "confirmationStatus": "None"
       }
   }
   ```

   For more information, see Input Event Format (p. 98).

   In addition to the information that the client sent, Amazon Lex also includes the following additional data:
   
   - messageVersion – Currently Amazon Lex supports only the 1.0 version.
   - invocationSource – Indicates the purpose of Lambda function invocation. In this case, it is to perform user data initialization and validation. At this time, Amazon Lex knows that the user has not provided all the slot data to fulfill the intent.
Exercise 1: Create a Bot Using a Blueprint

For information about the response format, see Response Format (p. 101).

Note the following:

- `dialogAction.type` – By setting this value to Delegate, Lambda function delegates the responsibility of deciding the next course of action to Amazon Lex.

Note
If Lambda function detects anything in the user data validation, it instructs Amazon Lex what to do next, as shown in the next few steps.

According to the `dialogAction.type`, Amazon Lex decides the next course of action. Because none of the slots are filled, it decides to elicit the value for the `FlowerType` slot. It selects one of the value elicitation prompts ("What type of flowers would you like to order?") for this slot and sends the following response back to the client:

The client displays the message in the response.

2. User: roses

a. The client sends the following PostText (p. 320) request to Amazon Lex:

```json
POST /bot/OrderFlowers/alias/#LATEST/user/ignw84y6seypre4xly5rimopuri2xwnd/text
"Content-Type":"application/json"
"Content-Encoding":"amz-1.0"
{
"inputText": "roses",
```
In the request body, the `inputText` provides user input. The `sessionAttributes` remains empty.

b. Amazon Lex first interprets the `inputText` in the context of the current intent. The service remembers that it had asked the specific user for information about the `FlowerType` slot. It updates the slot value in the current intent and invokes the Lambda function with the following event data:

```json
{
  "messageVersion": "1.0",
  "invocationSource": "DialogCodeHook",
  "userId": "ignw84y6aeypre4xly5rimopurizwud",
  "sessionAttributes": {},
  "bot": {
    "name": "OrderFlowers",
    "alias": null,
    "version": "$LATEST"
  },
  "outputDialogMode": "Text",
  "currentIntent": {
    "name": "OrderFlowers",
    "slots": {
      "PickupTime": null,
      "FlowerType": "roses",
      "PickupDate": null
    },
    "confirmationStatus": "None"
  }
}
```

Note the following:

- `invocationSource` - continues to be `DialogCodeHook` (we are simply validating user data).
- `currentIntent.slots` - Amazon Lex has updated the `FlowerType` slot to roses.

c. According to the `invocationSource` value of `DialogCodeHook`, the Lambda function performs user data validation. It recognizes `roses` as a valid slot value (and sets `Price` as a session attribute) and returns the following response to Amazon Lex.

```json
{
  "sessionAttributes": {
    "Price": 25
  },
  "dialogAction": {
    "type": "Delegate",
    "slots": {
      "PickupTime": null,
      "FlowerType": "roses",
      "PickupDate": null
    }
  }
}
```

Note the following:

- `sessionAttributes` - Lambda function has added `Price` (of the roses) as a session attribute.
• `dialogAction.type` – is set to `Delegate`. The user data was valid so the Lambda function directs Amazon Lex to choose the next course of action.

d. According to the `dialogAction.type`, Amazon Lex chooses the next course of action. Amazon Lex knows it needs more slot data so it picks the next unfilled slot (PickupDate) with the highest priority according to the intent configuration. Amazon Lex selects one of the value-elicitation prompt messages—“What day do you want the roses to be picked up?”—for this slot according to the intent configuration, and then sends the following response back to the client:

```json
{  
  "dialogState": "ElicitSlot",
  "intentName": "OrderFlowers",
  "message": "What day do you want the roses to be picked up?",
  "responseCard": null,
  "sessionAttributes": {  
    "PickupDate": "tomorrow"  
  },
  "slots": {  
    "Flower": "roses"  
  }
}
```

The client simply displays the message in the response – "What day do you want the roses to be picked up?"

3. User: tomorrow

a. The client sends the following `PostText` (p. 320) request to Amazon Lex:

```
POST /bot/OrderFlowers/alias/$LATEST/user/ignw84y6seypre4xly5rimopuri2xwnd2/text
"Content-Type": "application/json"
"Content-Encoding": "amz-1.0"
{
  "inputText": "tomorrow",
  "sessionAttributes": {
    "Price": "25"
  }
}
```

In the request body, `inputText` provides user input and the client passes the session attributes back to the service.

b. Amazon Lex remembers the context—that it was eliciting data for the PickupDate slot. In this context, it knows the `inputText` value is for the PickupDate slot. Amazon Lex then invokes the Lambda function by sending the following event:

```
{
  "messageVersion": "1.0",
  "invocationSource": "DialogCodeHook",
  "userId": "ignw84y6seypre4xly5rimopuri2xwnd2",
  "sessionAttributes": {
    "Price": "25"
  },
  "bot": {
    "name": "OrderFlowersCustomWithRespCard",
```
Exercise 1: Create a Bot Using a Blueprint

Amazon Lex has updated the `currentIntent.slots` by setting the `PickupDate` value. Also note that the service passes the `sessionAttributes` as it is to the Lambda function.

c. As per `invocationSource` value of `DialogCodeHook`, the Lambda function performs user data validation. It recognizes `PickupDate` slot value is valid and returns the following response to Amazon Lex:

```
{
    "sessionAttributes": {
        "Price": 25
    },
    "dialogAction": {
        "type": "Delegate",
        "slots": {
            "PickupTime": null,
            "FlowerType": "roses",
            "PickupDate": "2017-01-05"
        }
    }
}
```

Note the following:

- `sessionAttributes` – No change.
- `dialogAction.type` – is set to `Delegate`. The user data was valid, and the Lambda function directs Amazon Lex to choose the next course of action.

d. According to the `dialogAction.type`, Amazon Lex chooses the next course of action. Amazon Lex knows it needs more slot data so it picks the next unfilled slot (`PickupTime`) with the highest priority according to the intent configuration. Amazon Lex selects one of the prompt messages ("Deliver the roses at what time on 2017-01-01?") for this slot according to the intent configuration and sends the following response back to the client:
The client displays the message in the response – "Deliver the roses at what time on 2017-01-01?"

4. User: 4 pm
   a. The client sends the following PostText (p. 320) request to Amazon Lex:

   ```json
   POST /bot/OrderFlowers/alias/$LATEST/user/ignw84y6seypre4xly5rimopuri2xwnd/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   {
       "inputText": "4 pm",
       "sessionAttributes": {
           "Price": "25"
       }
   }
   ```

   In the request body, `inputText` provides user input. The client passes the `sessionAttributes` in the request.

   b. Amazon Lex understands context. It understands that it was eliciting data for the `PickupTime` slot. In this context, it knows that the `inputText` value is for the `PickupTime` slot. Amazon Lex then invokes the Lambda function by sending the following event:

   ```json
   {
       "messageVersion": "1.0",
       "invocationSource": "DialogCodeHook",
       "userId": "ignw84y6seypre4xly5rimopuri2xwnd",
       "sessionAttributes": {
           "Price": "25"
       },
       "bot": {
           "name": "OrderFlowersCustomWithRespCard",
           "alias": null,
           "version": "$LATEST"
       },
       "outputDialogMode": "Text",
       "currentIntent": {
           "name": "OrderFlowers",
           "slots": {
               "PickupTime": "16:00",
               "FlowerType": "roses",
               "PickupDate": "2017-01-05"
           },
           "confirmationStatus": "None"
       }
   }
   ```
Amazon Lex Developer Guide
Exercise 1: Create a Bot Using a Blueprint

Amazon Lex has updated the `currentIntent.slots` by setting the `PickupTime` value.

c. According to the `invocationSource` value of `DialogCodeHook`, the Lambda function performs user data validation. It recognizes `PickupDate` slot value is valid and returns the following response to Amazon Lex:

```
{
    "sessionAttributes": {
        "Price": 25
    },
    "dialogAction": {
        "type": "Delegate",
        "slots": {
            "PickupTime": "16:00",
            "FlowerType": "roses",
            "PickupDate": "2017-01-05"
        }
    }
}
```

Note the following:

- `sessionAttributes` – No change in session attribute.
- `dialogAction.type` – is set to `Delegate`. The user data was valid so the Lambda function directs Amazon Lex to choose the next course of action.

d. At this time Amazon Lex knows it has all the slot data. This intent is configured with a confirmation prompt. Therefore, Amazon Lex sends the following response to the user asking for confirmation before fulfilling the intent:

```
The client simply displays the message in the response and waits for the user response.
```

5. User: Yes

a. The client sends the following `PostText` (p. 320) request to Amazon Lex:

```
POST /bot/OrderFlowers/alias/$LATEST/user/ignw84y6seypre4xly5rimopuri2xwnd/text
"Content-Type":"application/json"
"Content-Encoding":"amz-1.0"
{
    "inputText": "yes",
```
b. Amazon Lex interprets the inputText in the context of confirming the current intent. Amazon Lex understands that the user wants to proceed with the order. This time Amazon Lex invokes the Lambda function to fulfill the intent by sending the following event, which sets the invocationSource to FulfillmentCodeHook in the event it sends to the Lambda function. Amazon Lex also sets the confirmationStatus to Confirmed.

```
{
   "messageVersion": "1.0",
   "invocationSource": "FulfillmentCodeHook",
   "userId": "ignw84y6seypre4xly5rimopuri2xwnd",
   "sessionAttributes": {
      "Price": "25"
   },
   "bot": {
      "name": "OrderFlowersCustomWithRespCard",
      "alias": null,
      "version": "$LATEST"
   },
   "outputDialogMode": "Text",
   "currentIntent": {
      "name": "OrderFlowers",
      "slots": {
         "PickupTime": "16:00",
         "FlowerType": "roses",
         "PickupDate": "2017-01-05"
      },
      "confirmationStatus": "Confirmed"
   }
}
```

Note the following:

- **invocationSource** – This time Amazon Lex set this value to FulfillmentCodeHook, directing the Lambda function to fulfill the intent.
- **confirmationStatus** – is set to Confirmed.

c. This time, the Lambda function fulfills the OrderFlowers intent, and returns the following response:

```
{
   "sessionAttributes": {
      "Price": "25"
   },
   "dialogAction": {
      "type": "Close",
      "fulfillmentState": "Fulfilled",
      "message": {
         "contentType": "PlainText",
         "content": "Thanks, your order for roses has been placed and will be ready for pickup by 16:00 on 2017-01-05"
      }
   }
}
```

Note the following:
• Sets the `dialogAction.type` – The Lambda function sets this value to `Close`, directing Amazon Lex to not expect a user response.

• `dialogAction.fulfillmentState` – is set to `Fulfilled` and includes an appropriate message to convey to the user.

d. Amazon Lex reviews the `fulfillmentState` and sends the following response back to the client.

Amazon Lex then returns the following to the client:

```
dialogState: "Fulfilled"
intentName: "OrderFlowers"
message: "Thanks, your order for roses has been placed and will be ready for pickup by 16:00 on 2017-01-05."
responseCard: null

sessionAttributes: Object
  Price: "25.00"
  slotToElicit: null

slots: Object
  FlowerType: "roses"
  PickupDate: "2017-01-05"
  PickupTime: "15:00"
```

Note that:

• `dialogState` – Amazon Lex sets this value to `fulfilled`.

• `message` – is the same message that the Lambda function provided.

The client displays the message.

6. Now test the bot again. To establish a new (user) context, choose the **Clear** link in the test window. Now provide invalid slot data for the `OrderFlowers` intent. This time the Lambda function performs the data validation, resets invalid slot data value to null, and asks Amazon Lex to prompt the user for valid data. For example, try the following:

• Jasmine as the flower type (it is not one of the supported flower types).

• Yesterday as the day when you want to pick up the flowers.

• After placing your order, enter another flower type instead of replying "yes" to confirm the order. In response, the Lambda function updates the `Price` in the session attribute, keeping a running total of flower orders.

The Lambda function also performs the fulfillment activity.

**Next Step**

**Step 6: Update the Intent Configuration to Add an Utterance (Console) (p. 54)**

**Step 6: Update the Intent Configuration to Add an Utterance (Console)**

The `OrderFlowers` bot is configured with only two utterances. This provides limited information for Amazon Lex to build a machine learning model that recognizes and responds to the user's intent. Try
typing "I want to order flowers" in the test window. Amazon Lex doesn't recognize the text, and responds with "I didn't understand you, what would you like to do?" You can improve the machine learning model by adding more utterances.

Each utterance that you add provides Amazon Lex with more information about how to respond to your users. You don't need to add an exact utterance, Amazon Lex generalizes from the samples that you provide to recognize both exact matches and similar input.

**To add an utterance (console)**

1. Add the utterance "I want flowers" to the intent by typing it in the Sample utterances section of the intent editor, and then clicking the plus icon next to the new utterance.

2. Build your bot to pick up the change. Choose Build, and then choose Build again.

3. Test your bot to confirm that it recognized the new utterance. In the test window, type "I want to order flowers." Amazon Lex recognizes the phrase and responds with "What type of flowers would you like to order?".
Next Step

Step 7 (Optional): Clean Up (Console) (p. 56)

Step 7 (Optional): Clean Up (Console)

Now, delete the resources that you created and clean up your account.

You can delete only resources that are not in use. In general, you should delete resources in the following order:

- Delete bots to free up intent resources.
- Delete intents to free up slot type resources.
- Delete slot types last.

To clean up your account (console)

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. From the list of bots, choose the check box next to OrderFlowers.
3. To delete the bot, choose Delete, and then choose Continue in the confirmation dialog box.
4. In the left pane, choose Intents.
5. In the list of intents, choose OrderFlowersIntent.
6. To delete the intent, choose Delete, and then choose Continue in the confirmation dialog box.
7. In the left pane, choose Slot types.
8. In the list of slot types, choose Flowers.
9. To delete the slot type, choose Delete, and then choose Continue in the confirmation dialog box.

You have removed all of the resources that you created and cleaned up your account.
Exercise 2: Create a Custom Amazon Lex Bot

In this exercise, you use the Amazon Lex console to create a custom bot that orders pizza (OrderPizzaBot). You configure the bot by adding a custom intent (OrderPizza), defining custom slot types, and defining the slots required to fulfill a pizza order (pizza crust, size, and so on). For more information about slot types and slots, see Amazon Lex: How It Works (p. 3).

Topics
• Step 1: Create a Lambda Function (p. 57)
• Step 2: Create a Bot (p. 59)
• Step 3: Build and Test the Bot (p. 64)
• Step 4 (Optional): Clean up (p. 67)

Step 1: Create a Lambda Function

First, create a Lambda function which fulfills a pizza order. You specify this function in your Amazon Lex bot, which you create in the next section.

To create a Lambda function

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create function.
3. On the Create function page, choose Author from scratch.

Because you are using custom code provided to you in this exercise to create a Lambda function, you choose author the function from scratch.

Do the following:
   a. Type the name (PizzaOrderProcessor).
   b. For the Runtime, choose Node.js 4.3.
   c. For the Role, choose Create new role from template(s).
   d. Enter a new role name (PizzaOrderProcessorRole).
   e. Choose Create function.
4. On the function page, do the following:

   In the Function code section, choose Edit code inline, and then copy the following Node.js function code and paste it in the window.

```
'use strict';

// Close dialog with the customer, reporting fulfillmentState of Failed or Fulfilled
("Thanks, your pizza will arrive in 20 minutes")
function close(sessionAttributes, fulfillmentState, message) {
    return {
        sessionAttributes,
        dialogAction: {
            type: 'Close',
            fulfillmentState,
            message,
        },
    };
}
```
function dispatch(intentRequest, callback) {
  console.log(`request received for userId=${intentRequest.userId}, intentName=${intentRequest.currentIntent.name}`);
  const sessionAttributes = intentRequest.sessionAttributes;
  const slots = intentRequest.currentIntent.slots;
  const crust = slots.crust;
  const size = slots.size;
  const pizzaKind = slots.pizzaKind;
  callback(close(sessionAttributes, 'Fulfilled',
    {'contentType': 'PlainText', 'content': `Okay, I have ordered your ${size} ${pizzaKind} pizza on ${crust} crust`}))
}

exports.handler = (event, context, callback) => {
  try {
    dispatch(event,
      (response) => {
        callback(null, response);
      });
  } catch (err) {
    callback(err);
  }
}

5. Choose Save.

Test the Lambda Function Using Sample Event Data

In the console, test the Lambda function by using sample event data to manually invoke it.

To test the Lambda function:

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. On the Lambda function page, choose the Lambda function (PizzaOrderProcessor).
3. On the function page, in the list of test events, choose Configure test events.
4. On the Configure test event page, do the following:
   a. Choose Create new test event.
   b. In the Event name field, enter a name for the event (PizzaOrderProcessorTest).
   c. Copy the following Amazon Lex event into the window.

```json
{
  "messageVersion": "1.0",
  "invocationSource": "FulfillmentCodeHook",
  "userId": "user-1",
  "sessionAttributes": {},
  "bot": {
    "name": "PizzaOrderingApp",
    "alias": "$LATEST",
    "version": "$LATEST"
  }
}
```
"outputDialogMode": "Text",
"currentIntent": {
  "name": "OrderPizza",
  "slots": {
    "size": "large",
    "pizzaKind": "meat",
    "crust": "thin"
  },
  "confirmationStatus": "None"
}
}

5. Choose Create.

AWS Lambda creates the test and you go back to the function page. Choose Test and Lambda executes your Lambda function.

In the result box, choose Details. The console displays the following output in the Execution result pane.

```
{
  "sessionAttributes": {},
  "dialogAction": {
    "type": "Close",
    "fulfillmentState": "Fulfilled",
    "message": {
      "contentType": "PlainText",
      "content": "Okay, I have ordered your large meat pizza on thin crust."
    }
  }
}
```

Next Step

Step 2: Create a Bot (p. 59)

**Step 2: Create a Bot**

In this step, you create a bot to handle pizza orders.

**Topics**

- Create the Bot (p. 59)
- Create an Intent (p. 60)
- Create Slot Types (p. 60)
- Configure the Intent (p. 62)
- Configure the Bot (p. 63)

**Create the Bot**

Create the PizzaOrderingBot bot with the minimum information needed. You add an intent, an action that the user wants to perform, for the bot later.

**To create the bot**

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. Create a bot.
a. If you are creating your first bot, choose **Get Started**. Otherwise, choose **Bots**, and then choose **Create**.

b. On the **Create your Lex bot** page, choose **Custom bot** and provide the following information:

- **App name**: PizzaOrderingBot
- **Output voice**: Salli
- **Session timeout**: 5 minutes.
- **Child-Directed**: Choose the appropriate response.

c. Choose **Create**.

The console sends Amazon Lex a request to create a new bot. Amazon Lex sets the bot version to **$LATEST**. After creating the bot, Amazon Lex shows the bot **Editor** tab:

- The bot version, **Latest**, appears next to the bot name in the console. New Amazon Lex resources have **$LATEST** as the version. For more information, see **Versioning and Aliases (p. 94)**.
- Because you haven't created any intents or slots types, none are listed.
- **Build** and **Publish** are bot-level activities. After you configure the entire bot, you'll learn more about these activities.

**Next Step**

Create an Intent (p. 60)

**Create an Intent**

Now, create the **OrderPizza** intent, an action that the user wants to perform, with the minimum information needed. You add slot types for the intent and then configure the intent later.

**To create an intent**

1. In the Amazon Lex console, choose the plus sign (+) next to **Intents**, and then choose **Create new intent**.
2. In the **Create intent** dialog box, type the name of the intent (OrderPizza), and then choose **Add**.

The console sends a request to Amazon Lex to create the **OrderPizza** intent. You configure the intent after you create slot types.

**Next Step**

Create Slot Types (p. 60)

**Create Slot Types**

Create the slot types, or parameter values, that the **OrderPizza** intent uses.
To create slot types

1. In the left menu, choose the plus sign (+) next to Slot types.
2. In the Add slot type dialog box, add the following:
   - **Slot type name** – Crusts
   - **Description** – Available crusts
   - Choose **Restrict to Slot values and Synonyms**
   - **Value** – Type **thick**. Press tab and in the Synonym field type **stuffed**. Choose the plus sign (+). Type **thin** and then choose the plus sign (+) again.

The dialog should look like this:

3. Choose **Add slot to intent**.
4. On the Intent page, choose **Required**. Change the name of the slot from **slotOne** to **crust**. Change the prompt to **What kind of crust would you like?**
5. Repeat Step 1 through Step 4 using the values in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Values</th>
<th>Slot name</th>
<th>Prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sizes</td>
<td>Available sizes</td>
<td>small, medium, large</td>
<td>size</td>
<td>What size pizza?</td>
</tr>
<tr>
<td>PizzaKind</td>
<td>Available pizzas</td>
<td>veg, cheese</td>
<td>pizzaKind</td>
<td>Do you want a veg or cheese pizza?</td>
</tr>
</tbody>
</table>

**Next Step**

Configure the Intent (p. 62)
Configure the Intent

Configure the OrderPizza intent to fulfill a user’s request to order a pizza.

To configure an intent

- On the OrderPizza configuration page, configure the intent as follows:
  - **Sample utterances** – Type the following strings. The curly braces {} enclose slot names.
    - I want to order pizza please
    - I want to order a pizza
    - I want to order a {pizzaKind} pizza
    - I want to order a {size} {pizzaKind} pizza
    - I want a {size} {crust} crust {pizzaKind} pizza
    - Can I get a pizza please
    - Can I get a {pizzaKind} pizza
    - Can I get a {size} {pizzaKind} pizza
  - **Lambda initialization and validation** – Leave the default setting.
  - **Confirmation prompt** – Leave the default setting.
  - **Fulfillment** – Perform the following tasks:
    - Choose AWS Lambda function.
    - Choose PizzaOrderProcessor.
    - If the Add permission to Lambda function dialog box is shown, choose OK to give the OrderPizza intent permission to call the PizzaOrderProcessor Lambda function.
    - Leave None selected.

The intent should look like the following:
Configure error handling for the PizzaOrderingBot bot.

1. Navigate to the PizzaOrderingBot bot. Choose Editor, and then choose Error Handling.
2. Use the Editor tab to configure bot error handling.

   • Information you provide in Clarification Prompts maps to the bot's clarificationPrompt configuration.

     When Amazon Lex can't determine the user intent, the service returns a response with this message

   • Information that you provide in the Hang-up phrase maps to the bot's abortStatement configuration.

     If the service can't determine the user's intent after a set number of consecutive requests, Amazon Lex returns a response with this message.

     Leave the defaults.

Next Step

Step 3: Build and Test the Bot (p. 64)

Step 3: Build and Test the Bot

Make sure the bot works, by building and testing it.

To build and test the bot

1. To build the PizzaOrderingBot bot, choose Build.

   Amazon Lex builds a machine learning model for the bot. When you test the bot, the console uses the runtime API to send the user input back to Amazon Lex. Amazon Lex then uses the machine learning model to interpret the user input.

   It can take some time to complete the build.

2. To test the bot, in the Test Bot window, start communicating with your Amazon Lex bot.

   • For example, you might say or type:
Use the sample utterances that you configured in the OrderPizza intent to test the bot. For example, the following is one of the sample utterances that you configured for the PizzaOrder intent:

I want a {size} {crust} crust {pizzaKind} pizza

To test it, type the following:

I want a large thin crust cheese pizza

When you type "I want to order a pizza," Amazon Lex detects the intent (OrderPizza). Then, Amazon Lex asks for slot information.

After you provide all of the slot information, Amazon Lex invokes the Lambda function that you configured for the intent.

The Lambda function returns a message ("Okay, I have ordered your ...") to Amazon Lex, which Amazon Lex returns to you.

**Inspecting the Response**

Underneath the chat window is a pane that enables you to inspect the response from Amazon Lex. The pane provides comprehensive information about the state of your bot that changes as you interact with your bot.

The contents of the pane show you the current state of the operation.
• **Dialog State** – The current state of the conversation with the user. It can be `ElicitIntent`, `ElicitSlot`, `ConfirmIntent` or `Fulfilled`.

• **Summary** – Shows a simplified view of the dialog that shows the slot values for the intent being fulfilled so that you can keep track of the information flow. It shows the intent name, the number of slots and the number of slots filled, and a list of all of the slots and their associated values.

```
Inspect Response
Dialog State: ElicitSlot

Summary  Detail

Intent: OrderPizza

Slots   (2/3)
crust   null
pizzaKind cheese
size    large
```

• **Detail** – Shows the raw JSON response from the chatbot to give you a deeper view into the bot interaction and the current state of the dialog as you test and debug your chatbot. If you type in the chat window, the inspection pane shows the JSON response from the `PostText` (p. 320) operation. If you speak to the chat window, the inspection pane shows the response headers from the `PostContent` (p. 312) operation.
Delete the resources that you created and clean up your account to avoid incurring more charges for the resources you created.

You can delete only resources that are not in use. For example, you cannot delete a slot type that is referenced by an intent. You cannot delete an intent that is referenced by a bot.

Delete resources in the following order:

- Delete bots to free up intent resources.
- Delete intents to free up slot type resources.
- Delete slot types last.

To clean up your account

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. From the list of bots, choose PizzaOrderingBot.
3. To delete the bot, choose Delete, and then choose Continue.
4. In the left pane, choose Intents.
5. In the list of intents, choose OrderPizza.
6. To delete the intent, choose **Delete**, and then choose **Continue**.
7. In the left menu, choose **Slot types**.
8. In the list of slot types, choose **Crusts**.
9. To delete the slot type, choose **Delete**, and then choose **Continue**.
10. Repeat Step 8 and Step 9 for the **Sizes** and **PizzaKind** slot types.

You have removed all of the resources that you created and cleaned up your account.

**Next Steps**

- Publish a Version and Create an Alias
- Create an Amazon Lex bot with the AWS Command Line Interface

**Exercise 3: Publish a Version and Create an Alias**

In Getting Started Exercises 1 and 2, you created a bot and tested it. In this exercise, you do the following:

- Publish a new version of the bot. Amazon Lex takes a snapshot copy of the $LATEST version to publish a new version.
- Create an alias that points to the new version.

For more information about versioning and aliases, see Versioning and Aliases (p. 94).

Do the following to publish a version of a bot you created for this exercise:

1. In the Amazon Lex console, choose one of the bots you created.
   Verify that the console shows the $LATEST as the bot version next to the bot name.
2. Choose **Publish**.
3. On the **Publish botname** wizard, specify an alias (BETA), and then choose **Publish**.
4. Verify that the Amazon Lex console shows the new version next to the bot name.

Now that you have a working bot with published version and an alias, you can deploy the bot (in your mobile application or integrate the bot with Facebook Messenger). For an example, see Integrating an Amazon Lex Bot with Facebook Messenger (p. 107).
Step 4: Getting Started (AWS CLI)

In this step, you use the AWS CLI to create, test, and modify an Amazon Lex bot. To complete these exercises, you need to be familiar with using the CLI and have a text editor. For more information, see Step 2: Set Up the AWS Command Line Interface (p. 29)

- Exercise 1 — Create and test an Amazon Lex bot. The exercise provides all of the JSON objects that you need to create a custom slot type, an intent, and a bot. For more information, see Amazon Lex: How It Works (p. 3)
- Exercise 2 — Update the bot that you created in Exercise 1 to add an additional sample utterance. Amazon Lex uses sample utterances to build the machine learning model for your bot.
- Exercise 3 — Update the bot that you created in Exercise 1 to add a Lambda function to validate user input and to fulfill the intent.
- Exercise 4 — Publish a version of the slot type, intent, and bot resources that you created in Exercise 1. A version is a snapshot of a resource that can't be changed.
- Exercise 5 — Create an alias for the bot that you created in Exercise 1.
- Exercise 6 — Clean up your account by deleting the slot type, intent, and bot that you created in Exercise 1, and the alias that you created in Exercise 5.

Topics
- Exercise 1: Create an Amazon Lex Bot (AWS CLI) (p. 69)
- Exercise 2: Add a New Utterance (AWS CLI) (p. 81)
- Exercise 3: Add a Lambda Function (AWS CLI) (p. 85)
- Exercise 4: Publish a Version (AWS CLI) (p. 88)
- Exercise 5: Create an Alias (AWS CLI) (p. 92)
- Exercise 6: Clean Up (AWS CLI) (p. 93)

Exercise 1: Create an Amazon Lex Bot (AWS CLI)

In general, when you create bots, you:

1. Create slot types to define the information that your bot will be working with.
2. Create intents that define the user actions that your bot supports. Use the custom slot types that you created earlier to define the slots, or parameters, that your intent requires.
3. Create a bot that uses the intents that you defined.

In this exercise you create and test a new Amazon Lex bot using the CLI. Use the JSON structures that we provide to create the bot.

Topics
- Step 1: Create a Service-Linked Role (AWS CLI) (p. 70)
- Step 2: Create a Custom Slot Type (AWS CLI) (p. 70)
- Step 3: Create an Intent (AWS CLI) (p. 71)
- Step 4: Create a Bot (AWS CLI) (p. 75)
- Step 5: Test a Bot (AWS CLI) (p. 77)
Step 1: Create a Service-Linked Role (AWS CLI)

Amazon Lex assumes AWS Identity and Access Management service-linked roles to call AWS services on behalf of your bots. The roles, which are in your account, are linked to Amazon Lex use cases and have predefined permissions. For more information, see Service Permissions (p. 8).

If you've already created an Amazon Lex bot using the console, the service-linked role was created automatically. Skip to Step 2: Create a Custom Slot Type (AWS CLI) (p. 70).

To create a service-linked role (AWS CLI)

1. In the AWS CLI, type the following command:

   ```bash
   aws iam create-service-linked-role --aws-service-name lex.amazonaws.com
   ```

2. Check the policy using the following command:

   ```bash
   aws iam get-role --role-name AWSServiceRoleForLexBots
   ```

   The response is:

   ```json
   {
     "Role": {
       "AssumeRolePolicyDocument": {
         "Version": "2012-10-17",
         "Statement": [
           {
             "Action": "sts:AssumeRole",
             "Effect": "Allow",
             "Principal": {
               "Service": "lex.amazonaws.com"
             }
           }
         ]
       },
       "RoleName": "AWSServiceRoleForLexBots",
       "Path": "/aws-service-role/lex.amazonaws.com/",
       "Arn": "arn:aws:iam::account-id:role/aws-service-role/lex.amazonaws.com/ AWSServiceRoleForLexBots"
     }
   }
   ```

Next Step

Step 2: Create a Custom Slot Type (AWS CLI) (p. 70)

Step 2: Create a Custom Slot Type (AWS CLI)

Create a custom slot type with enumeration values for the flowers that can be ordered. You use this type in the next step when you create the OrderFlowers intent. A slot type defines the possible values for a slot, or parameter, of the intent.

To create a custom slot type (AWS CLI)

1. Create a text file named `FlowerTypes.json`. Copy the JSON code from FlowerTypes.json (p. 71) into the text file.

2. Call the PutSlotType (p. 307) operation using the AWS CLI to create the slot type. The example is formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

   ```json
   {
     "Role": {
       "AssumeRolePolicyDocument": {
         "Version": "2012-10-17",
         "Statement": [
           {
             "Action": "sts:AssumeRole",
             "Effect": "Allow",
             "Principal": {
               "Service": "lex.amazonaws.com"
             }
           }
         ]
       },
       "RoleName": "AWSServiceRoleForLexBots",
       "Path": "/aws-service-role/lex.amazonaws.com/",
       "Arn": "arn:aws:iam::account-id:role/aws-service-role/lex.amazonaws.com/ AWSServiceRoleForLexBots"
     }
   }
   ```
aws lex-models put-slot-type \
--region region \
--endpoint endpoint \
--name FlowerTypes \
--cli-input-json file://FlowerTypes.json

The response from the server is:

```json
{
    "enumerationValues": [
        {
            "value": "tulips"
        },
        {
            "value": "lilies"
        },
        {
            "value": "roses"
        }
    ],
    "name": "FlowerTypes",
    "checksum": "checksum",
    "version": "$LATEST",
    "lastUpdatedDate": "timestamp",
    "createdDate": "timestamp",
    "description": "Types of flowers to pick up"
}
```

Next Step

Step 3: Create an Intent (AWS CLI) (p. 71)

FlowerTypes.json

The following code is the JSON data required to create the FlowerTypes custom slot type:

```json
{
    "enumerationValues": [
        {
            "value": "tulips"
        },
        {
            "value": "lilies"
        },
        {
            "value": "roses"
        }
    ],
    "name": "FlowerTypes",
    "description": "Types of flowers to pick up"
}
```

Step 3: Create an Intent (AWS CLI)

Create an intent for the OrderFlowersBot bot and provide three slots, or parameters. The slots allow the bot to fulfill the intent:

- FlowerType is a custom slot type that specifies which types of flowers can be ordered.
• **AMAZON.DATE** and **AMAZON.TIME** are built-in slot types used for getting the date and time to deliver the flowers from the user.

**To create the OrderFlowers intent (AWS CLI)**

1. Create a text file named **OrderFlowers.json**. Copy the JSON code from OrderFlowers.json (p. 73) into the text file.

2. In the AWS CLI, call the **PutIntent** (p. 297) operation to create the intent. The example is formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

   ```bash
   aws lex-models put-intent \
   --region region \
   --endpoint endpoint \
   --name OrderFlowers \
   --cli-input-json file://OrderFlowers.json
   ```

   The server responds with the following:

   ```json
   {
     "confirmationPrompt": {
       "maxAttempts": 2,
       "messages": [
         {
           "content": "Okay, your {FlowerType} will be ready for pickup by {PickupTime} on {PickupDate}. Does this sound okay?",
           "contentType": "PlainText"
         }
       ],
       "name": "OrderFlowers",
       "checksum": "checksum",
       "version": "$LATEST",
       "rejectionStatement": {
         "messages": [
           {
             "content": "Okay, I will not place your order.",
             "contentType": "PlainText"
           }
         ],
       },
       "createdDate": timestamp,
       "lastUpdatedDate": timestamp,
       "sampleUtterances": [
         "I would like to pick up flowers",
         "I would like to order some flowers"
       ],
       "slots": [
         {
           "slotType": "AMAZON_TIME",
           "name": "PickupTime",
           "slotConstraint": "Required",
           "valueElicitationPrompt": {
             "maxAttempts": 2,
             "messages": [
               {
                 "content": "Pick up the {FlowerType} at what time on {PickupDate}?",
                 "contentType": "PlainText"
               }
             ],
           }
         }
       ]
   }
   ```
Next Step

Step 4: Create a Bot (AWS CLI) (p. 75)

OrderFlowers.json

The following code is the JSON data required to create the OrderFlowers intent:

```json
{
  "confirmationPrompt": {
    "maxAttempts": 2,
    "messages": [
      {
        "content": "Okay, your {FlowerType} will be ready for pickup by {PickupTime} on {PickupDate}. Does this sound okay?",
        "contentType": "PlainText"
      }
    ]
  },
  "fulfillmentActivity": {
    "type": "ReturnIntent"
  },
  "description": "Intent to order a bouquet of flowers for pick up"
}
```
"contentType": "PlainText"

},
"name": "OrderFlowers",
"rejectionStatement": {
  "messages": [
    {
      "content": "Okay, I will not place your order.",
      "contentType": "PlainText"
    }
  ]
},
"sampleUtterances": [
  "I would like to pick up flowers",
  "I would like to order some flowers"
],
"slots": [
  {
    "slotType": "FlowerTypes",
    "name": "FlowerType",
    "slotConstraint": "Required",
    "valueElicitationPrompt": {
      "maxAttempts": 2,
      "messages": [
        {
          "content": "What type of flowers would you like to order?",
          "contentType": "PlainText"
        }
      ]
    },
    "priority": 1,
    "slotTypeVersion": "$LATEST",
    "sampleUtterances": [
      "I would like to order {FlowerType}"
    ],
    "description": "The type of flowers to pick up"
  },
  {
    "slotType": "AMAZON.DATE",
    "name": "PickupDate",
    "slotConstraint": "Required",
    "valueElicitationPrompt": {
      "maxAttempts": 2,
      "messages": [
        {
          "content": "What day do you want the {FlowerType} to be picked up?",
          "contentType": "PlainText"
        }
      ]
    },
    "priority": 2,
    "description": "The date to pick up the flowers"
  },
  {
    "slotType": "AMAZON.TIME",
    "name": "PickupTime",
    "slotConstraint": "Required",
    "valueElicitationPrompt": {
      "maxAttempts": 2,
      "messages": [
        {
          "content": "Pick up the {FlowerType} at what time on {PickupDate}?",
          "contentType": "PlainText"
        }
      ]
    },
    "priority": 3,
    "description": "The time to pick up the flowers"
  }
]
Step 4: Create a Bot (AWS CLI)

The OrderFlowersBot bot has one intent, the OrderFlowers intent that you created in the previous step.

Note
The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "$LATEST" to $LATEST.

To create the OrderFlowersBot bot (AWS CLI)

1. Create a text file named OrderFlowersBot.json. Copy the JSON code from OrderFlowersBot.json (p. 76) into the text file.

2. In the AWS CLI, call the PutBot (p. 285) operation to create the bot. The example is formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

```bash
aws lex-models put-bot \
  --region region \ 
  --endpoint endpoint \ 
  --name OrderFlowersBot \ 
  --cli-input-json file://OrderFlowersBot.json
```

The response from the server follows. When you create or update bot, the status field is set to BUILDING. This indicates that the bot isn't ready to use. To determine when the bot is ready for use, use the GetBot (p. 230) operation in the next step.

```json
{
  "status": "BUILDING",
  "intents": [
    {
      "intentVersion": "$LATEST",
      "intentName": "OrderFlowers"
    }
  ],
  "name": "OrderFlowersBot",
  "locale": "en-US",
  "checksum": "checksum",
  "abortStatement": {
    "messages": [
      {
        "content": "Sorry, I'm not able to assist at this time",
        "contentType": "PlainText"
      }
    ]
  },
  "version": "$LATEST",
  "lastUpdatedDate": "timestamp",
...}
Exercise 1: Create a Bot

3. To determine if your new bot is ready for use, run the following command. Repeat this command until the status field returns READY. The example is formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

```bash
aws lex-models get-bot
  --region region
  --endpoint endpoint
  --name OrderFlowersBot
  --version-or-alias "$LATEST"
```

Look for the status field in the response:

```json
{
  "status": "READY",
  ...
}
```

Next Step

Step 5: Test a Bot (AWS CLI) (p. 77)

OrderFlowersBot.json

The following code provides the JSON data required to build the OrderFlowers Amazon Lex bot:

```json
{
  "intents": [
    {
      "intentVersion": "$LATEST",
      "intentName": "OrderFlowers"
    }
  ],
  "name": "OrderFlowersBot",
  "locale": "en-US",
  "abortStatement": {
    "messages": [
      {
        "content": "Sorry, I'm not able to assist at this time",
        "contentType": "PlainText"
      }]
  }
}```
Step 5: Test a Bot (AWS CLI)

To test the bot, you can use either a text-based or a speech-based test.

Topics
- Test the Bot Using Text Input (AWS CLI) (p. 77)
- Test the Bot Using Speech Input (AWS CLI) (p. 78)

Test the Bot Using Text Input (AWS CLI)

To verify that the bot works correctly with text input, use the PostText (p. 320) operation.

**Note**
The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to $LATEST and replace the backslash (\) continuation character at the end of each line with a caret (^).

To use text to test the bot (AWS CLI)

1. In the AWS CLI, start a conversation with the OrderFlowersBot bot. The example is formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

   ```bash
   aws lex-runtime post-text \
   --region region \
   --endpoint endpoint \
   --bot-name OrderFlowersBot \
   --bot-alias "$LATEST" \
   --user-id UserOne \
   --input-text "i would like to order flowers"
   ``

Amazon Lex recognizes the user's intent and starts a conversation by returning the following response:

```json
{
   "slotToElicit": "FlowerType",
   "slots": {
      "PickupDate": null,
      "PickupTime": null,
      "FlowerType": null
   }
}
```
"dialogState": "ElicitSlot",
"message": "What type of flowers would you like to order?",
"intentName": "OrderFlowers"
}

2. Run the following commands to finish the conversation with the bot.

```
aws lex-runtime post-text \
--region region \
--endpoint endpoint \
--bot-name OrderFlowersBot \
--bot-alias "\$LATEST" \
--user-id UserOne \
--input-text "roses"
```

```
aws lex-runtime post-text \
--region region \
--endpoint endpoint \
--bot-name OrderFlowersBot \
--bot-alias "\$LATEST" \
--user-id UserOne \
--input-text "tuesday"
```

```
aws lex-runtime post-text \
--region region \
--endpoint endpoint \
--bot-name OrderFlowersBot --bot-alias "\$LATEST" \
--user-id UserOne \
--input-text "10:00 a.m."
```

```
aws lex-runtime post-text \
--region region \
--endpoint endpoint \
--bot-name OrderFlowersBot --bot-alias "\$LATEST" \
--user-id UserOne \
--input-text "yes"
```

After you confirm the order, Amazon Lex sends a fulfillment response to complete the conversation:

```
{
  "slots": {
    "PickupDate": "2017-05-16",
    "PickupTime": "10:00",
    "FlowerType": "roses"
  },
  "dialogState": "ReadyForFulfillment",
  "intentName": "OrderFlowers"
}
```

Next Step

Test the Bot Using Speech Input (AWS CLI) (p. 78)

Test the Bot Using Speech Input (AWS CLI)

To test the bot using audio files, use the PostContent (p. 312) operation. You generate the audio files using Amazon Polly text-to-speech operations.
Note
The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to $LATEST and replace the backslash (\) continuation character at the end of each line with a caret (^).

To use a speech input to test the bot (AWS CLI)

1. In the AWS CLI, create an audio file using Amazon Polly. The example is formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

```bash
aws polly synthesize-speech \
    --region region \
    --endpoint endpoint \
    --output-format pcm \
    --text "i would like to order flowers" \
    --voice-id "Kendra" \
    IntentSpeech.mpg
```

2. To send the audio file to Amazon Lex, run the following command. Amazon Lex saves the audio from the response in the specified output file.

```bash
aws lex-runtime post-content \
    --region region \
    --endpoint endpoint \
    --bot-name OrderFlowersBot \
    --bot-alias "\$LATEST" \
    --user-id UserOne \
    --content-type "audio/l16; rate=16000; channels=1" \
    --input-stream IntentSpeech.mpg \
    IntentOutputSpeech.mpg
```

Amazon Lex responds with a request for the first slot. It saves the audio response in the specified output file.

```
{
    "contentType": "audio/mpeg",
    "slotToElicit": "FlowerType",
    "dialogState": "ElicitSlot",
    "intentName": "OrderFlowers",
    "inputTranscript": "i would like to order some flowers",
    "slots": {
        "PickupDate": null,
        "PickupTime": null,
        "FlowerType": null
    },
    "message": "What type of flowers would you like to order?"
}
```

3. To set the appointment type, create the following audio file and send it to Amazon Lex:

```bash
aws polly synthesize-speech \
    --region region \
    --endpoint endpoint \
    --output-format pcm \
    --text "roses" \
    --voice-id "Kendra"
FlowerTypeSpeech.mpg
```

```bash
aws lex-runtime post-content \
```

79
4. To set the appointment date, create the following audio file and send it to Amazon Lex:

```
aws polly synthesize-speech
--region region
--endpoint endpoint
--output-format pcm
--text "tuesday"
--voice-id "Kendra"
DateSpeech.mpg
```

```
aws lex-runtime post-content
--region region
--endpoint endpoint
--bot-name OrderFlowersBot
--bot-alias "$LATEST"
--user-id UserOne
--content-type "audio/l16; rate=16000; channels=1"
--input-stream DateSpeech.mpg
DateOutputSpeech.mpg
```

5. To set the appointment time, create the following audio file and send it to Amazon Lex:

```
aws polly synthesize-speech
--region region
--endpoint endpoint
--output-format pcm
--text "10:00 a.m."
--voice-id "Kendra"
TimeSpeech.mpg
```

```
aws lex-runtime post-content
--region region
--endpoint endpoint
--bot-name OrderFlowersBot
--bot-alias "$LATEST"
--user-id UserOne
--content-type "audio/l16; rate=16000; channels=1"
--input-stream TimeSpeech.mpg
TimeOutputSpeech.mpg
```

6. To confirm the appointment, create the following audio file and send it to Amazon Lex:

```
aws polly synthesize-speech
--region region
--endpoint endpoint
--output-format pcm
--text "yes"
--voice-id "Kendra"
ConfirmSpeech.mpg
```

```
aws lex-runtime post-content
```

After you confirm the appointment, Amazon Lex sends a response that confirms fulfillment of the intent:

```json
{
    "contentType": "text/plain;charset=utf-8",
    "dialogState": "ReadyForFulfillment",
    "intentName": "OrderFlowers",
    "inputTranscript": "yes",
    "slots": {
        "PickupDate": "2017-05-16",
        "PickupTime": "10:00",
        "FlowerType": "roses"
    }
}
```

Next Step

Exercise 2: Add a New Utterance (AWS CLI) (p. 81)

**Exercise 2: Add a New Utterance (AWS CLI)**

To improve the machine learning model that Amazon Lex uses to recognize requests from your users, add another sample utterance to the bot.

Adding a new utterance is a four-step process.

1. Use the GetIntent (p. 262) operation to get an intent from Amazon Lex.
2. Update the intent.
3. Use the PutIntent (p. 297) operation to send the updated intent back to Amazon Lex.
4. Use the GetBot (p. 230) and PutBot (p. 285) operations to rebuild any bot that uses the intent.

The response from the GetIntent operation contains a field called checksum that identifies a specific revision of the intent. You must provide the checksum value when you use the PutIntent (p. 297) operation to update an intent. If you don't, you'll get the following error message:

```
An error occurred (PreconditionFailedException) when calling the PutIntent operation: Intent intent name already exists. If you are trying to update intent name you must specify the checksum.
```

Note

The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to $LATEST and replace the backslash (\) continuation character at the end of each line with a caret (^).
To update the OrderFlowers intent (AWS CLI)

1. In the AWS CLI, get the intent from Amazon Lex. Amazon Lex sends the output to a file called OrderFlowers-V2.json.

   ```bash
   aws lex-models get-intent \
   --region region \
   --endpoint endpoint \
   --name OrderFlowers \
   --intent-version "$LATEST" > OrderFlowers-V2.json
   ```

2. Open OrderFlowers-V2.json in a text editor.
   1. Find and delete the createdDate, lastUpdatedDate, and version fields.
   2. Add the following to the sampleUtterances field:

      ```json
      I want to order flowers
      ```

3. Save the file.

3. Send the updated intent to Amazon Lex with the following command:

   ```bash
   aws lex-models put-intent  \
   --region region \
   --endpoint endpoint \
   --name OrderFlowers \
   --cli-input-json file://OrderFlowers-V2.json
   ```

Amazon Lex sends the following response:

```json
{
   "confirmationPrompt": {
      "maxAttempts": 2,
      "messages": [
         {
            "content": "Okay, your {FlowerType} will be ready for pickup by {PickupTime} on {PickupDate}. Does this sound okay?",
            "contentType": "PlainText"
         }
      ],
      "name": "OrderFlowers",
      "checksum": "checksum",
      "version": "$LATEST",
      "rejectionStatement": {
         "messages": [
            {
               "content": "Okay, I will not place your order.",
               "contentType": "PlainText"
            }
         ],
         "createdDate": timestamp,
         "lastUpdatedDate": timestamp,
         "sampleUtterances": [
            "I would like to pick up flowers",
            "I would like to order some flowers",
            "I want to order flowers"
         ],
         "slots": [
            {
               "slotType": "AMAZON.TIME",
               "value": "value"
            }
         ]
      }
   }
}```
Now that you have updated the intent, rebuild any bot that uses it.
To rebuild the OrderFlowersBot bot (AWS CLI)

1. In the AWS CLI, get the definition of the OrderFlowersBot bot and save it to a file with the following command:

```bash
aws lex-models get-bot \
  --region region \
  --endpoint endpoint \
  --name OrderFlowersBot \
  --version-or-alias "$LATEST" > OrderFlowersBot-V2.json
```

2. In a text editor, open `OrderFlowersBot-V2.json`. Remove the createdDate, lastUpdatedDate, status and version fields.

3. In a text editor, add the following line to the bot definition:

```json
"processBehavior": "BUILD",
```

4. In the AWS CLI, build a new revision of the bot by running the following command to:

```bash
aws lex-models put-bot \
  --region region \
  --endpoint endpoint \
  --name OrderFlowersBot \
  --cli-input-json file://OrderFlowersBot-V2.json
```

The response from the server is:

```json
{
  "status": "BUILDING",
  "intents": [
    {
      "intentVersion": "$LATEST",
      "intentName": "OrderFlowers"
    },
    {
      "name": "OrderFlowersBot",
      "locale": "en-US",
      "checksum": "checksum",
      "abortStatement": {
        "messages": [
          {
            "content": "Sorry, I'm not able to assist at this time",
            "contentType": "PlainText"
          }
        ]
      },
      "version": "$LATEST",
      "lastUpdatedDate": "timestamp",
      "createdDate": "timestamp",
      "clarificationPrompt": {
        "maxAttempts": 2,
        "messages": [
          {
            "content": "I didn't understand you, what would you like to do?",
            "contentType": "PlainText"
          }
        ]
      },
      "voiceId": "Salli",
      "childDirected": false,
      "idleSessionTTLInSeconds": 600,
```
Next Step

Exercise 3: Add a Lambda Function (AWS CLI) (p. 85)

Exercise 3: Add a Lambda Function (AWS CLI)

Add a Lambda function that validates user input and fulfills the user’s intent to the bot.

Adding a Lambda expression is a five-step process.

1. Use the Lambda AddPermission function to enable the OrderFlowers intent to call the Lambda Invoke operation.
2. Use the GetIntent (p. 262) operation to get the intent from Amazon Lex.
3. Update the intent to add the Lambda function.
4. Use the PutIntent (p. 297) operation to send the updated intent back to Amazon Lex.
5. Use the GetBot (p. 230) and PutBot (p. 285) operations to rebuild any bot that uses the intent.

If you add a Lambda function to an intent before you add the InvokeFunction permission, you get the following error message:

```
An error occurred (BadRequestException) when calling the PutIntent operation: Lex is unable to access the Lambda function Lambda function ARN in the context of intent intent ARN. Please check the resource-based policy on the function.
```

The response from the GetIntent operation contains a field called checksum that identifies a specific revision of the intent. When you use the PutIntent (p. 297) operation to update an intent, you must provide the checksum value. If you don’t, you get the following error message:

```
An error occurred (PreconditionFailedException) when calling the PutIntent operation: Intent intent name already exists. If you are trying to update intent name you must specify the checksum.
```

This exercise uses the Lambda function from Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30). For instructions to create the Lambda function, see Step 3: Create a Lambda Function (Console) (p. 42).

**Note**

The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to "$LATEST".

To add a Lambda function to an intent

1. In the AWS CLI, add the InvokeFunction permission for the OrderFlowers intent:

```
aws lambda add-permission
   --region region 
```
--endpoint endpoint \n--function-name OrderFlowersCodeHook \n--statement-id LexGettingStarted-OrderFlowersBot \n--action lambda:InvokeFunction \n--principal lex.amazonaws.com \n--source-arn "arn:aws:lambda:region:account ID:intent:OrderFlowers:*"

Lambda sends the following response:

```json
{
}
```

2. Get the intent from Amazon Lex. Amazon Lex sends the output to a file called OrderFlowers-V3.json.

```
aws lex-models get-intent
--region region \n--endpoint endpoint \n--name OrderFlowers \n--intent-version "\$LATEST" > OrderFlowers-V3.json
```

3. In a text editor, open the OrderFlowers-V3.json.
   1. Find and delete the createdDate, lastUpdatedDate, and version fields.
   2. Update the fulfillmentActivity field:

```
"fulfillmentActivity": {
"type": "CodeHook",
"codeHook": {
"messageVersion": "1.0"
}
}
```

3. Save the file.
4. In the AWS CLI, send the updated intent to Amazon Lex:

```
aws lex-models put-intent
--region region \n--endpoint endpoint \n--name OrderFlowers \n--cli-input-json file://OrderFlowers-V3.json
```

Now that you have updated the intent, rebuild the bot.

To rebuild the OrderFlowersBot bot

1. In the AWS CLI, get the definition of the OrderFlowersBot bot and save it to a file:

```
aws lex-models get-bot
--region region \
```
2. In a text editor, open OrderFlowersBot-V3.json. Remove the createdDate, lastUpdatedDate, status, and version fields.

3. In the text editor, add the following line to the definition of the bot:

   "processBehavior": "BUILD",

4. In the AWS CLI, build a new revision of the bot:

   ```bash
   aws lex-models put-bot
   --region region \n   --endpoint endpoint \n   --name OrderFlowersBot \n   --cli-input-json file://OrderFlowersBot-V3.json
   ```

The response from the server is:

   ```json
   {
   "status": "READY",
   "intents": [
   {
   "intentVersion": "$LATEST",
   "intentName": "OrderFlowers"
   },
   "name": "OrderFlowersBot",
   "locale": "en-US",
   "checksum": "checksum",
   "abortStatement": {
   "messages": [
   {
   "content": "Sorry, I'm not able to assist at this time",
   "contentType": "PlainText"
   }
   ]
   },
   "version": "$LATEST",
   "lastUpdatedDate": "timestamp",
   "createdDate": "timestamp",
   "clarificationPrompt": {
   "maxAttempts": 2,
   "messages": [
   {
   "content": "I didn't understand you, what would you like to do?",
   "contentType": "PlainText"
   }
   ]
   },
   "voiceId": "Salli",
   "childDirected": false,
   "idleSessionTTLInSeconds": 600,
   "description": "Bot to order flowers on the behalf of a user"
   }
   ```

Next Step

Exercise 4: Publish a Version (AWS CLI) (p. 88)
Exercise 4: Publish a Version (AWS CLI)

Now, create a version of the bot that you created in Exercise 1. A version is a snapshot of the bot. After you create a version, you can’t change it. The only version of a bot that you can update is the $LATEST version. For more information about versions, see Versioning and Aliases (p. 94).

Before you can publish a version of a bot, you must publish the intents that it uses. Likewise, you must publish the slot types that those intents refer to. In general, to publish a version of a bot, you do the following:

1. Publish a version of a slot type with the CreateSlotTypeVersion (p. 208) operation.
2. Publish a version of an intent with the CreateIntentVersion (p. 202) operation.
3. Publish a version of a bot with the CreateBotVersion (p. 197) operation.

Topics
- Step 1: Publish the Slot Type (AWS CLI) (p. 88)
- Step 2: Publish the Intent (AWS CLI) (p. 89)
- Step 3: Publish the Bot (AWS CLI) (p. 91)

Step 1: Publish the Slot Type (AWS CLI)

Before you can publish a version of any intents that use a slot type, you must publish a version of that slot type. In this case, you publish the FlowerTypes slot type.

**Note**
The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to $LATEST and replace the backslash (\) continuation character at the end of each line with a caret (^).

To publish a slot type (AWS CLI)

1. In the AWS CLI, get the latest version of the slot type:

   ```bash
   aws lex-models get-slot-type
   --region region
   --endpoint endpoint
   --name FlowerTypes
   --slot-type-version "$LATEST"
   ```

   The response from Amazon Lex follows. Record the checksum for the current revision of the $LATEST version.

   ```json
   {
     "enumerationValues": [
       {
         "value": "tulips"
       },
       {
         "value": "lilies"
       },
       {
         "value": "roses"
       }
     ],
     "name": "FlowerTypes",
     "checksum": "checksum"
   }
   ```
2. Publish a version of the slot type. Use the checksum that you recorded in the previous step.

```bash
aws lex-models create-slot-type-version
  --region region
  --endpoint endpoint
  --name FlowerTypes
  --checksum "checksum"
```

The response from Amazon Lex follows. Record the version number for the next step.

```json
{
  "version": "1",
  "enumerationValues": [
    {
      "value": "tulips"
    },
    {
      "value": "lilies"
    },
    {
      "value": "roses"
    }
  ],
  "name": "FlowerTypes",
  "createdDate": timestamp,
  "lastUpdatedDate": timestamp,
  "description": "Types of flowers to pick up"
}
```

**Next Step**

Step 2: Publish the Intent (AWS CLI) (p. 89)

**Step 2: Publish the Intent (AWS CLI)**

Before you can publish an intent, you have to publish all of the slot types referred to by the intent. The slot types must be numbered versions, not the $LATEST version.

First, update the OrderFlowers intent to use the version of the FlowerTypes slot type that you published in the previous step. Then publish a new version of the OrderFlowers intent.

**Note**

The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to $LATEST and replace the backslash (\) continuation character at the end of each line with a caret (^).

**To publish a version of an intent (AWS CLI)**

1. In the AWS CLI, get the $LATEST version of the OrderFlowers intent and save it to a file:

```bash
aws lex-models get-intent
  --region region
  --endpoint endpoint
```
2. In a text editor, open the `OrderFlowers_V4.json` file. Delete the `createdDate`, `lastUpdatedDate`, and `version` fields. Find the `FlowerTypes` slot type and change the version to the version number that you recorded in the previous step. The following fragment of the `OrderFlowers_V4.json` file shows the location of the change:

```json
{
  "slotType": "FlowerTypes",
  "name": "FlowerType",
  "slotConstraint": "Required",
  "valueElicitationPrompt": {
    "maxAttempts": 2,
    "messages": [
      {
        "content": "What type of flowers?",
        "contentType": "PlainText"
      }
    ]
  },
  "priority": 1,
  "slotTypeVersion": "version",
  "sampleUtterances": []
},
```

3. In the AWS CLI, save the revision of the intent:

```
aws lex-models put-intent
  --name OrderFlowers
  --cli-input-json file://OrderFlowers_V4.json
```

4. Get the checksum of the latest revision of the intent:

```
aws lex-models get-intent
  --region region
  --endpoint endpoint
  --name OrderFlowers
  --intent-version "\$LATEST" > OrderFlowers_V4a.json
```

The following fragment of the response shows the checksum of the intent. Record this for the next step.

```
"name": "OrderFlowers",
"checksum": "checksum",
"version": "\$LATEST",
```

5. Publish a new version of the intent:

```
aws lex-models create-intent-version
  --region region
  --endpoint endpoint
  --name OrderFlowers
  --checksum "checksum"
```

The following fragment of the response shows the new version of the intent. Record the version number for the next step.

```
"name": "OrderFlowers",
"checksum": "checksum",
"version": "version",
```
Next Step

Step 3: Publish the Bot (AWS CLI) (p. 91)

Step 3: Publish the Bot (AWS CLI)

After you have published all of the slot types and intents that are used by your bot, you can publish the bot.

Update the OrderFlowersBot bot to use the OrderFlowers intent that you updated in the previous step. Then, publish a new version of the OrderFlowersBot bot.

Note

The following AWS CLI example is formatted for Unix, Linux, and macOS. For Windows, change "\$LATEST" to $LATEST and replace the backslash (\) continuation character at the end of each line with a caret (^).

To publish a version of a bot (AWS CLI)

1. In the AWS CLI, get the $LATEST version of the OrderFlowersBot bot and save it to a file:

   ```bash
   aws lex-models get-bot
   --region region \
   --endpoint endpoint \
   --name OrderFlowersBot \
   --version-or-alias "$LATEST" > OrderFlowersBot_V4.json
   ```

2. In a text editor, open the OrderFlowersBot_V4.json file. Delete the createdDate, lastUpdatedDate, status and version fields. Find the OrderFlowers intent and change the version to the version number that you recorded in the previous step. The following fragment of OrderFlowersBot_V4.json shows the location of the change.

   ```json
   "intents": [
   {
   "intentVersion": "version",
   "intentName": "OrderFlowers"
   }
   ]
   ```

3. In the AWS CLI, save the new revision of the bot:

   ```bash
   aws lex-models put-bot \n   --name OrderFlowersBot \n   --cli-input-json file://OrderFlowersBot_V4.json
   ```

4. Get the checksum of the latest revision of the bot:

   ```bash
   aws lex-models get-bot
   --region region \
   --endpoint endpoint \
   --name OrderFlowersBot > OrderFlowersBot_V4a.json
   ```

   The following fragment of the response shows the checksum of the bot. Record this for the next step.

   ```json
   "name": "OrderFlowersBot",
   ```
Exercise 5: Create an Alias

5. Publish a new version of the bot:

```bash
aws lex-models create-bot-version
--region region \ 
--endpoint endpoint \ 
--name OrderFlowersBot \ 
--checksum "checksum"
```

The following fragment of the response shows the new version of the bot.

```
"checksum": "checksum",
"abortStatement": {
    ...
},
"version": "1",
"lastUpdatedDate": timestamp,
```

Next Step

Exercise 5: Create an Alias (AWS CLI) (p. 92)

Exercise 5: Create an Alias (AWS CLI)

An alias is a pointer to a specific version of a bot. With an alias you can easily update the version that your client applications are using. For more information, see Versioning and Aliases (p. 94)

To create an alias (AWS CLI)

1. In the AWS CLI, get the version of the OrderFlowersBot bot that you created in Exercise 4: Publish a Version (AWS CLI) (p. 88).

```bash
aws lex-models get-bot
--region region \ 
--endpoint endpoint \ 
--name OrderFlowersBot \ 
--version-or-alias version > OrderFlowersBot_v5.json
```

2. In a text editor, open `OrderFlowersBot_v5.json`. Find and record the version number.

3. In the AWS CLI, create the bot alias:

```bash
aws lex-models put-bot-alias \ 
--region region \ 
--endpoint endpoint \ 
--name PROD \ 
--bot-name OrderFlowersBot \ 
--bot-version version
```

The following is the response from the server:

```
{
    "name": "PROD",
    "createdAt": timestamp,
    "checksum": "checksum",
    "lastUpdatedDate": timestamp,
}
Exercise 6: Clean Up (AWS CLI)

Delete the resources that you created and clean up your account.

You can delete only resources that are not in use. In general, you should delete resources in the following order.

1. Delete aliases to free up bot resources.
2. Delete bots to free up intent resources.
3. Delete intents to free up slot type resources.
4. Delete slot types.

To clean up your account (AWS CLI)

1. In the AWS CLI command line, delete the alias:

   ```bash
   aws lex-models delete-bot-alias
   --region region \n   --endpoint endpoint \n   --name PROD \n   --bot-name OrderFlowersBot
   ```

2. In the AWS CLI command line, delete the bot:

   ```bash
   aws lex-models delete-bot
   --region region \n   --endpoint endpoint \n   --name OrderFlowersBot
   ```

3. In the AWS CLI command line, delete the intent:

   ```bash
   aws lex-models delete-intent
   --region region \n   --endpoint endpoint \n   --name OrderFlowers
   ```

4. From the AWS CLI command line, delete the slot type:

   ```bash
   aws lex-models delete-slot-type
   --region region \n   --endpoint endpoint \n   --name FlowerTypes
   ```

You have removed all of the resources that you created and cleaned up your account.
Versioning and Aliases

Amazon Lex supports publishing versions of bots, intents, and slot types so that you can control the implementation that your client applications use. A version is a numbered snapshot of your work that you can publish for use in different parts of your workflow, such as development, beta deployment, and production.

Amazon Lex bots also support aliases. An alias is a pointer to a specific version of a bot. With an alias, you can easily update the version that your client applications are using. For example, you can point an alias to version 1 of your bot. When you are ready to update the bot, you publish version 2 and change the alias to point to the new version. Because your applications use the alias instead of a specific version, all of your clients get the new functionality without needing to be updated.

Topics
- Versioning (p. 94)
- Aliases (p. 96)

Versioning

When you version an Amazon Lex resource you create a snapshot of the resource so that you can use the resource as it existed when the version was made. Once you've created a version it will stay the same while you continue to work on your application.

The $LATEST Version

When you create an Amazon Lex bot, intent, or slot type there is only one version, the $LATEST version.

$LATEST is the working copy of your resource. You can update only the $LATEST version and until you publish your first version, $LATEST is the only version of the resource that you have.

Only the $LATEST version of a resource can use the $LATEST version of another resource. For example, the $LATEST version of a bot can use the $LATEST version of an intent, and the $LATEST version of an intent can use the $LATEST version of a slot type.

Publishing an Amazon Lex Resource Version

When you publish a resource, Amazon Lex makes a copy of the $LATEST version and saves it as a numbered version. The published version can't be changed.
You create and publish versions using the Amazon Lex console or the CreateBotVersion (p. 197) operation. For an example, see Exercise 3: Publish a Version and Create an Alias (p. 68).

When you modify the $LATEST version of a resource, you can publish the new version to make the changes available to your client applications. Every time you publish a version, Amazon Lex copies the $LATEST version to create the new version and increments the version number by 1. Version numbers are never reused. For example, if you remove a resource numbered version 10 and then recreate it, the next version number Amazon Lex assigns is version 11.

Before you can publish a bot, you must point it to a numbered version of any intent that it uses. If you try to publish a new version of a bot that uses the $LATEST version of an intent, Amazon Lex returns an HTTP 400 Bad Request exception. Before you can publish a numbered version of the intent, you must point the intent to a numbered version of any slot type that it uses. Otherwise you will get an HTTP 400 Bad Request exception.

Note
Amazon Lex publishes a new version only if the last published version is different from the $LATEST version. If you try to publish the $LATEST version without modifying it, Amazon Lex doesn't create or publish a new version.

Updating an Amazon Lex Resource

You can update only the $LATEST version of an Amazon Lex bot, intent, or slot type. Published versions can't be changed. You can publish a new version any time after you update a resource in the console or with the CreateBotVersion (p. 197), the CreateIntentVersion (p. 202) or the CreateSlotTypeVersion (p. 208) operations.

Deleting an Amazon Lex Resource or Version

Amazon Lex supports deleting a resource or version using the console or one of the API operations:

- DeleteBot (p. 212)
- DeleteBotVersion (p. 218)
- DeleteBotAlias (p. 214)
Aliases

An alias is a pointer to a specific version of an Amazon Lex bot. Use an alias to allow client applications to use a specific version of the bot without requiring the application to track which version that is.

The following example shows two versions of an Amazon Lex bot, version $LATEST$ and version 1. Each of these bot versions has an associated alias, DEV and PROD, respectively. Client applications use the PROD alias to access the bot.

When you create a second version of the bot, you can update the alias to point to the new version of the bot using the console or the `PutBot (p. 285)` operation. When you change the alias, all of your client applications use the new version. If there is a problem with the new version, you can roll back to the previous version by simply changing the alias to point to that version.
Note
Although you can test the $LATEST version of a bot in the console, we recommend that when you integrate a bot with your client application, you first publish a version and create an alias that points to that version. Use the alias in your client application for the reasons explained in this section. When you update an alias, Amazon Lex will wait until the session timeout of all current sessions expires before it starts using the new version. For more information about the session timeout, see the section called “Setting the Session Timeout” (p. 20)
Using Lambda Functions

You can create AWS Lambda functions to use as code hooks for your Amazon Lex bot. You can identify Lambda functions to perform initialization and validation, fulfillment, or both in your intent configuration.

We recommend that you use a Lambda function as a code hook for your bot. Without a Lambda function, your bot returns the intent information to the client application for fulfillment.

Topics
- Lambda Function Input Event and Response Format (p. 98)
- Amazon Lex and AWS Lambda Blueprints (p. 105)

Lambda Function Input Event and Response Format

This section describes the structure of the event data that Amazon Lex provides to a Lambda function. Use this information to parse the input in your Lambda code. It also explains the format of the response that Amazon Lex expects your Lambda function to return.

Topics
- Input Event Format (p. 98)
- Response Format (p. 101)

Input Event Format

The following shows the general format of an Amazon Lex event that is passed to a Lambda function. Use this information when you are writing your Lambda function.

Note
The input format may change without a corresponding change in the messageVersion. Your code should not throw an error if new fields are present.

```json
{
  "currentIntent": {
    "name": "intent-name",
    "slots": {
      "slot name": "value",
      "slot name": "value"
    },
    "slotDetails": {
      "slot name": {
        "resolutions": [
          { "value": "resolved value" },
          { "value": "resolved value" }
        ],
        "originalValue": "original text"
      }
    }
}
```
Note the following additional information about the event fields:

- **currentIntent** – Provides the intent name, slots, slotDetails and confirmationStatus fields.

The slot value in the input event may not match one of the values configured for the slot. For example, if the user responds to the prompt "What color car would you like?" with "pizza," Amazon Lex will return "pizza" as the slot value. Your function should validate the values to make sure that they make sense in context.

slotDetails provides additional information about a slot value. The resolutions array contains a list of additional values recognized for the slot. Each slot can have a maximum of five values.

The originalValue field contains the value that was entered by the user for the slot. When the slot type is configured to return the top resolution value as the slot value, the originalValue may be different from the value in the slots field.

confirmationStatus provides the user response to a confirmation prompt, if there is one. For example, if Amazon Lex asks "Do you want to order a large cheese pizza?," depending on the user
response, the value of this field can be Confirmed or Denied. Otherwise, this value of this field is None.

If the user confirms the intent, Amazon Lex sets this field to Confirmed. If the user denies the intent, Amazon Lex sets this value to Denied.

In the confirmation response, a user utterance might provide slot updates. For example, the user might say "yes, change size to medium." In this case, the subsequent Lambda event has the updated slot value, PizzaSize set to medium. Amazon Lex sets the confirmationStatus to None, because the user modified some slot data, requiring the Lambda function to perform user data validation.

- **bot** – Information about the bot that processed the request.
  - name – The name of the bot that processed the request.
  - alias – The alias of the bot version that processed the request.
  - version – The version of the bot that processed the request.

- **userId** – This value is provided by the client application. Amazon Lex passes it to the Lambda function.

- **inputTranscript** – The text used to process the request.
  
  If the input was text, the inputTranscript field contains the text that was input by the user.

  If the input was an audio stream, the inputTranscript field contains the text extracted from the audio stream. This is the text that is actually processed to recognize intents and slot values.

- **invocationSource** – To indicate why Amazon Lex is invoking the Lambda function, it sets this to one of the following values:
  - DialogCodeHook – Amazon Lex sets this value to direct the Lambda function to initialize the function and to validate the user's data input.
  - FulfillmentCodeHook – Amazon Lex sets this value to direct the Lambda function to fulfill an intent.

When the intent is configured to invoke a Lambda function as an initialization and validation code hook, Amazon Lex invokes the specified Lambda function on each user input (utterance) after Amazon Lex understands the intent.

**Note**
If the intent is not clear, Amazon Lex can't invoke the Lambda function.

- **FulfillmentCodeHook** – Amazon Lex sets this value to direct the Lambda function to fulfill an intent.
In your intent configuration, you can have two separate Lambda functions to initialize and validate user data and to fulfill the intent. You can also use one Lambda function to do both. In that case, your Lambda function can use the `invocationSource` value to follow the correct code path.

- **outputDialogMode** – For each user input, the client sends the request to Amazon Lex using one of the runtime API operations, `PostContent (p. 312)` or `PostText (p. 320)`. Amazon Lex uses the request parameters, `Amazon Lex` to determine whether the response to the client is text or voice, and sets this field accordingly.

  The Lambda function can use this information to generate an appropriate message. For example, if the client expects a voice response, your Lambda function could return Speech Synthesis Markup Language (SSML) instead of text.

- **messageVersion** – The version of the message that identifies the format of the event data going into the Lambda function and the expected format of the response from a Lambda function.

  **Note**
  You configure this value when you define an intent. In the current implementation, only message version 1.0 is supported. Therefore, the console assumes the default value of 1.0 and doesn't show the message version.

- **sessionAttributes** – Application-specific session attributes that the client sends in the request. If you want Amazon Lex to include them in the response to the client, your Lambda function should send these back to Amazon Lex in the response. For more information, see Setting Session Attributes (p. 17)

- **requestAttributes** – Request-specific attributes that the client sends in the request. Use request attributes to pass information that doesn't need to persist for the entire session. For more information, see Setting Request Attributes (p. 18)

**Response Format**

Amazon Lex expects a response from a Lambda function in the following format:

```json
{
  "sessionAttributes": {
    "key1": "value1",
    "key2": "value2"
  },
  "dialogAction": {
    "type": "ElicitIntent, ElicitSlot, ConfirmIntent, Delegate, or Close",
    Full structure based on the type field. See below for details.
  }
}
```

The response consists of two fields. The `sessionAttributes` field is optional, the `dialogAction` field is required. The contents of the `dialogAction` field depends on the value of the `type` field. For details, see `dialogAction (p. 102)`. 
sessionAttributes

Optional. If you include the sessionAttributes field it can be empty. If you want Amazon Lex to include any session attributes in the response to the client application, your Lambda function must return them in this field. For more information, see the PostContent (p. 312) and PostText (p. 320) operations.

```
"sessionAttributes": { 
  "key1": "value1",
  "key2": "value2"
}
```

dialogAction

Required. The dialogAction field directs Amazon Lex to the next course of action, and describes what to expect from the user after Amazon Lex returns a response to the client.

The type field indicates the next course of action. It also determines the other fields that the Lambda function needs to provide as part of the dialogAction value.

- **Close** — Informs Amazon Lex not to expect a response from the user. For example, "Your pizza order has been placed" does not require a response.

The fulfillmentState field is required. Amazon Lex uses this value to set the dialogState field in the PostContent (p. 312) or PostText (p. 320) response to the client application. The message and responseCard fields are optional. If you don’t specify a message, Amazon Lex uses the goodbye message or the follow-up message configured for the intent.

```
"dialogAction": { 
  "type": "Close",
  "fulfillmentState": "Fulfilled or Failed",
  "message": { 
    "contentType": "PlainText or SSML",
    "content": "Message to convey to the user. For example, Thanks, your pizza has been ordered."
  },
  "responseCard": { 
    "version": integer-value,
    "contentType": "application/vnd.amazonaws.card.generic",
    "genericAttachments": [ 
      { 
        "title": "card-title",
        "subTitle": "card-sub-title",
        "imageUrl": "URL of the image to be shown",
        "attachmentLinkUrl": "URL of the attachment to be associated with the card",
        "buttons": [ 
          { 
            "text": "button-text",
            "value": "Value sent to server on button click"
          }
        ]
      ]
    }
  }
}
```

- **ConfirmIntent** — Informs Amazon Lex that the user is expected to give a yes or no answer to confirm or deny the current intent.
You must include the `intentName` and `slots` fields. The `slots` field must contain an entry for each of the slots configured for the specified intent. If the value of a slot is unknown, you must set it to null. The `message` and `responseCard` fields are optional.

```json
"dialogAction": {
    "type": "ConfirmIntent",
    "message": {
        "contentType": "PlainText or SSML",
        "content": "Message to convey to the user. For example, Are you sure you want a large pizza?"
    },
    "intentName": "intent-name",
    "slots": {
        "slot-name": "value",
        "slot-name": "value",
        "slot-name": "value"
    },
    "responseCard": {
        "version": "integer-value",
        "contentType": "application/vnd.amazonaws.card.generic",
        "genericAttachments": [
            {
                "title": "card-title",
                "subTitle": "card-sub-title",
                "imageUrl": "URL of the image to be shown",
                "attachmentLinkUrl": "URL of the attachment to be associated with the card",
                "buttons": [
                    {
                        "text": "button-text",
                        "value": "Value sent to server on button click"
                    }
                ]
            }
        ]
    }
}
```

- **Delegate** — Directs Amazon Lex to choose the next course of action based on the bot configuration. The response must include any session attributes, and the `slots` field must include all of the slots specified for the requested intent. If the value of the field is unknown, you must set it to null. You will get a `DependencyFailedException` exception if your fulfillment function returns the `Delegate` dialog action without removing any slots.

```json
"dialogAction": {
    "type": "Delegate",
    "slots": {
        "slot-name": "value",
        "slot-name": "value",
        "slot-name": "value"
    }
}
```

- **ElicitIntent** — Informs Amazon Lex that the user is expected to respond with an utterance that includes an intent. For example, "I want a large pizza," which indicates the `OrderPizzaIntent`. The utterance "large," on the other hand, is not sufficient for Amazon Lex to infer the user’s intent.
The `message` and `responseCard` fields are optional. If you don't provide a message, Amazon Lex uses one of the bot's clarification prompts.

```json
{
   "dialogAction": {
      "type": "ElicitIntent",
      "message": {
         "contentType": "PlainText or SSML",
         "content": "Message to convey to the user. For example, What can I help you with?"
      },
      "responseCard": {
         "version": integer-value,
         "contentType": "application/vnd.amazonaws.card.generic",
         "genericAttachments": [
            {
               "title": "card-title",
               "subTitle": "card-sub-title",
               "imageUrl": "URL of the image to be shown",
               "attachmentLinkUrl": "URL of the attachment to be associated with the card",
               "buttons": [
                  {
                     "text": "button-text",
                     "value": "Value sent to server on button click"
                  }
               ]
            }
         ]
      }
   }
}
```

- **ElicitSlot** — Informs Amazon Lex that the user is expected to provide a slot value in the response.

The `intentName`, `slotToElicit`, and `slots` fields are required. The `slots` field must include all of the slots specified for the requested intent. The `message` and `responseCard` fields are optional. If you don't specify a message, Amazon Lex uses one of the slot elicitation prompts configured for the slot.

```json
"dialogAction": {
   "type": "ElicitSlot",
   "message": {
      "contentType": "PlainText or SSML",
      "content": "Message to convey to the user. For example, What size pizza would you like?"
   },
   "intentName": "intent-name",
   "slots": {
      "slot-name": "value",
      "slot-name": "value",
      "slot-name": "value"
   },
   "slotToElicit": "slot-name",
   "responseCard": {
      "version": integer-value,
      "contentType": "application/vnd.amazonaws.card.generic",
      "genericAttachments": [
         {
            "title": "card-title",
            "subTitle": "card-sub-title",
            "imageUrl": "URL of the image to be shown",
         }
      ]
   }
}
```
Amazon Lex and AWS Lambda Blueprints

The Amazon Lex console provides example bots (called bot blueprints) that are preconfigured so you can quickly create and test a bot in the console. For each of these bot blueprints, Lambda function blueprints are also provided. These blueprints provide sample code that works with their corresponding bots. You can use these blueprints to quickly create a bot that is configured with a Lambda function as a code hook, and test the end-to-end setup without having to write code.

You can use the following Amazon Lex bot blueprints and the corresponding AWS Lambda function blueprints as code hooks for bots:

- Amazon Lex blueprint — OrderFlowers
  - AWS Lambda blueprints — lex-order-flowers (Node.js code) and lex-order-flowers-python
- Amazon Lex blueprint — ScheduleAppointment
  - AWS Lambda blueprints — lex-make-appointment (Node.js code) and lex-make-appointment-python
- Amazon Lex blueprint — BookTrip
  - AWS Lambda blueprints — lex-book-trip (Node.js code) and lex-book-trip-python

To create a bot using a blueprint and configure it to use a Lambda function as a code hook, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30). For an example of using other blueprints, see Additional Examples: Creating Amazon Lex Bots (p. 122).
Deploying and Exporting Amazon Lex Bots

This section provides examples of deploying Amazon Lex bots on various messaging platforms, in mobile applications, and exporting them.

Topics
- Deploying an Amazon Lex Bot on a Messaging Platform (p. 106)
- Deploying an Amazon Lex Bot in Mobile Applications (p. 120)
- Exporting Amazon Lex Bots (p. 120)

Deploying an Amazon Lex Bot on a Messaging Platform

This section explains how to deploy Amazon Lex bots on the Facebook, Slack, and Twilio messaging platforms.

Note
When storing your Facebook, Slack, or Twilio configurations, Amazon Lex uses AWS Key Management Service customer master keys (CMK) to encrypt the information. The first time that you create a channel to one of these messaging platforms, Amazon Lex creates a default CMK (aws/lex). Alternatively, you can create your own CMK with AWS KMS. This gives you more flexibility, including the ability to create, rotate, and disable keys. You can also define access controls and audit the encryption keys used to protect your data. For more information, see the AWS Key Management Service Developer Guide.

When a messaging platform sends a request to Amazon Lex it includes platform-specific information as a request attribute to your Lambda function. Use these attributes to customize the way that your bot behaves. For more information, see Setting Request Attributes (p. 18).

All of the attributes take the namespace, x-amz-lex:, as the prefix. For example, the user-id attribute is called x-amz-lex:user-id. There are common attributes that are sent by all messaging platforms in addition to attributes that are specific to a particular platform. The following tables list the request attributes that messaging platforms send to your bot's Lambda function.

### Common Request Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>channel-id</td>
<td>The channel endpoint identifier from Amazon Lex</td>
</tr>
<tr>
<td>channel-name</td>
<td>The channel name from Amazon Lex</td>
</tr>
<tr>
<td>channel-type</td>
<td>One of the following values:</td>
</tr>
<tr>
<td></td>
<td>• Facebook</td>
</tr>
<tr>
<td></td>
<td>• Slack</td>
</tr>
<tr>
<td></td>
<td>• Twilio-SMS</td>
</tr>
</tbody>
</table>
## Integrating an Amazon Lex Bot with Facebook Messenger

### Topics
- Step 1: Create an Amazon Lex Bot (p. 108)
- Step 2: Create a Facebook Application (p. 108)
- Step 3: Integrate Facebook Messenger with the Amazon Lex Bot (p. 108)
- Step 4: Test the Integration (p. 109)

This exercise shows how to integrate Facebook Messenger with your Amazon Lex bot. You perform the following steps:

1. Create an Amazon Lex bot
2. Create a Facebook application
3. Integrate Facebook Messenger with your Amazon Lex bot
4. Validate the integration

Step 1: Create an Amazon Lex Bot

If you don’t already have an Amazon Lex bot, create and deploy one. In this topic, we assume that you are using the bot that you created in Getting Started Exercise 1. However, you can use any of the example bots provided in this guide. For Getting Started Exercise 1, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).

1. Create an Amazon Lex bot. For instructions, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).
2. Deploy the bot and create an alias. For instructions, see Exercise 3: Publish a Version and Create an Alias (p. 68).

Step 2: Create a Facebook Application

On the Facebook developer portal, create a Facebook application and a Facebook page. For instructions, see Quick Start in the Facebook Messenger platform documentation. Write down the following:

- The App Secret for the Facebook App
- The Page Access Token for the Facebook page

Step 3: Integrate Facebook Messenger with the Amazon Lex Bot

In this section, you integrate Facebook Messenger with your Amazon Lex bot.

After you complete this step, the console provides a callback URL. Write down this URL.

To integrate Facebook Messenger with your bot

1. a. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
   b. Choose your Amazon Lex bot.
   c. Choose Channels.
   d. Choose Facebook under Chatbots. The console displays the Facebook integration page.
   e. On the Facebook integration page, do the following:
      - Type the following name: BotFacebookAssociation.
      - For KMS key, choose aws/lex.
      - For Alias, choose the bot alias.
      - For Verify token, type a token. This can be any string you choose (for example, ExampleToken). You use this token later in the Facebook developer portal when you set up the webhook.
      - For Page access token, type the token that you obtained from Facebook in Step 2.
      - For App secret key, type the key that you obtained from Facebook in Step 2.
f. Choose **Activate**.

The console creates the bot channel association and returns a callback URL. Write down this URL.

2. On the Facebook developer portal, choose your app.
3. Choose the **Messenger** product, and choose **Setup webhooks** in the **Webhooks** section of the page.

   For instructions, see **Quick Start** in the Facebook Messenger platform documentation.
4. On the **webhook** page of the subscription wizard, do the following:

   • For **Callback URL**, type the callback URL provided in the Amazon Lex console earlier in the procedure.
   • For **Verify Token**, type the same token that you used in Amazon Lex.
   • Choose **Subscription Fields** (**messages**, **messaging_postbacks**, and **messaging_optins**).
   • Choose **Verify and Save**. This initiates a handshake between Facebook and Amazon Lex.
5. Enable Webhooks integration. Choose the page that you created, and then choose **subscribe**.

   **Note**
   If you update or recreate a webhook, unsubscribe and then resubscribe to the page.

**Step 4: Test the Integration**

You can now start a conversation from Facebook Messenger with your Amazon Lex bot.

1. Open your Facebook page, and choose **Message**.
2. In the Messenger window, use the same test utterances provided in **Step 1: Create an Amazon Lex Bot (Console)** (p. 32).
Integrating an Amazon Lex Bot with Kik

Topics
- Step 1: Create an Amazon Lex Bot (p. 110)
- Step 2: Create a Kik Bot (p. 110)
- Step 3: Integrate the Kik Bot with the Amazon Lex Bot (p. 111)
- Step 4: Test the Integration (p. 112)

This exercise provides instructions for integrating an Amazon Lex bot with the Kik messaging application. You perform the following steps:

1. Create an Amazon Lex bot.
2. Create a Kik bot using the Kik app and website.
3. Integrate the your Amazon Lex bot with the Kik bot using the Amazon Lex console.
4. Engage in a conversation with your Amazon Lex bot using Kik to test the association between your Amazon Lex bot and Kik.

Step 1: Create an Amazon Lex Bot

If you don't already have an Amazon Lex bot, create and deploy one. In this topic, we assume that you are using the bot that you created in Getting Started Exercise 1. However, you can use any of the example bots provided in this guide. For Getting Started Exercise 1, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30)

1. Create an Amazon Lex bot. For instructions, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).
2. Deploy the bot and create an alias. For instructions, see Exercise 3: Publish a Version and Create an Alias (p. 68).

Next Step

Step 2: Create a Kik Bot (p. 110)

Step 2: Create a Kik Bot

In this step you use the Kik user interface to create a Kik bot. You use information generated while creating the bot to connect it to your Amazon Lex bot.

1. If you haven't already, download and install the Kik app and sign up for a Kik account. If you have an account, log in.
2. Open the Kik website at https://dev.kik.com/. Leave the browser window open.
3. In the Kik app, choose the gear icon to open settings, and then choose Your Kik Code.
4. Scan the Kik code on the Kik website to open the Botsworth chatbot. Choose Yes to open the Bot Dashboard.
5. In the Kik app, choose Create a Bot. Follow the prompts to create your Kik bot.
6. Once the bot is created, choose Configuration in your browser. Make sure that your new bot is selected.
7. Note the bot name and the API key for the next section.

Next Step

110
Step 3: Integrate the Kik Bot with the Amazon Lex Bot

Now that you have created an Amazon Lex bot and a Kik bot, you are ready to create an channel association between them in Amazon Lex. When the association is activated, Amazon Lex automatically sets up a callback URL with Kik.

1. Sign in to the AWS Management Console, and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. Choose the Amazon Lex bot that you created in Step 1.
3. Choose the Channels tab.
4. In the Channels section, choose Kik.
5. On the Kik page, provide the following:
   - Type a name. For example, BotKikIntegration.
   - Type a description.
   - Choose "aws/lex" from the KMS key drop-down.
   - For Alias, choose an alias from the drop-down.
   - For Kik bot user name, type the name that you gave the bot on Kik.
   - For Kik API key, type the API key that was assigned to the bot on Kik.
   - For User greeting, type the greeting that you would like your bot to send the first time that a user chats with it.
   - For Error message, enter an error message that is shown to the user when part of the conversation is not understood.
   - For Group chat behavior, choose one of the options:
     - Enable – Enables the entire chat group to interact with your bot in a single conversation.
     - Disable – Restricts the conversation to one user in the chat group.
Choose **Activate** to create the association and link it to the Kik bot.

**Next Step**

**Step 4: Test the Integration (p. 112)**

**Step 4: Test the Integration**

Now that you have created an association between your Amazon Lex bot and Kik, you can use the Kik app to test the association.

1. Start the Kik app and log in. Select the bot that you created.
2. You can test the bot with the following:
As you enter each phrase, your Amazon Lex bot will respond through Kik with the prompt that you created for each slot.

Integrating an Amazon Lex Bot with Slack

Topics

- Step 1: Create an Amazon Lex Bot (p. 114)
- Step 2: Sign Up for Slack and Create a Slack Team (p. 114)
- Step 3: Create a Slack Application (p. 114)
- Step 4: Integrate the Slack Application with the Amazon Lex Bot (p. 115)
- Step 5: Complete Slack Integration (p. 116)
- Step 6: Test the Integration (p. 117)

This exercise provides instructions for integrating an Amazon Lex bot with the Slack messaging application. You perform the following steps:
1. Create an Amazon Lex bot.
2. Create a Slack messaging application.
3. Integrate the Slack application with your bot Amazon Lex.
4. Test the integration by engaging in conversation with your Amazon Lex bot. You send messages with the Slack application and test in a browser window.

**Step 1: Create an Amazon Lex Bot**

If you don’t already have an Amazon Lex bot, create and deploy one. In this topic, we assume that you are using the bot that you created in Getting Started Exercise 1. However, you can use any of the example bots provided in this guide. For Getting Started Exercise 1, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30)

1. Create an Amazon Lex bot. For instructions, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).
2. Deploy the bot and create an alias. For instructions, see Exercise 3: Publish a Version and Create an Alias (p. 68).

**Step 2: Sign Up for Slack and Create a Slack Team**

Sign up for a Slack account and create a Slack team. For instructions, see Using Slack. In the next section, you create a Slack application, which any Slack team can install.

**Step 3: Create a Slack Application**

In this section, you do the following:

1. Create a Slack application on the Slack API Console
2. Configure the application to add the following features to your bot:
   - A bot user
   - Interactive messaging

At the end of this section, you get application credentials (Client Id, Client Secret, and Verification Token). In the next section, you use this information to configure bot channel association in the Amazon Lex console.

2. Create an application.
   - After you have successfully created the application, Slack displays the **Basic Information** page for the application.
3. Configure the application features as follows:
   a. In the left menu, choose **Bot Users**.
• Provide a user name.
• For Always Show My Bot as Online, choose On.
• To save the changes, choose Add Bot User.

b. In the left menu, choose Interactive Messages.

• Choose Enable Interactive Messages.
• In the Request URL box, specify any valid URL. For example, you can use https://slack.com.

  Note
  For now, enter any valid URL to get the verification token that you need in the next step. You will update this URL after you add the bot channel association in the Amazon Lex console.

• Choose Enable Interactive Messages.

4. In the left menu, in Settings, choose Basic Information. Record the following application credentials:

  • Client ID
  • Client Secret
  • Verification Token

Next Step

Step 4: Integrate the Slack Application with the Amazon Lex Bot (p. 115)

Step 4: Integrate the Slack Application with the Amazon Lex Bot

Now that you have Slack application credentials, you can integrate the application with your Amazon Lex bot. To associate the Slack application with your bot, add a bot channel association in Amazon Lex.

In the Amazon Lex console, activate a bot channel association to associate the bot with your Slack application. When the bot channel association is activated, Amazon Lex returns two URLs (Postback URL and OAuth URL). Record these URLs because you need them later.

To integrate the Slack application with your Amazon Lex bot

1. Sign in to the AWS Management Console, and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. Choose the Amazon Lex bot that you created in Step 1.
3. Choose the Channels tab.
4. In the Chatbots section, choose Slack.
5. On the Slack page, provide the following:

  • Type a name. For example, BotSlackIntegration.
  • Choose "aws/lex" from the KMS key drop-down.
  • For Alias, choose the bot alias.
  • Type the Client Id, Client secret, and Verification Token, which you recorded in the preceding step. These are the credentials of the Slack application.
6. Choose **Activate**.

The console creates the bot channel association and returns two URLs (Postback URL and OAuth URL). Record them. In the next section, you update your Slack application configuration to use these endpoints as follows:

- The Postback URL is the Amazon Lex bot’s endpoint that listens to Slack events. You use this URL:
  - As the request URL in the **Event Subscriptions** feature of the Slack application.
  - To replace the placeholder value for the request URL in the **Interactive Messages** feature of the Slack application.
- The OAuth URL is your Amazon Lex bot’s endpoint for an OAuth handshake with Slack.

**Next Step**

**Step 5: Complete Slack Integration** (p. 116)

**Step 5: Complete Slack Integration**

In this section, use the Slack API console to complete integration of the Slack application.

1. Sign in to the Slack API console at [http://api.slack.com](http://api.slack.com). Choose the app that you created in **Step 3: Create a Slack Application** (p. 114).

2. Update the **OAuth & Permissions** feature as follows:
   a. In the **Redirect URLs** section, add the OAuth URL that Amazon Lex provided in the preceding step. Choose **Add a new Redirect URL**, and then choose **Save URLs**.
   b. In the **Scopes** section, choose two permissions in the **Select Permission Scopes** drop-down. Filter the list with the following text:
      - chat:write:bot
      - team:read
Choose **Save Changes**.

3. Update the **Interactive Components** feature by updating the **Request URL** value to the Postback URL that Amazon Lex provided in the preceding step. Choose **Add**, and then choose **Save URLs**.

4. Subscribe to the **Event Subscriptions** feature as follows:
   - Enable events by choosing the **On** option.
   - Set the **Request URL** value to the Postback URL that Amazon Lex provided in the preceding step.
   - In the **Subscribe to Bot Events** section, subscribe to the **message . im** bot event to enable direct messaging between the end user and the Slack bot.
   - Save the changes.

**Next Step**

**Step 6: Test the Integration**  (p. 117)

**Step 6: Test the Integration**

Now use a browser window to test the integration of Slack with your Amazon Lex bot.

1. Choose **Manage Distribution** under **Settings**. Choose **Add to Slack** to install the application. Authorize the bot to respond to messages.
2. You are redirected to your Slack team. In the left menu, in the **Direct Messages** section, choose your bot. If you don’t see your bot, choose the plus icon (+) next to **Direct Messages** to search for it.
3. Engage in a chat with your Slack application, which is linked to the Amazon Lex bot. Your bot now responds to messages.

   If you created the bot using Getting Started Exercise 1, you can use the example conversations provided in that exercise. For more information, see **Step 4: Add the Lambda Function as Code Hook (Console)**  (p. 43).

**Integrating an Amazon Lex Bot with Twilio Programmable SMS**

**Topics**

- **Step 1: Create an Amazon Lex Bot**  (p. 118)
- **Step 2: Create a Twilio SMS Account**  (p. 118)
- **Step 3: Integrate the Twilio Messaging Service Endpoint with the Amazon Lex Bot**  (p. 118)
- **Step 4: Test the Integration**  (p. 119)

This exercise provides instructions for integrating an Amazon Lex bot with the Twilio simple messaging service (SMS). You perform the following steps:

1. Create an Amazon Lex bot
2. Integrate Twilio programmable SMS with your bot Amazon Lex
3. Engage in an interaction with the Amazon Lex bot by testing the setup using the SMS service on your mobile phone
4. Test the integration
Step 1: Create an Amazon Lex Bot

If you don't already have an Amazon Lex bot, create and deploy one. In this topic, we assume that you are using the bot that you created in Getting Started Exercise 1. However, you can use any of the example bots provided in this guide. For Getting Started Exercise 1, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).

1. Create an Amazon Lex bot. For instructions, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).
2. Deploy the bot and create an alias. For instructions, see Exercise 3: Publish a Version and Create an Alias (p. 68).

Step 2: Create a Twilio SMS Account

Sign up for a Twilio account and record the following account information:

- ACCOUNT SID
- AUTH TOKEN

For sign-up instructions, see https://www.twilio.com/console.

Step 3: Integrate the Twilio Messaging Service Endpoint with the Amazon Lex Bot

To integrate Twilio with your Amazon Lex bot

1. To associate the Amazon Lex bot with your Twilio programmable SMS endpoint, activate bot channel association in the Amazon Lex console. When the bot channel association has been activated, Amazon Lex returns a callback URL. Record this callback URL because you need it later.
   a. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
   b. Choose the Amazon Lex bot that you created in Step 1.
   c. Choose the Channels tab.
   d. In the Chatbots section, choose Twilio SMS.
   e. On the Twilio SMS page, provide the following information:
      • Type a name. For example, BotTwilioAssociation.
      • Choose "aws/lex" from KMS key.
      • For Alias, choose the bot alias.
      • For Authentication Token, type the AUTH TOKEN for your Twilio account.
      • For Account SID, type the ACCOUNT SID for your Twilio account.
f. Choose **Activate**.

The console creates the bot channel association and returns a callback URL. Record this URL.

2. On the Twilio console, connect the Twilio SMS endpoint to the Amazon Lex bot.
   b. If you don't have a Twilio SMS endpoint, create it.
   c. Update the **Inbound Settings** configuration of the messaging service by setting the **REQUEST URL** value to the callback URL that Amazon Lex provided in the preceding step.

**Step 4: Test the Integration**

Use your mobile phone to test the integration between Twilio SMS and your bot.

**To test integration**

1. Sign in to the Twilio console at [https://www.twilio.com/console](https://www.twilio.com/console) and do the following:
   a. Verify that you have a Twilio number associated with the messaging service under **Manage Numbers**.

   You send messages to this number and engage in SMS interaction with the Amazon Lex bot from your mobile phone.

   b. Verify that your mobile phone is whitelisted as **Verified Caller ID**.

   If it isn't, follow instructions on the Twilio console to whitelist the mobile phone that you plan to use for testing.

   Now you can use your mobile phone to send messages to the Twilio SMS endpoint, which is mapped to the Amazon Lex bot.

2. Using your mobile phone, send messages to the Twilio number.
Deploying an Amazon Lex Bot in Mobile Applications

Using AWS SDKs, you can integrate your Amazon Lex bot with your mobile applications. For more information, see the following topics:

- **Android SDK** – Getting Started with Amazon Lex Android SDK
- **iOS SDK** – Getting Started with Amazon Lex iOS SDK

You can also use the AWS Mobile Hub to create a quickstart mobile app that demonstrates using the Amazon Lex SDK in iOS and Android mobile applications. For more information, see AWS Mobile Hub Conversational Bots.

Exporting Amazon Lex Bots

Amazon Lex enables you to export a bot in a format compatible with a target platform. When you export a bot you convert its associated intents, slot types, and dialog model into a JSON file. Use the Amazon Lex console or the GetExport (p. 259) operation to create the JSON file.

Export to an Alexa Skill

You can export your bot schema in a format compatible with an Alexa skill. After you export the bot, you upload it to Alexa using the skill builder.

First export your bot and its interaction model to a JSON file.

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. Under **Actions** choose **Export** to export the bot.
3. Choose the name and version of the bot that you want to export and then choose **Export**. Choose **Alexa Skills Kit** as the format to export.
4. In a moment a download dialog box will appear. Select a location for the file and choose **Save**.

The downloaded file is a ZIP archive containing one files, named after the bot that was exported. It contains the information necessary to import the bot as an Alexa skill.

**Note**

Note these differences between Amazon Lex and the Alexa Skills Kit.

- Session attributes, denoted by square brackets ([[]]), are not supported by the Alexa Skills Kit. You will need to update prompts that use session attributes.
- Punctuation marks are not supported by the Alexa Skills Kit. You will need to update utterances that use punctuation.

Once you have exported your bot, you can upload it into an Alexa skill using the skill builder.
1. Log in to the developer portal at https://developer.amazon.com/. Choose Developer Console and then choose ALEXA to open the Alexa console.

2. In the Alexa Skills Kit box, choose Get Started to open the Alexa Skill Kit page. This displays any skills you've created.

3. Choose Add a New Skill. Fill in the required fields:
   - Skill Type (select Custom Interaction Model)
   - Language
   - Name
   - Invocation Name

4. Choose Save to save the new skill and then choose Next.

5. Choose Launch Skill Builder. From the left menu, choose Code Editor.

6. Paste the contents of the JSON file that you downloaded from the Amazon Lex console into the code editor field.

7. Choose Apply Changes to save your changes and then choose Build Model.

Once you have uploaded the schema into an Alexa skill you can make any changes necessary for running the skill with Alexa. For more information about creating an Alexa skill, see Use the Skill Builder (Beta) in the Alexa Skills Kit.
Additional Examples: Creating Amazon Lex Bots

The following sections provide additional Amazon Lex exercises with step-by-step instructions.

Topics

- Example Bot: ScheduleAppointment (p. 122)
- Example Bot: BookTrip (p. 140)
- Example: Using a Response Card (p. 162)
- Example: Updating Utterances (p. 164)
- Example: Integrating with a Web site (p. 165)

Example Bot: ScheduleAppointment

The example bot in this exercise schedules appointments for a dentist's office. The example also illustrates using response cards to obtain user input with buttons. Specifically, the example illustrates generating response cards dynamically at runtime.

You can configure response cards at build time (also referred to as static response cards) or generate them dynamically in an AWS Lambda function. In this example, the bot uses the following response cards:

- A response card that lists buttons for appointment type. For example:

  ![Response Card Example](image)

- A response card that lists buttons for appointment date. For example:
A response card that lists buttons to confirm a suggested appointment time. For example:

The available appointment dates and times vary, which requires you to generate response cards at runtime. You use an AWS Lambda function to generate these response cards dynamically. The Lambda function returns response cards in its response to Amazon Lex. Amazon Lex includes the response card in its response to the client.

If a client (for example, Facebook Messenger) supports response cards, the user can either choose from the list of buttons or type the response. Otherwise, the user simply types the response.

In addition to the button shown in the preceding example, you can also include images, attachments, and other useful information to display on response cards. For information about response cards, see Response Cards (p. 13).

In this exercise, you do the following:

- Create and test a bot (using the ScheduleAppointment blueprint). For this exercise, you use a bot blueprint to quickly set up and test the bot. For a list of available blueprints, see Amazon Lex and AWS Lambda Blueprints (p. 105). This bot is preconfigured with one intent (MakeAppointment).

- Create and test a Lambda function (using the lex-make-appointment-python blueprint provided by Lambda). You configure the MakeAppointment intent to use this Lambda function as a code hook to perform initialization, validation, and fulfillment tasks.

  **Note**
  The provided example Lambda function showcases a dynamic conversation based on the mocked-up availability of a dentist appointment. In a real application, you might use a real calendar to set an appointment.

- Update the MakeAppointment intent configuration to use the Lambda function as a code hook. Then, test the end-to-end experience.
Publish the schedule appointment bot to Facebook Messenger so you can see the response cards in action (the client in the Amazon Lex console currently does not support response cards).

The following sections provide summary information about the blueprints you use in this exercise.

Topics
- Overview of the Bot Blueprint (ScheduleAppointment) (p. 124)
- Overview of the Lambda Function Blueprint (lex-make-appointment-python) (p. 125)
- Step 1: Create an Amazon Lex Bot (p. 125)
- Step 2: Create a Lambda Function (p. 127)
- Step 3: Update the Intent: Configure a Code Hook (p. 127)
- Step 4: Deploy the Bot on the Facebook Messenger Platform (p. 128)
- Details of Information Flow (p. 129)

Overview of the Bot Blueprint (ScheduleAppointment)

The ScheduleAppointment blueprint that you use to create a bot for this exercise is preconfigured with the following:

- **Slot types** – One custom slot type called AppointmentTypeValue, with the enumeration values root canal, cleaning, and whitening.
- **Intent** – One intent (MakeAppointment), which is preconfigured as follows:
  - **Slots** – The intent is configured with the following slots:
    - Slot AppointmentType, of the AppointmentTypes custom type.
    - Slot Date, of the AMAZON.DATE built-in type.
    - Slot Time, of the AMAZON.TIME built-in type.
  - **Utterances** – The intent is preconfigured with the following utterances:
    - "I would like to book an appointment"
    - "Book an appointment"
    - "Book a {AppointmentType}"
  
  If the user utters any of these, Amazon Lex determines that MakeAppointment is the intent, and then uses the prompts to elicit slot data.
  
  - **Prompts** – The intent is preconfigured with the following prompts:
    - Prompt for the AppointmentType slot – "What type of appointment would you like to schedule?"
    - Prompt for the Date slot – "When should I schedule your {AppointmentType}?"
    - Prompt for the Time slot – "At what time do you want to schedule the {AppointmentType}?" and "At what time on {Date}?"
    - Confirmation prompt – "{Time} is available, should I go ahead and book your appointment?"
    - Cancel message– "Okay, I will not schedule an appointment."
Overview of the Lambda Function Blueprint (lex-make-appointment-python)

The Lambda function blueprint (lex-make-appointment-python) is a code hook for bots that you create using the ScheduleAppointment bot blueprint.

This Lambda function blueprint code can perform both initialization/validation and fulfillment tasks.

- The Lambda function code showcases a dynamic conversation that is based on example availability for a dentist appointment (in real applications, you might use a calendar). For the day or date that the user specifies, the code is configured as follows:
  - If there are no appointments available, the Lambda function returns a response directing Amazon Lex to prompt the user for another day or date (by setting the dialogAction type to ElicitSlot). For more information, see Response Format (p. 101).
  - If there is only one appointment available on the specified day or date, the Lambda function suggests the available time in the response and directs Amazon Lex to obtain user confirmation by setting the dialogAction in the response to ConfirmIntent. This illustrates how you can improve the user experience by proactively suggesting the available time for an appointment.
  - If there are multiple appointments available, the Lambda function returns a list of available times in the response to Amazon Lex. Amazon Lex returns a response to the client with the message from the Lambda function.
- As the fulfillment code hook, the Lambda function returns a summary message indicating that an appointment is scheduled (that is, the intent is fulfilled).

Note
In this example, we show how to use response cards. The Lambda function constructs and returns a response card to Amazon Lex. The response card lists available days and times as buttons to choose from. When testing the bot using the client provided by the Amazon Lex console, you cannot see the response card. To see it, you must integrate the bot with a messaging platform, such as Facebook Messenger. For instructions, see Integrating an Amazon Lex Bot with Facebook Messenger (p. 107). For more information about response cards, see Managing Messages (Prompts and Statements) (p. 8).

When Amazon Lex invokes the Lambda function, it passes event data as input. One of the event fields is invocationSource, which the Lambda function uses to choose between an input validation and fulfillment activity. For more information, see Input Event Format (p. 98).

Next Step
Step 1: Create an Amazon Lex Bot (p. 125)

Step 1: Create an Amazon Lex Bot

In this section, you create an Amazon Lex bot using the ScheduleAppointment blueprint, which is provided in the Amazon Lex console.

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. On the Bots page, choose Create.
3. On the Create your Lex bot page, do the following:
   - Choose the ScheduleAppointment blueprint.
   - Leave the default bot name (ScheduleAppointment).
4. Choose **Create**.

This step saves and builds the bot. The console sends the following requests to Amazon Lex during the build process:

- Create a new version of the slot types (from the $LATEST version). For information about slot types defined in this bot blueprint, see Overview of the Bot Blueprint (ScheduleAppointment) (p. 124).
- Create a version of the **MakeAppointment** intent (from the $LATEST version). In some cases, the console sends a request for the update API operation before creating a new version.
- Update the $LATEST version of the bot.

At this time, Amazon Lex builds a machine learning model for the bot. When you test the bot in the console, the console uses the runtime API to send user input back to Amazon Lex. Amazon Lex then uses the machine learning model to interpret the user input.

5. The console shows the ScheduleAppointment bot. On the **Editor** tab, review the preconfigured intent (**MakeAppointment**) details.

6. Test the bot in the test window. Use the following screen shot to engage in a test conversation with your bot:

![Test Bot](image)

Note the following:

- From the initial user input ("Book an appointment"), the bot infers the intent (**MakeAppointment**).
- The bot then uses the configured prompts to get slot data from the user.
- The bot blueprint has the **MakeAppointment** intent configured with the following confirmation prompt:

```
After the user provides all of the slot data, Amazon Lex returns a response to the client with a
confirmation prompt as the message. The client displays the message for the user:

16:00 is available, should I go ahead and book your appointment?

Notice that the bot accepts any appointment date and time values because you don't have any code
to initialize or validate the user data. In the next section, you add a Lambda function to do this.

Next Step

Step 2: Create a Lambda Function (p. 127)

Step 2: Create a Lambda Function

In this section, you create a Lambda function using a blueprint (lex-make-appointment-python) that is
provided in the Lambda console. You also test the Lambda function by invoking it using sample Amazon
Lex event data that is provided by the console.

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://
   console.aws.amazon.com/lambda/.
2. Choose Create a Lambda function.
3. For Select blueprint, type lex to find the blueprint, and then choose the lex-make-appointment-
   python blueprint.
4. Configure the Lambda function as follows, and then choose Create Function.
   - Type the Lambda function name (MakeAppointmentCodeHook).
   - For the role, choose Create a new role from template(s), and then type a role name.
   - Leave other default values.
5. Test the Lambda function.
   a. Choose Actions, and then choose Configure test event.
   b. From the Sample event template list, choose Lex-Make Appointment (preview). This sample
event uses the Amazon Lex request/response model, with values set to match a request from
   your Amazon Lex bot. For information about the Amazon Lex request/response model, see
   Using Lambda Functions (p. 98).
   c. Choose Save and test.
   d. Verify that the Lambda function successfully executed. The response in this case matches the
   Amazon Lex response model.

Next Step

Step 3: Update the Intent: Configure a Code Hook (p. 127)

Step 3: Update the Intent: Configure a Code Hook

In this section, you update the configuration of the MakeAppointment intent to use the Lambda
function as a code hook for the validation and fulfillment activities.
1. In the Amazon Lex console, select the ScheduleAppointment bot. The console shows the MakeAppointment intent. Modify the intent configuration as follows.

   **Note**
   You can update only the $LATEST versions of any of the Amazon Lex resources, including the intents. Make sure that the intent version is set to $LATEST. You have not published a version of your bot yet, so it should still be the $LATEST version in the console.

   a. In the **Options** section, choose **Initialization and validation code hook**, and then choose the Lambda function from the list.
   b. In the **Fulfillment** section, choose **AWS Lambda function**, and then choose the Lambda function from the list.
   c. Choose **Goodbye message**, and type a message.

2. Choose **Save**, and then choose **Build**.

3. Test the bot.

![Test Bot](image)

**Next Step**

**Step 4: Deploy the Bot on the Facebook Messenger Platform (p. 128)**

**Step 4: Deploy the Bot on the Facebook Messenger Platform**

In the preceding section, you tested the ScheduleAppointment bot using the client in the Amazon Lex console. Currently, the Amazon Lex console does not support response cards. To test the dynamically
generated response cards that the bot supports, deploy the bot on the Facebook Messenger platform and test it.

For instructions, see Integrating an Amazon Lex Bot with Facebook Messenger (p. 107).

Next Step

Details of Information Flow (p. 129)

Details of Information Flow

The ScheduleAppointment bot blueprint primarily showcases the use of dynamically generated response cards. The Lambda function in this exercise includes response cards in its response to Amazon Lex. Amazon Lex includes the response cards in its reply to the client. This section explains both the following:

- Data flow between client and Amazon Lex.

The section assumes client sends requests to Amazon Lex using the PostText runtime API and shows request/response details accordingly. For more information about the PostText runtime API, see PostText (p. 320).

Note

For an example of information flow between client and Amazon Lex in which client uses the PostContent API, see Step 2a (Optional): Review the Details of the Spoken Information Flow (Console) (p. 34).

- Data flow between Amazon Lex and the Lambda function. For more information, see Lambda Function Input Event and Response Format (p. 98).

Note

The example assumes that you are using the Facebook Messenger client, which does not pass session attributes in the request to Amazon Lex. Accordingly, the example requests shown in this section show empty sessionAttributes. If you test the bot using the client provided in the Amazon Lex console, the client includes the session attributes.

This section describes what happens after each user input.

   a. The client (console) sends the following PostContent (p. 312) request to Amazon Lex:

   ```
   POST /bot/ScheduleAppointment/alias/$LATEST/user/bijt6rovckwecn2esbthrrd7lv3ja3n/text
   "Content-Type":"application/json"
   "Content-Encoding":"amz-1.0"
   {
     "inputText":"book appointment",
     "sessionAttributes":{}
   }
   ```

   Both the request URI and the body provide information to Amazon Lex:
Details of Information Flow

- Request URI – Provides the bot name (ScheduleAppointment), the bot alias ($LATEST), and the user name ID. The trailing text indicates that it is a PostText (not PostContent) API request.

- Request body – Includes the user input (inputText) and empty sessionAttributes.

b. From the inputText, Amazon Lex detects the intent (MakeAppointment). The service invokes the Lambda function, which is configured as a code hook, to perform initialization and validation by passing the following event. For details, see Input Event Format (p. 98).

```json
{
    "currentIntent": {
        "slots": {
            "AppointmentType": null,
            "Date": null,
            "Time": null
        },
        "name": "MakeAppointment",
        "confirmationStatus": "None"
    },
    "bot": {
        "alias": null,
        "version": "$LATEST",
        "name": "ScheduleAppointment"
    },
    "userId": "bijt6rovckweecnzesbthrr1d7tv3ja3n",
    "invocationSource": "DialogCodeHook",
    "outputDialogMode": "Text",
    "messageVersion": "1.0",
    "sessionAttributes": {}
}
```

In addition to the information sent by the client, Amazon Lex also includes the following data:

- **currentIntent** – Provides current intent information.
- **invocationSource** – Indicates the purpose of the Lambda function invocation. In this case, the purpose is to perform user data initialization and validation. (Amazon Lex knows that the user has not provided all of the slot data to fulfill the intent yet.)
- **messageVersion** – Currently Amazon Lex supports only the 1.0 version.

c. At this time, all of the slot values are null (there is nothing to validate). The Lambda function returns the following response to Amazon Lex, directing the service to elicit information for the AppointmentType slot. For information about the response format, see Response Format (p. 101).

```json
{
    "dialogAction": {
        "slotToElicit": "AppointmentType",
        "intentName": "MakeAppointment",
        "responseCard": {
            "genericAttachments": [
                {
                    "buttons": [
                        {
                            "text": "cleaning (30 min)",
                            "value": "cleaning"
                        },
                        {
                            "text": "root canal (60 min)",
                            "value": "root canal"
                        }
                    ]
                }
            ]
        }
    }
}
```
The response includes the dialogAction and sessionAttributes fields. Among other things, the dialogAction field returns the following fields:

- **type** – By setting this field to ElicitSlot, the Lambda function directs Amazon Lex to elicit the value for the slot specified in the slotToElicit field. The Lambda function also provides a message to convey to the user.

- **responseCard** – Identifies a list of possible values for the AppointmentType slot. A client that supports response cards (for example, the Facebook Messenger) displays a response card to allow the user to choose an appointment type, as follows:

  ![Response Card Example](image)

  d. As indicated by the dialogAction.type in the response from the Lambda function, Amazon Lex sends the following response back to the client:
The client reads the response, and then displays the message: "What type of appointment would you like to schedule?" and the response card (if the client supports response cards).

2. **User**: Depending on the client, the user has two options:

   - If the response card is shown, choose **root canal (60 min)** or type **root canal**.
   - If the client does not support response cards, type **root canal**.

   a. The client sends the following **PostText** request to Amazon Lex (line breaks have been added for readability):

   ```json
   POST /bot/BookTrip/alias/$LATEST/user/bijt6rovckwecnzesbthrr1d7lv3ja3n/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   {
     "inputText": "root canal",
     "sessionAttributes": {}
   }
   
   b. Amazon Lex invokes the Lambda function for user data validation by sending the following event as a parameter:

   ```json
   {
     "currentIntent": {
       "slots": {
         "AppointmentType": "root canal",
         "Date": null,
         "Time": null
       },
       "name": "MakeAppointment",
       "confirmationStatus": "None"
     },
     "bot": {
       "alias": null,
       "version": "$LATEST",
       "name": "ScheduleAppointment"
     },
     "userId": "bijt6rovckwecnzesbthrr1d7lv3ja3n",
     "invocationSource": "DialogCodeHook",
     "outputDialogMode": "Text",
     "messageVersion": "1.0",
   }
   ```
In the event data, note the following:

- `invocationSource` continues to be `DialogCodeHook`. In this step, we are just validating user data.
- Amazon Lex sets the `AppointmentType` field in the `currentIntent.slots` slot to `root canal`.
- Amazon Lex simply passes the `sessionAttributes` field between the client and the Lambda function.

c. The Lambda function validates the user input and returns the following response to Amazon Lex, directing the service to elicit a value for the appointment date.

```json
{
  "dialogAction": {
    "slotToElicit": "Date",
    "intentName": "MakeAppointment",
    "responseCard": {
      "genericAttachments": [
        {
          "buttons": [
            {
              "text": "2-15 (Wed)",
              "value": "Wednesday, February 15, 2017"
            },
            {
              "text": "2-16 (Thu)",
              "value": "Thursday, February 16, 2017"
            },
            {
              "text": "2-17 (Fri)",
              "value": "Friday, February 17, 2017"
            },
            {
              "text": "2-20 (Mon)",
              "value": "Monday, February 20, 2017"
            },
            {
              "text": "2-21 (Tue)",
              "value": "Tuesday, February 21, 2017"
            }
          ],
          "subTitle": "When would you like to schedule your root canal?",
          "title": "Specify Date"
        }
      ],
      "version": 1,
      "contentType": "application/vnd.amazonaws.card.generic"
    },
    "slots": {
      "AppointmentType": "root canal",
      "Date": null,
      "Time": null
    },
    "type": "ElicitSlot",
    "message": {
      "content": "When would you like to schedule your root canal?",
      "contentType": "PlainText"
    }
  },
  "sessionAttributes": {}
}
```
Again, the response includes the `dialogAction` and `sessionAttributes` fields. Among other things, the `dialogAction` field returns the following fields:

- **type** – By setting this field to `ElicitSlot`, the Lambda function directs Amazon Lex to elicit the value for the slot specified in the `slotToElicit` field. The Lambda function also provides a message to convey to the user.

- **responseCard** – Identifies a list of possible values for the `Date` slot. A client that supports response cards (for example, Facebook Messenger) displays a response card that allows the user to choose an appointment date:

![Response Card Example]

Although the Lambda function returned five dates, the client (Facebook Messenger) has a limit of three buttons for a response card. Therefore, you see only the first three values in the screen shot.

These dates are hard coded in the Lambda function. In a production application, you might use a calendar to get available dates in real time. Because the dates are dynamic, you must generate the response card dynamically in the Lambda function.

d. Amazon Lex notices the `dialogAction.type` and returns a response to the client that includes information from the Lambda function's response.

![Lambda Function Response]

The client displays the message: **When would you like to schedule your root canal?** and the response card (if the client supports response cards).

3. User: Types **Thursday**.
a. The client sends the following `PostText` request to Amazon Lex (line breaks have been added for readability):

```json
POST /bot/BookTrip/alias/$LATEST/user/bijt6rovck wcsbthrr1d7lv3ja3n/text
"Content-Type": "application/json"
"Content-Encoding": "amz-1.0"
{
"inputText": "Thursday",
"sessionAttributes": {}
}
```

b. Amazon Lex invokes the Lambda function for user data validation by sending in the following event as a parameter:

```json
{
"currentIntent": {
  "slots": {
    "AppointmentType": "root canal",
    "Date": "2017-02-16",
    "Time": null
  },
  "name": "MakeAppointment",
  "confirmationStatus": "None"
},
"bot": {
  "alias": null,
  "version": "$LATEST",
  "name": "ScheduleAppointment"
},
"userId": "u3fpr9gghj02zts7y5tpq5mm4din2xqy",
"invocationSource": "DialogCodeHook",
"outputDialogMode": "Text",
"messageVersion": "1.0",
"sessionAttributes": {}
}
```

In the event data, note the following:

- `invocationSource` continues to be `DialogCodeHook`. In this step, we are just validating the user data.
- Amazon Lex sets the `Date` field in the `currentIntent.slots` slot to `2017-02-16`.
- Amazon Lex simply passes the `sessionAttributes` between the client and the Lambda function.

c. The Lambda function validates the user input. This time the Lambda function determines that there are no appointments available on the specified date. It returns the following response to Amazon Lex, directing the service to again elicit a value for the appointment date.

```json
{
"dialogAction": {
  "slotToElicit": "Date",
  "intentName": "MakeAppointment",
  "responseCard": {
    "genericAttachments": [
    {
      "buttons": [
      {
        "text": "2-15 (Wed)",
        "value": "Wednesday, February 15, 2017"
      }]
    ]
  }
}
```
Again, the response includes the `dialogAction` and `sessionAttributes` fields. Among other things, the `dialogAction` returns the following fields:

- **dialogAction field**:
  - `type` - The Lambda function sets this value to `ElicitSlot` and resets the `slotToElicit` field to `Date`. The Lambda function also provides an appropriate `message` to convey to the user.
  - `responseCard` - Returns a list of values for the `Date` slot.
  - `sessionAttributes` - This time the Lambda function includes the `bookingMap` session attribute. Its value is the requested date of the appointment and available appointments (an empty object indicates that no appointments are available).

d. Amazon Lex notices the `dialogAction.type` and returns a response to the client that includes information from the Lambda function's response.
The client displays the message: **We do not have any availability on that date, is there another day which works for you?** and the response card (if the client supports response cards).

4. **User:** Depending on the client, the user has two options:

- If the response card is shown, choose **2-15 (Wed)** or type **Wednesday**.
- If the client does not support response cards, type **Wednesday**.

   a. The client sends the following **PostText** request to Amazon Lex:

   ```
   POST /bot/BookTrip/alias/$LATEST/user/bijt6rovckwecnzesbhrr1d7lv3ja3n/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   
   { "inputText": "Wednesday", "sessionAttributes": {} }
   
   **Note**
   The Facebook Messenger client does not set any session attributes. If you want to maintain session states between requests, you must do so in the Lambda function. In a real application, you might need to maintain these session attributes in a backend database.

   b. Amazon Lex invokes the Lambda function for user data validation by sending the following event as a parameter:

   ```
   { "currentIntent": { "slots": { "AppointmentType": "root canal", "Date": "2017-02-15", "Time": null }, "name": "MakeAppointment", "confirmationStatus": "None" }, "bot": { } }
   ```
Amazon Lex updated `currentIntent.slots` by setting the `Date` slot to `2017-02-15`.

c. The Lambda function validates the user input and returns the following response to Amazon Lex, directing it to elicit the value for the appointment time.

```json
{
    "dialogAction": {
        "type": "ConfirmIntent",
        "intentName": "MakeAppointment",
        "responseCard": {
            "genericAttachments": [
                {
                    "buttons": [
                        {
                            "text": "yes",
                            "value": "yes"
                        },
                        {
                            "text": "no",
                            "value": "no"
                        }
                    ],
                    "subTitle": "Is 4:00 p.m. on 2017-02-15 okay?",
                    "title": "Confirm Appointment"
                }
            ],
            "version": 1,
            "contentType": "application/vnd.amazonaws.card.generic"
        }
    },
    "sessionAttributes": {
        "bookingMap": "{"2017-02-15": ["10:00", "16:00", "16:30"]}"
    }
}
```

Again, the response includes the `dialogAction` and `sessionAttributes` fields. Among other things, the `dialogAction` returns the following fields:

- `dialogAction` field:
  - `type` – The Lambda function sets this value to `ConfirmIntent`, directing Amazon Lex to obtain user confirmation of the appointment time suggested in the `message`.

138
• **responseCard** – Returns a list of yes/no values for the user to choose from. If the client supports response cards, it displays the response card, as shown in the following example:

![Image of response card example](image)

• **sessionAttributes** - The Lambda function sets the bookingMap session attribute with its value set to the appointment date and available appointments on that date. In this example, these are 30-minute appointments. For a root canal that requires one hour, only 4 p.m. can be booked.

d. As indicated in the `dialogAction.type` in the Lambda function's response, Amazon Lex returns the following response to the client:

```json
{
  "currentIntent": {
    "slots": {
      "AppointmentType": "root canal",
      "Date": "2017-02-15",
      "Time": "16:00"
    },
    "name": "MakeAppointment",
    "confirmationStatus": "Confirmed"
  }
}
```

The client displays the message: **What time on 2017-02-15 works for you? 4:00 p.m. is our only availability, does that work for you?**

5. **User:** Choose **yes**.

Amazon Lex invokes the Lambda function with the following event data. Because the user replied **yes**, Amazon Lex sets the `confirmationStatus` to `Confirmed`, and sets the `Time` field in `currentIntent.slots` to 4 p.m.
Because the confirmationStatus is confirmed, the Lambda function processes the intent (books a dental appointment) and returns the following response to Amazon Lex:

```json
{
  "dialogAction": {
    "message": {
      "content": "Okay, I have booked your appointment. We will see you at 4:00 p.m. on 2017-02-15",
      "contentType": "PlainText"
    },
    "type": "Close",
    "fulfillmentState": "Fulfilled",
    "sessionAttributes": {
      "formattedTime": "4:00 p.m.",
      "bookingMap": "{{"2017-02-15\": ["10:00"]}}"
    }
  }
}
```

Note the following:

- The Lambda function has updated the `sessionAttributes`
- `dialogAction.type` is set to `Close`, which directs Amazon Lex to not expect a user response.
- `dialogAction.fulfillmentState` is set to `Fulfilled`, indicating that the intent is successfully fulfilled.

The client displays the message: **Okay, I have booked your appointment. We will see you at 4:00 p.m. on 2017-02-15.**

### Example Bot: BookTrip

This example illustrates creating a bot that is configured to support multiple intents. The example also illustrates how you can use session attributes for cross-intent information sharing. After creating the bot, you use a test client in the Amazon Lex console to test the bot (BookTrip). The client uses the `PostText` (p. 320) runtime API operation to send requests to Amazon Lex for each user input.

The BookTrip bot in this example is configured with two intents (BookHotel and BookCar). For example, suppose a user first books a hotel. During the interaction, the user provides information such as check-in dates, location, and number of nights. After the intent is fulfilled, the client can persist this information using session attributes. For more information about session attributes, see `PostText` (p. 320).

Now suppose that the user continues to book a car. Using information that the user provided in the previous BookHotel intent (that is, destination city, and check-in and check-out dates), the code hook (Lambda function) you configured to initialize and validate the BookCar intent, initializes slot data for
the BookCar intent (that is, destination, pick-up city, pick-up date, and return date). This illustrates how cross-intent information sharing enables you to build bots that can engage in dynamic conversation with the user.

In this example, we use the following session attributes. Only the client and the Lambda function can set and update session attributes. Amazon Lex only passes these between the client and the Lambda function. Amazon Lex doesn't maintain or modify any session attributes.

- **currentReservation** – Contains slot data for an in-progress reservation and other relevant information. For example, the following is a sample request from the client to Amazon Lex. It shows the currentReservation session attribute in the request body.

```
POST /bot/BookTrip/alias/$LATEST/user/wch89kjcpdkd48aenye7dly5x3otq6j3/text
"Content-Type":"application/json"
"Content-Encoding":"amz-1.0"
{
  "inputText":"Chicago",
  "sessionAttributes":{
    "currentReservation":"{"ReservationType":"Hotel",
    "Location":"Moscow",
    "RoomType":null,
    "CheckInDate":null,
    "Nights":null}"
  }
}
```

- **lastConfirmedReservation** – Contains similar information for a previous intent, if any. For example, if the user booked a hotel and then is in process of booking a car, this session attribute stores slot data for the previous BookHotel intent.

- **confirmationContext** – The Lambda function sets this to AutoPopulate when it prepopulates some of the slot data based on slot data from the previous reservation (if there is one). This enables cross-intent information sharing. For example, if the user previously booked a hotel and now wants to book a car, Amazon Lex can prompt the user to confirm (or deny) that the car is being booked for the same city and dates as their hotel reservation.

In this exercise you use blueprints to create an Amazon Lex bot and a Lambda function. For more information about blueprints, see Amazon Lex and AWS Lambda Blueprints (p. 105).

**Next Step**

**Step 1: Review the Blueprints Used in this Exercise**

**Step 1: Review the Blueprints Used in this Exercise**

**Topics**

- Overview of the Bot Blueprint (BookTrip) (p. 141)
- Overview of the Lambda Function Blueprint (lex-book-trip-python) (p. 143)

**Overview of the Bot Blueprint (BookTrip)**

The blueprint (BookTrip) you use to create a bot provides the following preconfiguration:
• **Slot types** – Two custom slot types:
  
  • RoomTypes with enumeration values: king, queen, and deluxe, for use in the BookHotel intent.
  
  • CarTypes with enumeration values: economy, standard, midsize, full size, luxury, and minivan, for use in the CarTypes intent.

• **Intent 1 (BookHotel)** – It is preconfigured as follows:
  
  **Preconfigured slots**
  
  • RoomType, of the RoomTypes custom slot type
  
  • Location, of the AMAZON.US_CITY built-in slot type
  
  • CheckInDate, of the AMAZON.DATE built-in slot type
  
  • Nights, of the AMAZON.NUMBER built-in slot type

  **Preconfigured utterances**
  
  • "Book a hotel"
  
  • "I want to make hotel reservations"
  
  • "Book a {Nights} stay in {Location}"

If the user utters any of these, Amazon Lex determines BookHotel is the intent and then prompts the user for slot data.

  **Preconfigured prompts**
  
  • Prompt for the Location slot – "What city will you be staying in?"
  
  • Prompt for the CheckInDate slot – "What day do you want to check in?"
  
  • Prompt for the Nights slot – "How many nights will you be staying?"
  
  • Prompt for the RoomType slot – "What type of room would you like, queen, king, or deluxe?"
  
  • Confirmation statement – "Okay, I have you down for a {Nights} night stay in {Location} starting {CheckInDate}. Shall I book the reservation?"
  
  • Denial – "Okay, I have cancelled your reservation in progress."

• **Intent 2 (BookCar)** – It is preconfigured as follows:

  **Preconfigured slots**

  • PickUpCity, of the AMAZON.US_CITY built-in type
  
  • PickUpDate, of the AMAZON.DATE built-in type
  
  • ReturnDate, of the AMAZON.DATE built-in type
  
  • DriverAge, of the AMAZON.NUMBER built-in type
  
  • CarType, of the CarTypes custom type

  **Preconfigured utterances**

  • "Book a car"
  
  • "Reserve a car"
  
  • "Make a car reservation"

If the user utters any of these, Amazon Lex determines BookCar is the intent and then prompts the user for slot data.

  **Preconfigured prompts**

  • Prompt for the PickUpCity slot – "In what city do you need to rent a car?"
  
  • Prompt for the PickUpDate slot – "What day do you want to start your rental?"
  
  • Prompt for the ReturnDate slot – "What day do you want to return this car?"
  
  • Prompt for the DriverAge slot – "How old is the driver for this rental?"
• Prompt for the CarType slot – "What type of car would you like to rent? Our most popular options are economy, midsize, and luxury"

• Confirmation statement – "Okay, I have you down for a {CarType} rental in {PickUpCity} from {PickUpDate} to {ReturnDate}. Should I book the reservation?"

• Denial – "Okay, I have cancelled your reservation in progress."

Overview of the Lambda Function Blueprint (lex-book-trip-python)

In addition to the bot blueprint, AWS Lambda provides a blueprint (lex-book-trip-python) that you can use as a code hook with the bot blueprint. For a list of bot blueprints and corresponding Lambda function blueprints, see Amazon Lex and AWS Lambda Blueprints (p. 105).

When you create a bot using the BookTrip blueprint, you update configuration of both the intents (BookCar and BookHotel) by adding this Lambda function as a code hook for both initialization/validation of user data input and fulfillment of the intents.

This Lambda function code provided showcases dynamic conversation using previously known information (persisted in session attributes) about a user to initialize slot values for an intent. For more information, see Managing Conversation Context (p. 17).

Next Step

Step 2: Create an Amazon Lex Bot (p. 143)

Step 2: Create an Amazon Lex Bot

In this section, you create an Amazon Lex bot (BookTrip).

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. On the Bots page, choose Create.
3. On the Create your Lex bot page,
   • Choose BookTrip blueprint.
   • Leave the default bot name (BookTrip).
4. Choose Create. The console sends a series of requests to Amazon Lex to create the bot. Note the following:
5. The console shows the BookTrip bot. On the Editor tab, review the details of the preconfigured intents (BookCar and BookHotel).
6. Test the bot in the test window. Use the following to engage in a test conversation with your bot:
From the initial user input ("Book a hotel"), Amazon Lex infers the intent (BookHotel). The bot then uses the prompts preconfigured in this intent to elicit slot data from the user. After user provide all of the slot data, Amazon Lex returns a response back to the client with a message that includes all the user input as a message. The client displays the message in the response as shown.

CheckInDate:2016-12-18 Location:Chicago Nights:4 RoomType:queen

Now you continue the conversation and try to book a car.
Note that,

- There is no user data validation at this time. For example, you can provide any city to book a hotel.
- You are providing some of the same information again (destination, pick-up city, pick-up date, and return date) to book a car. In a dynamic conversation, your bot should initialize some of this information based on prior input user provided for booking hotel.

In this next section, you create a Lambda function to do some of the user data validation, and initialization using cross-intent information sharing via session attributes. Then you update the intent configuration by adding the Lambda function as code hook to perform initialization/validation of user input and fulfill intent.

Next Step

Step 3: Create a Lambda function (p. 146)
Step 3: Create a Lambda function

In this section you create a Lambda function using a blueprint (lex-book-trip-python) provided in the Amazon Lex console. You also test the Lambda function by invoking it using sample event data provided by the console.

This Lambda function is written in Node.js.

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create a Lambda function.
3. On Select blueprint, type lex to find the blueprint, choose the lex-book-trip-python blueprint.
4. Configure the Lambda function as follows and then choose Create Function.
   - Type a Lambda function name (BookTripCodeHook).
   - For the role, choose Create a new role from template(s) and then type a role name.
   - Leave the other default values.
5. Test the Lambda function. You invoke the Lambda function twice, using sample data for both booking a car and booking a hotel.
   a. Choose Actions, Configure test event.
   b. Choose Lex-Book Hotel (preview) from the Sample event template list.
      This sample event matches the Amazon Lex request/response model. For more information, see Using Lambda Functions (p. 98).
   c. Choose Save and test.
   d. Verify that the Lambda function successfully executed. The response in this case matches the Amazon Lex response model.
   e. Repeat the step. This time you choose the Lex-Book Car (preview) from the Sample event template list. The Lambda function processes the car reservation.

Next Step

Step 4: Add the Lambda Function as a Code Hook (p. 146)

Step 4: Add the Lambda Function as a Code Hook

In this section, you update the configurations of both the BookCar and BookHotel intents by adding the Lambda function as a code hook for initialization/validation and fulfillment activities. Make sure you choose the $LATEST version of the intents because you can only update the $LATEST version of your Amazon Lex resources.

1. In the Amazon Lex console, choose the BookTrip bot.
2. On the Editor tab, choose the BookHotel intent. Update the intent configuration as follows:
   a. Make sure the intent version (next to the intent name) is $LATEST.
   b. Add the Lambda function as an initialization and validation code hook as follows:
      - In Options, choose Initialization and validation code hook.
      - Choose your Lambda function from the list.
   c. Add the Lambda function as a fulfillment code hook as follows:
      - In Fulfillment, choose AWS Lambda function.
• Choose your Lambda function from the list.
  • Choose **Goodbye message** and type a message.

  d. Choose **Save**.

3. On the **Editor** tab, choose the BookCar intent. Follow the preceding step to add your Lambda function as validation and fulfillment code hook.

4. Choose **Build**. The console sends a series of requests to Amazon Lex to save the configurations.

5. Test the bot. Now that you have a Lambda function performing the initialization, user data validation and fulfillment, you can see the difference in the user interaction.

For more information about the data flow from the client (console) to Amazon Lex, and from Amazon Lex to the Lambda function, see Data Flow: Book Hotel Intent (p. 149).

6. Continue the conversation and book a car as shown following:
When you choose to book a car, the client (console) sends a request to Amazon Lex that includes the session attributes (from the previous conversation, BookHotel). Amazon Lex passes this information to the Lambda function, which then initializes (that is, it prepopulates) some of the BookCar slot data (that is, PickUpDate, ReturnDate, and PickUpCity).

**Note**
This illustrates how session attributes can be used to maintain context across intents. The console client provides the Clear link in the test window that a user can use to clear any prior session attributes.

For more information about the data flow from the client (console) to Amazon Lex, and from Amazon Lex to the Lambda function, see Data Flow: Book Car Intent (p. 157).

**Details of the Information Flow**

In this exercise, you engaged in a conversation with the Amazon Lex BookTrip bot using the test window client provided in the Amazon Lex console. This section explains the following:
• The data flow between the client and Amazon Lex.

The section assumes that the client sends requests to Amazon Lex using the PostText runtime API and shows request and response details accordingly. For more information about the PostText runtime API, see PostText (p. 320).

Note
For an example of the information flow between the client and Amazon Lex in which the client uses the PostContent API, see Step 2a (Optional): Review the Details of the Spoken Information Flow (Console) (p. 34).

• The data flow between Amazon Lex and the Lambda function. For more information, see Lambda Function Input Event and Response Format (p. 98).

Topics
• Data Flow: Book Hotel Intent (p. 149)
• Data Flow: Book Car Intent (p. 157)

Data Flow: Book Hotel Intent

This section explains what happens after each user input.

1. User: "book a hotel"
   a. The client (console) sends the following PostText (p. 320) request to Amazon Lex:

   ```
   POST /bot/BookTrip/alias/$LATEST/user/wch89kjqcpkds8seny7dly5x3otq68j3/text
   "Content-Type":"application/json"
   "Content-Encoding":"amz-1.0"
   {
   "inputText":"book a hotel",
   "sessionAttributes":{}
   }
   ```

   Both the request URI and the body provides information to Amazon Lex:
   - Request URI – Provides bot name (BookTrip), bot alias ($LATEST) and the user name. The trailing text indicates that it is a PostText API request (and not PostContent).
   - Request body – Includes the user input (inputText) and empty sessionAttributes. Initially, this is an empty object and the Lambda function first sets the session attributes.
   b. From the inputText, Amazon Lex detects the intent (BookHotel). This intent is configured with a Lambda function as a code hook for user data initialization/validation. Therefore, Amazon Lex invokes that Lambda function by passing the following information as the event parameter (see Input Event Format (p. 98)):

   ```
   {
   "messageVersion":"1.0",
   "invocationSource":"DialogCodeHook",
   "userId":"wch89kjqcpkds8seny7dly5x3otq68j3",
   "sessionAttributes":{},
   "bot":{
   "name":"BookTrip",
   ```
In addition to the information sent by the client, Amazon Lex also includes the following additional data:

- **messageVersion** – Currently Amazon Lex supports only the 1.0 version.
- **invocationSource** – Indicates the purpose of Lambda function invocation. In this case, it is to perform user data initialization and validation (at this time Amazon Lex knows that the user has not provided all the slot data to fulfill the intent).
- **currentIntent** – All of the slot values are set to null.

At this time, all the slot values are null. There is nothing for the Lambda function to validate.

The Lambda function returns the following response to Amazon Lex. For information about response format, see Response Format (p. 101).

```json
{
    "sessionAttributes":{
        "currentReservation":"{"ReservationType":"Hotel","Location":null,"RoomType":null,"CheckInDate":null,"Nights":null}"
    },
    "dialogAction":{
        "type":"Delegate",
        "slots":{
            "RoomType":null,
            "CheckInDate":null,
            "Nights":null,
            "Location":null
        }
    }
}
```

**Note**

- **currentReservation** – The Lambda function includes this session attribute. Its value is a copy of the current slot information and the reservation type.

Only the Lambda function and the client can update these session attributes. Amazon Lex simply passes these values.

- **dialogAction.type** – By setting this value to Delegate, the Lambda function delegates the responsibility for the next course of action to Amazon Lex.

If the Lambda function detected anything in the user data validation, it instructs Amazon Lex what to do next.

As per the dialogAction.type, Amazon Lex decides the next course of action—elicit data from the user for the Location slot. It selects one of the prompt messages ("What city will you
be staying in?" for this slot, according to the intent configuration, and then sends the following response to the user:

<table>
<thead>
<tr>
<th>Headers</th>
<th>Cookies</th>
<th>Params</th>
<th>Response</th>
<th>Timings</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>JSON</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```json
dialogState: "UpdateSlot"
intentName: "BookHotel"
message: "What city will you be staying in?"
responseCard: null
```

```json
sessionAttributes: Object
  currentReservation: "{"ReservationType": "Hotel", "Location":null,"RoomType":null,"CheckInDate":null,"Nights":null}"  
  slotToElicit: "Location"
```

```json
slots: Object
  CheckInDate: null
  Location: null
  Nights: null
  RoomType: null
```

The session attributes are passed to the client.

The client reads the response and then displays the message: "What city will you be staying in?"

2. User: "Moscow"

   a. The client sends the following PostText request to Amazon Lex (line breaks added for readability):

   ```
   POST /bot/BookTrip/alias/$LATEST/user/wch89kjgcps8sney7dly5x3otq68j3/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   
   {
     "inputText": "Moscow",
     "sessionAttributes": {
       "currentReservation": "{"ReservationType": "Hotel", "Location":null,"RoomType":null,"CheckInDate":null,"Nights":null}"  
     }
   }
   ```

   In addition to the inputText, the client includes the same currentReservation session attributes it received.

   b. Amazon Lex first interprets the inputText in the context of the current intent (the service remembers that it had asked the specific user for information about Location slot). It updates the slot value for the current intent and invokes the Lambda function using the following event:

   ```
   {
     "messageVersion": "1.0",
     "invocationSource": "DialogCodeHook",
     "userId": "wch89kjgcps8sney7dly5x3otq68j3",
     "sessionAttributes": {
       "currentReservation": "{"ReservationType": "Hotel", "Location":null,"RoomType":null,"CheckInDate":null,"Nights":null}"
     },
     "bot": {
       "name": "BookTrip",
       "message": "What city will you be staying in?"
     }
   }
   ```
Note

- `invocationSource` continues to be `DialogCodeHook`. In this step, we are just validating user data.

- Amazon Lex is just passing the session attribute to the Lambda function.

- For `currentIntent.slots`, Amazon Lex has updated the `Location` slot to `Moscow`.

c. The Lambda function performs the user data validation and determines that `Moscow` is an invalid location.

**Note**
The Lambda function in this exercise has a simple list of valid cities and `Moscow` is not on the list. In a production application, you might use a back-end database to get this information.

It resets the slot value back to null and directs Amazon Lex to prompt the user again for another value by sending the following response:

```json
{
    "sessionAttributes": {
        "currentReservation": "{\"ReservationType\":\"Hotel\",\"Location\":\"Moscow\",\"RoomType\":null,\"CheckInDate\":null,\"Nights\":null}\n    },
    "dialogAction": {
        "type": "ElicitSlot",
        "intentName": "BookHotel",
        "slots": {
            "RoomType": null,
            "CheckInDate": null,
            "Nights": null,
            "Location": null
        },
        "slotToElicit": "Location",
        "message": {
            "contentType": "PlainText",
            "content": "We currently do not support Moscow as a valid destination. Can you try a different city?"
        }
    }
}
```

**Note**

- `currentIntent.slots.Location` is reset to null.
- `dialogAction.type` is set to `ElicitSlot`, which directs Amazon Lex to prompt the user again by providing the following:
  - `dialogAction.slotToElicit` – slot for which to elicit data from the user.
  - `dialogAction.message` – a message to convey to the user.

d. Amazon Lex notices the `dialogAction.type` and passes the information to the client in the following response:

```
<table>
<thead>
<tr>
<th>Headers</th>
<th>Cookies</th>
<th>Params</th>
<th>Response</th>
<th>Timings</th>
<th>Security</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter properties</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>JSON</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  dialogState: "ElicitSlot"
  intentName: "BookHotel"
  messages: "We currently do not support Moscow as a valid destination. Can you try a different city?"
  responseCard: null
  sessionAttributes: Object
    currentReservation: "{"ReservationType":"Hotel","Location":"Moscow","RoomType":null,"CheckInDate":null,"Nights":null}"
  slotToElicit: "Location"
  slots: Object
    CheckInDate: null
    Location: null
    Nights: null
    RoomType: null
```

The client simply displays the message: "We currently do not support Moscow as a valid destination. Can you try a different city?"

3. User: "Chicago"

a. The client sends the following `PostText` request to Amazon Lex:

```
POST /bot/BookTrip/alias/$LATEST/user/wch89kjqcpkds8seny7dly5x3otq68j3/text
"Content-Type":"application/json"
"Content-Encoding":"amz-1.0"
{
  "inputText":"Chicago",
  "sessionAttributes":{
    "currentReservation":"{"ReservationType":"Hotel","Location":"Moscow","RoomType":null,"CheckInDate":null,"Nights":null}"
  }
}
```

b. Amazon Lex knows the context, that it was eliciting data for the `Location` slot. In this context, it knows the `inputText` value is for the `Location` slot. It then invokes the Lambda function by sending the following event:

```
{
  "messageVersion": "1.0",
  "invocationSource": "DialogCodeHook",
  "userId": "wch89kjqcpkds8seny7dly5x3otq68j3",
  "sessionAttributes": {
    "currentReservation": "{"ReservationType":"Hotel","Location":"Moscow","RoomType":null,"CheckInDate":null,"Nights":null}"
  },
  "bot": {
    "name": "BookTrip",
```
Amazon Lex updated the `currentIntent.slots` by setting the `Location` slot to Chicago.

According to the `invocationSource` value of `DialogCodeHook`, the Lambda function performs user data validation. It recognizes Chicago as a valid slot value, updates the session attribute accordingly, and then returns the following response to Amazon Lex.

```
{
  "sessionAttributes": {
    "currentReservation": "{"ReservationType": "Hotel", "Location": "Chicago", "RoomType": null, "CheckInDate": null, "Nights": null}"
  },
  "dialogAction": {
    "type": "Delegate",
    "slots": {
      "RoomType": null,
      "CheckInDate": null,
      "Nights": null,
      "Location": "Chicago"
    }
  }
}
```

**Note**

- `currentReservation` – The Lambda function updates this session attribute by setting the `Location` to Chicago.
- `dialogAction.type` – Is set to `Delegate`. User data was valid, and the Lambda function directs Amazon Lex to choose the next course of action.

d. According to `dialogAction.type`, Amazon Lex chooses the next course of action. Amazon Lex knows that it needs more slot data and picks the next unfilled slot (`CheckInDate`) with the highest priority according to the intent configuration. It selects one of the prompt messages ("What day do you want to check in?") for this slot according to the intent configuration and then sends the following response back to the client:
The client displays the message: "What day do you want to check in?"

4. The user interaction continues—the user provides data, the Lambda function validates data, and then delegates the next course of action to Amazon Lex. Eventually the user provides all of the slot data, the Lambda function validates all of the user input, and then Amazon Lex recognizes it has all the slot data.

**Note**
In this exercise, after the user provides all of the slot data, the Lambda function computes the price of the hotel reservation and returns it as another session attribute (`currentReservationPrice`).

At this point, the intent is ready to be fulfilled, but the BookHotel intent is configured with a confirmation prompt requiring user confirmation before Amazon Lex can fulfill the intent. Therefore, Amazon Lex sends the following message to the client requesting confirmation before booking the hotel:

The client display the message: "Okay, I have you down for a 5 night in Chicago starting 2016-12-18. Shall I book the reservation?"

5. User: "yes"

a. The client sends the following **PostText** request to Amazon Lex:
b. Amazon Lex interprets the `inputText` in the context of confirming the current intent. Amazon Lex understands that the user wants to proceed with the reservation. This time Amazon Lex invokes the Lambda function to fulfill the intent by sending the following event. By setting the `invocationSource` to `FulfillmentCodeHook` in the event, it sends to the Lambda function. Amazon Lex also sets the `confirmationStatus` to `Confirmed`.

```json
{
  "messageVersion": "1.0",
  "invocationSource": "FulfillmentCodeHook",
  "userId": "wch89kjqcpkds8seny7dly5x3otq68j3",
  "sessionAttributes": {
    "currentReservation": "{"ReservationType":"Hotel","Location":"Chicago","RoomType":"queen","CheckInDate":"2016-12-18","Nights":"4"},
    "currentReservationPrice": "956"
  },
  "bot": {
    "name": "BookTrip",
    "alias": null,
    "version": "$LATEST"
  },
  "outputDialogMode": "Text",
  "currentIntent": {
    "name": "BookHotel",
    "slots": {
      "RoomType": "queen",
      "CheckInDate": "2016-12-18",
      "Nights": "4",
      "Location": "Chicago"
    },
    "confirmationStatus": "Confirmed"
  }
}
```

**Note**

- `invocationSource` – This time, Amazon Lex set this value to `FulfillmentCodeHook`, directing the Lambda function to fulfill the intent.
- `confirmationStatus` – Is set to `Confirmed`.

c. This time, the Lambda function fulfills the `BookHotel` intent, Amazon Lex completes the reservation, and then it returns the following response:

```json
{
  "sessionAttributes": {
```

156
"lastConfirmedReservation": "{"ReservationType":"Hotel","Location":"Chicago","RoomType":"queen","CheckInDate":"2016-12-18","Nights":"4"}"

"dialogAction": {
  "type": "Close",
  "fulfillmentState": "Fulfilled",
  "message": {
    "contentType": "PlainText",
    "content": "Thanks, I have placed your reservation. Please let me know if you would like to book a car rental, or another hotel."
  }
}

Note

- lastConfirmedReservation – Is a new session attribute that the Lambda function added (instead of the currentReservation, currentReservationPrice).
- dialogAction.type – The Lambda function sets this value to Close, indicating that Amazon Lex to not expect a user response.
- dialogAction.fulfillmentState – Is set to Fulfilled and includes an appropriate message to convey to the user.

d. Amazon Lex reviews the fulfillmentState and sends the following response to the client:

```json
{
  "dialogState": "Fulfilled",
  "intentName": "BookHotel",
  "message": "Thanks, I have placed your reservation. Please let me know if you would like to book a car rental, or another hotel."
}
```

Note

- dialogState – Amazon Lex sets this value to Fulfilled.
- message – Is the same message that the Lambda function provided.

The client displays the message.

Data Flow: Book Car Intent

The BookTrip bot in this exercise supports two intents (BookHotel and BookCar). After booking a hotel, the user can continue the conversation to book a car. As long as the session hasn't timed out, in each subsequent request the client continues to send the session attributes (in this example, the lastConfirmedReservation). The Lambda function can use this information to initialize slot data for the BookCar intent. This shows how you can use session attributes in cross-intent data sharing.
Specifically, when the user chooses the BookCar intent, the Lambda function uses relevant information in the session attribute to prepopulate slots (PickUpDate, ReturnDate, and PickUpCity) for the BookCar intent.

**Note**
The Amazon Lex console provides the **Clear** link that you can use to clear any prior session attributes.

Follow the steps in this procedure to continue the conversation.

1. **User: “also book a car”**
   
a. The client sends the following **PostText** request to Amazon Lex.

   ```
   POST /bot/BookTrip/alias/$LATEST/user/wch89kjqcpkds8seny7dly5x3otq68j3/text
   "Content-Type": "application/json"
   "Content-Encoding": "amz-1.0"
   {
     "inputText": "also book a car",
     "sessionAttributes": {
       "lastConfirmedReservation": "{ "ReservationType": "Hotel", "Location": "Chicago", "RoomType": "queen", "CheckInDate": "2016-12-18", "Nights": "4" }"
     }
   }
   ```

   The client includes the **lastConfirmedReservation** session attribute.

   b. Amazon Lex detects the intent (BookCar) from the **inputText**. This intent is also configured to invoke the Lambda function to perform the initialization and validation of the user data. Amazon Lex invokes the Lambda function with the following event:

   ```
   {
     "messageVersion": "1.0",
     "invocationSource": "DialogCodeHook",
     "userId": "wch89kjqcpkds8seny7dly5x3otq68j3",
     "sessionAttributes": {
       "lastConfirmedReservation": "{ "ReservationType": "Hotel", "Location": "Chicago", "RoomType": "queen", "CheckInDate": "2016-12-18", "Nights": "4" }"
     },
     "bot": {
       "name": "BookTrip",
       "alias": null,
       "version": "$LATEST"
     },
     "outputDialogMode": "Text",
     "currentIntent": {
       "name": "BookCar",
       "slots": {
         "PickUpDate": null,
         "ReturnDate": null,
         "DriverAge": null,
         "CarType": null,
         "PickUpCity": null
       },
       "confirmationStatus": "None"
     }
   }
   ```
Note

- messageVersion – Currently Amazon Lex supports the 1.0 version only.
- invocationSource – Indicates the purpose of invocation is to perform initialization and user data validation.
- currentIntent – It includes the intent name and the slots. At this time, all slot values are null.

c. The Lambda function notices all null slot values with nothing to validate. However, it uses session attributes to initialize some of the slot values (PickUpDate, ReturnDate, and PickUpCity), and then returns the following response:

```json
{
  "sessionAttributes": {
    "lastConfirmedReservation": "{"ReservationType":"Hotel","Location":"Chicago","RoomType":"queen","CheckInDate":"2016-12-18","Nights":"4"},
    "currentReservation": "{"ReservationType":"Car","PickUpCity":null,"PickUpDate":null,"ReturnDate":null,"CarType":null},
    "confirmationContext": "AutoPopulate"
  },
  "dialogAction": {
    "type": "ConfirmIntent",
    "intentName": "BookCar",
    "slots": {
      "PickUpCity": "Chicago",
      "PickUpDate": "2016-12-18",
      "ReturnDate": "2016-12-22",
      "CarType": null,
      "DriverAge": null
    },
    "message": {
      "contentType": "PlainText",
      "content": "Is this car rental for your 4 night stay in Chicago on 2016-12-18?"
    }
  }
}
```

Note

- In addition to the lastConfirmedReservation, the Lambda function includes more session attributes (currentReservation and confirmationContext).
- dialogAction.type is set to ConfirmIntent, which informs Amazon Lex that a yes, no reply is expected from the user (the confirmationContext set to AutoPopulate, the Lambda function knows that the yes/no user reply is to obtain user confirmation of the initialization the Lambda function performed (auto populated slot data).

The Lambda function also includes in the response an informative message in the dialogAction.message for Amazon Lex to return to the client.

Note

The term ConfirmIntent (value of the dialogAction.type) is not related to any bot intent. In the example, Lambda function uses this term to direct Amazon Lex to get a yes/no reply from the user.

d. According to the dialogAction.type, Amazon Lex returns the following response to the client:
The client displays the message: "Is this car rental for your 5 night stay in Chicago on 2016-12-18?"

2. User: "yes"

   a. The client sends the following PostText request to Amazon Lex.

```json
POST /bot/BookTrip/alias/$LATEST/user/wch89kjcpkds8seny7dly5x3otq68j3/text
"Content-Type": "application/json"
"Content-Encoding": "amz-1.0"

{"inputText": "yes",
"sessionAttributes": {
"confirmationContext": "AutoPopulate",
"currentReservation": "{"ReservationType": "Car",
\"PickUpCity\": null,
\"PickUpDate\": null,
\"ReturnDate\": null,
\"CarType\": null"},
"lastConfirmedReservation": "{"ReservationType": "Hotel",
\"Location\": "Chicago",
\"RoomType\": "queen",
\"CheckInDate\": "2016-12-18",
\"Nights\": "5"}"
}
```

b. Amazon Lex reads the inputText and it knows the context (asked the user to confirm the auto population). Amazon Lex invokes the Lambda function by sending the following event:

```json
{
"messageVersion": "1.0",
"invocationSource": "DialogCodeHook",
"userId": "wch89kjcpkds8seny7dly5x3otq68j3",
"sessionAttributes": {
"confirmationContext": "AutoPopulate",
"currentReservation": "{"ReservationType": "Car","PickUpCity":null,"PickUpDate":null,"ReturnDate":null,"CarType":null}"
}
```
Because the user replied Yes, Amazon Lex sets the confirmationStatus to Confirmed.

(c) From the confirmationStatus, the Lambda function knows that the prepopulated values are correct. The Lambda function does the following:

- Updates the currentReservation session attribute to slot value it had prepopulated.
- Sets the dialogAction.type to ElicitSlot
- Sets the slotToElicit value to DriverAge.

The following response is sent:

```json
{
  "sessionAttributes": {
    "currentReservation": "{"ReservationType":"Car","PickUpCity":"Chicago","PickUpDate":"2016-12-18","ReturnDate":"2016-12-22","CarType":null},
    "lastConfirmedReservation": "{"ReservationType":"Hotel","Location":"Chicago","RoomType":"queen","CheckInDate":"2016-12-18","Nights":4}"
  },
  "dialogAction": {
    "type": "ElicitSlot",
    "intentName": "BookCar",
    "slots": {
      "PickUpDate": "2016-12-18",
      "ReturnDate": "2016-12-22",
      "DriverAge": null,
      "CarType": null,
      "PickUpCity": "Chicago"
    },
    "slotToElicit": "DriverAge",
    "message": {
      "contentType": "PlainText",
      "content": "How old is the driver of this car rental?"
    }
  }
}
```

d. Amazon Lex returns following response:
The client displays the message "How old is the driver of this car rental?" and the conversation continues.

Example: Using a Response Card

In this exercise, you extend Getting Started Exercise 1 by adding a response card. You create a bot that supports the OrderFlowers intent, and then update the intent by adding a response card for the FlowerType slot. In addition to the following prompt for the FlowerType slot, the user can choose the type of flowers from the response card:

What type of flowers would you like to order?

The following is the response card:
The bot user can either type the text or choose from the list of flower types. This response card is configured with an image, which appears in the client as shown. For more information about response cards, see Response Cards (p. 13).

To create and test a bot with a response card:

1. Follow Getting Started Exercise 1 to create and test an OrderFlowers bot. You must complete steps 1, 2, and 3. You don’t need to add a Lambda function to test the response card. For instructions, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).

2. Update the bot by adding the response card, and then publish a version. When you publish a version, specify an alias (BETA) to point to it.

   a. In the Amazon Lex console, choose your bot.

   b. Choose the OrderFlowers intent.

   c. Choose the settings gear icon next to the “What type of flowers” Prompt to configure a response card for the FlowerType.

   d. Give the card a title and configure three buttons as shown in the following screen shot. You can optionally add an image to the response card, provided you have an image URL.
Example: Updating Utterances

In this exercise, you add additional utterances to those you created in Getting Started Exercise 1. You use the Monitoring tab in the Amazon Lex console to view utterances that your bot did not recognize. To improve the experience for your users, you add those utterances to the bot.

Note
Utterance statistics are generated once a day, generally in the evening. You can see the utterance that was not recognized, how many times it was heard, and the last date and time that the utterance was heard. It can take up to 24 hours for missed utterances to appear in the console.

To view and add missed utterances to a bot:

1. Follow the first step of Getting Started Exercise 1 to create and test an OrderFlowers bot. For instructions, see Exercise 1: Create an Amazon Lex Bot Using a Blueprint (Console) (p. 30).
2. Test the bot by typing the following utterances in the Test Bot window. Type each utterance several times. The example bot doesn't recognize the following utterances:

- Order flowers
Example: Integrating with a Web site

In this example you integrate a bot with a Web site using text and voice. You use JavaScript and AWS services to build an interactive experience for visitors to your Web site. The complete example is documented in two posts on the AWS AI Blog:

- "Greetings, visitor!"—Engage Your Web Users with Amazon Lex—Demonstrates using Amazon Lex, the AWS SDK for JavaScript in the Browser, and Amazon Cognito to create a conversational experience on your Web site.

- Capturing Voice Input in a Browser and Sending it to Amazon Lex—Demonstrates embedding a voice-based chatbot in a Web site using the SDK for JavaScript in the Browser. The application records audio, sends the audio to Amazon Lex, and then plays the response.
Monitoring Amazon Lex

Monitoring is important for maintaining the reliability, availability, and performance of your Amazon Lex chatbots. This topic describes how to use Amazon CloudWatch Logs and AWS CloudTrail to monitor Amazon Lex and describes the Amazon Lex runtime and channel association metrics.

Topics
- Monitoring Amazon Lex with Amazon CloudWatch (p. 166)
- Monitoring Amazon Lex API Calls with AWS CloudTrail Logs (p. 171)

Monitoring Amazon Lex with Amazon CloudWatch

To track the health of your Amazon Lex bots, use Amazon CloudWatch. With CloudWatch, you can get metrics for individual Amazon Lex operations or for global Amazon Lex operations for your account. You can also set up CloudWatch alarms to be notified when one or more metrics exceeds a threshold that you define. For example, you can monitor the number of requests made to a bot over a particular time period, view the latency of successful requests, or raise an alarm when errors exceed a threshold.

CloudWatch Metrics for Amazon Lex

To get metrics for your Amazon Lex operations, you must specify the following information:

- The metric dimension. A dimension is a set of name-value pairs that you use to identify a metric. Amazon Lex has three dimensions:
  - BotAlias, BotName, Operation
  - BotAlias, BotName, InputMode, Operation
  - BotName, BotVersion, InputMode, Operation
- The metric name, such as MissedUtteranceCount or RuntimeRequestCount.

You can get metrics for Amazon Lex with the AWS Management Console, the AWS CLI, or the CloudWatch API. You can use the CloudWatch API through one of the Amazon AWS Software Development Kits (SDKs) or the CloudWatch API tools. The Amazon Lex console displays graphs based on the raw data from the CloudWatch API.

You must have the appropriate CloudWatch permissions to monitor Amazon Lex with CloudWatch. For more information, see Authentication and Access Control for Amazon CloudWatch in the Amazon CloudWatch User Guide.

Viewing Amazon Lex Metrics

View Amazon Lex metrics using the Amazon Lex console and the CloudWatch console.

To view metrics (Amazon Lex console)

1. Sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/.
2. From the list of bots, choose the one whose metrics you want to see.
3. Choose **Monitoring**. Metrics are displayed in graphs.

**To view metrics (CloudWatch console)**

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, choose **All Metrics**, and then choose **AWS/Lex**.
3. Choose the dimension, and then choose a metric name. Choose **Add to graph**.
4. Choose a value for the date range. The metric count for the selected date range is displayed in the graph.

### Creating an Alarm

A CloudWatch alarm watches a single metric over a time period that you specify, and performs one or more actions: sending a notification to an Amazon SNS topic or Auto Scaling policy. The action or actions are based on the value of the metric relative to a given threshold over a number of time periods that you specify. CloudWatch can also send you an Amazon Simple Notification Service (Amazon SNS) message when the alarm changes state...

CloudWatch alarms invoke actions only when the state changes and has persisted for the period that you specify.

**To set an alarm**

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Alarms**, and then choose **Create Alarm**.
3. Choose **AWS/Lex Metrics**, and then choose a metric.
4. For **Time Range**, choose a time range to monitor, and then choose **Next**.
5. Type a **Name** and **Description**.
6. For **Whenever**, choose **>=**, and type a maximum value.
7. If you want CloudWatch to send an email when the alarm state is reached, in the **Actions** section, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose a mailing list or choose **New list** and create a new list.
8. Preview the alarm in the **Alarm Preview** section. If you are satisfied with the alarm, choose **Create Alarm**.

### CloudWatch Metrics for Amazon Lex

This topic explains the Amazon CloudWatch metrics and the dimensions that are available for the Amazon Lex runtime and channel associations.

**Topics**
- CloudWatch Metrics for Amazon Lex Runtime (p. 167)
- CloudWatch Metrics for Amazon Lex Channel Associations (p. 171)

### CloudWatch Metrics for Amazon Lex Runtime

The following table describes the Amazon Lex runtime metrics.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RuntimeInvalidLambdaResponses</td>
<td>The number of invalid Lambda responses in the specified period.</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostText operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td>RuntimeLambdaErrors</td>
<td>The number of AWS Lambda runtime errors in the specified period.</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostText operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td>MissedUtteranceCount</td>
<td>The number of utterances that were not recognized in the specified period.</td>
</tr>
<tr>
<td></td>
<td>Valid dimensions for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotVersion, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimensions for the PostText operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotVersion, Operation</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td>RuntimePollyErrors</td>
<td>The number of invalid Amazon Polly responses in the specified period.</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostText operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td>RuntimeRequestCount</td>
<td>The number of runtime requests in the specified period.</td>
</tr>
<tr>
<td></td>
<td>Valid dimensions for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotVersion, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Valid dimensions for the PostText operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotVersion, Operation</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>RuntimeSuccessfulRequestLatency</td>
<td>The latency for successful requests between the time that the request was made and the response was passed back.</td>
</tr>
<tr>
<td></td>
<td>Valid dimensions for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotVersion, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimensions for the PostText operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotVersion, Operation</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td></td>
<td>Unit: Milliseconds</td>
</tr>
<tr>
<td>RuntimeSystemErrors</td>
<td>The number of system errors in the specified period. The response code range for a system error is 500 to 599.</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostContent operation with the Text or Speech InputMode:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the PostText operation:</td>

<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RuntimeThrottledEvents</td>
<td>The number of throttled requests. Amazon Lex throttles a request when it receives more requests than the limit of transactions per second set for your account. If the limit set for your account is frequently exceeded, you can request a limit increase. To request an increase, see <a href="https://aws.amazon.com/service-quotas/">AWS Service Limits</a>.</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the <code>PostContent</code> operation with the <code>Text</code> or <code>Speech</code> <code>InputMode</code>:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the <code>PostText</code> operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>RuntimeUserErrors</td>
<td>The number of user errors in the specified period. The response code range for a user error is 400 to 499.</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the <code>PostContent</code> operation with <code>Text</code> or <code>Speech</code> <code>InputMode</code>:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation, InputMode</td>
</tr>
<tr>
<td></td>
<td>Valid dimension for the <code>PostText</code> operation:</td>
</tr>
<tr>
<td></td>
<td>• BotName, BotAlias, Operation</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
</tbody>
</table>

Amazon Lex runtime metrics use the `AWS/Lex` namespace, and provide metrics in the following dimensions. You can group metrics by dimensions in the CloudWatch console:

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BotName, BotAlias, Operation, InputMode</td>
<td>Groups metrics by the bot's alias, the bot's name, the operation (<code>PostContent</code>), and by whether the input was text or speech.</td>
</tr>
<tr>
<td>BotName, BotVersion, Operation, InputMode</td>
<td>Groups metrics by the bot's name, the version of the bot, the operation (<code>PostContent</code>), and by whether the input was text or speech.</td>
</tr>
<tr>
<td>BotName, BotVersion, Operation</td>
<td>Groups metrics by the bot's name, the bot's version, and by the operation, <code>PostText</code>.</td>
</tr>
<tr>
<td>BotName, BotAlias, Operation</td>
<td>Groups metrics by the bot's name, the bot's alias, and by the operation, <code>PostText</code>.</td>
</tr>
</tbody>
</table>
CloudWatch Metrics for Amazon Lex Channel Associations

A channel association is the association between Amazon Lex and a messaging channel, such as Facebook. The following table describes the Amazon Lex channel association metrics.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BotChannelAuthErrors</td>
<td>The number of authentication errors returned by the messaging channel in the specified time period. An authentication error indicates that the secret token provided during channel creation is invalid or has expired.</td>
</tr>
<tr>
<td>BotChannelConfigurationErrors</td>
<td>The number of configuration errors in the specified period. A configuration error indicates that one or more configuration entries for the channel are invalid.</td>
</tr>
<tr>
<td>BotChannelInboundThrottledEvents</td>
<td>The number of times that messages that were sent by the messaging channel were throttled by Amazon Lex in the specified period.</td>
</tr>
<tr>
<td>BotChannelOutboundThrottledEvents</td>
<td>The number of times that outbound events from Amazon Lex to the messaging channel were throttled in the specified time period.</td>
</tr>
<tr>
<td>BotChannelRequestCount</td>
<td>The number of requests made on a channel in the specified time period.</td>
</tr>
<tr>
<td>BotChannelResponseCardErrors</td>
<td>The number of times that Amazon Lex could not post response cards in the specified period.</td>
</tr>
<tr>
<td>BotChannelSystemErrors</td>
<td>The number of internal errors that occurred in Amazon Lex for a channel in the specified period.</td>
</tr>
</tbody>
</table>

Amazon Lex channel association metrics use the AWS/Lex namespace, and provide metrics for the following dimension. You can group metrics by dimensions in the CloudWatch console::

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BotAlias, BotChannelName, BotName, Source</td>
<td>Group metrics by the bot’s alias, the channel name, the bot’s name, and by the source of traffic.</td>
</tr>
</tbody>
</table>

Monitoring Amazon Lex API Calls with AWS CloudTrail Logs

Amazon Lex is integrated with AWS CloudTrail, a service that captures all of the Amazon Lex API calls and delivers log files to an S3 bucket, where they are written with other AWS service records. CloudTrail captures API calls from the Amazon Lex console or from Amazon Lex API operations. Using the information collected by CloudTrail, you can track requests made to Amazon Lex, the source IP address from which the requests were made, who made the requests, when they were made, and so on.

Each operation creates a log entry containing request information. Only the following operations contain response information:

- CreateBotVersion (p. 197), CreateIntentVersion (p. 202), CreateSlotTypeVersion (p. 208)
- PutBot (p. 285), PutBotAlias (p. 293), PutIntent (p. 297), PutSlotType (p. 307)
Every log entry contains information about who generated the request. Use the user identity in log entries to determine the following:

- Whether the request was made with root or IAM user credentials
- Whether the request was made with temporary security credentials for a role or federated user
- Whether the request was made by another AWS service

For more information, see the CloudTrail userIdentity Element.

For information about the Amazon Lex actions that are logged in CloudTrail logs, see Amazon Lex Model Building Service. For example, calls to the PutBot (p. 285), GetBot (p. 230), and DeleteBot (p. 212) operations generate entries in the CloudTrail log. The actions documented in Amazon Lex Runtime Service, PostContent (p. 312) and PostText (p. 320), are not logged.

Log files are stored in an S3 bucket. CloudTrail determines when to create and write to a new file based on a time period and file size that you specify.

You can store your log files in your S3 bucket for as long as you want. You can also define Amazon S3 lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted with Amazon S3 server-side encryption (SSE).

If you want to be notified when CloudTrail delivers log files, configure CloudTrail to publish Amazon SNS notifications when that happens. For more information, see Configuring Amazon SNS Notifications for CloudTrail.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

You can also aggregate Amazon Lex log files from multiple AWS Regions and multiple AWS accounts into a single S3 bucket. For more information, see Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts.

Example: Amazon Lex Log File Entries

CloudTrail log files can contain one or more log entries. A log entry represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Log entries are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example CloudTrail log entry shows the result of a call to the PutBot action.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "AssumedRole | FederatedUser | IAMUser | Root | SAMLUser | WebIdentityUser",

}
Guidelines and Limits in Amazon Lex

The following sections provide guidelines and limits when using Amazon Lex.

Topics
• General Guidelines (p. 175)
• Limits (p. 177)

General Guidelines

This section describes general guidelines when using Amazon Lex.

• Signing requests – All Amazon Lex model-building and runtime API operations in the API Reference (p. 194) use signature V4 for authenticating requests. For more information about authenticating requests, see Signature Version 4 Signing Process in the Amazon Web Services General Reference.

For PostContent (p. 312), uses the unsigned payload option described in Signature Calculations for the Authorization Header: Transferring Payload in a Single Chunk (AWS Signature Version 4) in the Amazon Simple Storage Service (S3) API Reference.

When you use the unsigned payload option, don't include the hash of the payload in the canonical request. Instead, you use the literal string "UNSIGNED-PAYLOAD" as the hash of the payload. Also include a header with the name x-amz-content-sha256 and the value UNSIGNED-PAYLOAD in the PostContent request.

• Note the following about how Amazon Lex captures slot values from user utterances:

Amazon Lex uses the enumeration values you provide in a slot type definition to train its machine learning models. Suppose you define an intent called GetPredictionIntent with the following sample utterance:

"Tell me the prediction for {Sign}"

Where {Sign} is a slot of custom type ZodiacSign. It has 12 enumeration values, Aries through Pisces. From the user utterance "Tell me the prediction for ..." Amazon Lex understands what follows is a zodiac sign.

When the valueSelectionStrategy field is set to ORIGINAL_VALUE using the PutSlotType (p. 307) operation, or if Expand values is selected in the console, if the user says "Tell
me the prediction for earth”, Amazon Lex infers that "earth" is a ZodiacSign and passes it to your client application or Lambda functions. You must check that slot values have valid values before using them in your fulfillment activity.

If you set the valueSelectionStrategy field to TOP_RESOLUTION using the PutSlotType (p. 307) operation, or if Restrict to slot values and synonyms is selected in the console, the values that are returned are limited to the values that you defined for the slot type. For example, if the user says "Tell me the prediction for earth" the value would not be recognized because it is not one of the values defined for the slot type. When you define synonyms for slot values, they are recognized the same as a slot value, however, the slot value is returned instead of the synonym.

When Amazon Lex calls a Lambda function or returns the result of a speech interaction with your client application, the case of the slot values is not guaranteed. For example, if you are eliciting values for the AMAZON.Movie built-in slot type, and a user says or types "Gone with the wind," Amazon Lex may return "Gone with the Wind," "gone with the wind," or "Gone With The Wind." In text interactions, the case of the slot values matches the text entered or the slot value, depending on the value of the valueResolutionStrategy field.

- Amazon Lex does not support the AMAZON.LITERAL built-in slot type that the Alexa Skills Kit supports. However, Amazon Lex supports creating custom slot types that you can use to implement this functionality. As mentioned in the previous bullet, you can capture values outside the custom slot type definition. Add more and diverse enumeration values to boost the automatic speech recognition (ASR) and natural language understanding (NLU) accuracy.

- The AMAZON.DATE and AMAZON.TIME built-in slot types capture both absolute and relative dates and times. Relative dates and times are resolved in the region where Amazon Lex is processing the request.

For the AMAZON.TIME built-in slot type, if the user doesn't specify that a time is before or after noon, the time is ambiguous and Amazon Lex will prompt the user again. We recommend prompts that elicit an absolute time. For example, use a prompt such as "When do you want your pizza delivered? You can say 6 PM or 6 in the evening."

- Providing confusable training data in your bot reduces Amazon Lex's ability to understand user input. Consider these examples:

Suppose you have two intents (OrderPizza and OrderDrink) in your bot and both are configured with an "I want to order" utterance. This utterance does not map to a specific intent that Amazon Lex can learn from while building the language model for the bot at build time. As a result, when a user inputs this utterance at runtime, Amazon Lex can't pick an intent with a high degree of confidence.

Consider another example where you define a custom intent for getting a confirmation from the user (for example, MyCustomConfirmationIntent) and configure the intent with the utterances "Yes" and "No." Note that Amazon Lex also has a language model for understanding user confirmations. This can create conflicting situation. When the user responds with a "Yes,” does this mean that this is a confirmation for the ongoing intent or that the user is requesting the custom intent that you created?
In general, the sample utterances you provide should map to a specific intent and, optionally, to specific slot values.

- The runtime API operations PostContent (p. 312) and PostText (p. 320) take a user ID as the required parameter. Developers can set this to any value that meets the constraints described in the API. We recommend you don’t use this parameter to send any confidential information such as user logins, emails, or social security numbers. This ID is primarily used to uniquely identify conversation with a bot (there can be multiple users ordering pizza).

- If your client application uses Amazon Cognito for authentication, you might use the Amazon Cognito user ID as Amazon Lex user ID. Note that any Lambda function configured for your bot must have its own authentication mechanism to identify the user on whose behalf Amazon Lex is invoking the Lambda function.

- We encourage you to define an intent that captures a user’s intention to discontinue the conversation. For example, you can define an intent (NothingIntent) with sample utterances (“I don’t want anything”, “exit”, “bye bye”), no slots, and no Lambda function configured as a code hook. This lets users gracefully close a conversation.

Limits

This section describes current limits in Amazon Lex. These limits are grouped by categories.

Topics
- General Limits (p. 177)
- Runtime Service Limits (p. 178)
- Model Building Limits (p. 179)

General Limits

Currently, Amazon Lex is available in the following regions:

<table>
<thead>
<tr>
<th>Service</th>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model building service</td>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>models.lex.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Model building service</td>
<td>EU (Ireland)</td>
<td>eu-west-1</td>
<td>models.lex.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Runtime service</td>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>runtime.lex.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>
Currently, Amazon Lex supports only US English language. That is, Amazon Lex trains your bots to understand only US English.

**Runtime Service Limits**

Currently, Amazon Lex is available in the following regions:

<table>
<thead>
<tr>
<th>Service</th>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Runtime service</td>
<td>EU (Ireland)</td>
<td>eu-west-1</td>
<td>runtime.lex.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Runtime service</td>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>runtime.lex.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Runtime service</td>
<td>EU (Ireland)</td>
<td>eu-west-1</td>
<td>runtime.lex.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

In addition to the limits described in the API reference, note the following:

**API Limits**

- Speech input to the `PostContent (p. 312)` operation can be up to 15 seconds long.

- In both the runtime API operations `PostContent (p. 312)` and `PostText (p. 320)`, the input text size can be up to 1024 Unicode characters.

- The maximum size of `PostContent` headers is 16 KB. The maximum size of request and session headers combined is 12 KB.

- The maximum input size to a Lambda function is 12 KB. The maximum output size is 25 KB, of which 12 KB can be session attributes.

**Using the $LATEST version**

- The $LATEST version of your bot should only be used for manual testing. Amazon Lex limits the number of runtime requests that you can make to the $LATEST version of the bot.

- When you update the $LATEST version of the bot, Amazon Lex terminates any in-progress conversations for any client application using the $LATEST version of the bot. Generally, you should not use the $LATEST version of a bot in production because $LATEST version can be updated. You should publish a version and use it instead.
• When you update an alias, Amazon Lex takes a few minutes to pick up the change. When you modify the \textit{LATEST} version of the bot, the change is picked up immediately.

**Session Timeout**

• The session timeout set when the bot was created determines how long the bot retains conversation context, such as current user intent and slot data.

• After a user starts the conversation with your bot and until the session expires, Amazon Lex uses the same bot version, even if you update the bot alias to point to another version.

**Model Building Limits**

Model building refers to creating and managing bots. This includes creating and managing bots, intents, slot types, slots, and bot channel associations.

Currently, Amazon Lex is available in the following regions:

<table>
<thead>
<tr>
<th>Service</th>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model building service</td>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>models.lex.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Model building service</td>
<td>EU (Ireland)</td>
<td>eu-west-1</td>
<td>models.lex.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

**Topics**

• Bot Limits (p. 179)
• Intent Limits (p. 180)
• Slot Type Limits (p. 181)

**Bot Limits**

• You configure prompts and statements throughout the model building API. Each of these prompts or statements can have up to five messages and each message can contain from 1 to 1000 UTF-8 characters.

• You can define sample utterances for intents and slots. You can use a maximum of 200,000 characters for all utterances.
• Each slot type can define a maximum of 10,000 values and synonyms. Each bot can contain a maximum of 50,000 slot type values and synonyms.

• Bot, alias, and bot channel association names are case insensitive at the time of creation. If you create PizzaBot and then try to create pizzaBot, you will get an error. However, when accessing a resource, the resource names are case sensitive, you must specify PizzaBot and not pizzaBot. These names must be between 2 and 50 ASCII characters.

• The maximum number of versions you can publish for all resource types is 100. Note that there is no versioning for aliases.

• Within a bot, intent names and slot names must be unique, you can’t have an intent and a slot by the same name.

• You can create a bot that is configured to support multiple intents. If two intents have a slot by the same name, then the corresponding slot type must be the same.

For example, suppose you create a bot to support two intents (OrderPizza and OrderDrink). If both these intents have the size slot, then the slot type must be the same in both places.

In addition, the sample utterances you provide for a slot in one of the intents applies to a slot with the same name in other intents.

• You can associate a maximum of 100 intents with a bot.

• When you create a bot, you specify a session timeout. The session timeout can be between one minute and one day. The default is five minutes.

• You can create up to five aliases for a bot.

• You can create up to 100 bots per AWS account.

• You cannot create multiple intents that extend from the same built-in intent.

**Intent Limits**

• Intent and slot names are case insensitive at the time of creation. That is, if you create OrderPizza intent and then again try to create another orderPizza intent, you will get an error. However, when accessing these resources, the resource names are case sensitive, specify OrderPizza and not orderPizza. These names must be between 1 and 100 ASCII characters.
• An intent can have up to 1,500 sample utterances. A minimum of one sample utterance is required. Each sample utterance can be up to 200 UTF-8 characters long. You can use up to 200,000 characters for all intent and slot utterances in a bot. A sample utterance for an intent:
  • Can refer to zero or more slot names.
  • Can refer to a slot name only once.

For example:

<table>
<thead>
<tr>
<th>Utterance</th>
</tr>
</thead>
<tbody>
<tr>
<td>I want a pizza</td>
</tr>
<tr>
<td>I want a {pizzaSize} pizza</td>
</tr>
<tr>
<td>I want a {pizzaSize} {pizzaTopping} pizza</td>
</tr>
</tbody>
</table>

• Although each intent supports up to 1,500 utterances, if you use fewer utterances Amazon Lex may have a better ability to recognize inputs outside your provided set.

• Each slot can have up to 10 sample utterances. Each sample utterance must refer to the slot name exactly once. For example:

<table>
<thead>
<tr>
<th>Utterance</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pizzaSize} please</td>
</tr>
</tbody>
</table>

• Each bot can have a maximum of 200,000 characters for intent and slot utterances combined.

• You cannot provide utterances for intents that extend from built-in intents. For all other intents you must provide at least one sample utterance. Intents contain slots, but the slot level sample utterances are optional.

• Built-in intents
  • Currently, Amazon Lex does not support slot elicitation for built-in intents. You cannot create Lambda functions to return the ElicitSlot directive in the response with an intent that is derived from built-in intents. For more information, see Response Format (p. 101).
  • The service does not support adding sample utterances to built-in intents. Similarly, you cannot add or remove slots to built-in intents.

• You can create up to 1,000 intents per AWS account. You can create up to 100 slots in an intent.

**Slot Type Limits**

• Slot type names are case insensitive at the time of creation. If you create the PizzaSize slot type and then again try to create the pizzaSize slot type, you will get an error. However, when accessing these resources, the resource names are case sensitive (you must specify PizzaSize and not pizzaSize). Names must be between 1 and 100 ASCII characters.
• A custom slot type you create can have a maximum of 10,000 enumeration values and synonyms. Each value can be up to 140 UTF-8 characters long. The enumeration values and synonyms cannot contain duplicates.

• For a slot type value, where appropriate, specify both upper and lower case. For example, for a slot type called Procedure, if value is MRI, specify both "MRI" and "mri" as values.

• Built-in slot types – Currently, Amazon Lex doesn’t support adding enumeration values or synonyms for the built-in slot types.
Authentication and Access Control for Amazon Lex

Access to Amazon Lex requires credentials that AWS can use to authenticate your requests. Those credentials must have permissions to access AWS resources, such as an Amazon Lex chatbot or an Amazon Lex slot type. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and Amazon Lex to help secure your resources by controlling who can access them.

- Authentication (p. 183)
- Access Control (p. 184)

Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

- **IAM user** – An IAM user is an identity within your AWS account that has specific custom permissions (for example, permissions to create a bot in Amazon Lex). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys to cryptographically sign your request. If you don’t use AWS tools, you must sign the request yourself. Amazon Lex supports Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 Signing Process in the AWS General Reference.

- **IAM role** – An IAM role is an IAM identity that you can create in your account that has specific permissions. It is similar to an IAM user, but it is not associated with a specific person. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources. IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – Instead of creating an IAM user, you can use existing user identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as
federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated Users and Roles in the IAM User Guide.

- **AWS service access** – You can use an IAM role in your account to grant an AWS service permissions to access your account’s resources. For example, you can create a role that allows Amazon Redshift to access an Amazon S3 bucket on your behalf and then load data from that bucket into an Amazon Redshift cluster. For more information, see Creating a Role to Delegate Permissions to an AWS Service in the IAM User Guide.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances in the IAM User Guide.

Access Control

You can have valid credentials to authenticate your requests, but unless you have permissions you cannot create or access Amazon Lex resources. For example, you must have permissions to create an Amazon Lex bot.

The following sections describe how to manage permissions for Amazon Lex. We recommend that you read the overview first.

- Overview of Managing Access Permissions to Your Amazon Lex Resources (p. 184)
- Using Identity-Based Polices (IAM Policies) for Amazon Lex (p. 188)

Overview of Managing Access Permissions to Your Amazon Lex Resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles), and some services (such as AWS Lambda) also support attaching permissions policies to resources.

**Note**

An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific actions that you want to allow on those resources.

**Topics**

- Amazon Lex Resources and Operations (p. 185)
- Understanding Resource Ownership (p. 185)
- Managing Access to Resources (p. 185)
Amazon Lex Resources and Operations

In Amazon Lex, the primary resource is a bot. Amazon Lex also supports additional resource types, the intent, the slot type, the alias, and the bot channel association. Aliases and bot channel associations are referred to as subresources. For Amazon Lex, you can create subresources only in the context of an existing bot.

These resources and subresources have unique Amazon Resource Names (ARNs) associated with them as shown in the following table.

Amazon Lex provides a set of operations to work with Amazon Lex resources. For a list of available operations, see Amazon Lex Actions (p. 194).

Understanding Resource Ownership

The AWS account owns the resources that are created in the account, regardless of who created the resources. Specifically, the resource owner is the AWS account of the principal entity (that is, the root account, an IAM user, or an IAM role) that authenticates the resource creation request. The following examples illustrate how this works:

- If you use the root account credentials of your AWS account to create a bot, your AWS account is the owner of the resource (in Amazon Lex, the resource is the bot).
- If you create an IAM user in your AWS account and grant permissions to create a bot to that user, the user can create a bot. However, your AWS account, to which the user belongs, owns the bot resource.
- If you create an IAM role in your AWS account with permissions to create a bot, anyone who can assume the role can create a bot. Your AWS account, to which the role belongs, owns the bot resource.

Managing Access to Resources

A permissions policy describes who has access to what. The following section explains the available options for creating permissions policies.

Note
This section discusses using IAM in the context of Amazon Lex. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

Policies attached to an IAM identity are referred to as identity-based policies (IAM polices) and policies attached to a resource are referred to as resource-based policies. Amazon Lex supports only identity-based policies (IAM policies).

Topics
- Identity-Based Policies (IAM Policies) (p. 185)
- Resource-Based Policies (p. 186)

Identity-Based Policies (IAM Policies)

You can attach policies to IAM identities. For example, you can do the following:
• **Attach a permissions policy to a user or a group in your account** – To grant a user or a group of users permissions to create a Amazon Lex resource, such as a bot, you can attach a permissions policy to a user or group that the user belongs to.

• **Attach a permissions policy to a role (grant cross-account permissions)** – To grant cross-account permissions, you can attach an identity-based permissions policy to an IAM role. For example, the administrator in Account A can create a role to grant cross-account permissions to another AWS account (for example, Account B) or an AWS service as follows:
  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in Account A.
  2. Account A administrator attaches a trust policy to the role identifying Account B as the principal who can assume the role.
  3. Account B administrator can then delegate permissions to assume the role to any users in Account B. Doing this allows users in Account B to create or access resources in Account A. If you want to grant an AWS service permissions to assume the role, the principal in the trust policy can also be an AWS service principal.

The following is an example policy that allows the user to perform the `PutBot` action for your AWS account.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "lex:PutBot",
            "*"
        ],
        "Resource": [
            "*"
        ]
      }
   ]
}
```

For more information about using identity-based policies with Amazon Lex, see [Using Identity-Based Policies (IAM Policies) for Amazon Lex](https://docs.aws.amazon.com/lexv2/latest/dg身份-based-politics.html). For more information about users, groups, roles, and permissions, see [Identities (Users, Groups, and Roles)](https://docs.aws.amazon.com/IAM/latest/UserGuide/index.html) in the IAM User Guide.

**Resource-Based Policies**

Other services, such as Lambda, support resource-based permissions policies. For example, you can attach a policy to an S3 bucket to manage access permissions to that bucket. Amazon Lex doesn’t support resource-based policies. However, it does use resource-based policies to access Lambda and Amazon Polly services.

**Specifying Policy Elements: Actions, Effects, and Principals**

For each Amazon Lex resource (see [Amazon Lex Resources and Operations](https://docs.aws.amazon.com/lexv2/latest/dg/resources-operations.html)), the service defines a set of API operations (see [Actions](https://docs.aws.amazon.com/lexv2/latest/dg/actions.html)). To grant permissions for these API operations, Amazon Lex defines a set of actions that you can specify in a policy. For example, for the Amazon Lex Intent resource, the following actions are defined: `CreateIntent` and `CreateIntentVersion`. Performing an API operation can require permissions for more than one action.
The following are the most basic policy elements:

- **Resource** – In a policy, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see Amazon Lex Resources and Operations (p. 185).

- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, depending on the specified Effect, lex:bBot either allows or denies the user permissions to perform the Amazon Lex CreateBot operation.

- **Effect** – You specify the effect of the action that occurs when the user requests the specific action —this can be either allow or deny. If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource. You might do this to make sure that a user cannot access the resource, even if a different policy grants access.

- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. For resource-based policies, you specify the user, account, service, or other entity that you want to receive permissions. This applies to resource-based policies only. Amazon Lex doesn't support resource-based policies.

To learn more about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

For a table showing all of the Amazon Lex API actions, see Amazon Lex API Permissions: Actions, Resources, and Conditions Reference (p. 193).

### Specifying Conditions in a Policy

When you grant permissions, you use the IAM policy language to specify the conditions under which a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

AWS provides a set of predefined condition keys for all AWS services that support IAM for access control. For example, you can use the aws:userid condition key to require a specific AWS ID when requesting an action. For more information and a complete list of AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.

**Note**

Condition keys are case sensitive.

Amazon Lex provides additional condition keys that you can include in Condition elements in an IAM permissions policy. The following table shows the Amazon Lex condition keys that apply to Amazon Lex resources.

### Example Policy: Using Condition Keys

The following example shows how to use condition keys in Amazon Lex IAM permissions policies.

**Example 1: Grant Permission to Create Bots Using the OrderPizza Intent**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "lex:PutBot"
            ],
            "Resource": [ "*" ]
        }
    ]
}
```
Using Identity-Based Policies (IAM Policies) for Amazon Lex

This topic provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on Amazon Lex resources.

**Important**
Before you proceed, we recommend that you review Overview of Managing Access Permissions to Your Amazon Lex Resources (p. 184).

The sections in this topic cover the following:

- Permissions Required to Use the Amazon Lex Console (p. 189)
- AWS Managed (Predefined) Policies for Amazon Lex (p. 191)
- Examples of Customer Managed Policies (p. 191)

The following is an example of a permissions policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "lex:PostText"
            ],
            "Resource": [
                "arn:aws:lex:us-east-1:account-id:bot:OrderPizza:*"
            ]
        }
    ]
}
```

The policy has one statement that grants permission to use the `PostText` action with the `OrderPizza` bot. The resource specifies a wildcard character (*) to give permission to any alias of the `OrderPizza` bot.

The policy doesn't specify the `Principal` element because you don't specify the principal who gets the permission in an identity-based policy. When you attach a policy to a user, the user is the implicit principal. When you attach a permissions policy to an IAM role, the principal identified in the role's trust policy gets the permissions.
Permissions Required to Use the Amazon Lex Console

The permissions reference table lists the Amazon Lex API operations and shows the required permissions for each operation. For more information about Amazon Lex API operations, see Amazon Lex API Permissions: Actions, Resources, and Conditions Reference (p. 193).

To use the Amazon Lex console, you need to grant permissions for additional actions as shown in the following permissions policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:GetMetricStatistics",
        "cloudwatch:DescribeAlarms",
        "cloudwatch:DescribeAlarmsForMetric",
        "kms:DescribeKey",
        "kms:ListAliases",
        "lambda:GetPolicy",
        "lambda:ListFunctions",
        "lex:*",
        "polly:DescribeVoices",
        "polly:SynthesizeSpeech"
      ],
      "Resource": ["*"]
    },
    {
      "Effect": "Allow",
      "Action": [
        "lambda:AddPermission",
        "lambda:RemovePermission"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "lambda:Principal": "lex.amazonaws.com"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:GetRole",
        "iam:DeleteRole"
      ],
      "Resource": ["arn:aws:iam::*:role/aws-service-role/lex.amazonaws.com/AWSServiceRoleForLexBots",
                   "arn:aws:iam::*:role/aws-service-role/channels.lex.amazonaws.com/AWSServiceRoleForLexChannels"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:CreateServiceLinkedRole"
      ]
    }
  ]
}
```
The Amazon Lex console needs these additional permissions for the following reasons:

- cloudwatch permissions to view performance and monitoring information in the console.
• **iam** actions to assume IAM roles for making calls to Lambda functions and processing data for a bot channel association.
• **kms** actions to manage the AWS Key Management Service keys used to encrypt data when creating a bot channel association.
• **lambda** actions to display Lambda functions that your bot can use, and to grant Lex the necessary permissions for your bot to invoke these functions.
• **lex** actions so that the console can display Amazon Lex resources in the account.
• **polly** actions so that the console can display Amazon Polly voices and so that it can translate text to speech.
• **iam** actions so that the console can manage server-linked roles that grant permission to use other AWS resources.

**AWS Managed (Predefined) Policies for Amazon Lex**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate which permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon Lex:

• **ReadOnly** — Grants read-only access to Amazon Lex resources.
• **RunBotsOnly** — Grants access to run Amazon Lex conversational bots.
• **FullAccess** — Grants full access to create, read, update, delete, and run all Amazon Lex resources. Grants access to associate Lambda functions whose name starts with AmazonLex with Amazon Lex intents.

**Note**
You can review these permissions policies by signing in to the IAM console and searching for specific policies.

You can also create your own custom IAM policies to allow permissions for Amazon Lex API actions. You can attach these custom policies to the IAM users or groups that require those permissions.

**Examples of Customer Managed Policies**

In this section, we provide examples of user policies that grant permissions for various Amazon Lex actions. These policies work with the AWS SDKs or the AWS command line interface (AWS). When you use the console, you need to grant additional permissions specific to the console, which is discussed in Permissions Required to Use the Amazon Lex Console (p. 189).

**Note**
All examples use the us-east-1 Region and contain fictitious account IDs.

**Examples**

• Example 1: Allow a User to Delete Any Bot (p. 192)
• Example 2: Allow a User to Update a Specific Bot (p. 192)
• Example 3: Allow a User to Manage a Specific Bot (p. 192)
Example 1: Allow a User to Delete Any Bot

The following permissions policy grants the user permissions to delete any bot that exists in the us-east-1 Region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["lex:DeleteBot"],
            "Resource": ["*"]
        }
    ]
}
```

Example 2: Allow a User to Update a Specific Bot

The following policy grants the user permissions to update a specific bot in the us-east-1 Region, in this case, the bot named "PizzaBot."

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["lex:PutBot"],
            "Resource": [
            ]
        }
    ]
}
```

Example 3: Allow a User to Manage a Specific Bot

The following permissions policy grants the user permissions to build and test a pizza ordering, and can only use the OrderPizza intent and Toppings slot type when editing the bot in the us-east-1 region. The policy uses the `lex:associatedIntents` and `lex:associatedSlotType` to limit the intent and slot types that the user can use for this bot.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["lex:Create*Version", "lex:Post*", "lex:Put*", "lex:Delete*"]
        },
        "Resource": [
```
Amazon Lex API Permissions: Actions, Resources, and Conditions Reference

Use the following table as a reference when setting up Access Control (p. 184) and writing a permissions policy that you can attach to an IAM identity (an identity-based policy). The list includes each Amazon Lex API operation, the corresponding action for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy’s Action field, and you specify the resource value in the policy’s Resource field.

To express conditions, you can use AWS-wide condition keys in your Amazon Lex policies. For a complete list of AWS-wide keys, see Available Keys in the IAM User Guide.

**Note**
To specify an action, use the `lex:` prefix followed by the API operation name, for example, `lex:PostText`.

**Note**
The `GetExport` function checks permission at the bot level and, if authorized, exports all relevant intent and slot type information associated with the specified bot. `GetExport` does not check intent-level and slot type-level permissions.
This section provides documentation for the Amazon Lex API operations. Amazon Lex is available in the following AWS region:

<table>
<thead>
<tr>
<th>Service</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model building service</td>
<td>US East (N. Virginia)</td>
<td>models.lex.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Model building service</td>
<td>EU (Ireland)</td>
<td>models.lex.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Runtime service</td>
<td>US East (N. Virginia)</td>
<td>runtime.lex.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>

<td>runtime.lex.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

**Topics**
- Actions (p. 194)
- Data Types (p. 325)

**Actions**

The following actions are supported by Amazon Lex Model Building Service:

- CreateBotVersion (p. 197)
- CreateIntentVersion (p. 202)
- CreateSlotTypeVersion (p. 208)
- DeleteBot (p. 212)
- DeleteBotAlias (p. 214)
- DeleteBotChannelAssociation (p. 216)
- DeleteBotVersion (p. 218)
- DeleteIntent (p. 220)
- DeleteIntentVersion (p. 222)
- DeleteSlotType (p. 224)
- DeleteSlotTypeVersion (p. 226)
- DeleteUtterances (p. 228)
- GetBot (p. 230)
- GetBotAlias (p. 235)
- GetBotAliases (p. 238)
- GetBotChannelAssociation (p. 241)
The following actions are supported by Amazon Lex Runtime Service:

- PostContent (p. 312)
- PostText (p. 320)

Amazon Lex Model Building Service

The following actions are supported by Amazon Lex Model Building Service:

- CreateBotVersion (p. 197)
- CreateIntentVersion (p. 202)
- CreateSlotTypeVersion (p. 208)
- DeleteBot (p. 212)
- DeleteBotAlias (p. 214)
- DeleteBotChannelAssociation (p. 216)
- DeleteBotVersion (p. 218)
- DeleteIntent (p. 220)
- DeleteIntentVersion (p. 222)
- DeleteSlotType (p. 224)
- DeleteSlotTypeVersion (p. 226)
- DeleteUtterances (p. 228)
- GetBot (p. 230)
- GetBotAlias (p. 235)
- GetBotAliases (p. 238)
- GetBotChannelAssociation (p. 241)
- GetBotChannelAssociations (p. 244)
- GetBots (p. 247)
- GetBotVersions (p. 250)
- GetBuiltInIntent (p. 253)
- GetBuiltInIntents (p. 255)
- GetBuiltInSlotTypes (p. 257)
- GetExport (p. 259)
- GetIntent (p. 262)
- GetIntents (p. 267)
- GetIntentVersions (p. 270)
- GetSlotType (p. 273)
- GetSlotTypes (p. 276)
- GetSlotTypeVersions (p. 279)
- GetUtterancesView (p. 282)
- PutBot (p. 285)
- PutBotAlias (p. 293)
- PutIntent (p. 297)
- PutSlotType (p. 307)
CreateBotVersion
Service: Amazon Lex Model Building Service

Creates a new version of the bot based on the $LATEST version. If the $LATEST version of this resource hasn't changed since you created the last version, Amazon Lex doesn't create a new version. It returns the last created version.

Note
You can update only the $LATEST version of the bot. You can't update the numbered versions that you create with the CreateBotVersion operation.

When you create the first version of a bot, Amazon Lex sets the version to 1. Subsequent versions increment by 1. For more information, see Versioning (p. 94).

This operation requires permission for the lex:CreateBotVersion action.

Request Syntax

POST /bots/name/versions HTTP/1.1
Content-type: application/json

{"checksum": "string"}

URI Request Parameters

The request requires the following URI parameters.

name (p. 197)

The name of the bot that you want to create a new version of. The name is case sensitive.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Request Body

The request accepts the following data in JSON format.

checksum (p. 197)

Identifies a specific revision of the $LATEST version of the bot. If you specify a checksum and the $LATEST version of the bot has a different checksum, a PreconditionFailedException exception is returned and Amazon Lex doesn't publish a new version. If you don't specify a checksum, Amazon Lex publishes the $LATEST version.

Type: String

Required: No

Response Syntax

HTTP/1.1 201
Content-type: application/json
Response Elements

If the action is successful, the service sends back an HTTP 201 response.

The following data is returned in JSON format by the service.

**abortStatement (p. 197)**

The message that Amazon Lex uses to abort a conversation. For more information, see PutBot (p. 285).

Type: Statement (p. 350) object

**checksum (p. 197)**

Checksum identifying the version of the bot that was created.

Type: String

**childDirected (p. 197)**

For each Amazon Lex bot created with the Amazon Lex Model Building Service, you must specify whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to the Children's
Online Privacy Protection Act (COPPA) by specifying true or false in the childDirected field. By specifying true in the childDirected field, you confirm that your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. By specifying false in the childDirected field, you confirm that your use of Amazon Lex is not related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. You may not specify a default value for the childDirected field that does not accurately reflect whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA.

If your use of Amazon Lex relates to a website, program, or other application that is directed in whole or in part, to children under age 13, you must obtain any required verifiable parental consent under COPPA. For information regarding the use of Amazon Lex in connection with websites, programs, or other applications that are directed or targeted, in whole or in part, to children under age 13, see the Amazon Lex FAQ.

Type: Boolean

clarificationPrompt (p. 197)

The message that Amazon Lex uses when it doesn't understand the user's request. For more information, see PutBot (p. 285).

Type: Prompt (p. 344) object

createdDate (p. 197)

The date when the bot version was created.

Type: Timestamp

description (p. 197)

A description of the bot.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

failureReason (p. 197)

If status is FAILED, Amazon Lex provides the reason that it failed to build the bot.

Type: String

idleSessionTTLInSeconds (p. 197)

The maximum time in seconds that Amazon Lex retains the data gathered in a conversation. For more information, see PutBot (p. 285).

Type: Integer

Valid Range: Minimum value of 60. Maximum value of 86400.

intents (p. 197)

An array of Intent objects. For more information, see PutBot (p. 285).

Type: Array of Intent (p. 340) objects

lastUpdatedDate (p. 197)

The date when the $LATEST version of this bot was updated.

Type: Timestamp
locale (p. 197)
Specifies the target locale for the bot.
Type: String
Valid Values: en-US

name (p. 197)
The name of the bot.
Type: String
Pattern: ^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_

status (p. 197)
When you send a request to create or update a bot, Amazon Lex sets the status response element to BUILDING. After Amazon Lex builds the bot, it sets status to READY. If Amazon Lex can’t build the bot, it sets status to FAILED. Amazon Lex returns the reason for the failure in the failureReason response element.
Type: String
Valid Values: BUILDING | READY | FAILED | NOT_BUILT

version (p. 197)
The version of the bot.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+

voiceId (p. 197)
The Amazon Polly voice ID that Amazon Lex uses for voice interactions with the user.
Type: String

Errors

BadRequestException
The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.
HTTP Status Code: 400

ConflictException
There was a conflict processing the request. Try your request again.
HTTP Status Code: 409

InternalFailureException
An internal Amazon Lex error occurred. Try your request again.
HTTP Status Code: 500
LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

PreconditionFailedException

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.

HTTP Status Code: 412

CreateIntentVersion
Service: Amazon Lex Model Building Service

Creates a new version of an intent based on the $LATEST version of the intent. If the $LATEST version of this intent hasn’t changed since you last updated it, Amazon Lex doesn’t create a new version. It returns the last version you created.

**Note**
You can update only the $LATEST version of the intent. You can’t update the numbered versions that you create with the CreateIntentVersion operation.

When you create a version of an intent, Amazon Lex sets the version to 1. Subsequent versions increment by 1. For more information, see Versioning (p. 94).

This operation requires permissions to perform the lex:CreateIntentVersion action.

**Request Syntax**

```json
POST /intents/name/versions HTTP/1.1
Content-type: application/json
{
  "checksum": "string"
}
```

**URI Request Parameters**
The request requires the following URI parameters.

**name (p. 202)**

The name of the intent that you want to create a new version of. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*)|_`

**Request Body**
The request accepts the following data in JSON format.

**checksum (p. 202)**

Checksum of the $LATEST version of the intent that should be used to create the new version. If you specify a checksum and the $LATEST version of the intent has a different checksum, Amazon Lex returns a PreconditionFailedException exception and doesn’t publish a new version. If you don’t specify a checksum, Amazon Lex publishes the $LATEST version.

Type: String

Required: No

**Response Syntax**

```
HTTP/1.1 201
Content-type: application/json
```
{
    "checksum": "string",
    "conclusionStatement": {
        "messages": [
            {
                "content": "string",
                "contentType": "string"
            }
        ],
        "responseCard": "string"
    },
    "confirmationPrompt": {
        "maxAttempts": number,
        "messages": [
            {
                "content": "string",
                "contentType": "string"
            }
        ],
        "responseCard": "string"
    },
    "createdDate": number,
    "description": "string",
    "dialogCodeHook": {

            "uri": "string"
        },
        "type": "string"
    },
    "lastUpdatedDate": number,
    "name": "string",
    "parentIntentSignature": "string",
    "rejectionStatement": {
        "messages": [
            {
                "content": "string",
                "contentType": "string"
            }
        ],
        "responseCard": "string"
    }
}
Response Elements

If the action is successful, the service sends back an HTTP 201 response.

The following data is returned in JSON format by the service.

checksum (p. 202)

Checksum of the intent version created.

Type: String

cellinitionStatement (p. 202)

After the Lambda function specified in the fulfillmentActivity field fulfills the intent, Amazon Lex conveys this statement to the user.

Type: Statement (p. 350) object

confirmationPrompt (p. 202)

If defined, the prompt that Amazon Lex uses to confirm the user's intent before fulfilling it.

Type: Prompt (p. 344) object

createdDate (p. 202)

The date that the intent was created.

Type: Timestamp

description (p. 202)

A description of the intent.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.
**dialogCodeHook (p. 202)**

If defined, Amazon Lex invokes this Lambda function for each user input.

Type: CodeHook (p. 336) object

**followUpPrompt (p. 202)**

If defined, Amazon Lex uses this prompt to solicit additional user activity after the intent is fulfilled.

Type: FollowUpPrompt (p. 338) object

**fulfillmentActivity (p. 202)**

Describes how the intent is fulfilled.

Type: FulfillmentActivity (p. 339) object

**lastUpdatedDate (p. 202)**

The date that the intent was updated.

Type: Timestamp

**name (p. 202)**

The name of the intent.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

**parentIntentSignature (p. 202)**

A unique identifier for a built-in intent.

Type: String

**rejectionStatement (p. 202)**

If the user answers "no" to the question defined in confirmationPrompt, Amazon Lex responds with this statement to acknowledge that the intent was canceled.

Type: Statement (p. 350) object

**sampleUtterances (p. 202)**

An array of sample utterances configured for the intent.

Type: Array of strings

Array Members: Minimum number of 0 items. Maximum number of 1500 items.

**slots (p. 202)**

An array of slot types that defines the information required to fulfill the intent.

Type: Array of Slot (p. 346) objects

Array Members: Minimum number of 0 items. Maximum number of 100 items.

**version (p. 202)**

The version number assigned to the new version of the intent.
Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**PreconditionFailedException**

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.

HTTP Status Code: 412

CreateSlotTypeVersion
Service: Amazon Lex Model Building Service

Creates a new version of a slot type based on the $LATEST version of the specified slot type. If the $LATEST version of this resource has not changed since the last version that you created, Amazon Lex doesn't create a new version. It returns the last version that you created.

**Note**
You can update only the $LATEST version of a slot type. You can't update the numbered versions that you create with the CreateSlotTypeVersion operation.

When you create a version of a slot type, Amazon Lex sets the version to 1. Subsequent versions increment by 1. For more information, see Versioning (p. 94).

This operation requires permissions for the lex:CreateSlotTypeVersion action.

**Request Syntax**

```
POST /slottypes/name/versions HTTP/1.1
Content-type: application/json

{
  "checksum": "string"
}
```

**URI Request Parameters**

The request requires the following URI parameters.

**name** *(p. 208)*

The name of the slot type that you want to create a new version for. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**Request Body**

The request accepts the following data in JSON format.

**checksum** *(p. 208)*

Checkum for the $LATEST version of the slot type that you want to publish. If you specify a checksum and the $LATEST version of the slot type has a different checksum, Amazon Lex returns a PreconditionFailedException exception and doesn't publish the new version. If you don't specify a checksum, Amazon Lex publishes the $LATEST version.

Type: String

Required: No

**Response Syntax**

```
HTTP/1.1 201
Content-type: application/json
```
### Response Elements

If the action is successful, the service sends back an HTTP 201 response.

The following data is returned in JSON format by the service.

**checksum** (p. 208)

Checksum of the $LATEST version of the slot type.

Type: String

**createdDate** (p. 208)

The date that the slot type was created.

Type: Timestamp

**description** (p. 208)

A description of the slot type.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

**enumerationValues** (p. 208)

A list of `EnumerationValue` objects that defines the values that the slot type can take.

Type: Array of `EnumerationValue` (p. 337) objects

Array Members: Minimum number of 1 item. Maximum number of 10000 items.

**lastUpdatedDate** (p. 208)

The date that the slot type was updated. When you create a resource, the creation date and last update date are the same.

Type: Timestamp

**name** (p. 208)

The name of the slot type.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_`
valueSelectionStrategy (p. 208)

The strategy that Amazon Lex uses to determine the value of the slot. For more information, see PutSlotType (p. 307).

Type: String

Valid Values: ORIGINAL_VALUE | TOP_RESOLUTION

version (p. 208)

The version assigned to the new slot type version.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|\d+|

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceedededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

PreconditionFailedException

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.

HTTP Status Code: 412

DeleteBot
Service: Amazon Lex Model Building Service

Deletes all versions of the bot, including the $LATEST version. To delete a specific version of the bot, use the DeleteBotVersion (p. 218) operation.

If a bot has an alias, you can’t delete it. Instead, the DeleteBot operation returns a ResourceInUseException exception that includes a reference to the alias that refers to the bot. To remove the reference to the bot, delete the alias. If you get the same exception again, delete the referring alias until the DeleteBot operation is successful.

This operation requires permissions for the lex:DeleteBot action.

Request Syntax

```
DELETE /bots/name HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

name (p. 212)

The name of the bot. The name is case sensitive.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.
HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**ResourceInUseException**

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```
{   "resourceType": BOT | BOTALIAS | BOTCHANNEL | INTENT,
   "resourceReference": {  
    "name": string, "version": string } }
```

HTTP Status Code: 400

**See Also**

- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V2
DeleteBotAlias
Service: Amazon Lex Model Building Service

Deletes an alias for the specified bot.

You can't delete an alias that is used in the association between a bot and a messaging channel. If an alias is used in a channel association, the DeleteBot operation returns a ResourceInUseException exception that includes a reference to the channel association that refers to the bot. You can remove the reference to the alias by deleting the channel association. If you get the same exception again, delete the referring association until the DeleteBotAlias operation is successful.

Request Syntax

DELETE /bots/botName/aliases/name HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

botName (p. 214)

The name of the bot that the alias points to.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

name (p. 214)

The name of the alias to delete. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 204

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException

There was a conflict processing the request. Try your request again.
HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**ResourceInUseException**

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```
{  "resourceType": BOT | BOTALIAS | BOTCHANNEL | INTENT,
   "resourceReference": {
      "name": string,  "version": string
   }
}
```

HTTP Status Code: 400

DeleteBotChannelAssociation
Service: Amazon Lex Model Building Service

Deletes the association between an Amazon Lex bot and a messaging platform.

This operation requires permission for the lex:DeleteBotChannelAssociation action.

Request Syntax

DELETE /bots/botName/aliases/aliasName/channels/name HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

botAlias (p. 216)

An alias that points to the specific version of the Amazon Lex bot to which this association is being made.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)  

botName (p. 216)

The name of the Amazon Lex bot.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)  

name (p. 216)

The name of the association. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)  

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 204  

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.
HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

DeleteBotVersion
Service: Amazon Lex Model Building Service

Deletes a specific version of a bot. To delete all versions of a bot, use the DeleteBot (p. 212) operation.

This operation requires permissions for the lex:DeleteBotVersion action.

Request Syntax

```
DELETE /bots/name/versions/version HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

name (p. 218)
The name of the bot.

Pattern: `^[a-zA-Z]+(_[a-zA-Z]*|([a-zA-Z]+_)*|)`

version (p. 218)
The version of the bot to delete. You cannot delete the $LATEST version of the bot. To delete the $LATEST version, use the DeleteBot (p. 212) operation.

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `[0-9]+`

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequestException
The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException
There was a conflict processing the request. Try your request again.

HTTP Status Code: 409
InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceeded Exception

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

ResourceInUseException

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```
{ "resourceType": BOT | BOTALIAS | BOTCHANNEL | INTENT,

"resourceReference": {

"name": string, "version": string } }```

HTTP Status Code: 400

- AWS SDK for Ruby V2
DeleteIntent
Service: Amazon Lex Model Building Service

Deletes all versions of the intent, including the $LATEST version. To delete a specific version of the intent, use the DeleteIntentVersion (p. 222) operation.

You can delete a version of an intent only if it is not referenced. To delete an intent that is referred to in one or more bots (see Amazon Lex: How It Works (p. 3)), you must remove those references first.

Note
If you get the ResourceInUseException exception, it provides an example reference that shows where the intent is referenced. To remove the reference to the intent, either update the bot or delete it. If you get the same exception when you attempt to delete the intent again, repeat until the intent has no references and the call to DeleteIntent is successful.

This operation requires permission for the lex:DeleteIntent action.

Request Syntax

DELETE /intents/name HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

name (p. 220)

The name of the intent. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 204

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException

There was a conflict processing the request. Try your request again.
HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**ResourceInUseException**

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```json
{ "resourceType": BOT | BOTALIAS | BOTCHANNEL | INTENT,
  "resourceReference": {
    "name": string, "version": string } }
```

HTTP Status Code: 400

DeleteIntentVersion
Service: Amazon Lex Model Building Service

Deletes a specific version of an intent. To delete all versions of a intent, use the DeleteIntent (p. 220) operation.

This operation requires permissions for the lex:DeleteIntentVersion action.

Request Syntax

```
DELETE /intents/name/versions/version HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

**name (p. 222)**

The name of the intent.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**version (p. 222)**

The version of the intent to delete. You cannot delete the $LATEST version of the intent. To delete the $LATEST version, use the DeleteIntent (p. 220) operation.

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `[0-9]+`

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.
HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**ResourceInUseException**

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```json
{  "resourceType": BOT | BOTALIAS | BOTCHANNEL | INTENT,

  "resourceReference": {

    "name": string, "version": string
  }
}
```

HTTP Status Code: 400

DeleteSlotType
Service: Amazon Lex Model Building Service

Deletes all versions of the slot type, including the $LATEST version. To delete a specific version of the slot type, use the DeleteSlotTypeVersion (p. 226) operation.

You can delete a version of a slot type only if it is not referenced. To delete a slot type that is referred to in one or more intents, you must remove those references first.

**Note**
If you get the ResourceInUseException exception, the exception provides an example reference that shows the intent where the slot type is referenced. To remove the reference to the slot type, either update the intent or delete it. If you get the same exception when you attempt to delete the slot type again, repeat until the slot type has no references and the DeleteSlotType call is successful.

This operation requires permission for the lex:DeleteSlotType action.

**Request Syntax**

```
DELETE /slottypes/name HTTP/1.1
```

**URI Request Parameters**

The request requires the following URI parameters.

**name (p. 224)**

The name of the slot type. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**Request Body**

The request does not have a request body.

**Response Syntax**

```
HTTP/1.1 204
```

**Response Elements**

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

**Errors**

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.
HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**ResourceInUseException**

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```json
{
  "resourceType": BOT | BOTALIAS | BOTCHANNEL | INTENT,
  "resourceReference": {
    "name": string, "version": string
  }
}
```

HTTP Status Code: 400

DeleteSlotTypeVersion
Service: Amazon Lex Model Building Service

Deletes a specific version of a slot type. To delete all versions of a slot type, use the DeleteSlotType (p. 224) operation.

This operation requires permissions for the lex:DeleteSlotTypeVersion action.

Request Syntax

```
DELETE /slottypes/name/version/version HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

**name (p. 226)**

The name of the slot type.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+(\_[a-zA-Z]+)*|([a-zA-Z]+_)*|`  

**version (p. 226)**

The version of the slot type to delete. You cannot delete the $LATEST version of the slot type. To delete the $LATEST version, use the DeleteSlotType (p. 224) operation.

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `[0-9]+`

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.
HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**ResourceInUseException**

The resource that you are attempting to delete is referred to by another resource. Use this information to remove references to the resource that you are trying to delete.

The body of the exception contains a JSON object that describes the resource.

```json
{
  "resourceType": "BOT | BOTALIAS | BOTCHANNEL | INTENT,
  "resourceReference": {
    "name": string, "version": string
  }
}
```

HTTP Status Code: 400

DeleteUtterances
Service: Amazon Lex Model Building Service

Deletes stored utterances.

Amazon Lex stores the utterances that users send to your bot unless the childDirected field in the bot is set to true. Utterances are stored for 15 days for use with the GetUtterancesView (p. 282) operation, and then stored indefinitely for use in improving the ability of your bot to respond to user input.

Use the DeleteStoredUtterances operation to manually delete stored utterances for a specific user.

This operation requires permissions for the lex:DeleteUtterances action.

Request Syntax

```
DELETE /bots/botName/utterances/userId HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

**botName (p. 228)**

The name of the bot that stored the utterances.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**userId (p. 228)**

The unique identifier for the user that made the utterances. This is the user ID that was sent in the PostContent or PostText operation request that contained the utterance.

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400
InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetBot
Service: Amazon Lex Model Building Service

Returns metadata information for a specific bot. You must provide the bot name and the bot version or alias.

This operation requires permissions for the lex:GetBot action.

Request Syntax

GET /bots/name/versions/versionOrAlias HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

name (p. 230)
The name of the bot. The name is case sensitive.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_) versionOrAlias (p. 230)
The version or alias of the bot.

Request Body
The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json
{
   "abortStatement": {
      "messages": [
      {   
         "content": "string",
         "contentType": "string"
      },
      "responseCard": "string"
   },
   "checksum": "string",
   "childDirected": boolean,
   "clarificationPrompt": {
      "maxAttempts": number,
      "messages": [
      {   
         "content": "string",
         "contentType": "string"
      },
      "responseCard": "string"
   },
   "createdDate": number,
   "clarificationPrompt": null
}
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

abortStatement (p. 230)

The message that Amazon Lex returns when the user elects to end the conversation without completing it. For more information, see PutBot (p. 285).

Type: Statement (p. 350) object

checksum (p. 230)

Checksum of the bot used to identify a specific revision of the bot's $LATEST version.

Type: String

childDirected (p. 230)

For each Amazon Lex bot created with the Amazon Lex Model Building Service, you must specify whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to the Children's Online Privacy Protection Act (COPPA) by specifying true or false in the childDirected field. By specifying true in the childDirected field, you confirm that your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. By specifying false in the childDirected field, you confirm that your use of Amazon Lex is not related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. You may not specify a default value for the childDirected field that does not accurately reflect whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA.

If your use of Amazon Lex relates to a website, program, or other application that is directed in whole or in part, to children under age 13, you must obtain any required verifiable parental consent under COPPA. For information regarding the use of Amazon Lex in connection with websites, programs, or other applications that are directed or targeted, in whole or in part, to children under age 13, see the Amazon Lex FAQ.

Type: Boolean

clarificationPrompt (p. 230)

The message Amazon Lex uses when it doesn't understand the user's request. For more information, see PutBot (p. 285).
Type: Prompt (p. 344) object

createdDate (p. 230)

The date that the bot was created.
Type: Timestamp
description (p. 230)

A description of the bot.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
failureReason (p. 230)

If status is FAILED, Amazon Lex explains why it failed to build the bot.
Type: String
idleSessionTTLInSeconds (p. 230)

The maximum time in seconds that Amazon Lex retains the data gathered in a conversation. For more information, see PutBot (p. 285).
Type: Integer
Valid Range: Minimum value of 60. Maximum value of 86400.

intents (p. 230)

An array of intent objects. For more information, see PutBot (p. 285).
Type: Array of Intent (p. 340) objects
lastUpdatedDate (p. 230)

The date that the bot was updated. When you create a resource, the creation date and last updated date are the same.
Type: Timestamp
locale (p. 230)

The target locale for the bot.
Type: String
Valid Values: en-US
name (p. 230)

The name of the bot.
Type: String
status (p. 230)

The status of the bot. If the bot is ready to run, the status is READY. If there was a problem with building the bot, the status is FAILED and the failureReason explains why the bot did not build. If the bot was saved but not built, the status is NOT BUILT.
Type: String

Valid Values: BUILDING | READY | FAILED | NOT_BUILT

version (p. 230)

The version of the bot. For a new bot, the version is always $LATEST.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|\d+

voiceId (p. 230)

The Amazon Polly voice ID that Amazon Lex uses for voice interaction with the user. For more information, see PutBot (p. 285).

Type: String

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetBotAlias
Service: Amazon Lex Model Building Service

Returns information about an Amazon Lex bot alias. For more information about aliases, see Versioning and Aliases (p. 94).

This operation requires permissions for the lex:GetBotAlias action.

Request Syntax

GET /bots/botName/aliases/name HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

botName (p. 235)

The name of the bot.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

name (p. 235)

The name of the bot alias. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
  "botName": "string",
  "botVersion": "string",
  "checksum": "string",
  "createdDate": number,
  "description": "string",
  "lastUpdatedDate": number,
  "name": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

botName (p. 235)

The name of the bot that the alias points to.
Type: String

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

**botVersion (p. 235)**

The version of the bot that the alias points to.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|[0-9]+ 

**checksum (p. 235)**

Checksum of the bot alias.

Type: String

**createdDate (p. 235)**

The date that the bot alias was created.

Type: Timestamp

**description (p. 235)**

A description of the bot alias.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

**lastUpdatedDate (p. 235)**

The date that the bot alias was updated. When you create a resource, the creation date and the last updated date are the same.

Type: Timestamp

**name (p. 235)**

The name of the bot alias.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

**Errors**

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.
HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**See Also**

GetBotAliases
Service: Amazon Lex Model Building Service

Returns a list of aliases for a specified Amazon Lex bot.

This operation requires permissions for the lex:GetBotAliases action.

Request Syntax

```
GET /bots/botName/aliases/?
maxResults=maxResults&nameContains=nameContains&nextToken=nextToken
HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

**botName (p. 238)**

The name of the bot.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

**maxResults (p. 238)**

The maximum number of aliases to return in the response. The default is 50.

**nameContains (p. 238)**

Substring to match in bot alias names. An alias will be returned if any part of its name matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz."

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

**nextToken (p. 238)**

A pagination token for fetching the next page of aliases. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of aliases, specify the pagination token in the next request.

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
  "BotAliases": [
    {
      "botName": "string",
      "botVersion": "string",
      "checksum": "string",
      "name": "string",
      "createdDate": "string",
      "lastUpdatedDate": "string"
    }
  ]
}
```
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**BotAliases (p. 238)**

An array of [BotAliasMetadata](p. 327) objects, each describing a bot alias.

Type: Array of [BotAliasMetadata](p. 327) objects

**nextToken (p. 238)**

A pagination token for fetching next page of aliases. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of aliases, specify the pagination token in the next request.

Type: String

**Errors**

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**See Also**

GetBotChannelAssociation
Service: Amazon Lex Model Building Service

Returns information about the association between an Amazon Lex bot and a messaging platform.

This operation requires permissions for the `lex:GetBotChannelAssociation` action.

Request Syntax

```
GET /bots/botName/aliases/aliasName/channels/name HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

botAlias (p. 241)

An alias pointing to the specific version of the Amazon Lex bot to which this association is being made.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

botName (p. 241)

The name of the Amazon Lex bot.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

name (p. 241)

The name of the association between the bot and the channel. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json
{
   "botAlias": "string",
   "botConfiguration": {
      "string": "string"
   },
   "botName": "string",
   "createdDate": number,
   "description": "string",
   "name": "string",
   "type": "string"
}
```
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**botAlias (p. 241)**

An alias pointing to the specific version of the Amazon Lex bot to which this association is being made.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+(_[a-zA-Z]+)*([^a-zA-Z]+)*|._`

**botConfiguration (p. 241)**

Provides information that the messaging platform needs to communicate with the Amazon Lex bot.

Type: String to string map

**botName (p. 241)**

The name of the Amazon Lex bot.

Type: String

Pattern: `^[a-zA-Z]+(_[a-zA-Z]+)*([^a-zA-Z]+)*|._`

**createdDate (p. 241)**

The date that the association between the bot and the channel was created.

Type: Timestamp

**description (p. 241)**

A description of the association between the bot and the channel.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

**name (p. 241)**

The name of the association between the bot and the channel.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+(_[a-zA-Z]+)*([^a-zA-Z]+)*|._`

**type (p. 241)**

The type of the messaging platform.

Type: String

Valid Values: Facebook | Slack | Twilio-Sms
Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetBotChannelAssociations
Service: Amazon Lex Model Building Service

Returns a list of all of the channels associated with the specified bot.

The GetBotChannelAssociations operation requires permissions for the lex:GetBotChannelAssociations action.

Request Syntax

GET /bots/botName/aliases/aliasName/channels/?
maxResults=maxResults&nameContains=nameContains&nextToken=nextToken HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

botAlias (p. 244)
An alias pointing to the specific version of the Amazon Lex bot to which this association is being made.
Length Constraints: Minimum length of 1. Maximum length of 100.
Pattern: ^(-|^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*))$

botName (p. 244)
The name of the Amazon Lex bot in the association.
Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

maxResults (p. 244)
The maximum number of associations to return in the response. The default is 50.

nameContains (p. 244)
Substring to match in channel association names. An association will be returned if any part of its name matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz." To return all bot channel associations, use a hyphen ("-" as the nameContains parameter.
Length Constraints: Minimum length of 1. Maximum length of 100.
Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

nextToken (p. 244)
A pagination token for fetching the next page of associations. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of associations, specify the pagination token in the next request.

Request Body

The request does not have a request body.
Response Syntax

HTTP/1.1 200
Content-type: application/json

{
   "botChannelAssociations": [
   {
      "botAlias": "string",
      "botConfiguration": {
         "string": "string"
      },
      "botName": "string",
      "createdDate": number,
      "description": "string",
      "name": "string",
      "type": "string"
   }
   ],
   "nextToken": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

botChannelAssociations (p. 245)

An array of objects, one for each association, that provides information about the Amazon Lex bot and its association with the channel.

Type: Array of BotChannelAssociation (p. 329) objects

nextToken (p. 245)

A pagination token that fetches the next page of associations. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of associations, specify the pagination token in the next request.

Type: String

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceeded Exception

The request exceeded a limit. Try your request again.
HTTP Status Code: 429

GetBots
Service: Amazon Lex Model Building Service

Returns bot information as follows:

- If you provide the nameContains field, the response includes information for the $LATEST version of all bots whose name contains the specified string.
- If you don't specify the nameContains field, the operation returns information about the $LATEST version of all of your bots.

This operation requires permission for the lex:GetBots action.

Request Syntax

```
GET /bots/?maxResults=\d+&nameContains=\d+&nextToken=\d+ HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

maxResults (p. 247)

The maximum number of bots to return in the response that the request will return. The default is 10.

nameContains (p. 247)

Substring to match in bot names. A bot will be returned if any part of its name matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz."

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

nextToken (p. 247)

A pagination token that fetches the next page of bots. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of bots, specify the pagination token in the next request.

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
   "bots": [
      {
         "createdDate": number,
         "description": "string",
         "lastUpdatedDate": number,
         "name": "string",
      }
   ]
```

247
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**bots (p. 247)**

An array of `botMetadata` objects, with one entry for each bot.

Type: Array of `BotMetadata (p. 331)` objects

**nextToken (p. 247)**

If the response is truncated, it includes a pagination token that you can specify in your next request to fetch the next page of bots.

Type: String

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetBotVersions
Service: Amazon Lex Model Building Service

Gets information about all of the versions of a bot.

The GetBotVersions operation returns a BotMetadata object for each version of a bot. For example, if a bot has three numbered versions, the GetBotVersions operation returns four BotMetadata objects in the response, one for each numbered version and one for the $LATEST version.

The GetBotVersions operation always returns at least one version, the $LATEST version.

This operation requires permissions for the lex:GetBotVersions action.

Request Syntax

GET /bots/name/versions/?maxResults=maxResults&nextToken=nextToken HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

maxResults (p. 250)

The maximum number of bot versions to return in the response. The default is 10.

name (p. 250)

The name of the bot for which versions should be returned.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

nextToken (p. 250)

A pagination token for fetching the next page of bot versions. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of versions, specify the pagination token in the next request.

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

```json
{
  "bots": [  
    {  
      "createdDate": number,
      "description": "string",
      "lastUpdatedDate": number,
      "name": "string",
      "status": "string",
      "version": "string"
    }
  ]
}
```

250
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**bots (p. 250)**

An array of `BotMetadata` objects, one for each numbered version of the bot plus one for the `$LATEST` version.

Type: Array of `BotMetadata` (p. 331) objects

**nextToken (p. 250)**

A pagination token for fetching the next page of bot versions. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of versions, specify the pagination token in the next request.

Type: String

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetBuiltinIntent
Service: Amazon Lex Model Building Service

Returns information about a built-in intent.

This operation requires permission for the lex:GetBuiltinIntent action.

Request Syntax

GET /builtins/intents/\{signature\} HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

signature (p. 253)

The unique identifier for a built-in intent. To find the signature for an intent, see Standard Built-in Intents in the Alexa Skills Kit.

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{  
  "signature": "string",
  "slots": [
    {  
      "name": "string"
    }
  ],  
  "supportedLocales": [ "string" ]
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

signature (p. 253)

The unique identifier for a built-in intent.

Type: String

slots (p. 253)

An array of BuiltinIntentSlot objects, one entry for each slot type in the intent.

Type: Array of BuiltinIntentSlot (p. 334) objects

supportedLocales (p. 253)

A list of locales that the intent supports.
Type: Array of strings

Valid Values: en-US

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetBuiltInIntents
Service: Amazon Lex Model Building Service

Gets a list of built-in intents that meet the specified criteria.

This operation requires permission for the lex:GetBuiltInIntents action.

Request Syntax

GET /builtins/intents/?
locale=locale&maxResults=maxResults&nextToken=nextToken&signatureContains=signatureContains
HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

locale (p. 255)
A list of locales that the intent supports.
Valid Values: en-US

maxResults (p. 255)
The maximum number of intents to return in the response. The default is 10.

nextToken (p. 255)
A pagination token that fetches the next page of intents. If this API call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of intents, use the pagination token in the next request.

signatureContains (p. 255)
Substring to match in built-in intent signatures. An intent will be returned if any part of its signature matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz." To find the signature for an intent, see Standard Built-in Intents in the Alexa Skills Kit.

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{  "intents": [  {   "signature": "string",   "supportedLocales": [ "string" ]  }  ],  "nextToken": "string" }
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**intents (p. 255)**

An array of `builtinIntentMetadata` objects, one for each intent in the response.

Type: Array of `BuiltinIntentMetadata (p. 333)` objects

**nextToken (p. 255)**

A pagination token that fetches the next page of intents. If the response to this API call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of intents, specify the pagination token in the next request.

Type: String

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

GetBuiltinsSlotTypes
Service: Amazon Lex Model Building Service

Gets a list of built-in slot types that meet the specified criteria.

For a list of built-in slot types, see Slot Type Reference in the Alexa Skills Kit.

This operation requires permission for the lex:GetBuiltInSlotTypes action.

Request Syntax

GET /builtins/slottypes/?
locale=locale&maxResults=maxResults&nextToken=nextToken&signatureContains=signatureContains
HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

locale (p. 257)
A list of locales that the slot type supports.

Valid Values: en-US

maxResults (p. 257)

The maximum number of slot types to return in the response. The default is 10.

nextToken (p. 257)

A pagination token that fetches the next page of slot types. If the response to this API call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of slot types, specify the pagination token in the next request.

signatureContains (p. 257)

Substring to match in built-in slot type signatures. A slot type will be returned if any part of its signature matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz."

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{  
"nextToken": "string",
"slotTypes": [  
{
  "signature": "string",
  "supportedLocales": [ "string" ]
}
]  
}
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

nextToken (p. 257)

If the response is truncated, the response includes a pagination token that you can use in your next request to fetch the next page of slot types.

Type: String

slotTypes (p. 257)

An array of BuiltInSlotTypeMetadata objects, one entry for each slot type returned.

Type: Array of BuiltInSlotTypeMetadata (p. 335) objects

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

GetExport
Service: Amazon Lex Model Building Service

Exports the contents of a Amazon Lex resource in a specified format.

Request Syntax

GET /exports/?exportType=exportType&name=name&resourceType=resourceType&version=version
HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

exportType (p. 259)
The format of the exported data.
Valid Values: ALEXA_SKILLS_KIT

name (p. 259)
The name of the bot to export.
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: [a-zA-Z_]+

resourceType (p. 259)
The type of resource to export.
Valid Values: BOT

version (p. 259)
The version of the bot to export.
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: [0-9]+

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{  
  "exportStatus": "string",
  "exportType": "string",
  "failureReason": "string",
  "name": "string",
  "resourceType": "string",
  "url": "string",
  "version": "string"
}
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**exportStatus (p. 259)**

The status of the export.
- **IN_PROGRESS** - The export is in progress.
- **READY** - The export is complete.
- **FAILED** - The export could not be completed.

Type: String

Valid Values: IN_PROGRESS | READY | FAILED

**exportType (p. 259)**

The format of the exported data.

Type: String

Valid Values: ALEXA_SKILLS_KIT

**failureReason (p. 259)**

If status is FAILED, Amazon Lex provides the reason that it failed to export the resource.

Type: String

**name (p. 259)**

The name of the bot being exported.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: [a-zA-Z_]+

**resourceType (p. 259)**

The type of the exported resource.

Type: String

Valid Values: BOT

**url (p. 259)**

An S3 pre-signed URL that provides the location of the exported resource. The exported resource is a ZIP archive that contains the exported resource in JSON format. The structure of the archive may change. Your code should not rely on the archive structure.

Type: String

**version (p. 259)**

The version of the bot being exported.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \([0-9]+\)

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetIntent
Service: Amazon Lex Model Building Service

Returns information about an intent. In addition to the intent name, you must specify the intent version.

This operation requires permissions to perform the lex:GetIntent action.

Request Syntax

GET /intents/name/versions/version HTTP/1.1

URI Request Parameters

The request requires the following URI parameters.

name (p. 262)

The name of the intent. The name is case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_]

version (p. 262)

The version of the intent.

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: ^$LATEST|[0-9]+$+

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

      ],
    },
    "values": [ "string" ]
  }
]
Response Elements

If the action is successful, the service sends back an HTTP 200 response. The following data is returned in JSON format by the service.

**checksum (p. 262)**

Checksum of the intent.

Type: String

**confirmationPrompt (p. 262)**

If defined in the bot, Amazon Lex uses prompt to confirm the intent before fulfilling the user's request. For more information, see PutIntent (p. 297).

Type: Prompt (p. 344) object

**createdDate (p. 262)**

The date that the intent was created.

Type: Timestamp

**description (p. 262)**

A description of the intent.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

**dialogCodeHook (p. 262)**

If defined in the bot, Amazon Lex invokes this Lambda function for each user input. For more information, see PutIntent (p. 297).

Type: CodeHook (p. 336) object

**fulfillmentActivity (p. 262)**

Describes how the intent is fulfilled. For more information, see PutIntent (p. 297).

Type: FulfillmentActivity (p. 339) object
lastUpdatedDate (p. 262)

The date that the intent was updated. When you create a resource, the creation date and the last updated date are the same.

Type: Timestamp

name (p. 262)

The name of the intent.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

parentIntentSignature (p. 262)

A unique identifier for a built-in intent.

Type: String

rejectionStatement (p. 262)

If the user answers "no" to the question defined in confirmationPrompt, Amazon Lex responds with this statement to acknowledge that the intent was canceled.

Type: Statement (p. 350) object

sampleUtterances (p. 262)

An array of sample utterances configured for the intent.

Type: Array of strings

Array Members: Minimum number of 0 items. Maximum number of 1500 items.

slots (p. 262)

An array of intent slots configured for the intent.

Type: Array of Slot (p. 346) objects

Array Members: Minimum number of 0 items. Maximum number of 100 items.

version (p. 262)

The version of the intent.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|[0-9]+

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.
HTTP Status Code: 400
**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500
**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429
**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS Command Line Interface

GetIntents
Service: Amazon Lex Model Building Service

Returns intent information as follows:

- If you specify the nameContains field, returns the $LATEST version of all intents that contain the specified string.
- If you don’t specify the nameContains field, returns information about the $LATEST version of all intents.

The operation requires permission for the lex:GetIntents action.

Request Syntax

```
GET /intents/?maxResults=maxResults&nameContains=nameContains&nextToken=nextToken HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

maxResults (p. 267)

The maximum number of intents to return in the response. The default is 10.

nameContains (p. 267)

Substring to match in intent names. An intent will be returned if any part of its name matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz."

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

nextToken (p. 267)

A pagination token that fetches the next page of intents. If the response to this API call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of intents, specify the pagination token in the next request.

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{  
  "intents": [  
    {  
      "createdDate": number,  
      "description": "string",  
      "lastUpdatedDate": number,  
      "name": "string",  
      "version": "string"
    }
  ]
}
```
response: {
  "nextToken": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**intents (p. 267)**

An array of Intent objects. For more information, see PutBot (p. 285).

Type: Array of IntentMetadata (p. 341) objects

**nextToken (p. 267)**

If the response is truncated, the response includes a pagination token that you can specify in your next request to fetch the next page of intents.

Type: String

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetIntentVersions
Service: Amazon Lex Model Building Service

Gets information about all of the versions of an intent.

The GetIntentVersions operation returns an IntentMetadata object for each version of an intent. For example, if an intent has three numbered versions, the GetIntentVersions operation returns four IntentMetadata objects in the response, one for each numbered version and one for the $LATEST version.

The GetIntentVersions operation always returns at least one version, the $LATEST version.

This operation requires permissions for the lex:GetIntentVersions action.

Request Syntax

```
GET /intents/name/versions/?maxResults=maxResults&nextToken=nextToken HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

maxResults (p. 270)

The maximum number of intent versions to return in the response. The default is 10.

name (p. 270)

The name of the intent for which versions should be returned.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

nextToken (p. 270)

A pagination token for fetching the next page of intent versions. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of versions, specify the pagination token in the next request.

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{

   "intents": [

      {

         "createdDate": number,
         "description": "string",
         "lastUpdatedDate": number,
         "name": "string",
         "version": "string"
      }

   ]

}
```
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**intents (p. 270)**

An array of `IntentMetadata` objects, one for each numbered version of the intent plus one for the $LATEST version.

Type: Array of `IntentMetadata` (p. 341) objects

**nextToken (p. 270)**

A pagination token for fetching the next page of intent versions. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of versions, specify the pagination token in the next request.

Type: String

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetSlotType
Service: Amazon Lex Model Building Service

Returns information about a specific version of a slot type. In addition to specifying the slot type name, you must specify the slot type version.

This operation requires permissions for the lex:GetSlotType action.

Request Syntax
GET /slottypes/name/versions/version HTTP/1.1

URI Request Parameters
The request requires the following URI parameters.

name (p. 273)
The name of the slot type. The name is case sensitive.
Length Constraints: Minimum length of 1. Maximum length of 100.

version (p. 273)
The version of the slot type.
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+

Request Body
The request does not have a request body.

Response Syntax
HTTP/1.1 200
Content-type: application/json
{
  "checksum": "string",
  "createdDate": number,
  "description": "string",
  "enumerationValues": [ 
    {
      "synonyms": [ "string" ],
      "value": "string"
    }
  ],
  "lastUpdatedDate": number,
  "name": "string",
  "valueSelectionStrategy": "string",
  "version": "string"
}

Response Elements
If the action is successful, the service sends back an HTTP 200 response.
The following data is returned in JSON format by the service.

**checksum (p. 273)**

Checksum of the $LATEST version of the slot type.

Type: String

**createdDate (p. 273)**

The date that the slot type was created.

Type: Timestamp

**description (p. 273)**

A description of the slot type.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

**enumerationValues (p. 273)**

A list of `EnumerationValue` objects that defines the values that the slot type can take.

Type: Array of `EnumerationValue (p. 337)` objects

Array Members: Minimum number of 1 item. Maximum number of 10000 items.

**lastUpdatedDate (p. 273)**

The date that the slot type was updated. When you create a resource, the creation date and last update date are the same.

Type: Timestamp

**name (p. 273)**

The name of the slot type.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**valueSelectionStrategy (p. 273)**

The strategy that Amazon Lex uses to determine the value of the slot. For more information, see `PutSlotType (p. 307)`.

Type: String

Valid Values: `ORIGINAL_VALUE | TOP_RESOLUTION`

**version (p. 273)**

The version of the slot type.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `\$LATEST|[0-9]+`
Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetSlotTypes
Service: Amazon Lex Model Building Service

Returns slot type information as follows:

- If you specify the `nameContains` field, returns the \$LATEST version of all slot types that contain the specified string.
- If you don't specify the `nameContains` field, returns information about the \$LATEST version of all slot types.

The operation requires permission for the `lex:GetSlotTypes` action.

**Request Syntax**

```
GET /slottypes/?maxResults=maxResults&nameContains=nameContains&nextToken=nextToken
HTTP/1.1

```

**URI Request Parameters**

The request requires the following URI parameters.

- **maxResults (p. 276)**
  
  The maximum number of slot types to return in the response. The default is 10.
  

- **nameContains (p. 276)**
  
  Substring to match in slot type names. A slot type will be returned if any part of its name matches the substring. For example, "xyz" matches both "xyzabc" and "abcxyz."
  
  Length Constraints: Minimum length of 1. Maximum length of 100.
  

- **nextToken (p. 276)**
  
  A pagination token that fetches the next page of slot types. If the response to this API call is truncated, Amazon Lex returns a pagination token in the response. To fetch next page of slot types, specify the pagination token in the next request.

**Request Body**

The request does not have a request body.

**Response Syntax**

```
HTTP/1.1 200
Content-type: application/json

{
  "nextToken": "string",
  "slotTypes": [
    {  
      "createdDate": number,
      "description": "string",
      "lastUpdatedDate": number,
    }
  ]
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

nextToken (p. 276)

If the response is truncated, it includes a pagination token that you can specify in your next request to fetch the next page of slot types.

Type: String

slotTypes (p. 276)

An array of objects, one for each slot type, that provides information such as the name of the slot type, the version, and a description.

Type: Array of SlotTypeMetadata (p. 348) objects

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

NotFoundException

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetSlotTypeVersions
Service: Amazon Lex Model Building Service

Gets information about all versions of a slot type.

The GetSlotTypeVersions operation returns a SlotTypeMetadata object for each version of a slot type. For example, if a slot type has three numbered versions, the GetSlotTypeVersions operation returns four SlotTypeMetadata objects in the response, one for each numbered version and one for the $LATEST version.

The GetSlotTypeVersions operation always returns at least one version, the $LATEST version.

This operation requires permissions for the lex:GetSlotTypeVersions action.

**Request Syntax**

```
GET /slottypes/name/versions/?maxResults=maxResults&nextToken=nextToken HTTP/1.1
```

**URI Request Parameters**

The request requires the following URI parameters.

**maxResults (p. 279)**

The maximum number of slot type versions to return in the response. The default is 10.

**name (p. 279)**

The name of the slot type for which versions should be returned.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)$

**nextToken (p. 279)**

A pagination token for fetching the next page of slot type versions. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of versions, specify the pagination token in the next request.

**Request Body**

The request does not have a request body.

**Response Syntax**

```
HTTP/1.1 200
Content-type: application/json

{
    "nextToken": "string",
    "slotTypes": [
    {
        "createdDate": number,
        "description": "string",
        "lastUpdatedDate": number,
        "name": "string",
        "version": "string"
    }
    ]
}
```
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**nextToken (p. 279)**

A pagination token for fetching the next page of slot type versions. If the response to this call is truncated, Amazon Lex returns a pagination token in the response. To fetch the next page of versions, specify the pagination token in the next request.

Type: String

**slotTypes (p. 279)**

An array of `SlotTypeMetadata` objects, one for each numbered version of the slot type plus one for the `$LATEST` version.

Type: Array of `SlotTypeMetadata (p. 348)` objects

Errors

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**NotFoundException**

The resource specified in the request was not found. Check the resource and try again.

HTTP Status Code: 404

GetUtterancesView
Service: Amazon Lex Model Building Service

Use the GetUtterancesView operation to get information about the utterances that your users have made to your bot. You can use this list to tune the utterances that your bot responds to.

For example, say that you have created a bot to order flowers. After your users have used your bot for a while, use the GetUtterancesView operation to see the requests that they have made and whether they have been successful. You might find that the utterance "I want flowers" is not being recognized. You could add this utterance to the OrderFlowers intent so that your bot recognizes that utterance.

After you publish a new version of a bot, you can get information about the old version and the new so that you can compare the performance across the two versions.

Data is available for the last 15 days. You can request information for up to 5 versions in each request. The response contains information about a maximum of 100 utterances for each version.

If the bot's childDirected field is set to true, utterances for the bot are not stored and cannot be retrieved with the GetUtterancesView operation. For more information, see PutBot (p. 285).

This operation requires permissions for the lex:GetUtterancesView action.

Request Syntax

```
GET /bots/botname/utterances?view=aggregation&bot_versions=botVersions&status_type=statusType HTTP/1.1
```

URI Request Parameters

The request requires the following URI parameters.

**botName (p. 282)**

The name of the bot for which utterance information should be returned.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)+)*|_

**botVersions (p. 282)**

An array of bot versions for which utterance information should be returned. The limit is 5 versions per request.

Array Members: Minimum number of 1 item. Maximum number of 5 items.

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|[0-9]+

**statusType (p. 282)**

To return utterances that were recognized and handled, use Detected. To return utterances that were not recognized, use Missed.

Valid Values: Detected | Missed

Request Body

The request does not have a request body.
**Response Syntax**

```json
HTTP/1.1 200
Content-type: application/json
{
    "botName": "string",
    "utterances": [
        {
            "botVersion": "string",
            "utterances": [
                {
                    "count": number,
                    "distinctUsers": number,
                    "firstUtteredDate": number,
                    "lastUtteredDate": number,
                    "utteranceString": "string"
                }
            ]
        }
    ]
}
```

**Response Elements**

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**botName (p. 283)**

The name of the bot for which utterance information was returned.

Type: String

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**utterances (p. 283)**

An array of UtteranceList (p. 352) objects, each containing a list of UtteranceData (p. 351) objects describing the utterances that were processed by your bot. The response contains a maximum of 100 UtteranceData objects for each version.

Type: Array of UtteranceList (p. 352) objects

**Errors**

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500
LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

See Also

- AWS SDK for Ruby V2
PutBot
Service: Amazon Lex Model Building Service

Creates an Amazon Lex conversational bot or replaces an existing bot. When you create or update a bot you are only required to specify a name. You can use this to add intents later, or to remove intents from an existing bot. When you create a bot with a name only, the bot is created or updated but Amazon Lex returns the response FAILED. You can build the bot after you add one or more intents. For more information about Amazon Lex bots, see Amazon Lex: How It Works (p. 3).

If you specify the name of an existing bot, the fields in the request replace the existing values in the $LATEST version of the bot. Amazon Lex removes any fields that you don't provide values for in the request, except for the idleTTLInSeconds and privacySettings fields, which are set to their default values. If you don't specify values for required fields, Amazon Lex throws an exception.

This operation requires permissions for the lex:PutBot action. For more information, see Authentication and Access Control for Amazon Lex (p. 183).

Request Syntax

PUT /bots/name/versions/$LATEST HTTP/1.1
Content-type: application/json

{
   "abortStatement": {
      "messages": [
         {
            "content": "string",
            "contentType": "string"
         },
         "responseCard": "string"
      ],
      "checksum": "string",
      "childDirected": boolean,
      "clarificationPrompt": {
         "maxAttempts": number,
         "messages": [
            {
               "content": "string",
               "contentType": "string"
            }
         ],
         "responseCard": "string"
      },
      "description": "string",
      "idleSessionTTLInSeconds": number,
      "intents": [
         {
            "intentName": "string",
            "intentVersion": "string"
         }
      ],
      "locale": "string",
      "processBehavior": "string",
      "voiceId": "string"
   }
}

URI Request Parameters

The request requires the following URI parameters.
name (p. 285)

The name of the bot. The name is not case sensitive.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)  

Request Body

The request accepts the following data in JSON format.

abortStatement (p. 285)

When Amazon Lex can't understand the user's input in context, it tries to elicit the information a few times. After that, Amazon Lex sends the message defined in abortStatement to the user, and then aborts the conversation. To set the number of retries, use the valueElicitationPrompt field for the slot type.

For example, in a pizza ordering bot, Amazon Lex might ask a user "What type of crust would you like?" If the user's response is not one of the expected responses (for example, "thin crust," etc.), Amazon Lex tries to elicit a correct response a few more times.

For example, in a pizza ordering application, OrderPizza might be one of the intents. This intent might require the CrustType slot. You specify the valueElicitationPrompt field when you create the CrustType slot.

Type: Statement (p. 350) object

Required: No

checksum (p. 285)

Identifies a specific revision of the $LATEST version.

When you create a new bot, leave the checksum field blank. If you specify a checksum you get a BadRequestException exception.

When you want to update a bot, set the checksum field to the checksum of the most recent revision of the $LATEST version. If you don't specify the checksum field, or if the checksum does not match the $LATEST version, you get a PreconditionFailedException exception.

Type: String

Required: No

childDirected (p. 285)

For each Amazon Lex bot created with the Amazon Lex Model Building Service, you must specify whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to the Children's Online Privacy Protection Act (COPPA) by specifying true or false in the childDirected field. By specifying true in the childDirected field, you confirm that your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. By specifying false in the childDirected field, you confirm that your use of Amazon Lex is not related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. You may not specify a default value for the childDirected field that does not accurately reflect whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA.
If your use of Amazon Lex relates to a website, program, or other application that is directed in whole or in part, to children under age 13, you must obtain any required verifiable parental consent under COPPA. For information regarding the use of Amazon Lex in connection with websites, programs, or other applications that are directed or targeted, in whole or in part, to children under age 13, see the Amazon Lex FAQ.

Type: Boolean
Required: Yes

clarificationPrompt (p. 285)

When Amazon Lex doesn't understand the user's intent, it uses this message to get clarification. To specify how many times Amazon Lex should repeat the clarification prompt, use the `maxAttempts` field. If Amazon Lex still doesn't understand, it sends the message in the `abortStatement` field.

When you create a clarification prompt, make sure that it suggests the correct response from the user. For example, for a bot that orders pizza and drinks, you might create this clarification prompt: "What would you like to do? You can say 'Order a pizza' or 'Order a drink.'"

Type: `Prompt (p. 344)` object
Required: No

description (p. 285)

A description of the bot.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

Required: No

idleSessionTTLInSeconds (p. 285)

The maximum time in seconds that Amazon Lex retains the data gathered in a conversation.

A user interaction session remains active for the amount of time specified. If no conversation occurs during this time, the session expires and Amazon Lex deletes any data provided before the timeout.

For example, suppose that a user chooses the OrderPizza intent, but gets sidetracked halfway through placing an order. If the user doesn't complete the order within the specified time, Amazon Lex discards the slot information that it gathered, and the user must start over.

If you don't include the `idleSessionTTLInSeconds` element in a `PutBot` operation request, Amazon Lex uses the default value. This is also true if the request replaces an existing bot.

The default is 300 seconds (5 minutes).

Type: Integer
Valid Range: Minimum value of 60. Maximum value of 86400.

Required: No

intents (p. 285)

An array of `Intent` objects. Each intent represents a command that a user can express. For example, a pizza ordering bot might support an OrderPizza intent. For more information, see Amazon Lex: How It Works (p. 3).

Type: Array of `Intent (p. 340)` objects
Required: No
locale (p. 285)

Specifies the target locale for the bot. Any intent used in the bot must be compatible with the locale of the bot.

The default is en-US.

Type: String

Valid Values: en-US

Required: Yes

processBehavior (p. 285)

If you set the processBehavior element to Build, Amazon Lex builds the bot so that it can be run. If you set the element to Save, Amazon Lex saves the bot, but doesn't build it.

If you don't specify this value, the default value is Save.

Type: String

Valid Values: SAVE | BUILD

Required: No

voiceId (p. 285)

The Amazon Polly voice ID that you want Amazon Lex to use for voice interactions with the user. The locale configured for the voice must match the locale of the bot. For more information, see Available Voices in the Amazon Polly Developer Guide.

Type: String

Required: No

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
    "abortStatement": {
        "messages": [
            {
                "content": "string",

  {
    "intentName": "string",
    "intentVersion": "string"
  }
],
"lastUpdatedDate": number,
"locale": "string",
"name": "string",
"status": "string",
"version": "string",
"voiceId": "string"

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**abortStatement (p. 288)**

The message that Amazon Lex uses to abort a conversation. For more information, see PutBot (p. 285).

Type: Statement (p. 350) object

**checksum (p. 288)**

Checksum of the bot that you created.

Type: String

**childDirected (p. 288)**

For each Amazon Lex bot created with the Amazon Lex Model Building Service, you must specify whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to the Children's Online Privacy Protection Act (COPPA) by specifying `true` or `false` in the `childDirected` field. By specifying `true` in the `childDirected` field, you confirm that your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. By specifying `false` in the `childDirected` field, you confirm that your use of Amazon Lex is not related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA. You may not specify a default value for the `childDirected` field that does not accurately reflect whether your use of Amazon Lex is related to a website, program, or other application that is directed or targeted, in whole or in part, to children under age 13 and subject to COPPA.

If your use of Amazon Lex relates to a website, program, or other application that is directed in whole or in part, to children under age 13, you must obtain any required verifiable parental consent under COPPA. For information regarding the use of Amazon Lex in connection with websites, programs, or other applications that are directed or targeted, in whole or in part, to children under age 13, see the Amazon Lex FAQ.

Type: Boolean

**clarificationPrompt (p. 288)**

The prompts that Amazon Lex uses when it doesn't understand the user's intent. For more information, see PutBot (p. 285).
Type: Prompt (p. 344) object

createdDate (p. 288)

The date that the bot was created.
Type: Timestamp

description (p. 288)

A description of the bot.
Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

failureReason (p. 288)

If status is FAILED, Amazon Lex provides the reason that it failed to build the bot.
Type: String

idleSessionTTLInSeconds (p. 288)

The maximum length of time that Amazon Lex retains the data gathered in a conversation. For more information, see PutBot (p. 285).
Type: Integer

Valid Range: Minimum value of 60. Maximum value of 86400.

intents (p. 288)

An array of Intent objects. For more information, see PutBot (p. 285).
Type: Array of Intent (p. 340) objects

lastUpdatedDate (p. 288)

The date that the bot was updated. When you create a resource, the creation date and last updated date are the same.
Type: Timestamp

locale (p. 288)

The target locale for the bot.
Type: String

Valid Values: en-US

name (p. 288)

The name of the bot.
Type: String

Pattern: ^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_

status (p. 288)

When you send a request to create a bot with processBehavior set to BUILD, Amazon Lex sets the status response element to BUILDING. After Amazon Lex builds the bot, it sets status to READY. If Amazon Lex can’t build the bot, Amazon Lex sets status to FAILED. Amazon Lex returns the reason for the failure in the failureReason response element.
When you set `processBehavior` to `SAVE`, Amazon Lex sets the status code to `NOT_BUILT`.

Type: String

Valid Values: BUILDING | READY | FAILED | NOT_BUILT

**version (p. 288)**

The version of the bot. For a new bot, the version is always `$LATEST`.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `\$LATEST|[0-9]+`

**voiceId (p. 288)**

The Amazon Polly voice ID that Amazon Lex uses for voice interaction with the user. For more information, see `PutBot (p. 285)`.

Type: String

**Errors**

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**PreconditionFailedException**

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.

HTTP Status Code: 412

**See Also**

- AWS SDK for Python
- AWS SDK for Ruby V2
PutBotAlias
Service: Amazon Lex Model Building Service

Creates an alias for the specified version of the bot or replaces an alias for the specified bot. To change the version of the bot that the alias points to, replace the alias. For more information about aliases, see Versioning and Aliases (p. 94).

This operation requires permissions for the lex:PutBotAlias action.

Request Syntax

```
PUT /bots/botName/aliases/name HTTP/1.1
Content-type: application/json

{
   "botVersion": "string",
   "checksum": "string",
   "description": "string"
}
```

URI Request Parameters

The request requires the following URI parameters.

**botName (p. 293)**

The name of the bot.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

**name (p. 293)**

The name of the alias. The name is not case sensitive.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: `^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)`

Request Body

The request accepts the following data in JSON format.

**botVersion (p. 293)**

The version of the bot.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `\$LATEST|^[0-9]+`

Required: Yes

**checksum (p. 293)**

Identifies a specific revision of the $LATEST version.
When you create a new bot alias, leave the checksum field blank. If you specify a checksum you get a BadRequestException exception.

When you want to update a bot alias, set the checksum field to the checksum of the most recent revision of the $LATEST version. If you don't specify the checksum field, or if the checksum does not match the $LATEST version, you get a PreconditionFailedException exception.

Type: String
Required: No

description (p. 293)

A description of the alias.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
Required: No

Response Syntax

HTTP/1.1 200
Content-type: application/json
{
  "botName": "string",
  "botVersion": "string",
  "checksum": "string",
  "createdAt": number,
  "description": "string",
  "lastUpdatedDate": number,
  "name": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

botName (p. 294)
The name of the bot that the alias points to.
Type: String
Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_) botVersion (p. 294)
The version of the bot that the alias points to.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+
checksum (p. 294)

The checksum for the current version of the alias.

Type: String

createdDate (p. 294)

The date that the bot alias was created.

Type: Timestamp

description (p. 294)

A description of the alias.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

lastUpdatedDate (p. 294)

The date that the bot alias was updated. When you create a resource, the creation date and the last updated date are the same.

Type: Timestamp

name (p. 294)

The name of the alias.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

PreconditionFailedException

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.
HTTP Status Code: 412

PutIntent
Service: Amazon Lex Model Building Service

Creates an intent or replaces an existing intent.

To define the interaction between the user and your bot, you use one or more intents. For a pizza ordering bot, for example, you would create an OrderPizza intent.

To create an intent or replace an existing intent, you must provide the following:

- Intent name. For example, OrderPizza.
- Sample utterances. For example, "Can I order a pizza, please." and "I want to order a pizza."
- Information to be gathered. You specify slot types for the information that your bot will request from the user. You can specify standard slot types, such as a date or a time, or custom slot types such as the size and crust of a pizza.
- How the intent will be fulfilled. You can provide a Lambda function or configure the intent to return the intent information to the client application. If you use a Lambda function, when all of the intent information is available, Amazon Lex invokes your Lambda function. If you configure your intent to return the intent information to the client application.

You can specify other optional information in the request, such as:

- A confirmation prompt to ask the user to confirm an intent. For example, "Shall I order your pizza?"
- A conclusion statement to send to the user after the intent has been fulfilled. For example, "I placed your pizza order."
- A follow-up prompt that asks the user for additional activity. For example, asking "Do you want to order a drink with your pizza?"

If you specify an existing intent name to update the intent, Amazon Lex replaces the values in the $LATEST version of the intent with the values in the request. Amazon Lex removes fields that you don’t provide in the request. If you don’t specify the required fields, Amazon Lex throws an exception. When you update the $LATEST version of an intent, the status field of any bot that uses the $LATEST version of the intent is set to NOT_BUILT.

For more information, see Amazon Lex: How It Works (p. 3).

This operation requires permissions for the lex:PutIntent action.

Request Syntax

PUT /intents/name/versions/$LATEST HTTP/1.1
Content-type: application/json

{
   "checksum": "string",
   "conclusionStatement": {
      "messages": [

        }
      ]
    },
    "slotTypeVersion": "string"  
  }  
]
URI Request Parameters

The request requires the following URI parameters.

name (p. 297)

The name of the intent. The name is not case sensitive.

The name can't match a built-in intent name, or a built-in intent name with "AMAZON." removed. For example, because there is a built-in intent called AMAZON.HelpIntent, you can't create a custom intent called HelpIntent.

For a list of built-in intents, see Standard Built-in Intents in the Alexa Skills Kit.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Request Body

The request accepts the following data in JSON format.

checksum (p. 297)

Identifies a specific revision of the $LATEST version.

When you create a new intent, leave the checksum field blank. If you specify a checksum you get a BadRequestException exception.

When you want to update a intent, set the checksum field to the checksum of the most recent revision of the $LATEST version. If you don't specify the checksum field, or if the checksum does not match the $LATEST version, you get a PreconditionFailedException exception.

Type: String

Required: No

conclusionStatement (p. 297)

The statement that you want Amazon Lex to convey to the user after the intent is successfully fulfilled by the Lambda function.

This element is relevant only if you provide a Lambda function in the fulfillmentActivity. If you return the intent to the client application, you can't specify this element.

Note

The followUpPrompt and conclusionStatement are mutually exclusive. You can specify only one.

Type: Statement (p. 350) object

Required: No
**confirmationPrompt (p. 297)**

Prompts the user to confirm the intent. This question should have a yes or no answer.

Amazon Lex uses this prompt to ensure that the user acknowledges that the intent is ready for fulfillment. For example, with the OrderPizza intent, you might want to confirm that the order is correct before placing it. For other intents, such as intents that simply respond to user questions, you might not need to ask the user for confirmation before providing the information.

**Note**

You must provide both the rejectionStatement and the confirmationPrompt, or neither.

Type: Prompt (p. 344) object

Required: No

**description (p. 297)**

A description of the intent.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

Required: No

**dialogCodeHook (p. 297)**

Specifies a Lambda function to invoke for each user input. You can invoke this Lambda function to personalize user interaction.

For example, suppose your bot determines that the user is John. Your Lambda function might retrieve John's information from a backend database and prepopulate some of the values. For example, if you find that John is gluten intolerant, you might set the corresponding intent slot, GlutenIntolerant, to true. You might find John's phone number and set the corresponding session attribute.

Type: CodeHook (p. 336) object

Required: No

**followUpPrompt (p. 297)**

Amazon Lex uses this prompt to solicit additional activity after fulfilling an intent. For example, after the OrderPizza intent is fulfilled, you might prompt the user to order a drink.

The action that Amazon Lex takes depends on the user's response, as follows:

- If the user says "Yes" it responds with the clarification prompt that is configured for the bot.
- If the user says "Yes" and continues with an utterance that triggers an intent it starts a conversation for the intent.
- If the user says "No" it responds with the rejection statement configured for the the follow-up prompt.
- If it doesn't recognize the utterance it repeats the follow-up prompt again.

The followUpPrompt field and the conclusionStatement field are mutually exclusive. You can specify only one.

Type: FollowUpPrompt (p. 338) object

Required: No
fulfillmentActivity (p. 297)

Required. Describes how the intent is fulfilled. For example, after a user provides all of the information for a pizza order, fulfillmentActivity defines how the bot places an order with a local pizza store.

You might configure Amazon Lex to return all of the intent information to the client application, or direct it to invoke a Lambda function that can process the intent (for example, place an order with a pizzeria).

Type: FulfillmentActivity (p. 339) object

parentIntentSignature (p. 297)

A unique identifier for the built-in intent to base this intent on. To find the signature for an intent, see Standard Built-in Intents in the Alexa Skills Kit.

Type: String

rejectionStatement (p. 297)

When the user answers "no" to the question defined in confirmationPrompt, Amazon Lex responds with this statement to acknowledge that the intent was canceled.

Note
You must provide both the rejectionStatement and the confirmationPrompt, or neither.

Type: Statement (p. 350) object

sampleUtterances (p. 297)

An array of utterances (strings) that a user might say to signal the intent. For example, "I want {PizzaSize} pizza", "Order {Quantity} {PizzaSize} pizzas".

In each utterance, a slot name is enclosed in curly braces.

Type: Array of strings

Array Members: Minimum number of 0 items. Maximum number of 1500 items.

Required: No

slots (p. 297)

An array of intent slots. At runtime, Amazon Lex elicits required slot values from the user using prompts defined in the slots. For more information, see Amazon Lex: How It Works (p. 3).

Type: Array of Slot (p. 346) objects

Array Members: Minimum number of 0 items. Maximum number of 100 items.

Required: No

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
  "checksum": "string",
  "conclusionStatement": {
    "messages": [
      {
        "content": "string",
        "contentType": "string"
      }
    ],

    },
    "rejectionStatement": {
      "messages": [
        {
          "content": "string",
          "contentType": "string"
        }
      ],
      "responseCard": "string"
    }
  },
  "fulfillmentActivity": {
    "codeHook": {
      "messageVersion": "string",
      "uri": "string"
    },
    "type": "string"
  },
  "lastUpdatedDate": number,
  "name": "string",
  "parentIntentSignature": "string",
  "rejectionStatement": {
    "messages": [
      {
        "content": "string",
        "contentType": "string"
      }
    ]
  }
}
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**checksum (p. 301)**

Checksum of the $LATEST version of the intent created or updated.

Type: String

**conclusionStatement (p. 301)**

After the Lambda function specified in the fulfillmentActivity intent fulfills the intent, Amazon Lex conveys this statement to the user.

Type: Statement (p. 350) object

**confirmationPrompt (p. 301)**

If defined in the intent, Amazon Lex prompts the user to confirm the intent before fulfilling it.

Type: Prompt (p. 344) object

**createdDate (p. 301)**

The date that the intent was created.

Type: Timestamp

**description (p. 301)**

A description of the intent.

Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.

dialogCodeHook (p. 301)

If defined in the intent, Amazon Lex invokes this Lambda function for each user input.

Type: CodeHook (p. 336) object

followUpPrompt (p. 301)

If defined in the intent, Amazon Lex uses this prompt to solicit additional user activity after the intent is fulfilled.

Type: FollowUpPrompt (p. 338) object

fulfillmentActivity (p. 301)

If defined in the intent, Amazon Lex invokes this Lambda function to fulfill the intent after the user provides all of the information required by the intent.

Type: FulfillmentActivity (p. 339) object

lastUpdatedDate (p. 301)

The date that the intent was updated. When you create a resource, the creation date and last update dates are the same.

Type: Timestamp

name (p. 301)

The name of the intent.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

parentIntentSignature (p. 301)

A unique identifier for the built-in intent that this intent is based on.

Type: String

rejectionStatement (p. 301)

If the user answers "no" to the question defined in confirmationPrompt Amazon Lex responds with this statement to acknowledge that the intent was canceled.

Type: Statement (p. 350) object

sampleUtterances (p. 301)

An array of sample utterances that are configured for the intent.

Type: Array of strings

Array Members: Minimum number of 0 items. Maximum number of 1500 items.

slots (p. 301)

An array of intent slots that are configured for the intent.

Type: Array of Slot (p. 346) objects
Array Members: Minimum number of 0 items. Maximum number of 100 items.

`version (p. 301)`

The version of the intent. For a new intent, the version is always `LATEST`.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: `\LATEST|\d+`

**Errors**

**BadRequestException**

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

**ConflictException**

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

**InternalFailureException**

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

**LimitExceededException**

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

**PreconditionFailedException**

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.

HTTP Status Code: 412

PutSlotType
Service: Amazon Lex Model Building Service

Creates a custom slot type or replaces an existing custom slot type.

To create a custom slot type, specify a name for the slot type and a set of enumeration values, which are the values that a slot of this type can assume. For more information, see Amazon Lex: How It Works (p. 3).

If you specify the name of an existing slot type, the fields in the request replace the existing values in the $LATEST version of the slot type. Amazon Lex removes the fields that you don't provide in the request. If you don't specify required fields, Amazon Lex throws an exception. When you update the $LATEST version of a slot type, if a bot uses the $LATEST version of an intent that contains the slot type, the bot's status field is set to NOT_BUILT.

This operation requires permissions for the lex:PutSlotType action.

Request Syntax

```
PUT /slottypes/name/versions/$LATEST HTTP/1.1
Content-type: application/json
{
    "checksum": "string",
    "description": "string",
    "enumerationValues": [ 
        { 
            "synonyms": [ "string" ],
            "value": "string"
        }
    ],
    "valueSelectionStrategy": "string"
}
```

URI Request Parameters

The request requires the following URI parameters.

name (p. 307)
The name of the slot type. The name is not case sensitive.

The name can't match a built-in slot type name, or a built-in slot type name with "AMAZON." removed. For example, because there is a built-in slot type called AMAZON.DATE, you can't create a custom slot type called DATE.

For a list of built-in slot types, see Slot Type Reference in the Alexa Skills Kit.

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_

Request Body

The request accepts the following data in JSON format.

checksum (p. 307)
Identifies a specific revision of the $LATEST version.
When you create a new slot type, leave the checksum field blank. If you specify a checksum you get a BadRequestException exception.

When you want to update a slot type, set the checksum field to the checksum of the most recent revision of the $LATEST version. If you don't specify the checksum field, or if the checksum does not match the $LATEST version, you get a PreconditionFailedException exception.

**Type:** String

**Required:** No

### description (p. 307)

A description of the slot type.

**Type:** String

**Length Constraints:** Minimum length of 0. Maximum length of 200.

**Required:** No

### enumerationValues (p. 307)

A list of EnumerationValue objects that defines the values that the slot type can take. Each value can have a list of synonyms, which are additional values that help train the machine learning model about the values that it resolves for a slot.

When Amazon Lex resolves a slot value, it generates a resolution list that contains up to five possible values for the slot. If you are using a Lambda function, this resolution list is passed to the function. If you are not using a Lambda function you can choose to return the value that the user entered or the first value in the resolution list as the slot value. The valueSelectionStrategy field indicates the option to use.

**Type:** Array of EnumerationValue (p. 337) objects

**Array Members:** Minimum number of 1 item. Maximum number of 10000 items.

**Required:** No

### valueSelectionStrategy (p. 307)

Determines the slot resolution strategy that Amazon Lex uses to return slot type values. The field can be set to one of the following values:

- **ORIGINAL_VALUE** - Returns the value entered by the user, if the user value is similar to the slot value.
- **TOP_RESOLUTION** - If there is a resolution list for the slot, return the first value in the resolution list as the slot type value. If there is no resolution list, null is returned.

If you don't specify the valueSelectionStrategy, the default is ORIGINAL_VALUE.

**Type:** String

**Valid Values:** ORIGINAL_VALUE | TOP_RESOLUTION

**Required:** No

### Response Syntax

```
HTTP/1.1 200
Content-type: application/json
```
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

checksum (p. 308)
Checksum of the $LATEST version of the slot type.
Type: String

createdDate (p. 308)
The date that the slot type was created.
Type: Timestamp

description (p. 308)
A description of the slot type.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.

enumerationValues (p. 308)
A list of EnumerationValue objects that defines the values that the slot type can take.
Type: Array of EnumerationValue (p. 337) objects
Array Members: Minimum number of 1 item. Maximum number of 10000 items.

lastUpdatedDate (p. 308)
The date that the slot type was updated. When you create a slot type, the creation date and last update date are the same.
Type: Timestamp

name (p. 308)
The name of the slot type.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 100.
Pattern: ^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_
valueSelectionStrategy (p. 308)

The slot resolution strategy that Amazon Lex uses to determine the value of the slot. For more information, see PutSlotType (p. 307).

Type: String

Valid Values: ORIGINAL_VALUE | TOP_RESOLUTION

version (p. 308)

The version of the slot type. For a new slot type, the version is always $LATEST.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|\{0-9\}+

Errors

BadRequestException

The request is not well formed. For example, a value is invalid or a required field is missing. Check the field values, and try again.

HTTP Status Code: 400

ConflictException

There was a conflict processing the request. Try your request again.

HTTP Status Code: 409

InternalFailureException

An internal Amazon Lex error occurred. Try your request again.

HTTP Status Code: 500

LimitExceededException

The request exceeded a limit. Try your request again.

HTTP Status Code: 429

PreconditionFailedException

The checksum of the resource that you are trying to change does not match the checksum in the request. Check the resource's checksum and try again.

HTTP Status Code: 412

- AWS Command Line Interface
- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
Amazon Lex Runtime Service

The following actions are supported by Amazon Lex Runtime Service:

- PostContent (p. 312)
- PostText (p. 320)
PostContent
Service: Amazon Lex Runtime Service

Sends user input (text or speech) to Amazon Lex. Clients use this API to send text and audio requests to Amazon Lex at runtime. Amazon Lex interprets the user input using the machine learning model that it built for the bot.

The PostContent operation supports audio input at 8kHz and 16kHz. You can use 8kHz audio to achieve higher speech recognition accuracy in telephone audio applications.

In response, Amazon Lex returns the next message to convey to the user. Consider the following example messages:

- For a user input "I would like a pizza," Amazon Lex might return a response with a message eliciting slot data (for example, PizzaSize): "What size pizza would you like?".
- After the user provides all of the pizza order information, Amazon Lex might return a response with a message to get user confirmation: "Order the pizza?".
- After the user replies "Yes" to the confirmation prompt, Amazon Lex might return a conclusion statement: "Thank you, your cheese pizza has been ordered."

Not all Amazon Lex messages require a response from the user. For example, conclusion statements do not require a response. Some messages require only a yes or no response. In addition to the message, Amazon Lex provides additional context about the message in the response that you can use to enhance client behavior, such as displaying the appropriate client user interface. Consider the following examples:

- If the message is to elicit slot data, Amazon Lex returns the following context information:
  - x-amz-lex-dialog-state header set to ElicitSlot
  - x-amz-lex-intent-name header set to the intent name in the current context
  - x-amz-lex-slot-to-elicit header set to the slot name for which the message is eliciting information
  - x-amz-lex-slots header set to a map of slots configured for the intent with their current values
- If the message is a confirmation prompt, the x-amz-lex-dialog-state header is set to Confirmation and the x-amz-lex-slot-to-elicit header is omitted.
- If the message is a clarification prompt configured for the intent, indicating that the user intent is not understood, the x-amz-dialog-state header is set to ElicitIntent and the x-amz-slot-to-elicit header is omitted.

In addition, Amazon Lex also returns your application-specific sessionAttributes. For more information, see Managing Conversation Context.

Request Syntax

```
POST /bot/botName/alias/botAlias/user/userId/content HTTP/1.1
x-amz-lex-session-attributes: sessionAttributes
x-amz-lex-request-attributes: requestAttributes
Content-Type: contentType
Accept: accept
inputStream
```

URI Request Parameters

The request requires the following URI parameters.
accept (p. 312)

You pass this value as the `Accept` HTTP header.

The message Amazon Lex returns in the response can be either text or speech based on the `Accept` HTTP header value in the request.

- If the value is `text/plain; charset=utf-8`, Amazon Lex returns text in the response.
- If the value begins with `audio/`, Amazon Lex returns speech in the response. Amazon Lex uses Amazon Polly to generate the speech (using the configuration you specified in the `Accept` header). For example, if you specify `audio/mpeg` as the value, Amazon Lex returns speech in the MPEG format.

The following are the accepted values:

- `audio/mpeg`
- `audio/ogg`
- `audio/pcm`
- `text/plain; charset=utf-8`
- `audio/*` (defaults to mpeg)

botAlias (p. 312)

Alias of the Amazon Lex bot.

botName (p. 312)

Name of the Amazon Lex bot.

contentType (p. 312)

You pass this value as the `Content-Type` HTTP header.

Indicates the audio format or text. The header value must start with one of the following prefixes:

- PCM format, audio data must be in little-endian byte order.
  - `audio/l16; rate=16000; channels=1`
  - `audio/x-l16; sample-rate=16000; channel-count=1`
  - `audio/lpcm; sample-rate=8000; sample-size-bits=16; channel-count=1; is-big-endian=false`
- Opus format
  - `audio/x-cbr-opus-with-preamble; preamble-size=0; bit-rate=256000; frame-size-milliseonds=4`
- Text format
  - `text/plain; charset=utf-8`

requestAttributes (p. 312)

You pass this value as the `x-amz-lex-request-attributes` HTTP header.

Request-specific information passed between Amazon Lex and a client application. The value must be a JSON serialized and base64 encoded map with string keys and values. The total size of the `requestAttributes` and `sessionAttributes` headers is limited to 12 KB.

The namespace `x-amz-lex:` is reserved for special attributes. Don't create any request attributes with the prefix `x-amz-lex:`.

For more information, see Setting Request Attributes.

sessionAttributes (p. 312)

You pass this value as the `x-amz-lex-session-attributes` HTTP header.
Application-specific information passed between Amazon Lex and a client application. The value must be a JSON serialized and base64 encoded map with string keys and values. The total size of the `sessionAttributes` and `requestAttributes` headers is limited to 12 KB.

For more information, see Setting Session Attributes.

**userId (p. 312)**

The ID of the client application user. Amazon Lex uses this to identify a user's conversation with your bot. At runtime, each request must contain the `userId` field.

To decide the user ID to use for your application, consider the following factors.

- The `userId` field must not contain any personally identifiable information of the user, for example, name, personal identification numbers, or other end user personal information.
- If you want a user to start a conversation on one device and continue on another device, use a user-specific identifier.
- If you want the same user to be able to have two independent conversations on two different devices, choose a device-specific identifier.
- A user can't have two independent conversations with two different versions of the same bot. For example, a user can't have a conversation with the PROD and BETA versions of the same bot. If you anticipate that a user will need to have conversation with two different versions, for example, while testing, include the bot alias in the user ID to separate the two conversations.

Pattern: `[0-9a-zA-Z._:-]+`

**Request Body**

The request accepts the following binary data.

**inputStream (p. 312)**

User input in PCM or Opus audio format or text format as described in the `Content-Type` HTTP header.

You can stream audio data to Amazon Lex or you can create a local buffer that captures all of the audio data before sending. In general, you get better performance if you stream audio data rather than buffering the data locally.

**Response Syntax**

```
HTTP/1.1 200
Content-Type: content-type
x-amz-lex-intent-name: intentName
x-amz-lex-slots: slots
x-amz-lex-session-attributes: sessionAttributes
x-amz-lex-message: message
x-amz-lex-dialog-state: dialogState
x-amz-lex-slot-to-elicit: slotToElicit
x-amz-lex-input-transcript: inputTranscript
audioStream
```

**Response Elements**

If the action is successful, the service sends back an HTTP 200 response.
The response returns the following HTTP headers.

contentType (p. 314)

Content type as specified in the Accept HTTP header in the request.

dialogState (p. 314)

Identifies the current state of the user interaction. Amazon Lex returns one of the following values as dialogState. The client can optionally use this information to customize the user interface.

- **ElicitIntent** - Amazon Lex wants to elicit the user's intent. Consider the following examples:

  For example, a user might utter an intent ("I want to order a pizza"). If Amazon Lex cannot infer the user intent from this utterance, it will return this dialog state.

- **ConfirmIntent** - Amazon Lex is expecting a "yes" or "no" response.

  For example, Amazon Lex wants user confirmation before fulfilling an intent. Instead of a simple "yes" or "no" response, a user might respond with additional information. For example, "yes, but make it a thick crust pizza" or "no, I want to order a drink." Amazon Lex can process such additional information (in these examples, update the crust type slot or change the intent from OrderPizza to OrderDrink).

- **ElicitSlot** - Amazon Lex is expecting the value of a slot for the current intent.

  For example, suppose that in the response Amazon Lex sends this message: "What size pizza would you like?". A user might reply with the slot value (e.g., "medium"). The user might also provide additional information in the response (e.g., "medium thick crust pizza"). Amazon Lex can process such additional information appropriately.

- **Fulfilled** - Conveys that the Lambda function has successfully fulfilled the intent.

- **ReadyForFulfillment** - Conveys that the client has to fulfill the request.

- **Failed** - Conveys that the conversation with the user failed.

  This can happen for various reasons, including that the user does not provide an appropriate response to prompts from the service (you can configure how many times Amazon Lex can prompt a user for specific information), or if the Lambda function fails to fulfill the intent.

Valid Values: ElicitIntent | ConfirmIntent | ElicitSlot | Fulfilled | ReadyForFulfillment | Failed

inputTranscript (p. 314)

The text used to process the request.

If the input was an audio stream, the inputTranscript field contains the text extracted from the audio stream. This is the text that is actually processed to recognize intents and slot values. You can use this information to determine if Amazon Lex is correctly processing the audio that you send.

intentName (p. 314)

Current user intent that Amazon Lex is aware of.

message (p. 314)

Message to convey to the user. It can come from the bot’s configuration or a code hook (Lambda function). If the current intent is not configured with a code hook or if the code hook returned Delegate as the dialogAction.type in its response, then Amazon Lex decides the next course of action and selects an appropriate message from the bot configuration based on the current user interaction context. For example, if Amazon Lex is not able to understand the user input, it uses a clarification prompt message (For more information, see the Error Handling section in the Amazon Lex console). Another example: if the intent requires confirmation before fulfillment, then Amazon Lex uses the confirmation prompt message in the intent configuration. If the code hook returns a message, Amazon Lex passes it as-is in its response to the client.

**sessionAttributes (p. 314)**

Map of key/value pairs representing the session-specific context information.

**slots (p. 314)**

Map of zero or more intent slots (name/value pairs) Amazon Lex detected from the user input during the conversation.

Amazon Lex creates a resolution list containing likely values for a slot. The value that it returns is determined by the valueSelectionStrategy selected when the slot type was created or updated. If valueSelectionStrategy is set to ORIGINAL_VALUE, the value provided by the user is returned, if the user value is similar to the slot values. If valueSelectionStrategy is set to TOP_RESOLUTION Amazon Lex returns the first value in the resolution list or, if there is no resolution list, null. If you don't specify a valueSelectionStrategy, the default is ORIGINAL_VALUE.

**slotToElicit (p. 314)**

If the dialogState value is ElicitSlot, returns the name of the slot for which Amazon Lex is eliciting a value.

The response returns the following as the HTTP body.

**audioStream (p. 314)**

The prompt (or statement) to convey to the user. This is based on the bot configuration and context. For example, if Amazon Lex did not understand the user intent, it sends the clarificationPrompt configured for the bot. If the intent requires confirmation before taking the fulfillment action, it sends the confirmationPrompt. Another example: Suppose that the Lambda function successfully fulfilled the intent, and sent a message to convey to the user. Then Amazon Lex sends that message in the response.

**Errors**

**BadGatewayException**

Either the Amazon Lex bot is still building, or one of the dependent services (Amazon Polly, AWS Lambda) failed with an internal service error.

HTTP Status Code: 502

**BadRequestException**

Request validation failed, there is no usable message in the context, or the bot build failed, is still in progress, or contains unbuilt changes.

HTTP Status Code: 400

**ConflictException**

Two clients are using the same AWS account, Amazon Lex bot, and user ID.

HTTP Status Code: 409

**DependencyFailedException**

One of the dependencies, such as AWS Lambda or Amazon Polly, threw an exception. For example,

- If Amazon Lex does not have sufficient permissions to call a Lambda function.
- If a Lambda function takes longer than 30 seconds to execute.
• If a fulfillment Lambda function returns a Delegate dialog action without removing any slot values.

   HTTP Status Code: 424
   InternalFailureException
   Internal service error. Retry the call.
   HTTP Status Code: 500
   LimitExceededException
   Exceeded a limit.
   HTTP Status Code: 429
   LoopDetectedException
   This exception is not used.
   HTTP Status Code: 508
   NotAcceptableException
   The accept header in the request does not have a valid value.
   HTTP Status Code: 406
   NotFoundException
   The resource (such as the Amazon Lex bot or an alias) that is referred to is not found.
   HTTP Status Code: 404
   RequestTimeoutException
   The input speech is too long.
   HTTP Status Code: 408
   UnsupportedMediaTypeException
   The Content-Type header (PostContent API) has an invalid value.
   HTTP Status Code: 415

Example

Example 1

In this request, the URI identifies a bot (Traffic), bot version ($LATEST), and end user name (someuser). The Content-Type header identifies the format of the audio in the body. Amazon Lex also supports other formats. To convert audio from one format to another, if necessary, you can use SoX open source software. You specify the format in which you want to get the response by adding the Accept HTTP header.

In the response, the x-amz-lex-message header shows the response that Amazon Lex returned. The client can then send this response to the user. The same message is sent in audio/MPEG format through chunked encoding (as requested).

Sample Request

"POST /bot/Traffic/alias/$LATEST/user/someuser/content HTTP/1.1[
]"
"x-amz-lex-session-attributes: eyJ1c2VyTmFtZSI6IkJvYiJ9[
]"
Sample Response

HTTP/1.1 200 OK
"x-amzn-RequestId: cc8b34af-cebb-11e6-a35c-55f3a992f28d[\r]\n"
"x-amzn-lex-message: Sorry, can you repeat that?[\r]\n"
"x-amzn-lex-dialog-state: ElicitIntent[\r]\n"
"x-amzn-lex-session-attributes: eyJ1c2VyTmFtZSI6IkJvYiJ9[\r]\n"
"Content-Type: audio/mpeg[\r]\n"
"Transfer-Encoding: chunked[\r]\n"
"Date: Fri, 30 Dec 2016 18:14:28 GMT[\r]\n"

- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V2
PostText
Service: Amazon Lex Runtime Service

Sends user input (text-only) to Amazon Lex. Client applications can use this API to send requests to Amazon Lex at runtime. Amazon Lex then interprets the user input using the machine learning model it built for the bot.

In response, Amazon Lex returns the next message to convey to the user an optional responseCard to display. Consider the following example messages:

- For a user input "I would like a pizza", Amazon Lex might return a response with a message eliciting slot data (for example, PizzaSize): "What size pizza would you like?"
- After the user provides all of the pizza order information, Amazon Lex might return a response with a message to obtain user confirmation "Proceed with the pizza order?".
- After the user replies to a confirmation prompt with a "yes", Amazon Lex might return a conclusion statement: "Thank you, your cheese pizza has been ordered."

Not all Amazon Lex messages require a user response. For example, a conclusion statement does not require a response. Some messages require only a "yes" or "no" user response. In addition to the message, Amazon Lex provides additional context about the message in the response that you might use to enhance client behavior, for example, to display the appropriate client user interface. These are the slotToElicit, dialogState, intentName, and slots fields in the response. Consider the following examples:

- If the message is to elicit slot data, Amazon Lex returns the following context information:
  - dialogState set to ElicitSlot
  - intentName set to the intent name in the current context
  - slotToElicit set to the slot name for which the message is eliciting information
  - slots set to a map of slots, configured for the intent, with currently known values
- If the message is a confirmation prompt, the dialogState is set to ConfirmIntent and slotToElicit is set to null.
- If the message is a clarification prompt (configured for the intent) that indicates that user intent is not understood, the dialogState is set to ElicitIntent and slotToElicit is set to null.

In addition, Amazon Lex also returns your application-specific sessionAttributes. For more information, see Managing Conversation Context.

Request Syntax

```json
POST /bot/botName/alias/botAlias/user/userId/text HTTP/1.1
Content-type: application/json

{
  "inputText" : "string",
  "requestAttributes" : {
    "string" : "string"
  },
  "sessionAttributes" : {
    "string" : "string"
  }
}
```

URI Request Parameters

The request requires the following URI parameters.
botAlias (p. 320)

The alias of the Amazon Lex bot.

botName (p. 320)

The name of the Amazon Lex bot.

userId (p. 320)

The ID of the client application user. Amazon Lex uses this to identify a user's conversation with your bot. At runtime, each request must contain the userId field.

To decide the user ID to use for your application, consider the following factors.

• The userId field must not contain any personally identifiable information of the user, for example, name, personal identification numbers, or other end user personal information.

• If you want a user to start a conversation on one device and continue on another device, use a user-specific identifier.

• If you want the same user to be able to have two independent conversations on two different devices, choose a device-specific identifier.

• A user can't have two independent conversations with two different versions of the same bot. For example, a user can't have a conversation with the PROD and BETA versions of the same bot. If you anticipate that a user will need to have conversation with two different versions, for example, while testing, include the bot alias in the user ID to separate the two conversations.

Pattern: [0-9a-zA-Z._:-]+

Request Body

The request accepts the following data in JSON format.

inputText (p. 320)

The text that the user entered (Amazon Lex interprets this text).

When you are using the AWS CLI, you can't pass a URL in the --input-text parameter. Pass the URL using the --cli-input-json parameter instead.

Type: String

Required: Yes

requestAttributes (p. 320)

Request-specific information passed between Amazon Lex and a client application.

The namespace x-amz-lex: is reserved for special attributes. Don't create any request attributes with the prefix x-amz-lex:.

For more information, see Setting Request Attributes.

Type: String to string map

Required: No
sessionAttributes (p. 320)

Application-specific information passed between Amazon Lex and a client application. For more information, see Setting Session Attributes.

Type: String to string map

Required: No

Response Syntax

HTTP/1.1 200
Content-type: application/json

```
{
    "dialogState": "string",
    "intentName": "string",
    "message": "string",
    "responseCard": {
        "contentType": "string",
        "genericAttachments": [
            {
                "attachmentLinkUrl": "string",
                "buttons": [
                    {
                        "text": "string",
                        "value": "string"
                    }
                ],
                "imageUrl": "string",
                "subTitle": "string",
                "title": "string"
            }
        ],
        "version": "string"
    },
    "sessionAttributes": {
        "string": "string"
    },
    "slots": {
        "string": "string"
    },
    "slotToElicit": "string"
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

dialogState (p. 322)

Identifies the current state of the user interaction. Amazon Lex returns one of the following values as dialogState. The client can optionally use this information to customize the user interface.

- **ElicitIntent** - Amazon Lex wants to elicit user intent.
  
  For example, a user might utter an intent ("I want to order a pizza"). If Amazon Lex cannot infer the user intent from this utterance, it will return this dialogState.
  
- **ConfirmIntent** - Amazon Lex is expecting a "yes" or "no" response.
For example, Amazon Lex wants user confirmation before fulfilling an intent.

Instead of a simple "yes" or "no," a user might respond with additional information. For example, "yes, but make it thick crust pizza" or "no, I want to order a drink". Amazon Lex can process such additional information (in these examples, update the crust type slot value, or change intent from OrderPizza to OrderDrink).

- **ElicitSlot** - Amazon Lex is expecting a slot value for the current intent.

  For example, suppose that in the response Amazon Lex sends this message: "What size pizza would you like?". A user might reply with the slot value (e.g., "medium"). The user might also provide additional information in the response (e.g., "medium thick crust pizza"). Amazon Lex can process such additional information appropriately.

- **Fulfilled** - Conveys that the Lambda function configured for the intent has successfully fulfilled the intent.

- **ReadyForFulfillment** - Conveys that the client has to fulfill the intent.

- **Failed** - Conveys that the conversation with the user failed.

  This can happen for various reasons including that the user did not provide an appropriate response to prompts from the service (you can configure how many times Amazon Lex can prompt a user for specific information), or the Lambda function failed to fulfill the intent.

  Type: String

  Valid Values: ElicitIntent | ConfirmIntent | ElicitSlot | Fulfilled | ReadyForFulfillment | Failed

**intentName (p. 322)**

The current user intent that Amazon Lex is aware of.

Type: String

**message (p. 322)**

A message to convey to the user. It can come from the bot's configuration or a code hook (Lambda function). If the current intent is not configured with a code hook or the code hook returned Delegate as the `dialogAction.type` in its response, then Amazon Lex decides the next course of action and selects an appropriate message from the bot configuration based on the current user interaction context. For example, if Amazon Lex is not able to understand the user input, it uses a clarification prompt message (for more information, see the Error Handling section in the Amazon Lex console). Another example: if the intent requires confirmation before fulfillment, then Amazon Lex uses the confirmation prompt message in the intent configuration. If the code hook returns a message, Amazon Lex passes it as-is in its response to the client.

Type: String

**responseCard (p. 322)**

Represents the options that the user has to respond to the current prompt. Response Card can come from the bot configuration (in the Amazon Lex console, choose the settings button next to a slot) or from a code hook (Lambda function).

Type: `ResponseCard (p. 356)` object

**sessionAttributes (p. 322)**

A map of key-value pairs representing the session-specific context information.

Type: String to string map
slots (p. 322)

The intent slots that Amazon Lex detected from the user input in the conversation.

Amazon Lex creates a resolution list containing likely values for a slot. The value that it returns is determined by the valueSelectionStrategy selected when the slot type was created or updated. If valueSelectionStrategy is set to ORIGINAL_VALUE, the value provided by the user is returned, if the user value is similar to the slot values. If valueSelectionStrategy is set to TOP_RESOLUTION Amazon Lex returns the first value in the resolution list or, if there is no resolution list, null. If you don't specify a valueSelectionStrategy, the default is ORIGINAL_VALUE.

Type: String to string map

slotToElicit (p. 322)

If the dialogState value is ElicitSlot, returns the name of the slot for which Amazon Lex is eliciting a value.

Type: String

Errors

BadGatewayException

Either the Amazon Lex bot is still building, or one of the dependent services (Amazon Polly, AWS Lambda) failed with an internal service error.

HTTP Status Code: 502

BadRequestException

Request validation failed, there is no usable message in the context, or the bot build failed, is still in progress, or contains unbuilt changes.

HTTP Status Code: 400

ConflictException

Two clients are using the same AWS account, Amazon Lex bot, and user ID.

HTTP Status Code: 409

DependencyFailedException

One of the dependencies, such as AWS Lambda or Amazon Polly, threw an exception. For example,

- If Amazon Lex does not have sufficient permissions to call a Lambda function.
- If a Lambda function takes longer than 30 seconds to execute.
- If a fulfillment Lambda function returns a Delegate dialog action without removing any slot values.

HTTP Status Code: 424

InternalFailureException

Internal service error. Retry the call.

HTTP Status Code: 500

LimitExceededException

Exceeded a limit.

HTTP Status Code: 429
LoopDetectedException

This exception is not used.

HTTP Status Code: 508

NotFoundException

The resource (such as the Amazon Lex bot or an alias) that is referred to is not found.

HTTP Status Code: 404

- AWS SDK for Ruby V2

Data Types

The following data types are supported by Amazon Lex Model Building Service:

- BotAliasMetadata (p. 327)
- BotChannelAssociation (p. 329)
- BotMetadata (p. 331)
- BuiltinIntentMetadata (p. 333)
- BuiltinIntentSlot (p. 334)
- BuiltinSlotTypeMetadata (p. 335)
- CodeHook (p. 336)
- EnumerationValue (p. 337)
- FollowUpPrompt (p. 338)
- FulfillmentActivity (p. 339)
- Intent (p. 340)
- IntentMetadata (p. 341)
- Message (p. 343)
- Prompt (p. 344)
- ResourceReference (p. 345)
- Slot (p. 346)
- SlotTypeMetadata (p. 348)
- Statement (p. 350)
- UtteranceData (p. 351)
• UtteranceList (p. 352)

The following data types are supported by Amazon Lex Runtime Service:

• Button (p. 353)
• GenericAttachment (p. 354)
• ResponseCard (p. 356)

Amazon Lex Model Building Service

The following data types are supported by Amazon Lex Model Building Service:

• BotAliasMetadata (p. 327)
• BotChannelAssociation (p. 329)
• BotMetadata (p. 331)
• BuiltinIntentMetadata (p. 333)
• BuiltinIntentSlot (p. 334)
• BuiltinSlotTypeMetadata (p. 335)
• CodeHook (p. 336)
• EnumerationValue (p. 337)
• FollowUpPrompt (p. 338)
• FulfillmentActivity (p. 339)
• Intent (p. 340)
• IntentMetadata (p. 341)
• Message (p. 343)
• Prompt (p. 344)
• ResourceReference (p. 345)
• Slot (p. 346)
• SlotTypeMetadata (p. 348)
• Statement (p. 350)
• UtteranceData (p. 351)
• UtteranceList (p. 352)
BotAliasMetadata
Service: Amazon Lex Model Building Service

Provides information about a bot alias.

Contents

botName

The name of the bot to which the alias points.
Type: String
Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|) Required: No

botVersion

The version of the Amazon Lex bot to which the alias points.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+ Required: No

checksum

Checksum of the bot alias.
Type: String
Required: No

description

A description of the bot alias.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
Required: No

lastUpdatedDate

The date that the bot alias was updated. When you create a resource, the creation date and last updated date are the same.
Type: Timestamp
Required: No
name

The name of the bot alias.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)|([a-zA-Z]+_)*|_)

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
BotChannelAssociation
Service: Amazon Lex Model Building Service

Represents an association between an Amazon Lex bot and an external messaging platform.

Contents

botAlias
An alias pointing to the specific version of the Amazon Lex bot to which this association is being made.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+([_][a-zA-Z]+)*|([a-zA-Z]+_[_]+)*|_

Required: No

botConfiguration
Provides information necessary to communicate with the messaging platform.

Type: String to string map

Required: No

botName
The name of the Amazon Lex bot to which this association is being made.

Note
Currently, Amazon Lex supports associations with Facebook and Slack, and Twilio.

Type: String

Pattern: ^[a-zA-Z]+$|([a-zA-Z]+_)*|([a-zA-Z]+)$

Required: No

createdDate
The date that the association between the Amazon Lex bot and the channel was created.

Type: Timestamp

Required: No

description
A text description of the association you are creating.

Type: String

Length Constraints: Minimum length of 0. Maximum length of 200.

Required: No

name
The name of the association between the bot and the channel.
Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Required: No

type

Specifies the type of association by indicating the type of channel being established between the Amazon Lex bot and the external messaging platform.

Type: String

Valid Values: Facebook | Slack | Twilio-Sms

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
BotMetadata
Service: Amazon Lex Model Building Service
Provides information about a bot.

Contents

createdDate
The date that the bot was created.
Type: Timestamp
Required: No
description
A description of the bot.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
Required: No
lastUpdatedDate
The date that the bot was updated. When you create a bot, the creation date and last updated date are the same.
Type: Timestamp
Required: No
name
The name of the bot.
Type: String
Pattern: ^[a-zA-Z0-9]+(_[a-zA-Z0-9]*)*|([a-zA-Z0-9]+_)*|_)
Required: No
status
The status of the bot.
Type: String
Valid Values: BUILDING | READY | FAILED | NOT_BUILT
Required: No
version
The version of the bot. For a new bot, the version is always $LATEST.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+
Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
BuiltInIntentMetadata

Service: Amazon Lex Model Building Service

Provides metadata for a built-in intent.

Contents

**signature**

A unique identifier for the built-in intent. To find the signature for an intent, see Standard Built-in Intents in the Alexa Skills Kit.

Type: String

Required: No

**supportedLocales**

A list of identifiers for the locales that the intent supports.

Type: Array of strings

Valid Values: en-US

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
**BuiltinIntentSlot**

Service: Amazon Lex Model Building Service

Provides information about a slot used in a built-in intent.

**Contents**

**name**

A list of the slots defined for the intent.

Type: String

Required: No

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
BuiltInSlotTypeMetadata

Service: Amazon Lex Model Building Service

Provides information about a built in slot type.

Contents

signature

A unique identifier for the built-in slot type. To find the signature for a slot type, see Slot Type Reference in the Alexa Skills Kit.

Type: String

Required: No

supportedLocales

A list of target locales for the slot.

Type: Array of strings

Valid Values: en-US

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
CodeHook
Service: Amazon Lex Model Building Service

Specifies a Lambda function that verifies requests to a bot or fulfills the user’s request to a bot.

Contents

**messageVersion**

The version of the request-response that you want Amazon Lex to use to invoke your Lambda function. For more information, see Using Lambda Functions (p. 98).

Type: String

Required: Yes

**uri**

The Amazon Resource Name (ARN) of the Lambda function.

Type: String

Pattern: arn:aws:lambda:[a-z]+-[a-z]+-[0-9]:[0-9]{12}:function:[a-zA-Z0-9-_.]+(/[0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12})?(:[a-zA-Z0-9-_.]+)?

Required: Yes

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
EnumerationValue
Service: Amazon Lex Model Building Service

Each slot type can have a set of values. Each enumeration value represents a value the slot type can take.

For example, a pizza ordering bot could have a slot type that specifies the type of crust that the pizza should have. The slot type could include the values

- thick
- thin
- stuffed

Contents

synonyms
Additional values related to the slot type value.
Type: Array of strings
Length Constraints: Minimum length of 1. Maximum length of 140.
Required: No

value
The value of the slot type.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 140.
Required: Yes

See Also
For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
FollowUpPrompt
Service: Amazon Lex Model Building Service

A prompt for additional activity after an intent is fulfilled. For example, after the OrderPizza intent is fulfilled, you might prompt the user to find out whether the user wants to order drinks.

Contents

prompt

Prompts for information from the user.

Type: Prompt (p. 344) object

Required: Yes

rejectionStatement

If the user answers "no" to the question defined in the prompt field, Amazon Lex responds with this statement to acknowledge that the intent was canceled.

Type: Statement (p. 350) object

Required: Yes

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
**FulfillmentActivity**  
Service: Amazon Lex Model Building Service

Describes how the intent is fulfilled after the user provides all of the information required for the intent. You can provide a Lambda function to process the intent, or you can return the intent information to the client application. We recommend that you use a Lambda function so that the relevant logic lives in the Cloud and limit the client-side code primarily to presentation. If you need to update the logic, you only update the Lambda function; you don't need to upgrade your client application.

Consider the following examples:

- In a pizza ordering application, after the user provides all of the information for placing an order, you use a Lambda function to place an order with a pizzeria.
- In a gaming application, when a user says "pick up a rock," this information must go back to the client application so that it can perform the operation and update the graphics. In this case, you want Amazon Lex to return the intent data to the client.

**Contents**

codeHook

A description of the Lambda function that is run to fulfill the intent.

Type: CodeHook (p. 336) object

Required: No

type

How the intent should be fulfilled, either by running a Lambda function or by returning the slot data to the client application.

Type: String

Valid Values: ReturnIntent | CodeHook

Required: Yes

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
Intent
Service: Amazon Lex Model Building Service

Identifies the specific version of an intent.

Contents

intentName

The name of the intent.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)

Required: Yes

intentVersion

The version of the intent.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: \$LATEST|\ [0-9]+ \n
Required: Yes

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
IntentMetadata
Service: Amazon Lex Model Building Service
Provides information about an intent.

Contents

createdDate
The date that the intent was created.
Type: Timestamp
Required: No

description
A description of the intent.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
Required: No

lastUpdatedDate
The date that the intent was updated. When you create an intent, the creation date and last updated date are the same.
Type: Timestamp
Required: No

name
The name of the intent.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 100.
Pattern: ^[a-zA-Z]+((_[a-zA-Z]+)*|([a-zA-Z]+_)*_)
Required: No

version
The version of the intent.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+
Required: No

See Also
For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
• AWS SDK for Go
• AWS SDK for Java
• AWS SDK for Ruby V2
Message
Service: Amazon Lex Model Building Service

The message object that provides the message text and its type.

Contents

content

The text of the message.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1000.

Required: Yes

cContentType

The content type of the message string.

Type: String

Valid Values: PlainText | SSML

Required: Yes

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
Prompt
Service: Amazon Lex Model Building Service

Obtains information from the user. To define a prompt, provide one or more messages and specify the number of attempts to get information from the user. If you provide more than one message, Amazon Lex chooses one of the messages to use to prompt the user. For more information, see Amazon Lex: How It Works (p. 3).

Contents
maxAttempts

The number of times to prompt the user for information.
Type: Integer
Required: Yes

messages

An array of objects, each of which provides a message string and its type. You can specify the message string in plain text or in Speech Synthesis Markup Language (SSML).
Type: Array of Message (p. 343) objects
Array Members: Minimum number of 1 item. Maximum number of 5 items.
Required: Yes

responseCard

A response card. Amazon Lex uses this prompt at runtime, in the PostText API response. It substitutes session attributes and slot values for placeholders in the response card. For more information, see Example: Using a Response Card (p. 162).
Type: String
Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
ResourceReference
Service: Amazon Lex Model Building Service

Describes the resource that refers to the resource that you are attempting to delete. This object is returned as part of the ResourceInUseException exception.

Contents

ame

The name of the resource that is using the resource that you are trying to delete.

Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: [a-zA-Z_]+
Required: No

version

The version of the resource that is using the resource that you are trying to delete.

Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \\$LATEST|[0-9]+\n
Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
Slot
Service: Amazon Lex Model Building Service
Identifies the version of a specific slot.

Contents

description
A description of the slot.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
Required: No

name
The name of the slot.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 100.
Pattern: ^[a-zA-Z-]+(((_|.)[a-zA-Z-]+)+|([a-zA-Z-]+(_|.)*)|(_|.)$)
Required: Yes

priority
Directs Lex the order in which to elicit this slot value from the user. For example, if the intent has two slots with priorities 1 and 2, AWS Lex first elicits a value for the slot with priority 1.

If multiple slots share the same priority, the order in which Lex elicits values is arbitrary.
Type: Integer
Valid Range: Minimum value of 0. Maximum value of 100.
Required: No

responseCard
A set of possible responses for the slot type used by text-based clients. A user chooses an option from the response card, instead of using text to reply.
Type: String
Required: No

sampleUtterances
If you know a specific pattern with which users might respond to an Amazon Lex request for a slot value, you can provide those utterances to improve accuracy. This is optional. In most cases, Amazon Lex is capable of understanding user utterances.
Type: Array of strings
Array Members: Minimum number of 0 items. Maximum number of 10 items.
slotConstraint

Specifies whether the slot is required or optional.
Type: String

Valid Values: Required | Optional

Required: Yes

slotType

The type of the slot, either a custom slot type that you defined or one of the built-in slot types.
Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Required: No

slotTypeVersion

The version of the slot type.
Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: $LATEST|[0-9]+[0-9]*

Required: No

valueElicitationPrompt

The prompt that Amazon Lex uses to elicit the slot value from the user.
Type: Prompt (p. 344) object

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
SlotTypeMetadata
Service: Amazon Lex Model Building Service

Provides information about a slot type.

Contents

createdDate
The date that the slot type was created.
Type: Timestamp
Required: No
description
A description of the slot type.
Type: String
Length Constraints: Minimum length of 0. Maximum length of 200.
Required: No
lastUpdatedDate
The date that the slot type was updated. When you create a resource, the creation date and last updated date are the same.
Type: Timestamp
Required: No
name
The name of the slot type.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 100.
Pattern: ^[a-zA-Z]+(_[a-zA-Z]+)*|([a-zA-Z]+_)*|_)
Required: No
version
The version of the slot type.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: \$LATEST|[0-9]+ Required: No

See Also
For more information about using this API in one of the language-specific AWS SDKs, see the following:
- AWS SDK for C++
• AWS SDK for Go
• AWS SDK for Java
• AWS SDK for Ruby V2
Statement
Service: Amazon Lex Model Building Service

A collection of messages that convey information to the user. At runtime, Amazon Lex selects the message to convey.

Contents
messages

A collection of message objects.

Type: Array of Message (p. 343) objects

Array Members: Minimum number of 1 item. Maximum number of 5 items.

Required: Yes

responseCard

At runtime, if the client is using the PostText API, Amazon Lex includes the response card in the response. It substitutes all of the session attributes and slot values for placeholders in the response card.

Type: String

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
UtteranceData
Service: Amazon Lex Model Building Service

Provides information about a single utterance that was made to your bot.

Contents

count
   The number of times that the utterance was processed.
   Type: Integer
   Required: No

distinctUsers
   The total number of individuals that used the utterance.
   Type: Integer
   Required: No

firstUtteredDate
   The date that the utterance was first recorded.
   Type: Timestamp
   Required: No

lastUtteredDate
   The date that the utterance was last recorded.
   Type: Timestamp
   Required: No

utteranceString
   The text that was entered by the user or the text representation of an audio clip.
   Type: String
   Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
UtteranceList
Service: Amazon Lex Model Building Service

Provides a list of utterances that have been made to a specific version of your bot. The list contains a maximum of 100 utterances.

Contents

botVersion

The version of the bot that processed the list.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: $LATEST|\d+
Required: No

utterances

One or more UtteranceData (p. 351) objects that contain information about the utterances that have been made to a bot. The maximum number of object is 100.

Type: Array of UtteranceData (p. 351) objects
Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2

Amazon Lex Runtime Service

The following data types are supported by Amazon Lex Runtime Service:

- Button (p. 353)
- GenericAttachment (p. 354)
- ResponseCard (p. 356)
**Button**  
Service: Amazon Lex Runtime Service

Represents an option to be shown on the client platform (Facebook, Slack, etc.)

**Contents**

**text**

Text that is visible to the user on the button.

Type: String

Required: Yes

**value**

The value sent to Amazon Lex when a user chooses the button. For example, consider button text "NYC." When the user chooses the button, the value sent can be "New York City."

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1000.

Required: Yes

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
GenericAttachment
Service: Amazon Lex Runtime Service

Represents an option rendered to the user when a prompt is shown. It could be an image, a button, a link, or text.

Contents

attachmentLinkUrl

The URL of an attachment to the response card.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 2048.
Required: No

buttons

The list of options to show to the user.
Type: Array of Button (p. 353) objects
Array Members: Minimum number of 0 items. Maximum number of 5 items.
Required: No

imageUrl

The URL of an image that is displayed to the user.
Type: String
Length Constraints: Minimum length of 1. Maximum length of 2048.
Required: No

subTitle

The subtitle shown below the title.
Type: String
Required: No

title

The title of the option.
Type: String
Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
ResponseCard
Service: Amazon Lex Runtime Service

If you configure a response card when creating your bots, Amazon Lex substitutes the session attributes and slot values that are available, and then returns it. The response card can also come from a Lambda function (dialogCodeHook and fulfillmentActivity on an intent).

Contents

cContentType
The content type of the response.

Type: String

Valid Values: application/vnd.amazonaws.card.generic

Required: No

genericAttachments
An array of attachment objects representing options.

Type: Array of GenericAttachment (p. 354) objects

Array Members: Minimum number of 0 items. Maximum number of 10 items.

Required: No

version
The version of the response card format.

Type: String

Required: No

See Also
For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for Ruby V2
Document History for Amazon Lex

The following table describes the documentation for this release of Amazon Lex.

- **Latest documentation update:** November 21, 2017

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region expansion</td>
<td>Amazon Lex is now available in EU (Ireland) (eu-west-1).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for deploying Amazon Lex bots on Kik. For more information see Integrating an Amazon Lex Bot with Kik (p. 110).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for new built-in slot types and request attributes. For more information, see the section called &quot;Built-in Slot Types&quot; (p. 22) and the section called &quot;Setting Request Attributes&quot; (p. 18).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Added export to Alexa Skills Kit feature. For more information, see Exporting Amazon Lex Bots (p. 120)</td>
<td>September 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Added synonym support for slot type values. For more information, see Custom Slot Types (p. 26)</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Added AWS CloudTrail integration. For more information, see Monitoring Amazon Lex API Calls with AWS CloudTrail Logs (p. 171).</td>
<td>August 15, 2017</td>
</tr>
<tr>
<td>Expanded documentation</td>
<td>Added Getting Started examples for the AWS CLI. For more information, see Step 4: Getting Started (AWS CLI) (p. 69).</td>
<td>May 22, 2017</td>
</tr>
<tr>
<td>New guide</td>
<td>This is the first release of the Amazon Lex User Guide.</td>
<td>April 19, 2017</td>
</tr>
</tbody>
</table>
AWS Glossary

For the latest AWS terminology, see the AWS Glossary in the AWS General Reference.
