The following demonstrates how to use the `batch_get_record` to get a batch of records.

```
all_records = sagemaker_session.boto_session.client(
    "sagemaker-featurestore-runtime", region_name=region
).batch_get_record(
    Identifiers=[
        {
            "FeatureGroupName": customers_feature_group_name,
            "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
        },
        {
            "FeatureGroupName": orders_feature_group_name,
            "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
        },
    ]
)
```

```
print(all_records)
```

Step 5: Clean up

Here we remove the Feature Groups that we created.

```
customers_feature_group.delete()
orders_feature_group.delete()
```

Step 6: Next steps

In this example notebook, you learned how to get started with Feature Store, create feature groups, and ingest data into them.

For an advanced example on how to use Feature Store for a fraud detection use case, see Fraud Detection with Feature Store.

Step 7: Code examples for programmers

In this notebook we used a variety of different API calls. Most of them are accessible through the SageMaker Python SDK, however some only exist within Boto3. You can invoke the SageMaker Python SDK API calls directly on your Feature Store objects, whereas to invoke API calls that exist within Boto3, you must first access a Boto3 client through your Boto3 and SageMaker sessions: for example, `sagemaker_session.boto_session.client()`.

The following is a list of API calls for this notebook. These calls exist within the SDK for Python and exist in Boto3, for your reference:

SDK for Python (Boto3) API Calls

```
describe()
ingest()
delete()
create()
load_feature_definitions()
```

Boto3 API Calls

```
list_feature_groups()
get_record()
```

Fraud detection with Feature Store example notebook

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide Permissions for Tagging SageMaker Resources.
> AWS Managed Policies for Amazon SageMaker that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

The example code on this page refers to the example notebook: Fraud Detection with Amazon SageMaker Feature Store. We recommend that you run this notebook in Studio Classic, notebook instances, or JupyterLab because the code in this guide is conceptual and not fully functional if copied.

Use the following to clone the aws/amazon-sagemaker-examples GitHub repository, containing the example notebook.

- **For Studio Classic**

  First launch Studio Classic. You can open Studio Classic if Studio or Studio Classic is enabled as your default experience. To open Studio Classic, see Launch Studio Classic Using the Amazon SageMaker Console.

  Clone the aws/amazon-sagemaker-examples GitHub repository to Studio Classic by following the steps in Clone a Git Repository in SageMaker Studio Classic.

- **For Amazon SageMaker notebook instances**

  First launch SageMaker notebook instance by following the instructions in Access Notebook Instances.

  Check if the examples are already in your notebooks by following the instructions in Example Notebooks. If not, follow the instructions in Add a Git Repository to Your Amazon SageMaker Account.

Now that you have the SageMaker example notebooks, navigate to the `amazon-sagemaker-examples/sagemaker-featurestore` directory and open the Fraud Detection with Amazon SageMaker Feature Store example notebook.

Step 1: Set up your Feature Store session

To start using Feature Store, create a SageMaker session, Boto3 session, and a Feature Store session. Also, set up the Amazon S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

> **Note**
>
> The role that you use to run the notebook must have the following managed policies attached to it: `AmazonSageMakerFullAccess` and

AmazonSageMakerFeatureStoreAccess. For information about adding policies to your IAM role, see Adding policies to your IAM role.

```
import boto3
import sagemaker
from sagemaker.session import Session

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
boto_session = boto3.Session(region_name=region)
role = sagemaker.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
prefix = 'sagemaker-featurestore'
offline_feature_store_bucket = 's3://{}/{}'.format(default_bucket, prefix)

sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
featurestore_runtime = boto_session.client(service_name='sagemaker-featurestore-
runtime', region_name=region)

feature_store_session = Session(
    boto_session=boto_session,
    sagemaker_client=sagemaker_client,
    sagemaker_featurestore_runtime_client=featurestore_runtime
)
```

Step 2: Load datasets and partition data into feature groups

Load your data into data frames for each of your features. You use these data frames after you set up the feature group. In the fraud detection example, you can see these steps in the following code.

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import io

s3_client = boto3.client(service_name='s3', region_name=region)

fraud_detection_bucket_name = 'sagemaker-featurestore-fraud-detection'
identity_file_key = 'sampled_identity.csv'
transaction_file_key = 'sampled_transactions.csv'
```

```
identity_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
 Key=identity_file_key)
transaction_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
 Key=transaction_file_key)

identity_data = pd.read_csv(io.BytesIO(identity_data_object['Body'].read()))
transaction_data = pd.read_csv(io.BytesIO(transaction_data_object['Body'].read()))

identity_data = identity_data.round(5)
transaction_data = transaction_data.round(5)

identity_data = identity_data.fillna(0)
transaction_data = transaction_data.fillna(0)

# Feature transformations for this dataset are applied before ingestion into
 FeatureStore.
# One hot encode card4, card6
encoded_card_bank = pd.get_dummies(transaction_data['card4'], prefix = 'card_bank')
encoded_card_type = pd.get_dummies(transaction_data['card6'], prefix = 'card_type')

transformed_transaction_data = pd.concat([transaction_data, encoded_card_type,
 encoded_card_bank], axis=1)
transformed_transaction_data =
 transformed_transaction_data.rename(columns={"card_bank_american express":
 "card_bank_american_express"})
```

Step 3: Set up feature groups

When you set up your feature groups, you need to customize the feature names with a unique name and set up each feature group with the `FeatureGroup` class.

```
from sagemaker.feature_store.feature_group import FeatureGroup
feature_group_name = "some string for a name"
feature_group = FeatureGroup(name=feature_group_name,
 sagemaker_session=feature_store_session)
```

For example, in the fraud detection example, the two feature groups are `identity` and `transaction`. In the following code you can see how the names are customized with a timestamp, and then each group is set up by passing in the name and the session.

```
import time
```

```
from time import gmtime, strftime, sleep
from sagemaker.feature_store.feature_group import FeatureGroup

identity_feature_group_name = 'identity-feature-group-' + strftime('%d-%H-%M-%S',
 gmtime())
transaction_feature_group_name = 'transaction-feature-group-' + strftime('%d-%H-%M-%S',
 gmtime())

identity_feature_group = FeatureGroup(name=identity_feature_group_name,
 sagemaker_session=feature_store_session)
transaction_feature_group = FeatureGroup(name=transaction_feature_group_name,
 sagemaker_session=feature_store_session)
```

Step 4: Set up record identifier and event time features

In this step, you specify a record identifier name and an event time feature name. This name maps to the column of the corresponding features in your data. For example, in the fraud detection example, the column of interest is `TransactionID`. `EventTime` can be appended to your data when no timestamp is available. In the following code, you can see how these variables are set, and then `EventTime` is appended to both feature's data.

```
record_identifier_name = "TransactionID"
event_time_feature_name = "EventTime"
current_time_sec = int(round(time.time()))
identity_data[event_time_feature_name] =
 pd.Series([current_time_sec]*len(identity_data), dtype="float64")
transformed_transaction_data[event_time_feature_name] =
 pd.Series([current_time_sec]*len(transaction_data), dtype="float64")
```

Step 5: Load feature definitions

You can now load the feature definitions by passing a data frame containing the feature data. In the following code for the fraud detection example, the identity feature and transaction feature are each loaded by using `load_feature_definitions`, and this function automatically detects the data type of each column of data. For developers using a schema rather than automatic detection, see the Export Feature Groups from Data Wrangler example for code that shows how to load the schema, map it, and add it as a `FeatureDefinition` that you can use to create the `FeatureGroup`. This example also covers a AWS SDK for Python (Boto3) implementation, which you can use instead of the SageMaker Python SDK.

```
identity_feature_group.load_feature_definitions(data_frame=identity_data); # output is
 suppressed
transaction_feature_group.load_feature_definitions(data_frame=transformed_transaction_data);
 # output is suppressed
```

Step 6: Create a feature group

In this step, you use the `create` function to create the feature group. The following code shows all of the available parameters. The online store is not created by default, so you must set this as `True` if you want to enable it. The `s3_uri` is the S3 bucket location of your offline store.

```
# create a FeatureGroup
feature_group.create(
    description = "Some info about the feature group",
    feature_group_name = feature_group_name,
    record_identifier_name = record_identifier_name,
    event_time_feature_name = event_time_feature_name,
    feature_definitions = feature_definitions,
    role_arn = role,
    s3_uri = offline_feature_store_bucket,
    enable_online_store = True,
    online_store_kms_key_id = None,
    offline_store_kms_key_id = None,
    disable_glue_table_creation = False,
    data_catalog_config = None,
    tags = ["tag1","tag2"])
```

The following code from the fraud detection example shows a minimal `create` call for each of the two features groups being created.

```
identity_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)

transaction_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
```

```
    role_arn=role,
    enable_online_store=True
)
```

When you create a feature group, it takes time to load the data, and you need to wait until the feature group is created before you can use it. You can check status using the following method.

```
status = feature_group.describe().get("FeatureGroupStatus")
```

While the feature group is being created, you receive `Creating` as a response. When this step has finished successfully, the response is `Created`. Other possible statuses are `CreateFailed`, `Deleting`, or `DeleteFailed`.

Step 7: Work with feature groups

Now that you've set up your feature group, you can perform any of the following tasks:

Topics

- Describe a feature group
- List feature groups
- Put records in a feature group
- Get records from a feature group
- Generate hive DDL commands
- Build a training dataset
- Write and execute an Athena query
- Delete a feature group

Describe a feature group

You can retrieve information about your feature group with the `describe` function.

```
feature_group.describe()
```

List feature groups

You can list all of your feature groups with the `list_feature_groups` function.

```
sagemaker_client.list_feature_groups()
```

Put records in a feature group

You can use the `ingest` function to load your feature data. You pass in a data frame of feature data, set the number of workers, and choose to wait for it to return or not. The following example demonstrates using the `ingest` function.

```
feature_group.ingest(
    data_frame=feature_data, max_workers=3, wait=True
)
```

For each feature group you have, run the `ingest` function on the feature data you want to load.

Get records from a feature group

You can use the `get_record` function to retrieve the data for a specific feature by its record identifier. The following example uses an example identifier to retrieve the record.

```
record_identifier_value = str(2990130)
featurestore_runtime.get_record(FeatureGroupName=transaction_feature_group_name,
 RecordIdentifierValueAsString=record_identifier_value)
```

An example response from the fraud detection example:

```
...
'Record': [{'FeatureName': 'TransactionID', 'ValueAsString': '2990130'},
  {'FeatureName': 'isFraud', 'ValueAsString': '0'},
  {'FeatureName': 'TransactionDT', 'ValueAsString': '152647'},
  {'FeatureName': 'TransactionAmt', 'ValueAsString': '75.0'},
  {'FeatureName': 'ProductCD', 'ValueAsString': 'H'},
  {'FeatureName': 'card1', 'ValueAsString': '4577'},
...
```

Generate hive DDL commands

The SageMaker Python SDK's `FeatureStore` class also provides the functionality to generate Hive DDL commands. The schema of the table is generated based on the feature definitions. Columns are named after feature name and data-type are inferred based on feature type.

```
print(feature_group.as_hive_ddl())
```

Example output:

```
CREATE EXTERNAL TABLE IF NOT EXISTS sagemaker_featurestore.identity-feature-
group-27-19-33-00 (
  TransactionID INT
  id_01 FLOAT
  id_02 FLOAT
  id_03 FLOAT
  id_04 FLOAT
 ...
```

Build a training dataset

Feature Store automatically builds an AWS Glue data catalog when you create feature groups and you can turn this off if you want. The following describes how to create a single training dataset with feature values from both identity and transaction feature groups created earlier in this topic. Also, the following describes how to run an Amazon Athena query to join data stored in the offline store from both identity and transaction feature groups.

To start, create an Athena query using `athena_query()` for both identity and transaction feature groups. The `table_name` is the AWS Glue table that is autogenerated by Feature Store.

```
identity_query = identity_feature_group.athena_query()
transaction_query = transaction_feature_group.athena_query()

identity_table = identity_query.table_name
transaction_table = transaction_query.table_name
```

Write and execute an Athena query

You write your query using SQL on these feature groups, and then execute the query with the `.run()` command and specify your Amazon S3 bucket location for the data set to be saved there.

```
# Athena query
query_string = 'SELECT * FROM "'+transaction_table+'" LEFT JOIN "'+identity_table+'" ON
 "'+transaction_table+'".transactionid = "'+identity_table+'".transactionid'

# run Athena query. The output is loaded to a Pandas dataframe.
```

```
dataset = pd.DataFrame()
identity_query.run(query_string=query_string,
 output_location='s3://'+default_s3_bucket_name+'/query_results/')
identity_query.wait()
dataset = identity_query.as_dataframe()
```

From here you can train a model using this data set and then perform inference.

Delete a feature group

You can delete a feature group with the `delete` function.

```
feature_group.delete()
```

The following code example is from the fraud detection example.

```
identity_feature_group.delete()
transaction_feature_group.delete()
```

For more information, see the Delete a feature group API.

Using Amazon SageMaker Feature Store in the console

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide Permissions for Tagging SageMaker Resources.
> AWS Managed Policies for Amazon SageMaker that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

You can use Amazon SageMaker Feature Store on the console to create, view, update, and monitor your feature groups. Monitoring in this guide includes viewing pipeline executions and lineage

of your feature groups. This guide provides instructions on how to achieve these tasks from the console.

For Feature Store examples and resources using the Amazon SageMaker APIs and AWS SDK for Python (Boto3), see Amazon SageMaker Feature Store resources.

Topics

Create a feature group from the console

The create feature group process has four steps:

1. Enter feature group information.
2. Enter feature definitions.
3. Enter required features.
4. Enter feature group tags.

Consider which of the following options fits your use case:

- Create an online store, an offline store, or both. For more information about the differences between online and offline stores, see Feature Store concepts.
- Use a default AWS Key Management Service key or your own KMS key. The default key is AWS KMS key (SSE-KMS). You can reduce AWS KMS request costs by configuring use of Amazon S3 Bucket Keys on the offline store Amazon S3 bucket. The Amazon S3 Bucket Key must be enabled before using the bucket for your feature groups. For more information about reducing the cost by using Amazon S3 Bucket Keys, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

  You can use the same key for both online and offline stores, or have a unique key for each. For more information about AWS KMS, see AWS Key Management Service.

- If you create an offline store:
  - Decide if you want to create an Amazon S3 bucket or use an existing one. When using an existing one, you must know the Amazon S3 bucket URL or Amazon S3 bucket name and dataset directory name, if applicable.
  - Choose which Amazon Resource Name (ARN) to use to specify the IAM role. For more information about how to find your role and attached policies, see Adding policies to your IAM role.
  - Decide whether to use the AWS Glue (default) or Apache Iceberg table format. In most use cases, you use the Apache Iceberg table format. For more information about table formats, see Use Feature Store with SDK for Python (Boto3).

You can use the console to view the lineage of a feature group. The instructions for using Feature Store on the console vary depending on whether you enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Create feature groups if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** from the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. Choose **Create feature group**.
5. Under **Feature group details**, enter a feature group name.
6. (Optional) Enter a description of the feature group.
7. Under **Feature group storage configuration**, choose a storage configuration from the dropdown list. For information about storage configurations, see Feature Store storage configurations.
8. If you have chosen to enable the online storage:
   a. If you *only* enable the online storage, you can choose a **Storage type** from the dropdown list. For information about online store storage types, see Online store.
   b. (Optional) Apply **Time to Live (TTL)** by toggling the switch to **On** and specifying the **Time to Live duration** value and unit. This will update the default TTL duration for all records added to the feature group *after the feature group is created*. For more information about TTL, see Time to live (TTL) duration for records.
9. If you have chosen to enable the offline storage:

a. Under the **Amazon S3 bucket name**, enter a new bucket name, or enter an existing bucket URL, manually.

b. From the **Table format** dropdown list, choose the table format. In most use cases, you should use the Apache Iceberg table format. For more information about table formats, see Use Feature Store with SDK for Python (Boto3).

c. Under **IAM role ARN**, choose the IAM role ARN you want to attach to this feature group. For more information about how to find your role and attached policies, see Adding policies to your IAM role.

d. If you have chosen to enable the offline storage **Table format** and AWS Glue (default) **Table format**, under **Data catalog**, you can choose one of the following two options:

- **Use default values for your AWS Glue Data Catalog**.
- Provide your existing Data Catalog name, table name, and database name to extend your existing AWS Glue Data Catalog.

10. Under the **Online store encryption key** or **Offline store encryption key** dropdown list, choose one of the following options:

- **Use AWS managed AWS KMS key (default)**
- **Enter an AWS KMS key ARN** and enter your AWS KMS key ARN under **Offline store encryption key ARN**. For more information about AWS KMS, see AWS Key Management Service.

11. If applicable, you will have the option to choose your throughput mode, which impacts how you are charged. Under **Throughput mode**, choose a mode from the dropdown list and input the read and write capacities when available. For information about throughput modes, like when the mode can be applied and capacity units, see Throughput modes.

12. After you specify all of the required information, the **Continue** button appears available. Choose **Continue**.

13. Under **Specify feature definitions**, you have two options for providing a schema for your features: a JSON editor, or a table editor.

- JSON editor: In the **JSON** tab, enter or copy and paste your feature definitions in the JSON format.
- Table editor: In the **Table** tab, enter the feature feature name and choose the corresponding data type for each feature in your feature group. Choose **+ Add feature definitions** to include more features. Be aware that you cannot remove feature definitions from your

feature groups. However, you can add and update feature definitions after the feature group is created.

There must be at least two features in a feature group that represent the record identifier and event time:

- The record **Feature type** can be a string, fractional, or an integral.
- The event time **Feature type** must be a string or a fractional. However, if you chose the Iceberg table format, the event time must be a string.

14. After all of the features are included, choose **Continue**.
15. Under **Select required features**, you must specify the record identifier and event time features. Do this by choosing the feature name under **Record identifier feature name** and **Event time feature name** dropdown lists, respectively.
16. After you choose the record identifier and event time features, choose **Continue**.
17. (Optional) To add tags for the feature group, choose **Add new tag**. Then enter a tag key and the corresponding value under **Key** and **Value**, respectively.
18. Choose **Continue**.
19. Under **Review feature group**, review the feature group information. To edit any step, choose the **Edit** button that corresponds to that step. This brings you to the corresponding step for editing. To return to step 5, choose **Continue** until you return to step 5.
20. After you finalize the setup for your feature group, choose **Create feature group**.

    If an issue occurs during setup, a pop-up alert message appears at the bottom of the page with tips for solving the issue. You can return to previous steps to fix the issues by choosing **Edit** for the step with conflicts.

    After the feature group has been successfully created, a green pop-up message appears at the bottom of the page. The new feature group also appears in your feature groups catalog.

Create feature groups if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.

2. Choose the **Home** icon
   ()
   on the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. Choose **Create feature group**.
6. Under **Feature group details**, enter a feature group name.
7. (Optional) Enter a description of the feature group.
8. Under **Feature group storage configuration**, choose a storage configuration from the dropdown list. For information about storage configurations, see Feature Store storage configurations.
9. If you have chosen to enable the online storage:
   a. If you *only* enable the online storage, you may choose a **Storage type** from the dropdown list. For information about online store storage types, see Online store.
   b. (Optional) Apply **Time to Live (TTL)** by toggling the switch to **On** and specifying the **Time to Live duration** value and unit. This will update the default TTL duration for all records added to the feature group *after the feature group is created*. For more information about TTL, see Time to live (TTL) duration for records.
10. If you have chosen to enable the offline storage:
    a. Under the **Amazon S3 bucket name**, enter a new bucket name or enter an existing bucket URL manually.
    b. From the **Table format** dropdown list, choose the table format. In most use cases, you should use the Apache Iceberg table format. For more information about table formats, see Use Feature Store with SDK for Python (Boto3).
    c. Under **IAM role ARN**, choose the IAM role ARN you want to attach to this feature group. For more information about how to find your role and attached policies, see Adding policies to your IAM role.
    d. If you have chosen to enable the offline storage **Table format** and AWS Glue (default) **Table format**, under **Data catalog**, you can choose one of the following two options:
       - **Use default values for your AWS Glue Data Catalog**.
       - Provide your existing Data Catalog name, table name, and database name to extend your existing AWS Glue Data Catalog.

11. Under the **Online store encryption key** or **Offline store encryption key** dropdown list, choose one of the following options:

    - **Use AWS managed AWS KMS key (default)**
    - **Enter an AWS KMS key ARN** and enter your AWS KMS key ARN under **Offline store encryption key ARN**. For more information about AWS KMS, see AWS Key Management Service.

12. After you specify all of the required information, the **Continue** button appears available. Choose **Continue**.

13. Under **Specify feature definitions**, you have two options for providing a schema for your features: a JSON editor, or a table editor.

    - JSON editor: In the **JSON** tab, enter or copy and paste your feature definitions in the JSON format.
    - Table editor: In the **Table** tab, enter the feature feature name and choose the corresponding data type for each feature in your feature group. Choose **+ Add feature definitions** to include more features. Be aware that you cannot remove feature definitions from your feature groups. However, you can add and update feature definitions after the feature group is created.

    There must be at least two features in a feature group that represent the record identifier and event time:

    - The record **Feature type** can be a string, fractional, or an integral.
    - The event time **Feature type** must be a string or a fractional. However, if you chose the Iceberg table format, the event time must be a string.

14. After all of the features are included, choose **Continue**.

15. Under **Select required features**, you must specify the record identifier and event time features. Do this by choosing the feature name under **Record identifier feature name** and **Event time feature name** dropdown lists, respectively.

16. After you choose the record identifier and event time features, choose **Continue**.

17. (Optional) To add tags for the feature group, choose **Add new tag**. Then enter a tag key and the corresponding value under **Key** and **Value**, respectively.

18. Choose **Continue**.

19. Under **Review feature group**, review the feature group information. To edit any step, choose the **Edit** button that corresponds to that step. This brings you to the corresponding step for editing. To return to step 5, choose **Continue** until you return to step 5.
20. After you finalize the setup for your feature group, choose **Create feature group**.

    If an issue occurs during setup, a pop-up alert message appears at the bottom of the page with tips for solving the issue. You can return to previous steps to fix the issues by choosing **Edit** for the step with conflicts.

    After the feature group has been successfully created, a green pop-up message appears at the bottom of the page. The new feature group also appears in your feature groups catalog.

View feature group details from the console

You can view details of your feature groups after a feature group has successfully been created in the Feature Store.

You can use the console or the Amazon SageMaker Feature Store API to view your feature group details. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

View feature group details if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Under the **Feature group catalog** tab, choose your feature group name from the list. This opens the feature group page.
6. On the **Features** tab, you can find a list of all of the features. Use the filter to refine your list. Choose a feature to view its details.
7. Under the **Details** tab and the **Information** subtab, you can review your feature group information. This includes **Latest execution**, **Offline storage settings**, **Online storage settings**, and more.

8. Under the **Details** tab and the **Tags** subtab, you can review your feature group tags. Choose **Add new tag** to add a new tag or **Remove** to remove a tag.
9. Under the **Pipeline Executions** tab, you can view the associated pipelines or pipeline executions for your feature group.
10. Under the **Lineage** tab, you can view the lineage of your feature group.

View feature group details if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Under the **Feature group catalog** tab, choose your feature group name from the list. This opens the feature group page.
7. On the **Features** tab, you can find a list of all of the features. Use the filter to refine your list. Choose a feature to view its details.
8. Under the **Details** tab and the **Information** subtab, you can review your feature group information, including **Latest execution**, **Offline storage settings**, **Online storage settings**, and more.
9. Under the **Details** tab and the **Tags** subtab, you can review your feature group tags. Choose **Add new tag** to add a new tag or **Remove** to remove a tag.
10. Under the **Pipeline Executions** tab, you can view the associated pipelines or pipeline executions for your feature group.
11. Under the **Lineage** tab, you can view the lineage of your feature group.

Update a feature group from the console

You can update your feature groups after a feature group has successfully been created in the Feature Store.

You can use the console or the Amazon SageMaker Feature Store API to update a feature group. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Update a feature group if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Under the **Feature group catalog** tab, search for and choose your feature group name from the list. This opens the feature group page.
6. Choose **Update feature group**.
7. (Optional) If applicable, you can change your throughput mode, which impacts how you are charged. Under **Throughput mode**, choose a mode from the dropdown list and input the read and write capacities when available. For information about throughput modes, like when the mode can be applied and capacity units, see Throughput modes.
8. (Optional) If your feature group uses the online store, you can update the default **Time to Live (TTL)**. If TTL hasn't been enabled for the feature group, toggle the switch button under **Time to Live (TTL)** to **On**. You can specify the TTL value and unit under **Time to Live duration**. This will update the default TTL duration for all records added to the feature group *after the feature group is updated*.
9. (Optional) You can add feature definitions to your feature group but be aware that you cannot remove feature definitions from your feature groups. To add a feature definition, choose **+ Add feature definition** and then specify the new feature definition name under the **Name** column and select the feature type under the **Feature type** column.
10. Choose **Save changes**.
11. To confirm your changes, choose **Confirm**.

Update a feature group if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.

2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Under the **Feature group catalog** tab, search for and choose your feature group name from the list. This opens the feature group page.
7. Choose **Update feature group**.
8. (Optional) If your feature group uses the online store, you can update the default **Time to Live (TTL)**. If TTL hasn't been enabled for the feature group, toggle the switch button under **Time to Live (TTL)** to **On**. You can specify the TTL value and unit under **Time to Live duration**. This will update the default TTL duration for all records added to the feature group *after the feature group is updated*.
9. (Optional) You can add feature definitions to your feature group but be aware that you cannot remove feature definitions from your feature groups. To add a feature definition, choose **+ Add feature definition** and then specify the new feature definition name under the **Name** column and select the feature type under the **Feature type** column.
10. Choose **Save changes**.
11. To confirm your changes, choose **Confirm**.

View pipeline executions from the console

You can view the latest pipeline execution information for a feature or feature group under **Pipeline executions**. You can also get links to pipelines, executions, code, and other useful execution information.

You can use the console to view your pipeline executions. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

View pipeline executions if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.

2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Choose a feature group or feature to view their pipeline executions.
6. Choose the **Pipeline executions** tab.
7. Search for a pipeline from the **Select a pipeline** dropdown list.
8. You can view the links for the pipeline, execution, and code details. You can also view the execution owner, status, date, and duration.

View pipeline executions if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Choose a feature group or feature to view their pipeline executions.
7. Choose the **Pipeline executions** tab.
8. Search for a pipeline from the **Select a pipeline** dropdown list.
9. You can view the links for the pipeline, execution, and code details. You can also view the execution owner, status, date, and duration.

View lineage from the console

You can view the lineage of a feature group. The lineage includes the information about the execution code of your feature processing workflow, what data sources were used, and how they are ingested to the feature group or feature.

You can use the console to view the lineage of a feature group. The instructions on using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

View lineage if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** from the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Choose a feature group or feature to view its lineage details.
6. Choose the **Lineage** tab.
7. Choose a feature group or pipeline node to expand the node. This contains more information about a feature group or pipeline.
8. You can zoom in, zoom out, or recenter the lineage graph by using the buttons on the bottom left of the screen.
9. You can move through the lineage map when you choose and drag the screen. To move your lineage maps using nodes as the focal point, you can press **Tab** or **Shift+Tab** to switch between nodes.
10. If applicable, you can navigate the lineage upstream (left, earlier) or downstream (right, most recent). Do this by choosing a node and then choosing **Query upstream lineage** or **Query downstream lineage**.

View lineage if Studio Classic is your default experience (console)

1. Open Studio Classic by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.

6. Choose a feature group or feature to view its lineage details.
7. Choose the **Lineage** tab.
8. Choose a feature group or pipeline node to expand the node. This contains more information about a feature group or pipeline.
9. You can zoom in, zoom out, or recenter the lineage graph by using the buttons on the bottom left of the screen.
10. You can move through the lineage map when you choose and drag the screen. To move your lineage maps using nodes as the focal point, you can press **Tab** or **Shift+Tab** to switch between nodes.
11. If applicable, you can navigate the lineage upstream (left, earlier) or downstream (right, most recent). Do this by choosing a node and then choosing **Query upstream lineage** or **Query downstream lineage**.

Delete a feature group

You can use the console or the Amazon SageMaker Feature Store API to delete your feature group. The instructions on using Feature Store through the console depends on if you have enabled Studio or Studio Classic as your default experience. For more information about the differences between the two, or how to change your default, see Amazon SageMaker Studio.

The following sections provide an overview on how to delete a feature group.

Topics

- Delete a feature group using the console
- Delete feature group example Python code

Delete a feature group using the console

This section shows two ways to delete a feature group in the console, depending on your default experience: Studio or Studio Classic.

Delete feature group if Studio is your default experience (console)

1. Open the Studio console by following instructions in Launch Amazon SageMaker Studio Classic.
2. Choose **Data** in the left navigation pane to expand the dropdown list.

3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. In the **Feature Group Catalog** tab, choose the feature group to delete under **Feature group name**.
6. Choose **Delete feature group**.
7. In the pop-up window, confirm deletion by entering **`delete`** in the field, then choose **Delete**.

Delete feature group if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. In the **Feature Group Catalog** tab, choose the feature group to delete under **Feature group name**.
7. Choose **Delete feature group**.
8. In the pop-up window, confirm deletion by typing **`delete`** in the field, then choose **Delete**.

Delete feature group example Python code

The following code uses the `DeleteFeatureGroup` API operation to delete your feature group using the AWS SDK for Python (Boto3). It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see Introduction to Feature Store example notebook.

```
import sagemaker
from sagemaker.feature_store.feature_group import FeatureGroup

sagemaker_session = sagemaker.Session()
```

```
fg_name = 'your-feature-group-name'

my_fg = FeatureGroup(name=fg_name, sagemaker_session=sagemaker_session)
my_fg.delete()
```

Data sources and ingestion

Records are added to your feature groups through ingestion. Depending on your desired use case, the ingested records may be kept within the feature group or not. This depends on the storage configuration, if your feature group uses the offline or online store. The offline store is used as a historical database, that is typically used for data exploration, machine learning (ML) model training, and batch inference. The online store is used as a real-time lookup of records, that is typically used for ML model serving. For more information on Feature Store concepts and ingestion, see Feature Store concepts.

There are multiple ways to bring your data into Amazon SageMaker Feature Store. Feature Store offers a single API call for data ingestion called `PutRecord` that enables you to ingest data in batches or from streaming sources. You can use Amazon SageMaker Data Wrangler to engineer features and then ingest your features into your Feature Store. You can also use Amazon EMR for batch data ingestion through a Spark connector.

In the following topics we will discuss the difference between

Topics

- Stream ingestion
- Data Wrangler with Feature Store
- Batch ingestion with Amazon SageMaker Feature Store Spark

Stream ingestion

You can use streaming sources such as Kafka or Kinesis as a data source, where records are extracted from, and directly feed records to the online store for training, inference or feature creation. Records can be ingested into your feature group by using the synchronous `PutRecord` API call. Since this is a synchronous API call it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon an update is detected. These are also called *streaming* features.

Data Wrangler with Feature Store

Data Wrangler is a feature of Studio Classic that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. Data Wrangler enables you to engineer your features and ingest them into your online or offline store feature groups.

The following instructions exports a Jupyter notebook that contains all of the source code needed to create a Feature Store feature group that adds your features from Data Wrangler to an online or offline store.

The instructions on exporting your Data Wrangler data flow to Feature Store on the console vary depending on whether you enabled enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Export your Data Wrangler data flow to Feature Store if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** from the left panel, to expand the dropdown list.
3. From the dropdown list, choose **Data Wrangler**.
4. If you have an instance of Amazon SageMaker Canvas already running, choose **Open Canvas**.

   If you don't have an instance of SageMaker Canvas running, choose **Run in Canvas**.
5. On the SageMaker Canvas console, choose **Data Wrangler** in the left navigation pane.
6. Choose **Data flows** to view your data flows.
7. Choose **+** to expand the dropdown list.
8. Choose **Export data flow** to expand the dropdown list.
9. Choose **Save to SageMaker Feature Store (via JupyterLab Notebook)**.
10. **Under Export data flow as notebook**, choose one of the following options:

    - **Download a local copy** to download the dataflow to your local machine.
    - **Export to S3 location** to download the dataflow to an Amazon Simple Storage Service location and enter the Amazon S3 location or choose **Browse** to find your Amazon S3 location.
11. Choose **Export**.

Export your Data Wrangler data flow to Feature Store if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Data Wrangler**.
5. Choose your workflow.
6. Choose the **Export** tab.
7. Choose **Export Step**.
8. Choose **Feature Store**.

After the feature group has been created, you can also select and join data across multiple feature groups to create new engineered features in Data Wrangler and then export your data set to an Amazon S3 bucket.

For more information on how to export to Feature Store, see Export to SageMaker Feature Store.

Batch ingestion with Amazon SageMaker Feature Store Spark

Amazon SageMaker Feature Store Spark is a Spark connector that connects the Spark library to Feature Store. Feature Store Spark simplifies data ingestion from Spark `DataFrames` to feature groups. Feature Store supports batch data ingestion with Spark, using your existing ETL pipeline, on Amazon EMR, GIS, an AWS Glue job, an Amazon SageMaker Processing job, or a SageMaker notebook.

Methods for installing and implementing batch data ingestion are provided for Python and Scala developers. Python developers can use the open-source `sagemaker-feature-store-pyspark` Python library for local development, installation on Amazon EMR, and for Jupyter Notebooks by following the instructions in the Amazon SageMaker Feature Store Spark GitHub repository. Scala developers can use the Feature Store Spark connector available in the Amazon SageMaker Feature Store Spark SDK Maven central repository.

You can use the Spark connector to ingest data in the following ways, depending on if the online store, offline store, or both are enabled.

1. Ingest by default – If the online store is enabled, Spark connector first ingests your dataframe into the online store using the PutRecord API. Only the record with the largest event time remains in the online store. If the offline store is enabled, within 15 minutes Feature Store ingests your dataframe into the offline store. For more information about how the online and offline stores work, see Feature Store concepts.

   You can accomplish this by not specifying `target_stores` in the `.ingest_data(...)` method.

2. Offline store direct ingestion – If offline store is enabled, Spark connector batch ingests your dataframe directly into the offline store. Ingesting the dataframe directly into the offline store doesn't update the online store.

   You can accomplish this by setting `target_stores=["OfflineStore"]` in the `.ingest_data(...)` method.

3. Online store only – If online store is enabled, Spark connector ingests your dataframe into the online store using the PutRecord API. Ingesting the dataframe directly into the online store doesn't update the offline store.

   You can accomplish this by setting `target_stores=["OnlineStore"]` in the `.ingest_data(...)` method.

For information about using the different ingestion methods, see Example implementations.

Topics

- Feature Store Spark installation
- Retrieving the JAR for Feature Store Spark
- Example implementations

Feature Store Spark installation

Scala users

The Feature Store Spark SDK is available in the Amazon SageMaker Feature Store Spark SDK Maven central repository for Scala users.

Requirements

- Spark >= 3.0.0 and <= 3.3.0
- `iceberg-spark-runtime` >= 0.14.0
- Scala >= 2.12.x
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)

Declare the dependency in POM.xml

The Feature Store Spark connector has a dependency on the `iceberg-spark-runtime` library. You must therefore add corresponding version of the `iceberg-spark-runtime` library to the dependency if you're ingesting data into a feature group that you've auto-created with the Iceberg table format. For example, if you're using Spark 3.1, you must declare the following in your project's `POM.xml`:

```
 <dependency>
 <groupId>software.amazon.sagemaker.featurestore</groupId>
 <artifactId>sagemaker-feature-store-spark-sdk_2.12</artifactId>
 <version>1.0.0</version>
 </dependency>

 <dependency>
   <groupId>org.apache.iceberg</groupId>
   <artifactId>iceberg-spark-runtime-3.1_2.12</artifactId>
   <version>0.14.0</version>
</dependency>
```

Python users

The Feature Store Spark SDK is available in the open-source [Amazon SageMaker Feature Store Spark GitHub repository].

Requirements

- Spark >= 3.0.0 and <= 3.3.0
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)
- Kernel = `conda_python3`

We recommend setting the $SPARK_HOME to the directory where you have Spark installed. During installation, Feature Store uploads the required JAR to SPARK_HOME, so that the dependencies load automatically. Spark starting a JVM is required to make this PySpark library work.

Local installation

To find more info about the installation, enable verbose mode by appending `--verbose` to the following installation command.

```
pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

Installation on Amazon EMR

Create an Amazon EMR cluster with the release version 6.1.0 or later. Enable SSH to help you troubleshoot any issues.

You can do one of the following to install the library:

- Create a custom step within Amazon EMR.
- Connect to your cluster using SSH and install the library from there.

> **Note**
>
> The following information uses Spark version 3.1, but you can specify any version that meets the requirements.

```
export SPARK_HOME=/usr/lib/spark
sudo -E pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all: --verbose
```

> **Note**
>
> If you want to install the dependent JARs automatically to SPARK_HOME, do not use the bootstrap step.

Installation on a SageMaker notebook instance

Install a version of PySpark that's compatible with the Spark connector using the following commands:

```
!pip3 install pyspark==3.1.1
!pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

If you're performing batch ingestion to the offline store, the dependencies aren't within the notebook instance environment.

```
from pyspark.sql import SparkSession
import feature_store_pyspark

extra_jars = ",".join(feature_store_pyspark.classpath_jars())

spark = SparkSession.builder \
    .config("spark.jars", extra_jars) \
    .config("spark.jars.packages", "org.apache.hadoop:hadoop-
aws:3.2.1,org.apache.hadoop:hadoop-common:3.2.1") \
    .getOrCreate()
```

Installation on notebooks with GIS

> **Important**
>
> You must use AWS Glue Version 2.0 or later.

Use the following information to help you install the PySpark connector in an AWS Glue Interactive Session (GIS).

Amazon SageMaker Feature Store Spark requires a specific Spark connector JAR during the initialization of the session to be uploaded to your Amazon S3 bucket. For more information on uploading the required JAR to your S3 bucket, see Retrieving the JAR for Feature Store Spark.

After you've uploaded the JAR, you must provide the GIS sessions with the JAR using the following command.

```
%extra_jars s3:/<YOUR_BUCKET>/spark-connector-jars/sagemaker-feature-store-spark-
sdk.jar
```

To install Feature Store Spark in the AWS Glue runtime, use the `%additional_python_modules` magic command within the GIS notebook. AWS Glue runs `pip` to the modules that you've specified under `%additional_python_modules`.

```
%additional_python_modules sagemaker-feature-store-pyspark-3.1
```

Before you start the AWS Glue session, you must use both of the preceding magic commands.

Installation on an AWS Glue job

> **Important**
>
> You must use AWS Glue Version 2.0 or later.

To install the Spark connector on a AWS Glue job, use the `--extra-jars` argument to provide the necessary JARs and `--additional-python-modules` to install the Spark Connector as job parameters when you create the AWS Glue job as shown in the following example. For more information on uploading the required JAR to your S3 bucket, see Retrieving the JAR for Feature Store Spark.

```
glue_client = boto3.client('glue', region_name=region)
response = glue_client.create_job(
    Name=pipeline_id,
    Description='Feature Store Compute Job',
    Role=glue_role_arn,
    ExecutionProperty={'MaxConcurrentRuns': max_concurrent_run},
    Command={
        'Name': 'glueetl',
        'ScriptLocation': script_location_uri,
        'PythonVersion': '3'
    },
    DefaultArguments={
        '--TempDir': temp_dir_location_uri,
        '--additional-python-modules': 'sagemaker-feature-store-pyspark-3.1',
        '--extra-jars': "s3:/<YOUR_BUCKET>/spark-connector-jars/sagemaker-feature-
store-spark-sdk.jar",
```

```
        ...
    },
    MaxRetries=3,
    NumberOfWorkers=149,
    Timeout=2880,
    GlueVersion='3.0',
    WorkerType='G.2X'
)
```

Installation on an Amazon SageMaker Processing job

To use Feature Store Spark with Amazon SageMaker Processing jobs, bring your own image. For more information about bringing your image, see Bring your own SageMaker image. Add the installation step to a Dockerfile. After you've pushed the Docker image to an Amazon ECR repository, you can use the PySparkProcessor to create the processing job. For more information about creating a processing job with the PySpark processor, see Data Processing with Apache Spark.

The following is an example of adding an installation step to the Dockerfile.

```
FROM <ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/sagemaker-spark-processing:3.1-
cpu-py38-v1.0

RUN /usr/bin/python3 -m pip install sagemaker-feature-store-pyspark-3.1 --no-
binary :all: --verbose
```

Retrieving the JAR for Feature Store Spark

To retrieve the Feature Store Spark dependency JAR, you must install the Spark connector from the Python Package Index (PyPI) repository using `pip` in any Python environment with network access. A SageMaker Jupyter Notebook is an example of a Python environment with network access.

The following command installs the Spark connector.

```
!pip install sagemaker-feature-store-pyspark-3.1
```

After you've installed Feature Store Spark, you can retrieve the JAR location and upload the JAR to Amazon S3.

The `feature-store-pyspark-dependency-jars` command provides the location of the necessary dependency JAR that Feature Store Spark added. You can use the command to retrieve the JAR and upload it to Amazon S3.

```
jar_location = !feature-store-pyspark-dependency-jars
jar_location = jar_location[0]

s3_client = boto3.client("s3")
s3_client.upload_file(jar_location, "<YOUR_BUCKET>","spark-connector-jars/sagemaker-
feature-store-spark-sdk.jar")
```

Example implementations

Example Python script

FeatureStoreBatchIngestion.py

```
from pyspark.sql import SparkSession
from feature_store_pyspark.FeatureStoreManager import FeatureStoreManager
import feature_store_pyspark

spark = SparkSession.builder \
                    .getOrCreate()

# Construct test DataFrame
columns = ["RecordIdentifier", "EventTime"]
data = [("1","2021-03-02T12:20:12Z"), ("2", "2021-03-02T12:20:13Z"), ("3",
 "2021-03-02T12:20:14Z")]

df = spark.createDataFrame(data).toDF(*columns)

# Initialize FeatureStoreManager with a role arn if your feature group is created by
 another account
feature_store_manager= FeatureStoreManager("arn:aws:iam::111122223333:role/role-
arn")

# Load the feature definitions from input schema. The feature definitions can be
 used to create a feature group
```

```
feature_definitions = feature_store_manager.load_feature_definitions_from_schema(df)

feature_group_arn = "arn:aws:sagemaker:<AWS_REGION>:<ACCOUNT_ID>:feature-
group/<YOUR_FEATURE_GROUP_NAME>"

# Ingest by default. The connector will leverage PutRecord API to ingest your data
 in stream
# https://docs.aws.amazon.com/sagemaker/latest/APIReference/
API_feature_store_PutRecord.html
feature_store_manager.ingest_data(input_data_frame=df,
 feature_group_arn=feature_group_arn)

# To select the target stores for ingestion, you can specify the target store as the
 paramter
# If OnlineStore is selected, the connector will leverage PutRecord API to ingest
 your data in stream
feature_store_manager.ingest_data(input_data_frame=df,
 feature_group_arn=feature_group_arn, target_stores=["OfflineStore", "OnlineStore"])

# If only OfflineStore is selected, the connector will batch write the data to
 offline store directly
feature_store_manager.ingest_data(input_data_frame=df,
 feature_group_arn=feature_group_arn, target_stores=["OfflineStore"])

# To retrieve the records failed to be ingested by spark connector
failed_records_df = feature_store_manager.get_failed_stream_ingestion_data_frame()
```

Submit a Spark job with example Python script

The PySpark version requires an extra dependent JAR to be imported, so extra steps are needed to run the Spark application.

If you did not specify SPARK_HOME during installation, then you have to load required JARs in JVM when running `spark-submit`. `feature-store-pyspark-dependency-jars` is a Python script installed by the Spark library to automatically fetch the path to all JARs for you.

```
spark-submit --jars `feature-store-pyspark-dependency-
jars` FeatureStoreBatchIngestion.py
```

If you are running this application on Amazon EMR, we recommended that you run the application in client mode, so that you do not need to distribute the dependent JARs to other task nodes. Add one more step in Amazon EMR cluster with Spark argument similar to the following:

```
spark-submit --deploy-mode client --master yarn s3:/<PATH_TO_SCRIPT>/
FeatureStoreBatchIngestion.py
```

Example Scala script

FeatureStoreBatchIngestion.scala

```
import software.amazon.sagemaker.featurestore.sparksdk.FeatureStoreManager
import org.apache.spark.sql.types.{StringType, StructField, StructType}
import org.apache.spark.sql.{Row, SparkSession}

object TestSparkApp {
  def main(args: Array[String]): Unit = {

    val spark = SparkSession.builder().getOrCreate()

    // Construct test DataFrame
    val data = List(
      Row("1", "2021-07-01T12:20:12Z"),
      Row("2", "2021-07-02T12:20:13Z"),
      Row("3", "2021-07-03T12:20:14Z")
    )

    val schema = StructType(
      List(StructField("RecordIdentifier", StringType), StructField("EventTime",
 StringType))
    )

    val df = spark.createDataFrame(spark.sparkContext.parallelize(data), schema)

    // Initialize FeatureStoreManager with a role arn if your feature group is
 created by another account
    val featureStoreManager = new
 FeatureStoreManager("arn:aws:iam::111122223333:role/role-arn")
```

```
    // Load the feature definitions from input schema. The feature definitions can
 be used to create a feature group
    val featureDefinitions =
 featureStoreManager.loadFeatureDefinitionsFromSchema(df)

    val featureGroupArn = "arn:aws:sagemaker:<AWS_REGION>:<ACCOUNT_ID>:feature-
group/<YOUR_FEATURE_GROUP_NAME>"

    // Ingest by default. The connector will leverage PutRecord API to ingest your
 data in stream
    // https://docs.aws.amazon.com/sagemaker/latest/APIReference/
API_feature_store_PutRecord.html
    featureStoreManager.ingestData(df, featureGroupArn)

    // To select the target stores for ingestion, you can specify the target store
 as the paramter
    // If OnlineStore is selected, the connector will leverage PutRecord API to
 ingest your data in stream
    featureStoreManager.ingestData(df, featureGroupArn, List("OfflineStore",
 "OnlineStore"))

    // If only OfflineStore is selected, the connector will batch write the data to
 offline store directly
    featureStoreManager.ingestData(df, featureGroupArn, ["OfflineStore"])

    // To retrieve the records failed to be ingested by spark connector
    val failedRecordsDf = featureStoreManager.getFailedStreamIngestionDataFrame()
  }
}
```

Submit a Spark job

Scala

You should be able to use Feature Store Spark as a normal dependency. No extra instruction is needed to run the application on all platforms.

Feature Processing

Amazon SageMaker Feature Store Feature Processing is a capability with which you can transform raw data into machine learning (ML) features. It provides you with a Feature Processor SDK with

which you can transform and ingest data from batch data sources into your feature groups. With this capability, Feature Store takes care of the underlying infrastructure including provisioning the compute environments and creating and maintaining SageMaker Pipelines to load and ingest data. This way you can focus on your feature processor definitions that includes a transformation function (for example, count of product views, mean of transaction value), sources (where to apply this transformation on), and sinks (where to write the computed feature values to).

Feature Processor pipeline is a SageMaker Pipelines pipeline. As a SageMaker Pipelines, you can also track scheduled Feature Processor pipelines with SageMaker lineage in the console. For more information on SageMaker Lineage, see Amazon SageMaker ML Lineage Tracking This includes tracking scheduled executions, visualizing lineage to trace features back to their data sources, and viewing shared feature processors in a single environment. For information on using Feature Store with the console, see View pipeline executions from the console.

Topics

Feature Store Feature Processor SDK

Declare a Feature Store Feature Processor definition by decorating your transformation functions with the `@feature_processor` decorator. The SageMaker SDK for Python (Boto3) automatically loads data from the configured input data sources, applies the decorated transformation function, and then ingests the transformed data to a target feature group. Decorated transformation functions must conform to the expected signature of the `@feature_processor` decorator. For more information about the `@feature_processor` decorator, see @feature_processor Decorator in the Amazon SageMaker Feature Store Read the Docs.

With the `@feature_processor` decorator, your transformation function runs in a Spark runtime environment where the input arguments provided to your function and its return value are Spark DataFrames. The number of input parameters in your transformation function must match the number of inputs configured in the `@feature_processor` decorator.

For more information on the `@feature_processor` decorator, see the Feature Processor Feature Store SDK for Python (Boto3).

The following code are basic examples on how to use the `@feature_processor` decorator. For more specific example usage cases, see Example Feature Processing code for common use cases.

The Feature Processor SDK can be installed from the SageMaker Python SDK and its extras using the following command.

```
pip install sagemaker[feature-processor]
```

In the following examples, *us-east-1* is the region of the resource, *111122223333* is the resource owner account ID, and *your-feature-group-name* is the feature group name.

The following is a basic feature processor definition, where the `@feature_processor` decorator configures a CSV input from Amazon S3 to be loaded and provided to your transformation function (for example, `transform`), and prepares it for ingestion to a feature group. The last line runs it.

```
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor

CSV_DATA_SOURCE = CSVDataSource('s3://your-bucket/prefix-to-csv/')
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-
name'

@feature_processor(inputs=[CSV_DATA_SOURCE], output=OUTPUT_FG)
def transform(csv_input_df):
   return csv_input_df

transform()
```

The `@feature_processor` parameters include:

- `inputs` (List[str]): A list of data sources that are used in your Feature Store Feature Processor. If your data sources are feature groups or stored in Amazon S3 you may be able to use Feature Store provided data source definitions for feature processor. For a full list of Feature Store

provided data source definitions, see the Feature Processor Data Source in the Amazon SageMaker Feature Store Read the Docs.

- `output` (str): The ARN of the feature group to ingest the output of the decorated function.
- `target_stores` (Optional[List[str]]): A list of stores (for example, `OnlineStore` or `OfflineStore`) to ingest to the output. If unspecified, data is ingested to all of the output feature group's enabled stores.
- `parameters` (Dict[str, Any]): A dictionary to be provided to your transformation function.
- `enable_ingestion` (bool): A flag to indicate whether the transformation function's outputs are ingested to the output feature group. This flag is useful during the development phase. If unspecified, ingestion is enabled.

Optional wrapped function parameters (provided as an argument if provided in the function signature) include:

- `params` (Dict[str, Any]): The dictionary defined in the `@feature_processor` parameters. It also contains system configured parameters that can be referenced with the key `system`, such as the `scheduled_time` parameter.
- `spark` (SparkSession): A reference to the SparkSession instance initialized for the Spark Application.

The following code is an example of using the `params` and `spark` parameters.

```
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor

CSV_DATA_SOURCE = CSVDataSource('s3://your-bucket/prefix-to-csv/')
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'

@feature_processor(inputs=[CSV_DATA_SOURCE], output=OUTPUT_FG)
def transform(csv_input_df, params, spark):

   scheduled_time = params['system']['scheduled_time']
   csv_input_df.createOrReplaceTempView('csv_input_df')
   return spark.sql(f'''
        SELECT *
        FROM csv_input_df
        WHERE date_add(event_time, 1) >= {scheduled_time}
   ''')
```

```
transform()
```

The `scheduled_time` system parameter (provided in the `params` argument to your function) is an important value to support retrying each execution. The value can help to uniquely identify the Feature Processor's execution and can be used as a reference point for daterange–based inputs (for example, only loading the last 24 hours worth of data) to guarantee the input range independent of the code's actual execution time. If the Feature Processor runs on a schedule (see Scheduled and event based executions for Feature Processor pipelines) then its value is fixed to the time it is scheduled to run. The argument can be overridden during synchronous execution using the SDK's execute API to support use cases such as data backfills or re-running a missed past execution. Its value is the current time if the Feature Processor runs any other way.

For information about authoring Spark code, see the Spark SQL Programming Guide.

For more code samples for common use-cases, see the Example Feature Processing code for common use cases.

Note that transformation functions decorated with `@feature_processor` do not return a value. To programmatically test your function, you can remove or monkey patch the `@feature_processor` decorator such that it acts as a pass-through to the wrapped function. For more details on the `@feature_processor` decorator, see Amazon SageMaker Feature Store Python SDK.

Running Feature Store Feature Processor remotely

To run your Feature Processors on large data sets that require hardware more powerful than what is locally available, you can decorate your code with the `@remote` decorator to run your local Python code as a single or multi-node distributed SageMaker training job. For more information on running your code as a SageMaker training job, see Run your local code as a SageMaker training job.

The following is a usage example of the `@remote` decorator along with the `@feature_processor` decorator.

```
from sagemaker.remote_function.spark_config import SparkConfig
from sagemaker.remote_function import remote
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor

CSV_DATA_SOURCE = CSVDataSource('s3://bucket/prefix-to-csv/')
```

```
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:123456789012:feature-group/feature-group'

@remote(
    spark_config=SparkConfig(),
    instance_type="ml.m5.2xlarge",
    dependencies="/local/requirements.txt"
)
@feature_processor(
    inputs=[CSV_DATA_SOURCE],
    output=OUTPUT_FG,
)
def transform(csv_input_df):
   return csv_input_df

transform()
```

The `spark_config` parameter indicates that the remote job runs as a Spark application. The `SparkConfig` instance can be used to configure the Spark Configuration and provide additional dependencies to the Spark application such as Python files, JARs, and files.

For faster iterations when developing your feature processing code, you can specify the `keep_alive_period_in_seconds` argument in the `@remote` decorator to retain configured resources in a warm pool for subsequent training jobs. For more information on warm pools, see `KeepAlivePeriodInSeconds` in the API Reference guide.

The following code is an example of local `requirements.txt`:

```
sagemaker>=2.167.0
```

This will install the corresponding SageMaker SDK version in remote job which is required for executing the method annotated by `@feature-processor`.

Creating and running Feature Store Feature Processor pipelines

The Feature Processor SDK provides APIs to promote your Feature Processor Definitions into a fully managed SageMaker Pipeline. For more information on SageMaker Pipelines, see SageMaker Pipelines Overview. To convert your Feature Processor Definitions in to a SageMaker Pipeline, use the `to_pipeline` API with your Feature Processor definition. You can schedule executions of your Feature Processor Definition can be scheduled, operationally monitor them with CloudWatch metrics, and integrate them with EventBridge to act as event sources or subscribers. For more

information about monitoring pipelines created with SageMaker Pipelines, see Monitor Amazon SageMaker Feature Store Feature Processor pipelines.

To view your Feature Processor pipelines, see View pipeline executions from the console.

If your function is also decorated with the `@remote` decorator, then its configurations is carried over to the Feature Processor pipeline. You can specify advanced configurations such as compute instance type and count, runtime dependencies, network and security configurations using the `@remote` decorator.

The following example uses the `to_pipeline` and `execute` APIs.

```
from sagemaker.feature_store.feature_processor import (
    execute, to_pipeline, describe, TransformationCode
)

pipeline_name="feature-processor-pipeline"
pipeline_arn = to_pipeline(
    pipeline_name=pipeline_name,
    step=transform,
    transformation_code=TransformationCode(s3_uri="s3://bucket/prefix"),
)

pipeline_execution_arn = execute(
    pipeline_name=pipeline_name
)
```

The `to_pipeline` API is semantically an upsert operation. It updates the pipeline if it already exists; otherwise, it creates a pipeline.

The `to_pipeline` API optionally accepts an Amazon S3 URI that references a file containing the Feature Processor definition to associate it with the Feature Processor pipeline to track the transformation function and its versions in its SageMaker machine learning lineage.

To retrieve a list of every Feature Processor pipeline in your account, you can use the `list_pipelines` API. A subsequent request to the `describe` API returns details related to the Feature Processor pipeline including, but not limited to, SageMaker Pipelines and schedule details.

The following example uses the `list_pipelines` and `describe` APIs.

```
from sagemaker.feature_store.feature_processor import list_pipelines, describe
```

```
feature_processor_pipelines = list_pipelines()

pipeline_description = describe(
    pipeline_name = feature_processor_pipelines[0]
)
```

Scheduled and event based executions for Feature Processor pipelines

Amazon SageMaker Feature Store Feature Processing pipeline executions can be configured to start automatically and asynchronously based on a preconfigured schedule or as a result of another AWS service event. For example, you can schedule Feature Processing pipelines to execute on the first of every month or chain two pipelines together so that a target pipeline is executed automatically after a source pipeline execution completes.

Topics

- Schedule based executions
- Event based executions

Schedule based executions

The Feature Processor SDK provides a `schedule` API to run Feature Processor pipelines on a recurring basis with Amazon EventBridge Scheduler integration. The schedule can be specified with an `at`, `rate`, or `cron` expression using the `ScheduleExpression` parameter with the same expressions supported by Amazon EventBridge. The schedule API is semantically an upsert operation in that it updates the schedule if it already exists; otherwise, it creates it. For more information on the EventBridge expressions and examples, see Schedule types on EventBridge Scheduler in the EventBridge Scheduler User Guide.

The following examples use the Feature Processor `schedule` API, using the `at`, `rate`, and `cron` expressions.

```
from sagemaker.feature_store.feature_processor import schedule
pipeline_name='feature-processor-pipeline'

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="at(2020-11-30T00:00:00)"
```

```
)

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="rate(24 hours)"
)

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="cron(0 0-23/1 ? * * 2023-2024)"
)
```

The default timezone for date and time inputs in the `schedule` API are in UTC. For more information about EventBridge Scheduler schedule expressions, see `ScheduleExpression` in the EventBridge Scheduler API Reference documentation.

Scheduled Feature Processor pipeline executions provide your transformation function with the scheduled execution time, to be used as an idempotency token or a fixed reference point for date range–based inputs. To disable (i.e., pause) or re-enable a schedule, use the `state` parameter of the `schedule` API with `'DISABLED'` or `'ENABLED'`, respectively.

For information about Feature Processor, see Feature Processor SDK data sources.

Event based executions

A Feature Processing pipeline can be configured to automatically execute when an AWS event occurs. The Feature Processing SDK provides a `put_trigger` function that accepts a list of source events and a target pipeline. The source events must be instances of `FeatureProcessorPipelineEvent`, that specifies a pipeline and execution status events.

The `put_trigger` function configures an Amazon EventBridge rule and target to route events and allows you to specify an EventBridge event pattern to respond to any AWS event. For information on these concepts, see Amazon EventBridge rules, targets, and event patterns.

Triggers can be enabled or disabled. EventBridge will start a target pipeline execution using the role provided in the `role_arn` parameter of the `put_trigger` API. The execution role is used by default if the SDK is used in a Amazon SageMaker Studio Classic or Notebook environment. For information on how to get your execution role, see Get execution role.

The following example sets up:

- A SageMaker Pipeline using the `to_pipeline` API, that takes in your target pipeline name (`target-pipeline`) and your transformation function (`transform`). For information on your Feature Processor and transform function, see Feature Processor SDK data sources.
- A trigger using the `put_trigger` API, that takes in `FeatureProcessorPipelineEvent` for the event and your target pipeline name (`target-pipeline`).

  The `FeatureProcessorPipelineEvent` defines the trigger for when the status of your source pipeline (`source-pipeline`) becomes `Succeeded`. For information on the Feature Processor Pipeline event function, see `FeatureProcessorPipelineEvent` in the Feature Store Read the Docs.

```
from sagemaker.feature_store.feature_processor import put_trigger, to_pipeline,
 FeatureProcessorPipelineEvent

to_pipeline(pipeline_name="target-pipeline", step=transform)

put_trigger(
    source_pipeline_events=[
        FeatureProcessorPipelineEvent(
            pipeline_name="source-pipeline",
            status=["Succeeded"]
        )
    ],
    target_pipeline="target-pipeline"
)
```

For an example of using event based triggers to create continuous executions and automatic retries for your Feature Processor pipeline, see Continuous executions and automatic retries using event based triggers.

For an example of using event based triggers to create continuous *streaming* and automatic retries using event based triggers, see Streaming custom data source examples.

Monitor Amazon SageMaker Feature Store Feature Processor pipelines

AWS provides monitoring tools to watch your Amazon SageMaker resources and applications in real time, report when something goes wrong, and take automatic actions when appropriate. Feature Store Feature Processor pipelines are SageMaker Pipelines, so the standard monitoring

mechanisms and integrations are available. Operational metrics such as execution failures can be monitored via Amazon CloudWatch metrics and Amazon EventBridge events.

For more information on how to monitor and operationalize Feature Store Feature Processor, see the following resources:

- Monitor AWS resources provisioned while using Amazon SageMaker - General guidance on monitoring and auditing activity for SageMaker resources.
- SageMaker Pipelines Metrics - CloudWatch Metrics emitted by SageMaker Pipelines.
- Pipeline execution state change - EventBridge events emitted for SageMaker Pipelines and executions.
- Troubleshooting Amazon SageMaker Model Building Pipelines - General debugging and troubleshooting tips for SageMaker Pipelines.

Feature Store Feature Processor execution logs can be found in Amazon CloudWatch Logs under the `/aws/sagemaker/TrainingJobs` log group, where you can find the execution log streams using lookup conventions. For executions created by directly invoking the `@feature_processor` decorated function, you can find logs in your local execution environment's console. For `@remote` decorated executions, the CloudWatch Logs stream name contains the name of the function and the execution timestamp. For Feature Processor pipeline executions, the CloudWatch Logs stream for the step contains the `feature-processor` string and the pipeline execution ID.

Feature Store Feature Processor pipelines and recent execution statuses can be found in Amazon SageMaker Studio Classic for a given feature group in the Feature Store UI. Feature groups related to the Feature Processor pipelines as either inputs or outputs are displayed in the UI. In addition, the lineage view can provide context into upstream executions, such as data producing Feature Processor pipelines and data sources, for further debugging. For more information on using the lineage view using Studio Classic, see View lineage from the console.

IAM permissions and execution roles

To use the The Amazon SageMaker Python SDK requires permissions to interact with AWS services. The following policies are required for full Feature Processor functionality. You can attach the AmazonSageMakerFullAccess and AmazonEventBridgeSchedulerFullAccess AWS Managed Policies attached to your IAM role. For information on attaching policies to your IAM role, see Adding policies to your IAM role. See the following examples for details.

The trust policy of the role to which this policy is applied must allow the "scheduler.amazonaws.com", "sagemaker.amazonaws.com", and "glue.amazonaws.com" principles.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "scheduler.amazonaws.com",
                    "sagemaker.amazonaws.com",
                    "glue.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Feature Processor restrictions, limits, and quotas

Amazon SageMaker Feature Store Feature Processing relies on SageMaker machine learning (ML) lineage tracking. The Feature Store Feature Processor uses lineage contexts to represent and track Feature Processing Pipelines and Pipeline versions. Each Feature Store Feature Processor consumes at least two lineage contexts (one for the Feature Processing Pipeline and another for the version). If the input or output data source of a Feature Processing Pipeline changes, an additional lineage context is created. You can update SageMaker ML lineage limits by reaching out to AWS support for a limit increase. Default limits for resources used by Feature Store Feature Processor are as follows. For information on SageMaker ML lineage tracking, see Amazon SageMaker ML Lineage Tracking.

For more information on SageMaker quotas, see Amazon SageMaker endpoints and quotas.

Lineage limits per Region

- Contexts – 500 (soft limit)
- Artifacts – 6,000 (soft limit)
- Associations – 6,000 (soft limit)

Training Limits per Region

- Longest run time for a training job – 432,000 seconds
- Maximum number of instances per training job – 20
- The maximum number of `CreateTrainingJob` requests that you can make, per second, in this account in the current Region – 1 TPS
- Keep alive period for cluster reuse – 3,600 seconds

Maximum number of Pipelines and concurrent pipeline executions per Region

- Maximum number of pipelines allowed per account – 500
- Maximum number of concurrent pipeline executions allowed per account – 20
- Time at which pipeline executions time out – 672 hours

Data sources

Amazon SageMaker Feature Store Feature Processing supports multiple data sources. The Feature Processor SDK for Python (Boto3) provides constructs to load data from feature groups or objects stored in Amazon S3. In addition, you can author custom data sources to load data from other data sources. For information about Feature Store provided data sources, see Feature Processor data source Feature Store Python SDK.

Topics

- Feature Processor SDK data sources
- Custom data sources
- Custom data source examples

Feature Processor SDK data sources

The Amazon SageMaker Feature Store Feature Processor SDK for Python (Boto3) provides constructs to load data from feature groups or objects stored in Amazon S3. For a full list of Feature Store provided data source definitions, see the Feature Processor data source Feature Store Python SDK.

For examples on how to use the Feature Store Python SDK data source definitions, see Example Feature Processing code for common use cases.

FeatureGroupDataSource

The `FeatureGroupDataSource` is used to specify a feature group as an input data source for a Feature Processor. Data can be loaded from an offline store feature group. Attempting to load your data from an online store feature group will result in a validation error. You can specify start and end offsets to limit the data that is loaded to a specific time range. For example, you can specify a start offset of ‘14 days' to load only the last two weeks of data, and you can additionally specify an end offset of '7 days' to limit the input to the previous week of data.

Feature Store provided data source definitions

The Feature Store Python SDK contain data source definitions that can be used to specify various input data sources for a Feature Processor. These include CSV, Parquet, and Iceberg table sources. For a full list of Feature Store provided data source definitions, see the Feature Processor data source Feature Store Python SDK.

Custom data sources

On this page we will describe how to create a custom data source class and show some usage examples. With custom data sources, you can use the SageMaker SDK for Python (Boto3) provided APIs in the same way as if you are using Amazon SageMaker Feature Store provided data sources.

To use a custom data source to transform and ingest data into a feature group using Feature Processing, you will need to extend the `PySparkDataSource` class with the following class members and function.

- `data_source_name` (str): an arbitrary name for the data source. For example, Amazon Redshift, Snowflake, or a Glue Catalog ARN.
- `data_source_unique_id` (str): a unique identifier that refers to the specific resource being accessed. For example, table name, DDB Table ARN, Amazon S3 prefix. All usage of the same `data_source_unique_id` in custom data sources will be associated to the same data source in the lineage view. Lineage includes information about the execution code of a feature processing workflow, what data sources were used, and how they are ingested into the feature group or feature. For information about viewing lineage of a feature group in **Studio**, see View lineage from the console.
- `read_data` (func): a method used to connect with the feature processor. Returns a Spark data frame. For examples, see Custom data source examples.

Both `data_source_name` and `data_source_unique_id` are used to uniquely identify your lineage entity. The following is an example for a custom data source class named `CustomDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
from pyspark.sql import DataFrame

class CustomDataSource(PySparkDataSource):

    data_source_name = "custom-data-source-name"
    data_source_unique_id = "custom-data-source-id"

    def read_data(self, parameter, spark) -> DataFrame:
        your own code here to read data into a Spark dataframe
        return dataframe
```

Custom data source examples

This section provides examples of custom data sources implementations for Feature Processors. For more information on custom data sources, see Custom data sources.

Security is a shared responsibility between AWS and our customers. AWS is responsible for protecting the infrastructure that runs the services in the AWS Cloud. Customers are responsible for all of their necessary security configuration and management tasks. For example, secrets such as access credentials to data stores should not be hard coded in your custom data sources. You can use AWS Secrets Manager to manage these credentials. For information about Secrets Manager, see What is AWS Secrets Manager? in the AWS Secrets Manager user guide. The following examples will use Secrets Manager for your credentials.

Topics

- Amazon Redshift Clusters (JDBC) custom data source examples
- Snowflake custom data source examples
- Databricks (JDBC) custom data source examples
- Streaming custom data source examples

Amazon Redshift Clusters (JDBC) custom data source examples

Amazon Redshift offers a JDBC driver that can be used to read data with Spark. For information about how to download the Amazon Redshift JDBC driver, see Download the Amazon Redshift JDBC driver, version 2.1.

To create the custom Amazon Redshift data source class, you will need to overwrite the `read_data` method from the Custom data sources.

To connect with an Amazon Redshift cluster you need your:

- Amazon Redshift JDBC URL (*`jdbc-url`*)

  For information about obtaining your Amazon Redshift JDBC URL, see Getting the JDBC URL in the Amazon Redshift Database Developer Guide.
- Amazon Redshift user name (*`redshift-user`*) and password (*`redshift-password`*)

  For information about how to create and manage database users using the Amazon Redshift SQL commands, see Users in the Amazon Redshift Database Developer Guide.
- Amazon Redshift table name (*`redshift-table-name`*)

  For information about how to create a table with some examples, see CREATE TABLE in the Amazon Redshift Database Developer Guide.
- (Optional) If using Secrets Manager, you'll need the secret name (*`secret-redshift-account-info`*) where you store your Amazon Redshift access username and password on Secrets Manager.

  For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.
- AWS Region (*`your-region`*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

The following example demonstrates how to retrieve the JDBC URL and personal access token from Secrets Manager and override the `read_data` for your custom data source class, `DatabricksDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
```

```
import json
import boto3

class RedshiftDataSource(PySparkDataSource):

    data_source_name = "Redshift"
    data_source_unique_id = "redshift-resource-arn"

    def read_data(self, spark, params):
        url = "jdbc-url?user=redshift-user&password=redshift-password"
        aws_iam_role_arn = "redshift-command-access-role"
        secret_name = "secret-redshift-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)
["SecretString"])
        jdbc_url = url.replace("jdbc-url", secrets["jdbcurl"]).replace("redshift-user",
 secrets['username']).replace("redshift-password", secrets['password'])

        return spark.read \
             .format("jdbc") \
             .option("url", url) \
             .option("driver", "com.amazon.redshift.Driver") \
             .option("dbtable", "redshift-table-name") \
             .option("tempdir", "s3a://your-bucket-name/your-bucket-prefix") \
             .option("aws_iam_role", aws_iam_role_arn) \
             .load()
```

The following example shows how to connect `RedshiftDataSource` to your `feature_processor` decorator.

```
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[RedshiftDataSource()],
    output="feature-group-arn",
```

```
    target_stores=["OfflineStore"],
    spark_config={"spark.jars.packages": "com.amazon.redshift:redshift-
jdbc42:2.1.0.16"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the jdbc driver by defining `SparkConfig` and pass it to the `@remote` decorator.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
      "spark.jars.packages": "com.amazon.redshift:redshift-jdbc42:2.1.0.16"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[RedshiftDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
)
def transform(input_df):
    return input_df
```

Snowflake custom data source examples

Snowflake provides a Spark connector that can be used for your `feature_processor` decorator. For information about Snowflake connector for Spark, see Snowflake Connector for Spark in the Snowflake documentation.

To create the custom Snowflake data source class, you will need to override the `read_data` method from the Custom data sources and add the Spark connector packages to the Spark classpath.

To connect with a Snowflake data source you need:

- Snowflake URL (*sf-url*)

  For information about URLs for accessing Snowflake web interfaces, see Account Identifiers in the Snowflake documentation.
- Snowflake database (*sf-database*)

  For information about obtaining the name of your database using Snowflake, see CURRENT_DATABASE in the Snowflake documentation.
- Snowflake database schema (*sf-schema*)

  For information about obtaining the name of your schema using Snowflake, see CURRENT_SCHEMA in the Snowflake documentation.
- Snowflake warehouse (*sf-warehouse*)

  For information about obtaining the name of your warehouse using Snowflake, see CURRENT_WAREHOUSE in the Snowflake documentation.
- Snowflake table name (*sf-table-name*)
- (Optional) If using Secrets Manager, you'll need the secret name (*secret-snowflake-account-info*) where you store your Snowflake access username and password on Secrets Manager.

  For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.
- AWS Region (*your-region*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

The following example demonstrates how to retrieve the Snowflake user name and password from Secrets Manager and override the `read_data` function for your custom data source class `SnowflakeDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
from sagemaker.feature_store.feature_processor import feature_processor
import json
import boto3
```

```
class SnowflakeDataSource(PySparkDataSource):

    sf_options = {
        "sfUrl" : "sf-url",
        "sfDatabase" : "sf-database",
        "sfSchema" : "sf-schema",
        "sfWarehouse" : "sf-warehouse",
    }

    data_source_name = "Snowflake"
    data_source_unique_id = "sf-url"

    def read_data(self, spark, params):
        secret_name = "secret-snowflake-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)
["SecretString"])
        self.sf_options["sfUser"] = secrets.get("username")
        self.sf_options["sfPassword"] = secrets.get("password")

        return spark.read.format("net.snowflake.spark.snowflake") \
                        .options(**self.sf_options) \
                        .option("dbtable", "sf-table-name") \
                        .load()
```

The following example shows how to connect `SnowflakeDataSource` to your `feature_processor` decorator.

```
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[SnowflakeDataSource()],
    output=feature-group-arn,
    target_stores=["OfflineStore"],
```

```
    spark_config={"spark.jars.packages": "net.snowflake:spark-snowflake_2.12:2.12.0-
spark_3.3"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the packages via defining `SparkConfig` and pass it to `@remote` decorator. The Spark packages in the following example are such that `spark-snowflake_2.12` is the Feature Processor Scala version, `2.12.0` is the Snowflake version you wish to use, and `spark_3.3` is the Feature Processor Spark version.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
      "spark.jars.packages": "net.snowflake:spark-snowflake_2.12:2.12.0-spark_3.3"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[SnowflakeDataSource()],
    output="feature-group-arn>",
    target_stores=["OfflineStore"],
)
def transform(input_df):
    return input_df
```

Databricks (JDBC) custom data source examples

Spark can read data from Databricks by using the Databricks JDBC driver. For information about the Databricks JDBC driver, see Configure the Databricks ODBC and JDBC drivers in the Databricks documentation.

> **Note**
>
> You can read data from any other database by including the corresponding JDBC driver in Spark classpath. For more information, see JDBC To Other Databases in the Spark SQL Guide.

To create the custom Databricks data source class, you will need to override the `read_data` method from the Custom data sources and add the JDBC jar to the Spark classpath.

To connect with a Databricks data source you need:

- Databricks URL (*`databricks-url`*)

  For information about your Databricks URL, see Building the connection URL for the Databricks driver in the Databricks documentation.
- Databricks personal access token (*`personal-access-token`*)

  For information about your Databricks access token, see Databricks personal access token authentication in the Databricks documentation.
- Data catalog name (*`db-catalog`*)

  For information about your Databricks catalog name, see Catalog name in the Databricks documentation.
- Schema name (*`db-schema`*)

  For information about your Databricks schema name, see Schema name in the Databricks documentation.
- Table name (*`db-table-name`*)

  For information about your Databricks table name, see Table name in the Databricks documentation.
- (Optional) If using Secrets Manager, you'll need the secret name (*`secret-databricks-account-info`*) where you store your Databricks access username and password on Secrets Manager.

  For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.

- AWS Region (*your-region*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

The following example demonstrates how to retrieve the JDBC URL and personal access token from Secrets Manager and overwrite the `read_data` for your custom data source class, `DatabricksDataSource`.

```
from sagemaker.feature_store.feature_processor import PySparkDataSource
import json
import boto3

class DatabricksDataSource(PySparkDataSource):

    data_source_name = "Databricks"
    data_source_unique_id = "databricks-url"

    def read_data(self, spark, params):
        secret_name = "secret-databricks-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)
["SecretString"])
        jdbc_url = secrets["jdbcurl"].replace("personal-access-token", secrets['pwd'])

        return spark.read.format("jdbc") \
                        .option("url", jdbc_url) \
                        .option("dbtable","`db-catalog`.`db-schema`.`db-table-name`") \
                        .option("driver", "com.simba.spark.jdbc.Driver") \
                        .load()
```

The following example shows how to upload the JDBC driver jar, *jdbc-jar-file-name*`.jar`, to Amazon S3 in order to add it to the Spark classpath. For information about downloading the

Spark JDBC driver (*jdbc-jar-file-name*.jar) from Databricks, see Download JDBC Driverin the Databricks website.

```
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[DatabricksDataSource()],
    output=feature-group-arn,
    target_stores=["OfflineStore"],
    spark_config={"spark.jars": "s3://your-bucket-name/your-bucket-prefix/jdbc-jar-file-name.jar"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the jars by defining SparkConfig and pass it to the @remote decorator.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
      "spark.jars": "s3://your-bucket-name/your-bucket-prefix/jdbc-jar-file-name.jar"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[DatabricksDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
)
def transform(input_df):
    return input_df
```

Streaming custom data source examples

You can connect to streaming data sources like Amazon Kinesis, and author transforms with Spark Structured Streaming to read from streaming data sources. For information about the Kinesis connector, see Kinesis Connector for Spark Structured Streaming in GitHub. For information about Amazon Kinesis, see What Is Amazon Kinesis Data Streams? in the Amazon Kinesis Developer Guide.

To create the custom Amazon Kinesis data source class, you will need to extend the `BaseDataSource` class and override the `read_data` method from Custom data sources.

To connect to an Amazon Kinesis data stream you need:

- Kinesis ARN (*`kinesis-resource-arn`*)

  For information on Kinesis data stream ARNs, see Amazon Resource Names (ARNs) for Kinesis Data Streams in the Amazon Kinesis Developer Guide.
- Kinesis data stream name (*`kinesis-stream-name`*)
- AWS Region (*`your-region`*)

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

```
from sagemaker.feature_store.feature_processor import BaseDataSource
from sagemaker.feature_store.feature_processor import feature_processor

class KinesisDataSource(BaseDataSource):

    data_source_name = "Kinesis"
    data_source_unique_id = "kinesis-resource-arn"

    def read_data(self, spark, params):
        return spark.readStream.format("kinesis") \
            .option("streamName", "kinesis-stream-name") \
            .option("awsUseInstanceProfile", "false") \
            .option("endpointUrl", "https://kinesis.your-region.amazonaws.com")
            .load()
```

The following example demonstrates how to connect `KinesisDataSource` to your `feature_processor` decorator.

```
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig
import feature_store_pyspark.FeatureStoreManager as fsm

def ingest_micro_batch_into_fg(input_df, epoch_id):
    feature_group_arn = "feature-group-arn"
    fsm.FeatureStoreManager().ingest_data(
        input_data_frame = input_df,
        feature_group_arn = feature_group_arn
    )

@remote(
    spark_config=SparkConfig(
        configuration={
            "Classification": "spark-defaults",
            "Properties":{
                "spark.sql.streaming.schemaInference": "true",
                "spark.jars.packages": "com.roncemer.spark/spark-sql-
kinesis_2.13/1.2.2_spark-3.2"
            }
        }
    ),
    instance_type="ml.m5.2xlarge",
    max_runtime_in_seconds=2419200 # 28 days
)
@feature_processor(
    inputs=[KinesisDataSource()],
    output="feature-group-arn"
)
def transform(input_df):
    output_stream = (
        input_df.selectExpr("CAST(rand() AS STRING) as partitionKey", "CAST(data AS
 STRING)")
        .writeStream.foreachBatch(ingest_micro_batch_into_fg)
        .trigger(processingTime="1 minute")
        .option("checkpointLocation", "s3a://checkpoint-path")
        .start()
    )
    output_stream.awaitTermination()
```

In the example code above we use a few Spark Structured Streaming options while streaming micro-batches into your feature group. For a full list of options, see the Structured Streaming Programming Guide in the Apache Spark documentation.

- The `foreachBatch` sink mode is a feature that allows you to apply operations and write logic on the output data of each micro-batch of a streaming query.

  For information on `foreachBatch`, see Using Foreach and ForeachBatch in the Apache Spark Structured Streaming Programming Guide.
- The `checkpointLocation` option periodically saves the state of the streaming application. The streaming log is saved in checkpoint location *`s3a://checkpoint-path`*.

  For information on the `checkpointLocation` option, see Recovering from Failures with Checkpointing in the Apache Spark Structured Streaming Programming Guide.
- The `trigger` setting defines how often the micro-batch processing is triggered in a streaming application. In the example, the processing time trigger type is used with one-minute micro-batch intervals, specified by `trigger(processingTime="1 minute")`. To backfill from a stream source, you can use the available-now trigger type, specified by `trigger(availableNow=True)`.

  For a full list of `trigger` types, see Triggers in the Apache Spark Structured Streaming Programming Guide.

Continuous streaming and automatic retries using event based triggers

The Feature Processor uses SageMaker Training as compute infrastructure and it has a maximum runtime limit of 28 days. You can use event based triggers to extend your continuous streaming for a longer period of time and recover from transient failures. For more information on schedule and event based executions, see Scheduled and event based executions for Feature Processor pipelines.

The following is an example of setting up an event based trigger to keep the streaming Feature Processor pipeline running continuously. This uses the streaming transform function defined in the previous example. A target pipeline can be configured to be triggered when a `STOPPED` or `FAILED` event occurs for a source pipeline execution. Note that the same pipeline is used as the source and target so that it run continuously.

```
import sagemaker.feature_store.feature_processor as fp
from sagemaker.feature_store.feature_processor import FeatureProcessorPipelineEvent
from sagemaker.feature_store.feature_processor import
 FeatureProcessorPipelineExecutionStatus

streaming_pipeline_name = "streaming-pipeline"
streaming_pipeline_arn = fp.to_pipeline(
```

```
    pipeline_name = streaming_pipeline_name,
    step = transform # defined in previous section
)

fp.put_trigger(
    source_pipeline_events=FeatureProcessorPipelineEvents(
        pipeline_name=source_pipeline_name,
        pipeline_execution_status=[
            FeatureProcessorPipelineExecutionStatus.STOPPED,
            FeatureProcessorPipelineExecutionStatus.FAILED]
    ),
    target_pipeline=target_pipeline_name
)
```

Example Feature Processing code for common use cases

The following examples provide sample Feature Processing code for common use cases. For a more detailed example notebook showcasing specific use cases, see Amazon SageMaker Feature Store Feature Processing notebook.

In the following examples, *us-east-1* is the region of the resource, *111122223333* is the resource owner account ID, and *your-feature-group-name* is the feature group name.

The `transactions` data set used in the following examples has the following schema:

```
'FeatureDefinitions': [
  {'FeatureName': 'txn_id', 'FeatureType': 'String'},
  {'FeatureName': 'txn_time', 'FeatureType': 'String'},
  {'FeatureName': 'credit_card_num', 'FeatureType': 'String'},
  {'FeatureName': 'txn_amount', 'FeatureType': 'Fractional'}
]
```

Topics

- Joining data from multiple data sources
- Sliding window aggregates
- Tumbling window aggregates
- Promotion from the offline store to online store
- Transformations with the Pandas library
- Continuous executions and automatic retries using event based triggers

Joining data from multiple data sources

```
@feature_processor(
    inputs=[
        CSVDataSource('s3://bucket/customer'),
        FeatureGroupDataSource('transactions')
    ],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'
)
def join(transactions_df, customer_df):
  '''Combine two data sources with an inner join on a common column'''

  return transactions_df.join(
    customer_df, transactions_df.customer_id == customer_df.customer_id, "inner"
  )
```

Sliding window aggregates

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'
)
def sliding_window_aggregates(transactions_df):
    '''Aggregates over 1-week windows, across 1-day sliding windows.'''
    from pyspark.sql.functions import window, avg, count

    return (
        transactions_df
            .groupBy("credit_card_num", window("txn_time", "1 week", "1 day"))
            .agg(avg("txn_amount").alias("avg_week"), count("*").alias("count_week"))
            .orderBy("window.start")
            .select("credit_card_num", "window.start", "avg_week", "count_week")
    )
```

Tumbling window aggregates

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'
```

```
)
def tumbling_window_aggregates(transactions_df, spark):
    '''Aggregates over 1-week windows, across 1-day tumbling windows, as a SQL
 query.'''

    transactions_df.createOrReplaceTempView('transactions')
    return spark.sql(f'''
        SELECT credit_card_num, window.start, AVG(amount) AS avg, COUNT(*) AS count
        FROM transactions
        GROUP BY credit_card_num, window(txn_time, "1 week")
        ORDER BY window.start
    ''')
```

Promotion from the offline store to online store

```
@feature_processor(
    inputs=[FeatureGroupDataSource('transactions')],
    target_stores=['OnlineStore'],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/transactions'
)
def offline_to_online():
    '''Move data from the offline store to the online store of the same feature
 group.'''

    transactions_df.createOrReplaceTempView('transactions')
    return spark.sql(f'''
        SELECT txn_id, txn_time, credit_card_num, amount
        FROM
            (SELECT *,
            row_number()
            OVER
                (PARTITION BY txn_id
                ORDER BY "txn_time" DESC, Api_Invocation_Time DESC, write_time DESC)
            AS row_number
            FROM transactions)
        WHERE row_number = 1
    ''')
```

Transformations with the Pandas library

Transformations with the Pandas library

```
@feature_processor(
```

```
    inputs=[FeatureGroupDataSource('transactions')],
    target_stores=['OnlineStore'],
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/transactions'
)
def pandas(transactions_df):
    '''Author transformations using the Pandas interface.

    Requires PyArrow to be installed via pip.
    For more details: https://spark.apache.org/docs/latest/api/python/user_guide/
pandas_on_spark
    '''
    import pyspark.pandas as ps

    # PySpark DF to Pandas-On-Spark DF (Distributed DF with Pandas interface).
    pandas_on_spark_df = transactions_df.pandas_api()
    # Pandas-On-Spark DF to Pandas DF (Single Machine Only).
    pandas_df = pandas_on_spark_df.to_pandas()

    # Reverse: Pandas DF to Pandas-On-Spark DF
    pandas_on_spark_df = ps.from_pandas(pandas_df)
    # Reverse: Pandas-On-Spark DF to PySpark DF
    spark_df = pandas_on_spark_df.to_spark()

    return spark_df
```

Continuous executions and automatic retries using event based triggers

```
from sagemaker.feature_store.feature_processor import put_trigger, to_pipeline,
 FeatureProcessorPipelineEvent
from sagemaker.feature_store.feature_processor import
 FeatureProcessorPipelineExecutionStatus

streaming_pipeline_name = "target-pipeline"

to_pipeline(
    pipeline_name=streaming_pipeline_name,
    step=transform
)

put_trigger(
    source_pipeline_events=[
        FeatureProcessorPipelineEvent(
            pipeline_name=streaming_pipeline_name,
```

```
            pipeline_execution_status=[
            FeatureProcessorPipelineExecutionStatus.STOPPED,
            FeatureProcessorPipelineExecutionStatus.FAILED]
        )
    ],
    target_pipeline=streaming_pipeline_name
)
```

Time to live (TTL) duration for records

Amazon SageMaker Feature Store provides the option for records to be hard deleted from the online store after a time duration is reached, with time to live (TTL) duration (`TtlDuration`). The record will expire after the record's `EventTime` plus the `TtlDuration` is reached, or `ExpiresAt` = `EventTime` + `TtlDuration`. The `TtlDuration` can be applied at a feature group level, where all records within the feature group will have the `TtlDuration` by default, or at an individual record level. If `TtlDuration` is unspecified, the default value is `null` and the record will remain in the online store until it is overwritten.

A record deleted using `TtlDuration` is hard deleted, or completely removed from the online store, and the deleted record is added to the offline store. For more information on hard delete and deletion modes, see `DeleteRecord` in the Amazon SageMaker API Reference guide. When a record is hard deleted it immediately becomes inaccessible using Feature Store APIs.

> **Important**
>
> TTL typically deletes expired items within a few days. Depending on the size and activity level of a table, the actual delete operation of an expired item can vary. Because TTL is meant to be a background process, the nature of the capacity used to expire and delete items via TTL is variable (but free of charge). For more information on how items are deleted from a DynamoDB table, see How it works: DynamoDB Time to Live (TTL).

`TtlDuration` must be a dictionary containing a `Unit` and a `Value`, where the `Unit` must be a string with values "Seconds", "Minutes", "Hours", "Days", or "Weeks" and `Value` must be an integer greater than or equal to 1. `TtlDuration` can be applied while using the `CreateFeatureGroup`, `UpdateFeatureGroup`, and `PutRecord` APIs. See the request and response syntax in the SDK for Python (Boto3) documentation for `CreateFeatureGroup`, `UpdateFeatureGroup`, and `PutRecord` APIs.

- When `TtlDuration` is applied at a feature group level (using the `CreateFeatureGroup` or `UpdateFeatureGroup` APIs), the applied `TtlDuration` becomes the default `TtlDuration` for all records that are added to the feature group *from the point in time that the API is called*. When applying `TtlDuration` with the `UpdateFeatureGroup` API, this will *not* become the default `TtlDuration` for records that were created *before* the API is called.

  To remove the default `TtlDuration` from an existing feature group, use the `UpdateFeatureGroup` API and set the `TtlDuration` `Unit` and `Value` to `null`.
- When `TtlDuration` is applied at a record level (for example, using `PutRecord` API), the `TtlDuration` duration applies to that record and is used instead of the feature group level default `TtlDuration`.
- When `TtlDuration` is applied on a feature group level it may take a few minutes for `TtlDuration` to come into effect.
- If `TtlDuration` is used when there is no online store, you will receive a `Validation Exception (400)` error.

The following example code shows how to apply `TtlDuration` while updating a feature group, such that the records added to the feature group *after running the API* will by default expire four weeks after their event times.

```
import boto3

sagemaker_client = boto3.client("sagemaker")
feature_group_name = '<YOUR_FEATURE_GROUP_NAME>'

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    OnlineStoreConfig={
        TtlDuration:{
            Unit: "Weeks",
            Value: 4
        }
    }
)
```

You can use the `DescribeFeatureGroup` API to view the default `TtlDuration`.

To view the expiration times, `ExpiresAt` (in UTC time ISO-8601 format), while using the `GetRecord` or `BatchGetRecord` APIs you must set `ExpirationTimeResponse` to `ENABLED`.

See the request and response syntax in the SDK for Python (Boto3) documentation for `DescribeFeatureGroup`, `GetRecord`, and `BatchGetRecord` APIs.

Cross account feature group discoverability and access

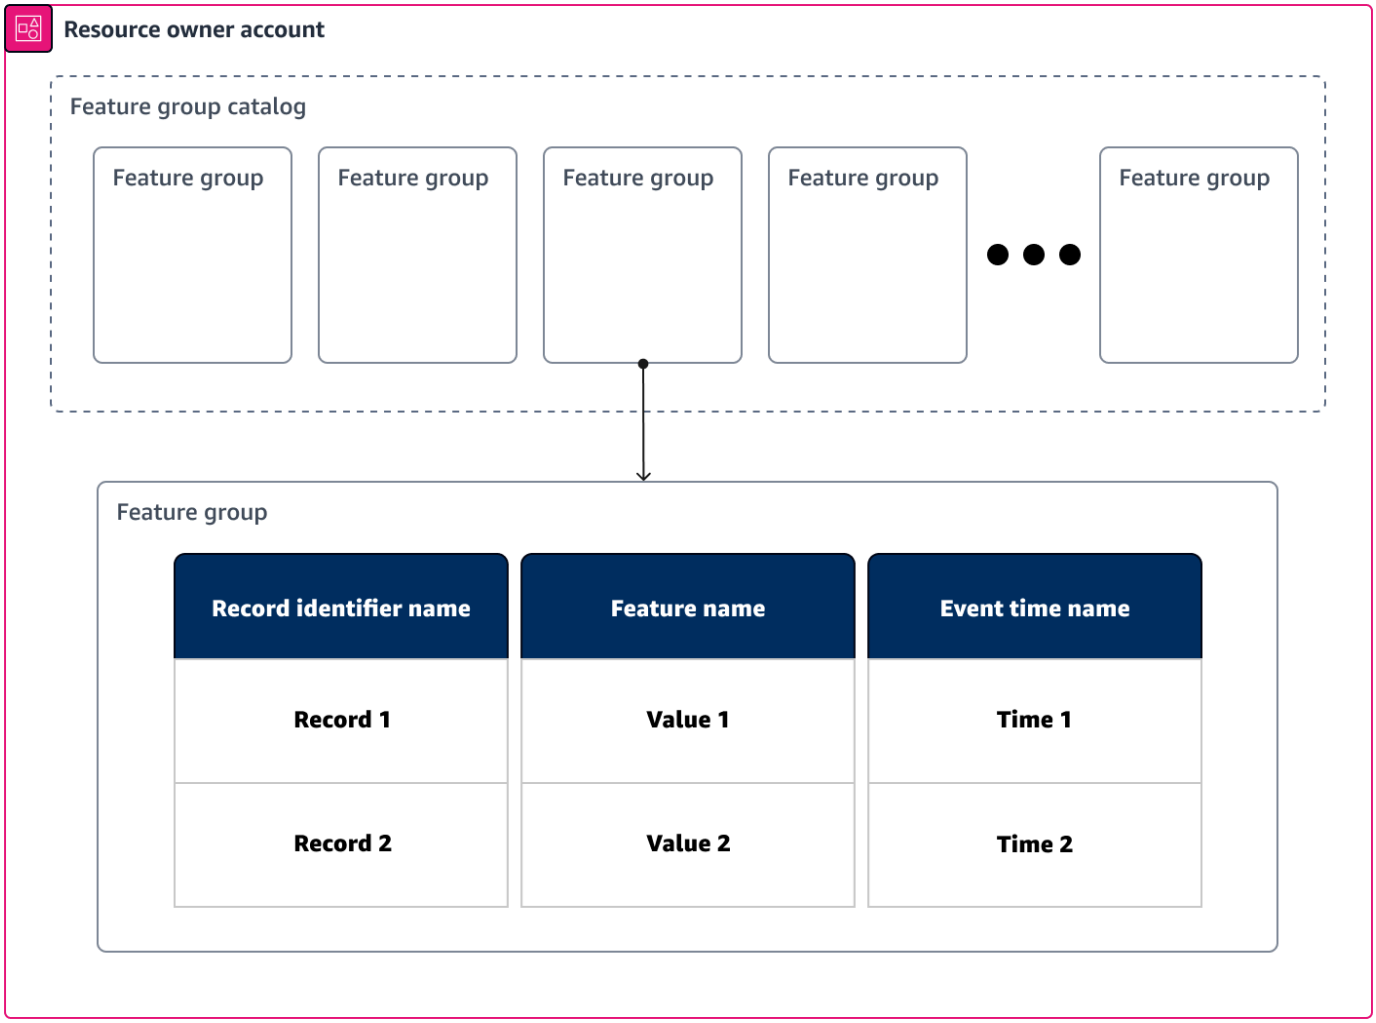
Data scientists and data engineers can benefit from exploring and accessing features that span multiple accounts, in order to promote data consistency, streamline collaboration, and reduce duplication of effort.

With Amazon SageMaker Feature Store, you can share feature group resources across accounts. The resources that can be shared in Feature Store are feature group entities or the feature group catalog, where the feature group catalog contains all of the feature group entities on your account. The resource owner account shares resources with the resource consumer accounts. There are two distinct categories of permissions associated with sharing resources:

- **Discoverability permission**: *Discoverability* means being able to see feature group names and metadata. When you share the feature group catalog and grant the discoverability permission, all feature group entities in the account that you share from (resource owner account) become discoverable by the accounts that you are sharing with (resource consumer account). For example, if you make the feature group catalog in the resource owner account discoverable to a resource consumer account, then principals of the resource consumer account can see all feature groups contained in the resource owner account. It means discoverability is “all or nothing” at the account level (regionalized). This permission is granted to resource consumer accounts by using the feature group catalog resource type.
- **Access permissions**: When you grant an access permission, you do so at a feature group resource level (not at account level). This gives you more granular control over granting access to data. The type of access permissions that can be granted are: read-only, read-write, and admin. For example, you can select only certain feature groups from the resource owner account to be accessible by principals of the resource consumer account, depending on your business needs. This permission is granted to resource consumer accounts by using the feature group resource type and specifying feature group entities.

The distinction between discoverability and access is important to keep in mind when you set up cross account sharing. Also, the methods of sharing resources differ depending on whether you are sharing online or offline feature groups. For information about online and offline feature groups, see Feature Store concepts. In the following topics, you can learn how to apply discoverability and access permissions to your shared resources.

The following example diagram visualizes the feature group catalog resource versus a feature group resource entity. The feature group catalog contains *all* of your feature group entities and can be shared using the discoverability permission. When granted a discoverability permission, the resource consumer account can search and discover *all* feature group entities within the resource owner account. A feature group entity contains your machine learning data and can be shared using the access permission. When granted an access permission, the resource consumer account can access the feature group data, with access determined by the relevant access permission.



Topics

- Enabling cross account discoverability
- Enabling cross account access

Enabling cross account discoverability

With AWS Resource Access Manager (AWS RAM) you can securely share the feature group catalog, which contains all of your feature group and feature resources, with other AWS accounts. This lets members of your team search and discover feature groups and features that span multiple accounts, promoting data consistency, streamlining collaboration, and reducing duplication of effort.

The resource owner account can share resources with other individual AWS accounts by granting permissions using AWS RAM. The resource consumer account is the AWS account with whom a resource is shared, limited by the permissions granted from the resource owner account. If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or in an Organization Unit (OU), without having to apply permissions to each account. For instructional videos and more information about AWS RAM concepts and benefits, see What is AWS Resource Access Manager? in the AWS RAM User Guide.

This section covers how the resource owner account can choose the feature group catalog and grant discoverability privilege to resource consumer accounts, and then how the resource consumer accounts with the discoverability privilege can use search and discover the feature groups within the resource owner account. The discoverability permission does not grant access permissions (read-only, read-write, or admin). Access permissions are granted at a resource level and not at the account level. For information about granting access permissions, see Enabling cross account access.

The following topics discuss how to share the feature group catalog and how to search for shared resources with discoverability permissions applied.

Topics

- Share your feature group catalog
- Search discoverable resources

Share your feature group catalog

The feature group catalog, `DefaultFeatureGroupCatalog`, contains *all* feature group entities owned by the resource owner account. The catalog can be shared by the resource owner account to grant discoverability to a single or multiple resource consumer accounts, by creating a resource

share in AWS Resource Access Manager (AWS RAM). A feature group is the main resource in Amazon SageMaker Feature Store and is composed of feature definitions and records that are managed by Feature Store. For more information about feature groups, see Feature Store concepts.

Discoverability means that the resource consumer accounts can search for the discoverable resources and view them as if they were in their own account (excluding tags). When allowing the feature group catalog to be discoverable, the resource consumer accounts by default are not granted access permissions (read-only, read-write, or admin). Access permissions are granted at a resource level and not at the account level. For information about granting access permissions, see Enabling cross account access.

In order to enable cross account discoverability you will need to specify the SageMaker Resource Catalog and the feature group catalog while using the AWS RAM Create a resources share instructions in the AWS RAM developer guide. In the following we give the specifications for using the AWS RAM console instructions.

1. **Specify resource share details**:

   - Resource type: Choose **SageMaker Resource Catalogs**.
   - ARN: Choose the feature group catalog ARN with the format: `arn:aws:sagemaker:`*`us-east-1`*`:`*`111122223333`*`:sagemaker-catalog/DefaultFeatureGroupCatalog`

     `us-east-1` is the region of the resource and *`111122223333`* is the resource owner account ID.
   - Resource ID: Choose `DefaultFeatureGroupCatalog`.
2. **Associate managed permissions**:

   - Managed permission: Choose `AWSRAMPermissionSageMakerCatalogResourceSearch`.
3. **Grant access to principals**:

   - Choose the principal types (AWS account, Organization, or Organizational unit) and enter the appropriate ID.

     If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or with an Organization Unit (OU), without having to apply permissions to each account. For more information about sharing your resources and granting permissions within AWS, see Enable resource sharing within AWS Organizations in the AWS Resource Access Manager Developer Guide.

4. **Review and create**:

   - Review then choose **Create resource share**.

It may take a few minutes for the resource share and principal, or resource consumer account, associations to complete. Once the resource share and principal associations are set, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer accounts can view and accept the invitations by opening the Shared with me: Resource shares page in the AWS RAM console. For more information on accepting and viewing resources in AWS RAM, see Access AWS resources shared with you. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share, see Search discoverable resources.

Share the feature group catalog using the AWS SDK for Python (Boto3)

You can use the AWS SDK for Python (Boto3) for AWS RAM APIs to create a resource share. The following code is an example of a resource owner account ID *111122223333* within the region *us-east-1* creating a resource share named *test-cross-account-catalog*, sharing the feature group catalog with the resource consumer account ID *444455556666*. To use the Python SDK for AWS RAM APIs, attach the `AWSRAMPermissionSageMakerCatalogResourceSearch` policy with the execution role. See AWS RAM APIs for more details.

```
#Call list resource catalogs as a prerequisite for RAM share
sagemaker_client.list_resource_catalogs()

# Share DefaultFeatureGroupCatalog with other account
ram_client = boto3.client("ram")
response = ram_client.create_resource_share(
    name='test-cross-account-catalog', # Change to your custom resource share name
    resourceArns=[
        'arn:aws:sagemaker:us-east-1:111122223333:sagemaker-catalog/' +
 'DefaultFeatureGroupCatalog', # Change 111122223333 to the resource owner account ID
```

```
    ],
    principals=[
        '444455556666', # Change 444455556666 to the resource consumer account ID
    ],
    permissionArns = ["arn:aws:ram::aws:permission/
AWSRAMPermissionSageMakerCatalogResourceSearch"] #
 AWSRAMPermissionSageMakerCatalogResourceSearch is the only policy allowed for
 SageMaker Catalog
)
```

Principals are actors in a security system. In a resource-based policy, the allowed principals are IAM users, IAM roles, the root account, or another AWS service.

Search discoverable resources

The resource owner account must grant permissions to resource consumer accounts to allow for discoverability or access (read-only, read-write, or admin) privileges with a shared resource. In the following sections, we provide instructions on how to accept an invitation to shared resources and examples showing how to search for discoverable feature groups.

Accept an invitation to shared resources

As the resource consumer account, you receive an invitation to join a resource share once the resource owner account has granted permission. To accept the invitation to any shared resources, open the Shared with me: Resource shares page in the AWS RAM console to view and respond to invitations. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Respond to the resource share invitation.

Search discoverable feature groups example

Once resources are shared with a resource consumer account with the discoverability permission applied, the resource consumer account can search for and discover the shared resources in

Amazon SageMaker Feature Store using the console UI and the Feature Store SDK. Note that you cannot search on tags for cross account resources. The maximum number of feature group catalogs viewable is 1000. For more information about granting discoverability permissions, see Enabling cross account discoverability.

For details about viewing shared feature groups in the console, see Find feature groups in your Feature Store.

In the following example, the resource consumer account uses SageMaker search to search for resources made discoverable to them when `CrossAccountFilterOption` is set to `"CrossAccount"`:

```
from sagemaker.session import Session

sagemaker_session = Session(boto_session=boto_session)

sagemaker_session.search(
    resource="FeatureGroup",
    search_expression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Value": "MyFeatureGroup",
                "Operator": "Contains",
            }
        ],
        "Operator": "And",
    },
    sort_by="Name",
    sort_order="Ascending",
    next_token="token",
    max_results=50,
    CrossAccountFilterOption="CrossAccount"
)
```

For more information about SageMaker search and the request parameters, see Search in the Amazon SageMaker API Reference.

Enabling cross account access

The access permissions are read-only, read-write, and admin permissions. The permission name, description, and list of specific APIs available for each permission are listed in the following:

- Read-only permission (`AWSRAMPermissionFeatureGroupReadOnly`): The read privilege allows resource consumer accounts to read records in the shared feature groups and view details and metadata.
  - `DescribeFeatureGroup`: Retrieves details about a feature group and its configuration
  - `DescribeFeatureMetadata`: Shows the metadata for a feature within a feature group
  - `BatchGetRecord`: Retrieves a batch of records from a feature group
  - `GetRecord`: Retrieves a record from a feature group
- Read-write permission (`AWSRAMPermissionSagemakerFeatureGroupReadWrite`): The read-write privilege allows resource consumer accounts to write records to, and delete records from, the shared feature groups, in addition to read permissions.
  - `PutRecord`: Writes a record to a feature group
  - `DeleteRecord`: Removes a record from a feature group
  - APIs listed in `AWSRAMPermissionFeatureGroupReadOnly`
- Admin permission (`AWSRAMPermissionSagemakerFeatureGroupAdmin`): The admin privilege allows the resource consumer accounts to update the description and parameters of features within the shared feature groups, update the configuration of the shared feature groups, in addition to read-write permissions.
  - `DescribeFeatureMetadata`: Shows the metadata for a feature within a feature group
  - `UpdateFeatureGroup`: Updates a feature group configuration
  - `UpdateFeatureMetadata`: Updates description and parameters of a feature in the feature group
  - APIs listed in `AWSRAMPermissionSagemakerFeatureGroupReadWrite`

In the following topics you can learn how to share online store and offline feature groups—there are differences between the two when it comes to sharing.

Topics

- Share online feature groups with AWS Resource Access Manager
- Cross account offline store access

Share online feature groups with AWS Resource Access Manager

With AWS Resource Access Manager (AWS RAM) you can securely share Amazon SageMaker Feature Store online feature groups with other AWS accounts. Members of your team can explore and access feature groups that span multiple accounts, promoting data consistency, streamlining collaboration, and reducing duplication of effort.

The resource owner account can share resources with other individual AWS accounts by granting permissions using AWS RAM. The resource consumer account is the AWS account with whom a resource is shared, limited by the permissions granted from the resource owner account. If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or in an Organization Unit (OU), without having to apply permissions to each account. For instructional videos and more information about AWS RAM concepts and benefits, see What is AWS Resource Access Manager? in the AWS RAM User Guide.

Note that there is a soft maximum limit to the transactions per second (TPS) per API per AWS account. The maximum TPS limit applies to *all* transactions on the resources within the resource owner account, so transactions from the resource consumer accounts also count towards this maximum limit. For information about service quotas and how to request a quota increase, see AWS service quotas.

This section covers how the resource owner account can choose feature groups and grant access privileges (read-only, read-write, and admin) to resource consumer accounts, and then how the resource consumer accounts with access privileges can use those feature groups. The access permissions do not allow for the resource consumer accounts to search and discover feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability.

The following topics show how to share Feature Store online store resources using the AWS RAM console. For information about sharing your resources and granting permissions within AWS using the AWS RAM console or AWS Command Line Interface (AWS CLI), see Sharing your AWS resources.

Topics

- Share your feature group entities
- Use online store shared resources with access permissions

Share your feature group entities

As the resource owner account you can use the feature group resource type for Amazon SageMaker Feature Store to share feature group entities, by creating a resource share in AWS Resource Access Manager (AWS RAM).

Use the following instructions along with the Sharing your AWS resources instructions in the AWS RAM User Guide.

When sharing the feature group resource type using the AWS RAM console, you need to make the following choices.

1. **Specify resource share details**:
   - Resource type: Choose **SageMaker Feature Groups**.
   - ARN: Choose your feature group ARN with the format: `arn:aws:sagemaker:us-east-1:111122223333:feature-group/`*`your-feature-group-name`*.

     `us-east-1` is the region of the resource, `111122223333` is the resource owner account ID, and *`your-feature-group-name`* is the feature group you are sharing.
   - Resource ID: Choose the feature group, *`your-feature-group-name`*, to which you want to grant access permissions.
2. **Associate managed permissions**:
   - Managed permission: Choose the access permission. For more information about access permissions, see Enabling cross account access.
3. **Grant access to principals**:
   - Choose the principal type (AWS account, Organization, Organizational unit, IAM role, or IAM user) and enter the appropriate ID or ARN.
4. **Review and create**:
   - Review then choose **Create resource share**.

Granting any access permission does not grant resource consumer accounts the discoverability permission, so the resource consumer accounts with access permissions cannot search and discover those feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant the

discoverability permission to the resource consumer accounts, where *all* of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability.

If the resource consumer accounts are only granted access permissions, the feature group entities can still be viewed on AWS RAM. To view resources on AWS RAM, see Access AWS resources shared with you in the AWS RAM User Guide.

It may take a few minutes for the resource share and principal, or resource consumer account, associations to complete. Once the resource share and principal associations are set, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer accounts can view and accept the invitations by opening the Shared with me: Resource shares page in the AWS RAM console. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Using shared AWS resources in the AWS RAM User Guide.

Share online store feature groups using the AWS SDK for Python (Boto3)

You can use the AWS SDK for Python (Boto3) for AWS RAM APIs to create a resource share. The following code is an example of a resource owner account ID `111122223333` creating a resource share named `'test-cross-account-fg'`, sharing the feature group named `'my-feature-group'` with the resource consumer account ID `444455556666` while granting the `AWSRAMPermissionSageMakerFeatureGroupReadOnly` permission. For more information about access permissions, see Enabling cross account access. To use the Python SDK for AWS RAM APIs, you need to attach AWS RAM full access managed policy with execution role. See create_resource_share AWS RAM API for more details.

```
import boto3

# Choose feature group name
feature_group_name = 'my-feature-group' # Change to your feature group name
```

```
# Share 'my-feature-group' with other account
ram_client = boto3.client("ram")
response = ram_client.create_resource_share(
    name='test-cross-account-fg', # Change to your custom resource share name
    resourceArns=[
        'arn:aws:sagemaker:us-east-1:111122223333:feature-group/' + feature_group_name,
 # Change 111122223333 to the resource owner account ID
    ],
    principals=[
        '444455556666', # Change 444455556666 to the resource consumer account ID
    ],
    permissionArns = ["arn:aws:ram::aws:permission/
AWSRAMPermissionSageMakerFeatureGroupReadOnly"]
)
```

Principals are actors in a security system. In a resource-based policy, the allowed principals are IAM users, IAM roles, the root account, or another AWS service.

Use online store shared resources with access permissions

The resource owner account must grant permissions to resource consumer accounts to allow for discoverability, read-only, write, or admin privileges with a shared resource. In the following sections, we provide instructions on how to accept an invitation to access shared resources and provide examples showing how to view and interact with shared feature groups.

Accept an invitation to access shared resources using AWS RAM

As the resource consumer account, you will receive an invitation to join a resource share once the resource owner account has granted permission. To accept the invitation to any shared resources, open the Shared with me: Resource shares page in the AWS RAM console to view and respond to invitations. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Using shared AWS resources in the AWS RAM User Guide.

View shared resources on the AWS RAM console

Granting any access permissions does not grant resource consumer accounts the discoverability permission, so the resource consumer accounts with access permissions cannot search and discover those feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant the discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability.

To view the shared resources on the AWS RAM console, open the Shared with me: Resource shares page in the AWS RAM console.

Read and write actions with a shared feature groups example

Once your resource consumer account is granted the appropriate permissions by the resource owner account, you can perform actions on the shared resources using the Feature Store SDK. You can do this by providing the resource ARN as the `FeatureGroupName`. To obtain the Feature Group ARN, you can use the AWS SDK for Python (Boto3) `DescribeFeatureGroup` function or use the console UI. For information about using the console UI to view feature group details, see View feature group details from the console.

The following examples use `PutRecord` and `GetRecord` with a shared feature group entity. See the request and response syntax in the AWS SDK for Python (Boto3) documentation for `PutRecord` and `GetRecordAPIs`.

```
import boto3

sagemaker_featurestore_runtime = boto3.client('sagemaker-featurestore-runtime')

# Put record into feature group named 'test-fg' within the resource owner account ID
 111122223333
featurestore_runtime.put_record(
    FeatureGroupName="arn:aws:sagemaker:us-east-1:111122223333:feature-group/test-fg",
    Record=[value.to_dict() for value in record] # You will need to define record prior
 to calling PutRecord
)
```

```
import boto3
```

```
sagemaker_featurestore_runtime = boto3.client('sagemaker-featurestore-runtime')

# Choose record identifier
record_identifier_value = str(2990130)

# Get record from feature group named 'test-fg' within the resource owner account ID
 111122223333
featurestore_runtime.get_record(
    FeatureGroupName="arn:aws:sagemaker:us-east-1:111122223333:feature-group/test-fg",
    RecordIdentifierValueAsString=record_identifier_value
)
```

For more information about granting permissions to feature group entities, see Share your feature group entities.

Cross account offline store access

Amazon SageMaker Feature Store allows users to create a feature group in one account (Account A) and configure it with an offline store using an Amazon S3 bucket in another account (Account B). You can set this up using the steps in the following section.

Topics

- Step 1: Set up the offline store access role in Account A
- Step 2: Set up an offline store Amazon S3 bucket in Account B
- Step 3: Set up an offline store AWS KMS encryption key in Account A
- Step 4: Create a feature group in Account A

Step 1: Set up the offline store access role in Account A

First, set up a role for Amazon SageMaker Feature Store to write the data into the offline store. The simplest way to accomplish this is to create a new role using the `AmazonSageMakerFeatureStoreAccess` policy or to use an existing role that already has the `AmazonSageMakerFeatureStoreAccess` policy attached. This document refers to this policy as `Account-A-Offline-Feature-Store-Role-ARN`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::*SageMaker*",
                "arn:aws:s3:::*Sagemaker*",
                "arn:aws:s3:::*sagemaker*"
            ]
        }
    ]
}
```

The preceding code snippet shows the `AmazonSageMakerFeatureStoreAccess` policy. The `Resource` section of the policy is scoped down by default to S3 buckets with names that contain `SageMaker`, `Sagemaker`, or `sagemaker`. This means the offline store Amazon S3 bucket being used must follow this naming convention. If this is not your case, or if you want to further scope down the resource, you can copy and paste the policy to your Amazon S3 bucket policy in the console, customize the `Resource` section to be `arn:aws:s3:::your-offline-store-bucket-name`, and then attach to the role.

Additionally, this role must have AWS KMS permissions attached. At a minimum, it requires the `kms:GenerateDataKey` permission to be able to write to the offline store using your customer managed key. See Step 3 to learn about why a customer managed key is needed for the cross account scenario and how to set it up. The following example shows an inline policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:*:Account-A-Account-Id:key/*"
        }
    ]
}
```

The `Resource` section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

Step 2: Set up an offline store Amazon S3 bucket in Account B

Create an Amazon S3 bucket in Account B. If you are using the default `AmazonSageMakerFeatureStoreAccess` policy, the bucket name must include `SageMaker`, `Sagemaker`, or `sagemaker`. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as `Account-B-Offline-Feature-Store-Bucket`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3CrossAccountBucketAccess",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:GetBucketAcl"
            ],
            "Principal": {
                "AWS": [
                    "*Account-A-Offline-Feature-Store-Role-ARN*"
                ],
            },
            "Resource": [
                "arn:aws:s3:::offline-store-bucket-name/*",
                "arn:aws:s3:::offline-store-bucket-name"
            ]
        }
    ]
}
```

In the preceding policy, the principal is `Account-A-Offline-Feature-Store-Role-ARN`, which is the role created in Account A in Step 1 and provided to Amazon SageMaker Feature Store to write to the offline store. You can provide multiple ARN roles under `Principal`.

Step 3: Set up an offline store AWS KMS encryption key in Account A

Amazon SageMaker Feature Store ensures that server-side encryption is always enabled for Amazon S3 objects in the offline store. For cross account use cases, you must provide a customer managed key so that you are in control of who can write to the offline store (in this case, `Account-A-Offline-Feature-Store-Role-ARN` from Account A) and who can read from the offline store (in this case, identities from Account B).

This document refers to the following example key policy as `Account-A-Offline-Feature-Store-KMS-Key-ARN`.

```
{
    "Version": "2012-10-17",
    "Id": "key-consolepolicy-3",
    "Statement": [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::Account-A-Account-Id:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "Allow access for Key Administrators",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::Account-A-Account-Id:role/Administrator",
                ]
            },
            "Action": [
                "kms:Create*",
                "kms:Describe*",
                "kms:Enable*",
                "kms:List*",
                "kms:Put*",
                "kms:Update*",
                "kms:Revoke*",
                "kms:Disable*",
                "kms:Get*",
                "kms:Delete*",
```

```
                "kms:TagResource",
                "kms:UntagResource",
                "kms:ScheduleKeyDeletion",
                "kms:CancelKeyDeletion"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow Feature Store to get information about the customer managed
key",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": [
                "kms:Describe*",
                "kms:Get*",
                "kms:List*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "*Account-A-Offline-Feature-Store-Role-ARN*",
                    "*arn:aws:iam::Account-B-Account-Id:root*"
                ]
            },
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:DescribeKey",
                "kms:CreateGrant",
                "kms:RetireGrant",
                "kms:ReEncryptFrom",
                "kms:ReEncryptTo",
                "kms:GenerateDataKey",
                "kms:ListAliases",
                "kms:ListGrants"
            ],
            "Resource": "*",
        }
```

```
    ]
}
```

Step 4: Create a feature group in Account A

Next, create the feature group in Account A, with an offline store Amazon S3 bucket in Account B. To do this, provide the following parameters for `RoleArn`, `OfflineStoreConfig.S3StorageConfig.KmsKeyId`, and `OfflineStoreConfig.S3StorageConfig.S3Uri`, respectively:

- Provide `Account-A-Offline-Feature-Store-Role-ARN` as the `RoleArn`.
- Provide `Account-A-Offline-Feature-Store-KMS-Key-ARN` for `OfflineStoreConfig.S3StorageConfig.KmsKeyId`.
- Provide `Account-B-Offline-Feature-Store-Bucket` for `OfflineStoreConfig.S3StorageConfig.S3Uri`.

Feature Store storage configurations

Amazon SageMaker Feature Store consists of an online store and an offline store. The online store enables real-time lookup of features for inference, while the offline store contains historical data for model training and batch inference. When creating a feature group, you have the option of enabling either the online store, offline store, or both. When you enable both, they sync to avoid discrepancies between training and serving data. For more information about the online and offline stores and other Feature Store concepts, see Feature Store concepts.

The following topics discuss online store storage types and offline store table formats.

Topics

Online store

The online store is a low-latency, high-availability data store that provides real-time lookup of features. It is typically used for machine learning (ML) model serving. You can chose between the standard online store (`Standard`) or an in-memory tier online store (`InMemory`), at the point when

you create a feature group. In this way, you can select the storage type that best matches the read and write patterns for a particular application, while considering performance and cost. For more details about pricing, see Amazon SageMaker Pricing.

The online store contains the following `StorageType` options. For more information about the online store contents, see `OnlineStoreConfig`.

Standard tier storage type

The `Standard` tier is a managed low-latency data store for online store feature groups. It provides fast data retrieval for ML model service for your applications. `Standard` is the default storage type.

In-memory tier storage type

The `InMemory` tier is a managed data store for online store feature groups that supports very low-latency retrieval. It provides large-scale real-time data retrieval for ML model serving used for high throughput applications. The `InMemory` tier is powered by Amazon ElastiCache for Redis. For more information, see What is Amazon ElastiCache for Redis?.

The online store `InMemory` tier supports collection types, namely list, set, and vector. For more information about the `InMemory` collection types, see Collection types.

Feature Store provides low latency read and writes to the online store. The application latency is primarily made up of two primary components: infrastructure or network latency and Feature Store API latency. Reduction of network latency helps with getting the lowest latency reads and writes to Feature Store. You can reduce the network latency to Feature Store by deploying AWS PrivateLink to Feature Store Runtime endpoint. With AWS PrivateLink, you can privately access all Feature Store Runtime API operations from your Amazon Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An AWS PrivateLink deployment with the `privateDNSEnabled` option set as true:

- It keeps all Feature Store read/write traffic within your VPC.
- It keeps traffic in the same AZ as the client that originated it when using Feature Store. This avoids the “hops” between AZs reducing the network latency.

Follow the steps in Access an AWS service using an interface VPC endpoint to setup AWS PrivateLink to Feature Store. The service name for Feature Store Runtime in AWS PrivateLink is `com.amazonaws.region.sagemaker.featurestore-runtime`.

The `InMemory` tier online store scales automatically based about storage usage and requests. The automated scaling can take a few minutes to adapt to a new usage pattern if it changes rapidly. During automated scaling:

- Write operations to the feature group may receive throttling errors. You should retry your requests a few minutes later.
- Read operations to the feature group may receive throttling errors. Standard retry strategies are suitable in this case.
- Read operations may see elevated latency.

The default `InMemory` tier feature group maximum size is 50 GiB.

Note that the `InMemory` tier currently supports online feature groups only, not online+offline feature groups, so there is not replication between online and offline stores for the `InMemory` tier. Also, the `InMemory` tier does not currently support customer managed KMS keys.

Offline store

The offline store is used for historical data when sub-second retrieval is not needed. It is typically used for data exploration, model training, and batch inference.

When you enable both the online and offline stores for your feature group, both stores sync to avoid discrepancies between training and serving data. Please note that an online store feature group with the `InMemory` storage type enabled does not currently support a corresponding feature group in the offline store (no online to offline replication). For more information about ML model serving in Amazon SageMaker Feature Store, see Online store.

The offline store contains the following `TableFormat` options. For information about the offline store contents, see `OfflineStoreConfig` in the Amazon SageMaker API Reference.

Glue table format

The `Glue` format (default) is a standard Hive type table format for AWS Glue. With AWS Glue, you can discover, prepare, move, and integrate data from multiple sources. It also includes additional productivity and data ops tooling for authoring, running jobs, and implementing business workflows. For more information about AWS Glue, see What is AWS Glue?.

Iceberg table format

The `Iceberg` format (recommended) is an open table format for very large analytic tables. With `Iceberg`, you can compact the small data files into fewer large files in the partition, resulting in significantly faster queries. This compaction operation is concurrent and does not affect ongoing read and write operations on the feature group. For more information about optimizing Iceberg tables, see the Amazon Athena and AWS Lake Formation user guides.

`Iceberg` manages large collections of files as tables and supports modern analytical data lake operations. If you choose the `Iceberg` option when creating new feature groups, Amazon SageMaker Feature Store creates the `Iceberg` tables using Parquet file format, and registers the tables with the AWS Glue Data Catalog. For more information about `Iceberg` table formats, see Using Apache Iceberg tables.

> **Important**
>
> Note that for feature groups in `Iceberg` table format, you must specify `String` as the feature type for the event time. If you specify any other type, you can't create the feature group successfully.

Throughput modes

Amazon SageMaker Feature Store provides two pricing models to choose from: on-demand (`On-demand`) and provisioned (`Provisioned`) throughput modes. `On-demand` works best for less predictable traffic, while `Provisioned` works best for consistent and predictable traffic.

You have the option to switch between `On-demand` and `Provisioned` throughput modes for a given feature group, to accommodate periods in which application traffic patterns are changing or less predictable. You can only update your feature group throughput mode to `On-demand` once in a 24 hour period. The throughput mode can be updated programmatically using the UpdateFeatureGroup API or through the console UI. For more information about using the console, see Using Amazon SageMaker Feature Store in the console.

You can use the `Provisioned` throughput mode with offline-only feature groups or feature groups with the `Standard` storage type. For other storage configurations, the `On-demand` throughput mode is used. For information about the online and offline storage configurations, see Online store and Offline store, respectively.

For more details about pricing, see Amazon SageMaker Pricing.

Topics

On-demand throughput mode

The `On-demand` (default) throughput mode works best when you are using feature groups with unknown workload, unpredictable application traffic, and you cannot forecast the capacity requirements.

The `On-demand` mode charges you for the reads and writes that your application performs on your feature groups. You do not need to specify how much read and write throughput you expect your application to perform because Feature Store instantly accommodates your workloads as they ramp up or down. You pay only for what you use, which is measured in `ReadRequestsUnits` and `WriteRequestsUnits`.

You can enable the `On-demand` throughput mode using the CreateFeatureGroup or UpdateFeatureGroup APIs or through the console UI. For more information about using the console UI, see Using Amazon SageMaker Feature Store in the console.

> **Important**
>
> You can only update your feature group throughput mode to `On-demand` once in a 24 hour period.

Provisioned throughput mode

The `Provisioned` throughput mode works best when you are using feature groups with predictable workloads and you can forecast the capacity requirements to control costs. This can make it more cost effective for certain workloads where you can anticipate throughput requirements in advance.

When you set a feature group to `Provisioned` mode, you specify capacity units which are the maximum amount of capacity that an application can consume from a feature group. If your application exceeds this `Provisioned` throughput capacity, it is subject to request throttling.

The following includes information about the read and write capacity units.

- Retrieving a single record of up to 4 KB using the `GetRecord` API will consume *at least* 1 RCU (read capacity unit). Retrieving larger payloads may take more. The total number of read capacity units required depends on the item size, including a small per record metadata added by the Feature Store service.
- A single write request with a payload of 1 KB using the `PutRecord` API will consume *at least* 1 WCU (write capacity unit), with fractional payloads rounded up to nearest KB. It may consume more depending on the event time, deletion status of the record, and time to live (TTL) status. For more information about TTL, see Time to live (TTL) duration for records.

Important

When setting your capacity units please consider the following:

- You will be charged for the read and write capacities you provision for your feature group, even if you do not fully utilize the `Provisioned` capacity.
- If you set a read or write capacity too low, your requests may experience throttling.
- In some cases, records may consume an extra capacity unit due to record level metadata that is added by the Feature Store service to enable various features.
- Retrieving only a subset of features using `GetRecord` or `BatchGetRecord` APIs will still consume RCU corresponding to the entire record.
- For write capacity, you should provision 2x the recent peak capacity to avoid throttling when performing backfills or bulk ingestion that may result in a large number of historical record writes. This is because writing historical records consumes additional write capacity.
- Feature Store does not currently support auto scaling for `Provisioned` mode.

You can enable the `On-demand` throughput mode using the CreateFeatureGroup or UpdateFeatureGroup APIs or through the console UI. For more information about using the console UI, see Using Amazon SageMaker Feature Store in the console.

The following describes how you can increase or decrease the RCU and WCU throughput for your feature groups when `Provisioned` mode is enabled.

Increasing provisioned throughput

You can increase RCU or WCU as often as needed using the UpdateFeatureGroup API or the console UI.

Decreasing provisioned throughput

You can decrease RCU and WCU (or both) for feature groups using UpdateFeatureGroup API or the console UI.

There is a default quota on the number of `Provisioned` capacity decreases you can perform on your feature group per day. A day is defined according to Universal Time Coordinated (UTC). On a given day, you can start by performing up to four decreases within one hour as long as you have not performed any other decreases yet during that day. Subsequently, you can perform one additional decrease per hour as long as there were no decreases in the preceding hour. This effectively brings the maximum number of decreases in a day to 27 times (4 decreases in the first hour, and 1 decrease for each of the subsequent 1-hour windows in a day).

Throughput mode metrics

A feature group in `On-demand` mode will emit `ConsumedReadRequestsUnits` and `ConsumedWriteRequestsUnits` metrics. A feature group in `Provisioned` mode will emit `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` metrics. For more information about Feature Store metrics, see Amazon SageMaker Feature Store Metrics.

Throughput mode limits

Each AWS account has default service quotas or limits that are applied to help ensure availability and manage billing risks. For information about the default quotas and limits, see Quotas, naming rules and data types.

In some cases, these limits may be lower than what is stated in the documentation. If you need higher limits, you can submit a request for an increase. It's a good idea to do so before reaching current limits to avoid interruptions to your work. For information about service quotas and how to request a quota increase, see AWS service quotas.

Collection types

Collection types provide a way to organize and structure data for efficient retrieval and analysis. They are used in ML databases to define the schema of a dataset and its elements. In Amazon SageMaker Feature Store, the supported collection types include list, set, and vector.

Collections are a grouping of elements in which each element within the collection must have the same feature type (`String`, `Integral`, or `Fractional`). For example, a collection can contain elements with all of the element feature types as `Fractional`, but a collection cannot contain elements with some feature types as `Fractional` and some feature types as `String`.

Only `InMemory` online store feature groups currently support collection types. The following list describes the collection type options.

List: An ordered collection of elements.

- The length of the list is determined by how many elements are in the collection.
- Example: You can have a list such as [‘a’, ‘b’, ‘a’], because the list preserves the order and can have repeat elements.

Set: An unordered collection of unique elements.

- The length of the set is determined by how many unique elements are in the collection.
- Example: You cannot have a set such as [‘a’, 'b', 'a'], because it contains a repeat element. The set will instead have the elements [‘a’, ‘b’], because the set only contains unique elements.

Vector: A specialized list that represents a fixed-size array of elements. The order of the elements hold significance, such that the positions of the elements represent certain properties of the data.

- The elements in the vector collection type *must* have the `Fractional` feature type.
- You may only have one vector collection type per online store `InMemory` tier feature group.
- The dimension (number of elements in the vector) of the vector is predetermined by you and is specified using `VectorDimension`. The max dimension limit is 8192.
- Example: You can have a vector such as [4.2, -6.3, 4.2], where the first, second, and third elements can represent the x, y, and z positions in physical space.

There are no limits on the length of the collections, as long as they don't exceed the maximum size of a record. For the maximum size of a record, see Quotas, naming rules and data types.

Add features and records to a feature group

You can use the Amazon SageMaker Feature Store API or the console to update and describe your feature group as well as add features and records to your feature group. A feature group is an object that contains your data and a feature describes a column in the table. When you add a feature to the feature group you are effectively adding a column to the table. When you add a new record to the feature group you are filling in values for features associated with a specific record identifier. For more information on Feature Store concepts, see Feature Store concepts.

After you successfully add features to a feature group, you cannot remove those features. The features that you have added do not add any data to your records. You can add new records to the feature group or overwrite them using the PutRecord API. For examples on updating, describing, and putting records into a feature group, see Example code.

You can use the console to add features to a feature group. For more information on how to update your feature groups using the console, see Update a feature group from the console.

The following sections provide an overview of using Feature Store APIs to add features to a feature group followed by examples. With the API, you can also add or overwrite records after you've updated the feature group.

Topics

- API
- Example code

API

Use the `UpdateFeatureGroup` operation to add features to a feature group.

You can use the `DescribeFeatureGroup` operation to see if you've added the features successfully.

To add or overwrite records, use the `PutRecord` operation.

To see the updates that you've made to a record, use the `GetRecord` operation. To see the updates that you've made to multiple records, use the `BatchGetRecord` operation. It can take up to five minutes for the updates that you've made to appear.

You can use the example code in the following section to walk through adding features and records using the AWS SDK for Python (Boto3).

Example code

The example code walks you through the following process:

1. Adding features to the feature group
2. Verifying that you've added them successfully
3. Adding a record to the feature group
4. Verifying that you've added it successfully

Step 1: Add features to a feature group

The following code uses the `UpdateFeatureGroup` operation to add new features to the feature group. It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see Introduction to Feature Store example notebook.

```
import boto3

sagemaker_client = boto3.client("sagemaker")

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    FeatureAdditions=[
        {"FeatureName": "new-feature-1", "FeatureType": "Integral"},
        {"FeatureName": "new-feature-2", "FeatureType": "Fractional"},
        {"FeatureName": "new-feature-3", "FeatureType": "String"}
    ]
)
```

The following code uses the `DescribeFeatureGroup` operation to check the status of the update. If the `LastUpdateStatus` field is `Successful`, you've added the features successfully.

```
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

Step 2: Add a new record to the feature group

The following code uses the PutRecord operation to add records to the feature group that you've created.

```
record_identifier_value = 'new_record'

sagemaker_featurestore_runtime_client = boto3.client("sagemaker-featurestore-runtime")

sagemaker_runtime_client.put_record(
    FeatureGroupName=feature_group_name,
    Record=[
        {
            'FeatureName': "record-identifier-feature-name",
            'ValueAsString': record_identifier_value
        },
        {
            'FeatureName': "event-time-feature",
            'ValueAsString': "timestamp-that-feature-store-returns"
        },
        {
            'FeatureName': "new-feature-1",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-2",
            'ValueAsString': "value-as-string"
        },
        {
            'FeatureName': "new-feature-3",
            'ValueAsString': "value-as-string"
        },
    ]
)
```

Use the GetRecord operation to see which records in your feature group don't have data for the features that you've added. You can use the PutRecord operation to overwrite the records that don't have data for the features that you've added.

Find features in your feature groups

With Amazon SageMaker Feature Store, you can search for the features that you created in your feature groups. You can search through all of your features without needing to select a feature group first. The search functionality helps find the features that are relevant to your use case.

> **Note**
>
> The feature groups where you're searching for features must be within your AWS Region and AWS account. For shared feature groups, the feature groups must be made discoverable to your AWS account. For more instructions on how to share the feature group catalog and grant discoverability, see Share your feature group catalog.

If you're on a team, and teammates are looking for features to use in their models, they can search through the features in all of the feature groups.

You can add searchable parameters and descriptions to make your features more discoverable. For more information, see Adding searchable metadata to your features.

You can search for features using either the console or by using the Search API operation in SageMaker. The following table lists all of the searchable metadata and whether you can search for it in the console or with the API.

Searchable metadata	API field name	Searchable in the console?
All Parameters	AllParameters	Yes
Creation time	CreationTime	Yes
Description	Description	Yes
Feature group name	FeatureGroupName	No
Feature name	FeatureName	Yes

Searchable metadata	API field name	Searchable in the console?
Feature type	FeatureType	No
Last modified time	LastModifiedTime	No
Parameters	Parameters.*key*	Yes

How to search for your features

The instructions for using Feature Store through the console depends on whether you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience. Choose one of the following instructions based on your use case.

Search for features if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
5. Under the **Feature Catalog** tab, choose **My account** to view your feature groups.
6. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
7. You can search for your feature in the **Search** dropdown list:

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features, specify time ranges, or clear (deselect) columns that you don't want to query.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.

Search for features if Studio Classic is your default experience (console)

Use the latest version of Amazon SageMaker Studio Classic so that you have the most recent version of the search functionality. For information about updating Studio Classic, see Shut down and Update SageMaker Studio Classic.

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
6. Under the **Feature Catalog** tab, choose **My account** to view your feature groups.
7. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
8. You can search for your feature in the **Search** dropdown list:

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features, specify time ranges, or clear (deselect) columns that you don't want to query.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.

Search for your features using SDK for Python (Boto3)

The code in this section uses the `Search` operation in the AWS SDK for Python (Boto3) to run the search query to find features in your feature groups. For information about the other languages to submit a query, see See Also in the *Amazon SageMaker API Reference*.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

The following code shows different example search queries using the API:

```
# Return all features in your feature groups
sagemaker_client.search(
    Resource="FeatureMetadata",
)

# Search for all features that belong to a feature group that contain the "ver"
 substring
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
        ]
    }
)

# Search for all features that belong to a feature group that have the EXACT name
 "airport"
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Equals',
                'Value': 'airport'
            },
        ]
    }
)

# Search for all features that belong to a feature group that contains the name "ver"
AND have a name that contains "wha"
AND have a parameter (key or value) that contains "hea"

sagemaker_client.search(
    Resource="FeatureMetadata",
```

```
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllParameters',
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ]
    }
)

# Search for all features that belong to a feature group with substring "ver" in its
 name
OR features that have a name that contain "wha"
OR features that have a parameter (key or value) that contains "hea"

sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllParameters',
                'Operator': 'Contains',
                'Value': 'hea'
```

```
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)

# Search for all features that belong to a feature group with substring "ver" in its
 name
OR features that have a name that contain "wha"
OR parameters with the value 'Sage' for the 'org' key

sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'Parameters.org',
                'Operator': 'Contains',
                'Value': 'Sage'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)
```

Find feature groups in your Feature Store

With Amazon SageMaker Feature Store, you can search for the feature groups using either the console or the Search operation. You can use the search functionality to find features and feature

groups that are relevant to the models that you're creating. You can use the search functionality to quickly find the feature groups that are relevant to your use case.

> **Note**
>
> The feature groups that you're searching for must be within your AWS Region and AWS account, or shared with and made discoverable to your AWS account. For more information about how to share the feature group catalog and grant discoverability, see Share your feature group catalog.

The following table shows the searchable fields and whether you can use the console to search for a specific field.

You can search for features using either Amazon SageMaker Studio Classic or the `Search` operation in the SageMaker API. The following table lists all of the searchable metadata and whether you can search for it in the console. Tags are searchable for your own feature groups but are not searchable for feature groups made discoverable to you.

Searchable metadata	API field name	Searchable in the console?	Searchable with cross account?
All Tags	AllTags	Yes	No
Creation Failure Reason	FailureReason	No	No
Creation Status	FeatureGroupStatus	Yes	Yes
Creation time	CreationTime	Yes	Yes
Description	Description	Yes	Yes
Event Time Feature Name	EventTimeFeatureName	No	No
Feature Definitions	FeatureDefinitions	No	No
Feature Group ARN	FeatureGroupARN	No	No

Searchable metadata	API field name	Searchable in the console?	Searchable with cross account?
Feature Group Name	FeatureGroupName	Yes	Yes
Offline Store Configuration	OfflineStoreConfig	No	No
Offline Store Status	OfflineStoreStatus	Yes	Yes
Last Update Status	LastUpdateStatus	No	No
Record Identfier Feature Name	RecordIdentifierFeatureName	Yes	Yes
Tags	Tags.key	Yes	No

How to find feature groups

You can use the console or the Amazon SageMaker Feature Store API to find your feature groups. The instructions for using Feature Store through the console depends on if you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Find feature groups if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
5. Under the **Feature Group Catalog** tab, choose **My account** to view your feature groups.
6. Under the **Feature Group Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
7. You can search for your feature groups in the **Search** dropdown list:

- (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your feature groups, you can specify time ranges, clear (deselect) columns that you don't want to query, choose stores to search, or search by status.
- For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, see Enabling cross account access.

Find feature groups if Studio Classic is your default experience (console)

Use the latest version of Amazon SageMaker Studio Classic to get the most recent version of the search functionality if you are accessing Feature Store through the Studio Classic application. For information about updating Studio Classic, see Shut down and Update SageMaker Studio Classic.

1. Open the Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. Choose the **Home** icon
   ()
   in the left navigation pane.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your feature groups, choose **My account**. To view shared feature groups, choose **Cross account**.
6. Under the **Feature Group Catalog** tab, choose **My account** to view your feature groups.
7. Under the **Feature Group Catalog** tab, choose **Cross account** to view feature groups that others made discoverable to you. Under **Created by**, you can view the resource owner account ID.
8. You can search for your feature groups in the **Search** dropdown list:

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your feature groups more easily, you can

specify time ranges, clear (deselect) columns that you don't want to query, choose stores to search, or search by status.

- For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. The discoverability permission alone won't allow you to edit metadata or feature definitions. For more information about granting access permissions, see Enabling cross account access.

Find feature groups using SDK for Python (Boto3)

The code in this section uses the `Search` operation in the AWS SDK for Python (Boto3) to run the search query to find feature groups. For information about the other languages to submit a query, see See Also in the *Amazon SageMaker API Reference*.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

The following code shows different example search queries using the API:

```
# Return all feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
)

# Search for feature groups that are shared with your account
sagemaker_session.search(
    resource="FeatureGroup",
    search_expression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Value": "MyFeatureGroup",
                "Operator": "Contains",
            }
        ],
        "Operator": "And",
    },
    sort_by="Name",
    sort_order="Ascending",
    next_token="token",
    max_results=50,
    CrossAccountFilterOption="SameAccount"
)
```

```
# Search for all feature groups with a name that contains the "ver" substring
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
        ]
    }
)

# Search for all feature groups that have the EXACT name "airport"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Equals',
                'Value': 'airport'
            },
        ]
    }
)

# Search for all feature groups that contains the name "ver"
# AND have a record identifier feature name that contains "wha"
# AND have a tag (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
```

```
            },
            {
                'Name': 'AllTags',
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ]
    }
)

# Search for all feature groups with substring "ver" in its name
# OR feature groups that have a record identifier feature name that contains "wha"
# OR feature groups that have a tag (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllTags',
                'Operator': 'Contains',
                'Value': 'hea'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)

# Search for all feature groups with substring "ver" in its name
# OR feature groups that have a record identifier feature name that contains "wha"
# OR tags with the value 'Sage' for the 'org' key
sagemaker_client.search(
    Resource="FeatureGroups",
```

```
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'Tags.org',
                'Operator': 'Contains',
                'Value': 'Sage'
            },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is
 "And"
    }
)

# Search for all offline only feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'NotEquals',
                'Value': 'true'
            },
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'Exists'
            }
        ]
    }
)

# Search for all online only feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
```

```
    SearchExpression={
        'Filters': [
            {
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'Equals',
                'Value': 'true'
            },
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'NotExists'
            }
        ]
    }
)

# Search for all feature groups that are BOTH online and offline
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'Equals',
                'Value': 'true'
            },
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'Exists'
            }
        ]
    }
)
```

You can also use python SDK of AWS RAM APIs to create resource share. The API signature is given below. To use python SDK of AWS RAM API, you need attach AWS RAM full access managed policy with execution Role.

```
response = client.create_resource_share(
    name='string',
    resourceArns=[
        'string',
    ],
```

```
    principals=[
        'string',
    ],
    tags=[
        {
            'key': 'string',
            'value': 'string'
        },
    ],
    allowExternalPrincipals=True|False,
    clientToken='string',
    permissionArns=[
        'string',
    ]
)
```

Adding searchable metadata to your features

In Amazon SageMaker Feature Store, you can search through all of your features. To make your features more discoverable, you can add metadata to them. You can add the following types of metadata:

- Description – A searchable description of the feature.
- Parameters – Searchable key-value pairs.

The description can have up to 255 characters. For parameters, you must specify a key-value pair in your search. You can add up to 25 parameters.

To update the metadata of a feature, you can use either the console or the `UpdateFeatureMetadata` operation.

How to add searchable metadata to your features

You can use the console or the Amazon SageMaker Feature Store API to add searchable metadata to your features. Instructions for using Feature Store through the console depend on whether you have enabled Amazon SageMaker Studio or Amazon SageMaker Studio Classic as your default experience.

Add searchable metadata to features if Studio is your default experience (console)

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Data** in the left navigation pane, to expand the dropdown list.
3. From the dropdown list, choose **Feature Store**.
4. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
5. To view your feature groups, under the **Feature Catalog** tab, choose **My account**.
6. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that others make discoverable to you. Under **Created by**, you can view the resource owner account ID of the feature group.
7. You can search for your feature in the **Search** dropdown list.
   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features more easily, you can specify time ranges or deselect columns that you don't want to query.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone doesn't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.
8. Choose your feature.
9. Choose **Edit metadata**.
10. In the **Description** field, add or update the description.
11. In the **Parameters** field under **Parameters**, specify a key-value pair for the parameter.
12. (Optional) Choose **Add new parameter** to add another parameter.
13. Choose **Save changes**.
14. Choose **Confirm**.

Add searchable metadata to your features if Studio Classic is your default experience (console)

1. Open the Studio Classic console by following the instructions in Launch Studio Classic Using the Amazon SageMaker Console.

2. In the left navigation pane, choose the **Home** icon
   ().
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. (Optional) To view your features, choose **My account**. To view shared features, choose **Cross account**.
6. To view your feature groups, under the **Feature Catalog** tab, choose **My account**.
7. Under the **Feature Catalog** tab, choose **Cross account** to view feature groups that other accounts made discoverable to you. Under **Created by**, you can view the resource owner account ID of the feature group.
8. You can search for your feature in the **Search** dropdown list.

   - (Optional) To filter your search, choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you search for a parameter, specify both its key and value. To find your features more easily, you can specify time ranges or deselect columns that you don't want to query.
   - For shared resources, you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone doesn't allow you to edit metadata or feature definitions. For more information about granting access permissions, seeEnabling cross account access.
9. Choose your feature.
10. Choose **Edit metadata**.
11. In the **Description** field, add or update the description.
12. In the **Parameters** field under **Parameters**, specify a key-value pair for the parameter.
13. (Optional) Choose **Add new parameter** to add another parameter.
14. Choose **Save changes**.
15. Choose **Confirm**.

Add searchable metadata to your features using SDK for Python (Boto3)

The code in this section uses the `UpdateFeatureMetadata` operation in the AWS SDK for Python (Boto3) to add searchable metadata to your features for different scenarios. For information about the other languages to submit a query, see See Also in the *Amazon SageMaker API Reference*.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

Add a list of parameters to a feature

To add a list of parameters to a feature, specify values for the following fields:

- `FeatureGroupName`
- `Feature`
- `Parameters`

The following example code uses the AWS SDK for Python (Boto3) to add two parameters.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterAdditions=[
        {"Key": "example-key-0", "Value": "example-value-0"},
        {"Key": "example-key-1", "Value": "example-value-1"},
    ]
)
```

Add a description to a feature

To add a description to a feature, specify values for the following fields:

- `FeatureGroupName`
- `Feature`
- `Description`

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="description"
)
```

Remove parameters for a feature

To remove all parameters for a feature, do the following.

Specify values for the following fields:

- `FeatureGroupName`
- `Feature`

Specify the keys for the parameters that you're removing under `ParameterRemovals`.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
        ParameterRemovals=[
        {"Key": "example-key-0"},
        {"Key": "example-key-1"},
    ]
)
```

Remove the description for a feature

To remove the description for a feature, do the following.

Specify values for the following fields:

- `FeatureGroupName`
- `Feature`

Specify an empty string for `Description`.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description=""
)
```

Example code

After you've updated the metadata for a feature, you can use the `DescribeFeatureMetadata` operation to see the updates that you've made.

The following code goes through an example workflow using the AWS SDK for Python (Boto3). The example code does the following:

1. Sets up your SageMaker environment.
2. Creates a feature group.
3. Adds features to the group.
4. Adds metadata to the features.

For more Feature Store examples and resources, see Amazon SageMaker Feature Store resources.

Step 1: Setup

To start using Feature Store, create SageMaker, boto3 and Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

> **Note**
>
> The role that you use must have the following managed policies attached to it: `AmazonS3FullAccess` and `AmazonSageMakerFeatureStoreAccess`.

```
# SageMaker Python SDK version 2.x is required
%pip install 'sagemaker>=2.0.0'
import sagemaker
import sys
```

```
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
```

```
from sagemaker import get_execution_role
from botocore.exceptions import ClientError

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
```

Step 2: Create a feature group and add features

The following code is an example of creating a feature group with feature definitions.

```
feature_group_name = "test-for-feature-metadata"
feature_definitions = [
    {"FeatureName": "feature-1", "FeatureType": "String"},
    {"FeatureName": "feature-2", "FeatureType": "String"},
    {"FeatureName": "feature-3", "FeatureType": "String"},
    {"FeatureName": "feature-4", "FeatureType": "String"},
    {"FeatureName": "feature-5", "FeatureType": "String"}
]
try:
    sagemaker_client.create_feature_group(
        FeatureGroupName=feature_group_name,
        RecordIdentifierFeatureName="feature-1",
        EventTimeFeatureName="feature-2",
        FeatureDefinitions=feature_definitions,
        OnlineStoreConfig={"EnableOnlineStore": True}
    )
except ClientError as e:
    if e.response["Error"]["Code"] == "ResourceInUse":
        pass
    else:
        raise e
```

Step 3: Add metadata

Before you add metadata, use the DescribeFeatureGroup operation to make sure that the status of the feature group is `Created`.

```
sagemaker_client.describe_feature_group(
        FeatureGroupName=feature_group_name
    )
```

Add a description to the feature.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    Description="new description"
)
```

You can use the DescribeFeatureMetadata operation to see if you successfully updated the description for the feature group.

```
    sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

You can also use it to add parameters to the feature group.

```
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    ParameterAdditions=[
        {"Key": "team", "Value": "featurestore"},
        {"Key": "org", "Value": "sagemaker"},
    ]
)
```

You can use the DescribeFeatureMetadata operation again to see if you have successfully added the parameters.

```
    sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```

Create a dataset from your feature groups

After a Feature Store feature group has been created in an offline store, you can choose to use the following methods to get your data:

- Using the Amazon SageMaker Python SDK
- Running SQL queries in the Amazon Athena

> **Important**
>
> Feature Store requires data to be registered in a AWS Glue data catalog. By default, Feature Store automatically builds an AWS Glue data catalog when you create a feature group.

After you've created feature groups for your offline store and populated them with data, you can create a dataset by running queries or using the SDK to join data stored in the offline store from different feature groups. You can also join the feature groups to a single pandas dataframe. You can use Amazon Athena to write and execute SQL queries.

> **Note**
>
> To make sure that your data is up to date, you can set up a AWS Glue crawler to run on a schedule.
> To set up a AWS Glue crawler, specify an IAM role that the crawler is using to access the offline store's Amazon S3 buckets. For more information, see Create an IAM role.

For more information on how to use AWS Glue and Athena to build a training dataset for model training and inference, see Use Feature Store with SDK for Python (Boto3).

Using the Amazon SageMaker Python SDK to get your data from your feature groups

You can use the Feature Store APIs to create a dataset from your feature groups. Data scientists create ML datasets for training by retrieving ML feature data from one or more feature groups in the offline store. Use the `create_dataset()` function to create the dataset. You can use the SDK to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from the feature groups and a pandas data frame.

By default, Feature Store doesn't include records that you've deleted from the dataset. It also doesn't include duplicated records. A duplicate record has the record ID and timestamp value in the event time column.

Before you use the SDK to create a dataset, you must start a SageMaker session. Use the following code to start the session.

```
import boto3
from sagemaker.session import Session
from sagemaker.feature_store.feature_store import FeatureStore

region = boto3.Session().region_name
boto_session = boto3.Session(region_name=region)

sagemaker_client = boto_session.client(
    service_name="sagemaker", region_name=region
 )
featurestore_runtime = boto_session.client(
    service_name="sagemaker-featurestore-runtime",region_name=region
)

feature_store_session = Session(
    boto_session=boto_session,
    sagemaker_client=sagemaker_client,
```

```
    sagemaker_featurestore_runtime_client=featurestore_runtime,
)

feature_store = FeatureStore(feature_store_session)
```

The following code shows an example of creating a dataset from multiple feature groups. The following code snippet uses the example feature groups "*base_fg_name*", "*first_fg_name*", and "*second_fg_name*", which may not exist or have the same schema within your Feature Store. It is recommended to replace these feature groups with feature groups that exist within your Feature Store. For information on how to create a feature group, see Step 3: Create feature groups.

```
from sagemaker.feature_store.feature_group import FeatureGroup

s3_bucket_name = "offline-store-sdk-test"

base_fg_name = "base_fg_name"
base_fg = FeatureGroup(name=base_fg_name, sagemaker_session=feature_store_session)

first_fg_name = "first_fg_name"
first_fg = FeatureGroup(name=first_fg_name, sagemaker_session=feature_store_session)

second_fg_name = "second_fg_name"
second_fg = FeatureGroup(name=second_fg_name, sagemaker_session=feature_store_session)

feature_store = FeatureStore(feature_store_session)
builder = feature_store.create_dataset(
    base=base_fg,
    output_path=f"s3://{DOC-EXAMPLE-BUCKET1}",
).with_feature_group(first_fg
).with_feature_group(second_fg, "base_id", ["base_feature_1"])
```

The following code shows an example of creating a dataset from multiple feature groups and a pandas dataframe.

```
base_data = [[1, 187512346.0, 123, 128],
             [2, 187512347.0, 168, 258],
             [3, 187512348.0, 125, 184],
             [1, 187512349.0, 195, 206]]
base_data_df = pd.DataFrame(
    base_data,
    columns=["base_id", "base_time", "base_feature_1", "base_feature_2"]
```

```
)

builder = feature_store.create_dataset(
    base=base_data_df,
    event_time_identifier_feature_name='base_time',
    record_identifier_feature_name='base_id',
    output_path=f"s3://{s3_bucket_name}"
).with_feature_group(first_fg
).with_feature_group(second_fg, "base_id", ["base_feature_1"])
```

The Feature Store APIs provides you with helper methods for the `create_dataset` function. You can use them to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from multiple feature groups and a pandas dataframe.
- Create a dataset from a single feature group and a pandas dataframe.
- Create a dataset using a point in time accurate join where records in the joined feature group follow sequentially.
- Create a dataset with the duplicated records, instead of following the default behavior of the function.
- Create a dataset with the deleted records, instead of following the default behavior of the function.
- Create a dataset for time periods that you specify.
- Save the dataset as a CSV file.
- Save the dataset as a pandas dataframe.

The *base* feature group is an important concept for joins. The base feature group is the feature group that has other feature groups or the pandas dataframe joined to it. For each dataset

You can add the following optional methods to the `create_dataset` function to configure how you're creating dataset:

- `with_feature_group` – Performs an inner join between the base feature group and another feature group using the record identifier and the target feature name in the base feature group. The following provides information about the parameters that you specify:
  - `feature_group` – The feature group that you're joining.

- `target_feature_name_in_base` – The name of the feature in the base feature group that you're using as a key in the join. The record identifier in the other feature groups are the other keys that Feature Store uses in the join.
- `included_feature_names` – A list of strings representing the feature names of the base feature group. You can use the field to specify the features that you want to include in the dataset.
- `feature_name_in_target` – Optional string representing the feature in the target feature group that will be compared to the target feature in the base feature group.
- `join_comparator` – Optional `JoinComparatorEnum` representing the comparator used when joining the target feature in the base feature group and the feature in the target feature group. These `JoinComparatorEnum` values can be `GREATER_THAN`, `GREATER_THAN_OR_EQUAL_TO`, `LESS_THAN`, `LESS_THAN_OR_EQUAL_TO`, `NOT_EQUAL_TO` or `EQUALS` by default.
- `join_type` – Optional `JoinTypeEnum` representing the type of join between the base and target feature groups. These `JoinTypeEnum` values can be `LEFT_JOIN`, `RIGHT_JOIN`, `FULL_JOIN`, `CROSS_JOIN` or `INNER_JOIN` by default.

- `with_event_time_range` – Creates a dataset using the event time range that you specify.
- `as_of` – Creates a dataset up to a timestamp that you specify. For example, if you specify `datetime(2021, 11, 28, 23, 55, 59, 342380)` as the value, creates a dataset up to November 28th, 2021.
- `point_time_accurate_join` – Creates a dataset where all of the event time values of the base feature group is less than all the event time values of the feature group or pandas dataframe that you're joining.
- `include_duplicated_records` – Keeps duplicated values in the feature groups.
- `include_deleted_records` – Keeps deleted values in the feature groups.
- `with_number_of_recent_records_by_record_identifier` – An integer that you specify to determine how many of the most recent records appear in the dataset.
- `with_number_of_records_by_record_identifier` – An integer that represents how many records appear in the dataset.

After you've configured the dataset, you can specify the output using one of the following methods:

- `to_csv_file` – Saves the dataset as a CSV file.

- `to_dataframe` – Saves the dataset as a pandas dataframe.

You can retrieve data that comes after a specific period in time. The following code retrieves data after a timestamp.

```
fg1 = FeatureGroup("example-feature-group-1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-S3-path"
).with_number_of_records_from_query_results(5).to_csv_file()
```

You can also retrieve data from a specific time period. You can use the following code to get data for a specific time range:

```
fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="example-S3-path"
).with_event_time_range(
    datetime(2021, 11, 28, 23, 55, 59, 342380),
    datetime(2020, 11, 28, 23, 55, 59, 342380)
).to_csv_file() #example time range specified in datetime functions
```

You might want to join multiple feature groups to a pandas dataframe where the event time values of the feature group happen no later than the event time of the data frame. Use the following code as a template to help you perform the join.

```
fg1 = FeatureGroup("fg1")
fg2 = FeatureGroup("fg2")
events = [['2020-02-01T08:30:00Z', 6, 1],
          ['2020-02-02T10:15:30Z', 5, 2],
          ['2020-02-03T13:20:59Z', 1, 3],
          ['2021-01-01T00:00:00Z', 1, 4]]
df = pd.DataFrame(events, columns=['event_time', 'customer-id', 'title-id'])
feature_store.create_dataset(
    base=df,
    event_time_identifier_feature_name='event_time',
    record_identifier_feature_name='customer_id',
    output_path="s3://example-S3-path"
).with_feature_group(fg1, "customer-id"
).with_feature_group(fg2, "title-id"
```

```
).point_in_time_accurate_join(
).to_csv_file()
```

You can also retrieve data that comes after a specific period in time. The following code retrieves data after the time specified by the timestamp in the `as_of` method.

```
fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-s3-file-path"
).as_of(datetime(2021, 11, 28, 23, 55, 59, 342380)
).to_csv_file() # example datetime values
```

Sample Amazon Athena queries

You can write queries in Amazon Athena to create a dataset from your feature groups. You can also write queries that create a dataset from feature groups and a single pandas dataframe.

Interactive Exploration

This query selects the first 1000 records.

```
SELECT *
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
LIMIT 1000
```

Latest snapshot without duplicates

This query selects the latest non-duplicate records.

```
SELECT *
FROM
    (SELECT *,
         row_number()
        OVER (PARTITION BY <RecordIdentiferFeatureName>
    ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC)
 AS row_num
    FROM
 <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1;
```

Latest snapshot without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from the offline store.

```
SELECT *
FROM
    (SELECT *,
         row_number()
        OVER (PARTITION BY <RecordIdentiferFeatureName>
    ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC)
 AS row_num
    FROM
 <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1 and
NOT is_deleted;
```

Time Travel without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from a particular point in time.

```
SELECT *
FROM
    (SELECT *,
         row_number()
        OVER (PARTITION BY <RecordIdentiferFeatureName>
    ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC)
 AS row_num
    FROM
 <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
    where <EventTimeFeatureName> <= timestamp '<timestamp>')
    -- replace timestamp '<timestamp>' with just <timestamp>  if EventTimeFeature is of
 type fractional
WHERE row_num = 1 and
NOT is_deleted
```

Delete records from your feature groups

You can use the Amazon SageMaker Feature Store API to delete records from your feature groups. A feature group is an object that contains your machine learning (ML) data, where the columns of your data are described by features and your data are contained in records. A record contains values for features that are associated with a specific record identifier.

There are two storage configurations for your feature groups: online store and offline store. The online store only keeps the record with the latest event time and is typically used for real-time lookup for ML inference. The offline store keeps all records and acts as a historical database and is typically used for feature exploration, ML training, and batch inference.

For more information on Feature Store concepts, see Ingestion diagrams.

There are two ways to delete records from your feature groups, and the behavior is different depending on the storage configuration. In the following topics we will describe how to soft and hard delete records from the online and offline stores and provide examples.

Topics

Delete records from the online store

You can soft or hard delete a record from the online store using the `DeleteRecord` API by using the `DeletionMode` request parameter to specify `SoftDelete` (default) or `HardDelete`. For more information on the `DeleteRecord` API, see `DeleteRecord` in the Amazon SageMaker API Reference.

With the online store:

- When you soft delete (default), the record is no longer retrievable by GetRecord or BatchGetRecord and the feature column values are set to `null`, except for the `RecordIdentifer` and `EventTime` feature values.
- When you hard delete, the record is completely removed from the online store.

In both cases Feature Store appends the deleted record marker to the `OfflineStore`. The deleted record marker is a record with the same `RecordIdentifer` as the original, but with `is_deleted` value set to `True`, `EventTime` set to the delete input `EventTime`, and other feature values set to `null`.

Note that the `EventTime` specified in `DeleteRecord` should be set later than the `EventTime` of the existing record in the `OnlineStore` for that same `RecordIdentifer`. If it is not, the deletion does not occur:

- For `SoftDelete`, the existing (not deleted) record remains in the `OnlineStore`, though the delete record marker is still written to the `OfflineStore`.
- `HardDelete` returns `EventTime: 400 ValidationException` to indicate that the delete operation failed. No delete record marker is written to the `OfflineStore`.

The following examples use the SDK for Python (Boto3) `delete_record` operation to delete a record from a feature group. To delete a record from a feature group, you will need:

- Feature group name (*`feature-group-name`*)
- Record identifier value as a string (*`record-identifier-value`*)
- Deletion event time (*`deletion-event-time`*)

  The deletion event time should be later than the event time of the record you wish to delete.

Online store soft delete example

For soft delete you will need use the `DeleteRecord` API and can use the default `DeletionMode` or set the `DeletionMode` to `SoftDelete`.

```
import boto3
client = boto3.client('sagemaker-featurestore-runtime')

client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-time',
    TargetStores=[
        'OnlineStore',
    ],
    DeletionMode='SoftDelete'
)
```

Online store hard delete example

For hard delete you will need use the `DeleteRecord` API and set the `DeletionMode` to `HardDelete`.

```
import boto3
```

```
client = boto3.client('sagemaker-featurestore-runtime')

client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-timestamp',
    TargetStores=[
        'OnlineStore',
    ],
    DeletionMode='HardDelete'
)
```

Delete records from the offline store

With Amazon SageMaker Feature Store you can soft and hard delete a record from the `OfflineStore` Iceberg table format. With the `OfflineStore` Iceberg table format:

- When you soft delete a record the latest version of the Iceberg table file will not contain the record, but previous versions will still contain the record and can be accessed using time travel. For information on time travel, see Querying Iceberg table data and performing time travel in the Athena user guide.
- When you hard delete a record you are removing previous versions of the Iceberg table that contain the record. In this case you should specify which versions of the Iceberg table you wish to delete.

Obtain your Iceberg table name

To soft and hard delete from your `OfflineStore` Iceberg table, you will need to obtain your Iceberg table name, *`iceberg-table-name`*. The following instructions assumes you have already used Feature Store to create a feature group using the offline store storage configuration using the Iceberg table format, with `DisableGlueTableCreation = False` (default). For more information on creating feature groups, see Get started with Amazon SageMaker Feature Store.

To obtain your *`iceberg-table-name`*, use the `DescribeFeatureGroup` API to obtain `DataCatalogConfig`. This contains the metadata of the Glue table which serves as data catalog for the `OfflineStore`. The `TableName` within the `DataCatalogConfig` is your *`iceberg-table-name`*.

Amazon Athena offline store soft and hard delete example

The following instructions use Amazon Athena to soft delete then hard delete a record from the `OfflineStore` Iceberg table. This assumes that the record you intend to delete in your `OfflineStore` is a deleted record marker. For information on the deleted record marker in your `OfflineStore`, see Delete records from the online store.

1. Obtain your Iceberg table name, *`iceberg-table-name`*. For information on how to obtain your Iceberg table name, see Obtain your Iceberg table name.
2. Run the `DELETE` command to soft delete the records on the `OfflineStore`, such that the latest version (or snapshot) of the Iceberg table will not contain the records. The following example deletes the records where `is_deleted` is `'True'` and the previous event-time versions of the those records .You may add additional conditions based on other features to restrict the deletion. For more information on using `DELETE` with Athena, see `DELETE` in the Athena user guide.

   ```
   DELETE FROM iceberg-table-name WHERE record-id-feature-name IS IN ( SELECT record-id-feature-name FROM iceberg-table-name WHERE is_deleted = 'True')
   ```

   The soft deleted records are still viewable on previous file versions by performing time travel. For information on performing time travel, see Querying Iceberg table data and performing time travel in the Athena user guide.
3. Remove the record from previous versions of your Iceberg tables to hard delete the record from `OfflineStore`:

   a. Run the `OPTIMIZE` command to rewrite the data files into a more optimized layout, based on their size and number of associated delete files. For more information on optimizing Iceberg tables and the syntax, see Optimizing Iceberg tables in the Athena user guide.

   ```
   OPTIMIZE iceberg-table-name REWRITE DATA USING BIN_PACK
   ```

   b. (Optional, only need to run once) Run the `ALTER TABLE` command to alter the Iceberg table set values, and set when previous file versions are to be hard deleted according to your specifications. This can be done by assigning values to `vacuum_min_snapshots_to_keep` and `vacuum_max_snapshot_age_seconds` properties. For more information on altering your Iceberg table set properties, see ALTER TABLE SET PROPERTIES in the Athena user guide. For more information on Iceberg table property key-value pairs, see Table properties in the Athena user guide.

```
ALTER TABLE iceberg-table-name SET TBLPROPERTIES (
  'vacuum_min_snapshots_to_keep'='your-specified-value',
  'vacuum_max_snapshot_age_seconds'='your-specified-value'
)
```

c. Run the VACUUM command to remove no longer needed data files for your Iceberg tables, not referenced by the current version. The VACUUM command should run after the deleted record is no longer referenced in the current snapshot. For example, vacuum_max_snapshot_age_seconds after the deletion. For more information on VACUUM with Athena and the syntax, see VACUUM.

```
VACUUM iceberg-table-name
```

Apache Spark offline store soft and hard delete example

To soft and then hard delete a record from the OfflineStore Iceberg table using Apache Spark, you can follow the same instructions as in the Amazon Athena offline store soft and hard delete example above, but using Spark procedures. For a full list of procedures, see Spark Procedures in the Apache Iceberg documentation.

- When soft deleting from the OfflineStore: instead of using the DELETE command in Athena, use the DELETE FROM command in Apache Spark.
- To remove the record from previous versions of your Iceberg tables to hard delete the record from OfflineStore:
  - When changing your Iceberg table configuration: instead of using the ALTER TABLE command from Athena, use expire_snapshots procedure.
  - To remove no longer needed data files from your Iceberg tables: instead of using the VACUUM command in Athena, use the remove_orphan_files procedure.

Logging Feature Store operations by using AWS CloudTrail

Amazon SageMaker Feature Store is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Feature Store. CloudTrail captures all of the API calls for Feature Store listed on this page. The logged events include API calls from Feature Store resource management and data operations. When you create a trail, you activate

continuous delivery of CloudTrail events from Feature Store to an Amazon S3 bucket. Using the information collected by CloudTrail, you can determine the request that was made to Feature Store, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Management events

Management events capture operations performed on Feature Store resources in your AWS account. For example, the log generated from the management events provides visibility if a user creates or deletes a Feature Store. The following APIs log management events with Amazon SageMaker Feature Store.

- `CreateFeatureGroup`
- `DeleteFeatureGroup`
- `DescribeFeatureGroup`
- `UpdateFeatureGroup`

Amazon SageMaker API calls and management events are logged by default when you create the account, as described in Log Amazon SageMaker API Calls with AWS CloudTrail. For more information, see Logging management events for trails.

Data events

Data events capture data plane operations performed using the Feature Store resources in your AWS account. For example, the log generated from the data events provides visibility if a user adds or deletes a record within a feature group. The following APIs log data events with Amazon SageMaker Feature Store.

- `BatchGetRecord`
- `DeleteRecord`
- `GetRecord`
- `PutRecord`

Data events are *not* logged by CloudTrail trails by default. To activate logging of data events, turn on logging of data plane API activity in CloudTrail. For more information, see CloudTrail's Logging data events for trails.

The following is an example CloudTrail event for a `PutRecord` API call:

```
{
    "eventVersion": "1.08",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "USERPRINCIPALID",
        "arn": "arn:aws:iam::123456789012:user/user",
        "accountId": "123456789012",
        "accessKeyId": "USERACCESSKEYID",
        "userName": "your-user-name"
    },
    "eventTime": "2023-01-01T01:00:00Z",
    "eventSource": "sagemaker.amazonaws.com",
    "eventName": "PutRecord",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "your-user-agent",
    "requestParameters": {
        "featureGroupName": "your-feature-group-name"
    },
    "responseElements": null,
    "requestID": "request-id",
    "eventID": "event-id",
    "readOnly": false,
    "resources": [
        {
            "accountId": "123456789012",
            "type": "AWS::SageMaker::FeatureGroup",
            "ARN": "arn:aws:sagemaker:us-east-1:123456789012:feature-group/your-
feature-group-name"
        }
    ],
    "eventType": "AwsApiCall",
    "managementEvent": false,
    "recipientAccountId": "123456789012",
    "eventCategory": "Data",
    "tlsDetails": {
        ...
```

```
    }
}
```

Security and access control

Amazon SageMaker Feature Store enables you to create two types of stores: an online store or offline store. The online store is used for low latency real-time inference use cases whereas the offline store is used for training and batch inference use cases. When you create a feature group for online or offline use you can provide a AWS Key Management Service customer managed key to encrypt all your data at rest. In case you do not provide a AWS KMS key then we ensure that your data is encrypted on the server side using an AWS owned AWS KMS key or AWS managed AWS KMS key. While creating a feature group, you can select storage type and optionally provide a AWS KMS key for encrypting data, then you can call various APIs for data management such as `PutRecord`, `GetRecord`, `DeleteRecord`.

Feature Store allows you to grant or deny access to individuals at the feature group-level and enables cross-account access to Feature Store. For example, you can set up developer accounts to access the offline store for model training and exploration that do not have write access to production accounts. You can set up production accounts to access both online and offline stores. Feature Store uses unique customer AWS KMS keys for offline and online store data at-rest encryption. Access control is enabled through both API and AWS KMS key access. You can also create feature group-level access control.

For more information about customer managed key, see customer managed keys. For more information about AWS KMS, see AWS KMS.

Using AWS KMS permissions for Amazon SageMaker Feature Store

Encryption at rest protects Feature Store under an AWS KMS customer managed key. By default, it uses an AWS owned customer managed key for OnlineStore and AWS managed customer managed key for OfflineStore. Feature Store supports an option to encrypt your online or offline store under customer managed key. You can select the customer managed key for Feature Store when you create your online or offline store, and they can be different for each store.

Feature Store supports only symmetric customer managed keys. You cannot use an asymmetric customer managed key to encrypt your data in your online or offline store. For help determining whether a customer managed key is symmetric or asymmetric, see Identifying symmetric and asymmetric customer managed keys.

When you use a customer managed key, you can take advantage of the following features:

- You create and manage the customer managed key, including setting the key policies, IAM policies and grants to control access to the customer managed key. You can enable and disable the customer managed key, enable and disable automatic key rotation, and delete the customer managed key when it is no longer in use.
- You can use a customer managed key with imported key material or a customer managed key in a custom key store that you own and manage.
- You can audit the encryption and decryption of your online or offline store by examining the API calls to AWS KMS in AWS CloudTrail logs.

You do not pay a monthly fee for AWS owned customer managed keys. Customer managed keys will incur a charge for each API call and AWS Key Management Service quotas apply to each customer managed key.

Authorizing use of a customer managed Key for your online store

If you use a customer managed key to protect your online store, the policies on that customer managed key must give Feature Store permission to use it on your behalf. You have full control over the policies and grants on a customer managed key.

Feature Store does not need additional authorization to use the default AWS owned KMS key to protect your online or offline stores in your AWS account.

Customer managed key policy

When you select a customer managed key to protect your Online Store, Feature Store must have permission to use the customer managed key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the customer managed key that Feature Store requires. You can provide these permissions in a key policy, an IAM policy, or a grant. At a minimum, Feature Store requires the following permissions on a customer managed key:

- "kms:Encrypt", "kms:Decrypt", "kms:DescribeKey", "kms:CreateGrant", "kms:RetireGrant", "kms:ReEncryptFrom", "kms:ReEncryptTo", "kms:GenerateDataKey", "kms:ListAliases", "kms:ListGrants", "kms:RevokeGrant"

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows Feature Store to use the customer managed key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use your Feature Store. If the principals specified in the policy statement don't have permission to use your Feature Store, the call fails, even when it comes from the Feature Store service.
- The kms:ViaService condition key allows the permissions only when the request comes from FeatureStore on behalf of the principals listed in the policy statement. These principals can't call these operations directly. The value for `kms:ViaService` should be `sagemaker.*.amazonaws.com`.

  > **Note**
  >
  > The `kms:ViaService` condition key can only be used for the online store customer managed AWS KMS key, and cannot be used for the offline store. If you add this special condition to your customer managed key, and use the same AWS KMS key for both the online and offline store, then it will fail the `CreateFeatureGroup` API operation.

- Gives the customer managed key administrators read-only access to the customer managed key and permission to revoke grants, including the grants that Feature Store uses to protect your data.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```
{"Id": "key-policy-feature-store",
   "Version":"2012-10-17",
   "Statement": [
     {"Sid" : "Allow access through Amazon SageMaker Feature Store for all principals
 in the account that are authorized to use  Amazon SageMaker Feature Store",
       "Effect": "Allow",
       "Principal": {"AWS": "arn:aws:iam::111122223333:user/featurestore-user"},
       "Action": [
         "kms:Encrypt",
         "kms:Decrypt",
         "kms:DescribeKey",
         "kms:CreateGrant",
         "kms:RetireGrant",
         "kms:ReEncryptFrom",
         "kms:ReEncryptTo",
         "kms:GenerateDataKey",
```

```
        "kms:ListAliases",
        "kms:ListGrants"
      ],
      "Resource": "*",
      "Condition": {"StringLike": {"kms:ViaService" : "sagemaker.*.amazonaws.com"
         }
      }
    },
    {"Sid":  "Allow administrators to view the customer managed key and revoke
grants",
      "Effect": "Allow",

```

Using grants to authorize Feature Store

In addition to key policies, Feature Store uses grants to set permissions on the customer managed key. To view the grants on a customer managed key in your account, use the `ListGrants` operation. Feature Store does not need grants, or any additional permissions, to use the AWS owned customer managed key to protect your online store.

Feature Store uses the grant permissions when it performs background system maintenance and continuous data protection tasks.

Each grant is specific to an online store. If the account includes multiple stores encrypted under the same customer managed key, there will be unique grants per `FeatureGroup` using the same customer managed key.

The key policy can also allow the account to revoke the grant on the customer managed key. However, if you revoke the grant on an active encrypted online store, Feature Store won't be able to protect and maintain the store.

Monitoring Feature Store interaction with AWS KMS

If you use a customer managed key to protect your online or offline store, you can use AWS CloudTrail logs to track the requests that Feature Store sends to AWS KMS on your behalf.

Accessing data in your online store

The **caller (either user or role)** to **ALL DataPlane operations (Put, Get, DeleteRecord)** must have below permissions on the customer managed key:

```
"kms:Decrypt"
```

Authorizing use of a customer managed key for your offline store

The **roleArn** that is passed as a parameter to `createFeatureGroup` must have below permissions to the OfflineStore KmsKeyId:

```
"kms:GenerateDataKey"
```

> **Note**
>
> The key policy for the online store also works for the offline store, only when the `kms:ViaService` condition is not specified.

> **Important**
>
> You can specify a AWS KMS encryption key to encrypt the Amazon S3 location used for your offline feature store when you create a feature group. If AWS KMS encryption key is

not specified, by default we encrypt all data at rest using AWS KMS key. By defining your bucket-level key for SSE, you can reduce AWS KMS requests costs by up to 99 percent.

Quotas, naming rules and data types

Quota terminologies

- Read Request Unit (RRU): Measure of read throughput, where the number of RRUs per read request is equal to the ceiling of read record's size divided into 4KB chunks. The minimum RRU per request is 0.
- Write Request Unit (WRU): Measure of write throughput, where the number of WRUs per write request is equal to the ceiling of the written record's size divided into 1KB chunks. The minimum WRU per request is 1 (including delete operations).

Limits and quotas

Note

Soft limits can be increased based on your needs.

- **Maximum number of feature groups per AWS account:** Soft limit of 100.
- **Maximum number of feature definitions per feature group:** 2500.
- **Maximum number of RRU per record identifier:** 2400 RRU per second.
- **Maximum number of WRU per record identifier:** 500 WRU per second.
- **Max Read Capacity Units (RCU) that can be provisioned on a single feature group:** 40000 RCU.
- **Max Write Capacity Units (WCU) that can be provisioned on a single feature group:** 40000 WCU.
- **Max Read Capacity Units that can be provisioned across all feature groups in a region:** 80000 RCU.
- **Max Write Capacity Units that can be provisioned across all feature groups in a region:** 80000 WCU.
- **Maximum Transactions per second (TPS) per API per AWS account:** Soft limit of 10000 TPS per API excluding the `BatchGetRecord` API call, which has a soft limit of 500 TPS.

- **Maximum size of a record:** 350KB.
- **Maximum size of a record identifier:** 2KB.
- **Maximum size of a feature value:** 350KB.
- **Maximum number of concurrent feature group creation workflows:** 4.
- **BatchGetRecord API:** Can contain as many as 100 records and can query up to 100 feature groups.

For information about service quotas and how to request a quota increase, see AWS service quotas.

Naming rules

- **Reserved Words:** The following are reserved words and cannot be used as feature names in feature definitions: `is_deleted`, `write_time`, and `api_invocation_time`.

Data types

- **String Feature Type:** Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, the maximum length is constrained by the maximum size of a record.
- **Fractional Feature Type:** Fractional feature values must conform to a double precision floating point number as defined by the IEEE 754 standard.
- **Integral Feature Type:** Feature Store supports integral values in the range of a 64-bit signed integer. Minimum value of -2^{63} and a maximum value: $2^{63} - 1$.
- **Event Time Features:** All feature groups have an event time feature with nanosecond precision. Any event time with lower than nanosecond precision will lead to backwards incompatibility. The feature can have a feature type of either String or Fractional.
  - A string event time is accepted in ISO-8601 format, in UTC time, conforming to the pattern(s): [yyyy-MM-dd'T'HH:mm:ssZ, yyyy-MM-dd'T'HH:mm:ss.SSSSSSSSSZ].
  - A fractional event time value is accepted as seconds from unix epoch. Event times must be in the range of [0000-01-01T00:00:00.000000000Z, 9999-12-31T23:59:59.999999999Z]. For feature groups in the `Iceberg` table format, you can only use String type for the event time.

Amazon SageMaker Feature Store offline store data format

Amazon SageMaker Feature Store supports the AWS Glue and Apache Iceberg table formats for the offline store. You can choose the table format when you're creating a new feature group. AWS Glue is the default format.

Amazon SageMaker Feature Store offline store data is stored in an Amazon S3 bucket within your account. When you call `PutRecord`, your data is buffered, batched, and written into Amazon S3 within 15 minutes. Feature Store only supports the Parquet file format when writing your data to your offline store. Specifically, when your data is written to your offline store, the data can be retrieved from your Amazon S3 bucket in Parquet format. Each file can contain multiple `Records`.

For the Iceberg format, Feature Store saves the table's metadata in the same Amazon S3 bucket that you're using to store the offline store data. You can find it under the `metadata` prefix.

Feature Store also exposes the OfflineStoreConfig.S3StorageConfig.ResolvedOutputS3Uri field, which can be found from in the DescribeFeatureGroup API call. This is the S3 path under which the files for the specific feature group are written.

The following additional fields are added by Feature Store to each record when they persist in the offline store:

- **api_invocation_time** – The timestamp when the service receives the `PutRecord` or `DeleteRecord` call. If using managed ingestion (e.g. Data Wrangler), this is the timestamp when data was written into the offline store.
- **write_time** – The timestamp when data was written into the offline store. Can be used for constructing time-travel related queries.
- **is_deleted** – `False` by default. If `DeleteRecord` is called, a new `Record` is inserted into `RecordIdentifierValue` and set to `True` in the offline store.

Amazon SageMaker Feature Store offline store URI structures

In the following examples `DOC-EXAMPLE-BUCKET` is the Amazon S3 bucket within your account, *`example-prefix`* is your example prefix, *`111122223333`* is your account ID, *`AWS Region`* is your region, *`feature-group-name`* is the name of your feature group.

AWS Glue table format

Records in the offline store stored using the AWS Glue table format are partitioned by event time into hourly partitions. You can't configure the partitioning scheme. The following URI structure shows the organization of a Parquet file using the AWS Glue format:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-
store/feature-group-name-feature-group-creation-time/data/year=year/month=month/
day=day/hour=hour/timestamp_of_latest_event_time_in_file_16-random-alphanumeric-
digits.parquet
```

The following example is the output location of a Parquet file for a file with *feature-group-name* as `customer-purchase-history-patterns`:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-
store/customer-purchase-history-patterns-1593511200/data/year=2020/month=06/day=31/
hour=00/20200631T064401Z_108934320012Az11.parquet
```

Iceberg table format

Records in the offline store stored in the Iceberg table format are partitioned by event time into daily partitions. You can't configure the partitioning scheme. The following URI structure shows the organization of the data files saved in the Iceberg table format:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-
store/feature-group-name-feature-group-creation-time/data/8-random-alphanumeric-
digits/event-time-feature-name_trunc=event-time-year-event-time-month-event-time-day/
timestamp-of-latest-event-time-in-file_16-random-alphanumeric-digits.parquet
```

The following example is the output location of a Parquet file for a file with *feature-group-name* as `customer-purchase-history-patterns`, and the *event-time-feature-name* is `EventTime`:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/
offline-store/customer-purchase-history-patterns-1593511200/data/0aec19ca/
EventTime_trunc=2022-11-09/20221109T215231Z_yolTtpyuWbkaeGIl.parquet
```

The following example is the location of a metadata file for data files saved in the Iceberg table format.

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-
store/feature-group-name-feature-group-creation-time/metadata/
```

Amazon SageMaker Feature Store resources

The following lists the available resources for Amazon SageMaker Feature Store users. For the Feature Store main page, see Amazon SageMaker Feature Store.

Feature Store example notebooks and workshops

To get started using Amazon SageMaker Feature Store, you can choose from a variety of example Jupyter notebooks from the following table. If this is your first time using Feature Store, try out the Introduction to Feature Store notebook. To run any these notebooks, you must attach this policy to your IAM execution role: `AmazonSageMakerFeatureStoreAccess`.

See IAM Roles to access your role and attach this policy. For a walkthrough on how to view the policies attached to a role and how to add a policy to your role, see Adding policies to your IAM role.

The following table lists a variety of resources to help you get started with Feature Store. This table contains examples, instructions, and example notebooks to guide you in how to use Feature Store for the first time to specific use cases. The code in these resources use the SageMaker SDK for Python (Boto3).

Page	Description
Get started with Amazon SageMaker Feature Store in Read the Docs.	A list of example notebooks to introduce you to Feature Store and its features to help you get started.
Amazon SageMaker Feature Store guide in Read the Docs.	A Feature Store guide on how to set up, create a feature group, load data into a feature group, and how to use Feature Store in general.
Amazon SageMaker Feature Store end-to-end workshop in the `aws-samples` Github repository	An end-to-end Feature Store workshop.
Feature Store example notebooks in the SageMaker example notebooks repository.	Specific use case example notebooks for Feature Store.

Feature Store Python SDK and API

Python Software Development Kit (SDK) and Application Programming Interface (API) are tools used for creating software applications. The Feature Store SDK for Python (Boto3) and API are listed in the following table.

Page	Description
Feature Store APIs in the Amazon SageMaker Python SDK Read the Docs	The Feature Store APIs in Read the Docs.
Feature Store Python SDK in the Amazon SageMaker Python SDK Github repository	The Feature Store Python SDK Github repository.
Feature Store Runtime operations and data types in the SDK for Python (Boto3) documentation	Feature Store Runtime client that contains all data plane API operations and data types for Feature Store.
Amazon SageMaker Feature Store Runtime in the Amazon SageMaker API Reference	Some feature group level actions supported by Feature Store. If the API operation or data type you are looking for is not listed here, please use search in the guide.
Amazon SageMaker Feature Store Runtime in the Amazon SageMaker API Reference	Record level actions supported by Feature Store. If the API operation or data type you are looking for is not listed here, please use search in the guide.

Train machine learning models

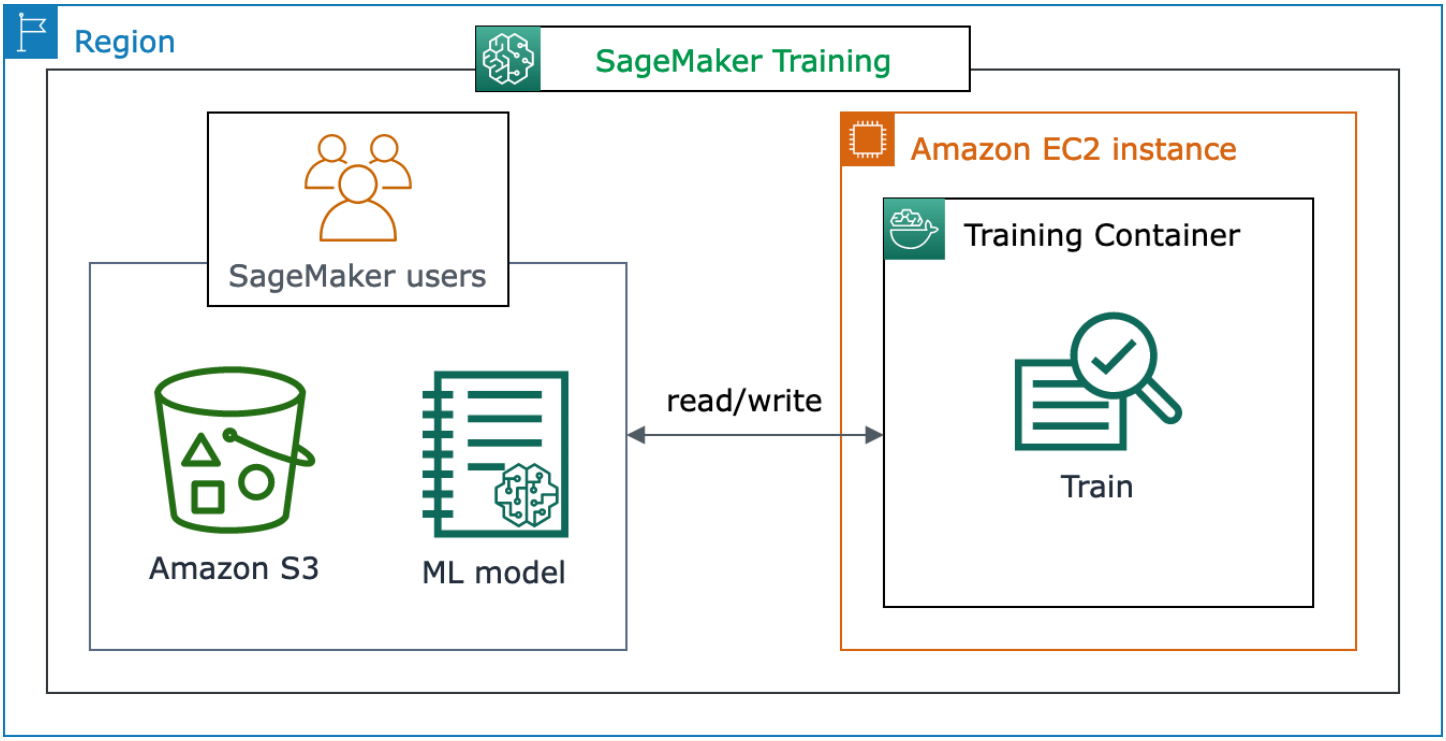
The training stage of the full machine learning (ML) lifecycle spans from accessing your training dataset to generating a final model and selecting the best performing model for deployment. The following sections provide an overview of available SageMaker training features and resources with in-depth technical information for each.

The simplest training workflow in SageMaker

If you're using SageMaker for the first time and want to find a quick ML solution to train a model on your dataset, consider using a no-code or low-code solution such as SageMaker Canvas, SageMaker JumpStart within SageMaker Studio Classic, or SageMaker Autopilot.

For intermediate coding experiences, consider using a SageMaker Studio Classic notebook or SageMaker Notebook Instances. To get started, follow the instructions at the section called "Step 4: Train a Model" of the SageMaker *Getting Started* guide. We recommend this for use cases in which you create your own model and training script using an ML framework.

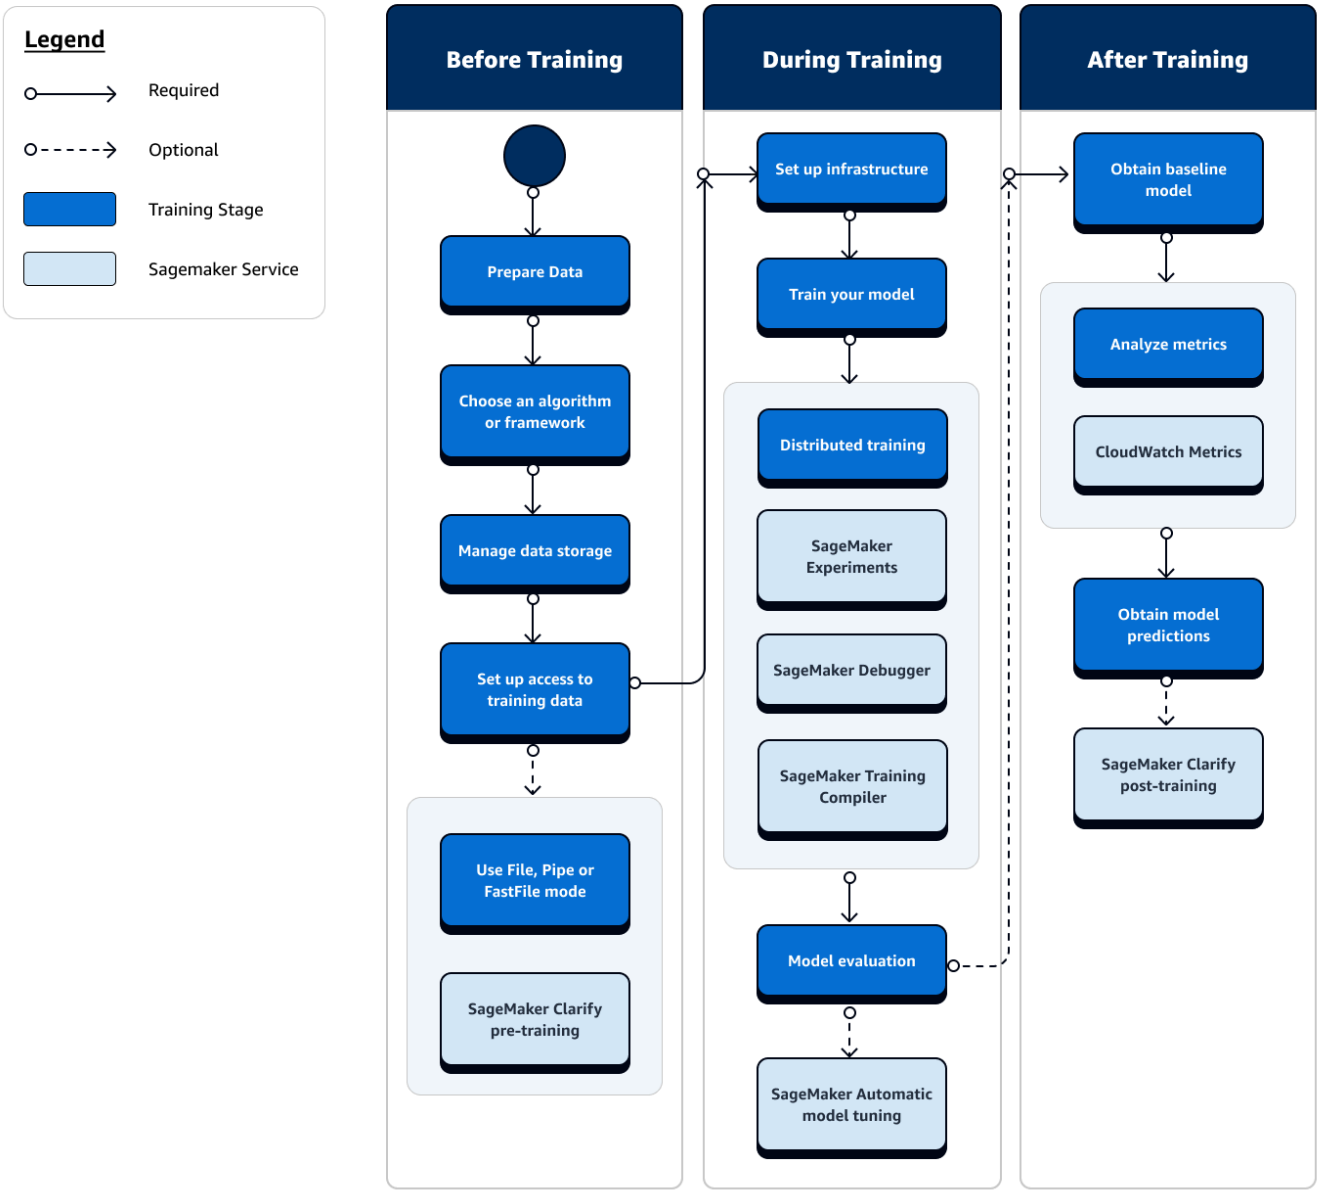
The following architecture diagram shows how SageMaker manages ML training jobs and provisions Amazon EC2 instances on behalf of SageMaker users. You as a SageMaker user can bring your own training dataset, saving it to Amazon S3. You can choose an ML model training from available SageMaker built-in algorithms, or bring your own training script with a model built with popular machine learning frameworks.



Full view of the SageMaker Training workflow and features

The full journey of ML training involves tasks beyond data ingestion to ML models, training models on compute instances, and obtaining model artifacts and outputs. You need to evaluate every phase of before, during, and after training to make sure your model is trained well to meet the target accuracy for your objectives.

The following flow chart shows a high-level overview of your actions (in blue boxes) and available SageMaker Training features (in light blue boxes) throughout the training phase of the ML lifecycle.



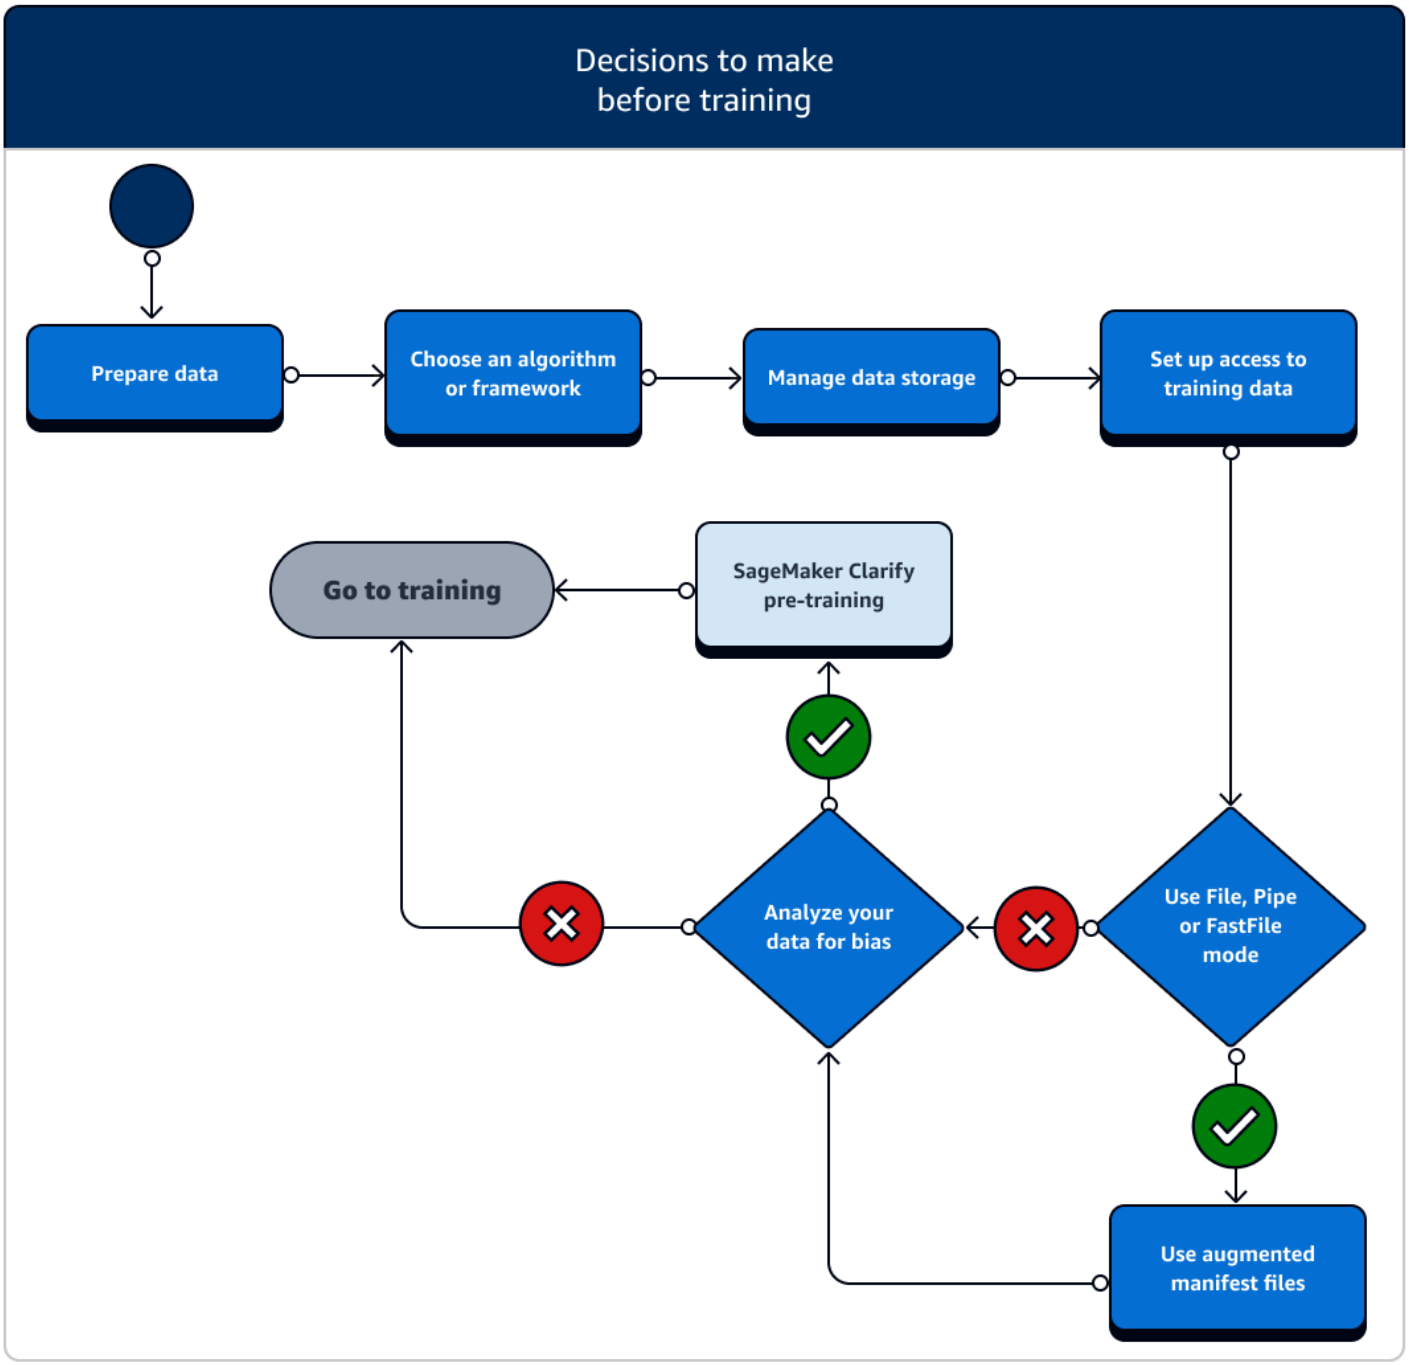
The following sections walk you through each phase of training depicted in the previous flow chart and useful features offered by SageMaker throughout the three sub-stages of the ML training.

Topics

- Before training
- During training
- After training

Before training

There are a number of scenarios of setting up data resources and access you need to consider before training. Refer to the following diagram and details of each before-training stage to get a sense of what decisions you need to make.



- **Prepare data:** Before training, you must have finished data cleaning and feature engineering during the data preparation stage. SageMaker has several labeling and feature engineering tools

to help you. See Label Data, Prepare and Analyze Datasets, Process Data, and Create, Store, and Share Features for more information.

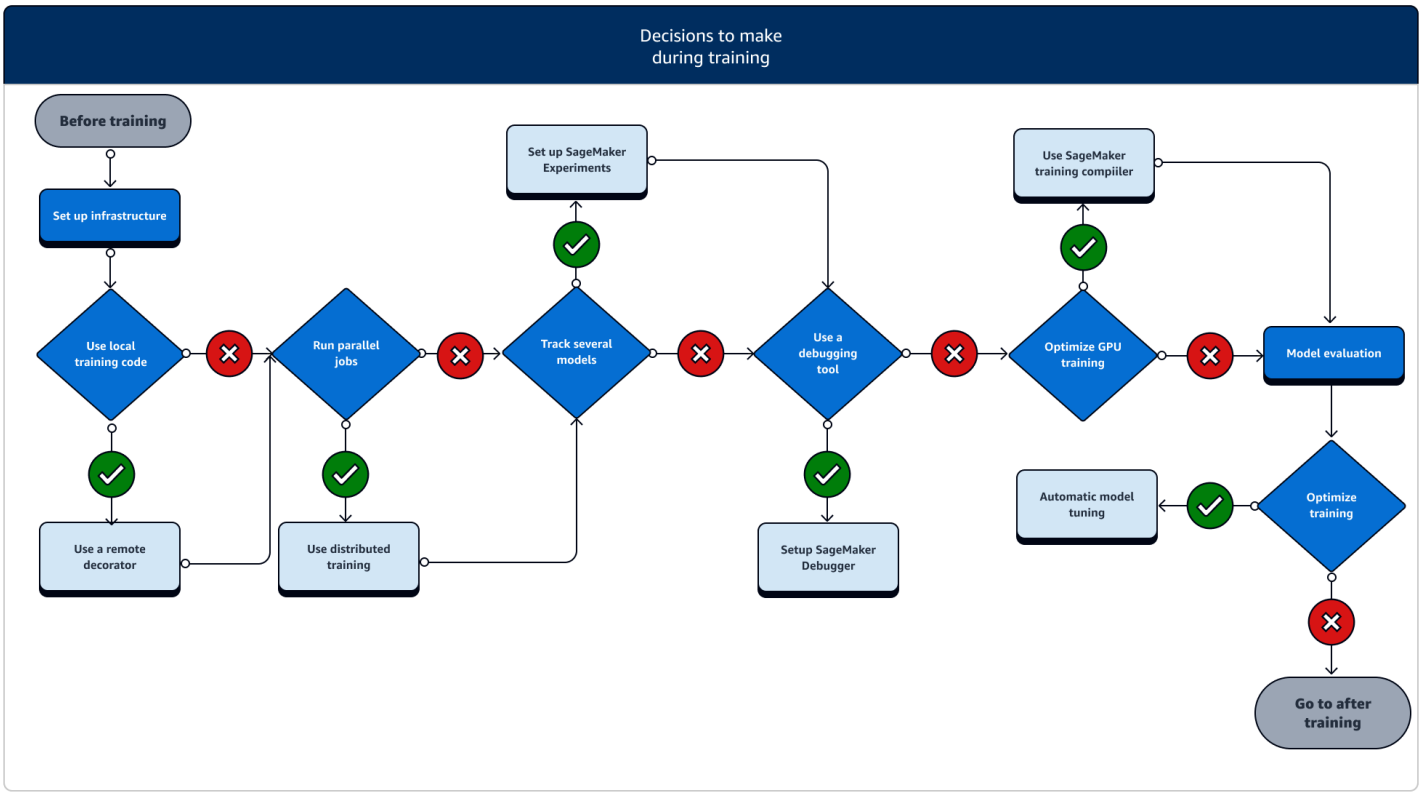
- **Choose an algorithm or framework:** Depending on how much customization you need, there are different options for algorithms and frameworks.
  - If you prefer a low-code implementation of a pre-built algorithm, use one of the built-in algorithms offered by SageMaker. For more information, see Choose an Algorithm.
  - If you need more flexibility to customize your model, run your training script using your preferred frameworks and toolkits within SageMaker. For more information, see ML Frameworks and Toolkits.
  - To extend pre-built SageMaker Docker images as the base image of your own container, see Use Pre-built SageMaker Docker images.
  - To bring your custom Docker container to SageMaker, see Adapting your own Docker container to work with SageMaker. You need to install the sagemaker-training-toolkit to your container.
- **Manage data storage:** Understand mapping between the data storage (such as Amazon S3, Amazon EFS, or Amazon FSx) and the training container that runs in the Amazon EC2 compute instance. SageMaker helps map the storage paths and local paths in the training container. You can also manually specify them. After mapping is done, consider using one of the data transmission modes: File, Pipe, and FastFile mode. To learn how SageMaker maps storage paths, see Training Storage Folders.
- **Set up access to training data:** Use Amazon SageMaker domain, a domain user profile, IAM, Amazon VPC, and AWS KMS to meet the requirements of the most security-sensitive organizations.
  - For account administration, see Amazon SageMaker domain.
  - For a complete reference about IAM policies and security, see Security in Amazon SageMaker.
- **Stream your input data:** SageMaker provides three data input modes, *File*, *Pipe*, and *FastFile*. The default input mode is File mode, which loads the entire dataset during initializing the training job. To learn about general best practices for streaming data from your data storage to the training container, see Access Training Data.

  In case of Pipe mode, you can also consider using an augmented manifest file to stream your data directly from Amazon Simple Storage Service (Amazon S3) and train your model. Using pipe mode reduces disk space because Amazon Elastic Block Store only needs to store your final model artifacts, rather than storing your full training dataset. For more information, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.

- **Analyze your data for bias:** Before training, you can analyze your dataset and model for bias against a disfavored group so that you can check that your model learns an unbiased dataset using SageMaker Clarify.
- **Choose which SageMaker SDK to use:** There are two ways to launch a training job in SageMaker: using the high-level SageMaker Python SDK, or using the low-level SageMaker APIs for the SDK for Python (Boto3) or the AWS CLI. The SageMaker Python SDK abstracts the low-level SageMaker API to provide convenient tools. As aforementioned in the section called "The simplest training workflow in SageMaker", you can also pursue no-code or minimal-code options using SageMaker Canvas, SageMaker JumpStart within SageMaker Studio Classic, or SageMaker Autopilot.

During training

During training, you need to continuously improve training stability, training speed, training efficiency while scaling compute resources, cost optimization, and, most importantly, model performance. Read on for more information about during-training stages and relevant SageMaker Training features.



- **Set up infrastructure:** Choose the right instance type and infrastructure management tools for your use case. You can start from a small instance and scale up depending on your workload. For training a model on a tabular dataset, start with the smallest CPU instance of the C4 or C5 instance families. For training a large model for computer vision or natural language processing, start with the smallest GPU instance of the P2, P3, G4dn or G5 instance families. You can also mix different instance types in a cluster, or keep instances in warm pools using the following instance management tools offered by SageMaker. You can also use persistent cache to reduce latency and billable time on iterative training jobs over the latency reduction from warm pools alone. To learn more, see the following topics.
  - Train Using a Heterogeneous Cluster
  - Train Using SageMaker Managed Warm Pools
  - Using persistent cache

  You must have sufficient quota to run a training job. If you run your training job on an instance where you have insufficient quota, you will receive a `ResourceLimitExceeded` error. To check the currently available quotas in your account, use your Service Quotas console. To learn how to request a quota increase, see Supported Regions and Quotas. Also, to find pricing information and available instance types depending on the AWS Regions, look up the tables in the Amazon SageMaker Pricing page.
- **Run a training job from a local code:** You can annotate your local code with a remote decorator to run your code as a SageMaker training job from inside Amazon SageMaker Studio Classic, an Amazon SageMaker notebook or from your local integrated development environment. For more information, see Run your local code as a SageMaker training job.
- **Track training jobs:** Monitor and track your training jobs using SageMaker Experiments, SageMaker Debugger, or Amazon CloudWatch. You can watch the model performance in terms of accuracy and convergence, and run comparative analysis of metrics between multiple training jobs by using SageMaker Experiments. You can watch the compute resource utilization rate by using SageMaker Debugger's profiling tools or Amazon CloudWatch. To learn more, see the following topics.
  - Manage Machine Learning with Amazon SageMaker Experiments
  - Profile Training Jobs Using Amazon SageMaker Debugger
  - Monitor and Analyze Using CloudWatch Metrics

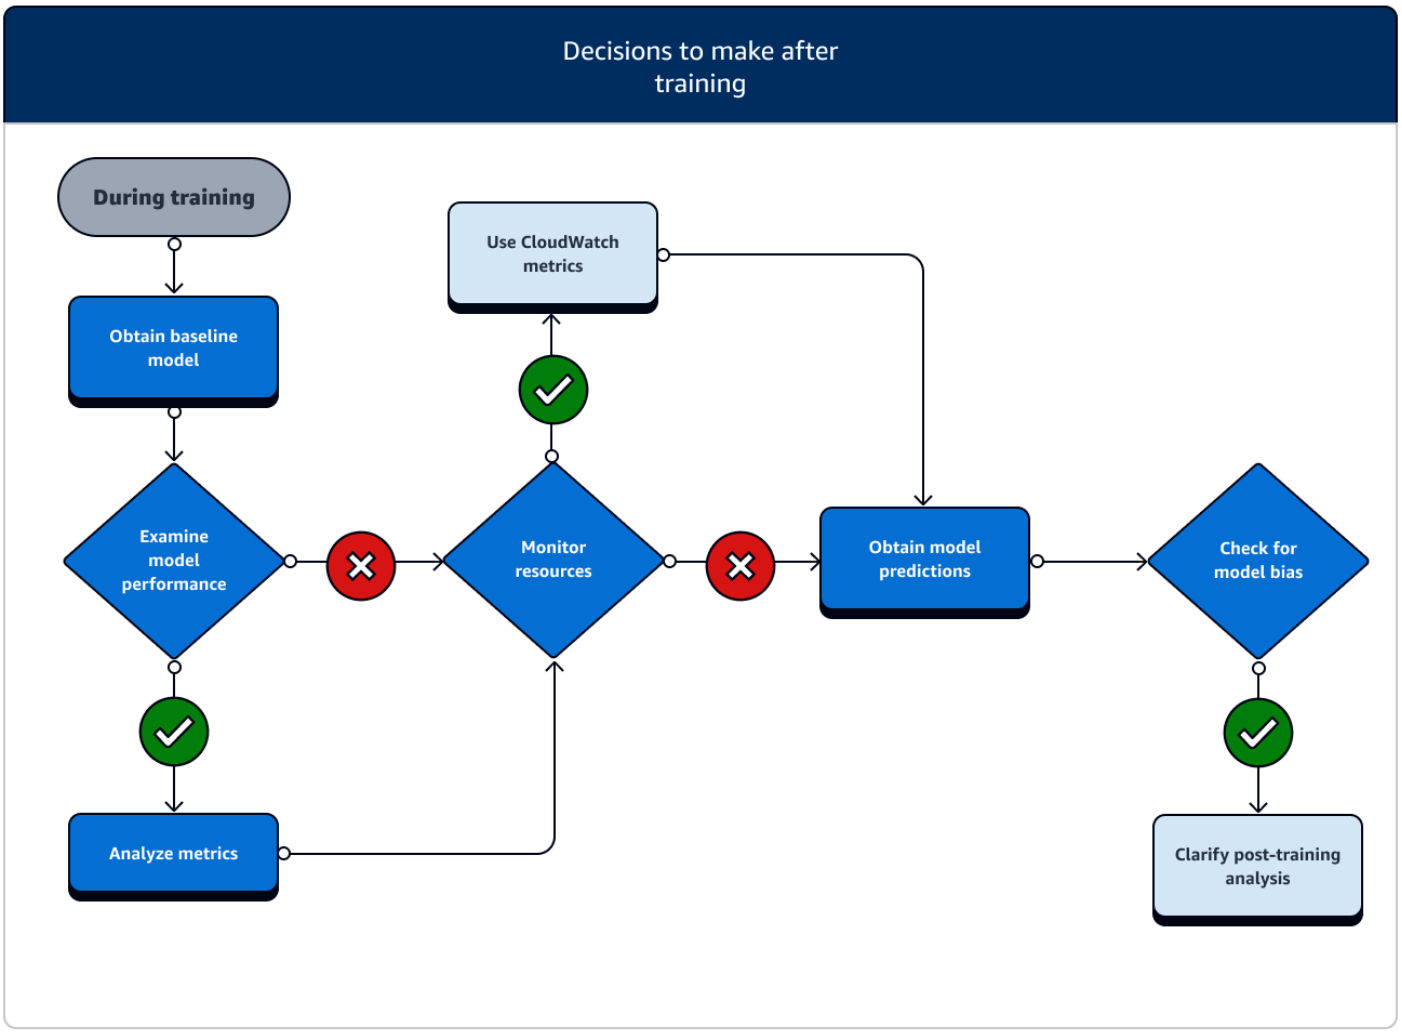
  Additionally, for deep learning tasks, use the Amazon SageMaker Debugger model debugging tools and built-in rules to identify more complex issues in model convergence and weight update processes.

- **Distributed training:** If your training job is going into a stable stage without breaking due to misconfiguration of the training infrastructure or out-of-memory issues, you might want to find more options to scale your job and run over an extended period of time for days and even months. When you're ready to scale up, consider distributed training. SageMaker provides various options for distributed computation from light ML workloads to heavy deep learning workloads.

  For deep learning tasks that involve training very large models on very large datasets, consider using one of the SageMaker distributed training strategies to scale up and achieve data parallelism, model parallelism, or a combination of the two. You can also use SageMaker Training Compiler for compiling and optimizing model graphs on GPU instances. These SageMaker features support deep learning frameworks such as PyTorch, TensorFlow, and Hugging Face Transformers.
- **Model hyperparameter tuning:** Tune your model hyperparameters using Automatic Model Tuning with SageMaker. SageMaker provides hyperparameter tuning methods such as grid search and Bayesian search, launching parallel hyperparameter tuning jobs with early-stopping functionality for non-improving hyperparameter tuning jobs.
- **Checkpointing and cost saving with Spot instances:** If training time is not a big concern, you might consider optimizing model training costs with managed Spot instances. Note that you must activate checkpointing for Spot training to keep restoring from intermittent job pauses due to Spot instance replacements. You can also use the checkpointing functionality to back up your models in case of unexpected training job termination. To learn more, see the following topics.
  - Managed Spot Training
  - Use Checkpoints

After training

After training, you obtain a final model artifact to use for model deployment and inference. There are additional actions involved in the after-training phase as shown in the following diagram.



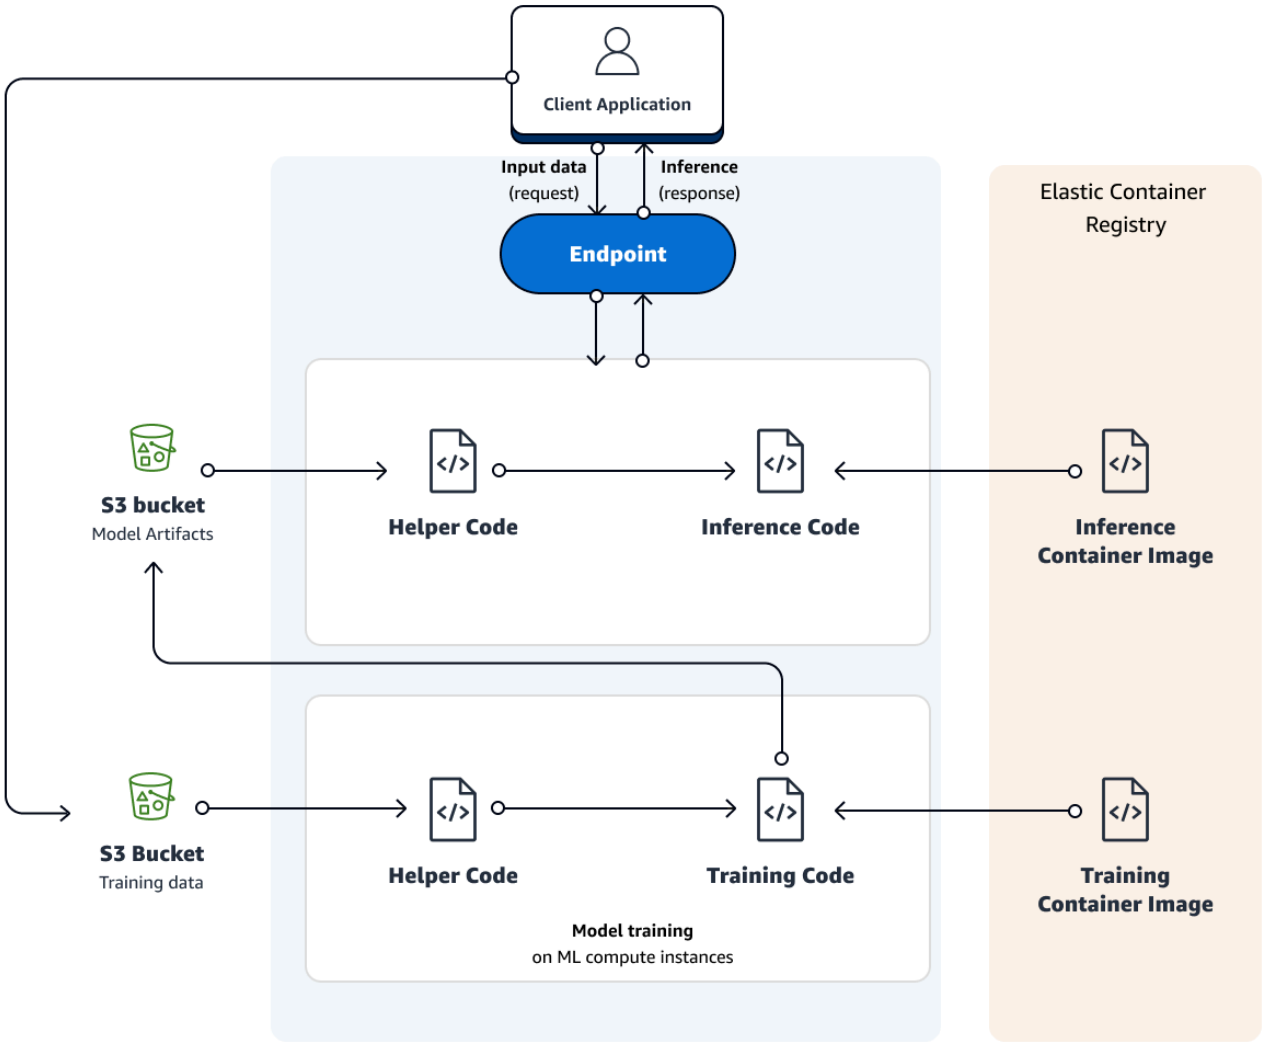
- **Obtain baseline model:** After you have the model artifact, you can set it as a baseline model. Consider the following post-training actions and using SageMaker features before moving on to model deployment to production.
- **Examine model performance and check for bias:** Use Amazon CloudWatch Metrics and SageMaker Clarify for post-training bias to detect any bias in incoming data and model over time against the baseline. You need to evaluate your new data and model predictions against the new data regularly or in real time. Using these features, you can receive alerts about any acute changes or anomalies, as well as gradual changes or drifts in data and model.
- You can also use the Incremental Training functionality of SageMaker to load and update your model (or fine-tune) with an expanded dataset.
- You can register model training as a step in your SageMaker Pipeline or as part of other Workflow features offered by SageMaker in order to orchestrate the full ML lifecycle.

Train a Model with Amazon SageMaker

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide Permissions for Tagging SageMaker Resources.
AWS Managed Policies for Amazon SageMaker that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

The following diagram shows how you train and deploy a model with Amazon SageMaker. Your training code accesses your training data and outputs model artifacts from an S3 bucket. Then you can make requests to a model endpoint to run inference. You can store both the training and inference container images in an Amazon Elastic Container Registry (ECR).



The following guide highlights two components of SageMaker: model training and model deployment.

To train a model in SageMaker, you create a training job. The training job includes the following information:

- The URL of the Amazon Simple Storage Service (Amazon S3) bucket where you've stored the training data.
- The compute resources that you want SageMaker to use for model training. Compute resources are machine learning (ML) compute instances that are managed by SageMaker.
- The URL of the S3 bucket where you want to store the output of the job.

- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code.

> **Note**
>
> Your input dataset must be in the same AWS Region as your training job.

You have the following options for a training algorithm:

- **Use an algorithm provided by SageMaker**—SageMaker provides dozens of built-in training algorithms and hundreds of pre-trained models. If one of these meets your needs, it's a great out-of-the-box solution for quick model training. For a list of algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models. To try an exercise that uses an algorithm provided by SageMaker, see Setting up Amazon SageMaker. You can also use SageMaker JumpStart to use algorithms and models through the Studio Classic UI.
- **Use SageMaker Debugger**—to inspect training parameters and data throughout the training process when working with the TensorFlow, PyTorch, and Apache MXNet learning frameworks or the XGBoost algorithm. Debugger automatically detects and alerts users to commonly occurring errors such as parameter values getting too large or small. For more information about using Debugger, see Use Amazon SageMaker Debugger to debug and improve model performance. Debugger sample notebooks are available at Amazon SageMaker Debugger Samples.
- **Use Apache Spark with SageMaker**—SageMaker provides a library that you can use in Apache Spark to train models with SageMaker. Using the library provided by SageMaker is similar to using Apache Spark MLLib. For more information, see Use Apache Spark with Amazon SageMaker.
- **Submit custom code to train with deep learning frameworks**—You can submit custom Python code that uses TensorFlow, PyTorch, or Apache MXNet for model training. For more information, see Use TensorFlow with Amazon SageMaker, Use PyTorch with Amazon SageMaker, and Use Apache MXNet with Amazon SageMaker.
- **Use your own custom algorithms**—Put your code together as a Docker image and specify the registry path of the image in a SageMaker `CreateTrainingJob` API call. For more information, see Use Docker containers to build models.
- **Use an algorithm that you subscribe to from AWS Marketplace**—For information, see Find and Subscribe to Algorithms and Model Packages on AWS Marketplace.

After you create the training job, SageMaker launches the ML compute instances and uses the training code and the training dataset to train the model. It saves the resulting model artifacts and other output in the S3 bucket you specified for that purpose.

You can create a training job with the SageMaker console or the API. For information about creating a training job with the API, see the `CreateTrainingJob` API.

When you create a training job with the API, SageMaker replicates the entire dataset on ML compute instances by default. To make SageMaker replicate a subset of the data on each ML compute instance, you must set the `S3DataDistributionType` field to `ShardedByS3Key`. You can set this field using the low-level SDK. For more information, see `S3DataDistributionType` in `S3DataSource`.

> **Important**
>
> To prevent your algorithm container from contending for memory, we reserve memory for our SageMaker critical system processes on your ML compute instances and therefore you cannot expect to see all the memory for your instance type.

Choose an Algorithm

Machine learning can help you accomplish empirical tasks that require some sort of inductive inference. This task involves induction as it uses data to train algorithms to make generalizable inferences. This means that the algorithms can make statistically reliable predictions or decisions, or complete other tasks when applied to new data that was not used to train them.

To help you select the best algorithm for your task, we classify these tasks on various levels of abstraction. At the highest level of abstraction, machine learning attempts to find patterns or relationships between features or less structured items, such as text in a data set. Pattern recognition techniques can be classified into distinct machine learning paradigms, each of which address specific problem types. There are currently three basic paradigms for machine learning used to address various problem types:

- Supervised learning
- Unsupervised learning
- Reinforcement learning

The types of problems that each learning paradigm can address are identified by considering the inferences (or predictions, decisions, or other tasks) you want to make from the type of data that you have or could collect. Machine learning paradigms use algorithmic methods to address their various problem types. The algorithms provide recipes for solving these problems.

However, many algorithms, such as neural networks, can be deployed with different learning paradigms and on different types of problems. Multiple algorithms can also address a specific problem type. Some algorithms are more generally applicable and others are quite specific for certain kinds of objectives and data. So the mapping between machine learning algorithms and problem types is many-to-many. Also, there are various implementation options available for algorithms.

The following sections provide guidance concerning implementation options, machine learning paradigms, and algorithms appropriate for different problem types.

Topics

Choose an algorithm implementation

After choosing an algorithm, you must decide which implementation of it you want to use. Amazon SageMaker supports three implementation options that require increasing levels of effort.

- **Pre-trained models** require the least effort and are models ready to deploy or to fine-tune and deploy using SageMaker JumpStart.
- **Built-in algorithms** require more effort and scale if the data set is large and significant resources are needed to train and deploy the model.
- If there is no built-in solution that works, try to develop one that uses **pre-made images for machine and deep learning frameworks** for supported frameworks such as Scikit-Learn, TensorFlow, PyTorch, MXNet, or Chainer.
- If you need to run custom packages or use any code which isn't a part of a supported framework or available via PyPi, then you need to build **your own custom Docker image** that is configured

to install the necessary packages or software. The custom image must also be pushed to an online repository like the Amazon Elastic Container Registry.

Topics

- Use a built-in algorithm
- Use script mode in a supported framework
- Use a custom Docker image

Algorithm implementation guidance

Implement ation	Requires code	Pre-coded algorithms	Support for third party packages	Support for custom code	Level of effort
Built-in	No	Yes	No	No	Low
Scikit-learn	Yes	Yes	PyPi only	Yes	Medium
Spark ML	Yes	Yes	PyPi only	Yes	Medium
XGBoost (open source)	Yes	Yes	PyPi only	Yes	Medium
TensorFlow	Yes	No	PyPi only	Yes	Medium-high
PyTorch	Yes	No	PyPi only	Yes	Medium-high
MXNet	Yes	No	PyPi only	Yes	Medium-high
Chainer	Yes	No	PyPi only	Yes	Medium-high
Custom image	Yes	No	Yes, from any source	Yes	High

Use a built-in algorithm

When choosing an algorithm for your type of problem and data, the easiest option is to use one of Amazon SageMaker's built-in algorithms. These built-in algorithms come with two major benefits.

- The built-in algorithms require no coding to start running experiments. The only inputs you need to provide are the data, hyperparameters, and compute resources. This allows you to run experiments more quickly, with less overhead for tracking results and code changes.
- The built-in algorithms come with parallelization across multiple compute instances and GPU support right out of the box for all applicable algorithms (some algorithms may not be included due to inherent limitations). If you have a lot of data with which to train your model, most built-in algorithms can easily scale to meet the demand. Even if you already have a pre-trained model, it may still be easier to use its corollary in SageMaker and input the hyper-parameters you already know than to port it over, using script mode on a supported framework.

For more information on the built-in algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models.

For important information about docker registry paths, data formats, recommended EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms.

Use script mode in a supported framework

If the algorithm you want to use for your model is not supported by a built-in choice and you are comfortable coding your own solution, then you should consider using an Amazon SageMaker supported framework. This is referred to as "script mode" because you write your custom code (script) in a text file with a `.py` extension. As the table above indicates, SageMaker supports most of the popular machine learning frameworks. These frameworks come preloaded with the corresponding framework and some additional Python packages, such as Pandas and NumPy, so you can write your own code for training an algorithm. These frameworks also allow you to install any Python package hosted on PyPi by including a requirements.txt file with your training code or to include your own code directories. R is also supported natively in SageMaker notebook kernels. Some frameworks, like scikit-learn and Spark ML, have pre-coded algorithms you can use easily, while other frameworks like TensorFlow and PyTorch may require you to implement the algorithm yourself. The only limitation when using a supported framework image is that you cannot import any software packages that are not hosted on PyPi or that are not already included with the framework's image.

For more information on the frameworks supported by SageMaker, see Machine Learning Frameworks and Languages.

Use a custom Docker image

Amazon SageMaker's built-in algorithms and supported frameworks should cover most use cases, but there are times when you may need to use an algorithm from a package not included in any of the supported frameworks. You might also have a pre-trained model picked or persisted somewhere which you need to deploy. SageMaker uses Docker images to host the training and serving of all models, so you can supply your own custom Docker image if the package or software you need is not included in a supported framework. This may be your own Python package or an algorithm coded in a language like Stan or Julia. For these images you must also configure the training of the algorithm and serving of the model properly in your Dockerfile. This requires intermediate knowledge of Docker and is not recommended unless you are comfortable writing your own machine learning algorithm. Your Docker image must be uploaded to an online repository, such as the Amazon Elastic Container Registry (ECR) before you can train and serve your model properly.

For more information on custom Docker images in SageMaker, see Use Docker containers to build models.

Problem types for the basic machine learning paradigms

The following three sections describe the main problem types addressed by the three basic paradigms for machine learning. For a list of the built-in algorithms that SageMaker provides to address these problem types, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models.

Topics

- Supervised learning
- Unsupervised learning
- Reinforcement learning

Supervised learning

If your data set consists of features or attributes (inputs) that contain target values (outputs), then you have a supervised learning problem. If your target values are categorical (mathematically discrete), then you have a **classification problem**. It is a standard practice to distinguish binary from multiclass classification.

- **Binary classification** is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.
- **Multiclass classification** is a type of supervised learning that assigns an individual to one of several classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about religion, politics, or finance, or as about one of several other predefined topic classes.

If the target values you are trying to predict are mathematically continuous, then you have a **regression** problem. Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms and the square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

For more information on the built-in supervised learning algorithms provided by SageMaker, see Supervised Learning.

Unsupervised learning

If your data set consists of features or attributes (inputs) that do not contain labels or target values (outputs), then you have an unsupervised learning problem. In this type of problem, the output must be predicted based on the pattern discovered in the input data. The goal in unsupervised learning problems is to discover patterns such as groupings within the data. There are a large variety of tasks or problem types to which unsupervised learning can be applied. Principal component and cluster analyses are two of the main methods commonly deployed for preprocessing data. Here is a short list of problem types that can be addressed by unsupervised learning:

- **Dimension reduction** is typically part of a data exploration step used to determine the most relevant features to use for model construction. The idea is to transform data from a high-dimensional, sparsely populated space into a low-dimensional space that retains most significant properties of the original data. This provides relief for the curse of dimensionality that can arise with sparsely populated, high-dimensional data on which statistical analysis becomes

problematic. It can also be used to help understand data, reducing high-dimensional data to a lower dimensionality that can be visualized.

- **Cluster analysis** is a class of techniques that are used to classify objects or cases into groups called clusters. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the features or attributes that you want the algorithm to use to determine similarity, select a distance function to measure similarity, and specify the number of clusters to use in the analysis.
- **Anomaly detection** is the identification of rare items, events, or observations in a data set which raise suspicions because they differ significantly from the rest of the data. The identification of anomalous items can be used, for example, to detect bank fraud or medical errors. Anomalies are also referred to as outliers, novelties, noise, deviations, and exceptions.
- **Density estimation** is the construction of estimates of unobservable underlying probability density functions based on observed data. A natural use of density estimates is for data exploration. Density estimates can discover features such as skewness and multimodality in the data. The most basic form of density estimation is a rescaled histogram.

SageMaker provides several built-in machine learning algorithms that you can use for these unsupervised learning tasks. For more information on the built-in unsupervised algorithms provided by SageMaker, see Unsupervised Learning.

Reinforcement learning

Reinforcement learning is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

For more information on SageMaker's frameworks, toolkits, and environments for reinforcement learning, see Use Reinforcement Learning with Amazon SageMaker.

Use Amazon SageMaker Built-in Algorithms or Pre-trained Models

Amazon SageMaker provides a suite of built-in algorithms, pre-trained models, and pre-built solution templates to help data scientists and machine learning practitioners get started on training and deploying machine learning models quickly. For someone who is new to SageMaker,

choosing the right algorithm for your particular use case can be a challenging task. The following table provides a quick cheat sheet that shows how you can start with an example problem or use case and find an appropriate built-in algorithm offered by SageMaker that is valid for that problem type. Additional guidance organized by learning paradigms (supervised and unsupervised) and important data domains (text and images) is provided in the sections following the table.

Table: Mapping use cases to built-in algorithms

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Here a few examples out of the 15 problem types that can be addressed by the pre-trained models and pre-built solution templates provided by SageMaker JumpStart: Question answering: chatbot that outputs an answer for a given question. Text analysis: analyze texts from models specific to an industry domain such as finance.	Pre-trained models and pre-built solution templates	Image Classification Tabular Classification Tabular Regression Text Classification Object Detection Text Embedding Question Answering Sentence Pair Classification Image Embedding Named Entity Recognition	Image, Text, Tabular	Popular models, including Mobilenet, YOLO, Faster R-CNN, BERT, lightGBM, and CatBoost For a list of pre-trained models available, see JumpStart Models. For a list of pre-built solution templates available, see JumpStart Solutions.

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
		Instance Segmentation Text Generation Text Summarization Semantic Segmentation Machine Translation		
Predict if an item belongs to a category: an email spam filter	Supervised Learning	Binary/multi-class classification	Tabular	AutoGluon-Tabular, CatBoost, Factorization Machines Algorithm, K-Nearest Neighbors (k-NN) Algorithm, LightGBM, Linear Learner Algorithm, TabTransformer, XGBoost Algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Predict a numeric/c ontinuous value: estimate the value of a house		Regression	Tabular	AutoGluon -Tabular, CatBoost, Factorization Machines Algorithm , K-Nearest Neighbors (k-NN) Algorithm , LightGBM, Linear Learner Algorithm , TabTransf ormer, XGBoost Algorithm
Based on historical data for a behavior, predict future behavior: predict sales on a new product based on previous sales data.		Time-series forecasting	Tabular	DeepAR Forecasting Algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Improve the data embeddings of the high-dimensional objects: identify duplicate support tickets or find the correct routing based on similarity of text in the tickets		Embeddings: convert high-dimensional objects into low-dimensional space.	Tabular	Object2Vec Algorithm
Drop those columns from a dataset that have a weak relation with the label/target variable: the color of a car when predicting its mileage.	Unsupervised Learning	Feature engineering: dimensionality reduction	Tabular	Principal Component Analysis (PCA) Algorithm
Detect abnormal behavior in application: spot when an IoT sensor is sending abnormal readings		Anomaly detection	Tabular	Random Cut Forest (RCF) Algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Protect your application from suspiciou s users: detect if an IP address accessing a service might be from a bad actor		IP anomaly detection	Tabular	IP Insights
Group similar objects/data together: find high-, medium-, and low-spend ing customers from their transaction histories		Clustering or grouping	Tabular	K-Means Algorithm
Organize a set of documents into topics (not known in advance): tag a document as belonging to a medical category based on the terms used in the document.		Topic modeling	Text	Latent Dirichlet Allocation (LDA) Algorithm, Neural Topic Model (NTM) Algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Assign pre-defined categories to documents in a corpus: categorize books in a library into academic disciplines	Textual Analysis	Text classification	Text	BlazingText algorithm, Text Classification - TensorFlow
Convert text from one language to other: Spanish to English		Machine translation algorithm	Text	Sequence-to-Sequence Algorithm
Summarize a long text corpus: an abstract for a research paper		Text summarization	Text	Sequence-to-Sequence Algorithm
Convert audio files to text: transcribe call center conversations for further analysis		Speech-to-text	Text	Sequence-to-Sequence Algorithm

Example problems and use cases	Learning paradigm or domain	Problem types	Data input format	Built-in algorithms
Label/tag an image based on the content of the image: alerts about adult content in an image	Image Processing	Image and multi-label classification	Image	Image Classification - MXNet
Classify something in an image using transfer learning.		Image classification	Image	Image Classification - TensorFlow
Detect people and objects in an image: police review a large photo gallery for a missing person		Object detection and classification	Image	Object Detection - MXNet, Object Detection - TensorFlow
Tag every pixel of an image individually with a category: self-driving cars prepare to identify objects in their way		Computer vision	Image	Semantic Segmentation Algorithm

For important information about Docker registry paths, data formats, recommenced Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms.

The following sections provide additional guidance for the Amazon SageMaker built-in algorithms grouped by the supervised and unsupervised learning paradigms to which they belong. For descriptions of these learning paradigms and their associated problem types, see Choose an Algorithm. Sections are also provided for the SageMaker built-in algorithms available to address two important machine learning domains: textual analysis and image processing.

- Pre-trained Models and Solution Templates
- Supervised Learning
- Unsupervised Learning
- Textual Analysis
- Image Processing

Pre-trained Models and Solution Templates

SageMaker JumpStart provides a wide range of pre-trained models, pre-built solution templates, and examples for popular problem types that use the SageMaker SDK as well as Studio Classic. For more information about these models, solutions, and the example notebooks provided by SageMaker JumpStart, see SageMaker JumpStart.

Supervised Learning

Amazon SageMaker provides several built-in general purpose algorithms that can be used for either classification or regression problems.

- AutoGluon-Tabular—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- CatBoost—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- Factorization Machines Algorithm—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- K-Nearest Neighbors (k-NN) Algorithm—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- LightGBM—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).

- Linear Learner Algorithm—learns a linear function for regression or a linear threshold function for classification.
- TabTransformer—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
- XGBoost Algorithm—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Amazon SageMaker also provides several built-in supervised learning algorithms that are used for more specialized tasks during feature engineering and forecasting from time series data.

- Object2Vec Algorithm—a new highly customizable multi-purpose algorithm used for feature engineering. It can learn low-dimensional dense embeddings of high-dimensional objects to produce features that improve training efficiencies for downstream models. While this is a supervised algorithm, as it requires labeled data for training, there are many scenarios in which the relationship labels can be obtained purely from natural clusterings in data, without any explicit human annotation.
- DeepAR Forecasting Algorithm—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

Unsupervised Learning

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- Principal Component Analysis (PCA) Algorithm—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- K-Means Algorithm—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- IP Insights—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- Random Cut Forest (RCF) Algorithm—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

Textual Analysis

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- BlazingText algorithm—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- Sequence-to-Sequence Algorithm—a supervised algorithm commonly used for neural machine translation.
- Latent Dirichlet Allocation (LDA) Algorithm—an algorithm suitable for determining topics in a set of documents. It is an *unsupervised algorithm*, which means that it doesn't use example data with answers during training.
- Neural Topic Model (NTM) Algorithm—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- Text Classification - TensorFlow—a supervised algorithm that supports transfer learning with available pretrained models for text classification.

Image Processing

SageMaker also provides image processing algorithms that are used for image classification, object detection, and computer vision.

- Image Classification - MXNet—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Image Classification - TensorFlow—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Semantic Segmentation Algorithm—provides a fine-grained, pixel-level approach to developing computer vision applications.
- Object Detection - MXNet—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- Object Detection - TensorFlow—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.

Topics

Common Information About Built-in Algorithms

The following table lists parameters for each of the algorithms provided by Amazon SageMaker.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
AutoGluon-Tabular	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No	
BlazingText	train	File or Pipe	Text file (one sentence per line with space-separated tokens)	CPU or GPU (single instance only)	No	
CatBoost	training and (optionally) validation	File	CSV	CPU (single instance only)	No	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
DeepAR Forecasting	train and (optionally) test	File	JSON Lines or Parquet	CPU or GPU	Yes	
Factorization Machines	train and (optionally) test	File or Pipe	recordIO-protobuf	CPU (GPU for dense data)	Yes	
Image Classification - MXNet	train and validation, (optionally) train_lst, validation_lst, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes	
Image Classification - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	CPU or GPU	Yes (only across multiple GPUs on a single instance)	
IP Insights	train and (optionally) validation	File	CSV	CPU or GPU	Yes	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
K-Means	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPUCommon (single GPU device on one or more instances)	No	
K-Nearest-Neighbors (k-NN)	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPU (single GPU device on one or more instances)	Yes	
LDA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU (single instance only)	No	
LightGBM	train/training and (optionally) validation	File	CSV	CPU	Yes	
Linear Learner	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
Neural Topic Model	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes	
Object2Vec	train and (optionally) validation, test, or both	File	JSON Lines	CPU or GPU (single instance only)	No	
Object Detection - MXNet	train and validation, (optionally) train_annotation, validation_annotation, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes	
Object Detection - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	GPU	Yes (only across multiple GPUs on a single instance)	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
PCA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes
Random Cut Forest	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU	Yes
Semantic Segmentation	train and validation, train_annotation, validation_annotation, and (optionally) label_map and model	File or Pipe	Image files	GPU (single instance only)	No
Seq2Seq Modeling	train, validation, and vocab	File	recordIO-protobuf	GPU (single instance only)	No
TabTransformer	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
Text Classification - TensorFlow	training and validation	File	CSV	CPU or GPU	Yes (only across multiple GPUs on a single instance)	
XGBoost (0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-21)	train and (optionally) validation	File or Pipe	CSV, LibSVM, or Parquet	CPU (or GPU for 1.2-1)	Yes	

Algorithms that are *parallelizable* can be deployed on multiple compute instances for distributed training.

The following topics provide information about data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by Amazon SageMaker.

> **Note**
>

- Instance Types for Built-in Algorithms
- Logs for Built-in Algorithms

Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

Topics

Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data must go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

Topics

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported `ContentType` values and the algorithms that use them:

ContentTypes for Built-in Algorithms

ContentType	Algorithm
application/x-image	Object Detection Algorithm, Semantic Segmentation
application/x-recordio	Object Detection Algorithm
application/x-recordio-protobuf	Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, Sequence-to-Sequence
application/jsonlines	BlazingText, DeepAR
image/jpeg	Object Detection Algorithm, Semantic Segmentation
image/png	Object Detection Algorithm, Semantic Segmentation
text/csv	IP Insights, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, XGBoost
text/libsvm	XGBoost

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

Using Pipe Mode

In *Pipe mode*, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to *File mode*, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the `AlgorithmSpecification` for additional details on the training input mode.

Using CSV Format

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify **`text/csv`** as the

ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case **'content_type=text/csv;label_size=0'**. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms.

Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

> **Note**
>
> For an example that shows how to convert the commonly used numPy array into the protobuf recordIO format, see *An Introduction to Factorization Machines with MNIST* .

```
syntax = "proto2";

 package aialgs.data;

 option java_package = "com.amazonaws.aialgorithms.proto";
 option java_outer_classname = "RecordProtos";

 // A sparse or dense rank-R tensor that stores data as doubles (float64).
 message Float32Tensor   {
     // Each value in the vector. If keys is empty, this is treated as a
     // dense vector.
     repeated float values = 1 [packed = true];

     // If key is not empty, the vector is treated as sparse, with
     // each key specifying the location of the value in the sparse vector.
     repeated uint64 keys = 2 [packed = true];

     // An optional shape that allows the vector to represent a matrix.
     // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
     // and keys[i] % 20 gives the column.
     // This also supports n-dimensonal tensors.
```

```
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated double values = 1 [packed = true];

    // If this is not empty, the vector is treated as sparse, with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];

    // An optional shape that allows the vector to represent a matrix.
    // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
    // and keys[i] % 20 gives the column.
    // This also supports n-dimensonal tensors.
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated int32 values = 1 [packed = true];

    // If this is not empty, the vector is treated as sparse with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];

    // An optional shape that allows the vector to represent a matrix.
    // For Exmple, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
    // and keys[i] % 20 gives the column.
    // This also supports n-dimensonal tensors.
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
    repeated bytes value = 1;
```

```
    // If the content type of the data is known, stores it.
    // This allows for the possibility of using decoders for common formats
    // in the future.
    optional string content_type = 2;
}

message Value {
    oneof value {
        // The numbering assumes the possible use of:
        // - float16, float128
        // - int8, int16, int32
        Float32Tensor float32_tensor = 2;
        Float64Tensor float64_tensor = 3;
        Int32Tensor int32_tensor = 7;
        Bytes bytes = 9;
    }
}

message Record {
    // Map from the name of the feature to the value.
    //
    // For vectors and libsvm-like datasets,
    // a single feature with the name `values`
    // should be specified.
    map<string, Value> features = 1;

    // An optional set of labels for this record.
    // Similar to the features field above, the key used for
    // generic scalar / vector labels should be 'values'.
    map<string, Value> label = 2;

    // A unique identifier for this record in the dataset.
    //
    // Whilst not necessary, this allows better
    // debugging where there are data issues.
    //
    // This is not used by the algorithm directly.
    optional string uid = 3;

    // Textual metadata describing the record.
    //
    // This may include JSON-serialized information
    // about the source of the record.
```

```
    //
    // This is not used by the algorithm directly.
    optional string metadata = 4;

    // An optional serialized JSON object that allows per-record
    // hyper-parameters/configuration/other information to be set.
    //
    // The meaning/interpretation of this field is defined by
    // the algorithm author and may not be supported.
    //
    // This is used to pass additional inference configuration
    // when batch inference is used (e.g. types of scores to return).
    optional string configuration = 5;
}
```

After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of `InputDataConfig` in `create_training_job`.

> **Note**
>
> For all Amazon SageMaker algorithms, the `ChannelName` in `InputDataConfig` must be set to `train`. Some algorithms also support a validation or test `input channels`. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

Trained Model Deserialization

Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in `OutputDataConfig` `S3OutputPath` parameter of the `create_training_job` call. The S3 bucket must be in the same AWS Region as the notebook instance. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When `model.tar.gz` is untarred, it contains `model_algo-1`, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

Common Data Formats for Inference

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

Topics

Convert Data for Inference Request Serialization

Content type options for Amazon SageMaker algorithm inference requests include: `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports `text/csv` from this list, but also supports `text/libsvm`.

For `text/csv`, the value for the Body argument to `invoke_endpoint` should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like `1.5,16.0,14,23.0`. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

`application/json` is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```
let request = {
```

```
  // Instances might contain multiple rows that predictions are sought for.
  "instances": [
    {
      // Request and algorithm specific inference parameters.
      "configuration": {},
      // Data in the specific format required by the algorithm.
      "data": {
         "<field name>": dataElement
       }
    }
  ]
}
```

You have the following options for specifying the `dataElement`:

Protocol buffers equivalent

```
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}
```

Simple numeric vector

```
// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": {
    "values": dataElement
  }
}
```

For multiple records

```
let request = {
  "instances": [
    // First instance.
```

```
    {
      "features": [ 1.5, 16.0, 14.0, 23.0 ]
    },
    // Second instance.
    {
      "features": [ -2.0, 100.2, 15.2, 9.2 ]
    }
  ]
}
```

Convert Data for Inference Response Deserialization

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

```
let response = {
  "predictions": [{
    // Fields in the response object are defined on a per algorithm-basis.
  }]
}
```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

Single-record inference

```
let response = {
  "predictions": [{
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  }]
}
```

Multi-record inference

```
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
```

```
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

Multi-record inference with protobuf input

```
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the `jsonlines` response type by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

Common Request Formats for All Algorithms

Most algorithms use several of the following inference request formats.

JSON Request Format

Content type: application/JSON

Dense format

```
let request =   {
    "instances":    [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}

let request =   {
    "instances":    [
        {
            "data": {
                "features": {
                    "values": [ 1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

Sparse format

```
{
 "instances": [
  {"data": {"features": {
     "keys": [26, 182, 232, 243, 431],
     "shape": [2000],
     "values": [1, 1, 1, 4, 1]
    }
   }
  },
  {"data": {"features": {
     "keys": [0, 182, 232, 243, 431],
     "shape": [2000],
     "values": [13, 1, 1, 4, 1]
    }
   }
  },
 ]
}
```

JSONLINES Request Format

Content type: application/JSONLINES

Dense format

A single record in dense format can be represented as either:

```
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } }
```

Sparse Format

A single record in sparse format is represented as:

```
{"data": {"features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values":
 [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```
{"data": {"features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } }
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

CSV Request Format

Content type: text/CSV; label_size=0

> **Note**
>
> CSV support is not available for factorization machines.

RECORDIO Request Format

Content type: application/x-recordio-protobuf

Use Batch Transform with Built-in Algorithms

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

When you create a transform job, the `SplitType` must be set according to the `ContentType` of the input data. Similarly, depending on the `Accept` field in the `CreateTransformJobRequest`, `AssembleWith` must be set accordingly. Please use the following table to help appropriately set these fields:

ContentType	Recommended SplitType
`application/x-recordio-protobuf`	`RecordIO`
`text/csv`	`Line`
`application/jsonlines`	`Line`
`application/json`	`None`
`application/x-image`	`None`
`image/*`	`None`
Accept	**Recommended AssembleWith**
`application/x-recordio-protobuf`	`None`
`application/json`	`None`
`application/jsonlines`	`Line`

For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats
- Factorization Machines Response Formats
- IP Insights Inference Data Formats
- K-Means Response Formats

- k-NN Request and Response Formats
- Linear learner response formats
- NTM Response Formats
- Data Formats for Object2Vec Inference
- Encoder Embeddings for Object2Vec
- PCA Response Formats
- RCF Response Formats

Instance Types for Built-in Algorithms

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.12xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. For most algorithm training, we support P2, P3, G4dn, and G5 GPU instances. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution. To get an automatic instance recommendation or conduct custom load tests, use Amazon SageMaker Inference Recommender.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose

CloudWatch, choose **Logs**, and then choose the /aws/sagemaker/TrainingJobs **log group**. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the `TrainingJobName` parameter when the job was created.

> **Note**
>
> If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

Common Errors

If a training job fails, some details about the failure are provided by the `FailureReason` return value in the training job description, as follows:

```
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   From the CloudWatch Log

   ```
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
   Additional properties are not allowed (u'mini_batch_siz' was
   unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   FailureReason

```
AlgorithmError: u'abc' is not valid under any of the given
schemas\n\nFailed validating u'oneOf' in
schema[u'properties'][u'feature_dim']:\n    {u'oneOf':
[{u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'},\n
{u'minimum': 1, u'type': u'integer'}]}\
```

FailureReason

```
[10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc'
is not valid under any of the given schemas
```

3. Inaccurate protobuf file format.

From the CloudWatch log

```
[10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot
                  copy sequence with size 785 to array axis with dimension 784
```

Built-in SageMaker Algorithms for Tabular Data

Amazon SageMaker provides built-in algorithms that are tailored to the analysis of tabular data. Tabular data refers to any datasets that are organized in tables consisting of rows (observations) and columns (features). The built-in SageMaker algorithms for tabular data can be used for either classification or regression problems.

- AutoGluon-Tabular—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- CatBoost—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- Factorization Machines Algorithm—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- K-Nearest Neighbors (k-NN) Algorithm—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- LightGBM—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).

- Linear Learner Algorithm—learns a linear function for regression or a linear threshold function for classification.
- TabTransformer—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
- XGBoost Algorithm—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
AutoGluon-Tabular	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No	
CatBoost	training and (optionally) validation	File	CSV	CPU (single instance only)	No	
Factorization Machines	train and (optionally) test	File or Pipe	recordIO-protobuf	CPU (GPU for dense data)	Yes	
K-Nearest-Neighbors (k-NN)	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPU (single GPU device on one or more instances)	Yes	
LightGBM	training and	File	CSV	CPU (single	No	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
	(optionally) validation			instance only)		
Linear Learner	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	CPU or GPU	Yes	
TabTransformer	training and (optionally) validation	File	CSV	CPU or GPU (single instance only)	No	
XGBoost (0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-21)	train and (optionally) validation	File or Pipe	CSV, LibSVM, or Parquet	CPU (or GPU for 1.2-1)	Yes	

AutoGluon-Tabular

AutoGluon-Tabular is a popular open-source AutoML framework that trains highly accurate machine learning models on an unprocessed tabular dataset. Unlike existing AutoML frameworks that primarily focus on model and hyperparameter selection, AutoGluon-Tabular succeeds by ensembling multiple models and stacking them in multiple layers.

How to use SageMaker AutoGluon-Tabular

You can use AutoGluon-Tabular as an Amazon SageMaker built-in algorithm. The following section describes how to use AutoGluon-Tabular with the SageMaker Python SDK. For information on how to use AutoGluon-Tabular from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

- **Use AutoGluon-Tabular as a built-in algorithm**

  Use the AutoGluon-Tabular built-in algorithm to build an AutoGluon-Tabular training container as shown in the following code example. You can automatically spot the AutoGluon-Tabular built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the AutoGluon-Tabular image URI, you can use the AutoGluon-Tabular container to construct an estimator using the SageMaker Estimator API and initiate a training job. The AutoGluon-Tabular built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own AutoGluon-Tabular training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "autogluon-classification-
ensemble", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
```

```
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_binary/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "auto_stack"
] = "True"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
```

```
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up the AutoGluon-Tabular as a built-in algorithm, see the following notebook examples. Any S3 bucket used in these examples must be in the same AWS Region as the notebook instance used to run them.

- Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm
- Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm

Input and Output interface for the AutoGluon-Tabular algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of AutoGluon-Tabular supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the AutoGluon-Tabular model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `training` and `validation` channels to provide your input data. Alternatively, you can use only the `training` channel.

Use both the `training` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `training` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file. If you provide a JSON file for categorical features, your `training` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `training` channel:

You can alternatively provide your input data by way of a single S3 path for the `training` channel. This S3 path should point to a directory with a subdirectory named `training/` that contains a CSV file. You can optionally include another subdirectory in the same location called `validation/` that also has a CSV file. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker AutoGluon-Tabular uses the `autogluon.tabular.TabularPredictor` module to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker AutoGluon-Tabular with the AutoGluon framework

- Use the following Python code:

```
import tarfile
from autogluon.tabular import TabularPredictor

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = TabularPredictor.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ...,
 feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the AutoGluon-Tabular algorithm

SageMaker AutoGluon-Tabular supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AutoGluon-Tabular currently does not support multi-GPU training.

AutoGluon-Tabular sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AutoGluon-Tabular algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm	This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular classific ation model.
Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm	This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular regressio n model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How AutoGluon-Tabular works

AutoGluon-Tabular performs advanced data processing, deep learning, and multi-layer model ensemble methods. It automatically recognizes the data type in each column for robust data preprocessing, including special handling of text fields.

AutoGluon fits various models ranging from off-the-shelf boosted trees to customized neural networks. These models are ensembled in a novel way: models are stacked in multiple layers and trained in a layer-wise manner that guarantees raw data can be translated into high-quality predictions within a given time constraint. This process mitigates overfitting by splitting the data in various ways with careful tracking of out-of-fold examples.

The AutoGluon-Tabular algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, and distributions. You can use AutoGluon-Tabular for regression, classification (binary and multiclass), and ranking problems.

Refer to the following diagram illustrating how the multi-layer stacking strategy works.

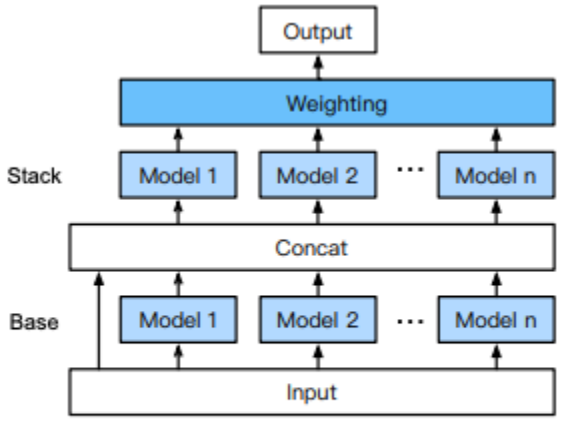

Figure 2. AutoGluon's multi-layer stacking strategy, shown here using two stacking layers and n types of base learners.

For more information, see *AutoGluon-Tabular: Robust and Accurate AutoML for Structured Data*.

AutoGluon-Tabular hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AutoGluon-Tabular algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AutoGluon-Tabular algorithm is an implementation of the open-source AutoGluon-Tabular package.

> **Note**
>
> The default hyperparameters are based on example datasets in the AutoGluon-Tabular sample notebooks.

By default, the SageMaker AutoGluon-Tabular algorithm automatically chooses an evaluation metric based on the type of classification problem. The algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error. For binary classification problems, the evaluation metric is area under the receiver operating characteristic curve (AUC). For multiclass classification problems, the evaluation metric is accuracy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on AutoGluon-Tabular hyperparameters, including descriptions, valid values, and default values.

Parameter Name	Description
`eval_metric`	The evaluation metric for validation data. If `eval_metric` is set to the default `"auto"` value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem: • `"root_mean_squared_error"` for regression • `"roc_auc"` for binary classification • `"accuracy"` for multi-class classification Valid values: string, refer to the AutoGluon documentation for valid values. Default value: `"auto"`.
`presets`	List of preset configurations for various arguments in `fit()`. • `"best_quality"` : high predictive accuracy, slower inference times and higher disk usage • `"high_quality"` : high predictive accuracy and fast inference • `"good_quality"` : good predictive accuracy and very fast inference • `"medium_quality"` : medium predictive accuracy, very fast inference and training time • `"optimize_for_deployment"` : delete unused models and remove training artifacts • `"interpretable"` : fits only interpretable rule-based models from the `imodels` package For more details, see AutoGluon Predictors. Valid values: string, any of the following: (`"best_quality"` , `"high_quality"` , `good_quality"` , `"medium_q`

Parameter Name	Description
	uality" ,"optimize_for_deployment" , or "interpretable"). Default value: "medium_quality" .
auto_stack	Whether AutoGluon should automatically utilize bagging and multi-layer stack ensembling to boost predictive accuracy. Set auto_stack to "True" if you are willing to tolerate longer training times in order to maximize predictive accuracy. This automatically sets the num_bag_folds and num_stack _levels arguments based on dataset properties. Valid values: string, "True" or "False". Default value: "False".
num_bag_folds	Number of folds used for bagging of models. When num_bag_folds is equal to k, training time is roughly increased by a factor of k. Set num_bag_folds to 0 to deactivate bagging. This is disabled by default, but we recommend using values between 5 and 10 to maximize predictive performance. Increasing num_bag_folds results in models with lower bias, but that are more prone to overfitti ng. One is an invalid value for this parameter, and will raise a ValueError . Values greater than 10 may produce diminishi ng returns and can even harm overall results due to overfitting. To further improve predictions, avoid increasing num_bag_f olds and instead increase num_bag_sets . Valid values: string, any integer between (and including) "0" and "10". Default value: "0".

Parameter Name	Description
num_bag_sets	Number of repeats of kfold bagging to perform (values must be greater than or equal to 1). The total number of models trained during bagging is equal to num_bag_folds * num_bag_sets . This parameter defaults to one if time_limit is not specified. This parameters is disabled if num_bag_folds is not specified. Values greater than one result in superior predictive performance, especially on smaller problems and with stacking enabled. Valid values: integer, range: [1, 20]. Default value: 1.
num_stack_levels	Number of stacking levels to use in stack ensemble. Roughly increases model training time by factor of num_stack_levels + 1. Set this parameter to 0 to deactivate stack ensembling. This parameter is deactivated by default, but we recommend using values between 1 and 3 to maximize predictive performance. To prevent overfitting and a ValueError , num_bag_folds must be greater than or equal to 2. Valid values: float, range: [0, 3]. Default value: 0.
refit_full	Whether or not to retrain all models on all of the data (training and validation) after the normal training procedure. For more details, see AutoGluon Predictors. Valid values: string, "True" or "False". Default value: "False".

Parameter Name	Description
`set_best_to_refit_full`	Whether or not to change the default model that the predictor uses for prediction. If `set_best_to_refit_full` is set to `"True"`, the default model changes to the model that exhibited the highest validation score as a result of refitting (activated by `refit_full`). Only valid if `refit_full` is set. Valid values: string, `"True"` or `"False"`. Default value: `"False"`.
`save_space`	Whether or note to reduce the memory and disk size of predictor by deleting auxiliary model files that aren't needed for prediction on new data. This has no impact on inference accuracy. We recommend setting `save_space` to `"True"` if the only goal is to use the trained model for prediction. Certain advanced functionality may no longer be available if `save_space` is set to `"True"`. Refer to the `predictor.save_space()` documentation for more details. Valid values: string, `"True"` or `"False"`. Default value: `"False"`.
`verbosity`	The verbosity of print messages. `verbosity` levels range from `0` to `4`, with higher levels corresponding to more detailed print statements. A `verbosity` of `0` suppresses warnings. Valid values: integer, any of the following: (`0`, 1, 2, 3, or 4). Default value: 2.

Tuning an AutoGluon-Tabular model

Although AutoGluon-Tabular can be used with model tuning, its design can deliver good performance using stacking and ensemble methods, meaning hyperparameter optimization is not necessary. Rather than focusing on model tuning, AutoGluon-Tabular succeeds by stacking models in multiple layers and training in a layer-wise manner.

For more information about AutoGluon-Tabular hyperparameters, see AutoGluon-Tabular hyperparameters.

CatBoost

CatBoost is a popular and high-performance open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.

CatBoost introduces two critical algorithmic advances to GBDT:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

How to use SageMaker CatBoost

You can use CatBoost as an Amazon SageMaker built-in algorithm. The following section describes how to use CatBoost with the SageMaker Python SDK. For information on how to use CatBoost from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

- **Use CatBoost as a built-in algorithm**

  Use the CatBoost built-in algorithm to build a CatBoost training container as shown in the following code example. You can automatically spot the CatBoost built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the CatBoost image URI, you can use the CatBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. The CatBoost built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own CatBoost training scripts.

```
from sagemaker import image_uris, model_uris, script_uris
```

```
train_model_id, train_model_version, train_scope = "catboost-classification-model",
 "*", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
```

```
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "iterations"
] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up CatBoost as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the CatBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of CatBoost supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the CatBoost model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `training` and `validation` channels to provide your input data. Alternatively, you can use only the `training` channel.

Use both the `training` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `training` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the `training` or `validation` channels, the CatBoost algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your `training` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should

indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `training` channel:

You can alternatively provide your input data by way of a single S3 path for the `training` channel. This S3 path should point to a directory with a subdirectory named `training/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called `validation/` that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker CatBoost uses the `catboost.CatBoostClassifier` and `catboost.CatBoostRegressor` modules to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker CatBoost with `catboost`

- Use the following Python code:

```
import tarfile
from catboost import CatBoostClassifier

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

file_path = os.path.join(model_file_path, "model")
model = CatBoostClassifier()
model.load_model(file_path)
```

```
# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ...,
 feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the CatBoost algorithm

SageMaker CatBoost currently only trains using CPUs. CatBoost is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

CatBoost sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker CatBoost algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker CatBoost algorithm to train and host a tabular classification model.
Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker CatBoost algorithm to train and host a tabular regression model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How CatBoost Works

CatBoost implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two critical algorithmic advances:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm

2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

The CatBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use CatBoost for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works. For in-depth details about the additional GOSS and EFB techniques used in the CatBoost method, see *CatBoost: unbiased boosting with categorical features*.

CatBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker CatBoost algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker CatBoost algorithm is an implementation of the open-source CatBoost package.

> **Note**
>
> The default hyperparameters are based on example datasets in the CatBoost sample notebooks.

By default, the SageMaker CatBoost algorithm automatically chooses an evaluation metric and loss function based on the type of classification problem. The CatBoost algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric and loss functions are both root mean squared error. For binary classification problems, the evaluation metric is Area Under the Curve (AUC) and the loss function is log loss. For multiclass classification problems, the evaluation metric and loss functions are multiclass cross entropy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

Parameter Name	Description
`iterations`	The maximum number of trees that can be built. Valid values: integer, range: Positive integer. Default value: `500`.
`early_stopping_rounds`	The training will stop if one metric of one validation data point does not improve in the last `early_stopping_rounds` round. If `early_stopping_rounds` is less than or equal to zero, this hyperparameter is ignored. Valid values: integer. Default value: 5.
`eval_metric`	The evaluation metric for validation data. If `eval_metric` is set to the default `"auto"` value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem: • `"RMSE"` for regression • `"AUC"` for binary classification • `"MultiClass"` for multi-class classification Valid values: string, refer to the CatBoost documentation for valid values. Default value: `"auto"`.
`learning_rate`	The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: (`0.0`, `1.0`). Default value: `0.009`.
`depth`	Depth of the tree.

Parameter Name	Description
	Valid values: integer, range: (1, 16). Default value: 6.
`l2_leaf_reg`	Coefficient for the L2 regularization term of the cost function. Valid values: integer, range: Positive integer. Default value: 3.
`random_strength`	The amount of randomness to use for scoring splits when the tree structure is selected. Use this parameter to avoid overfitti ng the model. Valid values: float, range: Positive floating point number. Default value: `1.0`.
`max_leaves`	The maximum number of leaves in the resulting tree. Can only be used with the `"Lossguide"` growing policy. Valid values: integer, range: [2, 64]. Default value: 31.
`rsm`	Random subspace method. The percentage of features to use at each split selection, when features are selected over again at random. Valid values: float, range: (`0.0`, `1.0`]. Default value: `1.0`.
`sampling_frequency`	Frequency to sample weights and objects when building trees. Valid values: string, either: (`"PerTreeLevel"` or `"PerTree"`). Default value: `"PerTreeLevel"` .

Parameter Name	Description
`min_data_in_leaf`	The minimum number of training samples in a leaf. CatBoost does not search for new splits in leaves with a sample count less than the specified value. Can only be used with the `"Lossguide"` and `"Depthwise"` growing policies. Valid values: integer, range: (1 or ∞). Default value: 1.
`bagging_temperature`	Defines the settings of the Bayesian bootstrap. Use the Bayesian bootstrap to assign random weights to objects. If `bagging_temperature` is set to `1.0`, then the weights are sampled from an exponential distribution. If `bagging_temperature` is set to `0.0`, then all weights are 1.0. Valid values: float, range: Non-negative float. Default value: `1.0`.
`boosting_type`	The boosting scheme. "Auto" means that the `boosting_type` is selected based on processing unit type, the number of objects in the training dataset, and the selected learning mode. Valid values: string, any of the following: (`"Auto"`, `"Ordered"`, `"Plain"`). Default value: `"Auto"`.
`scale_pos_weight`	The weight for positive class in binary classification. The value is used as a multiplier for the weights of objects from positive class. Valid values: float, range: Positive float. Default value: `1.0`.

Parameter Name	Description
max_bin	The number of splits for numerical features. "Auto" means that max_bin is selected based on the processing unit type and other parameters. For details, see the CatBoost documentation. Valid values: string, either: ("Auto" or string of integer from "1" to "65535" inclusively). Default value: "Auto".
grow_policy	The tree growing policy. Defines how to perform greedy tree construction. Valid values: string, any of the following: ("SymmetricTree" , "Depthwise" , or "Lossguide"). Default value: "SymmetricTree" .
random_seed	The random seed used for training. Valid values: integer, range: Non-negative integer. Default value: 1.0.
thread_count	The number of threads to use during the training. If thread_count is -1, then the number of threads is equal to the number of processor cores. thread_count cannot be 0. Valid values: integer, either: (-1 or positive integer). Default value: -1.
verbose	The verbosity of print messages, with higher levels corresponding to more detailed print statements. Valid values: integer, range: Positive integer. Default value: 1.

Tune a CatBoost model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

> **Note**
>
> The learning loss function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see CatBoost hyperparameters.

- A learning loss function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

> **Note**
>
> Automatic model tuning for CatBoost is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Evaluation metrics computed by the CatBoost algorithm

The SageMaker CatBoost algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Metric Name	Description	Optimization Direction	Regex Pattern
RMSE	root mean square error	minimize	"bestTest = ([0-9\\.]+)"
MAE	mean absolute error	minimize	"bestTest = ([0-9\\.]+)"
MedianAbsoluteError	median absolute error	minimize	"bestTest = ([0-9\\.]+)"
R2	r2 score	maximize	"bestTest = ([0-9\\.]+)"
Logloss	binary cross entropy	maximize	"bestTest = ([0-9\\.]+)"
Precision	precision	maximize	"bestTest = ([0-9\\.]+)"
Recall	recall	maximize	"bestTest = ([0-9\\.]+)"
F1	f1 score	maximize	"bestTest = ([0-9\\.]+)"
AUC	auc score	maximize	"bestTest = ([0-9\\.]+)"

Metric Name	Description	Optimization Direction	Regex Pattern
MultiClass	multiclass cross entropy	maximize	"bestTest = ([0-9\\.]+)"
Accuracy	accuracy	maximize	"bestTest = ([0-9\\.]+)"
BalancedAccuracy	balanced accuracy	maximize	"bestTest = ([0-9\\.]+)"

Tunable CatBoost hyperparameters

Tune the CatBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the CatBoost evaluation metrics are: `learning_rate`, `depth`, `l2_leaf_reg`, and `random_strength`. For a list of all the CatBoost hyperparameters, see CatBoost hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
learning_rate	ContinuousParameterRanges	MinValue: 0.001, MaxValue: 0.01
depth	IntegerParameterRanges	MinValue: 4, MaxValue: 10
l2_leaf_reg	IntegerParameterRanges	MinValue: 2, MaxValue: 10
random_strength	ContinuousParameterRanges	MinValue: 0, MaxValue: 10

Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

> **Note**
>
> The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

Topics

Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the **test** channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For **training**, the Factorization Machines algorithm currently supports only the `recordIO-protobuf` format with `Float32` tensors. Because their use case is predominantly on sparse data,

CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For **inference**, the Factorization Machines algorithm supports the `application/json` and `x-recordio-protobuf` formats.

- For the **binary classification** problem, the algorithm predicts a score and a label. The label is a number and can be either `0` or `1`. The score is a number that indicates how strongly the algorithm believes that the label should be `1`. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is `1`.
- For the **regression** problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see Factorization Machines Sample Notebooks for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data. The Factorization Machines algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function ŷ from a feature set x_i to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset (x_i,y_j) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

$$\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j>i} < v_i, v_j > x_i x_j$$

The three terms in this equation correspond respectively to the three components of the model:

- The w_0 term represents the global bias.
- The w_i linear terms model the strength of the i^{th} variable.
- The $<v_i,v_j>$ factorization terms model the pairwise interaction between the i^{th} and j^{th} variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction $\hat{y}_n$ and the target value y_n. This is known as the square loss:

$$L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2$$

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

$$L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]$$

where:

$$\hat{p}_n = \frac{1}{1 + e^{-\hat{y}_n}}$$

For more information about loss functions for classification, see Loss functions for classification.

Factorization Machines Hyperparameters

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

Parameter Name	Description
`feature_dim`	The dimension of the input feature space. This could be very high with sparse input. **Required** Valid values: Positive integer. Suggested value range: [10000,10000000]
`num_factors`	The dimensionality of factorization. **Required** Valid values: Positive integer. Suggested value range: [2,1000], 64 typically generates good outcomes and is a good starting point.
`predictor_type`	The type of predictor. • `binary_classifier` : For binary classification tasks. • `regressor` : For regression tasks. **Required** Valid values: String: `binary_classifier` or `regressor`
`bias_init_method`	The initialization method for the bias term:

Parameter Name	Description
	• `normal`: Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by `bias_init_sigma` . • `uniform`: Initializes weights with random values uniformly sampled from a range specified by [`-bias_init_scale` , `+bias_init_scale`]. • `constant`: Initializes the weights to a scalar value specified by `bias_init_value` . **Optional** Valid values: `uniform`, `normal`, or `constant` Default value: `normal`
`bias_init_scale`	Range for initialization of the bias term. Takes effect if `bias_init_method` is set to `uniform`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: None
`bias_init_sigma`	The standard deviation for initialization of the bias term. Takes effect if `bias_init_method` is set to `normal`. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.01

Parameter Name	Description
bias_init_value	The initial value of the bias term. Takes effect if bias_init_method is set to constant. **Optional** Valid values: Float. Suggested value range: [1e-8, 512]. Default value: None
bias_lr	The learning rate for the bias term. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.1
bias_wd	The weight decay for the bias term. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.01
clip_gradient	Gradient clipping optimizer parameter. Clips the gradient by projecting onto the interval [-clip_gradient , +clip_gradient]. **Optional** Valid values: Float Default value: None

Parameter Name	Description
epochs	The number of training epochs to run. **Optional** Valid values: Positive integer Default value: 1
eps	Epsilon parameter to avoid division by 0. **Optional** Valid values: Float. Suggested value: small. Default value: None
factors_init_method	The initialization method for factorization terms: • normal Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by factors_init_sigma . • uniform: Initializes weights with random values uniformly sampled from a range specified by [-factors_init_scale , +factors_init_scale]. • constant: Initializes the weights to a scalar value specified by factors_init_value . **Optional** Valid values: uniform, normal, or constant. Default value: normal

Parameter Name	Description
factors_init_scale	The range for initialization of factorization terms. Takes effect if factors_init_method is set to uniform. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: None
factors_init_sigma	The standard deviation for initialization of factorization terms. Takes effect if factors_init_method is set to normal. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.001
factors_init_value	The initial value of factorization terms. Takes effect if factors_init_method is set to constant. **Optional** Valid values: Float. Suggested value range: [1e-8, 512]. Default value: None
factors_lr	The learning rate for factorization terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.0001

Parameter Name	Description
factors_wd	The weight decay for factorization terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.00001
linear_lr	The learning rate for linear terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.001
linear_init_method	The initialization method for linear terms: • normal Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by linear_init_sigma . • uniform Initializes weights with random values uniformly sampled from a range specified by [-linear_init_scale , +linear_init_scale]. • constant Initializes the weights to a scalar value specified by linear_init_value . **Optional** Valid values: uniform, normal, or constant. Default value: normal

Parameter Name	Description
linear_init_scale	Range for initialization of linear terms. Takes effect if linear_init_method is set to uniform. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: None
linear_init_sigma	The standard deviation for initialization of linear terms. Takes effect if linear_init_method is set to normal. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.01
linear_init_value	The initial value of linear terms. Takes effect if linear_in it_method is set to *constant*. **Optional** Valid values: Float. Suggested value range: [1e-8, 512]. Default value: None
linear_wd	The weight decay for linear terms. **Optional** Valid values: Non-negative float. Suggested value range: [1e-8, 512]. Default value: 0.001

Parameter Name	Description
`mini_batch_size`	The size of mini-batch used for training. **Optional** Valid values: Positive integer Default value: 1000
`rescale_grad`	Gradient rescaling optimizer parameter. If set, multiplies the gradient with `rescale_grad` before updating. Often choose to be 1.0/`batch_size` . **Optional** Valid values: Float Default value: None

Tune a Factorization Machines Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a `test:rmse` regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

Metric Name	Description	Optimization Direction
test:rmse	Root Mean Square Error	Minimize

The Factorization Machines algorithm reports three binary classification metrics, which are computed during training. When tuning the model for binary classification tasks, choose one of these as the objective.

Metric Name	Description	Optimization Direction
test:binary_classification_accuracy	Accuracy	Maximize
test:binary_classification_cross_entropy	Cross Entropy	Minimize
test:binary_f_beta	Beta	Maximize

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: `uniform`, `normal`, and `constant`. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is `uniform`, then only the `scale` parameters are tunable. Specifically, if `bias_init_method==uniform`, then `bias_init_scale`, `linear_init_scale`, and `factors_init_scale` are tunable. Similarly, if the initialization method is `normal`, then

only `sigma` parameters are tunable. If the initialization method is `constant`, then only `value` parameters are tunable. These dependencies are listed in the following table.

Parameter Name	Parameter Type	Recommended Ranges	Dependency
`bias_init_scale`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
`bias_init_sigma`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
`bias_init_value`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
`bias_lr`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
`bias_wd`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
`epoch`	IntegerParameterRange	MinValue: 1, MaxValue: 1000	None
`factors_init_scale`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
`factors_init_sigma`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
`factors_init_value`	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant

Parameter Name	Parameter Type	Recommended Ranges	Dependency
factors_lr	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
factors_wd	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512]	None
linear_init_scale	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
linear_init_sigma	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
linear_init_value	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
linear_lr	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
linear_wd	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
mini_batch_size	IntegerParameterRange	MinValue: 100, MaxValue: 10000	None

Factorization Machines Response Formats

JSON Response Format

Binary classification

```
let response =   {
    "predictions":    [
        {
            "score": 0.4,
```

```
            "predicted_label": 0
        }
    ]
}
```

Regression

```
let response =   {
    "predictions":    [
        {
            "score": 0.4
        }
    ]
}
```

JSONLINES Response Format

Binary classification

```
{"score": 0.4, "predicted_label": 0}
```

Regression

```
{"score": 0.4}
```

RECORDIO Response Format

Binary classification

```
[
    Record = {
        features = {},
        label = {
            'score’: {
                keys: [],
                values: [0.4]  # float32
            },
            'predicted_label': {
                keys: [],
                values: [0.0]  # float32
```

```
            }
        }
    }
]
```

Regression

```
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            }
        }
    }
]
```

K-Nearest Neighbors (k-NN) Algorithm

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the *k* points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the *k* closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d >1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

Input/Output Interface for the k-NN Algorithm

SageMaker k-NN supports train and test data channels.

- Use a *train channel* for data that you want to sample and construct into the k-NN index.
- Use a *test channel* to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for `classifier`, mean-squared error (mse) for `regressor` for score.

For training inputs, k-NN supports `text/csv` and `application/x-recordio-protobuf` data formats. For input type `text/csv`, the first `label_size` columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as CSV.

For inference inputs, k-NN supports the `application/json`, `application/x-recordio-protobuf`, and `text/csv` data formats. The `text/csv` format accepts a `label_size` and encoding parameter. It assumes a `label_size` of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the `application/json` and `application/x-recordio-protobuf` data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the `application/jsonlines` data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
```

```
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}
```

An example output is as follows:

```
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input for training, k-NN Request and Response Formats for inference, and the k-NN Sample Notebooks.

k-NN Sample Notebooks

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype .

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How the k-NN Algorithm Works

Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the `sample_size`parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs,

and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires O(ndk) time to reduce the dimension of a batch of n points of dimension d into a target dimension k. The `fjlt` method requires O(nd log(d)) time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.

Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- model_algo-1: Contains the serialized index for computing the nearest neighbors.
- model_algo-1.labels: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- model_algo-1.json: Contains the JSON-formatted model metadata which stores the `k` and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change `k` to 10 or change `predictor_type` to *regressor*.

```
{
  "k": 5,
  "predictor_type": "classifier",
  "dimension_reduction": {"type": "sign", "seed": 3, "target_dim": 10, "input_dim":
 20},
  "normalize": False,
  "version": "1.0"
}
```

EC2 Instance Recommendation for the k-NN Algorithm

We recommend training on a CPU instance (such as ml.m5.2xlarge) or on a GPU instance. The k-NN algorithm supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

k-NN Hyperparameters

Parameter Name	Description
`feature_dim`	The number of features in the input data. **Required** Valid values: positive integer.
k	The number of nearest neighbors. **Required** Valid values: positive integer
`predictor_type`	The type of inference to use on the data labels. **Required** Valid values: *classifier* for classification or *regressor* for regression.
`sample_size`	The number of data points to be sampled from the training data set. **Required** Valid values: positive integer
`dimension_reduction_target`	The target dimension to reduce to. **Required** when you specify the `dimension_reduction_type` parameter.

Parameter Name	Description
	Valid values: positive integer greater than 0 and less than `feature_dim` .
`dimension_reduction_type`	The type of dimension reduction method. **Optional** Valid values: *sign* for random projection or *fjlt* for the fast Johnson-Lindenstrauss transform. Default value: No dimension reduction
`faiss_index_ivf_nlists`	The number of centroids to construct in the index when `index_type` is *faiss.IVFFlat* or *faiss.IVFPQ*. **Optional** Valid values: positive integer Default value: *auto*, which resolves to `sqrt(sample_size)` .
`faiss_index_pq_m`	The number of vector sub-components to construct in the index when `index_type` is set to *faiss.IVFPQ*. The FaceBook AI Similarity Search (FAISS) library requires that the value of `faiss_index_pq_m` is a divisor of the data dimension . If `faiss_index_pq_m` is not a divisor of the data dimension , we increase the data dimension to smallest integer divisible by `faiss_index_pq_m` . If no dimension reduction is applied, the algorithm adds a padding of zeros. If dimension reduction is applied, the algorithm increase the value of the `dimension_reduction_target` hyper-parameter. **Optional** Valid values: One of the following positive integers: 1, 2, 3, 4, 8, 12, 16, 20, 24, 28, 32, 40, 48, 56, 64, 96

Parameter Name	Description
`index_metric`	The metric to measure the distance between points when finding nearest neighbors. When training with `index_type` set to `faiss.IVFPQ` , the `INNER_PRODUCT` distance and `COSINE` similarity are not supported. **Optional** Valid values: *L2* for Euclidean-distance, *INNER_PRODUCT* for inner-product distance, *COSINE* for cosine similarity. Default value: *L2*
`index_type`	The type of index. **Optional** Valid values: *faiss.Flat*, *faiss.IVFFlat*, *faiss.IVFPQ*. Default values: *faiss.Flat*
`mini_batch_size`	The number of observations per mini-batch for the data iterator. **Optional** Valid values: positive integer Default value: 5000

Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- *classifier* specifies a classification task and computes `test:accuracy`
- *regressor* specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

Metric Name	Description	Optimization Direction
`test:accuracy`	When `predictor_type` is set to *classifier*, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).	Maximize
`test:mse`	When `predictor_type` is set to *regressor* , k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels.	Minimize

Tunable k-NN Hyperparameters

Tune the Amazon SageMaker k-nearest neighbor model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
k	IntegerParameterRanges	MinValue: 1, MaxValue: 1024
`sample_size`	IntegerParameterRanges	MinValue: 256, MaxValue: 20000000

Data Formats for k-NN Training Input

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in Common Data Formats - Training. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

CSV Data Format

content-type: text/csv; label_size=1

```
4,1.2,1.3,9.6,20.3
```

The first `label_size` columns are interpreted as the label vector for that row.

RECORDIO Data Format

content-type: application/x-recordio-protobuf

```
[
    Record = {
        features = {
            'values': {
                values: [1.2, 1.3, 9.6, 20.3]  # float32
            }
        },
```

```
        label = {
            'values': {
                values: [4]  # float32
            }
        }
    }
]

}
```

k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

INPUT: CSV Request Format

content-type: text/csv

```
1.2,1.3,9.6,20.3
```

This accepts a `label_size` or encoding parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

INPUT: JSON Request Format

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": [-3, -1, -4, 2]}}},
    {"features": [3.0, 0.1, 0.04, 0.002]}]
}
```

INPUT: JSONLINES Request Format

content-type: application/jsonlines

```
{"features": [1.5, 16.0, 14.0, 23.0]}
```

```
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}
```

INPUT: RECORDIO Request Format

content-type: application/x-recordio-protobuf

```
[
    Record = {
        features = {
            'values': {
                values: [-3, -1, -4, 2]  # float32
            }
        },
        label = {}
    },
    Record = {
        features = {
            'values': {
                values: [3.0, 0.1, 0.04, 0.002]  # float32
            }
        },
        label = {}
    },
]
```

OUTPUT: JSON Response Format

accept: application/json

```
{
  "predictions": [
    {"predicted_label": 0.0},
    {"predicted_label": 2.0}
  ]
}
```

OUTPUT: JSONLINES Response Format

accept: application/jsonlines

```
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

OUTPUT: VERBOSE JSON Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/json; verbose=true

```
{
  "predictions": [
    {
        "predicted_label": 0.0,
        "distances": [3.11792408, 3.89746071, 6.32548437],
        "labels": [0.0, 1.0, 0.0]
    },
    {
        "predicted_label": 2.0,
        "distances": [1.08470316, 3.04917915, 5.25393973],
        "labels": [2.0, 2.0, 0.0]
    }
  ]
}
```

OUTPUT: RECORDIO-PROTOBUF Response Format

content-type: application/x-recordio-protobuf

```
[
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0]  # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [2.0]  # float32
            }
        }
    }
```

```
]
```

OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/x-recordio-protobuf; verbose=true

```
[
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0]  # float32
            },
            'distances': {
                values: [3.11792408, 3.89746071, 6.32548437]  # float32
            },
            'labels': {
                values: [0.0, 1.0, 0.0]  # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0]  # float32
            },
            'distances': {
                values: [1.08470316, 3.04917915, 5.25393973]  # float32
            },
            'labels': {
                values: [2.0, 2.0, 0.0]  # float32
            }
        }
    }
]
```

SAMPLE OUTPUT for the k-NN Algorithm

For regressor tasks:

```

 0.98666666666666669)
```

LightGBM

LightGBM is a popular and efficient open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. LightGBM uses additional techniques to significantly improve the efficiency and scalability of conventional GBDT.

How to use SageMaker LightGBM

You can use LightGBM as an Amazon SageMaker built-in algorithm. The following section describes how to use LightGBM with the SageMaker Python SDK. For information on how to use LightGBM from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

- **Use LightGBM as a built-in algorithm**

  Use the LightGBM built-in algorithm to build a LightGBM training container as shown in the following code example. You can automatically spot the LightGBM built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the LightGBM image URI, you can use the LightGBM container to construct an estimator using the SageMaker Estimator API and initiate a training job. The LightGBM built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own LightGBM training scripts.

  ```
  from sagemaker import image_uris, model_uris, script_uris

  train_model_id, train_model_version, train_scope = "lightgbm-classification-model",
   "*", "training"
  training_instance_type = "ml.m5.xlarge"
  ```

```
# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
```

```
hyperparameters[
    "num_boost_round"
] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1, # for distributed training, specify an instance_count greater
 than 1
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "train": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up the LightGBM as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the LightGBM algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of LightGBM supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the LightGBM model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `train` and `validation` channels to provide your input data. Alternatively, you can use only the `train` channel.

> **Note**
>
> Both `train` and `training` are valid channel names for LightGBM training.

Use both the `train` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `train` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the `train` or `validation` channels, the LightGBM algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your `train` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `train` channel:

You can alternatively provide your input data by way of a single S3 path for the `train` channel. This S3 path should point to a directory with a subdirectory named `train/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called `validation/` that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker LightGBM uses the Python Joblib module to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker LightGBM with the JobLib module

- Use the following Python code:

```
import joblib
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
```

```
model = joblib.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ...,
 feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the LightGBM algorithm

SageMaker LightGBM currently supports single-instance and multi-instance CPU training. For multi-instance CPU training (distributed training), specify an `instance_count` greater than 1 when you define your Estimator. For more information on distributed training with LightGBM, see Amazon SageMaker LightGBM Distributed training using Dask.

LightGBM is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

LightGBM sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker LightGBM algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular classification model.
Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm	This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular regression model.
Amazon SageMaker LightGBM Distributed training using Dask	This notebook demonstrates distribut ed training with the Amazon SageMaker LightGBM algorithm using the Dask framework.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How LightGBM works

LightGBM implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two novel techniques: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to significantly improve the efficiency and scalability of GBDT.

The LightGBM algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use LightGBM for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works. For in-depth details about the additional GOSS and EFB techniques used in the LightGBM method, see *LightGBM: A Highly Efficient Gradient Boosting Decision Tree*.

LightGBM hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker LightGBM algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker LightGBM algorithm is an implementation of the open-source LightGBM package.

> **Note**
>
> The default hyperparameters are based on example datasets in the LightGBM sample notebooks.

By default, the SageMaker LightGBM algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The LightGBM algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error and the objective function is L2 loss. For binary classification problems, the evaluation metric and objective function are both binary

cross entropy. For multiclass classification problems, the evaluation metric is multiclass cross entropy and the objective function is softmax. You can use the `metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

Parameter Name	Description
`num_boost_round`	The maximum number of boosting iterations. **Note:** Internally, LightGBM constructs `num_class * num_boost_round` trees for multi-class classification problems. Valid values: integer, range: Positive integer. Default value: `100`.
`early_stopping_rounds`	The training will stop if one metric of one validation data point does not improve in the last `early_stopping_rounds` round. If `early_stopping_rounds` is less than or equal to zero, this hyperparameter is ignored. Valid values: integer. Default value: `10`.
`metric`	The evaluation metric for validation data. If `metric` is set to the default `"auto"` value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem: • `rmse` for regression • `binary_logloss` for binary classification • `multi_logloss` for multi-class classification Valid values: string, any of the following: (`"auto"`, `"rmse"`, `"l1"`, `"l2"`, `"huber"`, `"fair"`, `"binary_logloss"`, `"binary_error"`, `"auc"`, `"average_precision"`, `"multi_logloss"`, `"multi_error"`, `"auc_mu"`, or `"cross_entropy"`).

Parameter Name	Description
	Default value: "auto".
learning_rate	The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: (0.0, 1.0). Default value: 0.1.
num_leaves	The maximum number of leaves in one tree. Valid values: integer, range: (1, 131072). Default value: 64.
feature_fraction	A subset of features to be selected on each iteration (tree). Must be less than 1.0. Valid values: float, range: (0.0, 1.0). Default value: 0.9.
bagging_fraction	A subset of features similar to feature_fraction , but bagging_fraction randomly selects part of the data without resampling. Valid values: float, range: (0.0, 1.0]. Default value: 0.9.
bagging_freq	The frequency to perform bagging. At every bagging_freq iteration, LightGBM randomly selects a percentage of the data to use for the next bagging_freq iteration. This percentage is determined by the bagging_fraction hyperparameter. If bagging_freq is zero, then bagging is deactivated. Valid values: integer, range: Non-negative integer. Default value: 1.

Parameter Name	Description
max_depth	The maximum depth for a tree model. This is used to deal with overfitting when the amount of data is small. If max_depth is less than or equal to zero, this means there is no limit for maximum depth. Valid values: integer. Default value: 6.
min_data_in_leaf	The minimum amount of data in one leaf. Can be used to deal with overfitting. Valid values: integer, range: Non-negative integer. Default value: 3.
max_delta_step	Used to limit the max output of tree leaves. If max_delta_step is less than or equal to 0, then there is no constrain t. The final max output of leaves is learning_rate * max_delta_step . Valid values: float. Default value: 0.0.
lambda_l1	L1 regularization. Valid values: float, range: Non-negative float. Default value: 0.0.
lambda_l2	L2 regularization. Valid values: float, range: Non-negative float. Default value: 0.0.

Parameter Name	Description
boosting	Boosting type Valid values: string, any of the following: ("gbdt", "rf", "dart", or "goss"). Default value: "gbdt".
min_gain_to_split	The minimum gain to perform a split. Can be used to speed up training. Valid values: integer, float: Non-negative float. Default value: 0.0.
scale_pos_weight	The weight of the labels with positive class. Used only for binary classification tasks. scale_pos_weight cannot be used if is_unbalance is set to "True". Valid values: float, range: Positive float. Default value: 1.0.
tree_learner	Tree learner type. Valid values: string, any of the following: ("serial", "feature" , "data", or "voting"). Default value: "serial".
feature_fraction_bynode	Selects a subset of random features on each tree node. For example, if feature_fraction_bynode is 0.8, then 80% of features are selected. Can be used to deal with overfitting. Valid values: integer, range: (0.0, 1.0]. Default value: 1.0.

Parameter Name	Description
`is_unbalance`	Set to `"True"` if training data is unbalanced. Used only for binary classification tasks. `is_unbalance` cannot be used with `scale_pos_weight` . Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`max_bin`	The maximum number of bins used to bucket feature values. A small number of bins may reduce training accuracy, but may increase general performance. Can be used to deal with overfitting. Valid values: integer, range: (1, ∞). Default value: `255`.
`tweedie_variance_power`	Controls the variance of the Tweedie distribution. Set this closer to `2.0` to shift toward a gamma distribution. Set this closer to `1.0` to shift toward a Poisson distribution. Used only for regression tasks. Valid values: float, range: [`1.0`, `2.0`). Default value: `1.5`.
`num_threads`	Number of parallel threads used to run LightGBM. Value 0 means default number of threads in OpenMP. Valid values: integer, range: Non-negative integer. Default value: `0`.

Parameter Name	Description
`verbosity`	The verbosity of print messages. If the `verbosity` is less than `0`, then print messages only show fatal errors. If `verbosity` is set to `0`, then print messages include errors and warnings. If `verbosity` is 1, then print messages show more information. A `verbosity` greater than 1 shows the most information in print messages and can be used for debugging. Valid values: integer. Default value: 1.

Tune a LightGBM model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

> **Note**
>
> The learning objective function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see LightGBM hyperparameters.

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your specified hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

> **Note**
>
> Automatic model tuning for LightGBM is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Evaluation metrics computed by the LightGBM algorithm

The SageMaker LightGBM algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Metric Name	Description	Optimization Direction	Regex Pattern
`rmse`	root mean square error	minimize	`"rmse: ([0-9\\.]+)"`
`l1`	mean absolute error	minimize	`"l1: ([0-9\\.]+)"`
`l2`	mean squared error	minimize	`"l2: ([0-9\\.]+)"`
`huber`	huber loss	minimize	`"huber: ([0-9\\.]+)"`
`fair`	fair loss	minimize	`"fair: ([0-9\\.]+)"`
`binary_logloss`	binary cross entropy	maximize	`"binary_logloss: ([0-9\\.]+)"`

Metric Name	Description	Optimization Direction	Regex Pattern
binary_error	binary error	minimize	"binary_error: ([0-9\\.]+)"
auc	AUC	maximize	"auc: ([0-9\\.]+)"
average_precision	average precision score	maximize	"average_precision: ([0-9\\.]+)"
multi_logloss	multiclass cross entropy	maximize	"multi_logloss: ([0-9\\.]+)"
multi_error	multiclass error score	minimize	"multi_error: ([0-9\\.]+)"
auc_mu	AUC-mu	maximize	"auc_mu: ([0-9\\.]+)"
cross_entropy	cross entropy	minimize	"cross_entropy: ([0-9\\.]+)"

Tunable LightGBM hyperparameters

Tune the LightGBM model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the LightGBM evaluation metrics are: `learning_rate`,

num_leaves, feature_fraction, bagging_fraction, bagging_freq, max_depth and min_data_in_leaf. For a list of all the LightGBM hyperparameters, see LightGBM hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
learning_rate	ContinuousParameterRanges	MinValue: 0.001, MaxValue: 0.01
num_leaves	IntegerParameterRanges	MinValue: 10, MaxValue: 100
feature_fraction	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1.0
bagging_fraction	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1.0
bagging_freq	IntegerParameterRanges	MinValue: 0, MaxValue: 10
max_depth	IntegerParameterRanges	MinValue: 15, MaxValue: 100
min_data_in_leaf	IntegerParameterRanges	MinValue: 10, MaxValue: 200

Linear Learner Algorithm

Linear models are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples (*x*, *y*). *x* is a high-dimensional vector and *y* is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to num_classes - 1. For regression problems, *y* is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector *x* to an approximation of the label *y*.

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different

training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see `CreateTrainingJob`. You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you're using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

Topics

- Input/Output interface for the linear learner algorithm
- EC2 instance recommendation for the linear learner algorithm

- Linear learner response formats

Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the `S3DataDistributionType`

should be `FullyReplicated`. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both `recordIO-wrapped protobuf` and `CSV` formats. For the `application/x-recordio-protobuf` input type, only Float32 tensors are supported. For the `text/csv` input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference, the linear learner algorithm supports the `application/json`, `application/x-recordio-protobuf`, and `text/csv` formats. When you make predictions on new data, the format of the response depends on the type of model. **For regression** (`predictor_type='regressor'`), the `score` is the prediction produced by the model. **For classification** (`predictor_type='binary_classifier'` or `predictor_type='multiclass_classifier'`), the model returns a `score` and also a `predicted_label`. The `predicted_label` is the class predicted by the model and the `score` measures the strength of that prediction.

- **For binary classification**, `predicted_label` is `0` or `1`, and `score` is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- **For multiclass classification**, the `predicted_class` will be an integer from `0` to `num_classes-1`, and `score` will be a list of one floating point number per class.

To interpret the `score` in classification problems, you have to consider the loss function used. If the `loss` hyperparameter value is `logistic` for binary classification or `softmax_loss` for multiclass classification, then the `score` can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the `loss` value is `auto` default value. But if the loss is set to `hinge_loss`, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats. For more information on inference formats, and the Linear learner sample notebooks.

EC2 instance recommendation for the linear learner algorithm

The linear learner algorithm supports both CPU and GPU instances for training and inference. For GPU, the linear learner algorithm supports P2, P3, G4dn, and G5 GPU families.

During testing, we have not found substantial evidence that multi-GPU instances are faster than single-GPU instances. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

Notebook Title	Description
An Introduction with the MNIST dataset	Using the MNIST dataset, we train a binary classifier to predict a single digit.
How to Build a Multiclass Classifier?	Using UCI's Covertype dataset, we demonstra te how to train a multiclass classifier.
How to Build a Machine Learning (ML) Pipeline for Inference?	Using a Scikit-learn container, we demonstrate how to build an end-to-end ML pipeline.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of

a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

> **Note**
>
> For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.

> **Note**
>
> If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

Linear learner hyperparameters

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to `auto`, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

Parameter Name	Description
`num_classes`	The number of classes for the response variable. The algorithm assumes that classes are labeled `0`, ..., `num_classes - 1` . **Required** when `predictor_type` is `multiclass_classifier` . Otherwise, the algorithm ignores it. Valid values: Integers from 3 to 1,000,000
`predictor_type`	Specifies the type of target variable as a binary classification, multiclass classification, or regression. **Required** Valid values: `binary_classifier` , `multiclass_classifier` , or `regressor`
`accuracy_top_k`	When computing the top-k accuracy metric for multiclass classification, the value of *k*. If the model assigns one of the top-k scores to the true label, an example is scored as correct. **Optional**

Parameter Name	Description
	Valid values: Positive integers Default value: 3
balance_multiclass_weights	Specifies whether to use class weights, which give each class equal importance in the loss function. Used only when the predictor_type is multiclass_classifier . **Optional** Valid values: true, false Default value: false
beta_1	The exponential decay rate for first-moment estimates. Applies only when the optimizer value is adam. **Optional** Valid values: auto or floating-point value between 0 and 1.0 Default value: auto
beta_2	The exponential decay rate for second-moment estimates. Applies only when the optimizer value is adam. **Optional** Valid values: auto or floating-point integer between 0 and 1.0 Default value: auto
bias_lr_mult	Allows a different learning rate for the bias term. The actual learning rate for the bias is learning_rate * bias_lr_mult . **Optional** Valid values: auto or positive floating-point integer Default value: auto

Parameter Name	Description
bias_wd_mult	Allows different regularization for the bias term. The actual L2 regularization weight for the bias is wd * bias_wd_mult . By default, there is no regularization on the bias term. **Optional** Valid values: auto or non-negative floating-point integer Default value: auto
binary_classifier_model_selection_criteria	When predictor_type is set to binary_classifier , the model evaluation criteria for the validation dataset (or for the training dataset if you don't provide a validation dataset). Criteria include: • accuracy—The model with the highest accuracy. • f_beta—The model with the highest F1 score. The default is F1. • precision_at_target_recall —The model with the highest precision at a given recall target. • recall_at_target_precision —The model with the highest recall at a given precision target. • loss_function —The model with the lowest value of the loss function used in training. **Optional** Valid values: accuracy, f_beta, precision_at_target_recall , recall_at_target_precision , or loss_function Default value: accuracy

Parameter Name	Description
early_stopping_patience	If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for binary_classifier_model_selection_criteria . the metric is that value. Otherwise, the metric is the same as the value specified for the loss hyperparameter. The metric is evaluated on the validation data. If you haven't provided validation data, the metric is always the same as the value specified for the loss hyperparameter and is evaluated on the training data. To disable early stopping, set early_stopping_patience to a value greater than the value specified for epochs. **Optional** Valid values: Positive integer Default value: 3
early_stopping_tolerance	The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero. **Optional** Valid values: Positive floating-point integer Default value: 0.001
epochs	The maximum number of passes over the training data. **Optional** Valid values: Positive integer Default value: 15

Parameter Name	Description
f_beta	The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for binary_classifier_model_selection_criteria is f_beta. **Optional** Valid values: Positive floating-point integers Default value: 1.0
feature_dim	The number of features in the input data. **Optional** Valid values: auto or positive integer Default values: auto
huber_delta	The parameter for Huber loss. During training and metric evaluatio n, compute L2 loss for errors smaller than delta and L1 loss for errors larger than delta. **Optional** Valid values: Positive floating-point integer Default value: 1.0
init_bias	Initial weight for the bias term. **Optional** Valid values: Floating-point integer Default value: 0

Parameter Name	Description
init_method	Sets the initial distribution function used for model weights. Functions include: • uniform—Uniformly distributed between (-scale, +scale) • normal—Normal distribution, with mean 0 and sigma **Optional** Valid values: uniform or normal Default value: uniform
init_scale	Scales an initial uniform distribution for model weights. Applies only when the init_method hyperparameter is set to uniform. **Optional** Valid values: Positive floating-point integer Default value: 0.07
init_sigma	The initial standard deviation for the normal distribution. Applies only when the init_method hyperparameter is set to normal. **Optional** Valid values: Positive floating-point integer Default value: 0.01
l1	The L1 regularization parameter. If you don't want to use L1 regularization, set the value to 0. **Optional** Valid values: auto or non-negative float Default value: auto

Parameter Name	Description
learning_rate	The step size used by the optimizer for parameter updates. **Optional** Valid values: auto or positive floating-point integer Default value: auto, whose value depends on the optimizer chosen.
loss	Specifies the loss function. The available loss functions and their default values depend on the value of predictor_type : • If the predictor_type is set to regressor , the available options are auto, squared_loss , absolute_loss , eps_insensitive_squared_loss , eps_insensitive_absolute_loss , quantile_loss , and huber_loss . The default value for auto is squared_loss . • If the predictor_type is set to binary_classifier , the available options are auto,logistic, and hinge_loss . The default value for auto is logistic. • If the predictor_type is set to multiclass_classifier , the available options are auto and softmax_loss . The default value for auto is softmax_loss . Valid values: auto, logistic, squared_loss , absolute_loss , hinge_loss , eps_insensitive_squared_loss , eps_insensitive_absolute_loss , quantile_loss , or huber_loss **Optional** Default value: auto

Parameter Name	Description
loss_insensitivity	The parameter for the epsilon-insensitive loss type. During training and metric evaluation, any error smaller than this value is considered to be zero. **Optional** Valid values: Positive floating-point integer Default value: 0.01
lr_scheduler_factor	For every lr_scheduler_step hyperparameter, the learning rate decreases by this quantity. Applies only when the use_lr_scheduler hyperparameter is set to true. **Optional** Valid values: auto or positive floating-point integer between 0 and 1 Default value: auto
lr_scheduler_minimum_lr	The learning rate never decreases to a value lower than the value set for lr_scheduler_minimum_lr . Applies only when the use_lr_scheduler hyperparameter is set to true. **Optional** Valid values: auto or positive floating-point integer Default values: auto
lr_scheduler_step	The number of steps between decreases of the learning rate. Applies only when the use_lr_scheduler hyperparameter is set to true. **Optional** Valid values: auto or positive integer Default value: auto

Parameter Name	Description
`margin`	The margin for the `hinge_loss` function. **Optional** Valid values: Positive floating-point integer Default value: 1.0
`mini_batch_size`	The number of observations per mini-batch for the data iterator. **Optional** Valid values: Positive integer Default value: 1000
`momentum`	The momentum of the `sgd` optimizer. **Optional** Valid values: `auto` or a floating-point integer between 0 and 1.0 Default value: `auto`
`normalize_data`	Normalizes the feature data before training. Data normalization shifts the data for each feature to have a mean of zero and scales it to have unit standard deviation. **Optional** Valid values: `auto`, `true`, or `false` Default value: `true`

Parameter Name	Description
normalize_label	Normalizes the label. Label normalization shifts the label to have a mean of zero and scales it to have unit standard deviation. The auto default value normalizes the label for regression problems but does not for classification problems. If you set the normalize_label hyperparameter to true for classification problems, the algorithm ignores it. **Optional** Valid values: auto, true, or false Default value: auto
num_calibration_samples	The number of observations from the validation dataset to use for model calibration (when finding the best threshold). **Optional** Valid values: auto or positive integer Default value: auto
num_models	The number of models to train in parallel. For the default, auto, the algorithm decides the number of parallel models to train. One model is trained according to the given training parameter (regularization, optimizer, loss), and the rest by close parameters. **Optional** Valid values: auto or positive integer Default values: auto

Parameter Name	Description
num_point_for_scaler	The number of data points to use for calculating normalization or unbiasing of terms. **Optional** Valid values: Positive integer Default value: 10,000
optimizer	The optimization algorithm to use. **Optional** Valid values: • auto—The default value. • sgd—Stochastic gradient descent. • adam—Adaptive momentum estimation. • rmsprop—A gradient-based optimization technique that uses a moving average of squared gradients to normalize the gradient. Default value: auto. The default setting for auto is adam.
positive_example_weight_mult	The weight assigned to positive examples when training a binary classifier. The weight of negative examples is fixed at 1. If you want the algorithm to choose a weight so that errors in classifying negative *vs.* positive examples have equal impact on training loss, specify balanced. If you want the algorithm to choose the weight that optimizes performance, specify auto. **Optional** Valid values: balanced, auto, or a positive floating-point integer Default value: 1.0

Parameter Name	Description
quantile	The quantile for quantile loss. For quantile q, the model attempts to produce predictions so that the value of true_label is greater than the prediction with probability q. **Optional** Valid values: Floating-point integer between 0 and 1 Default value: 0.5
target_precision	The target precision. If binary_classifier_model_selection_criteria is recall_at_target_precision, then precision is held at this value while recall is maximized. **Optional** Valid values: Floating-point integer between 0 and 1.0 Default value: 0.8
target_recall	The target recall. If binary_classifier_model_selection_criteria is precision_at_target_recall, then recall is held at this value while precision is maximized. **Optional** Valid values: Floating-point integer between 0 and 1.0 Default value: 0.8
unbias_data	Unbiases the features before training so that the mean is 0. By default data is unbiased as the use_bias hyperparameter is set to true. **Optional** Valid values: auto, true, or false Default value: auto

Parameter Name	Description
unbias_label	Unbiases labels before training so that the mean is 0. Applies to regression only if the use_bias hyperparameter is set to true. **Optional** Valid values: auto, true, or false Default value: auto
use_bias	Specifies whether the model should include a bias term, which is the intercept term in the linear equation. **Optional** Valid values: true or false Default value: true
use_lr_scheduler	Whether to use a scheduler for the learning rate. If you want to use a scheduler, specify true. **Optional** Valid values: true or false Default value: true
wd	The weight decay parameter, also known as the L2 regularization parameter. If you don't want to use L2 regularization, set the value to 0. **Optional** Valid values:auto or non-negative floating-point integer Default value: auto

Tune a linear learner model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

Metric Name	Description	Optimization Direction
`test:absolute_loss`	The absolute loss of the final model on the test dataset. This objective metric is only valid for regression.	Minimize
`test:binary_classification_accuracy`	The accuracy of the final model on the test dataset. This objective metric is only valid for binary classification.	Maximize
`test:binary_f_beta`	The F-beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall.	Maximize

Metric Name	Description	Optimization Direction
	This objective metric is only valid for binary classification.	
test:dcg	The discounted cumulative gain of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
test:macro_f_beta	The F-beta score of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
test:macro_precision	The precision score of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
test:macro_recall	The recall score of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
test:mse	The mean square error of the final model on the test dataset. This objective metric is only valid for regression.	Minimize
test:multiclass_accuracy	The accuracy of the final model on the test dataset. This objective metric is only valid for multiclass classification.	Maximize
test:multiclass_top_k_accuracy	The accuracy among the top k labels predicted on the test dataset. If you choose this metric as the objective, we recommend setting the value of k using the accuracy_top_k hyperparameter. This objective metric is only valid for multiclass classification.	Maximize

Metric Name	Description	Optimization Direction
`test:objective_loss`	The mean value of the objective loss function on the test dataset after the model is trained. By default, the loss is logistic loss for binary classification and squared loss for regression. To set the loss to other types, use the `loss` hyperparameter.	Minimize
`test:precision`	The precision of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the `binary_classifier_model_selection` hyperparameter to `precision_at_target_recall` and setting the value for the `target_recall` hyperparameter. This objective metric is only valid for binary classification.	Maximize
`test:recall`	The recall of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the `binary_classifier_model_selection` hyperparameter to `recall_at_target_precision` and setting the value for the `target_precision` hyperparameter. This objective metric is only valid for binary classification.	Maximize
`test:roc_auc_score`	The area under receiving operating characteristic curve (ROC curve) of the final model on the test dataset. This objective metric is only valid for binary classification.	Maximize

Metric Name	Description	Optimization Direction
validation:absolute_loss	The absolute loss of the final model on the validation dataset. This objective metric is only valid for regression.	Minimize
validation:binary_classification_accuracy	The accuracy of the final model on the validation dataset. This objective metric is only valid for binary classification.	Maximize
validation:binary_f_beta	The F-beta score of the final model on the validation dataset. By default, the F-beta score is the F1 score, which is the harmonic mean of the validation:precision and validation:recall metrics. This objective metric is only valid for binary classification.	Maximize
validation:dcg	The discounted cumulative gain of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:macro_f_beta	The F-beta score of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:macro_precision	The precision score of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:macro_recall	The recall score of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:mse	The mean square error of the final model on the validation dataset. This objective metric is only valid for regression.	Minimize

Metric Name	Description	Optimization Direction
validation:multiclass_accuracy	The accuracy of the final model on the validation dataset. This objective metric is only valid for multiclass classification.	Maximize
validation:multiclass_top_k_accuracy	The accuracy among the top k labels predicted on the validation dataset. If you choose this metric as the objective, we recommend setting the value of k using the accuracy_top_k hyperparameter. This objective metric is only valid for multiclass classification.	Maximize
validation:objective_loss	The mean value of the objective loss function on the validation dataset every epoch. By default, the loss is logistic loss for binary classification and squared loss for regression. To set loss to other types, use the loss hyperparameter.	Minimize
validation:precision	The precision of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the binary_classifier_model_selection hyperparameter to precision_at_target_recall and setting the value for the target_recall hyperparameter. This objective metric is only valid for binary classification.	Maximize

Metric Name	Description	Optimization Direction
validation:recall	The recall of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the binary_classifier_model_selection hyperparameter to recall_at_target_precision and setting the value for the target_precision hyperparameter. This objective metric is only valid for binary classification.	Maximize
validation:rmse	The root mean square error of the final model on the validation dataset. This objective metric is only valid for regression.	Minimize
validation:roc_auc_score	The area under receiving operating characteristic curve (ROC curve) of the final model on the validation dataset. This objective metric is only valid for binary classification.	Maximize

Tuning linear learner hyperparameters

You can tune a linear learner model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
wd	ContinuousParameterRanges	MinValue: 1e-7, MaxValue: 1
l1	ContinuousParameterRanges	MinValue: 1e-7, MaxValue: 1
learning_rate	ContinuousParameterRanges	MinValue: 1e-5, MaxValue: 1

Parameter Name	Parameter Type	Recommended Ranges
mini_batch_size	IntegerParameterRanges	MinValue: 100, MaxValue: 5000
use_bias	CategoricalParameterRanges	[True, False]
positive_example_weight_mult	ContinuousParameterRanges	MinValue: 1e-5, MaxValue: 1e5

Linear learner response formats

JSON response formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker linear learner algorithm.

Binary Classification

```
let response =   {
    "predictions":    [
        {
            "score": 0.4,
            "predicted_label": 0
        }
    ]
}
```

Multiclass Classification

```
let response =   {
    "predictions":    [
        {
            "score": [0.1, 0.2, 0.4, 0.3],
            "predicted_label": 2
        }
    ]
```

```
}
```

Regression

```
let response =   {
    "predictions":    [
        {
            "score": 0.4
        }
    ]
}
```

JSONLINES response formats

Binary Classification

```
{"score": 0.4, "predicted_label": 0}
```

Multiclass Classification

```
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

Regression

```
{"score": 0.4}
```

RECORDIO response formats

Binary Classification

```
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            },
            'predicted_label': {
                keys: [],
                values: [0.0]  # float32
```

```
            }
        }
    }
]
```

Multiclass Classification

```
[
    Record = {
    "features": [],
    "label":    {
            "score":  {
                    "values":   [0.1, 0.2, 0.3, 0.4]
            },
            "predicted_label":  {
                    "values":   [3]
            }
       },
    "uid":  "abc123",
    "metadata": "{created_at: '2017-06-03'}"
   }
]
```

Regression

```
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            }
        }
    }
]
```

TabTransformer

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer architecture is built on self-attention-based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve

higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

How to use SageMaker TabTransformer

You can use TabTransformer as an Amazon SageMaker built-in algorithm. The following section describes how to use TabTransformer with the SageMaker Python SDK. For information on how to use TabTransformer from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

- **Use TabTransformer as a built-in algorithm**

  Use the TabTransformer built-in algorithm to build a TabTransformer training container as shown in the following code example. You can automatically spot the TabTransformer built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the TabTransformer image URI, you can use the TabTransformer container to construct an estimator using the SageMaker Estimator API and initiate a training job. The TabTransformer built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own TabTransformer training scripts.

```
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "pytorch-
tabtransformerclassification-model", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 script_scope=train_scope
```

```
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version,
 model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_binary/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/
validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "n_epochs"
] = "50"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
```

```
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)
```

For more information about how to set up the TabTransformer as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker TabTransformer algorithm
- Tabular regression with Amazon SageMaker TabTransformer algorithm

Input and Output interface for the TabTransformer algorithm

TabTransformer operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of TabTransformer supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be *text/csv*.
- For **Inference ContentType**, valid inputs must be *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
> For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the TabTransformer model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the `training` and `validation` channels to provide your input data. Alternatively, you can use only the `training` channel.

Use both the `training` and `validation` channels

You can provide your input data by way of two S3 paths, one for the `training` channel and one for the `validation` channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the `training` or `validation` channels, the TabTransformer algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your `training` channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the `training` channel:

You can alternatively provide your input data by way of a single S3 path for the `training` channel. This S3 path should point to a directory with a subdirectory named `training/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called `validation/` that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

> **Note**
>
> For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

Amazon EC2 instance recommendation for the TabTransformer algorithm

SageMaker TabTransformer supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker TabTransformer currently does not support multi-GPU training.

TabTransformer sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker TabTransformer algorithm.

Notebook Title	Description
Tabular classification with Amazon SageMaker TabTransformer algorithm	This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular classification model.
Tabular regression with Amazon SageMaker TabTransformer algorithm	This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular regression model.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How TabTransformer works

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer is built upon self-attention based Transformers. The Transformer layers transform

the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

TabTransformer performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use TabTransformer for regression, classification (binary and multiclass), and ranking problems.

The following diagram illustrates the TabTransformer architecture.

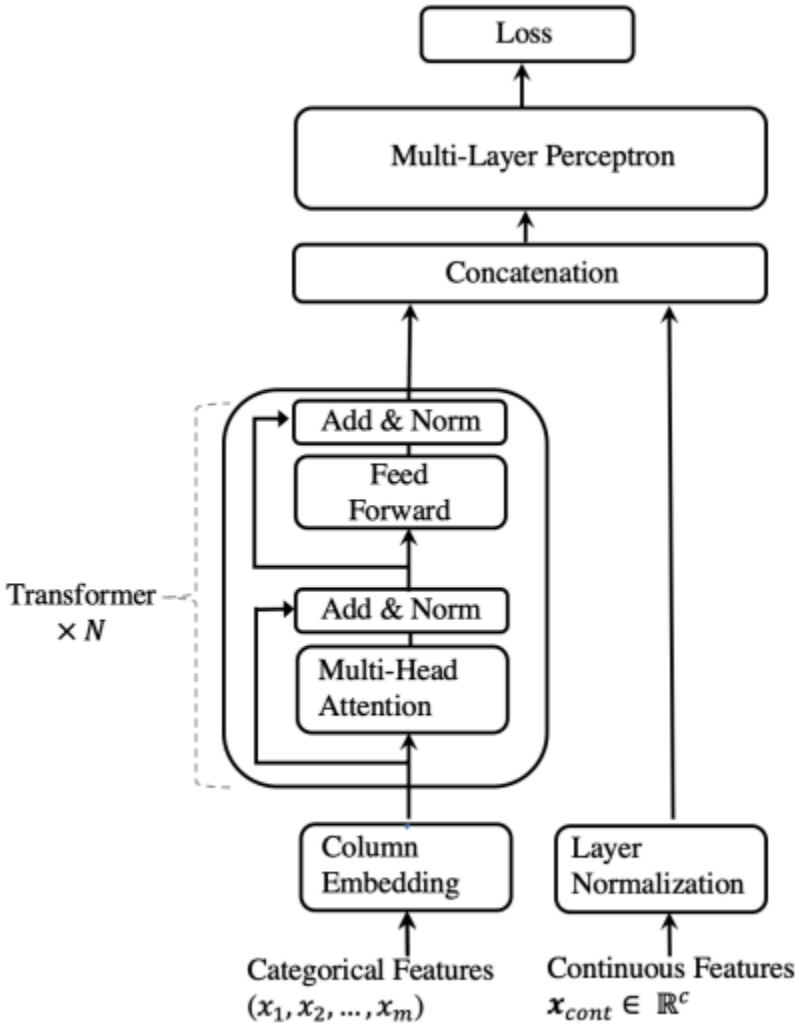

Figure 1: The architecture of TabTransformer.

For more information, see *TabTransformer: Tabular Data Modeling Using Contextual Embeddings*.

TabTransformer hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker TabTransformer algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker TabTransformer algorithm is an implementation of the open-source TabTransformer package.

> **Note**
>
> The default hyperparameters are based on example datasets in the TabTransformer sample notebooks.

The SageMaker TabTransformer algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The TabTransformer algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is r square and the objective function is mean square error. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric and objective function are both multiclass cross entropy.

> **Note**
>
> The TabTransformer evaluation metric and objective functions are not currently available as hyperparameters. Instead, the SageMaker TabTransformer built-in algorithm automatically detects the type of classification task (regression, binary, or multiclass) based on the number of unique integers in the label column and assigns an evaluation metric and objective function.

Parameter Name	Description
n_epochs	Number of epochs to train the deep neural network. Valid values: integer, range: Positive integer. Default value: 5.

Parameter Name	Description
patience	The training will stop if one metric of one validation data point does not improve in the last patience round. Valid values: integer, range: (2, 60). Default value: 10.
learning_rate	The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: Positive floating point number. Default value: 0.001.
batch_size	The number of examples propagated through the network. Valid values: integer, range: (1, 2048). Default value: 256.
input_dim	The dimension of embeddings to encode the categorical and/or continuous columns. Valid values: string, any of the following: "16", "32", "64", "128", "256", or "512". Default value: "32".
n_blocks	The number of Transformer encoder blocks. Valid values: integer, range: (1, 12). Default value: 4.
attn_dropout	Dropout rate applied to the Multi-Head Attention layers. Valid values: float, range: (0, 1). Default value: 0.2.

Parameter Name	Description
`mlp_dropout`	Dropout rate applied to the FeedForward network within the encoder layers and the final MLP layers on top of Transformer encoders. Valid values: float, range: (`0`, `1`). Default value: `0.1`.
`frac_shared_embed`	The fraction of embeddings shared by all the different categories for one particular column. Valid values: float, range: (`0`, `1`). Default value: `0.25`.

Tune a TabTransformer model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

> **Note**
>
> The learning objective function and evaluation metric are both automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see TabTransformer hyperparameters.

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

> **Note**
>
> Automatic model tuning for TabTransformer is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Evaluation metrics computed by the TabTransformer algorithm

The SageMaker TabTransformer algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Metric Name	Description	Optimization Direction	Regex Pattern
`r2`	r square	maximize	`"metrics={'r2': (\\S+)}"`
`f1_score`	binary cross entropy	maximize	`"metrics={'f1': (\\S+)}"`
`accuracy_score`	multiclass cross entropy	maximize	`"metrics={'accuracy': (\\S+)}"`

Tunable TabTransformer hyperparameters

Tune the TabTransformer model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the TabTransformer evaluation metrics are: `learning_rate`, `input_dim`, `n_blocks`, `attn_dropout`, `mlp_dropout`, and `frac_shared_embed`. For a list of all the TabTransformer hyperparameters, see TabTransformer hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
learning_rate	ContinuousParameterRanges	MinValue: 0.001, MaxValue: 0.01
input_dim	CategoricalParameterRanges	[16, 32, 64, 128, 256, 512]
n_blocks	IntegerParameterRanges	MinValue: 1, MaxValue: 12
attn_dropout	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.8
mlp_dropout	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.8
frac_shared_embed	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.5

XGBoost Algorithm

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as a Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost `estimator` that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 1.0, 1.2, 1.3, 1.5, and 1.7.

Supported versions

- Framework (open source) mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1, 1.7-1
- Algorithm mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1, 1.7-1

Warning

Due to required compute capacity, version 1.7-1 of SageMaker XGBoost is not compatible with GPU instances from the P2 instance family for training or inference.

Important

When you retrieve the SageMaker XGBoost image URI, do not use `:latest` or `:1` for the image URI tag. You must specify one of the Supported versions to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the **XGBoost (algorithm)** section.

Warning

The XGBoost 0.90 versions are deprecated. Supports for security updates or bug fixes for XGBoost 0.90 is discontinued. It is highly recommended to upgrade the XGBoost version to one of the newer versions.

Note

XGBoost v1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost v1.2. Consider using SageMaker XGBoost 1.2-2 or later.

How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts. The following sections describe how to use XGBoost with the SageMaker Python SDK. For information on how to use XGBoost from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

- **Use XGBoost as a framework**

  Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
        "max_depth":"5",
        "eta":"0.2",
        "gamma":"4",
        "min_child_weight":"6",
        "subsample":"0.7",
        "verbosity":"1",
        "objective":"reg:squarederror",
        "num_round":"50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.7-1',
                    hyperparameters=hyperparameters,
```

```
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
 content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix,
 'validation'), content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

- **Use XGBoost as a built-in algorithm**

  Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the `image_uris.retrieve` API finds the correct URI, see Common parameters for built-in algorithms and look up `xgboost` from the full list of built-in algorithm image URIs and available regions.

  After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

  > **Important**
  >
  > When you retrieve the SageMaker XGBoost image URI, do not use `:latest` or `:1` for the image URI tag. You must specify one of the Supported versions to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the **XGBoost (algorithm)** section.

```
import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
        "max_depth":"5",
        "eta":"0.2",
        "gamma":"4",
        "min_child_weight":"6",
        "subsample":"0.7",
        "objective":"reg:squarederror",
        "num_round":"50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-
algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost
 container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.7-1")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
 content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix,
 'validation'), content_type=content_type)
```

```
# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports the following data formats for training and inference:

- *text/libsvm* (default)
- *text/csv*
- *application/x-parquet*
- *application/x-recordio-protobuf*

Note

There are a few considerations to be aware of regarding training and inference input:

- For increased performance, we recommend using XGBoost with *File mode*, in which your data from Amazon S3 is stored on the training instance volumes.
- For training with columnar input, the algorithm assumes that the target variable (label) is the first column. For inference, the algorithm assumes that the input has no label column.
- For CSV data, the input should not have a header record.
- For LIBSVM training, the algorithm assumes that subsequent columns after the label column contain the zero-based index value pairs for features. So each row has the format: : <label> <index0>:<value0> <index1>:<value1>.

- For information on instance types and distributed training, see EC2 Instance Recommendation for the XGBoost Algorithm.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the `InstanceType`) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

For v1.3-1 and later, SageMaker XGBoost saves the model in the XGBoost internal binary format, using `Booster.save_model`. Previous versions use the Python pickle module to serialize/deserialize the model.

> **Note**
>
> Be mindful of versions when using an SageMaker XGBoost model in open source XGBoost. Versions 1.3-1 and later use the XGBoost internal binary format while previous versions use the Python pickle module.

To use a model trained with SageMaker XGBoost v1.3-1 or later in open source XGBoost

- Use the following Python code:

```
import xgboost as xgb

xgb_model = xgb.Booster()
xgb_model.load_model(model_file_path)
xgb_model.predict(dtest)
```

To use a model trained with previous versions of SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```
import pickle as pkl
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
```

```
model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For *text/libsvm* input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For *text/csv* input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`).

EC2 Instance Recommendation for the XGBoost Algorithm

SageMaker XGBoost supports CPU and GPU training and inference. Instance recommendations depend on training and inference needs, as well as the version of the XGBoost algorithm. Choose one of the following options for more information:

- CPU training
- GPU training
- Distributed CPU training
- Distributed GPU training
- Inference

Training

The SageMaker XGBoost algorithm supports CPU and GPU training.

CPU training

SageMaker XGBoost 1.0-1 or earlier only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use

of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

GPU training

SageMaker XGBoost version 1.2-2 or later supports GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective.

SageMaker XGBoost version 1.2-2 or later supports P2, P3, G4dn, and G5 GPU instance families.

SageMaker XGBoost version 1.7-1 or later supports P3, G4dn, and G5 GPU instance families. Note that due to compute capacity requirements, version 1.7-1 or later does not support the P2 instance family.

To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script.

Distributed training

SageMaker XGBoost supports CPU and GPU instances for distributed training.

Distributed CPU training

To run CPU training on multiple instances, set the `instance_count` parameter for the estimator to a value greater than one. The input data must be divided between the total number of instances.

Divide input data across instances

Divide the input data using the following steps:

1. Break the input data down into smaller files. The number of files should be at least equal to the number of instances used for distributed training. Using multiple smaller files as opposed to one large file also decreases the data download time for the training job.
2. When creating your TrainingInput, set the distribution parameter to `ShardedByS3Key`. This parameter ensures that each instance gets approximately *1/n* of the number of files in S3 if there are *n* instances specified in the training job.

Distributed GPU training

You can use distributed training with either single-GPU or multi-GPU instances.

Distributed training with single-GPU instances

SageMaker XGBoost versions 1.2-2 through 1.3-1 only support single-GPU instance training. This means that even if you select a multi-GPU instance, only one GPU is used per instance.

If you use XGBoost versions 1.2-2 through 1.3-1, or if you do not need to use multi-GPU instances, then you must divide your input data between the total number of instances. For more information, see Divide input data across instances.

> **Note**
>
> Versions 1.2-2 through 1.3-1 of SageMaker XGBoost only use one GPU per instance even if you choose a multi-GPU instance.

Distributed training with multi-GPU instances

Starting with version 1.5-1, SageMaker XGBoost offers distributed GPU training with Dask. With Dask you can utilize all GPUs when using one or more multi-GPU instances. Dask also works when using single-GPU instances.

Train with Dask using the following steps:

1. Either omit the `distribution` parameter in your TrainingInput or set it to `FullyReplicated`.
2. When defining your hyperparameters, set `use_dask_gpu_training` to `"true"`.

> **Important**
>
> Distributed training with Dask only supports CSV and Parquet input formats. If you use other data formats such as LIBSVM or PROTOBUF, the training job fails.
> For Parquet data, ensure that the column names are saved as strings. Columns that have names of other data types will fail to load.

> **Important**
>
> Distributed training with Dask does not support pipe mode. If pipe mode is specified, the training job fails.

There are a few considerations to be aware of when training SageMaker XGBoost with Dask. Be sure to split your data into smaller files. Dask reads each Parquet file as a partition. There is a Dask worker for every GPU, so the number of files should be greater than the total number of GPUs (instance count * number of GPUs per instance). Having a very large number of files can also degrade performance. For more information, see Dask Best Practices.

Variations in output

The specified `tree_method` hyperparameter determines the algorithm that is used for XGBoost training. The tree methods `approx`, `hist` and `gpu_hist` are all approximate methods and use sketching for quantile calculation. For more information, see Tree Methods in the XGBoost documentation. Sketching is an approximate algorithm. Therefore, you can expect variations in the model depending on factors such as the number of workers chosen for distributed training. The significance of the variation is data-dependent.

Inference

SageMaker XGBoost supports CPU and GPU instances for inference. For information about the instance types for inference, see Amazon SageMaker ML Instance Types.

XGBoost Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.

Notebook Title	Description
How to Create a Custom XGBoost container?	This notebook shows you how to build a custom XGBoost Container with Amazon SageMaker Batch Transform.

Notebook Title	Description
Regression with XGBoost using Parquet	This notebook shows you how to use the Abalone dataset in Parquet to train a XGBoost model.
How to Train and Host a Multiclass Classific ation Model?	This notebook shows how to use the MNIST dataset to train and host a multiclass classific ation model.
How to train a Model for Customer Churn Prediction?	This notebook shows you how to train a model to Predict Mobile Customer Departure in an effort to identify unhappy customers.
An Introduction to Amazon SageMaker Managed Spot infrastructure for XGBoost Training	This notebook shows you how to use Spot Instances for training with a XGBoost Container.
How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs?	This notebook shows you how to use Amazon SageMaker Debugger to monitor training jobs to detect inconsistencies using built-in debugging rules.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

For more information about the Amazon SageMaker XGBoost algorithm, see the following blog posts:

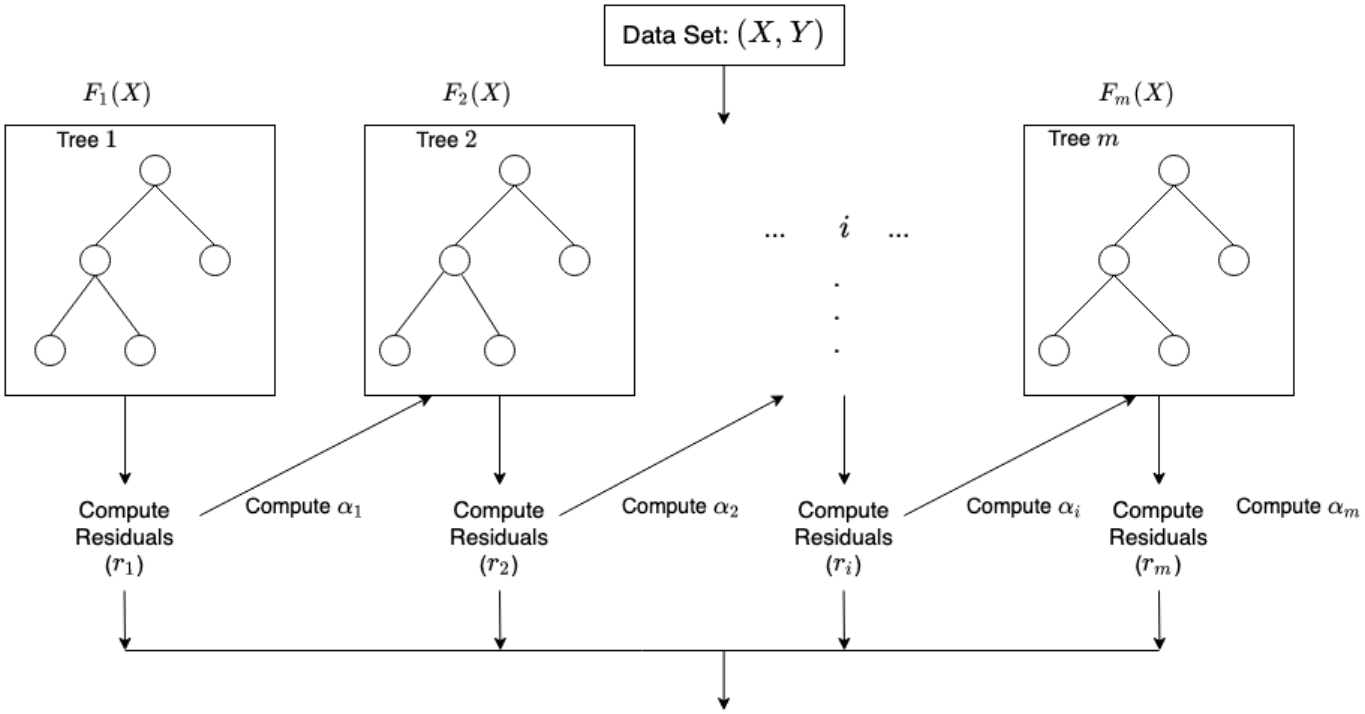
- Introducing the open-source Amazon SageMaker XGBoost algorithm container
- Amazon SageMaker XGBoost now offers fully distributed GPU training

How XGBoost Works

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.



$$F_m(X) = F_{m-1}(X) + \alpha_m h_m(X, r_{m-1}),$$

where α_i, and r_i are the regularization parameters and residuals computed with the i^{th} tree respectfully, and h_i is a function that is trained to predict residuals, r_i using X for the i^{th} tree. To compute α_i we use the residuals computed, r_i and compute the following: $arg \min_{\alpha} = \sum_{i=1}^{m} L(Y_i, F_{i-1}(X_i) + \alpha h_i(X_i, r_{i-1}))$ where $L(Y, F(X))$ is a differentiable loss function.

For more detail on XGBoost, see:

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

XGBoost Hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

Parameter Name	Description
`num_class`	The number of classes. **Required** if `objective` is set to *multi:softmax* or *multi:softprob*. Valid values: Integer.
`num_round`	The number of rounds to run the training. **Required** Valid values: Integer.
`alpha`	L1 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: Float. Default value: 0

Parameter Name	Description
base_score	The initial prediction score of all instances, global bias. **Optional** Valid values: Float. Default value: 0.5
booster	Which booster to use. The gbtree and dart values use a tree-based model, while gblinear uses a linear function. **Optional** Valid values: String. One of "gbtree", "gblinear" , or "dart". Default value: "gbtree"
colsample_bylevel	Subsample ratio of columns for each split, in each level. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
colsample_bynode	Subsample ratio of columns from each node. **Optional** Valid values: Float. Range: (0,1]. Default value: 1

Parameter Name	Description
`colsample_bytree`	Subsample ratio of columns when constructing each tree. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`csv_weights`	When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights. **Optional** Valid values: 0 or 1 Default value: 0
`deterministic_histogram`	When this flag is enabled, XGBoost builds histogram on GPU deterministically. Used only if `tree_method` is set to `gpu_hist`. For a full list of valid inputs, please refer to XGBoost Parameters. **Optional** Valid values: String. Range: `"true"` or `"false"`. Default value: `"true"`

Parameter Name	Description
`early_stopping_rounds`	The model trains until the validation score stops improving. Validation error needs to decrease at least every `early_stopping_rounds` to continue training. SageMaker hosting uses the best model for inference. **Optional** Valid values: Integer. Default value: -
`eta`	Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The `eta` parameter actually shrinks the feature weights to make the boosting process more conservative. **Optional** Valid values: Float. Range: [0,1]. Default value: 0.3
`eval_metric`	Evaluation metrics for validation data. A default metric is assigned according to the objective: • `rmse`: for regression • `error`: for classification • `map`: for ranking For a list of valid inputs, see XGBoost Learning Task Parameters. **Optional** Valid values: String. Default value: Default according to objective.

Parameter Name	Description
gamma	Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is. **Optional** Valid values: Float. Range: [0,∞). Default value: 0
grow_policy	Controls the way that new nodes are added to the tree. Currently supported only if tree_method is set to hist. **Optional** Valid values: String. Either "depthwise" or "lossguide" . Default value: "depthwise"
interaction_constraints	Specify groups of variables that are allowed to interact. **Optional** Valid values: Nested list of integers. Each integer represents a feature, and each nested list contains features that are allowed to interact e.g., [[1,2], [3,4,5]]. Default value: None
lambda	L2 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: Float. Default value: 1

Parameter Name	Description
`lambda_bias`	L2 regularization term on bias. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0
`max_bin`	Maximum number of discrete bins to bucket continuous features. Used only if `tree_method` is set to `hist`. **Optional** Valid values: Integer. Default value: 256
`max_delta_step`	Maximum delta step allowed for each tree's weight estimatio n. When a positive integer is used, it helps make the update more conservative. The preferred option is to use it in logistic regression. Set it to 1-10 to help control the update. **Optional** Valid values: Integer. Range: [0,∞). Default value: 0
`max_depth`	Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit. 0 indicates no limit. A limit is required when `grow_policy =depth-wise` . **Optional** Valid values: Integer. Range: [0,∞) Default value: 6

Parameter Name	Description
max_leaves	Maximum number of nodes to be added. Relevant only if grow_policy is set to lossguide . **Optional** Valid values: Integer. Default value: 0
min_child_weight	Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than min_child_weight , the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is. **Optional** Valid values: Float. Range: [0,∞). Default value: 1
monotone_constraints	Specifies monotonicity constraints on any feature. **Optional** Valid values: Tuple of Integers. Valid integers: -1 (decreasing constraint), 0 (no constraint), 1 (increasing constraint). E.g., (0, 1): No constraint on first predictor, and an increasing constraint on the second. (-1, 1): Decreasing constraint on first predictor, and an increasing constraint on the second. Default value: (0, 0)

Parameter Name	Description
`normalize_type`	Type of normalization algorithm. **Optional** Valid values: Either *tree* or *forest*. Default value: *tree*
`nthread`	Number of parallel threads used to run *xgboost*. **Optional** Valid values: Integer. Default value: Maximum number of threads.
`objective`	Specifies the learning task and the corresponding learning objective. Examples: `reg:logistic` , `multi:softmax` , `reg:squarederror` . For a full list of valid inputs, refer to XGBoost Learning Task Parameters. **Optional** Valid values: String Default value: `"reg:squarederror"`
`one_drop`	When this flag is enabled, at least one tree is always dropped during the dropout. **Optional** Valid values: 0 or 1 Default value: 0

Parameter Name	Description
process_type	The type of boosting process to run. **Optional** Valid values: String. Either "default" or "update". Default value: "default"
rate_drop	The dropout rate that specifies the fraction of previous trees to drop during the dropout. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0
refresh_leaf	This is a parameter of the 'refresh' updater plug-in. When set to true (1), tree leaves and tree node stats are updated. When set to false(0), only tree node stats are updated. **Optional** Valid values: 0/1 Default value: 1
sample_type	Type of sampling algorithm. **Optional** Valid values: Either uniform or weighted. Default value: uniform

Parameter Name	Description
`scale_pos_weight`	Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: `sum(negative cases) / sum(positive cases)` . **Optional** Valid values: float Default value: 1
`seed`	Random number seed. **Optional** Valid values: integer Default value: 0
`single_precision_histogram`	When this flag is enabled, XGBoost uses single precision to build histograms instead of double precision. Used only if `tree_method` is set to `hist` or `gpu_hist`. For a full list of valid inputs, please refer to XGBoost Parameters. **Optional** Valid values: String. Range: `"true"` or `"false"` Default value: `"false"`

Parameter Name	Description
sketch_eps	Used only for approximate greedy algorithm. This translates into O(1 / sketch_eps) number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy. **Optional** Valid values: Float, Range: [0, 1]. Default value: 0.03
skip_drop	Probability of skipping the dropout procedure during a boosting iteration. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0
subsample	Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
tree_method	The tree construction algorithm used in XGBoost. **Optional** Valid values: One of auto, exact, approx, hist, or gpu_hist. Default value: auto

Parameter Name	Description
`tweedie_variance_power`	Parameter that controls the variance of the Tweedie distribution. **Optional** Valid values: Float. Range: (1, 2). Default value: 1.5
`updater`	A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees. For a full list of valid inputs, please refer to XGBoost Parameters. **Optional** Valid values: comma-separated string. Default value: `grow_colmaker` , prune
`use_dask_gpu_training`	Set `use_dask_gpu_training` to `"true"` if you want to run distributed GPU training with Dask. Dask GPU training is only supported for versions 1.5-1 and later. Do not set this value to `"true"` for versions preceding 1.5-1. For more information, see Distributed GPU training. **Optional** Valid values: String. Range: `"true"` or `"false"` Default value: `"false"`

Parameter Name	Description
`verbosity`	Verbosity of printing messages. Valid values: 0 (silent), 1 (warning), 2 (info), 3 (debug). **Optional** Default value: 1

Tune an XGBoost Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning `objective` function to optimize during model training
- an `eval_metric` to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

> **Note**
>
> Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters

Metric Name	Description	Optimization Direction
validation:accuracy	Classification rate, calculated as #(right)/#(all cases).	Maximize
validation:auc	Area under the curve.	Maximize
validation:error	Binary classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
validation:f1	Indicator of classification accuracy, calculated as the harmonic mean of precision and recall.	Maximize
validation:logloss	Negative log-likelihood.	Minimize
validation:mae	Mean absolute error.	Minimize
validation:map	Mean average precision.	Maximize
validation:merror	Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
validation:mlogloss	Negative log-likelihood for multiclass classification.	Minimize
validation:mse	Mean squared error.	Minimize
validation:ndcg	Normalized Discounted Cumulative Gain.	Maximize
validation:rmse	Root mean square error.	Minimize

Tunable XGBoost Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: `alpha`, `min_child_weight`, `subsample`, `eta`, and `num_round`.

Parameter Name	Parameter Type	Recommended Ranges
alpha	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
colsample_bylevel	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
colsample_bynode	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
colsample_bytree	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1
eta	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 0.5
gamma	ContinuousParameterRanges	MinValue: 0, MaxValue: 5
lambda	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
max_delta_step	IntegerParameterRanges	[0, 10]
max_depth	IntegerParameterRanges	[0, 10]
min_child_weight	ContinuousParameterRanges	MinValue: 0, MaxValue: 120
num_round	IntegerParameterRanges	[1, 4000]
subsample	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

Topics

Upgrade XGBoost Version 0.90 to Version 1.5

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.5, you must have version 2.x of the SDK installed and change the XGBoost `version` and `framework_version` parameters to 1.5-1. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.

Topics

Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must to upgrade version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.5-1

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrive`.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.5-1',
                    hyperparameters=hyperparameters,
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
 content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
 content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (1, 0.72, 0.90-1 or 0.90-2) to 1.5-1.

```
{
    "AlgorithmSpecification":: {
```

```
        "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-
xgboost:1.5-1"
    }
    ...
}
```

If you using the SageMaker Python SDK to retrieve registry path, change the `version` parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
```

Update Hyperparameters and Learning Objectives

The silent parameter has been deprecated and is no longer available in XGBoost 1.5 and later versions. Use `verbosity` instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```
hyperparameters = {
    "verbosity": "2",
    "objective": "reg:squarederror",
    "num_round": "50",
    ...
}

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          ...)
```

XGBoost Version 0.72

> **Important**
>
> The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with `:1` is for the old version.
>
> SageMaker Python SDK v1
>
> ```
> import boto3
> from sagemaker.amazon.amazon_estimator import get_image_uri
> ```

```
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
 repo_version="1")
```

SageMaker Python SDK v2

```
import boto3
from sagemaker import image_uris

xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name,
 "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm. They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are *text/libsvm* (default) or *text/csv*.
- For Inference ContentType, valid inputs are *text/libsvm* or (the default) *text/csv*.

> **Note**
>
> For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.
> For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the `InstanceType`) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

To use a model trained with SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))
```

```
# prediction with test data
pred = model.predict(dtest)
```

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For *text/libsvm* input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For *text/csv* input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`).

EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see Regression with Amazon SageMaker XGBoost algorithm. To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The

required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see XGBoost Parameters.

Parameter Name	Description
`num_class`	The number of classes. **Required** if `objective` is set to *multi:softmax* or *multi:softprob*. Valid values: integer
`num_round`	The number of rounds to run the training. **Required** Valid values: integer
`alpha`	L1 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: float Default value: 0
`base_score`	The initial prediction score of all instances, global bias. **Optional** Valid values: float Default value: 0.5
`booster`	Which booster to use. The `gbtree` and `dart` values use a tree-based model, while `gblinear` uses a linear function.

Parameter Name	Description
	Optional Valid values: String. One of `gbtree`, `gblinear`, or `dart`. Default value: `gbtree`
`colsample_bylevel`	Subsample ratio of columns for each split, in each level. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`colsample_bytree`	Subsample ratio of columns when constructing each tree. **Optional** Valid values: Float. Range: [0,1]. Default value: 1
`csv_weights`	When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights. **Optional** Valid values: 0 or 1 Default value: 0

Parameter Name	Description
`early_stopping_rounds`	The model trains until the validation score stops improving. Validation error needs to decrease at least every `early_stopping_rounds` to continue training. SageMaker hosting uses the best model for inference. **Optional** Valid values: integer Default value: -
`eta`	Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The `eta` parameter actually shrinks the feature weights to make the boosting process more conservative. **Optional** Valid values: Float. Range: [0,1]. Default value: 0.3
`eval_metric`	Evaluation metrics for validation data. A default metric is assigned according to the objective: • `rmse`: for regression • `error`: for classification • `map`: for ranking For a list of valid inputs, see XGBoost Parameters. **Optional** Valid values: string Default value: Default according to objective.

Parameter Name	Description
gamma	Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is. **Optional** Valid values: Float. Range: [0,∞). Default value: 0
grow_policy	Controls the way that new nodes are added to the tree. Currently supported only if tree_method is set to hist. **Optional** Valid values: String. Either depthwise or lossguide . Default value: depthwise
lambda	L2 regularization term on weights. Increasing this value makes models more conservative. **Optional** Valid values: float Default value: 1
lambda_bias	L2 regularization term on bias. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0

Parameter Name	Description
max_bin	Maximum number of discrete bins to bucket continuous features. Used only if tree_method is set to hist. **Optional** Valid values: integer Default value: 256
max_delta_step	Maximum delta step allowed for each tree's weight estimatio n. When a positive integer is used, it helps make the update more conservative. The preferred option is to use it in logistic regression. Set it to 1-10 to help control the update. **Optional** Valid values: Integer. Range: [0,∞). Default value: 0
max_depth	Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit. 0 indicates no limit. A limit is required when grow_policy =depth-wise . **Optional** Valid values: Integer. Range: [0,∞) Default value: 6
max_leaves	Maximum number of nodes to be added. Relevant only if grow_policy is set to lossguide . **Optional** Valid values: integer Default value: 0

Parameter Name	Description
`min_child_weight`	Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than `min_child_weight` , the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is. **Optional** Valid values: Float. Range: [0,∞). Default value: 1
`normalize_type`	Type of normalization algorithm. **Optional** Valid values: Either *tree* or *forest*. Default value: *tree*
`nthread`	Number of parallel threads used to run *xgboost*. **Optional** Valid values: integer Default value: Maximum number of threads.

Parameter Name	Description
`objective`	Specifies the learning task and the corresponding learning objective. Examples: `reg:logistic` , `reg:softmax` , `multi:squarederror` . For a full list of valid inputs, refer to XGBoost Parameters. **Optional** Valid values: string Default value: `reg:squarederror`
`one_drop`	When this flag is enabled, at least one tree is always dropped during the dropout. **Optional** Valid values: 0 or 1 Default value: 0
`process_type`	The type of boosting process to run. **Optional** Valid values: String. Either `default` or `update`. Default value: `default`
`rate_drop`	The dropout rate that specifies the fraction of previous trees to drop during the dropout. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0

Parameter Name	Description
`refresh_leaf`	This is a parameter of the 'refresh' updater plug-in. When set to `true` (1), tree leaves and tree node stats are updated. When set to `false`(0), only tree node stats are updated. **Optional** Valid values: 0/1 Default value: 1
`sample_type`	Type of sampling algorithm. **Optional** Valid values: Either `uniform` or `weighted`. Default value: `uniform`
`scale_pos_weight`	Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: `sum(negative cases) / sum(positive cases)` . **Optional** Valid values: float Default value: 1
`seed`	Random number seed. **Optional** Valid values: integer Default value: 0

Parameter Name	Description
`silent`	0 means print running messages, 1 means silent mode. Valid values: 0 or 1 **Optional** Default value: 0
`sketch_eps`	Used only for approximate greedy algorithm. This translate s into O(1 / `sketch_eps`) number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy. **Optional** Valid values: Float, Range: [0, 1]. Default value: 0.03
`skip_drop`	Probability of skipping the dropout procedure during a boosting iteration. **Optional** Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0
`subsample`	Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting. **Optional** Valid values: Float. Range: [0,1]. Default value: 1

Parameter Name	Description
`tree_method`	The tree construction algorithm used in XGBoost. **Optional** Valid values: One of `auto`, `exact`, `approx`, or `hist`. Default value: `auto`
`tweedie_variance_power`	Parameter that controls the variance of the Tweedie distribution. **Optional** Valid values: Float. Range: (1, 2). Default value: 1.5
`updater`	A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees. For a full list of valid inputs, please refer to XGBoost Parameters. **Optional** Valid values: comma-separated string. Default value: `grow_colmaker` , prune

Tune an XGBoost Release 0.72 Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning `objective` function to optimize during model training
- an `eval_metric` to use to evaluate model performance during validation

- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the XGBoost Release 0.72 Algorithm

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters

Metric Name	Description	Optimization Direction
`validation:auc`	Area under the curve.	Maximize
`validation:error`	Binary classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
`validation:logloss`	Negative log-likelihood.	Minimize
`validation:mae`	Mean absolute error.	Minimize
`validation:map`	Mean average precision.	Maximize
`validation:merror`	Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
`validation:mlogloss`	Negative log-likelihood for multiclass classification.	Minimize
`validation:ndcg`	Normalized Discounted Cumulative Gain.	Maximize
`validation:rmse`	Root mean square error.	Minimize

Tunable XGBoost Release 0.72 Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: `alpha`, `min_child_weight`, `subsample`, `eta`, and `num_round`.

Parameter Name	Parameter Type	Recommended Ranges
`alpha`	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
`colsample_bylevel`	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
`colsample_bytree`	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1
`eta`	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 0.5
`gamma`	ContinuousParameterRanges	MinValue: 0, MaxValue: 5
`lambda`	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
`max_delta_step`	IntegerParameterRanges	[0, 10]
`max_depth`	IntegerParameterRanges	[0, 10]
`min_child_weight`	ContinuousParameterRanges	MinValue: 0, MaxValue: 120

`subsample`	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1

Built-in SageMaker Algorithms for Text Data

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- BlazingText algorithm—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- Latent Dirichlet Allocation (LDA) Algorithm—an algorithm suitable for determining topics in a set of documents. It is an *unsupervised algorithm*, which means that it doesn't use example data with answers during training.
- Neural Topic Model (NTM) Algorithm—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- Object2Vec Algorithm—a general-purpose neural embedding algorithm that can be used for recommendation systems, document classification, and sentence embeddings.
- Sequence-to-Sequence Algorithm—a supervised algorithm commonly used for neural machine translation.
- Text Classification - TensorFlow—a supervised algorithm that supports transfer learning with available pretrained models for text classification.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
BlazingText	train	File or Pipe	Text file (one sentence per line with space-separated tokens)	GPU (single instance only) or CPU	No	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
LDA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU (single instance only)	No	
Neural Topic Model	train and (optionally) validation, test, or both	File or Pipe	recordIO-protobuf or CSV	GPU or CPU	Yes	
Object2Vec	train and (optionally) validation, test, or both	File	JSON Lines	GPU or CPU (single instance only)	No	
Seq2Seq Modeling	train, validation, and vocab	File	recordIO-protobuf	GPU (single instance only)	No	
Text Classification - TensorFlow	training and validation	File	CSV	CPU or GPU	Yes (only across multiple GPUs on a single instance)	

BlazingText algorithm

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a *word embedding*. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.

- A `batch_skipgram` mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The `batch_skipgram` mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

Modes	**Word2Vec (Unsupervised Learning)**	**Text Classification (Supervised Learning)**

Single CPU instance	`cbow`
	`Skip-gram`
	`Batch Skip-gram`
		`supervised`

Single GPU instance (with 1 or more GPUs)	`cbow` `Skip-gram`	`supervised` with one GPU
Multiple CPU instances	`Batch Skip-gram`	None

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

- BlazingText Hyperparameters
- Tune a BlazingText Model

Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the *train* channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For `supervised` mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string *__label__*. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time , intel says , despite all the linux hype , the
 open-source movement has yet to make a huge splash in the desktop market . that may be
 about to change , thanks to chipmaking giant intel corp .

__label__2  bowled by the slower one again , kolkata , november 14 the past caught up
 with sourav ganguly as the indian skippers return to international cricket was short
 lived .
```

> **Note**
>
> The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

Supervised mode for CPU instances also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the `source` tag and the label can be specified using the `label` tag. Both `source` and `label` tags should be provided under the `AttributeNames` parameter value as specified in the request.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype",
 "label":1}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up
 with sourav ganguly", "label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype",
 "label": [1, 3]}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up
 with sourav ganguly", "label": [2, 4, 5]}
```

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of *vectors.txt*, which contains words-to-vectors mapping, and *vectors.bin*, a binary used by BlazingText for hosting, inference, or both. *vectors.txt* stores the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to `True`, an additional file, *eval.json*, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353

dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to `True` during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

Sample JSON Request

Mime-type: `application/json`

```
{
"instances": ["word1", "word2", "word3"]
}
```

Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a *model.bin* file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

Sample JSON Request

Mime-type: `application/json`

```
{
 "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top *k* predictions, you can set *k* in the configuration, as follows:

```
{
 "instances": ["the movie was excellent", "i did not like the plot ."],
 "configuration": {"k": 2}
}
```

For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}

if you need to pass the value of k for top-k, then you can do it in the following way:

{"source": "source_0", "k": 2}
{"source": "source_1", "k": 3}
```

The format for output follows:

```
accept: application/jsonlines

{"prob": [prob_1], "label": ["__label__1"]}
{"prob": [prob_1], "label": ["__label__1"]}

If you have passed the value of k to be more than 1, then response will be in this
 format:

{"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
{"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
```

For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (**.bin*) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```

#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz
```

```
#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

EC2 Instance Recommendation for the BlazingText Algorithm

For `cbow` and `skipgram` modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of `subwords` embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For `batch_skipgram` mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the `S3DataDistributionType` field of the `S3DataSource` object that you pass to `CreateTrainingJob` to `FullyReplicated`. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU. BlazingText supports P2, P3, G4dn, and G5 instances for training and inference.

BlazingText Sample Notebooks

For a sample notebook that trains and deploys the SageMaker BlazingText algorithm to generate word vectors, see Learning Word2Vec Word Representations using BlazingText. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After creating and opening a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

BlazingText Hyperparameters

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

Parameter Name	Description
`mode`	The Word2vec architecture used for training. **Required** Valid values: `batch_skipgram` , `skipgram`, or `cbow`
`batch_size`	The size of each batch when `mode` is set to `batch_skipgram` . Set to a number between 10 and 20. **Optional** Valid values: Positive integer Default value: 11
`buckets`	The number of hash buckets to use for subwords. **Optional** Valid values: positive integer Default value: 2000000
`epochs`	The number of complete passes through the training data. **Optional** Valid values: Positive integer Default value: 5
`evaluation`	Whether the trained model is evaluated using the WordSimilarity-353 Test. **Optional**

Parameter Name	Description
	Valid values: (Boolean) `True` or `False` Default value: `True`
`learning_rate`	The step size used for parameter updates. **Optional** Valid values: Positive float Default value: 0.05
`min_char`	The minimum number of characters to use for subwords/character n-grams. **Optional** Valid values: positive integer Default value: 3
`min_count`	Words that appear less than `min_count` times are discarded. **Optional** Valid values: Non-negative integer Default value: 5
`max_char`	The maximum number of characters to use for subwords/character n-grams **Optional** Valid values: positive integer Default value: 6

Parameter Name	Description
`negative_samples`	The number of negative samples for the negative sample sharing strategy. **Optional** Valid values: Positive integer Default value: 5
`sampling_threshold`	The threshold for the occurrence of words. Words that appear with higher frequency in the training data are randomly down-sampled. **Optional** Valid values: Positive fraction. The recommended range is (0, 1e-3] Default value: 0.0001
`subwords`	Whether to learn subword embeddings on not. **Optional** Valid values: (Boolean) `True` or `False` Default value: `False`
`vector_dim`	The dimension of the word vectors that the algorithm learns. **Optional** Valid values: Positive integer Default value: 100

Parameter Name	Description
`window_size`	The size of the context window. The context window is the number of words surrounding the target word used for training. **Optional** Valid values: Positive integer Default value: 5

Text Classification Hyperparameters

The following table lists the hyperparameters for the Text Classification training algorithm provided by Amazon SageMaker.

> **Note**
>
> Although some of the parameters are common between the Text Classification and Word2Vec modes, they might have different meanings depending on the context.

Parameter Name	Description
`mode`	The training mode. **Required** Valid values: `supervised`
`buckets`	The number of hash buckets to use for word n-grams. **Optional** Valid values: Positive integer Default value: 2000000

Parameter Name	Description
`early_stopping`	Whether to stop training if validation accuracy doesn't improve after a `patience` number of epochs. Note that a validation channel is required if early stopping is used. **Optional** Valid values: (Boolean) `True` or `False` Default value: `False`
`epochs`	The maximum number of complete passes through the training data. **Optional** Valid values: Positive integer Default value: 5
`learning_rate`	The step size used for parameter updates. **Optional** Valid values: Positive float Default value: 0.05
`min_count`	Words that appear less than `min_count` times are discarded. **Optional** Valid values: Non-negative integer Default value: 5

Parameter Name	Description
`min_epochs`	The minimum number of epochs to train before early stopping logic is invoked. **Optional** Valid values: Positive integer Default value: 5
`patience`	The number of epochs to wait before applying early stopping when no progress is made on the validation set. Used only when `early_stopping` is `True`. **Optional** Valid values: Positive integer Default value: 4
`vector_dim`	The dimension of the embedding layer. **Optional** Valid values: Positive integer Default value: 100
`word_ngrams`	The number of word n-gram features to use. **Optional** Valid values: Positive integer Default value: 2

Tune a BlazingText Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the

tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (`skipgram`, `cbow`, and `batch_skipgram` modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (`supervised` mode), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

Metric Name	Description	Optimization Direction
`train:mean_rho`	The mean rho (Spearman's rank correlation coefficient) on WS-353 word similarity datasets	Maximize
`validation:accuracy`	The classification accuracy on the user-specified validation dataset	Maximize

Tunable BlazingText Hyperparameters

Tunable Hyperparameters for the Word2Vec Algorithm

Tune an Amazon SageMaker BlazingText Word2Vec model with the following hyperparameters. The hyperparameters that have the greatest impact on Word2Vec objective metrics are: `mode`, `learning_rate`, `window_size`, `vector_dim`, and `negative_samples`.

Parameter Name	Parameter Type	Recommended Ranges or Values
batch_size	IntegerParameterRange	[8-32]
epochs	IntegerParameterRange	[5-15]
learning_rate	ContinuousParameterRange	MinValue: 0.005, MaxValue: 0.01
min_count	IntegerParameterRange	[0-100]
mode	CategoricalParameterRange	['batch_skipgram', 'skipgram', 'cbow']
negative_samples	IntegerParameterRange	[5-25]
sampling_threshold	ContinuousParameterRange	MinValue: 0.0001, MaxValue: 0.001
vector_dim	IntegerParameterRange	[32-300]
window_size	IntegerParameterRange	[1-10]

Tunable Hyperparameters for the Text Classification Algorithm

Tune an Amazon SageMaker BlazingText text classification model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges or Values
buckets	IntegerParameterRange	[1000000-10000000]
epochs	IntegerParameterRange	[5-15]

Parameter Name	Parameter Type	Recommended Ranges or Values
learning_rate	ContinuousParameterRange	MinValue: 0.005, MaxValue: 0.01
min_count	IntegerParameterRange	[0-100]
vector_dim	IntegerParameterRange	[32-300]
word_ngrams	IntegerParameterRange	[1-3]

Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat*, *sleep*, *play*, *meow*, and *bark*, LDA might produce topics like the following:

Topic	*eat*	*sleep*	*play*	*meow*	*bark*
Topic 1	0.1	0.3	0.2	0.4	0.0
Topic 2	0.2	0.1	0.4	0.0	0.3

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

Topics

Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on

CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

Topics

Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both `recordIO-wrapped-protobuf` (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to *number of records * vocabulary size*. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. LDA inference returns `application/json` or `application/x-recordio-protobuf` *predictions*, which include the `topic_mixture` vector for each observation.

Please see the LDA Sample Notebooks for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker,

see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

> **Note**
>
> Lemmatization significantly increases algorithm performance and accuracy. Consider pre-processing any input text data. For more information, see Stemming and lemmatization.

An LDA model is defined by two parameters:

- α—A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- β—a collection of k topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture $\theta \sim Dirichlet(\alpha)$.

For each word in the document:

- Choose a topic $z \sim Multinomial(\theta)$

- Choose the corresponding topic-word distribution β_z.
- Draw a word w ~ Multinomial(β_z).

When training the model, the goal is to find parameters α and β, which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results**. The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable**. The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast**. Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a **V** x **V** x **V** tensor, which summarizes the moments of the documents in our corpus. **V** is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters α and β, which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this **V** x **V** x **V** tensor is prohibitively large to store in memory.
2. Instead, it uses a **V** x **V** moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension **V** x **k**. This matrix can be used to convert the **V** x **V** moment matrix into a **k** x **k** identity matrix. **k** is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller **k** x **k** x **k** tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the **V** x **V** x **V** tensor.
4. *Alternating Least Squares* is used to decompose the smaller **k** x *k* x **k** tensor. This provides a substantial improvement in memory consumption and speed. The parameters α and β can be found by "unwhitening" these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:

LDA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see How LDA Works.

Parameter Name	Description
num_topics	The number of topics for LDA to find within the data. **Required** Valid values: positive integer
feature_dim	The size of the vocabulary of the input document corpus. **Required** Valid values: positive integer
mini_batch_size	The total number of documents in the input document corpus. **Required** Valid values: positive integer
alpha0	Initial guess for the concentration parameter: the sum of the elements of the Dirichlet prior. Small values are more likely to generate sparse topic mixtures and large values (greater than 1.0) produce more uniform mixtures. **Optional** Valid values: Positive float Default value: 1.0
max_restarts	The number of restarts to perform during the Alternating Least Squares (ALS) spectral decomposition phase of the algorithm. Can be used to find better quality local minima at the expense of additional computation, but typically should not be adjusted. **Optional** Valid values: Positive integer

Parameter Name	Description
	Default value: 10
max_iterations	The maximum number of iterations to perform during the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted. **Optional** Valid values: Positive integer Default value: 1000
tol	Target error tolerance for the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted. **Optional** Valid values: Positive float Default value: 1e-8

Tune an LDA Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the LDA Algorithm

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
`test:pwll`	Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.	Maximize

Tunable LDA Hyperparameters

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

Parameter Name	Parameter Type	Recommended Ranges
`alpha0`	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 10
`num_topics`	IntegerParameterRanges	MinValue: 1, MaxValue: 150

Neural Topic Model (NTM) Algorithm

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into *topics* that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information

or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a *latent representation* because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the `S3DataDistributionType` parameter for them to `FullyReplicated`. If you provide validation data, the loss on this data is logged at every epoch,

and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both `recordIO-wrapped-protobuf` (dense and sparse) and `CSV` file formats. For `CSV` format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The `ContentType` for the auxiliary channel is `text/plain`, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named `vocab.txt` and currently only UTF-8 encoding is supported.

For inference, `text/csv`, `application/json`, `application/jsonlines`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. NTM inference returns `application/json` or `application/x-recordio-protobuf` *predictions*, which include the `topic_weights` vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.

For more information on input and output file formats, see NTM Response Formats for inference and the NTM Sample Notebooks.

EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference. NTM training supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

NTM Sample Notebooks

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

NTM Hyperparameters

Parameter Name	Description
`feature_dim`	The vocabulary size of the dataset. **Required** Valid values: Positive integer (min: 1, max: 1,000,000)
`num_topics`	The number of required topics. **Required** Valid values: Positive integer (min: 2, max: 1000)
`batch_norm`	Whether to use batch normalization during training. **Optional** Valid values: *true* or *false* Default value: *false*
`clip_gradient`	The maximum magnitude for each gradient component. **Optional** Valid values: Float (min: 1e-3)

Parameter Name	Description
	Default value: Infinity
`encoder_layers`	The number of layers in the encoder and the output size of each layer. When set to *auto*, the algorithm uses two layers of sizes 3 x `num_topics` and 2 x `num_topics` respectively. **Optional** Valid values: Comma-separated list of positive integers or *auto* Default value: *auto*
`encoder_layers_activation`	The activation function to use in the encoder layers. **Optional** Valid values: • `sigmoid`: Sigmoid function • `tanh`: Hyperbolic tangent • `relu`: Rectified linear unit Default value: `sigmoid`
`epochs`	The maximum number of passes over the training data. **Optional** Valid values: Positive integer (min: 1) Default value: 50
`learning_rate`	The learning rate for the optimizer. **Optional** Valid values: Float (min: 1e-6, max: 1.0) Default value: 0.001

Parameter Name	Description
mini_batch_size	The number of examples in each mini batch. **Optional** Valid values: Positive integer (min: 1, max: 10000) Default value: 256
num_patience_epochs	The number of successive epochs over which early stopping criterion is evaluated. Early stopping is triggered when the change in the loss function drops below the specified tolerance within the last num_patience_epochs number of epochs. To disable early stopping, set num_patience_epochs to a value larger than epochs. **Optional** Valid values: Positive integer (min: 1) Default value: 3
optimizer	The optimizer to use for training. **Optional** Valid values: • sgd: Stochastic gradient descent • adam: Adaptive momentum estimation • adagrad: Adaptive gradient algorithm • adadelta: An adaptive learning rate algorithm • rmsprop: Root mean square propagation Default value: adadelta

Parameter Name	Description
`rescale_gradient`	The rescale factor for gradient. **Optional** Valid values: float (min: 1e-3, max: 1.0) Default value: 1.0
`sub_sample`	The fraction of the training data to sample for training per epoch. **Optional** Valid values: Float (min: 0.0, max: 1.0) Default value: 1.0
`tolerance`	The maximum relative change in the loss function. Early stopping is triggered when change in the loss function drops below this value within the last `num_patience_epochs` number of epochs. **Optional** Valid values: Float (min: 1e-6, max: 0.1) Default value: 0.001
`weight_decay`	The weight decay coefficient. Adds L2 regularization. **Optional** Valid values: Float (min: 0.0, max: 1.0) Default value: 0.0

Tune an NTM Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. *Training loss* measures how well the model fits the training data. *Validation loss* measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which is has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the NTM Algorithm

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

Metric Name	Description	Optimization Direction
`validation:total_loss`	Total Loss on validation set	Minimize

Tunable NTM Hyperparameters

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although

it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`encoder_layers_activation`	CategoricalParameterRanges	['sigmoid', 'tanh', 'relu']
`learning_rate`	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 0.1
`mini_batch_size`	IntegerParameterRanges	MinValue: 16, MaxValue:2048
`optimizer`	CategoricalParameterRanges	['sgd', 'adam', 'adadelta']
`rescale_gradient`	ContinuousParameterRange	MinValue: 0.1, MaxValue: 1.0
`weight_decay`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0

NTM Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.

JSON Response Format

```
{
    "predictions":    [
        {"topic_weights": [0.02, 0.1, 0,...]},
        {"topic_weights": [0.25, 0.067, 0,...]}
    ]
```

```
}
```

JSONLINES Response Format

```
{"topic_weights": [0.02, 0.1, 0,...]}
{"topic_weights": [0.25, 0.067, 0,...]}
```

RECORDIO Response Format

```
[
    Record = {
        features = {},
        label = {
            'topic_weights': {
                keys: [],
                values: [0.25, 0.067, 0, ...]  # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'topic_weights': {
                keys: [],
                values: [0.25, 0.067, 0, ...]  # float32
            }
        }
    }
]
```

Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm. For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

Topics

I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

Input Data Type	Example
Sentence-sentence pairs	"A soccer game with multiple males playing." and "Some men are playing a sport."
Labels-sequence pairs	The genre tags of the movie "Titanic", such as "Romance" and "Drama", and its short description: "James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912."
Customer-customer pairs	The customer ID of Jane and customer ID of Jackie.
Product-product pairs	The product ID of football and product ID of basketball.

Input Data Type	Example
Item review user-item pairs	A user's ID and the items she has bought, such as apple, pear, and orange.

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single `integer-id`. For example, `[10]`.
- A sequences of discrete tokens, which is represented as a list of `integer-ids`. For example, `[0,12,10,13]`.

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

EC2 Instance Recommendation for the Object2Vec Algorithm

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inference.

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs. Object2Vec supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the the section called "GPU optimization: Classification or Regression" or the section called "GPU optimization: Encoder Embeddings" inference network is loaded into GPU.

Object2Vec Sample Notebooks

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings

> **Note**
>
> To run the notebooks on a notebook instance, see Example Notebooks. To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Classic Notebook.

How Object2Vec Works

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

Topics

- Step 1: Process Data
- Step 2: Train a Model
- Step 3: Produce Inferences

Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training . To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

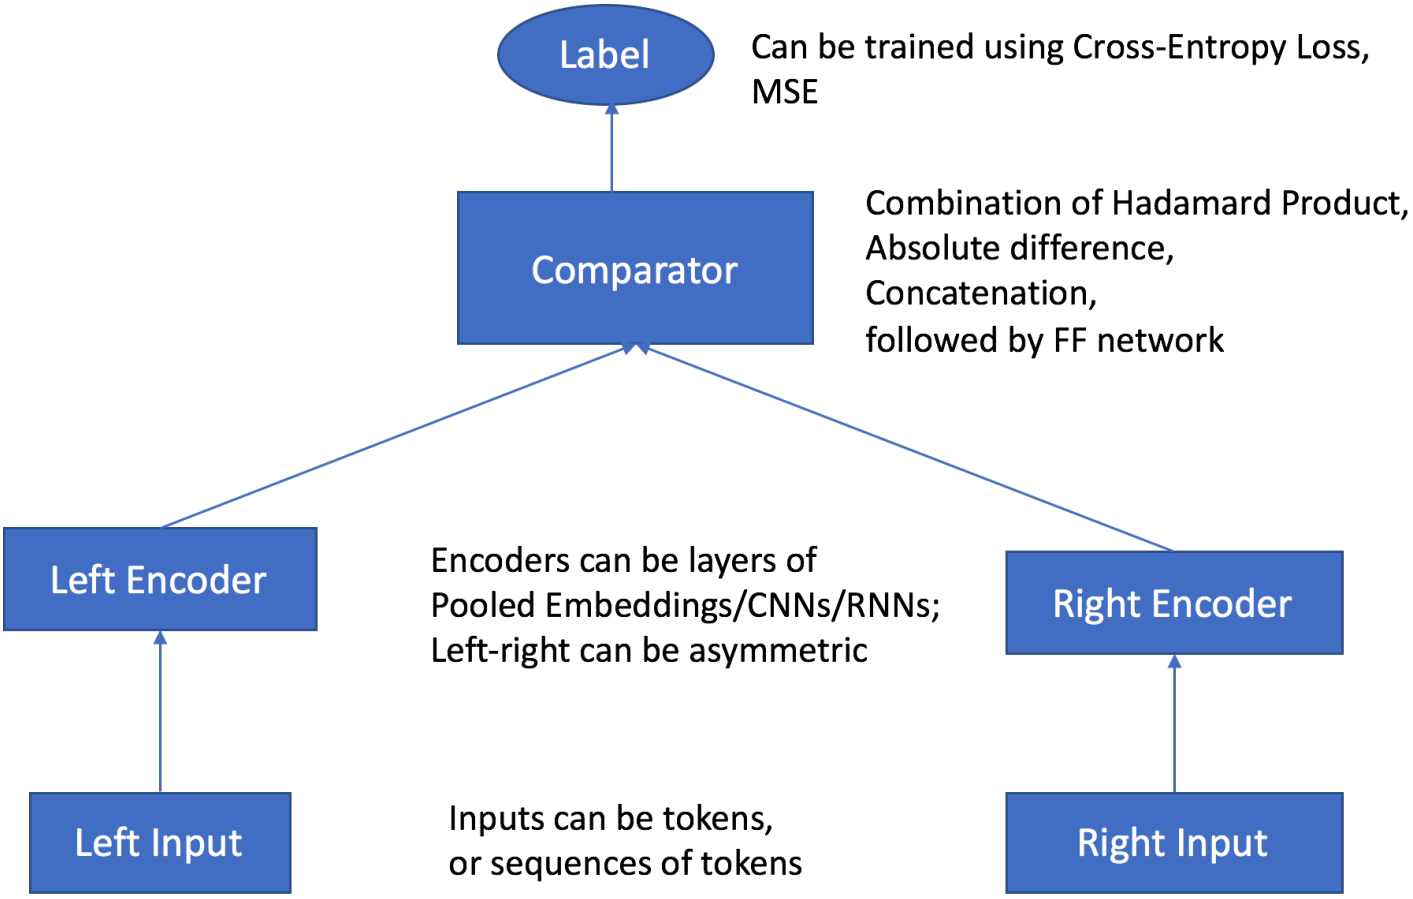
Step 2: Train a Model

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.
- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.
- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to `True` when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the he `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.



Architecture of the Object2Vec Algorithm from Data Inputs to Scores

Step 3: Produce Inferences

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

Object2Vec Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

Parameter Name	Description
`enc0_max_seq_len`	The maximum sequence length for the enc0 encoder. **Required** Valid values: 1 ≤ integer ≤ 5000
`enc0_vocab_size`	The vocabulary size of enc0 tokens. **Required** Valid values: 2 ≤ integer ≤ 3000000
`bucket_width`	The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter. **Optional** Valid values: 0 ≤ integer ≤ 100 Default value: 0 (no bucketing)
`comparator_list`	A list used to customize the way in which two embedding s are compared. The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvector s. The string values passed to the `comparator_list` and the order in which they are passed determine how these subvectors are assembled. For example, if `comparato r_list="hadamard, concat"` , then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two

Parameter Name	Description
	encodings. If, on the other hand, `comparator_list="hadamard"` , then the comparator operator constructs the vector as the hadamard product of only two encodings. **Optional** Valid values: A string that contains any combination of the names of the three binary operators: `hadamard`, `concat`, or `abs_diff`. The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows: • `hadamard`: Constructs a vector as the Hadamard (element-wise) product of two encodings. • `concat`: Constructs a vector as the concatenation of two encodings. • `abs_diff`: Constructs a vector as the absolute difference between two encodings. Default value: `"hadamard, concat, abs_diff"`
`dropout`	The dropout probability for network layers. *Dropout* is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons. **Optional** Valid values: 0.0 ≤ float ≤ 1.0 Default value: 0.0

Parameter Name	Description
`early_stopping_patience`	The number of consecutive epochs without improvement allowed before early stopping is applied. Improvement is defined by with the `early_stopping_tolerance` hyperparameter. **Optional** Valid values: 1 ≤ integer ≤ 5 Default value: 3
`early_stopping_tolerance`	The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the `early_stopping_patience` hyperparameter concludes. **Optional** Valid values: 0.000001 ≤ float ≤ 0.1 Default value: 0.01
`enc_dim`	The dimension of the output of the embedding layer. **Optional** Valid values: 4 ≤ integer ≤ 10000 Default value: 4096

Parameter Name	Description
enc0_network	The network model for the enc0 encoder. **Optional** Valid values: hcnn, bilstm, or pooled_embedding • hcnn: A hierarchical convolutional neural network. • bilstm: A bidirectional long short-term memory network (biLSTM), in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks. • pooled_embedding : Averages the embeddings of all of the tokens in the input. Default value: hcnn
enc0_cnn_filter_width	The filter width of the convolutional neural network (CNN) enc0 encoder. **Conditional** Valid values: 1 ≤ integer ≤ 9 Default value: 3
enc0_freeze_pretrained_embedding	Whether to freeze enc0 pretrained embedding weights. **Conditional** Valid values: True or False Default value: True

Parameter Name	Description
enc0_layers	The number of layers in the enc0 encoder. **Conditional** Valid values: auto or 1 ≤ integer ≤ 4 • For hcnn, auto means 4. • For bilstm, auto means 1. • For pooled_embedding , auto ignores the number of layers. Default value: auto
enc0_pretrained_embedding_file	The filename of the pretrained enc0 token embedding file in the auxiliary data channel. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
enc0_token_embedding_dim	The output dimension of the enc0 token embedding layer. **Conditional** Valid values: 2 ≤ integer ≤ 1000 Default value: 300

Parameter Name	Description
`enc0_vocab_file`	The vocabulary file for mapping pretrained enc0 token embedding vectors to numerical vocabulary IDs. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
`enc1_network`	The network model for the enc1 encoder. If you want the enc1 encoder to use the same network model as enc0, including the hyperparameter values, set the value to `enc0`. **Note** Even when the enc0 and enc1 encoder networks have symmetric architectures, you can't shared parameter values for these networks. **Optional** Valid values: `enc0`, `hcnn`, `bilstm`, or `pooled_embedding` • `enc0`: The network model for the enc0 encoder. • `hcnn`: A hierarchical convolutional neural network. • `bilstm`: A bidirectional LSTM, in which the signal propagate s backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks. • `pooled_embedding` : The averages of the embeddings of all of the tokens in the input. Default value: `enc0`

Parameter Name	Description
`enc1_cnn_filter_width`	The filter width of the CNN enc1 encoder. **Conditional** Valid values: 1 ≤ integer ≤ 9 Default value: 3
`enc1_freeze_pretrained_embedding`	Whether to freeze enc1 pretrained embedding weights. **Conditional** Valid values: `True` or `False` Default value: `True`
`enc1_layers`	The number of layers in the enc1 encoder. **Conditional** Valid values: `auto` or 1 ≤ integer ≤ 4 • For `hcnn`, `auto` means 4. • For `bilstm`, `auto` means 1. • For `pooled_embedding` , `auto` ignores the number of layers. Default value: `auto`
`enc1_max_seq_len`	The maximum sequence length for the enc1 encoder. **Conditional** Valid values: 1 ≤ integer ≤ 5000

Parameter Name	Description
enc1_pretrained_embedding_file	The name of the enc1 pretrained token embedding file in the auxiliary data channel. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
enc1_token_embedding_dim	The output dimension of the enc1 token embedding layer. **Conditional** Valid values: 2 ≤ integer ≤ 1000 Default value: 300
enc1_vocab_file	The vocabulary file for mapping pretrained enc1 token embeddings to vocabulary IDs. **Conditional** Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\._] Default value: "" (empty string)
enc1_vocab_size	The vocabulary size of enc0 tokens. **Conditional** Valid values: 2 ≤ integer ≤ 3000000

Parameter Name	Description
`epochs`	The number of epochs to run for training. **Optional** Valid values: 1 ≤ integer ≤ 100 Default value: 30
`learning_rate`	The learning rate for training. **Optional** Valid values: 1.0E-6 ≤ float ≤ 1.0 Default value: 0.0004
`mini_batch_size`	The batch size that the dataset is split into for an `optimizer` during training. **Optional** Valid values: 1 ≤ integer ≤ 10000 Default value: 32
`mlp_activation`	The type of activation function for the multilayer perceptron (MLP) layer. **Optional** Valid values: `tanh`, `relu`, or `linear` • `tanh`: Hyperbolic tangent • `relu`: Rectified linear unit (ReLU) • `linear`: Linear function Default value: `linear`

Parameter Name	Description
`mlp_dim`	The dimension of the output from MLP layers. **Optional** Valid values: 2 ≤ integer ≤ 10000 Default value: 512
`mlp_layers`	The number of MLP layers in the network. **Optional** Valid values: 0 ≤ integer ≤ 10 Default value: 2
`negative_sampling_rate`	The ratio of negative samples, generated to assist in training the algorithm, to positive samples that are provided by users. Negative samples represent data that is unlikely to occur in reality and are labelled negatively for training. They facilitate training a model to discriminate between the positive samples observed and the negative samples that are not. To specify the ratio of negative samples to positive samples used for training, set the value to a positive integer. For example, if you train the algorithm on input data in which all of the samples are positive and set `negative_sampling_rate` to 2, the Object2Vec algorithm internally generates two negative samples per positive sample. If you don't want to generate or use negative samples during training, set the value to 0. **Optional** Valid values: 0 ≤ integer Default value: 0 (off)

Parameter Name	Description
num_classes	The number of classes for classification training. Amazon SageMaker ignores this hyperparameter for regression problems. **Optional** Valid values: 2 ≤ integer ≤ 30 Default value: 2
optimizer	The optimizer type. **Optional** Valid values: adadelta, adagrad, adam, sgd, or rmsprop. • adadelta: A per-dimension learning rate method for gradient descent • adagrad: The adaptive gradient algorithm • adam: The adaptive moment estimation algorithm • sgd: Stochastic gradient descent • rmsprop: Root mean square propagation Default value: adam
output_layer	The type of output layer where you specify that the task is regression or classification. **Optional** Valid values: softmax or mean_squared_error • softmax: The Softmax function used for classification. • mean_squared_error : The MSE used for regression. Default value: softmax

Parameter Name	Description
`tied_token_embeddi ng_weight`	Whether to use a shared embedding layer for both encoders. If the inputs to both encoders use the same token-level units, use a shared token embedding layer. For example, for a collection of documents, if one encoder encodes sentences and another encodes whole documents, you can use a shared token embedding layer. That's because both sentences and documents are composed of word tokens from the same vocabulary. **Optional** Valid values: `True` or `False` Default value: `False`

Parameter Name	Description
token_embedding_storage_type	The mode of gradient update used during training: when the dense mode is used, the optimizer calculates the full gradient matrix for the token embedding layer even if most rows of the gradient are zero-valued. When sparse mode is used, the optimizer only stores rows of the gradient that are actually being used in the mini-batch. If you want the algorithm to perform lazy gradient updates, which calculate the gradients only in the non-zero rows and which speed up training, specify row_sparse . Setting the value to row_sparse constrains the values available for other hyperparameters, as follows: • The optimizer hyperparameter must be set to adam, adagrad, or sgd. Otherwise, the algorithm throws a CustomerValueError . • The algorithm automatically disables bucketing, setting the bucket_width hyperparameter to 0. **Optional** Valid values: dense or row_sparse Default value: dense
weight_decay	The weight decay parameter used for optimization. **Optional** Valid values: 0 ≤ float ≤ 10000 Default value: 0 (no decay)

Tune an Object2Vec Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective

metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

Regressor Metrics Computed by the Object2Vec Algorithm

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

Metric Name	Description	Optimization Direction
`test:mean_squared_error`	The Mean Square Error	Minimize
`validation:mean_squared_error`	The Mean Square Error	Minimize

Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

Metric Name	Description	Optimization Direction
`test:accuracy`	Accuracy	Maximize
`test:cross_entropy`	Cross-entropy	Minimize

Metric Name	Description	Optimization Direction
validation:accuracy	Accuracy	Maximize
validation:cross_entropy	Cross-entropy	Minimize

Tunable Object2Vec Hyperparameters

You can tune the following hyperparameters for the Object2Vec algorithm.

Hyperparameter Name	Hyperparameter Type	Recommended Ranges and Values
dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0
early_stopping_patience	IntegerParameterRange	MinValue: 1, MaxValue: 5
early_stopping_tolerance	ContinuousParameterRange	MinValue: 0.001, MaxValue: 0.1
enc_dim	IntegerParameterRange	MinValue: 4, MaxValue: 4096
enc0_cnn_filter_width	IntegerParameterRange	MinValue: 1, MaxValue: 5
enc0_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4

Hyperparameter Name	Hyperparameter Type	Recommended Ranges and Values
enc0_token_embedding_dim	IntegerParameterRange	MinValue: 5, MaxValue: 300
enc1_cnn_filter_width	IntegerParameterRange	MinValue: 1, MaxValue: 5
enc1_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4
enc1_token_embedding_dim	IntegerParameterRange	MinValue: 5, MaxValue: 300
epochs	IntegerParameterRange	MinValue: 4, MaxValue: 20
learning_rate	ContinuousParameterRange	MinValue: 1e-6, MaxValue: 1.0
mini_batch_size	IntegerParameterRange	MinValue: 1, MaxValue: 8192
mlp_activation	CategoricalParameterRanges	[tanh, relu, linear]
mlp_dim	IntegerParameterRange	MinValue: 16, MaxValue: 1024
mlp_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4

Hyperparameter Name	Hyperparameter Type	Recommended Ranges and Values
optimizer	CategoricalParameterRanges	[adagrad, adam, rmsprop, sgd, adadelta]
weight_decay	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0

Data Formats for Object2Vec Training

Input: JSON Lines Request Format

Content-type: application/jsonlines

```
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80,
 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9,
 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The “in0” and “in1” are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field `"label"` can accept real valued inputs.

Data Formats for Object2Vec Inference

GPU optimization: Classification or Regression

Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the classification/regression or the the section called “Output: Encoder Embeddings” inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify `INFERENCE_PREFERRED_MODE=classification`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```
transformer = o2v.transformer(instance_count=4,
```

```
                            instance_type="ml.p2.xlarge",
                            max_concurrent_transforms=2,
                            max_payload=1,  # 1MB
                            strategy='MultiRecord',
                            env={'INFERENCE_PREFERRED_MODE': 'classification'},  #
 only useful with GPU
                            output_path=output_s3_path)
```

Input: Classification or Regression Request Format

Content-type: application/json

```
{
  "instances" : [
    {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69,
 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]},
    {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107,
 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]},
    {"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
  ]
}
```

Content-type: application/jsonlines

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821,
 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
 "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

For classification problems, the length of the scores vector corresponds to `num_classes`. For regression problems, the length is 1.

Output: Classification or Regression Response Format

Accept: application/json

```
{
    "predictions": [
        {
            "scores": [
                0.6533935070037842,
```

```
                0.07582679390907288,
                0.2707797586917877
            ]
        },
        {
            "scores": [
                0.026291321963071823,
                0.6577019095420837,
                0.31600672006607056
            ]
        }
    ]
}
```

Accept: application/jsonlines

```
{"scores":[0.195667684078216,0.395351558923721,0.408980727195739]}
{"scores":[0.251988261938095,0.258233487606048,0.489778339862823]}
{"scores":[0.280087798833847,0.368331134319305,0.351581096649169]}
```

In both the classification and regression formats, the scores apply to individual labels.

Encoder Embeddings for Object2Vec

GPU optimization: Encoder Embeddings

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the the section called “Inference Formats: Scoring” or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFERENCE_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```
transformer = o2v.transformer(instance_count=4,
                              instance_type="ml.p2.xlarge",
                              max_concurrent_transforms=2,
                              max_payload=1,  # 1MB
                              strategy='MultiRecord',
                              env={'INFERENCE_PREFERRED_MODE': 'embedding'},  # only
 useful with GPU
```

```
                                    output_path=output_s3_path)
```

Input: Encoder Embeddings

Content-type: application/json; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{
  "instances" : [
    {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69,
 821, 4]},
    {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107,
 4]},
    {"in0": [774, 14, 21, 206]}
  ]
}
```

Content-type: application/jsonlines; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821,
 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0": [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: "`in0`" or "`in1.`" The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

Output: Encoder Embeddings

Content-type: application/json

```
{
  "predictions": [
    {"embeddings":
[0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.00
    {"embeddings":
[0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.015
```

```
  ]
}
```

Content-type: application/jsonlines

```
{"embeddings":
[0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.00
{"embeddings":
[0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.015
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: `enc0_token_embedding_dim`, `enc1_token_embedding_dim`, or `enc_dim`.

Sequence-to-Sequence Algorithm

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

Topics

Input/Output Interface for the Sequence-to-Sequence Algorithm

Training

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- `train`: It should contain the training data (for example, the `train.rec` file generated by the preprocessing script).
- `validation`: It should contain the validation data (for example, the `val.rec` file generated by the preprocessing script).
- `vocab`: It should contain two vocabulary files (`vocab.src.json` and `vocab.trg.json`)

If the algorithm doesn't find data in any of these three channels, training results in an error.

Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the `application/json` format. Otherwise, use the `recordio-protobuf` format to work with the integer encoded data. Both modes support batching of input data. `application/json` format also allows you to visualize the attention matrix.

- `application/json`: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be `application/json`. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:

  `configuration`: {`attention_matrix`: `true`}: Returns the attention matrix for the particular input sequence.
- `application/x-recordio-protobuf`: Expects the input in `recordio-protobuf` format and returns the output in `recordio-protobuf format`. Both content and accept types should be `applications/x-recordio-protobuf`. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be `application/jsonlines`. The format for input is as follows:

```
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```
accept: application/jsonlines

{"target": "predicted_sequence_0"}
{"target": "predicted_sequence_1"}
```

For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the Sequence-to-Sequence Sample Notebooks .

EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm

The Amazon SageMaker seq2seq algorithm only supports on GPU instance types and can only train on a single machine. However, you can use instances with multiple GPUs. The seq2seq algorithm supports P2, P3, G4dn, and G5 GPU instance families.

Sequence-to-Sequence Sample Notebooks

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train a English-German translation model, see Machine Translation English-German Example Using SageMaker Seq2Seq. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- An **embedding layer**. In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.
- An **encoder layer**. After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah's blog explains LSTM in a great detail.)
- A **decoder layer**. The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

Attention mechanism. The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

Sequence-to-Sequence Hyperparameters

Parameter Name	Description
`batch_size`	Mini batch size for gradient descent. **Optional**

Parameter Name	Description
	Valid values: positive integer Default value: 64
`beam_size`	Length of the beam for beam search. Used during training for computing `bleu` and used during inference . **Optional** Valid values: positive integer Default value: 5
`bleu_sample_size`	Number of instances to pick from validation dataset to decode and compute `bleu` score during training. Set to -1 to use full validation set (if `bleu` is chosen as `optimized_metric`). **Optional** Valid values: integer Default value: 0
`bucket_width`	Returns (source,target) buckets up to (`max_seq_len_source` , `max_seq_len_target`). The longer side of the data uses steps of `bucket_width` while the shorter side uses steps scaled down by the average target/source length ratio. If one sided reaches its maximum length before the other, width of extra buckets on that side is fixed to that side of `max_len`. **Optional** Valid values: positive integer Default value: 10

Parameter Name	Description
`bucketing_enabled`	Set to `false` to disable bucketing, unroll to maximum length. **Optional** Valid values: `true` or `false` Default value: `true`
`checkpoint_frequency_num_batches`	Checkpoint and evaluate every x batches. This checkpointing hyperparameter is passed to the SageMaker's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped. **Optional** Valid values: positive integer Default value: 1000

Parameter Name	Description
checkpoint_threshold	Maximum number of checkpoints model is allowed to not improve in optimized_metric on validation dataset before training is stopped. This checkpointing hyperparameter is passed to the SageMaker's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped. **Optional** Valid values: positive integer Default value: 3
clip_gradient	Clip absolute gradient values greater than this. Set to negative to disable. **Optional** Valid values: float Default value: 1
cnn_activation_type	The cnn activation type to be used. **Optional** Valid values: String. One of glu, relu, softrelu, sigmoid, or tanh. Default value: glu

Parameter Name	Description
cnn_hidden_dropout	Dropout probability for dropout between convolutional layers. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
cnn_kernel_width_decoder	Kernel width for the cnn decoder. **Optional** Valid values: positive integer Default value: 5
cnn_kernel_width_encoder	Kernel width for the cnn encoder. **Optional** Valid values: positive integer Default value: 3
cnn_num_hidden	Number of cnn hidden units for encoder and decoder. **Optional** Valid values: positive integer Default value: 512
decoder_type	Decoder type. **Optional** Valid values: String. Either rnn or cnn. Default value: *rnn*

Parameter Name	Description
embed_dropout_source	Dropout probability for source side embeddings. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
embed_dropout_target	Dropout probability for target side embeddings. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
encoder_type	Encoder type. The rnn architecture is based on attention mechanism by Bahdanau et al. and *cnn* architecture is based on Gehring et al. **Optional** Valid values: String. Either rnn or cnn. Default value: rnn
fixed_rate_lr_half_life	Half life for learning rate in terms of number of checkpoints for fixed_rate_ * schedulers. **Optional** Valid values: positive integer Default value: 10

Parameter Name	Description
learning_rate	Initial learning rate. **Optional** Valid values: float Default value: 0.0003
loss_type	Loss function for training. **Optional** Valid values: String. cross-entropy Default value: cross-entropy
lr_scheduler_type	Learning rate scheduler type. plateau_reduce means reduce the learning rate whenever optimized_metric on validation_accuracy plateaus. inv_t is inverse time decay. learning_rate / (1+decay_rate *t) **Optional** Valid values: String. One of plateau_reduce , fixed_rate_inv_t , or fixed_rate_inv_sqrt_t . Default value: plateau_reduce
max_num_batches	Maximum number of updates/batches to process. -1 for infinite. **Optional** Valid values: integer Default value: -1

Parameter Name	Description
max_num_epochs	Maximum number of epochs to pass through training data before fitting is stopped. Training continues until this number of epochs even if validation accuracy is not improving if this parameter is passed. Ignored if not passed. **Optional** Valid values: Positive integer and less than or equal to max_num_epochs. Default value: none
max_seq_len_source	Maximum length for the source sequence length. Sequences longer than this length are truncated to this length. **Optional** Valid values: positive integer Default value: 100
max_seq_len_target	Maximum length for the target sequence length. Sequences longer than this length are truncated to this length. **Optional** Valid values: positive integer Default value: 100

Parameter Name	Description
`min_num_epochs`	Minimum number of epochs the training must run before it is stopped via `early_stopping` conditions. **Optional** Valid values: positive integer Default value: 0
`momentum`	Momentum constant used for `sgd`. Don't pass this parameter if you are using `adam` or `rmsprop`. **Optional** Valid values: float Default value: none
`num_embed_source`	Embedding size for source tokens. **Optional** Valid values: positive integer Default value: 512
`num_embed_target`	Embedding size for target tokens. **Optional** Valid values: positive integer Default value: 512

Parameter Name	Description
num_layers_decoder	Number of layers for Decoder *rnn* or *cnn*. **Optional** Valid values: positive integer Default value: 1
num_layers_encoder	Number of layers for Encoder rnn or cnn. **Optional** Valid values: positive integer Default value: 1
optimized_metric	Metrics to optimize with early stopping. **Optional** Valid values: String. One of perplexity , accuracy, or bleu. Default value: perplexity
optimizer_type	Optimizer to choose from. **Optional** Valid values: String. One of adam, sgd, or rmsprop. Default value: adam

Parameter Name	Description
`plateau_reduce_lr_factor`	Factor to multiply learning rate with (for `plateau_reduce`). **Optional** Valid values: float Default value: 0.5
`plateau_reduce_lr_threshold`	For `plateau_reduce` scheduler, multiply learning rate with reduce factor if `optimized_metric` didn't improve for this many checkpoints. **Optional** Valid values: positive integer Default value: 3
`rnn_attention_in_upper_layers`	Pass the attention to upper layers of *rnn*, like Google NMT paper. Only applicable if more than one layer is used. **Optional** Valid values: boolean (`true` or `false`) Default value: `true`
`rnn_attention_num_hidden`	Number of hidden units for attention layers. defaults to `rnn_num_hidden` . **Optional** Valid values: positive integer Default value: `rnn_num_hidden`

Parameter Name	Description
rnn_attention_type	Attention model for encoders. mlp refers to concat and bilinear refers to general from the Luong et al. paper. **Optional** Valid values: String. One of dot, fixed, mlp, or bilinear. Default value: mlp
rnn_cell_type	Specific type of rnn architecture. **Optional** Valid values: String. Either lstm or gru. Default value: lstm
rnn_decoder_state_init	How to initialize rnn decoder states from encoders. **Optional** Valid values: String. One of last, avg, or zero. Default value: last
rnn_first_residual_layer	First *rnn* layer to have a residual connection, only applicable if number of layers in encoder or decoder is more than 1. **Optional** Valid values: positive integer Default value: 2

Parameter Name	Description
`rnn_num_hidden`	The number of *rnn* hidden units for encoder and decoder. This must be a multiple of 2 because the algorithm uses bi-directional Long Term Short Term Memory (LSTM) by default. **Optional** Valid values: positive even integer Default value: 1024
`rnn_residual_connections`	Add residual connection to stacked *rnn*. Number of layers should be more than 1. **Optional** Valid values: boolean (`true` or `false`) Default value: `false`
`rnn_decoder_hidden_dropout`	Dropout probability for hidden state that combines the context with the *rnn* hidden state in the decoder. **Optional** Valid values: Float. Range in [0,1]. Default value: 0
`training_metric`	Metrics to track on training on validation data. **Optional** Valid values: String. Either `perplexity` or `accuracy`. Default value: `perplexity`

Parameter Name	Description
`weight_decay`	Weight decay constant. **Optional** Valid values: float Default value: 0
`weight_init_scale`	Weight initialization scale (for `uniform` and `xavier` initialization). **Optional** Valid values: float Default value: 2.34
`weight_init_type`	Type of weight initialization. **Optional** Valid values: String. Either `uniform` or `xavier`. Default value: `xavier`
`xavier_factor_type`	Xavier factor type. **Optional** Valid values: String. One of `in`, `out`, or `avg`. Default value: `in`

Tune a Sequence-to-Sequence Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches

the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the Sequence-to-Sequence Algorithm

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

Metric Name	Description	Optimization Direction
`validation:accuracy`	Accuracy computed on the validation dataset.	Maximize
`validation:bleu`	Bleu score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the `bleu_sample_size` parameter to specify the subsample.	Maximize
`validation:perplexity`	Perplexity, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values, Models that are good at predicting a sample have a low perplexity.	Minimize

Tunable Sequence-to-Sequence Hyperparameters

You can tune the following hyperparameters for the SageMaker Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective

metrics are: batch_size, optimizer_type, learning_rate, num_layers_encoder, and num_layers_decoder.

Parameter Name	Parameter Type	Recommended Ranges
num_layers_encoder	IntegerParameterRange	[1-10]
num_layers_decoder	IntegerParameterRange	[1-10]
batch_size	CategoricalParameterRange	[16,32,64,128,256,512,1024,2048]
optimizer_type	CategoricalParameterRange	['adam', 'sgd', 'rmsprop']
weight_init_type	CategoricalParameterRange	['xavier', 'uniform']
weight_init_scale	ContinuousParameterRange	For the xavier type: MinValue: 2.0, MaxValue: 3.0 For the uniform type: MinValue: -1.0, MaxValue: 1.0
learning_rate	ContinuousParameterRange	MinValue: 0.00005, MaxValue: 0.2
weight_decay	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.1
momentum	ContinuousParameterRange	MinValue: 0.5, MaxValue: 0.9
clip_gradient	ContinuousParameterRange	MinValue: 1.0, MaxValue: 5.0

Parameter Name	Parameter Type	Recommended Ranges
rnn_num_hidden	CategoricalParameterRange	Applicable only to recurrent neural networks (RNNs). [128,256,512,1024, 2048]
cnn_num_hidden	CategoricalParameterRange	Applicable only to convolutional neural networks (CNNs). [128,256,512,1024, 2048]
num_embed _source	IntegerParameterRange	[256-512]
num_embed _target	IntegerParameterRange	[256-512]
embed_dro pout_source	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
embed_dro pout_target	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
rnn_decod er_hidden _dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
cnn_hidde n_dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
lr_schedu ler_type	CategoricalParameterRange	['plateau_reduce', 'fixed_rate_inv_t', 'fixed_rate_inv_sq rt_t']

Parameter Name	Parameter Type	Recommended Ranges
plateau_reduce_lr_factor	ContinuousParameterRange	MinValue: 0.1, MaxValue: 0.5
plateau_reduce_lr_threshold	IntegerParameterRange	[1-5]
fixed_rate_lr_half_life	IntegerParameterRange	[10-30]

Text Classification - TensorFlow

The Amazon SageMaker Text Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of text data is not available. The text classification algorithm takes a text string as input and outputs a probability for each of the class labels. Training datasets must be in CSV format.

Topics

How to use the SageMaker Text Classification - TensorFlow algorithm

You can use Text Classification - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Text Classification - TensorFlow with the SageMaker Python SDK. For information on how to use Text Classification - TensorFlow from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

The Text Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Hub Models. Every pretrained model has a unique `model_id`. The following example uses BERT Base Uncased (`model_id`: `tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2`) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with `hyperparameters.retrieve_default`. For more information, see Text Classification - TensorFlow Hyperparameters. Use these values to construct a SageMaker Estimator.

> **Note**
>
> Default hyperparameter values are different for different models. For example, for larger models, the default batch size is smaller.

This example uses the SST2 dataset, which contains positive and negative movie reviews. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset. Any S3 bucket used in a notebook must be in the same AWS Region as the notebook instance that accesses it.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2", "*"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
```

```
train_image_uri =
 image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",insta

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
 script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
 model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
 model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/SST2/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tc-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create an Estimator instance
tf_tc_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job
```

```
tf_tc_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

Input and output interface for the Text Classification - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset made up of text sentences with any number of classes. The pretrained model attaches a classification layer to the Text Embedding model and initializes the layer parameters to random values. The output dimension of the classification layer is determined based on the number of classes detected in the input data.

Be mindful of how to format your training data for input to the Text Classification - TensorFlow model.

- **Training data input format:** A directory containing a `data.csv` file. Each row of the first column should have integer class labels between 0 and the number of classes. Each row of the second column should have the corresponding text data.

The following is an example of an input CSV file. Note that the file should not have any header. The file should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://`*`bucket_name`*`/`*`input_directory`*`/`. Note that the trailing `/` is required.

```
|   |  |
|---|---|
|0 |hide new secretions from the parental units|
|0 |contains no wit , only labored gags|
|1 |that loves its characters and communicates something rather beautiful about human
 nature|
|...|...|
```

Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

> **Note**
>
> You can only seed a SageMaker Text Classification - TensorFlow model with another Text Classification - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model.

For more information on using incremental training with the SageMaker Text Classification - TensorFlow algorithm, see the Introduction to JumpStart - Text Classification sample notebook.

Inference with the Text Classification - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Text Classification training for inference. Any raw text formats for inference must be content type `application/x-text`.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Text Classification - TensorFlow model processes a single string per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

{"probabilities": [prob_0, prob_1, prob_2, ...],
"labels": [label_0, label_1, label_2, ...],
"predicted_label": predicted_label}
```

If `accept` is set to `application/json`, then the model only outputs probabilities.

Amazon EC2 instance recommendation for the Text Classification - TensorFlow algorithm

The Text Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:

- `ml.p2.xlarge`
- `ml.p2.16xlarge`
- `ml.p3.2xlarge`

- `ml.p3.16xlarge`
- `ml.g4dn.xlarge`
- `ml.g4dn.16.xlarge`
- `ml.g5.xlarge`
- `ml.g5.48xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Text Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How Text Classification - TensorFlow Works

The Text Classification - TensorFlow algorithm takes text as classifies it into one of the output class labels. Deep learning networks such as BERT are highly accurate for text classification. There are also deep learning networks that are trained on large text datasets, such as TextNet, which has more than 11 million texts with about 11,000 categories. After a network is trained with TextNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific text classification tasks. The Amazon SageMaker Text Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a text classification layer is attached to the pretrained TensorFlow model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully connected layer with 2-norm regularization, and is initialized with random weights. You can change the hyperparameter values for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer.

You can fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Text Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Model Name	model_id	Source

Text Classification - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Object Detection - TensorFlow algorithm. See Tune a Text Classification - TensorFlow model for information on hyperparameter tuning.

Parameter Name	Description
batch_size	The batch size for training. For training on instances with multiple GPUs, this batch size is used across the GPUs. Valid values: positive integer. Default value: 32.
beta_1	The beta1 for the "adam" and "adamw" optimizers. Represents the exponential decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0].

Parameter Name	Description
	Default value: `0.9`.
`beta_2`	The beta2 for the `"adam"` and `"adamw"` optimizers. Represents the exponential decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.999`.
`dropout_rate`	The dropout rate for the dropout layer in the top classification layer. Used only when `reinitialize_top_layer` is set to `"True"`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.2`
`early_stopping`	Set to `"True"` to use early stopping logic during training. If `"False"`, early stopping is not used. Valid values: string, either: (`"True"` or `"False"`). Default value: `"False"`.
`early_stopping_min_delta`	The minimum change needed to qualify as an improvement. An absolute change less than the value of `early_stopping_min_delta` does not qualify as improvement. Used only when `early_stopping` is set to `"True"`. Valid values: float, range: [`0.0`, `1.0`]. Default value: `0.0`.

Parameter Name	Description
early_stopping_patience	The number of epochs to continue training with no improvement. Used only when early_stopping is set to "True". Valid values: positive integer. Default value: 5.
epochs	The number of training epochs. Valid values: positive integer. Default value: 10.
epsilon	The epsilon for "adam", "rmsprop", "adadelta", and "adagrad" optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 1e-7.
initial_accumulator_value	The starting value for the accumulators, or the per-parameter momentum values, for the "adagrad" optimizer. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.0001.
learning_rate	The optimizer learning rate. Valid values: float, range: [0.0, 1.0]. Default value: 0.001.

Parameter Name	Description
momentum	The momentum for the "sgd" and "nesterov" optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.
optimizer	The optimizer type. For more information, see Optimizers in the TensorFlow documentation. Valid values: string, any of the following: ("adamw", "adam", "sgd", "nesterov" , "rmsprop" , "adagrad" , "adadelta"). Default value: "adam".
regularizers_l2	The L2 regularization factor for the dense layer in the classific ation layer. Used only when reinitialize_top_layer is set to "True". Valid values: float, range: [0.0, 1.0]. Default value: 0.0001.
reinitialize_top_l ayer	If set to "Auto", the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to "True". Valid values: string, any of the following: ("Auto", "True" or "False"). Default value: "Auto".

Parameter Name	Description
rho	The discounting factor for the gradient of the "adadelta" and "rmsprop" optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.95.
train_only_on_top_layer	If "True", only the top classification layer parameters are fine-tuned. If "False", all model parameters are fine-tuned. Valid values: string, either: ("True" or "False"). Default value: "False".
validation_split_ratio	The fraction of training data to randomly split to create validation data. Only used if validation data is not provided through the validation channel. Valid values: float, range: [0.0, 1.0]. Default value: 0.2.
warmup_steps_fraction	The fraction of the total number of gradient update steps, where the learning rate increases from 0 to the initial learning rate as a warm up. Only used with the adamw optimizer. Valid values: float, range: [0.0, 1.0]. Default value: 0.1.

Tune a Text Classification - TensorFlow model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics computed by the Text Classification - TensorFlow algorithm

Refer to the following chart to find which metrics are computed by the Text Classification - TensorFlow algorithm.

Metric Name	Description	Optimization Direction	Regex Pattern
`validation:accuracy`	The ratio of the number of correct predictions to the total number of predictions made.	Maximize	`val_accuracy=([0-9\.]+)`

Tunable Text Classification - TensorFlow hyperparameters

Tune a text classification model with the following hyperparameters. The hyperparameters that have the greatest impact on text classification objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adamw` or `adam` is the `optimizer`.

For more information about which hyperparameters are used for each `optimizer`, see Text Classification - TensorFlow Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`batch_size`	IntegerParameterRanges	MinValue: 4, MaxValue: 128
`beta_1`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`beta_2`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999

Parameter Name	Parameter Type	Recommended Ranges
eps	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
learning_rate	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
momentum	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['adamw', 'adam', 'sgd', 'rmsprop', 'nesterov', 'adagrad', 'adadelta']
regularizers_l2	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
train_only_on_top_layer	CategoricalParameterRanges	['True', 'False']

Built-in SageMaker Algorithms for Time-Series Data

SageMaker provides algorithms that are tailored to the analysis of time-series data for forecasting product demand, server loads, webpage requests, and more.

- DeepAR Forecasting Algorithm—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
DeepAR Forecasting	train and (optionally) test	File	JSON Lines or Parquet	GPU or CPU	Yes	

DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more `target` time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the `cat` field and a vector of dynamic (time-dependent) time series provided by the `dynamic_feat` field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the `context_length` hyperparameter. To control how far in the future predictions can be made, use the `prediction_length` hyperparameter. For more information, see How the DeepAR Algorithm Works.

Topics

Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required `train` channel describes the training dataset. The optional `test` channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named *_SUCCESS*. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (`.json`, `.json.gz`, or `.parquet`) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the `content_type` parameter of the s3_input class.

The records in your input files should contain the following fields:

- `start`—A string with the format `YYYY-MM-DD HH:MM:SS`. The start timestamp can't contain time zone information.
- `target`—An array of floating-point values or integers that represent the time series. You can encode missing values as `null` literals, or as `"NaN"` strings in JSON, or as `nan` floating-point values in Parquet.

- `dynamic_feat` (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated `target` value plus `prediction_length`. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated `dynamic_feat` might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

  ```
  {"start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]}
  ```

- `cat` (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the `embedding_dimension` hyperparameter. For more information, see DeepAR Hyperparameters.

If you use a JSON file, it must be in JSON Lines format. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
 "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3],
 "dynamic_feat": [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
 [[1.3, 0.4]]}
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, `"start"` can be the `datetime` type. You can compress Parquet files using gzip (`gzip`) or the Snappy compression library (`snappy`).

If the algorithm is trained without `cat` and `dynamic_feat` fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the `cat` and `dynamic_feat` feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding `cat` features. For example, if the `target` time series represents the demand of clothing items, you can associate a two-dimensional `cat` vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with `cat` values that are combinations of the `cat` values observed in the training data, for example:

```
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the `start` field correctly. The algorithm uses the `start` timestamp to derive the internal features.
- If you use categorical features (`cat`), all time series must have the same number of categorical features. If the dataset contains the `cat` field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, `cardinality` is `"auto"`. If the dataset contains the `cat` field, but you don't want to use it, you can disable it by setting `cardinality` to `""`. If a model was trained using a `cat` feature, you must include it for inference.
- If your dataset contains the `dynamic_feat` field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the `dynamic_feat` field should have the same length as the `target`. If the dataset contains the `dynamic_feat` field, but you don't want to use it, disable it by setting(`num_dynamic_feat` to `""`). If the model was trained with the `dynamic_feat` field, you must provide this field for

inference. In addition, each of the features has to have the length of the provided target plus the `prediction_length`. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

$$\text{RMSE} = \sqrt{\frac{1}{nT}\sum_{i,t}\left(\hat{y}_{i,t} - y_{i,t}\right)^2}$$

$y_{i,t}$ is the true value of time series *i* at the time *t*. $\hat{y}_{i,t}$ is the mean prediction. The sum is over all *n* time series in the test set and over the last T time points for each time series, where T corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the `prediction_length` hyperparameter. For more information, see DeepAR Hyperparameters.

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range [0, 1], the weighted quantile loss is defined as follows:

$$\text{wQuantileLoss}[\tau] = 2\frac{\sum_{i,t} Q_{i,t}^{(\tau)}}{\sum_{i,t}|y_{i,t}|}, \quad \text{with} \quad Q_{i,t}^{(\tau)} = \begin{cases} (1-\tau)|q_{i,t}^{(\tau)} - y_{i,t}| & \text{if } q_{i,t}^{(\tau)} > y_{i,t} \\ \tau|q_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise} \end{cases}$$

$q_{i,t}^{(\tau)}$ is the τ-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the `test_quantiles` hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters.

For inference, DeepAR accepts JSON format and the following fields:

- `"instances"`, which includes one or more time series in JSON Lines format
- A name of `"configuration"`, which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats.

Best Practices for Using the DeepAR Algorithm

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set

`context_length`, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.

- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholds the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model.
- Avoid using very large values (>400) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use `5min` instead of `1min`.
- Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.
- We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for `context_length`, `prediction_length`, `num_cells`, `num_layers`, or `mini_batch_size` can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

DeepAR Sample Notebooks

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After creating and opening a notebook instance, choose the **SageMaker Examples** tab to see a list of all of the SageMaker examples. To open a notebook, choose its **Use** tab, and choose **Create copy**.

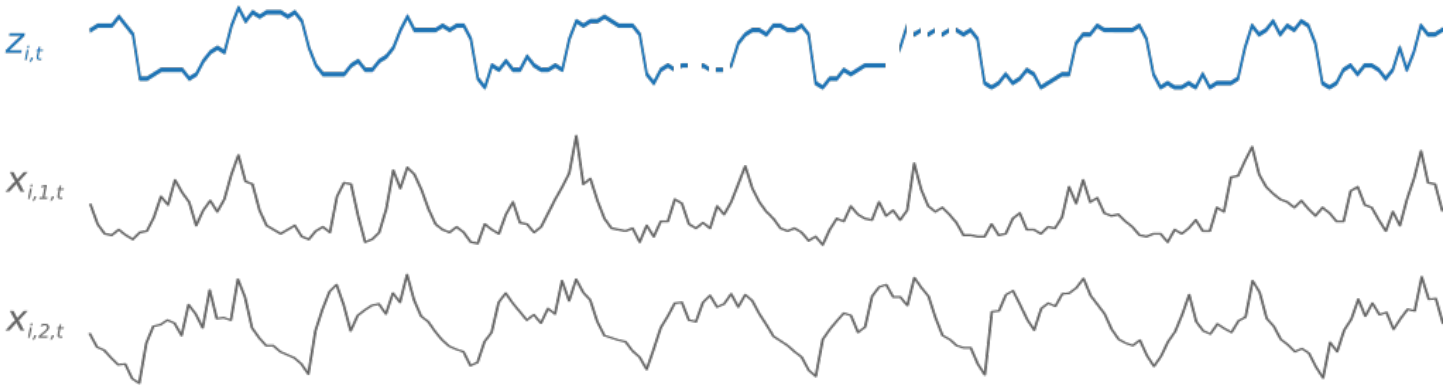
For more information about the Amazon SageMaker DeepAR algorithm, see the following blog posts:

- Now available in Amazon SageMaker: DeepAR algorithm for more accurate time series forecasting
- Deep demand forecasting with Amazon SageMaker

How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm.

For example, the following is an element of a training set indexed by i which consists of a target time series, $Z_{i,t}$, and two associated feature time series, $X_{i,1,t}$ and $X_{i,2,t}$:

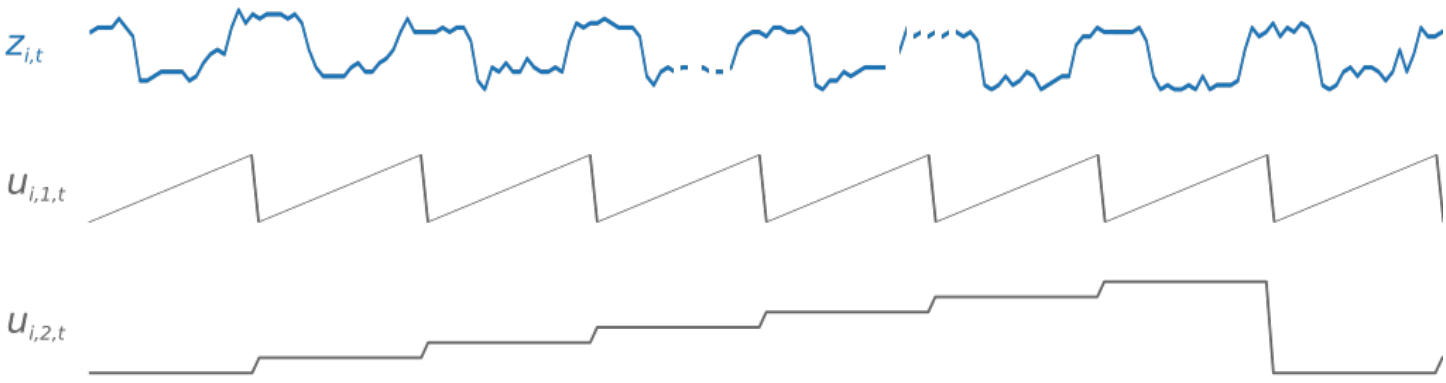


The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

How Feature Time Series Work in the DeepAR Algorithm

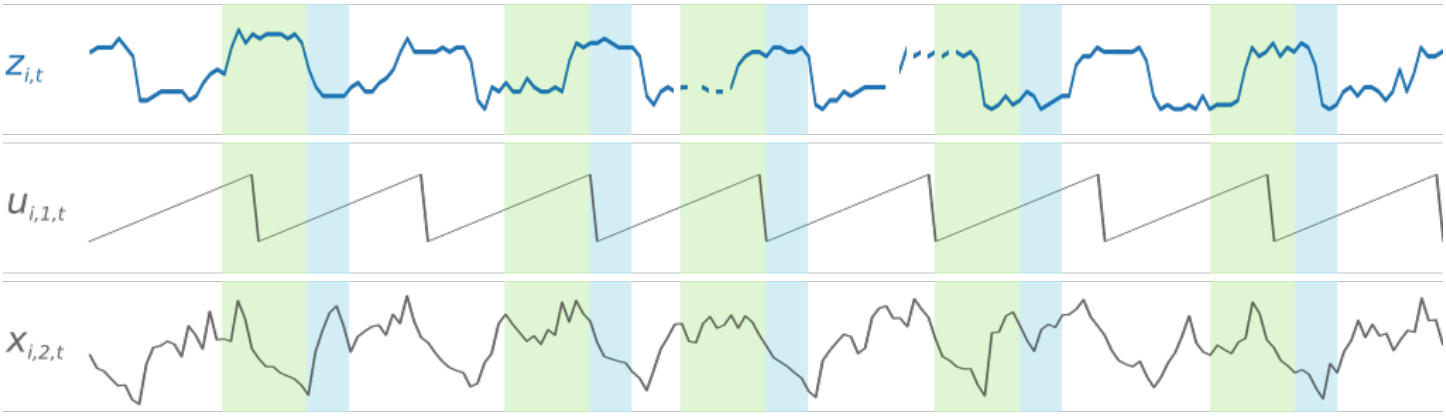
To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: $u_{i,1,t}$ represents the hour of the day and $u_{i,2,t}$ the day of the week.



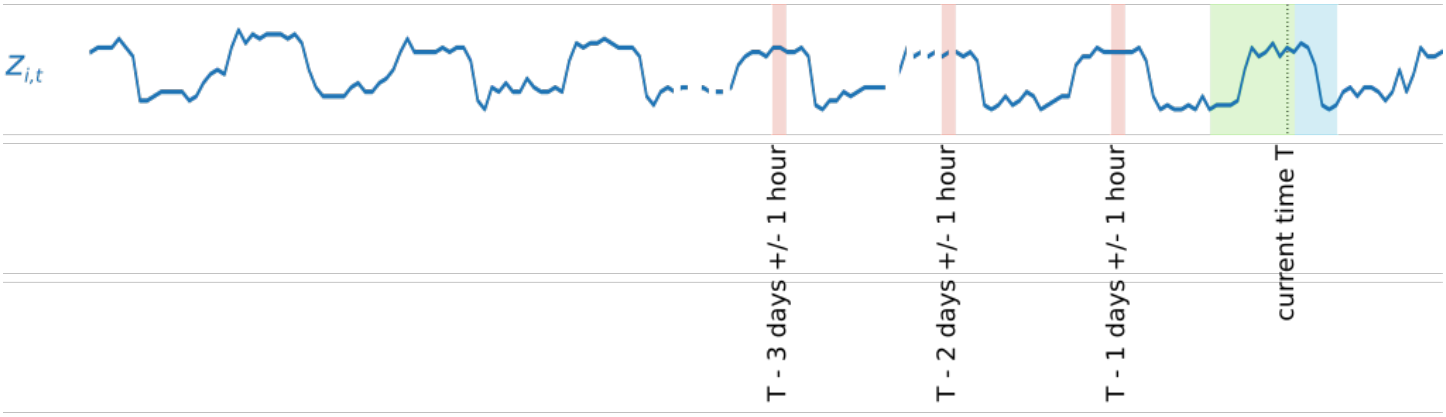
The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

Frequency of the Time Series	Derived Features
`Minute`	`minute-of-hour ,hour-of-day ,day-of-week ,day-of-month ,day-of-year`
`Hour`	`hour-of-day ,day-of-week ,day-of-month ,day-of-year`
`Day`	`day-of-week ,day-of-month ,day-of-year`
`Week`	`day-of-month ,week-of-year`
`Month`	month-of-year

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The `context_length` hyperparameter controls how far in the past the network can see, and the `prediction_length` hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element *i*. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$.



To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, $t = T$, the model exposes the $z_{i,t}$ values, which occurred approximately one, two, and three days in the past.



For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next `prediction_length` values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

DeepAR Hyperparameters

Parameter Name	Description
`context_length`	The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the `prediction_length` . The model also receives lagged inputs from the target, so `context_length` can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. **Required**

Parameter Name	Description
	Valid values: Positive integer
epochs	The maximum number of passes over the training data. The optimal value depends on your data size and learning rate. See also early_stopping_patience . Typical values range from 10 to 1000. **Required** Valid values: Positive integer
prediction_length	The number of time-steps that the model is trained to predict, also called the forecast horizon. The trained model always generates forecasts with this length. It can't generate longer forecasts. The prediction_length is fixed when a model is trained and it cannot be changed later. **Required** Valid values: Positive integer

Parameter Name	Description
`time_freq`	The granularity of the time series in the dataset. Use `time_freq` to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, `5min` specifies a frequency of 5 minutes. • *M*: monthly • *W*: weekly • *D*: daily • *H*: hourly • *min*: every minute **Required** Valid values: An integer followed by *M*, *W*, *D*, *H*, or *min*. For example, `5min`.

Parameter Name	Description
`cardinality`	When using the categorical features (`cat`), `cardinality` is an array specifying the number of categories (groups) per categorical feature. Set this to `auto` to infer the cardinality from the data. The `auto` mode also works when no categoric al features are used in the dataset. This is the recommended setting for the parameter. Set cardinality to `ignore` to force DeepAR to not use categoric al features, even it they are present in the data. To perform additional data validation, it is possible to explicitl y set this parameter to the actual value. For example, if two categorical features are provided where the first has 2 and the other has 3 possible values, set this to [2, 3]. For more information on how to use categorical feature, see the data-section on the main documentation page of DeepAR. **Optional** Valid values: `auto`, `ignore`, array of positive integers, empty string, or Default value: `auto`
`dropout_rate`	The dropout rate to use during training. The model uses zoneout regularization. For each iteration, a random subset of hidden neurons are not updated. Typical values are less than 0.2. **Optional** Valid values: float Default value: 0.1

Parameter Name	Description
early_stopping_patience	If this parameter is set, training stops when no progress is made within the specified number of epochs. The model that has the lowest loss is returned as the final model. **Optional** Valid values: integer
embedding_dimension	Size of embedding vector learned per categorical feature (same value is used for all categorical features). The DeepAR model can learn group-level time series patterns when a categorical grouping feature is provided. To do this, the model learns an embedding vector of size embedding_dimension for each group, capturing the common properties of all time series in the group. A larger embedding_dimension allows the model to capture more complex patterns. However, because increasing the embedding_dimension increases the number of parameters in the model, more training data is required to accurately learn these parameters. Typical values for this parameter are between 10-100. **Optional** Valid values: positive integer Default value: 10
learning_rate	The learning rate used in training. Typical values range from 1e-4 to 1e-1. **Optional** Valid values: float Default value: 1e-3

Parameter Name	Description
`likelihood`	The model generates a probabilistic forecast, and can provide quantiles of the distribution and return samples. Depending on your data, select an appropriate likelihood (noise model) that is used for uncertainty estimates. The following likelihoods can be selected: • *gaussian*: Use for real-valued data. • *beta*: Use for real-valued targets between 0 and 1 inclusive. • *negative-binomial*: Use for count data (non-negative integers). • *student-T*: An alternative for real-valued data that works well for bursty data. • *deterministic-L1*: A loss function that does not estimate uncertainty and only learns a point forecast. **Optional** Valid values: One of *gaussian*, *beta*, *negative-binomial*, *student-T*, or *deterministic-L1*. Default value: `student-T`
`mini_batch_size`	The size of mini-batches used during training. Typical values range from 32 to 512. **Optional** Valid values: positive integer Default value: 128

Parameter Name	Description
num_cells	The number of cells to use in each hidden layer of the RNN. Typical values range from 30 to 100. **Optional** Valid values: positive integer Default value: 40
num_dynamic_feat	The number of dynamic_feat provided in the data. Set this to auto to infer the number of dynamic features from the data. The auto mode also works when no dynamic features are used in the dataset. This is the recommended setting for the parameter. To force DeepAR to not use dynamic features, even it they are present in the data, set num_dynamic_feat to ignore. To perform additional data validation, it is possible to explicitl y set this parameter to the actual integer value. For example, if two dynamic features are provided, set this to 2. **Optional** Valid values: auto, ignore, positive integer, or empty string Default value: auto

Parameter Name	Description
num_eval_samples	The number of samples that are used per time-series when calculating test accuracy metrics. This parameter does not have any influence on the training or the final model. In particular, the model can be queried with a different number of samples. This parameter only affects the reported accuracy scores on the test channel after training. Smaller values result in faster evaluation, but then the evaluation scores are typically worse and more uncertain. When evaluating with higher quantiles, for example 0.95, it may be important to increase the number of evaluation samples. **Optional** Valid values: integer Default value: 100
num_layers	The number of hidden layers in the RNN. Typical values range from 1 to 4. **Optional** Valid values: positive integer Default value: 2
test_quantiles	Quantiles for which to calculate quantile loss on the test channel. **Optional** Valid values: array of floats Default value: [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9]

Tune a DeepAR Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see Best Practices for Using the DeepAR Algorithm.

Metric Name	Description	Optimization Direction
`test:RMSE`	The root mean square error between the forecast and the actual target computed on the test set.	Minimize
`test:mean_wQuantileLoss`	The average overall quantile losses computed on the test set. To control which quantiles are used, set the `test_quantiles` hyperparameter.	Minimize
`train:final_loss`	The training negative log-likelihood loss averaged over the last training epoch for the model.	Minimize

Tunable Hyperparameters for the DeepAR Algorithm

Tune a DeepAR model with the following hyperparameters. The hyperparameters that have the greatest impact, listed in order from the most to least impactful, on DeepAR objective metrics are: `epochs`, `context_length`, `mini_batch_size`, `learning_rate`, and `num_cells`.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRanges	MinValue: 1, MaxValue: 1000
context_length	IntegerParameterRanges	MinValue: 1, MaxValue: 200
mini_batch_size	IntegerParameterRanges	MinValue: 32, MaxValue: 1028
learning_rate	ContinuousParameterRange	MinValue: 1e-5, MaxValue: 1e-1
num_cells	IntegerParameterRanges	MinValue: 30, MaxValue: 200
num_layers	IntegerParameterRanges	MinValue: 1, MaxValue: 8
dropout_rate	ContinuousParameterRange	MinValue: 0.00, MaxValue: 0.2
embedding_dimension	IntegerParameterRanges	MinValue: 1, MaxValue: 50

DeepAR Inference Formats

DeepAR JSON Request Formats

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the `instances` field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a `cat` for each instance. If the model was trained without the `cat` field, it should be omitted.

If the model was trained with a custom feature time series (`dynamic_feat`), you have to provide the same number of `dynamic_feat`values for each instance. Each of them should have a length given by `length(target) + prediction_length`, where the last `prediction_length` values correspond to the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```
{
    "instances": [
        {
            "start": "2009-11-01 00:00:00",
            "target": [4.0, 10.0, "NaN", 100.0, 113.0],
            "cat": [0, 1],
            "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
        },
        {
            "start": "2012-01-30",
            "target": [1.0],
            "cat": [2, 1],
            "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
        },
        {
            "start": "1999-01-30",
            "target": [2.0, 1.0],
            "cat": [1, 3],
            "dynamic_feat": [[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
        }
    ],
    "configuration": {
         "num_samples": 50,
         "output_types": ["mean", "quantiles", "samples"],
         "quantiles": ["0.5", "0.9"]
    }
}
```

The `configuration` field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are `"mean"` `"quantiles"` and `"samples"`. If you specify `"quantiles"`, each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify `"samples"`, the model also returns the raw samples used to calculate the other outputs.

DeepAR JSON Response Formats

The following is the format of a response, where `[...]` are arrays of numbers:

```
{
    "predictions": [
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        },
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        },
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        }
    ]
}
```

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each

CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable `MODEL_SERVER_WORKERS` For example, by setting `MODEL_SERVER_WORKERS=1`) when calling the SageMaker `CreateModel` API.

Batch Transform with the DeepAR Algorithm

DeepAR forecasting supports getting inferences by using batch transform from data using the JSON Lines format. In this format, each record is represented on a single line as a JSON object, and lines are separated by newline characters. The format is identical to the JSON Lines format used for model training. For information, see Input/Output Interface for the DeepAR Algorithm. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
 "dynamic_feat": [[1.1, 1.2, 0.5, ..]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3],
 "dynamic_feat": [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
 [[1.3, 0.4]]}
```

Note

When creating the transformation job with `CreateTransformJob`, set the `BatchStrategy` value to `SingleRecord` and set the `SplitType` value in the `TransformInput` configuration to `Line`, as the default values currently cause runtime failures.

Similar to the hosted endpoint inference request format, the `cat` and the `dynamic_feat` fields for each instance are required if both of the following are true:

- The model is trained on a dataset that contained both the `cat` and the `dynamic_feat` fields.
- The corresponding `cardinality` and `num_dynamic_feat` values used in the training job are not set to `""`.

Unlike hosted endpoint inference, the configuration field is set once for the entire batch inference job using an environment variable named `DEEPAR_INFERENCE_CONFIG`. The value of `DEEPAR_INFERENCE_CONFIG` can be passed when the model is created by calling

CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment, the inference container uses the following default:

```
{
    "num_samples": 100,
    "output_types": ["mean", "quantiles"],
    "quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]
}
```

The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

Note that in the TransformInput configuration of the SageMaker CreateTransformJob request clients must explicitly set the AssembleWith value to Line, as the default value None concatenates all JSON objects on the same line.

For example, here is a SageMaker CreateTransformJob request for a DeepAR job with a custom DEEPAR_INFERENCE_CONFIG:

```
{
   "BatchStrategy": "SingleRecord",
   "Environment": {
      "DEEPAR_INFERENCE_CONFIG" : "{ \"num_samples\": 200, \"output_types\": [\"mean
\"] }",
      ...
   },
   "TransformInput": {
      "SplitType": "Line",
      ...
   },
   "TransformOutput": {
      "AssembleWith": "Line",
      ...
   },
   ...
}
```

Unsupervised Built-in SageMaker Algorithms

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- IP Insights—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- K-Means Algorithm—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- Principal Component Analysis (PCA) Algorithm—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- Random Cut Forest (RCF) Algorithm—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
IP Insights	train and (optionally) validation	File	CSV	CPU or GPU	Yes
K-Means	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU or GPUCommon (single GPU device on one or more instances)	No

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable
PCA	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	GPU or CPU	Yes
Random Cut Forest	train and (optionally) test	File or Pipe	recordIO-protobuf or CSV	CPU	Yes

IP Insights

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as *embeddings*. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

Topics

Input/Output Interface for the IP Insights Algorithm

Training and Validation

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in `text/csv` format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats.

Inference

For inference, IP Insights supports `text/csv`, `application/json`, and `application/jsonlines` data content types. For more information about the common data formats for inference provided by SageMaker, see Common Data Formats for Inference. IP Insights inference returns output formatted as either `application/json` or `application/jsonlines`. Each record in the output data contains the corresponding `dot_product` (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats.

EC2 Instance Recommendation for the IP Insights Algorithm

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances. IP Insights supports P2, P3, G4dn, and G5 GPU families.

GPU Instances for the IP Insights Algorithm

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the `mini_batch_size` is divided equally into the number of GPUs used. You may want to increase the value of the `mini_batch_size` to compensate for this.

CPU Instances for the IP Insights Algorithm

The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: `vector_dim` and `num_entity_vectors`. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for `vector_dim` in the first column range from 32 to 2048 and the values for `num_entity_vectors` in the first row range from 10,000 to 50,000,000.

vector_dim \ num_entity_vectors	**10,000**	**50,000**	**100,000**	**500,000**	**1,000,000**	**5,000,000**	**10,000,000**	**50,000,000**
32	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.2xlarge	ml.m5.4xlarge
64	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.2xlarge	ml.m5.2xlarge	
128	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.2xlarge	ml.m5.4xlarge	
256	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.4xlarge		
512	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.2xlarge			

vector_dim \ num_entity_vectors	10,000	50,000	100,000	500,000	1,000,000	5,000,000	10,000,000	50,000,000
1024	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.4xlarge			
2048	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.xlarge				

The values for the `mini_batch_size`, `num_ip_encoder_layers`, `random_negative_sampling_rate`, and `shuffled_negative_sampling_rate` hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.

IP Insights Sample Notebooks

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see An Introduction to the SageMakerIP Insights Algorithm . For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After creating a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How IP Insights Works

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity

identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to ensure that the number of *collisions*, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see Feature Hashing for Large Scale Multitask Learning. For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the *cross entropy*, also known as the *log loss*, defined as follows:

$$L = \frac{1}{N} \sum_{n} \left[y_n \log p_n + (1 - y_n) \log (1 - p_n) \right]$$

y_n is the label that indicates whether the sample is from the real distribution governing observed data (y_n=1) or from the distribution generating negative samples (y_n=0). p_n is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the `random_negative_sampling_rate` and `shuffled_negative_sampling_rate` hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a *score*, S_n , that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log\left(\frac{P_{real}(n)}{P_{neg}(n)}\right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, p_n, to use in the cross entropy minimization, where:

$$p_n = \frac{1}{1 + e^{-S_n}}$$

IP Insights Hyperparameters

In the `CreateTransformJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

Parameter Name	Description
`num_entity_vectors`	The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers.

Parameter Name	Description
	Required Valid values: 1 ≤ positive integer ≤ 250,000,000
`vector_dim`	The size of embedding vectors to represent entities and IP addresses. The larger the value, the more informati on that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommend ed value is 128. **Required** Valid values: 4 ≤ positive integer ≤ 4096
`batch_metrics_publ ish_interval`	The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second). **Optional** Valid values: positive integer ≥ 1 Default value: 1,000

Parameter Name	Description
epochs	The number of passes over the training data. The optimal value depends on your data size and learning rate. Typical values range from 5 to 100. **Optional** Valid values: positive integer ≥ 1 Default value: 10
learning_rate	The learning rate for the optimizer. IP Insights use a gradient-descent-based Adam optimizer. The learning rate effectively controls the step size to update model parameters at each iteration. Too large a learning rate can cause the model to diverge because the training is likely to overshoot a minima. On the other hand, too small a learning rate slows down convergence. Typical values range from 1e-4 to 1e-1. **Optional** Valid values: 1e-6 ≤ float ≤ 10.0 Default value: 0.001

Parameter Name	Description
`mini_batch_size`	The number of examples in each mini batch. The training procedure processes data in mini batches. The optimal value depends on the number of unique account identifiers in the dataset. In general, the larger the `mini_batch_size` , the faster the training and the greater the number of possible shuffled-negative-sample combinations. However, with a large `mini_batch_size` , the training is more likely to converge to a poor local minimum and perform relatively worse for inference. **Optional** Valid values: 1 ≤ positive integer ≤ 500000 Default value: 10,000
`num_ip_encoder_layers`	The number of fully connected layers used to encode the IP address embedding. The larger the number of layers, the greater the model's capacity to capture patterns among IP addresses. However, using a large number of layers increases the chance of overfitting. **Optional** Valid values: 0 ≤ positive integer ≤ 100 Default value: 1

Parameter Name	Description
`random_negative_sampling_rate`	The number of random negative samples, R, to generate per input example. The training procedure relies on negative samples to prevent the vector representations of the model collapsing to a single point. Random negative sampling generates R random IP addresses for each input account in the mini batch. The sum of the `random_negative_sampling_rate` (R) and `shuffled_negative_sampling_rate` (S) must be in the interval: 1 ≤ R + S ≤ 500. **Optional** Valid values: 0 ≤ positive integer ≤ 500 Default value: 1
`shuffled_negative_sampling_rate`	The number of shuffled negative samples, S, to generate per input example. In some cases, it helps to use more realistic negative samples that are randomly picked from the training data itself. This kind of negative sampling is achieved by shuffling the data within a mini batch. Shuffled negative sampling generates S negative IP addresses by shuffling the IP address and account pairings within a mini batch. The sum of the `random_negative_sampling_rate` (R) and `shuffled_negative_sampling_rate` (S) must be in the interval: 1 ≤ R + S ≤ 500. **Optional** Valid values: 0 ≤ positive integer ≤ 500 Default value: 1

Parameter Name	Description
`weight_decay`	The weight decay coefficient. This parameter adds an L2 regularization factor that is required to prevent the model from overfitting the training data. **Optional** Valid values: 0.0 ≤ float ≤ 10.0 Default value: 0.00001

Tune an IP Insights Model

Automatic model tuning, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model , which learns to separate observed data points (*positive samples*) from randomly generated data points (*negative samples*). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This `validation:discriminator_auc` metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a `validation:discriminator_auc` metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

Metric Name	Description	Optimization Direction
validation:discriminator_auc	Area under the receiver operating characteristic curve on the validation dataset. The validation dataset is not labeled. Area Under the Curve (AUC) is a metric that describes the model's ability to discriminate validation data points from randomly generated data points.	Maximize

Tunable IP Insights Hyperparameters

You can tune the following hyperparameters for the SageMaker IP Insights algorithm.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRange	MinValue: 1, MaxValue: 100
learning_rate	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 0.1
mini_batch_size	IntegerParameterRanges	MinValue: 100, MaxValue: 50000
num_entity_vectors	IntegerParameterRanges	MinValue: 10000, MaxValue: 1000000
num_ip_encoder_layers	IntegerParameterRanges	MinValue: 1, MaxValue: 10
random_negative_sampling_rate	IntegerParameterRanges	MinValue: 0, MaxValue: 10

Parameter Name	Parameter Type	Recommended Ranges
`shuffled_negative_sampling_rate`	IntegerParameterRanges	MinValue: 0, MaxValue: 10
`vector_dim`	IntegerParameterRanges	MinValue: 8, MaxValue: 256
`weight_decay`	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0

IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

Topics

- IP Insights Training Data Formats
- IP Insights Inference Data Formats

IP Insights Training Data Formats

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for Training. However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

IP Insights Training Data Input Formats

INPUT: CSV

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

IP Insights Inference Data Formats

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference. However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

IP Insights Input Request Formats

INPUT: CSV Format

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

INPUT: JSON Format

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference.

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}}},
    {"features": ["entity_id_2", "10.10.1.2"]}
  ]
}
```

INPUT: JSONLINES Format

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference. For more information on running batch transform jobs, see Use Batch Transform.

content-type: application/jsonlines

```
{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}}},
{"features": ["entity_id_2", "10.10.1.2"]}]
```

IP Insights Output Response Formats

OUTPUT: JSON Response Format

The default output of the SageMaker IP Insights algorithm is the `dot_product` between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The `dot_product` is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the `dot_product` for anomaly detection, see the An Introduction to the SageMakerIP Insights Algorithm.

accept: application/json

```
{
  "predictions": [
    {"dot_product": 0.0},
    {"dot_product": 2.0}
  ]
}
```

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter `verbose=True` to the Accept heading. You can use the `entity_embedding` and `ip_embedding` for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

accept: application/json;verbose=True

```
{
  "predictions": [
    {
        "dot_product": 0.0,
        "entity_embedding": [1.0, 0.0, 0.0],
        "ip_embedding": [0.0, 1.0, 0.0]
    },
```

```
    {
        "dot_product": 2.0,
        "entity_embedding": [1.0, 0.0, 1.0],

K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see Web-scale k-means Clustering.

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The *n* attributes in each row represent a point in *n*-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar

attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see How K-Means Clustering Works.

Topics

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the *train* channel (recommended `S3DataDistributionType=ShardedByS3Key`), with an optional *test* channel (recommended `S3DataDistributionType=FullyReplicated`) to score the data on. Both `recordIO-wrapped-protobuf` and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as CSV.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` are supported. k-means returns a `closest_cluster` label and the `distance_to_cluster` for each observation.

For more information on input and output file formats, see K-Means Response Formats for inference and the K-Means Sample Notebooks. The k-means algorithm does not support multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

EC2 Instance Recommendation for the K-Means Algorithm

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to single-GPU instances (such as ml.g4dn.xlarge) because only one GPU is used per instance. The k-means algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

K-Means Sample Notebooks

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see Analyze US census data for population segmentation using Amazon SageMaker. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, click on its **Use** tab and select **Create copy**.

How K-Means Clustering Works

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the *n*-dimensional space (where *n* is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points (*t, h*) in 2-dimensional space.

> **Note**
>
> Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used. For more information, see Unsupervised learning.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters (*k*) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, …, 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space (x,y). To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point

from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

> **Note**
>
> Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create *k* clusters, you might choose to improve model accuracy by specifying extra cluster centers *(K = k*x)*. However, the algorithm ultimately reduces these to *k* clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see `CreateTrainingJob`. In the request body, you add the `HyperParameters` string map to specify the k and `extra_center_factor` strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial *K* cluster centers.

   > **Note**
   >
   > In the following topics, *K* clusters refer to *k * x*, where you specify *k* and *x* when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to *k* (if the data scientist specified the creation of *k*x* clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the `HyperParameters` string map.

Topics

- Step 1: Determine the Initial Cluster Centers
- Step 2: Iterate over the Training Dataset and Calculate Cluster Centers
- Step 3: Reduce the Clusters from K to k

Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- The random approach—Randomly choose *K* observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.
- The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
     - For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
     - Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the *K* cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following `HyperParameters` string maps:

- To specify the number of clusters to create, add the `k` string.
- For greater accuracy, add the optional `extra_center_factor` string.

- To specify the strategy that you want to use to determine the initial cluster centers, add the `init_method` string and set its value to `random` or `k-means++`.

For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the *K* cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   > **Note**
   >
   > When creating a model training job, you specify the batch size in the `mini_batch_size` string in the `HyperParameters` string map.

   a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

   b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

      For example, consider the following clusters:

      Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

      Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

      Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

Calculate the proportion of new points assigned to each of clusters as follows:

```
p1 = proportion of points assigned to c1 = 25/(100+25)
p2 = proportion of points assigned to c2 = 40/(150+40)
p3 = proportion of points assigned to c3 = 5/(450+5)
```

c. Compute the center of the new points added to each cluster:

```
d1 = center of the new points added to cluster 1
d2 = center of the new points added to cluster 2
d3 = center of the new points added to cluster 3
```

d. Compute the weighted average to find the updated cluster centers as follows:

```
Center of cluster 1 = ((1 - p1) * center of cluster 1) + (p1 * d1)
Center of cluster 2 = ((1 - p2) * center of cluster 2) + (p2 * d2)
Center of cluster 3 = ((1 - p3) * center of cluster 3) + (p3 * d3)
```

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.
3. For more information about mini-batch *k*-means, see Web-scale k-means Clustering).

Step 3: Reduce the Clusters from *K* to *k*

If the algorithm created *K* clusters—*(K = k*x)* where *x* is greater than 1—then it reduces the *K* clusters to *k* clusters. (For more information, see `extra_center_factor` in the preceding discussion.) It does this by applying Lloyd's method with `kmeans++` initialization to the *K* cluster centers. For more information about Lloyd's method, see k-means clustering.

K-Means Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see How K-Means Clustering Works.

Parameter Name	Description
`feature_dim`	The number of features in the input data. **Required**

Parameter Name	Description
	Valid values: Positive integer
k	The number of required clusters. **Required** Valid values: Positive integer
epochs	The number of passes done over the training data. **Optional** Valid values: Positive integer Default value: 1
eval_metrics	A JSON list of metric types used to report a score for the model. Allowed values are msd for Means Square Deviation and ssd for Sum of Square Distance. If test data is provided, the score is reported for each of the metrics requested. **Optional** Valid values: Either [\"msd\"] or [\"ssd\"] or [\"msd\",\"ssd\"] . Default value: [\"msd\"]
extra_center_factor	The algorithm creates K centers = num_clusters * extra_center_factor as it runs and reduces the number of centers from K to k when finalizing the model. **Optional** Valid values: Either a positive integer or auto. Default value: auto

Parameter Name	Description
`half_life_time_size`	Used to determine the weight given to an observation when computing a cluster mean. This weight decays exponentially as more points are observed. When a point is first observed, it is assigned a weight of 1 when computing the cluster mean. The decay constant for the exponential decay function is chosen so that after observing `half_life_time_size` points, its weight is 1/2. If set to 0, there is no decay. **Optional** Valid values: Non-negative integer Default value: 0
`init_method`	Method by which the algorithm chooses the initial cluster centers. The standard k-means approach chooses them at random. An alternative k-means++ method chooses the first cluster center at random. Then it spreads out the position of the remaining initial clusters by weighting the selection of centers with a probability distribution that is proportional to the square of the distance of the remaining data points from existing centers. **Optional** Valid values: Either `random` or `kmeans++`. Default value: `random`
`local_lloyd_init_method`	The initialization method for Lloyd's expectation-maximization (EM) procedure used to build the final model containing k centers. **Optional** Valid values: Either `random` or `kmeans++`. Default value: `kmeans++`

Parameter Name	Description
`local_lloyd_max_iter`	The maximum number of iterations for Lloyd's expectation-maximization (EM) procedure used to build the final model containing k centers. **Optional** Valid values: Positive integer Default value: 300
`local_lloyd_num_trials`	The number of times the Lloyd's expectation-maximization (EM) procedure with the least loss is run when building the final model containing k centers. **Optional** Valid values: Either a positive integer or `auto`. Default value: `auto`
`local_lloyd_tol`	The tolerance for change in loss for early stopping of Lloyd's expectation-maximization (EM) procedure used to build the final model containing k centers. **Optional** Valid values: Float. Range in [0, 1]. Default value: 0.0001
`mini_batch_size`	The number of observations per mini-batch for the data iterator. **Optional** Valid values: Positive integer Default value: 5000

Tune a K-Means Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the K-Means Algorithm

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

Metric Name	Description	Optimization Direction
`test:msd`	Mean squared distances between each record in the test set and the closest center of the model.	Minimize
`test:ssd`	Sum of the squared distances between each record in the test set and the closest center of the model.	Minimize

Tunable K-Means Hyperparameters

Tune the Amazon SageMaker k-means model with the following hyperparameters.
The hyperparameters that have the greatest impact on k-means objective metrics are:

mini_batch_size, extra_center_factor, and init_method. Tuning the hyperparameter epochs generally results in minor improvements.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRanges	MinValue: 1, MaxValue:10
extra_center_factor	IntegerParameterRanges	MinValue: 4, MaxValue:10
init_method	CategoricalParameterRanges	['kmeans++', 'random']
mini_batch_size	IntegerParameterRanges	MinValue: 3000, MaxValue:15000

K-Means Response Formats

All SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-means algorithm.

JSON Response Format

```
{
    "predictions": [
        {
            "closest_cluster": 1.0,
            "distance_to_cluster": 3.0,
        },
        {
            "closest_cluster": 2.0,
            "distance_to_cluster": 5.0,
        },

        ....
    ]
}
```

JSONLINES Response Format

```
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

RECORDIO Response Format

```
[
    Record = {
        features = {},
        label = {
            'closest_cluster': {
                keys: [],
                values: [1.0, 2.0]  # float32
            },
            'distance_to_cluster': {
                keys: [],
                values: [3.0, 5.0]  # float32
            },
        }
    }
]
```

CSV Response Format

The first value in each line corresponds to `closest_cluster`.

The second value in each line corresponds to `distance_to_cluster`.

```
1.0,3.0
2.0,5.0
```

Principal Component Analysis (PCA) Algorithm

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called *components*, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

Topics

Input/Output Interface for the PCA Algorithm

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both `recordIO-wrapped-protobuf` and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as CSV.

For inference, PCA supports `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Results are returned in either `application/json` or `application/x-recordio-protobuf` format with a vector of "projections."

For more information on input and output file formats, see PCA Response Formats for inference and the PCA Sample Notebooks.

EC2 Instance Recommendation for the PCA Algorithm

PCA supports CPU and GPU instances for training and inference. Which instance type is most performant depends heavily on the specifics of the input data. For GPU instances, PCA supports P2, P3, G4dn, and G5.

PCA Sample Notebooks

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called *components*, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

Given the input of a matrix with rows

$x_1, \ldots, x_n$

each of dimension 1 * d, the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm's last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

Mode 1: Regular

The workers jointly compute both
$\sum x_i^T x_i$
and
$\sum x_i$
.

> **Note**
>
> Because
> x_i
> are 1 * d row vectors,
> $x_i^T x_i$
> is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as
$\sum x_i^T x_i - (1/n)(\sum x_i)^T \sum x_i$
, and its top `num_components` singular vectors form the model.

> **Note**
>
> If `subtract_mean` is `False`, we avoid computing and subtracting
> $\sum x_i$
> .

Use this algorithm when the dimension d of the vectors is small enough so that d^2 can fit in memory.

Mode 2: Randomized

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch X_t of dimension b `*` d, we randomly initialize a `(num_components + extra_components)` `*` b matrix that we multiply by each mini-batch, to create a `(num_components + extra_components)` `*` d matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final `(num_components + extra_components)` `*` d matrix. The top right `num_components` singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let ℓ = `num_components + extra_components`. Given a mini-batch X_t of dimension b `*` d, the worker draws a random matrix H_t of dimension $\ell * b$. Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is +-1 or a *FJLT* (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes $H_t X_t$ and maintains $B = \sum H_t X_t$. The worker also maintains h^T, the sum of columns of $H_1, \ldots, H_T$ (T being the total number of mini-batches), and s, the sum of all input rows. After processing the entire shard of data, the worker sends the server B, h, s, and n (the number of input rows).

Denote the different inputs to the server as

B^1, h^1, s^1, n^1

The server computes B, h, s, n the sums of the respective inputs. It then computes

$C = B - (1/n)h^T s$

, and finds its singular value decomposition. The top-right singular vectors and singular values of C are used as the approximate solution to the problem.

PCA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see How PCA Works.

Parameter Name	Description
`feature_dim`	Input dimension. **Required** Valid values: positive integer
`mini_batch_size`	Number of rows in a mini-batch. **Required** Valid values: positive integer
`num_components`	The number of principal components to compute. **Required** Valid values: positive integer
`algorithm_mode`	Mode for computing the principal components. **Optional** Valid values: *regular* or *randomized* Default value: *regular*

Parameter Name	Description
`extra_components`	As the value increases, the solution becomes more accurate but the runtime and memory consumption increase linearly. The default, -1, means the maximum of 10 and `num_components` . Valid for *randomized* mode only. **Optional** Valid values: Non-negative integer or -1 Default value: -1
`subtract_mean`	Indicates whether the data should be unbiased both during training and at inference. **Optional** Valid values: One of *true* or *false* Default value: *true*

PCA Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker PCA algorithm.

JSON Response Format

Accept—application/json

```
{
    "projections": [
        {
            "projection": [1.0, 2.0, 3.0, 4.0, 5.0]
        },
        {
            "projection": [6.0, 7.0, 8.0, 9.0, 0.0]
        },
        ....
```

```
    ]
}
```

JSONLINES Response Format

Accept—application/jsonlines

```
{ "projection": [1.0, 2.0, 3.0, 4.0, 5.0] }
{ "projection": [6.0, 7.0, 8.0, 9.0, 0.0] }
```

RECORDIO Response Format

Accept—application/x-recordio-protobuf

```
[
    Record = {
        features = {},
        label = {
            'projection': {
                keys: [],
                values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    },
    Record = {
        features = {},
        label = {
            'projection': {
                keys: [],
                values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    }
]
```

Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when

viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

Topics

Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the `train` and `test` data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either `application/x-recordio-protobuf` or `text/csv` formats. For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`

The train channel only supports `S3DataDistributionType=ShardedByS3Key` and the test channel only supports `S3DataDistributionType=FullyReplicated`. The following example specifies the S3 distribution type for the train channel using the Amazon SageMaker Python SDK.

> **Note**
>
> The `sagemaker.inputs.s3_input` method was renamed to `sagemaker.inputs.TrainingInput` in SageMaker Python SDK v2.

```
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.TrainingInput(
     s3_data=s3_training_data_location,
     content_type='text/csv;label_size=0',
     distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, `AmazonSageMakerFullAccess` and `AmazonEC2ContainerRegistryFullAccess`. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger then the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the `S3DataSource` for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports `application/x-recordio-protobuf`, `text/csv` and `application/json` input data content types. See the Common Data Formats for Built-in Algorithms documentation for more information. RCF inference returns `application/x-recordio-protobuf` or `application/json` formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats for inference and the RCF Sample Notebooks.

Instance Recommendations for the RCF Algorithm

For training, we recommend the `ml.m4`, `ml.c4`, and `ml.c5` instance families. For inference we recommend using a `ml.c5.xl` instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

RCF Sample Notebooks

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, click on its **Use** tab and select **Create copy**.

For a blog post on using the RCF algorithm, see Use the built-in Amazon SageMaker Random Cut Forest algorithm for anomaly detection.

How RCF Works

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an

anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size K from N total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw K elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

Reservoir sampling is an algorithm for efficiently drawing random samples from a dataset $S = \{S_1, \ldots, S_N\}$ where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when N is not known *a priori*. If only one sample is requested, such as when $K = 1$, the algorithm is like this:

Algorithm: Reservoir Sampling

- Input: dataset or data stream $S = \{S_1, \ldots, S_N\}$
- Initialize the random sample $X = S_1$
- For each observed sample $S_n, n = 2, \ldots, N$:
  - Pick a uniform random number $\xi \in [0, 1]$
  - If $\xi < 1/n$

- Set

  $X = S_n$

- Return

  X

This algorithm selects a random sample such that

$P(X = S_n) = 1/N$

for all

$n = 1, \ldots, N$

When

$K > 1$

the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

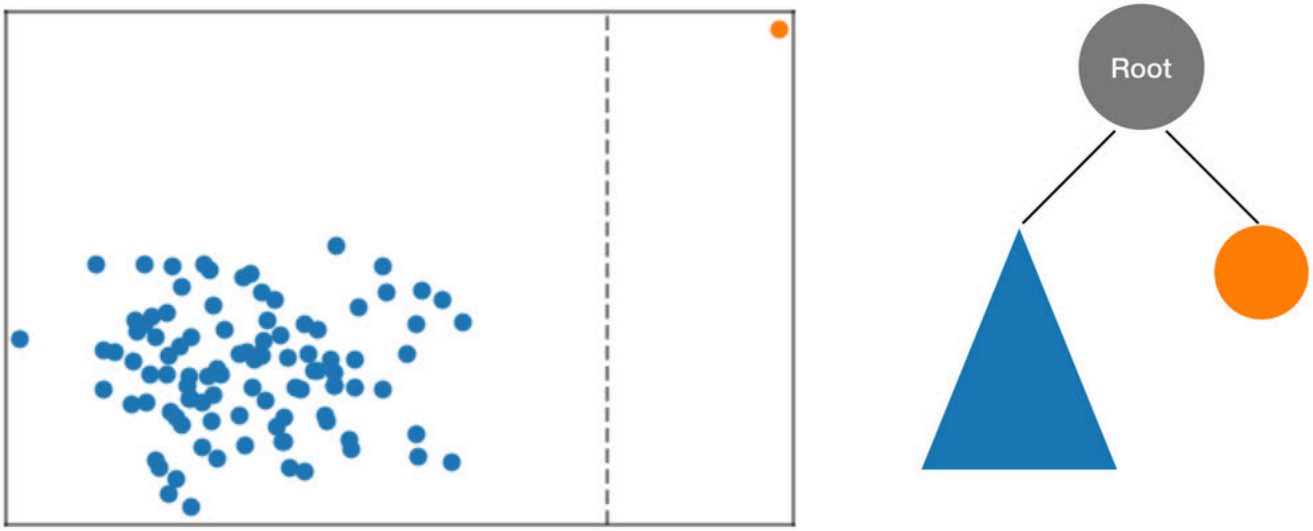
Train a RCF Model and Produce Inferences

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.



A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the

input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm describe above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that `1/num_samples_per_tree` approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies 1/256 or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

RCF Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker RCF algorithm. For more information, including recommendations on how to choose hyperparameters, see How RCF Works.

Parameter Name	Description
feature_dim	The number of features in the data set. (If you use the Random Cut Forest estimator, this value is calculated for you and need not be specified.) **Required** Valid values: Positive integer (min: 1, max: 10000)
eval_metrics	A list of metrics used to score a labeled test data set. The following metrics can be selected for output: • accuracy - returns fraction of correct predictions. • precision_recall_fscore - returns the positive and negative precision, recall, and F1-scores. **Optional** Valid values: a list with possible values taken from accuracy or precision_recall_fscore . Default value: Both accuracy, precision_recall_fscore are calculated.
num_samples_per_tree	Number of random samples given to each tree from the training data set. **Optional** Valid values: Positive integer (min: 1, max: 2048) Default value: 256
num_trees	Number of trees in the forest. **Optional** Valid values: Positive integer (min: 50, max: 1000)

Parameter Name	Description
	Default value: 100

Tune an RCF Model

Automatic model tuning, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test data points and then labels the data points as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the RCF Algorithm

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
`test:f1`	F1-score on the test dataset, based on the difference between calculated labels and actual labels.	Maximize

Tunable RCF Hyperparameters

You can tune a RCF model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
num_samples_per_tree	IntegerParameterRanges	MinValue: 1, MaxValue:2048
num_trees	IntegerParameterRanges	MinValue: 50, MaxValue:1000

RCF Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

JSON Response Format

ACCEPT: application/json.

```
    {

        "scores":    [

            {"score": 0.02},

            {"score": 0.25}

        ]
```

```
    }
```

JSONLINES Response Format

ACCEPT: application/jsonlines.

```
{"score": 0.02},
{"score": 0.25}
```

RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

```
    [

         Record = {

             features = {},

             label = {

                 'score': {

                     keys: [],

                     values: [0.25]  # float32

                 }
```

```
        }

    },

    Record = {

        features = {},

        label = {

            'score': {

                keys: [],

                values: [0.23]  # float32

            }

        }

    }
```

]
```

Built-in SageMaker Algorithms for Computer Vision

SageMaker provides image processing algorithms that are used for image classification, object detection, and computer vision.

- Image Classification - MXNet—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Image Classification - TensorFlow—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- Object Detection - MXNet—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- Object Detection - TensorFlow—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.
- Semantic Segmentation Algorithm—provides a fine-grained, pixel-level approach to developing computer vision applications.

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
Image Classification - MXNet	train and validation, (optionally) train_lst, validation_lst, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
Image Classification - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	CPU or GPU	Yes (only across multiple GPUs on a single instance)	
Object Detection	train and validation, (optionally) train_annotation, validation_annotation, and model	File or Pipe	recordIO or image files (.jpg or .png)	GPU	Yes	
Object Detection - TensorFlow	training and validation	File	image files (.jpg, .jpeg, or .png)	GPU	Yes (only across multiple GPUs on a single instance)	

Algorithm name	Channel name	Training input mode	File type	Instance class	Parallelizable	
Semantic Segmentation	train and validation, train_annotation, validation_annotation, and (optionally) label_map and model	File or Pipe	Image files	GPU (single instance only)	No	

Image Classification - MXNet

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network that can be trained from scratch or trained using transfer learning when a large number of training images are not available

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to this discussion for a broad overview of efficient data preparation and loading for machine learning systems.

> **Note**
>
> To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:

Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (`application/x-recordio`) and image (`image/png`, `image/jpeg`, and `application/x-image`) content types for training in file mode, and supports the RecordIO (`application/x-recordio`) content type for training in pipe mode. However, you can also train in pipe mode using the image files (`image/png`, `image/jpeg`, and `application/x-image`), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the `S3DataDistributionType` of the `S3DataSource` to `FullyReplicated`. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports `image/png`, `image/jpeg`, and `application/x-image` for inference.

Train with RecordIO Format

If you use the RecordIO format for training, specify both `train` and `validation` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (`.rec`) file in the `train` channel and one RecordIO file in the `validation` channel. Set the content type for both channels to `application/x-recordio`.

Train with Image Format

If you use the Image format for training, specify `train`, `validation`, `train_lst`, and `validation_lst` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify the individual image data (`.jpg` or `.png` files) for the `train` and `validation` channels. Specify one `.lst` file in each of the `train_lst` and `validation_lst` channels. Set the content type for all four channels to `application/x-image`.

> **Note**
>
> SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A `.lst` file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a `.lst` file:

```
5       1   your_image_directory/train_img_dog1.jpg
1000    0   your_image_directory/train_img_cat1.jpg
22      1   your_image_directory/train_img_dog2.jpg
```

For example, if your training images are stored in `s3://<your_bucket>/train/class_dog`, `s3://<your_bucket>/train/class_cat`, and so on, specify the path for your `train` channel as `s3://<your_bucket>/train`, which is the top-level directory for your data. In the `.lst` file, specify the relative path for an individual file named `train_image_dog1.jpg` in the `class_dog` class directory as `class_dog/train_image_dog1.jpg`. You can also store all your image files under one subdirectory inside the `train` directory. In that case, use that subdirectory for the relative path. For example, `s3://<your_bucket>/train/your_image_directory`.

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values

for the `InputDataConfig` parameter of the `CreateTrainingJob` request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the `'source-ref'` tag that points to the S3 location of the image. The annotations are provided under the `"AttributeNames"` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the following example, the `"AttributeNames"` are contained in the list of image and annotation references `["source-ref", "class"]`. The corresponding label value is `"0"` for the first image and `“1”` for the second image:

```
{"source-ref":"s3://image/filename1.jpg", "class":"0"}
{"source-ref":"s3://image/filename2.jpg", "class":"1", "class-metadata": {"class-name":
 "cat", "type" : "groundtruth/image-classification"}}
```

The order of `"AttributeNames"` in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with `image` first, followed by `label`. So the "AttributeNames" in this example are provided with `"source-ref"` first, followed by `"class"`. When using the ImageClassification algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be `"RecordIO"`.

Multi-label training is also supported by specifying a JSON array of values. The `num_classes` hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[1, 0, 1]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}
```

In the class-id format, each label is a list of the class ids, from [0, `num_classes`), which apply to the data point. The previous example would instead look like this:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[0, 2]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}
```

The multi-hot format is the default, but can be explicitly set in the content type with the `label-format` parameter: `"application/x-recordio; label-format=multi-hot"`. The class-id format, which is the format outputted by GroundTruth, must be set explicitly: `"application/x-recordio; label-format=class-id"`.

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker image classification models can be seeded only with another built-in image classification model trained in SageMaker.

To use a pretrained model, in the `CreateTrainingJob` request, specify the `ChannelName` as "model" in the `InputDataConfig` parameter. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the `num_layers`, `image_shape` and `num_classes` input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

Inference with the Image Classification Algorithm

The generated models can be hosted for inference and support encoded `.jpg` and `.png` image formats as `image/png, image/jpeg`, and `application/x-image` content-type. The input image is resized automatically. The output is the probability values for all classes encoded in JSON format, or in JSON Lines text format for batch transform. The image classification model processes a single image per request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a response in JSON Lines format:

```
accept: application/jsonlines

 {"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}
```

For more details on training and inference, see the image classification sample notebook instances referenced in the introduction.

EC2 Instance Recommendation for the Image Classification Algorithm

For image classification, we support P2, P3, G4dn, and G5 instances. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. Both CPU (such as C4) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

Image Classification Sample Notebooks

For a sample notebook that uses the SageMaker image classification algorithm, see Build and Register an MXNet Image Classification Model via SageMaker Pipelines. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

How Image Classification Works

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet, DenseNet, Inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.

Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See Tune an Image Classification Model for information on image classification hyperparameter tuning.

Parameter Name	Description
num_classes	Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. Besides multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm for details on how to work with multi-label classification with augmented manifest files. **Required** Valid values: positive integer
num_training_samples	Number of training examples in the input dataset. If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter is undefined and distribut ed training accuracy might be affected. **Required** Valid values: positive integer
augmentation_type	Data augmentation type. The input images can be augmented in multiple ways as specified below. • crop: Randomly crop the image and flip the image horizonta lly • crop_color : In addition to 'crop', three random values in the range [-36, 36], [-50, 50], and [-50, 50] are added to the

Parameter Name	Description
	corresponding Hue-Saturation-Lightness channels respectiv ely • `crop_color_transform` : In addition to `crop_colo r` , random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25. **Optional** Valid values: `crop`, `crop_color` , or `crop_color_transfo rm` . Default value: no default value
`beta_1`	The beta1 for `adam`, that is the exponential decay rate for the first moment estimates. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.9
`beta_2`	The beta2 for `adam`, that is the exponential decay rate for the second moment estimates. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.999

Parameter Name	Description
checkpoint_frequency	Period to store model parameters (in number of epochs). Note that all checkpoint files are saved as part of the final model file "model.tar.gz" and uploaded to S3 to the specified model location. This increases the size of the model file proportionally to the number of checkpoints saved during training. **Optional** Valid values: positive integer no greater than epochs. Default value: no default value (Save checkpoint at the epoch that has the best validation accuracy)
early_stopping	True to use early stopping logic during training. False not to use it. **Optional** Valid values: True or False Default value: False
early_stopping_min_epochs	The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when early_stopping = True. **Optional** Valid values: positive integer Default value: 10

Parameter Name	Description
`early_stopping_patience`	The number of epochs to wait before ending training if no improvement is made in the relevant metric. It is used only when `early_stopping = True`. **Optional** Valid values: positive integer Default value: 5
`early_stopping_tolerance`	Relative tolerance to measure an improvement in accuracy validation metric. If the ratio of the improvement in accuracy divided by the previous best accuracy is smaller than the `early_stopping_tolerance` value set, early stopping considers there is no improvement. It is used only when `early_stopping = True`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.0
`epochs`	Number of training epochs. **Optional** Valid values: positive integer Default value: 30
`eps`	The epsilon for `adam` and `rmsprop`. It is usually set to a small value to avoid division by 0. **Optional** Valid values: float. Range in [0, 1]. Default value: 1e-8

Parameter Name	Description
gamma	The gamma for rmsprop, the decay factor for the moving average of the squared gradient. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.9
image_shape	The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels , height, width'. The image dimension can take on any value as the network can handle varied dimension s of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3,224,224'. This is similar to the ImageNet dataset. For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken. At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped. **Optional** Valid values: string Default value: ‘3,224,224’

Parameter Name	Description
`kv_store`	Weight update synchronization mode during distributed training. The weight updates can be updated either synchrono usly or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See distributed training in MXNet for more details. This parameter is not applicable to single machine training. • `dist_sync` : The gradients are synchronized after every batch with all the workers. With `dist_sync` , batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then `dist_sync` behaves like local with batch size n*b • `dist_async` : Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed. **Optional** Valid values: `dist_sync` or `dist_async` Default value: no default value
`learning_rate`	Initial learning rate. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.1

Parameter Name	Description
lr_scheduler_factor	The ratio to reduce learning rate used in conjunction with the lr_scheduler_step parameter, defined as lr_new = lr_old * lr_scheduler_factor . **Optional** Valid values: float. Range in [0, 1]. Default value: 0.1
lr_scheduler_step	The epochs at which to reduce the learning rate. As explained in the lr_scheduler_factor parameter, the learning rate is reduced by lr_scheduler_factor at these epochs. For example, if the value is set to "10, 20", then the learning rate is reduced by lr_scheduler_factor after 10th epoch and again by lr_scheduler_factor after 20th epoch. The epochs are delimited by ",". **Optional** Valid values: string Default value: no default value
mini_batch_size	The batch size for training. In a single-machine multi-GPU setting, each GPU handles mini_batch_size /num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size *number of machines. See MXNet docs for more details. **Optional** Valid values: positive integer Default value: 32

Parameter Name	Description
momentum	The momentum for sgd and nag, ignored for other optimizers. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.9
multi_label	Flag to use for multi-label classification where each sample can be assigned multiple labels. Average accuracy across all classes is logged. **Optional** Valid values: 0 or 1 Default value: 0
num_layers	Number of layers for the network. For data with large image size (for example, 224x224 - like ImageNet), we suggest selecting the number of layers from the set [18, 34, 50, 101, 152, 200]. For data with small image size (for example, 28x28 - like CIFAR), we suggest selecting the number of layers from the set [20, 32, 44, 56, 110]. The number of layers in each set is based on the ResNet paper. For transfer learning, the number of layers defines the architecture of base network and hence can only be selected from the set [18, 34, 50, 101, 152, 200]. **Optional** Valid values: positive integer in [18, 34, 50, 101, 152, 200] or [20, 32, 44, 56, 110] Default value: 152

Parameter Name	Description
optimizer	The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API. **Optional** Valid values: One of sgd, adam, rmsprop, or nag. • sgd: Stochastic gradient descent • adam: Adaptive momentum estimation • rmsprop: Root mean square propagation • nag: Nesterov accelerated gradient Default value: sgd
precision_dtype	The precision of the weights used for training. The algorithm can use either single precision (float32) or half precision (float16) for the weights. Using half-precision for weights results in reduced memory consumption. **Optional** Valid values: float32 or float16 Default value: float32

Parameter Name	Description
`resize`	The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of `image_shape` to prevent training failure. **Required** when using image content types **Optional** when using the RecordIO content type Valid values: positive integer Default value: no default value
`top_k`	Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported. **Optional** Valid values: positive integer larger than 1. Default value: no default value
`use_pretrained_model`	Flag to use pre-trained model for training. If set to 1, then the pretrained model with the corresponding number of layers is loaded and used for training. Only the top FC layer are reinitial ized with random weights. Otherwise, the network is trained from scratch. **Optional** Valid values: 0 or 1 Default value: 0

Parameter Name	Description
use_weighted_loss	Flag to use weighted cross-entropy loss for multi-label classification (used only when multi_label = 1), where the weights are calculated based on the distribution of classes. **Optional** Valid values: 0 or 1 Default value: 0
weight_decay	The coefficient weight decay for sgd and nag, ignored for other optimizers. **Optional** Valid values: float. Range in [0, 1]. Default value: 0.0001

Tune an Image Classification Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
validation:accuracy	The ratio of the number of correct predictions to the total number of predictions made.	Maximize

Tunable Image Classification Hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: mini_batch_size, learning_rate, and optimizer. Tune the optimizer-related hyperparameters, such as momentum, weight_decay, beta_1, beta_2, eps, and gamma, based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used in each optimizer, see Image Classification Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
beta_1	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
beta_2	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
eps	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
gamma	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 0.999
learning_rate	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
mini_batch_size	IntegerParameterRanges	MinValue: 8, MaxValue: 512

Parameter Name	Parameter Type	Recommended Ranges
momentum	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'nag']
weight_decay	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999

Image Classification - TensorFlow

The Amazon SageMaker Image Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The image classification algorithm takes an image as input and outputs a probability for each provided class label. Training datasets must consist of images in .jpg, .jpeg, or .png format.

How to use the SageMaker Image Classification - TensorFlow algorithm

You can use Image Classification - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Image Classification - TensorFlow with the SageMaker

Python SDK. For information on how to use Image Classification - TensorFlow from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

The Image Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow Hub models. For a list of all available pretrained models, see TensorFlow Hub Models. Every pretrained model has a unique `model_id`. The following example uses MobileNet V2 1.00 224 (`model_id`: `tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4`) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with `hyperparameters.retrieve_default`. For more information, see Image Classification - TensorFlow Hyperparameters. Use these values to construct a SageMaker Estimator.

> **Note**
>
> Default hyperparameter values are different for different models. For larger models, the default batch size is smaller and the `train_only_top_layer` hyperparameter is set to `"True"`.

This example uses the `tf_flowers` dataset, which contains five classes of flower images. We pre-downloaded the dataset from TensorFlow under the Apache 2.0 license and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-ic-imagenet-mobilenet-v2-100-224-
classification-4", "*"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
 image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",insta
```

```
# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
 script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
 model_scope="training")

# Retrieve the default hyper-parameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
 model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# The sample training data is available in the following S3 bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tf_flowers/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-ic-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create SageMaker Estimator instance
tf_ic_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Use S3 path of the training data to launch SageMaker TrainingJob
tf_ic_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

Input and output interface for the Image Classification - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Image Classification - TensorFlow model.

- **Training data input format:** Your training data should be a directory with as many subdirectories as the number of classes. Each subdirectory should contain images belonging to that class in .jpg, .jpeg, or .png format.

The following is an example of an input directory structure. This example dataset has two classes: `roses` and `dandelion`. The image files in each class folder can have any name. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://bucket_name/input_directory/`. Note that the trailing `/` is required.

```
input_directory
    |--roses
        |--abc.jpg
        |--def.jpg
    |--dandelion
        |--ghi.jpg
        |--jkl.jpg
```

Trained models output label mapping files that map class folder names to the indices in the list of output class probabilities. This mapping is in alphabetical order. For example, in the preceding example, the dandelion class is index 0 and the roses class is index 1.

After training, you have a fine-tuned model that you can further train using incremental training or deploy for inference. The Image Classification - TensorFlow algorithm automatically adds a pre-processing and post-processing signature to the fine-tuned model so that it can take in images as input and return class probabilities. The file mapping class indices to class labels is saved along with the models.

Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

> **Note**
>
> You can only seed a SageMaker Image Classification - TensorFlow model with another Image Classification - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For an example of incremental training with the SageMaker Image Classification - TensorFlow algorithm, see the Introduction to SageMaker TensorFlow - Image Classification sample notebook.

Inference with the Image Classification - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Image Classification training for inference. Any input image for inference must be in `.jpg`, `.jpeg`, or `.png` format and be content type `application/x-image`. The Image Classification - TensorFlow algorithm resizes input images automatically.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Image Classification - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

 {"probabilities": [prob_0, prob_1, prob_2, ...],
  "labels":        [label_0, label_1, label_2, ...],
  "predicted_label": predicted_label}
```

If `accept` is set to `application/json`, then the model only outputs probabilities. For more information on training and inference with the Image Classification - TensorFlow algorithm, see the Introduction to SageMaker TensorFlow - Image Classification sample notebook.

Amazon EC2 instance recommendation for the Image Classification - TensorFlow algorithm

The Image Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:

- `ml.p2.xlarge`

- `ml.p2.16xlarge`
- `ml.p3.2xlarge`
- `ml.p3.16xlarge`
- `ml.g4dn.xlarge`
- `ml.g4dn.16.xlarge`
- `ml.g5.xlarge`
- `ml.g5.48xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

Image Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker Image Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Image Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How Image Classification - TensorFlow Works

The Image Classification - TensorFlow algorithm takes an image as input and classifies it into one of the output class labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for image classification. There are also deep learning networks that are trained on large image datasets, such as ImageNet, which has over 11 million images and almost 11,000 classes. After a network is trained with ImageNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific classification tasks. The Amazon SageMaker Image Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a classification layer is attached to the pretrained TensorFlow Hub model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully-connected layer with 2-norm regularizer that is initialized with random weights. The model has hyperparameters for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer. You can then fine-tune either the entire network

(including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Image Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Model Name	model_id	Source

Image Classification - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification - TensorFlow algorithm. See Tune an Image Classification - TensorFlow model for information on hyperparameter tuning.

Parameter Name	Description
augmentation	Set to "True" to apply augmentation_random_flip , augmentation_random_rotation , and augmentation_random_zoom to the training data. Valid values: string, either: ("True" or "False"). Default value: "False".
augmentation_random_flip	Indicates which flip mode to use for data augmentation when augmentation is set to "True". For more information, see RandomFlip in the TensorFlow documentation. Valid values: string, any of the following: ("horizontal_and_vertical" , "vertical" , or "None"). Default value: "horizontal_and_vertical" .
augmentation_random_rotation	Indicates how much rotation to use for data augmentation when augmentation is set to "True". Values represent a fraction of 2π. Positive values rotate counterclockwise while negative values rotate clockwise. 0 means no rotation. For more information, see RandomRotation in the TensorFlow documentation. Valid values: float, range: [-1.0, 1.0]. Default value: 0.2.
augmentation_random_zoom	Indicates how much vertical zoom to use for data augmentation when augmentation is set to "True". Positive values zoom out while negative values zoom in. 0 means no zoom. For more information, see RandomZoom in the TensorFlow documentation. Valid values: float, range: [-1.0, 1.0]. Default value: 0.1.

Parameter Name	Description
batch_size	The batch size for training. For training on instances with multiple GPUs, this batch size is used across the GPUs. Valid values: positive integer. Default value: 32.
beta_1	The beta1 for the "adam" optimizer. Represents the exponential decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.
beta_2	The beta2 for the "adam" optimizer. Represents the exponential decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.999.
binary_mode	When binary_mode is set to "True", the model returns a single probability number for the positive class and can use additional eval_metric options. Use only for binary classification problems. Valid values: string, either: ("True" or "False"). Default value: "False".
dropout_rate	The dropout rate for the dropout layer in the top classification layer. Valid values: float, range: [0.0, 1.0]. Default value: 0.2

Parameter Name	Description
early_stopping	Set to "True" to use early stopping logic during training. If "False", early stopping is not used. Valid values: string, either: ("True" or "False"). Default value: "False".
early_stopping_min_delta	The minimum change needed to qualify as an improvement. An absolute change less than the value of early_stopping_min_delta does not qualify as improvement. Used only when early_stopping is set to "True". Valid values: float, range: [0.0, 1.0]. Default value: 0.0.
early_stopping_patience	The number of epochs to continue training with no improvement. Used only when early_stopping is set to "True". Valid values: positive integer. Default value: 5.
epochs	The number of training epochs. Valid values: positive integer. Default value: 3.
epsilon	The epsilon for "adam", "rmsprop", "adadelta", and "adagrad" optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 1e-7.

Parameter Name	Description
eval_metric	If binary_mode is set to "False", eval_metric can only be "accuracy". If binary_mode is "True", select any of the valid values. For more information, see Metrics in the TensorFlow documentation. Valid values: string, any of the following: ("accuracy", "precision", "recall", "auc", or "prc"). Default value: "accuracy".
image_resize_interpolation	Indicates interpolation method used when resizing images. For more information, see image.resize in the TensorFlow documentation. Valid values: string, any of the following: ("bilinear", "nearest", "bicubic", "area", "lanczos3", "lanczos5", "gaussian", or "mitchellcubic"). Default value: "bilinear".
initial_accumulator_value	The starting value for the accumulators, or the per-parameter momentum values, for the "adagrad" optimizer. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.0001.
label_smoothing	Indicates how much to relax the confidence on label values. For example, if label_smoothing is 0.1, then non-target labels are 0.1/num_classes and target labels are 0.9+0.1/num_classes. Valid values: float, range: [0.0, 1.0]. Default value: 0.1.

Parameter Name	Description
learning_rate	The optimizer learning rate. Valid values: float, range: [0.0, 1.0]. Default value: 0.001.
momentum	The momentum for "sgd", "nesterov" , and "rmsprop" optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.
optimizer	The optimizer type. For more information, see Optimizers in the TensorFlow documentation. Valid values: string, any of the following: ("adam", "sgd", "nesterov" , "rmsprop" , "adagrad" , "adadelta"). Default value: "adam".
regularizers_l2	The L2 regularization factor for the dense layer in the classific ation layer. Valid values: float, range: [0.0, 1.0]. Default value: .0001.
reinitialize_top_l ayer	If set to "Auto", the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to "True". Valid values: string, any of the following: ("Auto", "True" or "False"). Default value: "Auto".

Parameter Name	Description
rho	The discounting factor for the gradient of the "adadelta" and "rmsprop" optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.95.
train_only_top_layer	If "True", only the top classification layer parameters are fine-tuned. If "False", all model parameters are fine-tuned. Valid values: string, either: ("True" or "False"). Default value: "False".

Tune an Image Classification - TensorFlow model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics computed by the Image Classification - TensorFlow algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
validation:accuracy	The ratio of the number of correct predictions to the total number of predictions made.	Maximize

Tunable Image Classification - TensorFlow hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adam` is the `optimizer`.

For more information about which hyperparameters are used for each `optimizer`, see Image Classification - TensorFlow Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`batch_size`	IntegerParameterRanges	MinValue: 8, MaxValue: 512
`beta_1`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`beta_2`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`eps`	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
`learning_rate`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
`momentum`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
`optimizer`	CategoricalParameterRanges	['sgd', ‘adam’, ‘rmsprop’, 'nesterov', 'adagrad', 'adadelta']
`regularizers_l2`	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999

Parameter Name	Parameter Type	Recommended Ranges
`train_only_top_layer`	ContinuousParameterRanges	['True', 'False']

Object Detection - MXNet

The Amazon SageMaker Object Detection - MXNet algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

Input/Output Interface for the Object Detection Algorithm

The SageMaker Object Detection algorithm supports both RecordIO (`application/x-recordio`) and image (`image/png`, `image/jpeg`, and `application/x-image`) content types for training in file mode and supports RecordIO (`application/x-recordio`) for training in pipe mode. However you can also train in pipe mode using the image files (`image/png`, `image/jpeg`, and `application/x-image`), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms

is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only `application/x-image` for inference.

> **Note**
>
> To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks for more details on data formats.

Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to `application/x-recordio`. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

Train with the Image Format

If you use the image format for training, specify `train`, `validation`, `train_annotation`, and `validation_annotation` channels as values for the `InputDataConfig` parameter of `CreateTrainingJob` request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the `train_annotation` and `validation_annotation` channels. Set the content type for all four channels to `image/png` or `image/jpeg` based on the image type. You can also use the content type `application/x-image` when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```
{
   "file": "your_image_directory/sample_image1.jpg",
   "image_size": [
      {
         "width": 500,
         "height": 400,
         "depth": 3
```

```
      }
   ],
   "annotations": [
      {
         "class_id": 0,
         "left": 111,
         "top": 134,
         "width": 61,
         "height": 128
      },
      {
         "class_id": 0,
         "left": 161,
         "top": 250,
         "width": 79,
         "height": 143
      },
      {
         "class_id": 1,
         "left": 101,
         "top": 185,
         "width": 42,
         "height": 130
      }
   ],
   "categories": [
      {
         "class_id": 0,
         "name": "dog"
      },
      {
         "class_id": 1,
         "name": "cat"
      }
   ]
}
```

Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://*your_bucket*/train/sample_image and s3://*your_bucket*/train_annotation,

specify the path for your train and train_annotation channels as s3://*your_bucket*/train and s3://*your_bucket*/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The `"image_size"` property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The `"annotations"` property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a `"class_id"` index and by four bounding box coordinates (`"left"`, `"top"`, `"width"`, `"height"`). The `"left"` (x-coordinate) and `"top"` (y-coordinate) values represent the upper-left corner of the bounding box. The `"width"` (x-coordinate) and `"height"` (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The `"categories"` property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The `"categories"` property is optional for the annotation .json file

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the `'source-ref'` tag that points to the S3 location of the image. The annotations are provided under the `"AttributeNames"` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the following example, the `"AttributeNames` are contained in the list `["source-ref", "bounding-box"]`:

```
{"source-ref": "s3://your_bucket/image1.jpg", "bounding-box":{"image_size":[{ "width":
 500, "height": 400, "depth":3}], "annotations":[{"class_id": 0, "left": 111, "top":
 134, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width":
 80, "height": 50}]}, "bounding-box-metadata":{"class-map":{"0": "dog", "5": "horse"},
 "type": "groundtruth/object-detection"}}
{"source-ref": "s3://your_bucket/image2.jpg", "bounding-box":{"image_size":[{ "width":
 400, "height": 300, "depth":3}], "annotations":[{"class_id": 1, "left": 100, "top":
 120, "width": 43, "height": 78}]}, "bounding-box-metadata":{"class-map":{"1": "cat"},
 "type": "groundtruth/object-detection"}}
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For more information on incremental training and for instructions on how to use it, see Use Incremental Training in Amazon SageMaker.

EC2 Instance Recommendation for the Object Detection Algorithm

The object detection algorithm supports P2, P3, G4dn, and G5 GPU instance families. We recommend using GPU instances with more memory for training with large batch sizes. You can run the object detection algorithm on multi-GPU and mult-machine settings for distributed training.

You can use both CPU (such as C5 and M5) and GPU (such as P3 and G4dn) instances for inference.

Object Detection Sample Notebooks

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the

Caltech Birds (CUB 200 2011) dataset using the Single Shot multibox Detector algorithm, see Amazon SageMaker Object Detection for Bird Species. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The object detection example notebook using the Object Detection algorithm is located in the **Introduction to Amazon Algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

For more information about the Amazon SageMaker Object Detection algorithm, see the following blog posts:

- Training the Amazon SageMaker object detection model and running it on AWS IoT Greengrass – Part 1 of 3: Preparing training data
- Training the Amazon SageMaker object detection model and running it on AWS IoT Greengrass – Part 2 of 3: Training a custom object detection model
- Training the Amazon SageMaker object detection model and running it on AWS IoT Greengrass – Part 3 of 3: Deploying to the edge

How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the Single Shot multibox Detector (SSD) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as VGG and ResNet have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see How Object Detection Works.

Parameter Name	Description
`num_classes`	The number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. **Required** Valid values: positive integer
`num_training_samples`	The number of training examples in the input dataset. **Note** If there is a mismatch between this value and the number of samples in the training set, then the behavior of the `lr_scheduler_step` parameter will be undefined and distributed training accuracy may be affected. **Required** Valid values: positive integer
`base_network`	The base network architecture to use. **Optional** Valid values: 'vgg-16' or 'resnet-50' Default value: 'vgg-16'

Parameter Name	Description
early_stopping	True to use early stopping logic during training. False not to use it. **Optional** Valid values: True or False Default value: False
early_stopping_min_epochs	The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when early_stopping = True. **Optional** Valid values: positive integer Default value: 10
early_stopping_patience	The number of epochs to wait before ending training if no improvement, as defined by the early_stopping_tolerance hyperparameter, is made in the relevant metric. It is used only when early_stopping = True. **Optional** Valid values: positive integer Default value: 5

Parameter Name	Description
`early_stopping_tolerance`	The tolerance value that the relative improvement in `validation:mAP` , the mean average precision (mAP), is required to exceed to avoid early stopping. If the ratio of the change in the mAP divided by the previous best mAP is smaller than the `early_stopping_tolerance` value set, early stopping considers that there is no improvement. It is used only when `early_stopping = True`. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.0
`image_shape`	The image size for input images. We rescale the input image to a square image with this size. We recommend using 300 and 512 for better performance. **Optional** Valid values: positive integer ≥300 Default: 300
`epochs`	The number of training epochs. **Optional** Valid values: positive integer Default: 30

Parameter Name	Description
`freeze_layer_pattern`	The regular expression (regex) for freezing layers in the base network. For example, if we set `freeze_layer_pattern = "^(conv1_|conv2_).*"` , then any layers with a name that contains `"conv1_"` or `"conv2_"` are frozen, which means that the weights for these layers are not updated during training. The layer names can be found in the network symbol files vgg16-symbol.json and resnet-50-symbol.json. Freezing a layer means that its weights can not be modified further. This can reduce training time significantly in exchange for modest losses in accuracy. This technique is commonly used in transfer learning where the lower layers in the base network do not need to be retrained. **Optional** Valid values: string Default: No layers frozen.

Parameter Name	Description
`kv_store`	The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the Distributed Training MXNet tutorial for details. **Note** This parameter is not applicable to single machine training. **Optional** Valid values: `'dist_sync'` or `'dist_async'` • `'dist_sync'` : The gradients are synchronized after every batch with all the workers. With `'dist_sync'` , batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b. • `'dist_async'` : Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed. Default: -

Parameter Name	Description
label_width	The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the label_width should be no smaller than (10*5 + header information length). The header information length is usually 2. We recommend using a slightly larger label_width for the training, such as 60 for this example. **Optional** Valid values: Positive integer large enough to accommodate the largest annotation information length in the data. Default: 350
learning_rate	The initial learning rate. **Optional** Valid values: float in (0, 1] Default: 0.001
lr_scheduler_factor	The ratio to reduce learning rate. Used in conjunction with the lr_scheduler_step parameter defined as lr_new = lr_old * lr_scheduler_factor . **Optional** Valid values: float in (0, 1) Default: 0.1

Parameter Name	Description
lr_scheduler_step	The epochs at which to reduce the learning rate. The learning rate is reduced by lr_scheduler_factor at epochs listed in a comma-delimited string: "epoch1, epoch2, ...". For example, if the value is set to "10, 20" and the lr_schedu ler_factor is set to 1/2, then the learning rate is halved after 10th epoch and then halved again after 20th epoch. **Optional** Valid values: string Default: empty string
mini_batch_size	The batch size for training. In a single-machine multi-gpu setting, each GPU handles mini_batch_size /num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size *number of machines. A large mini_batch_size usually leads to faster training, but it may cause out of memory problem. The memory usage is related to mini_batch_size , image_sha pe , and base_network architecture. For example, on a single p3.2xlarge instance, the largest mini_batch_size without an out of memory error is 32 with the base_network set to "resnet-50" and an image_shape of 300. With the same instance, you can use 64 as the mini_batch_size with the base network vgg-16 and an image_shape of 300. **Optional** Valid values: positive integer Default: 32

Parameter Name	Description
momentum	The momentum for sgd. Ignored for other optimizers. **Optional** Valid values: float in (0, 1] Default: 0.9
nms_threshold	The non-maximum suppression threshold. **Optional** Valid values: float in (0, 1] Default: 0.45
optimizer	The optimizer types. For details on optimizer values, see MXNet's API. **Optional** Valid values: ['sgd', 'adam', 'rmsprop', 'adadelta'] Default: 'sgd'
overlap_threshold	The evaluation overlap threshold. **Optional** Valid values: float in (0, 1] Default: 0.5

Parameter Name	Description
`use_pretrained_model`	Indicates whether to use a pre-trained model for training. If set to 1, then the pre-trained model with corresponding architect ure is loaded and used for training. Otherwise, the network is trained from scratch. **Optional** Valid values: 0 or 1 Default: 1
`weight_decay`	The weight decay coefficient for `sgd` and `rmsprop`. Ignored for other optimizers. **Optional** Valid values: float in (0, 1) Default: 0.0005

Tune an Object Detection Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: `validation:mAP`. When tuning a model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
validation:mAP	Mean Average Precision (mAP) computed on the validation set.	Maximize

Tunable Object Detection Hyperparameters

Tune the Amazon SageMaker object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on the object detection objective metric are: mini_batch_size, learning_rate, and optimizer.

Parameter Name	Parameter Type	Recommended Ranges
learning_rate	ContinuousParameterRange	MinValue: 1e-6, MaxValue: 0.5
mini_batch_size	IntegerParameterRanges	MinValue: 8, MaxValue: 64
momentum	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'adadelta']
weight_decay	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.999

Object Detection Request and Response Formats

Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with image/jpeg and image/png content-types.

Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```
{"prediction":[
  [4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636,
 0.7110607028007507, 0.9345266819000244],
  [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895,
 0.827075183391571, 0.9712159633636475],
  [4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486,
 0.6318609714508057, 0.5967587828636169],
  [8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051,
 0.8985623121261597],
  [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702,
 0.39093565940856934, 0.9574796557426453]
]}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide examples of scripts that use a threshold to remove low confidence detections and to plot bounding boxes on the original images.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id,
 confidence_score, xmin, ymin, xmax, ymax]]}
```

For more details on training and inference, see the Object Detection Sample Notebooks.

Object Detection - TensorFlow

The Amazon SageMaker Object Detection - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Model Garden. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The object detection algorithm takes an image as input and outputs a list of bounding boxes. Training datasets must consist of images in `.jpg`, `.jpeg`, or `.png` format.

How to use the SageMaker Object Detection - TensorFlow algorithm

You can use Object Detection - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Object Detection - TensorFlow with the SageMaker Python SDK. For information on how to use Object Detection - TensorFlow from the Amazon SageMaker Studio Classic UI, see SageMaker JumpStart.

The Object Detection - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Models. Every pretrained model has a unique `model_id`. The following example uses ResNet50 (`model_id`: `tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8`) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with `hyperparameters.retrieve_default`. For more information, see Object Detection - TensorFlow Hyperparameters. Use these values to construct a SageMaker Estimator.

> **Note**
>
> Default hyperparameter values are different for different models. For example, for larger models, the default number of epochs is smaller.

This example uses the PennFudanPed dataset, which contains images of pedestriants in the street. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call `.fit` using the Amazon S3 location of your training dataset.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8",
 "*"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
 image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",insta

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
 script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
 model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
 model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"
```

```
# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/PennFudanPed_COCO_format/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-od-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create an Estimator instance
tf_od_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job
tf_od_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about how to use the SageMaker Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Input and output interface for the Object Detection - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Object Detection - TensorFlow model.

- **Training data input format:** Your training data should be a directory with an `images` subdirectory and an `annotations.json` file.

The following is an example of an input directory structure. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://bucket_name/input_directory/`. Note that the trailing `/` is required.

```
input_directory
    |--images
        |--abc.png
        |--def.png
    |--annotations.json
```

The `annotations.json` file should contain information for bounding boxes and their class labels in the form of a dictionary `"images"` and `"annotations"` keys. The value for the `"images"` key should be a list of dictionaries. There should be one dictionary for each image with the following information: `{"file_name": image_name, "height": height, "width": width, "id": image_id}`. The value for the `"annotations"` key should also be a list of dictionaries. There should be one dictionary for each bounding box with the following information: `{"image_id": image_id, "bbox": [xmin, ymin, xmax, ymax], "category_id": bbox_label}`.

After training, a label mapping file and trained model are saved to your Amazon S3 bucket.

Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

> **Note**
>
> You can only seed a SageMaker Object Detection - TensorFlow model with another Object Detection - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For more information about how to use incremental training with the SageMaker Object Detection - TensorFlow, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Inference with the Object Detection - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Object Detection training for inference. Any input image for inference must be in `.jpg`, `.jpeg`, or `.png` format and be content type `application/x-image`. The Object Detection - TensorFlow algorithm resizes input images automatically.

Running inference results in bounding boxes, predicted classes, and the scores of each prediction encoded in JSON format. The Object Detection - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

{"normalized_boxes":[[xmin1, xmax1, ymin1, ymax1],....],
    "classes":[classidx1, class_idx2,...],
    "scores":[score_1, score_2,...],
    "labels": [label1, label2, ...],
    "tensorflow_model_output":<original output of the model>}
```

If `accept` is set to `application/json`, then the model only outputs normalized boxes, classes, and scores.

Amazon EC2 instance recommendation for the Object Detection - TensorFlow algorithm

The Object Detection - TensorFlow algorithm supports all GPU instances for training, including:

- `ml.p2.xlarge`
- `ml.p2.16xlarge`
- `ml.p3.2xlarge`
- `ml.p3.16xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2 or P3) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Object Detection - TensorFlow sample notebooks

For more information about how to use the SageMaker Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, choose its **Use** tab and choose **Create copy**.

How Object Detection - TensorFlow Works

The Object Detection - TensorFlow algorithm takes an image as input and predicts bounding boxes and object labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for object detection. There are also deep learning networks that are trained on large image datasets, such as Common Objects in Context (COCO), which has 328,000 images. After a network is trained with COCO data, you can then fine-tune the network on a dataset with a particular focus to perform more specific object detection tasks. The Amazon SageMaker Object Detection - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Model Garden.

According to the number of class labels in your training data, an object detection layer is attached to the pretrained TensorFlow model of your choice. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Models

The following pretrained models are available to use for transfer learning with the Object Detection - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Model Name	`model_id`	Source
ResNet50 V1 FPN 640	`tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8`	TensorFlow Model Garden link

Object Detection - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Object Detection - TensorFlow algorithm. See Tune an Object Detection - TensorFlow model for information on hyperparameter tuning.

Parameter Name	Description
batch_size	The batch size for training. Valid values: positive integer. Default value: 3.

Parameter Name	Description
beta_1	The beta1 for the "adam" optimizer. Represents the exponential decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.
beta_2	The beta2 for the "adam" optimizer. Represents the exponential decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.999.
early_stopping	Set to "True" to use early stopping logic during training. If "False", early stopping is not used. Valid values: string, either: ("True" or "False"). Default value: "False".
early_stopping_min_delta	The minimum change needed to qualify as an improvement. An absolute change less than the value of early_stopping_min_delta does not qualify as improvement. Used only when early_stopping is set to "True". Valid values: float, range: [0.0, 1.0]. Default value: 0.0.
early_stopping_patience	The number of epochs to continue training with no improvement. Used only when early_stopping is set to "True". Valid values: positive integer. Default value: 5.

Parameter Name	Description
epochs	The number of training epochs. Valid values: positive integer. Default value: 5 for smaller models, 1 for larger models.
epsilon	The epsilon for "adam", "rmsprop" , "adadelta" , and "adagrad" optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 1e-7.
initial_accumulator_value	The starting value for the accumulators, or the per-parameter momentum values, for the "adagrad" optimizer. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.1.
learning_rate	The optimizer learning rate. Valid values: float, range: [0.0, 1.0]. Default value: 0.001.
momentum	The momentum for the "sgd" and "nesterov" optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.

Parameter Name	Description
optimizer	The optimizer type. For more information, see Optimizers in the TensorFlow documentation. Valid values: string, any of the following: ("adam", "sgd", "nesterov" , "rmsprop" , "adagrad" , "adadelta"). Default value: "adam".
reinitialize_top_layer	If set to "Auto", the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to "True". Valid values: string, any of the following: ("Auto", "True" or "False"). Default value: "Auto".
rho	The discounting factor for the gradient of the "adadelta" and "rmsprop" optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.95.
train_only_on_top_layer	If "True", only the top classification layer parameters are fine-tuned. If "False", all model parameters are fine-tuned. Valid values: string, either: ("True" or "False"). Default value: "False".

Tune an Object Detection - TensorFlow model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches

the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker.

Metrics computed by the Object Detection - TensorFlow algorithm

Refer to the following chart to find which metrics are computed by the Object Detection - TensorFlow algorithm.

Metric Name	Description	Optimization Direction	Regex Pattern
`validation:localization_loss`	The localization loss for box prediction.	Minimize	`Val_localization=([0-9\\.]+)`

Tunable Object Detection - TensorFlow hyperparameters

Tune an object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on object detection objective metrics are: `batch_size`, `learning_rate`, and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `regularizers_l2`, `beta_1`, `beta_2`, and `eps` based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adam` is the `optimizer`.

For more information about which hyperparameters are used for each `optimizer`, see Object Detection - TensorFlow Hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
`batch_size`	IntegerParameterRanges	MinValue: 8, MaxValue: 512
`beta_1`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
`beta_2`	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999

Parameter Name	Parameter Type	Recommended Ranges
eps	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
learning_rate	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
momentum	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'nesterov', 'adagrad', 'adadelta']
regularizers_l2	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
train_only_on_top_layer	CategoricalParameterRanges	['True', 'False']
initial_accumulator_value	CategoricalParameterRanges	MinValue: 0.0, MaxValue: 0.999

Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker Image Classification - MXNet is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection - MXNet is a supervised learning algorithm that detects and classifies all instances

of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a *segmentation mask*. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker semantic segmentation algorithm is built using the MXNet Gluon framework and the Gluon CV toolkit. It provides you with a choice of three built-in algorithms to train a deep neural network. You can use the Fully-Convolutional Network (FCN) algorithm , Pyramid Scene Parsing (PSP) algorithm, or DeepLabV3.

Each of the three algorithms has two distinct components:

- The *backbone* (or *encoder*)—A network that produces reliable activation maps of features.
- The *decoder*—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: ResNet50 or ResNet101. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

Topics

Semantic Segmentation Sample Notebooks

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the Semantic Segmentation Example. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances.

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the **SageMaker Examples** tab. The example semantic segmentation notebooks are located under **Introduction to Amazon algorithms**. To open a notebook, choose its **Use** tab, and choose **Create copy**.

Input/Output Interface for the Semantic Segmentation Algorithm

SageMaker semantic segmentation expects the customer's training dataset to be on Amazon Simple Storage Service (Amazon S3). Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for `train` and one for `validation` using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (`application/x-image`) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an `image/jpeg` content type.

How Training Works

The training data is split into four directories: `train`, `train_annotation`, `validation`, and `validation_annotation`. There is a channel for each of these directories. The dataset also expected to have one `label_map.json` file per channel for `train_annotation` and `validation_annotation` respectively. If you don't provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
    |
    |- train
                |
                | - 0000.jpg
                | - coffee.jpg
```

```
    |- validation
                |
                | - 00a0.jpg
                | - bananna.jpg
    |- train_annotation
                |
                | - 0000.png
                | - coffee.png
    |- validation_annotation
                |
                | - 00a0.png
                | - bananna.png
    |- label_map
                | - train_label_map.json
                | - validation_label_map.json
```

Every JPG image in the train and validation directories has a corresponding PNG label image with the same name in the `train_annotation` and `validation_annotation` directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The `train`, `train_annotation`, `validation`, and `validation_annotation` channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the Python Image Library documentation. We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the *label map*. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don't provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
  "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn't convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than

or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
  "scale": "3"
}
```

The following example shows how this "scale" value is used to rescale the encoded_label values of the input annotation image when they are mapped to the mapped_label values to be used in training. The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a label_map file:

```
{
    "map": {
        "0": 5,
        "1": 0,
        "2": 2
    }
}
```

This label mapping for this example is:

```
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the label_map channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

Training with the Augmented Manifest Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be

in JSON Lines format, as described in the `CreateTrainingJob` request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a `source-ref` key. The `source-ref` key should contain the value of the Amazon S3 URI to the image. The labels are provided under the `AttributeNames` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the `AttributeNames` are contained in the list of image and annotation references `["source-ref", "city-streets-ref"]`. These names must have `-ref` appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be `"RecordIO"` and value of the `ContentType` parameter must be `application/x-recordio`.

```
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-
streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.

Incremental Training

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.

To use your own pre-trained model, specify the `ChannelName` as "model" in the `InputDataConfig` for the `CreateTrainingJob` request. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The `backbone`, `algorithm`, `crop_size`, and `num_classes` input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see Use Incremental Training in Amazon SageMaker.

Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an `AcceptType` that denotes the type of output required. The endpoint takes JPEG images with an

`image/jpeg` content type. If you request an `AcceptType` of `image/png`, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of`application/x-recordio-protobuf`, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2, P3, G4dn, or G5 instances in single machine configurations.

For inference, you can use either CPU instances (such as C5 and M5) and GPU instances (such as P3 and G4dn) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker ML Instance Types.

Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the `AlgorithmName` of the `CreateTrainingJob` request.

Network Architecture Hyperparameters

Parameter Name	Description
`backbone`	The backbone to use for the algorithm's encoder component. **Optional** Valid values: `resnet-50` , `resnet-101` Default value: `resnet-50`
`use_pretrained_model`	Whether a pretrained model is to be used for the backbone. **Optional** Valid values: `True`, `False`

Parameter Name	Description
	Default value: `True`
`algorithm`	The algorithm to use for semantic segmentation. **Optional** Valid values: • `fcn`: Fully-Convolutional Network (FCN) algorithm • `psp`: Pyramid Scene Parsing (PSP) algorithm • `deeplab`: DeepLab V3 algorithm Default value: `fcn`

Data Hyperparameters

Parameter Name	Description
`num_classes`	The number of classes to segment. **Required** Valid values: 2 ≤ positive integer ≤ 254
`num_training_samples`	The number of samples in the training data. The algorithm uses this value to set up the learning rate scheduler. **Required** Valid values: positive integer
`base_size`	Defines how images are rescaled before cropping. Images are rescaled such that the long size length is set to `base_size` multiplied by a random number from 0.5 to 2.0, and the short size is computed to preserve the aspect ratio. **Optional**

Parameter Name	Description
	Valid values: positive integer > 16 Default value: 520
`crop_size`	The image size for input during training. We randomly rescale the input image based on `base_size` , and then take a random square crop with side length equal to `crop_size` . The `crop_size` will be automatically rounded up to multiples of 8. **Optional** Valid values: positive integer > 16 Default value: 240

Training Hyperparameters

Parameter Name	Description
`early_stopping`	Whether to use early stopping logic during training. **Optional** Valid values: `True`, `False` Default value: `False`
`early_stopping_min_epochs`	The minimum number of epochs that must be run. **Optional** Valid values: integer Default value: 5
`early_stopping_patience`	The number of epochs that meet the tolerance for lower performance before the algorithm enforces an early stop. **Optional**

Parameter Name	Description
	Valid values: integer Default value: 4
early_stopping_tolerance	If the relative improvement of the score of the training job, the mIOU, is smaller than this value, early stopping considers the epoch as not improved. This is used only when early_stopping = True. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.0
epochs	The number of epochs with which to train. **Optional** Valid values: positive integer Default value: 10
gamma1	The decay factor for the moving average of the squared gradient for rmsprop. Used only for rmsprop. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.9
gamma2	The momentum factor for rmsprop. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.9

Parameter Name	Description
learning_rate	The initial learning rate. **Optional** Valid values: 0 < float ≤ 1 Default value: 0.001
lr_scheduler	The shape of the learning rate schedule that controls its decrease over time. **Optional** Valid values: • step: A stepwise decay, where the learning rate is reduced (multiplied) by the lr_scheduler_factor after epochs specified by lr_scheduler_step . • poly: A smooth decay using a polynomial function. • cosine: A smooth decay using a cosine function. Default value: poly
lr_schedu ler_factor	If lr_scheduler is set to step, the ratio by which to reduce (multipy) the learning_rate after each of the epochs specified by the lr_scheduler_step . Otherwise, ignored. **Optional** Valid values: 0 ≤ float ≤ 1 Default value: 0.1

Parameter Name	Description
lr_scheduler_step	A comma delimited list of the epochs after which the learning_rate is reduced (multiplied) by an lr_scheduler_factor . For example, if the value is set to "10, 20", then the learning-rate is reduced by lr_scheduler_factor after the 10th epoch and again by this factor after 20th epoch. **Conditionally Required** if lr_scheduler is set to step. Otherwise , ignored. Valid values: string Default value: (No default, as the value is required when used.)
mini_batch_size	The batch size for training. Using a large mini_batch_size usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the mini_batch_size and image_shape parameters, and the backbone architecture. **Optional** Valid values: positive integer Default value: 16
momentum	The momentum for the sgd optimizer. When you use other optimizers, the semantic segmentation algorithm ignores this parameter. **Optional** Valid values: 0 < float ≤ 1 Default value: 0.9

Parameter Name	Description
optimizer	The type of optimizer. For more information about an optimizer, choose the appropriate link: • adam: Adaptive momentum estimation • adagrad: Adaptive gradient descent • nag: Nesterov accelerated gradient • rmsprop: Root mean square propagation • sgd: Stochastic gradient descent **Optional** Valid values: adam, adagrad, nag, rmsprop, sgd Default value: sgd
syncbn	If set to True, the batch normalization mean and variance are computed over all the samples processed across the GPUs. **Optional** Valid values: True, False Default value: False

Parameter Name	Description
validation_mini_batch_size	The batch size for validation. A large mini_batch_size usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the mini_batch_size and image_shape parameters, and the backbone architecture. • To score the validation on the entire image without cropping the images, set this parameter to 1. Use this option if you want to measure performance on the entire image as a whole. **Note** Setting the validation_mini_batch_size parameter to 1 causes the algorithm to create a new network model for every image. This might slow validation and training. • To crop images to the size specified in the crop_size parameter, even during evaluation, set this parameter to a value greater than 1. **Optional** Valid values: positive integer Default value: 16
weight_decay	The weight decay coefficient for the sgd optimizer. When you use other optimizers, the algorithm ignores this parameter. **Optional** Valid values: 0 < float < 1 Default value: 0.0001

Tuning a Semantic Segmentation Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Metrics Computed by the Semantic Segmentation Algorithm

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

Metric Name	Description	Optimization Direction
`validation:mIOU`	The area of the intersection of the predicted segmentation and the ground truth divided by the area of union between them for images in the validation set. Also known as the Jaccard Index.	Maximize
`validation:pixel_accuracy`	The percentage of pixels that are correctly classified in images from the validation set.	Maximize

Tunable Semantic Segmentation Hyperparameters

You can tune the following hyperparameters for the semantic segmentation algorithm.

Parameter Name	Parameter Type	Recommended Ranges
`learning_rate`	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 1e-1

Parameter Name	Parameter Type	Recommended Ranges
mini_batch_size	IntegerParameterRanges	MinValue: 1, MaxValue: 128
momentum	ContinuousParameterRange	MinValue: 0.9, MaxValue: 0.999
optimzer	CategoricalParameterRanges	['sgd', 'adam', 'adadelta']
weight_decay	ContinuousParameterRange	MinValue: 1e-5, MaxValue: 1e-3

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent's current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

Topics

Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.

Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

Action

What the agent does. For example, the robot takes a step forward.

Reward

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a *policy*.

Observation

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many *episodes*. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.

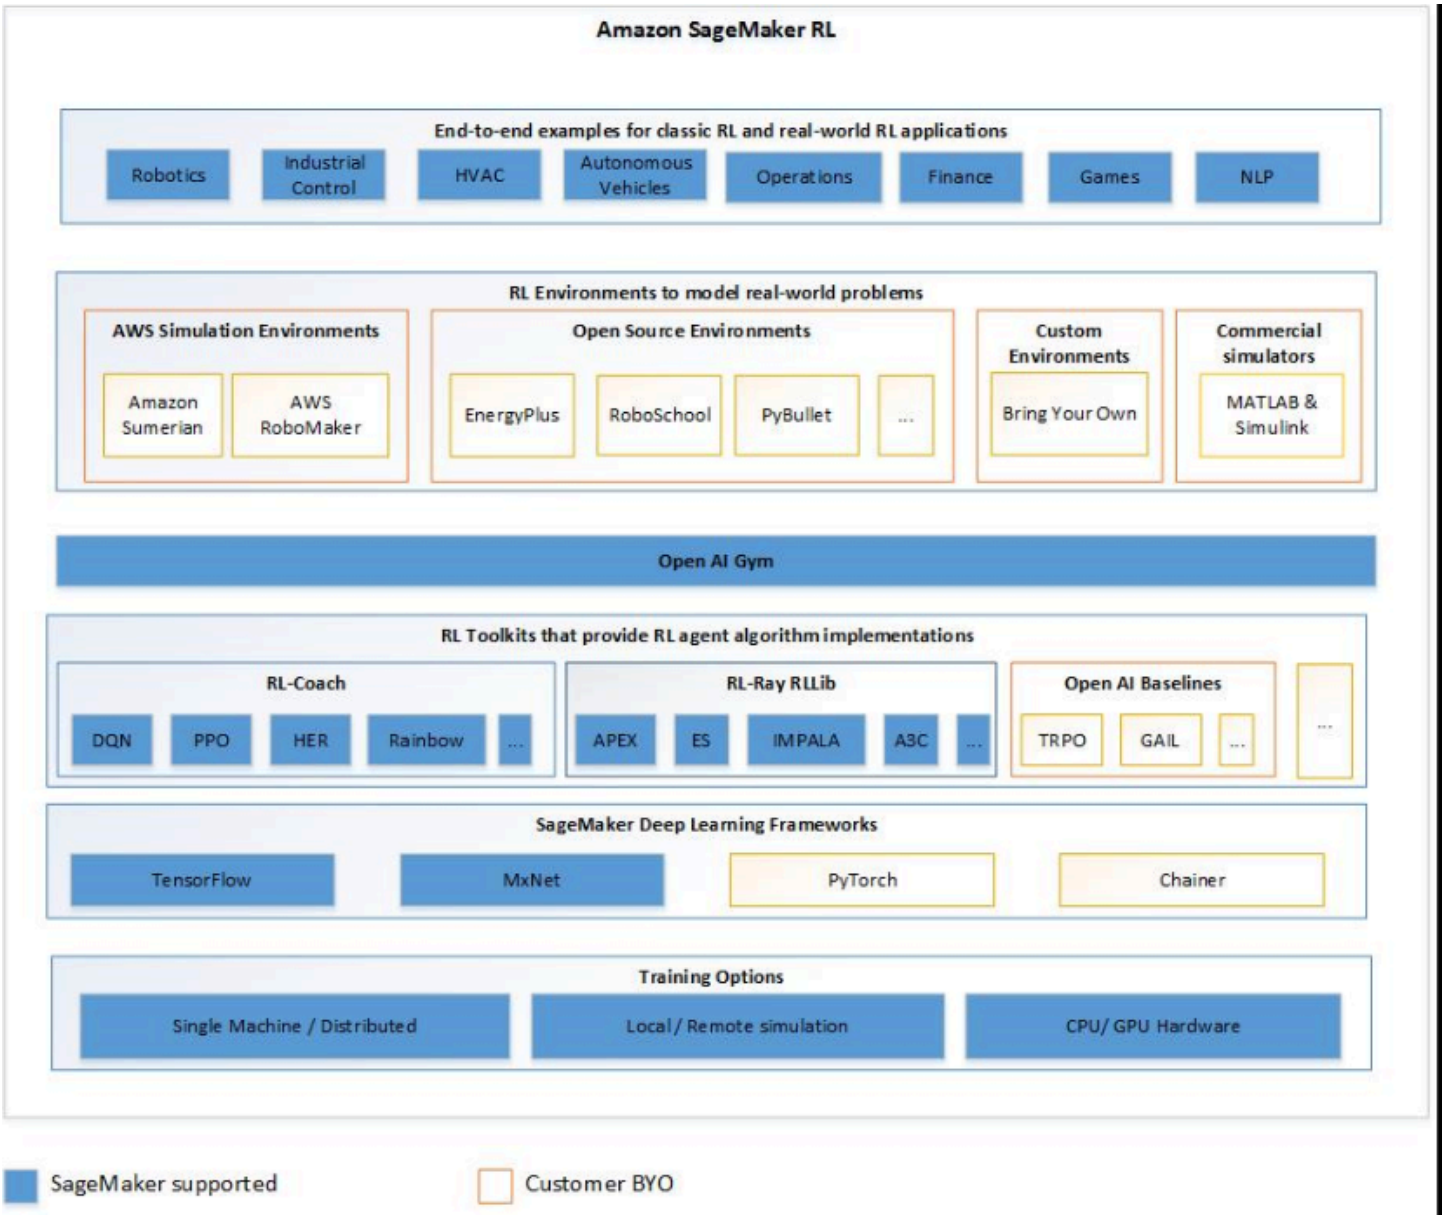
Key Features of Amazon SageMaker RL

To train RL models in SageMaker RL, use the following components:

- A deep learning (DL) framework. Currently, SageMaker supports RL in TensorFlow and Apache MXNet.

- An RL toolkit. An RL toolkit manages the interaction between the agent and the environment and provides a wide selection of state of the art RL algorithms. SageMaker supports the Intel Coach and Ray RLlib toolkits. For information about Intel Coach, see https://nervanasystems.github.io/coach/. For information about Ray RLlib, see https://ray.readthedocs.io/en/latest/rllib.html.
- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see RL Environments in Amazon SageMaker.

The following diagram shows the RL components that are supported in SageMaker RL.



Reinforcement Learning Sample Notebooks

For complete code examples, see the reinforcement learning sample notebooks in the SageMaker Examples repository.

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:

   a. **Objective**—Scale instance capacity so that it matches the desired load profile.

   b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.

   c. **State**—The current load, number of failed jobs, and number of active machines.

   d. **Action**—Remove, add, or keep the same number of instances.

   e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the `main()` function.

5. **Train the RL Model**—Use the SageMaker `RLEstimator` in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance. When you use SageMaker for training, you can select GPU or CPU

instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

The `RLEstimator` requires the following information as parameters.

a. The source directory where the environment, presets, and training code are uploaded.
b. The path to the training script.
c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.
d. The training parameters, such as the instance count, job name, and S3 path for output.
e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch,. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   > **Note**
   >
   > If you train in local mode, you can't visualize metrics in CloudWatch.

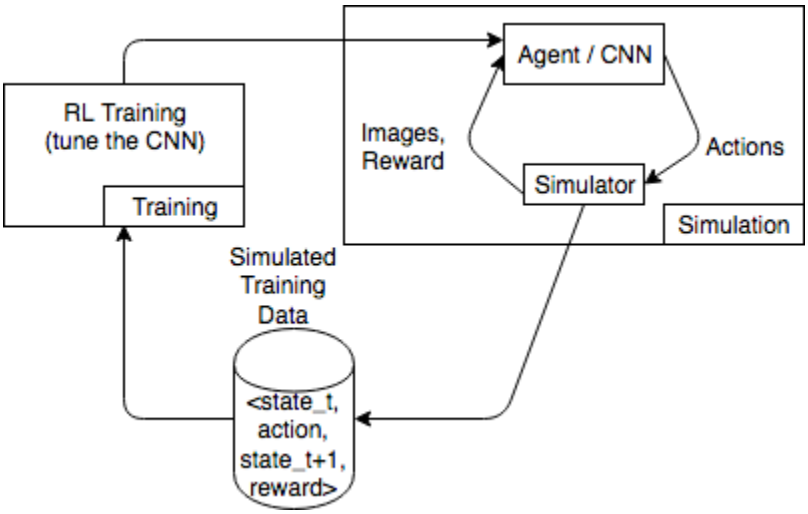
7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.
8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see Using RL with the SageMaker Python SDK.

RL Environments in Amazon SageMaker

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.



The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form `state_t`, `action`, `state_t+1`, and `reward_t+1`. Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

Topics

- Use OpenAI Gym Interface for Environments in SageMaker RL
- Use Open-Source Environments
- Use Commercial Environments

Use OpenAI Gym Interface for Environments in SageMaker RL

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see Gym Documentation.

- `env.action_space`—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- `env.observation_space`—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- `env.reset()`—Initializes a training episode. The `reset()` function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is

then sent to `step()` repeatedly until the episode reaches a terminal state. When `step()` returns `done = True`, the episode ends. The RL toolkit re-initializes the environment by calling `reset()`.

- `step()`—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an `info` dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- `env.render()`—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the `step()` function.

Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is light-weight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Run your local code as a SageMaker training job

You can run your local machine learning (ML) Python code as a large single-node Amazon SageMaker training job or as multiple parallel jobs. You can do this by annotating your code with an @remote decorator, as shown in the following code example. Distributed training (across multiple instances) are not supported with remote functions.

```
@remote(**settings)
def divide(x, y):
    return x / y
```

The SageMaker Python SDK will automatically translate your existing workspace environment and any associated data processing code and datasets into a SageMaker training job that runs on the SageMaker training platform. You can also activate a persistent cache feature, which will further reduce job start latency by caching previously downloaded dependency packages. This reduction in job latency is greater than the reduction in latency from using SageMaker managed warm pools alone. For more information, see Using persistent cache.

> **Note**
>
> Distributed training jobs are not supported by remote functions.

The following sections show how to annotate your local ML code with an @remote decorator and tailor your experience for your use case. This includes customizing your environment and integrating with SageMaker Experiments.

Topics

- Set up your environment
- Invoking a function

- Configuration file
- Customize your runtime environment
- Container image compatibility
- Logging parameters and metrics with Amazon SageMaker Experiments
- Using modular code with the @remote decorator
- Private repository for runtime dependencies
- Example notebooks

Set up your environment

Choose one of the following three options to set up your environment.

Run your code from Amazon SageMaker Studio Classic

You can annotate and run your local ML code from SageMaker Studio Classic by creating a SageMaker Notebook and attaching any image available on SageMaker Studio Classic image. The following instructions help you create a SageMaker Notebook, install the SageMaker Python SDK, and annotate your code with the decorator.

1. Create a SageMaker Notebook and attach an image in SageMaker Studio Classic as follows:
   a. Follow the instructions in Launch Amazon SageMaker Studio Classic in the *Amazon SageMaker Developer Guide*.
   b. Select **Studio** from the left navigation pane. This opens a new window.
   c. In the **Get Started** dialog box, select a user profile from the down arrow. This opens a new window.
   d. Select **Open Studio Classic**.
   e. Select **Open Launcher** from the main working area. This opens a new page.
   f. Select **Create notebook** from the main working area.
   g. Select **Base Python 3.0** from the down arrow next to **Image** in the **Change environment** dialog box.

      The @remote decorator automatically detects the image attached to the SageMaker Studio Classic notebook and uses it to run the SageMaker training job. If `image_uri` is specified either as an argument in the decorator or in the configuration file, then the value specified in `image_uri` will be used instead of the detected image.

For more information about how to create a notebook in SageMaker Studio Classic, see the **Create a Notebook from the File Menu** section in Create or Open an Amazon SageMaker Studio Classic Notebook.

For a list of available images, see Supported Docker images.

2. Install the SageMaker Python SDK.

   To annotate your code with the @remote function inside a SageMaker Studio Classic Notebook, you must have the SageMaker Python SDK installed. Install the SageMaker Python SDK, as shown in the following code example.

   ```
   !pip install sagemaker
   ```

3. Use @remote decorator to run functions in a SageMaker training job.

   To run your local ML code, first create a dependencies file to instruct SageMaker where to locate your local code. To do so, follow these steps:

   a. From the SageMaker Studio Classic Launcher main working area, in **Utilities and files**, choose **Text file**. This opens a new tab with a text file called `untitled.txt`.

      For more information about the SageMaker Studio Classic user interface (UI), see Amazon SageMaker Studio Classic UI Overview.

   b. Rename `untitled.txt` to `requirements.txt`.

   c. Add all the dependencies required for the code along with the SageMaker library to `requirements.txt`.

      A minimal code example for `requirements.txt` for the example `divide` function is provided in the following section, as follows.

      ```
      sagemaker
      ```

   d. Run your code with the remote decorator by passing the dependencies file, as follows.

      ```
      from sagemaker.remote_function import remote

      @remote(instance_type="ml.m5.xlarge", dependencies='./requirements.txt')
      def divide(x, y):
          return x / y
      ```

```
divide(2, 3.0)
```

For additional code examples, see the sample notebook quick_start.ipynb.

If you're already running a SageMaker Studio Classic notebook, and you install the Python SDK as instructed in **2. Install the SageMaker Python SDK**, you must restart your kernel. For more information, see Use the SageMaker Studio Classic Notebook Toolbar in the *Amazon SageMaker Developer Guide*.

Run your code from an Amazon SageMaker notebook

You can annotate your local ML code from a SageMaker notebook instance. The following instructions show how to create a notebook instance with a custom kernel, install the SageMaker Python SDK, and annotate your code with the decorator.

1. Create a notebook instance with a custom conda kernel.

   You can annotate your local ML code with an @remote decorator to use inside of a SageMaker training job. First you must create and customize a SageMaker notebook instance to use a kernel with Python version 3.7 or higher, up to 3.10.x. To do so, follow these steps:

   a. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/.

   b. In the left navigation panel, choose **Notebook** to expand its options.

   c. Choose **Notebook Instances** from the expanded options.

   d. Choose the **Create Notebook Instance** button. This opens a new page.

   e. For **Notebook instance name**, enter a name with a maximum of 63 characters and no spaces. Valid characters: **A-Z**, **a-z**, **0-9**, and **.:+=@ _%-** (hyphen).

   f. In the **Notebook instance settings** dialog box, expand the right arrow next to **Additional Configuration**.

   g. Under **Lifecycle configuration - optional**, expand the down arrow and select **Create a new lifecycle configuration**. This opens a new dialog box.

   h. Under **Name**, enter a name for your configuration setting.

   i. In the **Scripts** dialog box, in the **Start notebook** tab, replace the existing contents of the text box with the following script.

   ```
   #!/bin/bash
   ```

```
set -e

sudo -u ec2-user -i <<'EOF'
unset SUDO_UID
WORKING_DIR=/home/ec2-user/SageMaker/custom-miniconda/
source "$WORKING_DIR/miniconda/bin/activate"
for env in $WORKING_DIR/miniconda/envs/*; do
    BASENAME=$(basename "$env")
    source activate "$BASENAME"
    python -m ipykernel install --user --name "$BASENAME" --display-name "Custom
 ($BASENAME)"
done
EOF

echo "Restarting the Jupyter server.."
# restart command is dependent on current running Amazon Linux and JupyterLab
CURR_VERSION_AL=$(cat /etc/system-release)
CURR_VERSION_JS=$(jupyter --version)

if [[ $CURR_VERSION_JS == *$"jupyter_core     : 4.9.1"* ]] && [[ $CURR_VERSION_AL
 == *$" release 2018"* ]]; then
 sudo initctl restart jupyter-server --no-wait
else
 sudo systemctl --no-block restart jupyter-server.service
fi
```

j. In the **Scripts** dialog box, in the **Create notebook** tab, replace the existing contents of the text box with the following script.

```
#!/bin/bash

set -e

sudo -u ec2-user -i <<'EOF'
unset SUDO_UID
# Install a separate conda installation via Miniconda
WORKING_DIR=/home/ec2-user/SageMaker/custom-miniconda
mkdir -p "$WORKING_DIR"
wget https://repo.anaconda.com/miniconda/Miniconda3-4.6.14-Linux-x86_64.sh -O
 "$WORKING_DIR/miniconda.sh"
bash "$WORKING_DIR/miniconda.sh" -b -u -p "$WORKING_DIR/miniconda"
rm -rf "$WORKING_DIR/miniconda.sh"
# Create a custom conda environment
```

```
source "$WORKING_DIR/miniconda/bin/activate"
KERNEL_NAME="custom_python310"
PYTHON="3.10"
conda create --yes --name "$KERNEL_NAME" python="$PYTHON" pip
conda activate "$KERNEL_NAME"
pip install --quiet ipykernel
# Customize these lines as necessary to install the required packages
EOF
```

k. Choose the **Create configuration** button on the bottom right of the window.

l. Choose the **Create notebook instance** button on the bottom right of the window.

m. Wait for the notebook instance **Status** to change from **Pending** to **InService**.

2. Create a Jupyter notebook in the notebook instance.

   The following instructions show how to create a Jupyter notebook using Python 3.10 in your newly created SageMaker instance.

   a. After the notebook instance **Status** from the previous step is **InService**, do the following:

      i. Select **Open Jupyter** under **Actions** in the row containing your newly created notebook instance **Name**. This opens a new Jupyter server.

   b. In the Jupyter server, select **New** from the top right menu.

   c. From the down arrow, select **conda_custom_python310**. This creates a new Jupyter notebook that uses a Python 3.10 kernel. This new Jupyter notebook can now be used similarly to a local Jupyter notebook.

3. Install the SageMaker Python SDK.

   After your virtual environment is running, install the SageMaker Python SDK by using the following code example.

   ```
   !pip install sagemaker
   ```

4. Use an @remote decorator to run functions in a SageMaker training job.

   When you annotate your local ML code with an @remote decorator inside the SageMaker notebook, SageMaker training will automatically interpret the function of your code and run it as a SageMaker training job. Set up your notebook by doing the following:

   a. Select the kernel name in the notebook menu from the SageMaker notebook instance that you created in step 1, **Create a SageMaker Notebook instance with a custom kernel**.

For more information, see Change an Image or a Kernel.

b. From the down arrow, choose the a custom conda kernel that uses a version of Python that is 3.7 or higher.

As an example, selecting conda_custom_python310 chooses the kernel for Python 3.10.

c. Choose **Select**.

d. Wait for the kernel's status to show as idle, which indicates that the kernel has started.

e. In the Jupyter Server Home, select **New** from the top right menu.

f. Next to the down arrow, select **Text file**. This creates a new text file called untitled.txt.

g. Rename untitled.txt to requirements.txt and add any dependencies required for the code along with sagemaker.

h. Run your code with the remote decorator by passing the dependencies file as shown below.

```
from sagemaker.remote_function import remote

@remote(instance_type="ml.m5.xlarge", dependencies='./requirements.txt')
def divide(x, y):
    return x / y

divide(2, 3.0)
```

See the sample notebook quick_start.ipynb for additional code examples.

Run your code from within your local IDE

You can annotate your local ML code with an @remote decorator inside your preferred local IDE. The following steps show the necessary prerequisites, how to install the Python SDK, and how to annotate your code with the @remote decorator.

1. Install prerequisites by setting up the AWS Command Line Interface (AWS CLI) and creating a role, as follows:
   - Onboard to a SageMaker domain following the instructions in the **AWS CLI Prerequisites** section of Set Up Amazon SageMaker Prerequisites.
   - Create an IAM role following the **Create execution role** section of SageMaker Roles.
2. Create a virtual environment by using either PyCharm or conda and using Python version 3.7 or higher, up to 3.10.x.

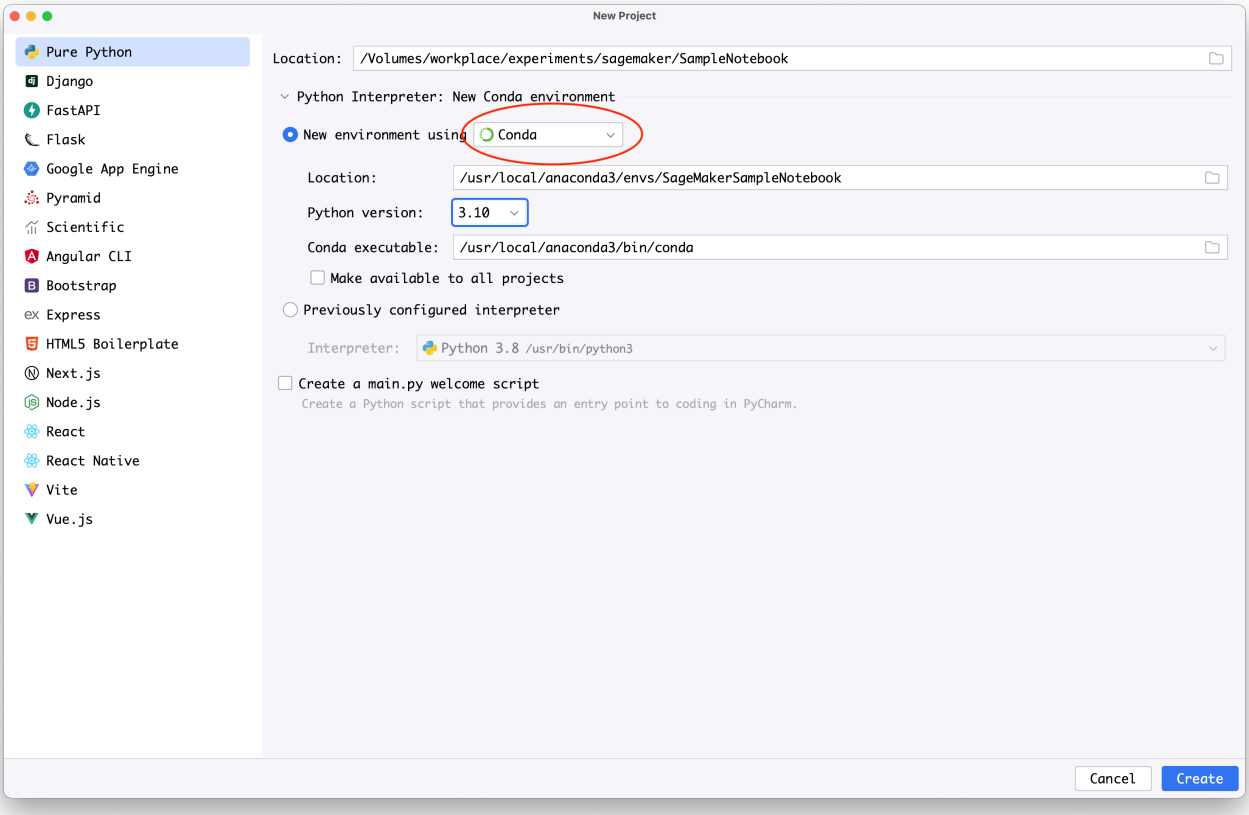
- Set up a virtual environment using PyCharm as follows:

  a. Select **File** from the main menu.

  b. Choose **New Project**.

  c. Choose **Conda** from the down arrow under **New environment using**.

  d. In the field for **Python version** use the down arrow to select a version of Python that is 3.7 or above. You can go up to 3.10.x from the list.



- If you have Anaconda installed, you can set up a virtual environment using conda, as follows:
  - Open an Anaconda prompt terminal interface.
  - Create and activate a new conda environment using a Python version of 3.7 or higher, up to 3.10x. The following code example shows how to create a conda environment using Python version 3.10.

```
conda create -n sagemaker_jobs_quick_start python=3.10 pip
conda activate sagemaker_jobs_quick_start
```

3. Install the SageMaker Python SDK.

To package your code from your preferred IDE, you must have a virtual environment set up using Python 3.7 or higher, up to 3.10x. You also need a compatible container image. Install the SageMaker Python SDK using the following code example.

```
pip install sagemaker
```

4. Wrap your code inside the @remote decorator. The SageMaker Python SDK will automatically interpret the function of your code and run it as a SageMaker training job. The following code examples show how to import the necessary libraries, set up a SageMaker session, and annotate a function with the @remote decorator.

   You can run your code by either providing the dependencies needed directly, or by using dependencies from the active `conda` environment.

   - To provide the dependencies directly, do the following:
     - Create a `requirements.txt` file in the working directory that the code resides in.
     - Add all of the dependencies required for the code along with the SageMaker library. The following section provides a minimal code example for `requirements.txt` for the example `divide` function.

       ```
       sagemaker
       ```

     - Run your code with the @remote decorator by passing the dependencies file. In the following code example, replace `The IAM role name` with an AWS Identity and Access Management (IAM) role ARN that you would like SageMaker to use to run your job.

       ```
       import boto3
       import sagemaker
       from sagemaker.remote_function import remote

       sm_session =
        sagemaker.Session(boto_session=boto3.session.Session(region_name="us-west-2"))
       settings = dict(
           sagemaker_session=sm_session,
           role=<The IAM role name>,
           instance_type="ml.m5.xlarge",
           dependencies='./requirements.txt'
       )

       @remote(**settings)
       ```

```
def divide(x, y):
    return x / y

if __name__ == "__main__":
    print(divide(2, 3.0))
```

- To use dependencies from the active conda environment, use the value `auto_capture` for the `dependencies` parameter, as shown in the following.

```
import boto3
import sagemaker
from sagemaker.remote_function import remote

sm_session = sagemaker.Session(boto_session=boto3.session.Session(region_name="us-west-2"))
settings = dict(
    sagemaker_session=sm_session,
    role=<The IAM role name>,
    instance_type="ml.m5.xlarge",
    dependencies="auto_capture"
)

@remote(**settings)
def divide(x, y):
    return x / y

if __name__ == "__main__":
    print(divide(2, 3.0))
```

> **Note**
>
> You can also implement the previous code inside a Jupyter notebook. PyCharm Professional Edition supports Jupyter natively. For more guidance, see Jupyter notebook support in PyCharm's documentation.

Invoking a function

To invoke a function inside the @remote decorator, use either of the following methods:

- Use an @remote decorator to invoke a function.
- Use the `RemoteExecutor` API to invoke a function.

If you use the @remote decorator method to invoke a function, the training job will wait for the function to complete before starting a new task. However, if you use the `RemoteExecutor` API, you can run more than one job in parallel. The following sections show both ways of invoking a function.

Use an @remote decorator to invoke a function

You can use the @remote decorator to annotate a function. SageMaker will transform the code inside the decorator into a SageMaker training job. The training job will then invoke the function inside the decorator and wait for the job to complete. The following code example shows how to import the required libraries, start a SageMaker instance, and annotate a matrix multiplication with the @remote decorator.

```
from sagemaker.remote_function import remote
import numpy as np

@remote(instance_type="ml.m5.large")
def matrix_multiply(a, b):
    return np.matmul(a, b)

a = np.array([[1, 0],
              [0, 1]])
b = np.array([1, 2])

assert (matrix_multiply(a, b) == np.array([1,2])).all()
```

The decorator is defined as follows.

```
def remote(
    *,
    **kwarg):
        ...
```

When you invoke a decorated function, SageMaker Python SDK loads any exceptions raised by an error into local memory. In the following code example, the first call to the divide function completes successfully and the result is loaded into local memory. In the second call to the divide function, the code returns an error and this error is loaded into local memory.

```
from sagemaker.remote_function import remote
import pytest

@remote()
def divide(a, b):
    return a/b

# the underlying job is completed successfully
# and the function return is loaded
assert divide(10, 5) == 2

# the underlying job fails with "AlgorithmError"
# and the function exception is loaded into local memory
with pytest.raises(ZeroDivisionError):
    divide(10, 0)
```

Note

The decorated function is run as a remote job. If the thread is interrupted, the underlying job will not be stopped.

How to change the value of a local variable

The decorator function is run on a remote machine. Changing a non-local variable or input arguments inside a decorated function will not change the local value.

In the following code example, a list and a dict are appended inside the decorator function. This does not change when the decorator function is invoked.

```
a = []

@remote
def func():
    a.append(1)

# when func is invoked, a in the local memory is not modified
func()
func()

# a stays as []
```

```
a = {}
@remote
def func(a):
    # append new values to the input dictionary
    a["key-2"] = "value-2"

a = {"key": "value"}
func(a)

# a stays as {"key": "value"}
```

To change the value of a local variable declared inside of a decorator function, return the variable from the function. The following code example shows that the value of a local variable is changed when it is returned from the function.

```
a = {"key-1": "value-1"}

@remote
def func(a):
    a["key-2"] = "value-2"
    return a

a = func(a)

-> {"key-1": "value-1", "key-2": "value-2"}
```

Data serialization and deserialization

When you invoke a remote function, SageMaker automatically serializes your function arguments during the input and output stages. Function arguments and returns are serialized using cloudpickle. SageMaker supports serializing the following Python objects and functions.

- Built-in Python objects including dicts, lists, floats, ints, strings, boolean values and tuples
- Numpy arrays
- Pandas Dataframes
- Scikit-learn datasets and estimators
- PyTorch models
- TensorFlow models
- The Booster class for XGBoost

The following can be used with some limitations.

- Dask DataFrames
- The XGBoost Dmatrix class
- TensorFlow datasets and subclasses
- PyTorch models

The following section contains best practices for using the previous Python classes with some limitations in your remote function, information about where SageMaker stores your serialized data and how to manage access to it.

Best practices for Python classes with limited support for remote data serialization

You can use the Python classes listed in this section with limitations. The next sections discuss best practices for how to use the following Python classes.

- Dask DataFrames
- The XGBoost DMatric class
- TensorFlow datasets and subclasses
- PyTorch models

Best practices for Dask

Dask is an open-source library used for parallel computing in Python. This section shows the following.

- How to pass a Dask DataFrame into your remote function
- How to convert summary statistics from a Dask DataFrame into a Pandas DataFrame

How to pass a Dask DataFrame into your remote function

Dask DataFrames are often used to process large datasets because they can hold datasets that require more memory than is available. This is because a Dask DataFrame does not load your local data into memory. If you pass a Dask DataFrame as a function argument to your remote function, Dask may pass a reference to the data in your local disk or cloud storage, instead of the data itself. The following code shows an example of passing a Dask DataFrame inside your remote function that will operate on an empty DataFrame.

```
#Do not pass a Dask DataFrame  to your remote function as follows
def clean(df: dask.DataFrame ):
    cleaned = df[] \ ...
```

Dask will load the data from the Dask DataFrame into memory only when you use the DataFrame . If you want to use a Dask DataFrame inside a remote function, provide the path to the data . Then Dask will read the dataset directly from the data path that you specify when the code runs.

The following code example shows how to use a Dask DataFrame inside the remote function `clean`. In the code example, `raw_data_path` is passed to clean instead of the Dask DataFrame. When the code runs, the dataset is read directly from the location of an Amazon S3 bucket specified in `raw_data_path`. Then the `persist` function keeps the dataset in memory to facilitate the subsequent `random_split` function and written back to the output data path in an S3 bucket using Dask DataFrame API functions.

```
import dask.dataframe as dd

@remote(
   instance_type='ml.m5.24xlarge',
   volume_size=300,
   keep_alive_period_in_seconds=600)
#pass the data path to your remote function rather than the Dask DataFrame  itself
def clean(raw_data_path: str, output_data_path: str: split_ratio: list[float]):
    df = dd.read_parquet(raw_data_path) #pass the path to your DataFrame
    cleaned = df[(df.column_a >= 1) & (df.column_a < 5)]\
        .drop(['column_b', 'column_c'], axis=1)\
        .persist() #keep the data in memory to facilitate the following random_split
 operation

    train_df, test_df = cleaned.random_split(split_ratio, random_state=10)

    train_df.to_parquet(os.path.join(output_data_path, 'train')
    test_df.to_parquet(os.path.join(output_data_path, 'test'))

clean("s3://my-bucket/raw/", "s3://my-bucket/cleaned/", split_ratio=[0.7, 0.3])
```

How to convert summary statistics from a Dask DataFrame into a Pandas DataFrame

Summary statistics from a Dask DataFrame can be converted into a Pandas DataFrame by invoking the `compute` method as shown in the following example code. In the example, the S3 bucket

contains a large Dask DataFrame that cannot fit into memory or into a Pandas dataframe. In the following example, a remote function scans the data set and returns a Dask DataFrame containing the output statistics from `describe` to a Pandas DataFrame.

```
executor = RemoteExecutor(
    instance_type='ml.m5.24xlarge',
    volume_size=300,
    keep_alive_period_in_seconds=600)

future = executor.submit(lambda: dd.read_parquet("s3://my-bucket/
raw/").describe().compute())

future.result()
```

Best practices for the XGBoost DMatric class

DMatrix is an internal data structure used by XGBoost to load data. A DMatrix object can't be pickled in order to move easily between compute sessions. Directly passing DMatrix instances will fail with a `SerializationError`.

How to pass a data object to your remote function and train with XGBoost

To convert a Pandas DataFrame into a DMatrix instance and use it for training in your remote function, pass it directly to the remote function as shown in the following code example.

```
import xgboost as xgb

@remote
def train(df, params):
    #Convert a pandas dataframe into a DMatrix DataFrame and use it for training
    dtrain = DMatrix(df)
    return xgb.train(dtrain, params)
```

Best practices for TensorFlow datasets and sub-classes

TensorFlow datasets and subclasses are internal objects used by TensorFlow to load data during training. TensorFlow datasets and subclasses can't be pickled in order to move easily between compute sessions. Directly passing Tensorflow datasets or subclasses will fail with a `SerializationError`. Use the Tensorflow I/O APIs to load data from the storage, as shown in the following code example.

```
import tensorflow as tf
import tensorflow_io as tfio

@remote
def train(data_path: str, params):

    dataset = tf.data.TextLineDataset(tf.data.Dataset.list_files(f"{data_path}/*.txt"))
    ...

train("s3://my-bucket/data", {})
```

Best practices for PyTorch models

PyTorch models are serializable and can be passed between your local environment and remote function. If your local environment and remote environment have different device types, such as (GPUs and CPUs), you cannot return a trained model to your local environment. For example, if the following code is developed in a local environment without GPUs but run in an instance with GPUs, returning the trained model directly will lead to a `DeserializationError`.

```
# Do not return a model trained on GPUs to a CPU-only environment as follows

@remote(instance_type='ml.g4dn.xlarge')
def train(...):
    if torch.cuda.is_available():
        device = torch.device("cuda")
    else:
        device = torch.device("cpu") # a device without GPU capabilities

    model = Net().to(device)

    # train the model
    ...

    return model

model = train(...) #returns a DeserializationError if run on a device with GPU
```

To return a model trained in a GPU environment to one that contains only CPU capabilities, use the PyTorch model I/O APIs directly as shown in the code example below.

```
import s3fs
```

```
model_path = "s3://my-bucket/folder/"

@remote(instance_type='ml.g4dn.xlarge')
def train(...):
    if torch.cuda.is_available():
        device = torch.device("cuda")
    else:
        device = torch.device("cpu")

    model = Net().to(device)

    # train the model
    ...

    fs = s3fs.FileSystem()
    with fs.open(os.path.join(model_path, 'model.pt'), 'wb') as file:
        torch.save(model.state_dict(), file) #this writes the model in a device-
agnostic way (CPU vs GPU)

train(...) #use the model to train on either CPUs or GPUs

model = Net()
fs = s3fs.FileSystem()with fs.open(os.path.join(model_path, 'model.pt'), 'rb') as file:
    model.load_state_dict(torch.load(file, map_location=torch.device('cpu')))
```

Where SageMaker stores your serialized data

When you invoke a remote function, SageMaker automatically serializes your function arguments and return values during the input and output stages. This serialized data is stored under a root directory in your S3 bucket. You specify the root directory, `<s3_root_uri>`, in a configuration file. The parameter `job_name` is automatically generated for you.

Under the root directory, SageMaker creates a `<job_name>` folder, which holds your current work directory, serialized function, the arguments for your serialized function, results and any exceptions that arose from invoking the serialized function.

Under `<job_name>`, the directory `workdir` contains a zipped archive of your current working directory. The zipped archive includes any Python files in your working directory and the `requirements.txt` file, which specifies any dependencies needed to run your remote function.

The following is an example of the folder structure under an S3 bucket that you specify in your configuration file.

```
<s3_root_uri>/ # specified by s3_root_uri or S3RootUri
    <job_name>/ #automatically generated for you
        workdir/workspace.zip # archive of the current working directory (workdir)
        function/ # serialized function
        arguments/ # serialized function arguments
        results/ # returned output from the serialized function including the model
        exception/ # any exceptions from invoking the serialized function
```

The root directory that you specify in your S3 bucket is not meant for long term storage. The serialized data are tightly tied to the Python version and machine learning (ML) framework version that were used during serialization. If you upgrade the Python version or ML framework, you may not be able to use your serialized data. Instead, do the following.

- Store your model and model artifacts in a format that is agnostic to your Python version and ML framework.
- If you upgrade your Python or ML framework, access your model results from your long-term storage.

Important

To delete your serialized data after a specified amount of time, set a lifetime configuration on your S3 bucket.

Note

Files that are serialized with the Python pickle module can be less portable than other data formats including CSV, Parquet and JSON. Be wary of loading pickled files from unknown sources.

For more information about what to include in a configuration file for a remote function, see Configuration File.

Access to your serialized data

Administrators can provide settings for your serialized data, including its location and any encryption settings in a configuration file. By default, the serialized data are encrypted with an AWS Key Management Service (AWS KMS) Key. Administrators can also restrict access to the root directory that you specify in your configuration file with a bucket policy. The configuration file can be shared and used across projects and jobs. For more information, see Configuration File.

Use the `RemoteExecutor` API to invoke a function

You can use the `RemoteExecutor` API to invoke a function. SageMaker Python SDK will transform the code inside the `RemoteExecutor` call into a SageMaker training job. The training job will then invoke the function as an asynchronous operation and return a future. If you use the `RemoteExecutor` API, you can run more than one training job in parallel. For more information about futures in Python, see Futures.

The following code example shows how to import the required libraries, define a function, start a SageMaker instance, and use the API to submit a request to run 2 jobs in parallel.

```
from sagemaker.remote_function import RemoteExecutor

def matrix_multiply(a, b):
    return np.matmul(a, b)

a = np.array([[1, 0],
              [0, 1]])
b = np.array([1, 2])

with RemoteExecutor(max_parallel_job=2, instance_type="ml.m5.large") as e:
    future = e.submit(matrix_multiply, a, b)

assert (future.result() == np.array([1,2])).all()
```

The `RemoteExecutor` class is an implementation of the concurrent.futures.Executor library.

The following code example shows how to define a function and call it using the `RemoteExecutorAPI`. In this example, the `RemoteExecutor` will submit 4 jobs in total, but only 2 in parallel. The last two jobs will reuse the clusters with minimal overhead.

```
from sagemaker.remote_function.client import RemoteExecutor
```

```
def divide(a, b):
    return a/b

with RemoteExecutor(max_parallel_job=2, keep_alive_period_in_seconds=60) as e:
    futures = [e.submit(divide, a, 2) for a in [3, 5, 7, 9]]

for future in futures:
    print(future.result())
```

The `max_parallel_job` parameter only serves as a rate limiting mechanism without optimizing compute resource allocation. In the previous code example, `RemoteExecutor` doesn't reserve compute resources for the two parallel jobs before any jobs are submitted. For more information about `max_parallel_job` or other parameters for the @remote decorator, see Remote function classes and methods specification.

Future class for the `RemoteExecutor` API

A future class is a public class that represents the return function from the training job when it is invoked asynchronously. The future class implements the concurrent.futures.Future class. This class can be used to do operations on the underlying job and load data into memory.

Configuration file

The Amazon SageMaker Python SDK supports setting of default values for AWS infrastructure primitive types. After administrators configure these defaults, they are automatically passed when SageMaker Python SDK calls supported APIs. The arguments for the decorator function can be put inside of configuration files. This is so that you can separate settings that are related to the infrastructure from the code base. For more information about parameters and arguments for the remote function and methods, see Remote function classes and methods specification.

You can set infrastructure settings for the network configuration, IAM roles, Amazon S3 folder for input, output data, and tags inside the configuration file. The configuration file can be used when invoking a function using either the @remote decorator or the `RemoteExecutor` API.

An example configuration file that defines the dependencies, resources, and other arguments follows. This example configuration file is used to invoke a function that is initiated either using the @remote decorator or the RemoteExecutor API.

```
SchemaVersion: '1.0'
SageMaker:
```

```
  PythonSDK:
    Modules:
      RemoteFunction:
        Dependencies: 'path/to/requirements.txt'
        EnableInterContainerTrafficEncryption: true
        EnvironmentVariables: {'EnvVarKey': 'EnvVarValue'}
        ImageUri: '366666666666.dkr.ecr.us-west-2.amazonaws.com/my-image:latest'
        IncludeLocalWorkDir: true
        CustomFileFilter:
          IgnoreNamePatterns:
          - "*.ipynb"
          - "data"
        InstanceType: 'ml.m5.large'
        JobCondaEnvironment: 'your_conda_env'
        PreExecutionCommands:
            - 'command_1'
            - 'command_2'
        PreExecutionScript: 'path/to/script.sh'
        RoleArn: 'arn:aws:iam::366666666666:role/MyRole'
        S3KmsKeyId: 'yourkmskeyid'
        S3RootUri: 's3://my-bucket/my-project'
        VpcConfig:
            SecurityGroupIds:
            - 'sg123'
            Subnets:
            - 'subnet-1234'
        Tags: [{'Key': 'yourTagKey', 'Value':'yourTagValue'}]
        VolumeKmsKeyId: 'yourkmskeyid'
```

The @remote decorator and `RemoteExecutor` will look for `Dependencies` in the following configuration files:

- An admin-defined configuration file.
- A user-defined configuration file.

The default locations for these configuration files depend on, and are relative to, your environment. The following code example returns the default location of your admin and user configuration files. These commands must be run in the same environment where you're using the SageMaker Python SDK.

```
import os
```

```
from platformdirs import site_config_dir, user_config_dir

#Prints the location of the admin config file
print(os.path.join(site_config_dir("sagemaker"), "config.yaml"))

#Prints the location of the user config file
print(os.path.join(user_config_dir("sagemaker"), "config.yaml"))
```

You can override the default locations of these files by setting the `SAGEMAKER_ADMIN_CONFIG_OVERRIDE` and `SAGEMAKER_USER_CONFIG_OVERRIDE` environment variables for the admin-defined and user-defined configuration file paths, respectively.

If a key exists in both the admin-defined and user-defined configuration files, the value in the user-defined file will be used.

Customize your runtime environment

You can customize your runtime environment to use your preferred local integrated development environments (IDEs), SageMaker notebooks, or SageMaker Studio Classic notebooks to write your ML code. SageMaker will help package and submit your functions and its dependencies as a SageMaker training job. This allows you to access the capacity of the SageMaker training server to run your training jobs.

Both the remote decorator and the `RemoteExecutor` methods to invoke a function allow users to define and customize their runtime environment. You can use either a `requirements.txt` file or a conda environment YAML file.

To customize a runtime environment using both a conda environment YAML file and a `requirements.txt` file, refer to the following code example.

```
# specify a conda environment inside a yaml file
@remote(instance_type="ml.m5.large",
        image_uri = "my_base_python:latest",
        dependencies = "./environment.yml")
def matrix_multiply(a, b):
    return np.matmul(a, b)

# use a requirements.txt file to import dependencies
@remote(instance_type="ml.m5.large",
        image_uri = "my_base_python:latest",
        dependencies = './requirements.txt')
def matrix_multiply(a, b):
```

```
    return np.matmul(a, b)
```

Alternatively, you can set `dependencies` to `auto_capture` to let the SageMaker Python SDK capture the installed dependencies in the active conda environment. The following are required for `auto_capture` to work reliably:

- You must have an active conda environment. We recommend not using the `base` conda environment for remote jobs so that you can reduce potential dependency conflicts. Not using the `base` conda environment also allows for faster environment setup in the remote job.
- You must not have any dependencies installed using pip with a value for the parameter `--extra-index-url`.
- You must not have any dependency conflicts between packages installed with conda and packages installed with pip in the local development environment.
- Your local development environment must not contain operating system-specific dependencies that are not compatible with Linux.

In case `auto_capture` does not work, we recommend that you pass in your dependencies as a requirement.txt or conda environment.yaml file, as described in the first coding example in this section.

Container image compatibility

The following table shows a list of SageMaker training images that are compatible with the @remote decorator.

Name	Python Version	Image URI - CPU	Image URI - GPU
Data Science	3.7(py37)	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.

Name	Python Version	Image URI - CPU	Image URI - GPU
Data Science 2.0	3.8(py38)	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.
Data Science 3.0	3.10(py310)	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.
Base Python 2.0	3.8(py38)	Python SDK selects this image when it detects that development environment is using Python 3.8 runtime. Otherwise Python SDK automatic ally selects this image when used as SageMaker Studio Classic Notebook kernel image	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Classic Notebook kernel image.

Name	Python Version	Image URI - CPU	Image URI - GPU
Base Python 3.0	3.10(py310)	Python SDK selects this image when it detects that development environment is using Python 3.8 runtime. Otherwise Python SDK automatic ally selects this image when used as SageMaker Studio Classic Notebook kernel image	For SageMaker Studio Classic Notebooks only. Python SDK automatically selects the image URI when used as Studio Classic Notebook kernel image.
DLC-TensorFlow 2.12.0 for SageMaker Training	3.10(py310)	763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.12.0-cpu-py310-ubuntu20.04-sagemaker	763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.12.0-gpu-py310-cu118-ubuntu20.04-sagemaker

Note

To run jobs locally using AWS Deep Learning Containers (DLC) images, use the image URIs found in the DLC documentation. The DLC images do not support the `auto_capture` value for dependencies.
Jobs with SageMaker Distribution in SageMaker Studio run in a container as a non-root user named `sagemaker-user`. This user needs full permission to access `/opt/ml` and `/tmp`. Grant this permission by adding `sudo chmod -R 777 /opt/ml /tmp` to the `pre_execution_commands` list, as shown in the following snippet:

```
@remote(pre_execution_commands=["sudo chmod -R 777 /opt/ml /tmp"])
def func():
    pass
```

You can also run remote functions with your custom images. For compatibility with remote functions, custom images should be built with Python version 3.7.x-3.10.x. The following is a minimal Dockerfile example showing you how to use a Docker image with Python 3.10.

```
FROM python:3.10
```

```
#... Rest of the Dockerfile
```

To create conda environments in your image and use it to run jobs, set the environment variable SAGEMAKER_JOB_CONDA_ENV to the conda environment name. If your image has the SAGEMAKER_JOB_CONDA_ENV value set, the remote function cannot create a new conda environment during the training job runtime. Refer to the following Dockerfile example that uses a conda environment with Python version 3.10.

```
FROM continuumio/miniconda3:4.12.0

ENV SHELL=/bin/bash \
    CONDA_DIR=/opt/conda \
    SAGEMAKER_JOB_CONDA_ENV=sagemaker-job-env

RUN conda create -n $SAGEMAKER_JOB_CONDA_ENV \
   && conda install -n $SAGEMAKER_JOB_CONDA_ENV python=3.10 -y \
   && conda clean --all -f -y \
```

For SageMaker to use mamba to manage your Python virtual environment in the container image, install the mamba toolkit from miniforge. To use mamba, add the following code example to your Dockerfile. Then, SageMaker will detect the mamba availability at runtime and use it instead of conda.

```
#Mamba Installation
RUN curl -L -O "https://github.com/conda-forge/miniforge/releases/latest/download/
Mambaforge-Linux-x86_64.sh" \
    && bash Mambaforge-Linux-x86_64.sh -b -p "/opt/conda"  \
    && /opt/conda/bin/conda init bash
```

Using a custom conda channel on an Amazon S3 bucket is not compatible with mamba when using a remote function. If you choose to use mamba, make sure you are not using a custom conda channel on Amazon S3. For more information, see the **Prerequisites** section under **Custom conda repository using Amazon S3**.

The following is a complete Dockerfile example showing how to create a compatible Docker image.

```
FROM python:3.10

RUN apt-get update -y \
    # Needed for awscli to work
```

```
    # See: https://github.com/aws/aws-cli/issues/1957#issuecomment-687455928
    && apt-get install -y groff unzip curl \
    && pip install --upgrade \
        'boto3>1.0<2' \
        'awscli>1.0<2' \
        'ipykernel>6.0.0<7.0.0' \
#Use ipykernel with --sys-prefix flag, so that the absolute path to
    #/usr/local/share/jupyter/kernels/python3/kernel.json python is used
    # in kernelspec.json file
    && python -m ipykernel install --sys-prefix

#Install Mamba
RUN curl -L -O "https://github.com/conda-forge/miniforge/releases/latest/download/
Mambaforge-Linux-x86_64.sh" \
    && bash Mambaforge-Linux-x86_64.sh -b -p "/opt/conda"  \
    && /opt/conda/bin/conda init bash

#cleanup
RUN apt-get clean \
    && rm -rf /var/lib/apt/lists/* \
    && rm -rf ${HOME}/.cache/pip \
    && rm Mambaforge-Linux-x86_64.sh

ENV SHELL=/bin/bash \
    PATH=$PATH:/opt/conda/bin
```

The resulting image from running the previous Dockerfile example can also be used as a SageMaker Studio Classic kernel image.

Logging parameters and metrics with Amazon SageMaker Experiments

This guide show how to log parameters and metrics with Amazon SageMaker Experiments. A SageMaker experiment consists of runs, and each run consists of all the inputs, parameters, configurations and results for a single model training interaction.

You can log parameters and metrics from a remote function using either the @remote decorator or the `RemoteExecutor` API.

To log parameters and metrics from a remote function, choose one of the following methods:

- Instantiate a SageMaker experiment run inside a remote function using Run from the SageMaker Experiments library. For more information, see Create an Amazon SageMaker Experiment.

- Use the `load_run` function inside a remote function from the SageMaker Experiments library. This will load a Run instance that is declared outside of the remote function.

The following sections show how to create and track lineage with SageMaker experiment runs by using the previous listed methods. The sections also describe cases that are not supported by SageMaker training.

Use the @remote decorator to integrate with SageMaker Experiments

You can either instantiate an experiment in SageMaker, or load a current SageMaker experiment from inside a remote function. The following sections show you show to use either method.

Create an experiment with SageMaker Experiments

You can create an experiment run in SageMaker experiment. To do this you pass your experiment name, run name, and other parameters into your remote function.

The following code example imports the name of your experiment, the name of the run, and the parameters to log during each run. The parameters `param_1` and `param_2` are logged over time inside a training loop. Common parameters may include batch size or epochs. In this example, the metrics `metric_a` and `metric_b` are logged for a run over time inside a training loop. Other common metrics may include `accuracy` or `loss`.

```
from sagemaker.remote_function import remote
from sagemaker.experiments.run import Run

# Define your remote function
@remote
def train(value_1, value_2, exp_name, run_name):
    ...
    ...
    #Creates the experiment
    with Run(
        experiment_name=exp_name,
        run_name=run_name,
    ) as run:
        ...
        #Define values for the parameters to log
        run.log_parameter("param_1", value_1)
        run.log_parameter("param_2", value_2)
        ...
```

```
        #Define metrics to log
        run.log_metric("metric_a", 0.5)
        run.log_metric("metric_b", 0.1)

# Invoke your remote function
train(1.0, 2.0, "my-exp-name", "my-run-name")
```

Load current SageMaker Experiments with a job initiated by the @remote decorator

Use the `load_run()` function from the SageMaker Experiments library to load the current run object from the run context. You can also use the `load_run()` function within your remote function. Load the run object initialized locally by the `with` statement on the run object as shown in the following code example.

```
from sagemaker.experiments.run import Run, load_run

# Define your remote function
@remote
def train(value_1, value_2):
    ...
    ...
    with load_run() as run:
        run.log_metric("metric_a", value_1)
        run.log_metric("metric_b", value_2)

# Invoke your remote function
with Run(
    experiment_name="my-exp-name",
    run_name="my-run-name",
) as run:
    train(0.5, 1.0)
```

Load a current experiment run within a job initiated with the `RemoteExecutor` API

You can also load a current SageMaker experiment run if your jobs were initiated with the `RemoteExecutor` API. The following code example shows how to use `RemoteExecutor` API with the SageMaker Experiments `load_run` function. You do this to load a current SageMaker experiment run and capture metrics in the job submitted by `RemoteExecutor`.

```
from sagemaker.experiments.run import Run, load_run

def square(x):
    with load_run() as run:
        result = x * x
        run.log_metric("result", result)
    return result

with RemoteExecutor(
    max_parallel_job=2,
    instance_type="ml.m5.large"
) as e:
    with Run(
        experiment_name="my-exp-name",
        run_name="my-run-name",
    ):
        future_1 = e.submit(square, 2)
```

Unsupported uses for SageMaker Experiments while annotating your code with an @remote decorator

SageMaker does not support passing a Run type object to an @remote function or using global Run objects. The following examples show code that will throw a `SerializationError`.

The following code example attempts to pass a Run type object to an @remote decorator, and it generates an error.

```
@remote
def func(run: Run):
    run.log_metrics("metric_a", 1.0)

with Run(...) as run:
    func(run) ---> SerializationError caused by NotImplementedError
```

The following code example attempts to use a global `run` object instantiated outside of the remote function. In the code example, the `train()` function is defined inside the `with Run` context, referencing a global run object from within. When `train()` is called, it generates an error.

```
with Run(...) as run:
    @remote
```

```
    def train(metric_1, value_1, metric_2, value_2):
        run.log_parameter(metric_1, value_1)
        run.log_parameter(metric_2, value_2)

    train("p1", 1.0, "p2", 0.5) ---> SerializationError caused by NotImplementedError
```

Using modular code with the @remote decorator

You can organize your code into modules for ease of workspace management during development and still use the @remote function to invoke a function. You can also replicate the local modules from your development environment to the remote job environment. To do so, set the parameter `include_local_workdir` to `True`, as shown in the following code example.

```
@remote(
  include_local_workdir=True,
)
```

> **Note**
>
> The @remote decorator and parameter must appear in the main file, rather than in any of the dependent files.

When `include_local_workdir` is set to `True`, SageMaker packages all of the Python scripts while maintaining the directory structure in the process' current directory. It also makes the dependencies available in the job's working directory.

For example, suppose your Python script which processes the MNIST dataset is divided into a `main.py` script and a dependent `pytorch_mnist.py` script. `main.py` calls the dependent script. Also, the `main.py` script contains code to import the dependency as shown.

```
from mnist_impl.pytorch_mnist import ...
```

The `main.py` file must also contain the `@remote` decorator, and it must set the `include_local_workdir` parameter to `True`.

The `include_local_workdir` parameter by default includes all the Python scripts in the directory. You can customize which files you want to upload to the job by using this parameter in

conjunction with the `custom_file_filter` parameter. You can either pass a function that filters job dependencies to be uploaded to S3, or a `CustomFileFilter` object that specifies the local directories and files to ignore in the remote function. You can use `custom_file_filter` only if `include_local_workdir` is set to `True`—otherwise the parameter is ignored.

The following example uses `CustomFileFilter` to ignore all notebook files and folders or files named `data` when uploading files to S3.

```
@remote(
   include_local_workdir=True,
   custom_file_filter=CustomFileFilter(
      ignore_pattern_names=[ # files or directories to ignore
        "*.ipynb", # all notebook files
        "data", # folter or file named data
      ]
   )
)
```

The following example demonstrates how you can package an entire workspace.

```
@remote(
   include_local_workdir=True,
   custom_file_filter=CustomFileFilter(
      ignore_pattern_names=[] # package whole workspace
   )
)
```

The following example shows how you can use a function to filter files.

```
import os

def my_filter(path: str, files: List[str]) -> List[str]:
    to_ignore = []
   for file in files:
       if file.endswith(".txt") or file.endswith(".ipynb"):
           to_ignore.append(file)
   return to_ignore

@remote(
   include_local_workdir=True,
   custom_file_filter=my_filter
```

```
)
```

Best practices in structuring your working directory

The following best practices suggest how you can organize your directory structure while using the `@remote` decorator in your modular code.

- Put the @remote decorator in a file that resides at the root level directory of the workspace.
- Structure the local modules at the root level.

The following example image shows the recommended directory structure. In this example structure, the `main.py` script is located at the root level directory.

```
.
### config.yaml
### data/
### main.py <----------------- @remote used here
### mnist_impl
# ### __pycache__/
# # ### pytorch_mnist.cpython-310.pyc
# ### pytorch_mnist.py <-------- dependency of main.py
### requirements.txt
```

The following example image shows a directory structure that will result in inconsistent behavior when it is used to annotate your code with an @remote decorator.

In this example structure, the `main.py` script that contains the @remote decorator is **not** located at the root level directory. The following structure is **NOT** recommended.

```
.
### config.yaml
### entrypoint
# ### data
# ### main.py <----------------- @remote used here
### mnist_impl
# ### __pycache__
# # ### pytorch_mnist.cpython-310.pyc
# ### pytorch_mnist.py <-------- dependency of main.py
### requirements.txt
```

Private repository for runtime dependencies

You can use pre-execution commands or script to configure a dependency manager like pip or conda in your job environment. To achieve network isolation, use either of these options to redirect your dependency managers to access your private repositories and run remote functions within a VPC. The pre-execution commands or script will run before your remote function runs. You can define them with the @remote decorator, the `RemoteExecutor` API, or within a configuration file.

The following sections show you how to access a private Python Package Index (PyPI) repository managed with AWS CodeArtifact. The sections also show how to access a custom conda channel hosted on Amazon Simple Storage Service (Amazon S3).

How to use a custom PyPI repository managed with AWS CodeArtifact

To use CodeArtifact to manage a custom PyPI repository, the following prerequisites are required:

- Your private PyPI repository should already have been created. You can utilize AWS CodeArtifact to create and manage your private package repositories. To learn more about CodeArtifact, see the CodeArtifact User Guide.
- Your VPC should have access to your CodeArtifact repository. To allow a connection from your VPC to your CodeArtifact repository, you must do the following:
  - Create VPC endpoints for CodeArtifact.
  - Create an Amazon S3 gateway endpoint for your VPC, which allows CodeArtifact to store package assets.

The following pre-execution command example shows how to configure pip in the SageMaker training job to point to your CodeArtifact repository. For more information, see Configure and use pip with CodeArtifact.

```
# use a requirements.txt file to import dependencies
@remote(
    instance_type="ml.m5.large"
    image_uri = "my_base_python:latest",
    dependencies = './requirements.txt',
    pre_execution_commands=[
        "aws codeartifact login --tool pip --domain my-org --domain-owner
 <000000000000> --repository my-codeartifact-python-repo --endpoint-url https://vpce-
xxxxx.api.codeartifact.us-east-1.vpce.amazonaws.com"
```

```
    ]
)
def matrix_multiply(a, b):
    return np.matmul(a, b)
```

How to use a custom conda channel hosted on Amazon S3

To use Amazon S3 to manage a custom conda repository, the following prerequisites are required:

- Your private conda channel must already be set up in your Amazon S3 bucket, and all dependent packages must be indexed and uploaded to your Amazon S3 bucket. For instructions on how to index your conda packages, see Creating custom channels.
- Your VPC should have access to the Amazon S3 bucket. For more information, see Endpoints for Amazon S3.
- The base conda environment in your job image should have `boto3` installed. To check your environment, enter the following in your Anaconda prompt to check that `boto3` appears in the resulting generated list.

  ```
  conda list -n base
  ```

- You job image should be installed with conda, not mamba. To check your environment, ensure that the previous code prompt does not return `mamba`.

The following pre-execution commands example shows how to configure conda in the SageMaker training job to point to your private channel on Amazon S3 The pre-execution commands removes the defaults channel and adds custom channels to a `.condarc` conda configuration file.

```
# specify your dependencies inside a conda yaml file
@remote(
    instance_type="ml.m5.large"
    image_uri = "my_base_python:latest",
    dependencies = "./environment.yml",
    pre_execution_commands=[
        "conda config --remove channels 'defaults'"
        "conda config --add channels 's3://my_bucket/my-conda-repository/conda-
forge/'",
        "conda config --add channels 's3://my_bucket/my-conda-repository/main/'"
    ]
)
def matrix_multiply(a, b):
```

```
    return np.matmul(a, b)
```

Example notebooks

You can transform a training code in an existing workspace environment and any associated data processing code and datasets into a SageMaker training job. The following notebooks show you how to customize your environment, job settings, and more for an image classification problem, using the XGBoost algorithm and Hugging Face.

The quick_start notebook contains the following code examples:

- How to customize your job settings with a configuration file.
- How to invoke Python functions as jobs, asynchronously.
- How to customize the job runtime environment by bringing in additional dependencies.
- How to use local dependencies with the @remote function method.

The following notebooks provide additional code examples for different ML problems types and implementations.

- To see code examples to use the @remote decorator for an image classification problem, open the pytorch_mnist.ipynb notebook. This classification problem recognizes handwritten digits using the Modified National Institute of Standards and Technology (MNIST) sample dataset.
- To see code examples for using the @remote decorator for the previous image classification problem with a script, see the Pytorch MNIST sample script, train.py.
- To see how the XGBoost algorithm implemented with an @remote decorator: Open the xgboost_abalone.ipynb notebook.
- To see how Hugging Face is integrated with an @remote decorator: Open the huggingface.ipynb notebook.

Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you create, manage, analyze, and compare your machine learning experiments.

Experimentation in machine learning

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithms, and parameters, all while observing the impact of incremental changes on model accuracy. Over time, this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It's also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements. Use SageMaker Experiments to organize, view, analyze, and compare iterative ML experimentation to gain comparative insights and track your best performing models.

Manage ML experimentation with SageMaker Experiments

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as *runs*. You can assign, group, and organize these runs into *experiments*. SageMaker Experiments is integrated with Amazon SageMaker Studio Classic, providing a visual interface to browse your active and past experiments, compare runs on key performance metrics, and identify the best performing models. SageMaker Experiments tracks all of the steps and artifacts that went into creating a model, and you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

Use SageMaker Experiments to view, manage, analyze, and compare both custom experiments that you programmatically create and experiments automatically created from SageMaker jobs.

Supported AWS Regions

SageMaker Experiments is generally available in all AWS commercial Regions where Amazon SageMaker Studio Classic is available, except the China Regions.

Topics

Create an Amazon SageMaker Experiment

Create an Amazon SageMaker experiment to track your machine learning (ML) workflows with a few lines of code from your preferred development environment. You can then browse your experiments, create visualizations for analysis, and find the best performing model. You can also integrate SageMaker Experiments into your SageMaker training script using the SageMaker Python SDK.

Overview

The following components make up the building blocks of an experiment in Amazon SageMaker.

- `experiment`: An experiment is a collection of runs. When you initialize a run in your training loop, you include the name of the experiment that the run belongs to. Experiment names must be unique within your AWS account.
- Run: A run consists of all the inputs, parameters, configurations, and results for one interaction of model training. Initialize an experiment run for tracking a training job with `Run.init()`.

> **Note**
>
> We recommend that you initialize a Run object in a Jupyter Notebook, and create the SageMaker job for your experiment within the context of this Run object initialization. To refer to this Run object in script mode, use the `load_run()` operation. For examples, see Example notebooks for Amazon SageMaker Experiments.

> **Note**
>
> The SageMaker Python SDK automatically turns experiment names and run names to lowercase.

- `load_run`: To run your experiments in script mode, refer to an initialized Run object with `load_run()`. If an experiment for a run exists, `load_run` returns the experiment context. Generally, you use `load_run` with no arguments to track metrics, parameters, and artifacts within a SageMaker training or processing job script.

```
# Load run from a local script passing experiment and run names
with load_run(experiment_name=experiment_name, run_name=run_name) as run:
```

```
    run.log_parameter("param1", "value1")
```

```
# Load run within a training or processing Job (automated context sharing)
with load_run() as run:
    run.log_parameter("param1", "value1")
```

- `log_parameter`: Log parameters for a run, such as batch size or epochs, over time in a training loop with `run.log_parameter()`. `log_parameter` records a single name-value pair in a run. You can use `run.log_parameters()` to log multiple parameters. If called multiple times within a run for a parameter of the same name, `log_parameter` overwrites any previous value. The name must be a string and the value must be either a string, integer, or float.

```
# Log a single parameter
run.log_parameter("param1", "value1")
```

```
# Log multiple parameters
run.log_parameters({
    "param2": "value2",
    "param3": "value3"
})
```

- `log_metric`: Log metrics for a run, such as accuracy or loss, over time in a training loop with `run.log_metric()`. `log_metric` records a name-value pair where the name is a string and the value is an integer or float. To declare the frequency of logging over the course of the run, define a `step` value. You can then visualize these metrics in the Studio Classic Experiments UI. For more information, see View, search, and compare experiment runs.

```
# Log a metric over the course of a run
run.log_metric(name="Final_loss", value=finalloss)
```

```
# Log a metric over the course of a run at each epoch
run.log_metric(name="test:loss", value=loss, step=epoch)
```

- `log_artifact`: Log any input or output artifacts related to a run with `run.log_artifact()`. Log artifacts such as S3 URIs, datasets, models, and more for your experiment to help you keep track of artifacts across multiple runs. `is_output` is `True` by default. To record the artifact as an input artifact instead of an output artifact, set `is_output` to `False`.

```
# Track a string value as an input or output artifact
```

```
run.log_artifact(name="training_data", value="data.csv" is_output=False)
```

- `log_file`: Log any input or output files related to a run, such as training or test data, and store them in Amazon S3 with `run.log_file()`. `is_output` is `True` by default. To record the file as an input artifact instead of an output artifact, set `is_output` to `False`.

```
# Upload a local file to S3 and track it as an input or output artifact
run.log_file("training_data.csv", name="training_data", is_output=False)
```

For more information on initializing a Run object, see Experiments in the *SageMaker Python SDK documentation*. For information on visualizing logged experiment data and automatic logging, see View, search, and compare experiment runs.

Create an experiment with the SageMaker Python SDK

The following section demonstrates how to create an Amazon SageMaker Experiment using the SageMaker Python SDK. This example uses the Run class to track a Keras model in a notebook environment. The Keras `Callback` class provides an operation on_epoch_end which emits metrics at the end of each epoch. First, define a `Callback` class.

```
class ExperimentCallback(keras.callbacks.Callback):
    """ """

    def __init__(self, run, model, x_test, y_test):
        """Save params in constructor"""
        self.run = run
        self.model = model
        self.x_test = x_test
        self.y_test = y_test

    def on_epoch_end(self, epoch, logs=None):
        """ """
        keys = list(logs.keys())
        for key in keys:
            run.log_metric(name=key, value=logs[key], step=epoch)
            print("Epoch: {}\n{} -> {}".format(epoch, key, logs[key]))
```

Next, train the Keras model in a notebook environment and track it as an experiment.

> **Note**
>
> This example carries out jobs sequentially. To run SageMaker jobs asynchronously, you may need to increase your resource limit.

```
from sagemaker.experiments import Run

# The run name is an optional argument to `run.init()`
with Run(experiment_name = 'my-experiment') as run:

    # Define values for the parameters to log
    run.log_parameter("batch_size", batch_size)
    run.log_parameter("epochs", epochs)
    run.log_parameter("dropout", 0.5)

    # Define input artifacts
    run.log_file('datasets/input_train.npy', is_output = False)
    run.log_file('datasets/input_test.npy', is_output = False)
    run.log_file('datasets/input_train_labels.npy', is_output = False)
    run.log_file('datasets/input_test_labels.npy', is_output = False)

    # Train locally
    model.fit(
        x_train,
        y_train,
        batch_size=batch_size,
        epochs=epochs,
        validation_split=0.1,
        callbacks = [ExperimentCallback(run, model, x_test, y_test)]
    )

    score = model.evaluate(x_test, y_test, verbose=0)
    print("Test loss:", score[0])
    print("Test accuracy:", score[1])

    # Define metrics to log
    run.log_metric(name = "Final Test Loss", value = score[0])
    run.log_metric(name = "Final Test Accuracy", value = score[1])
```

For more code examples and example notebooks, see Example notebooks for Amazon SageMaker Experiments.

Create an experiment using SageMaker script mode

You can use SageMaker script mode to write your own code to train a model and track it as an experiment. When creating an experiment with script mode, use `load_run()`.

```
# Make sure that you have the latest version of the SageMaker Python SDK
import os
os.system("pip install -U sagemaker")

# Import additional requirements
import boto3
from sagemaker.session import Session
from sagemaker.experiments.run import load_run

# Define training script
if __name__ == "__main__":
    session = Session(boto3.session.Session(region_name=args.region))
    with load_run(sagemaker_session=session) as run:
        # Define values for the parameters to log
        run.log_parameters({
            "batch_size": batch_size,
            "epochs": epochs,
            "dropout": 0.5
        })
        # Define input artifacts
        run.log_file('datasets/input_train.npy', is_output = False)
        run.log_file('datasets/input_test.npy', is_output = False)
        run.log_file('datasets/input_train_labels.npy', is_output = False)
        run.log_file('datasets/input_test_labels.npy', is_output = False)

        # Train the model
        model.fit(
            x_train,
            y_train,
            batch_size=batch_size,
            epochs=epochs,
            validation_split=0.1,
            callbacks = [ExperimentCallback(run, model, x_test, y_test)]
        )

        score = model.evaluate(x_test, y_test, verbose=0)
        print("Test loss:", score[0])
        print("Test accuracy:", score[1])
```

```
        # Define metrics to log
        run.log_metric(name = "Final Test Loss", value = score[0])
        run.log_metric(name = "Final Test Accuracy", value = score[1])
```

For more code examples and example notebooks on using Amazon SageMaker Experiments in SageMaker script mode, see Track experiments for SageMaker training jobs using script mode.

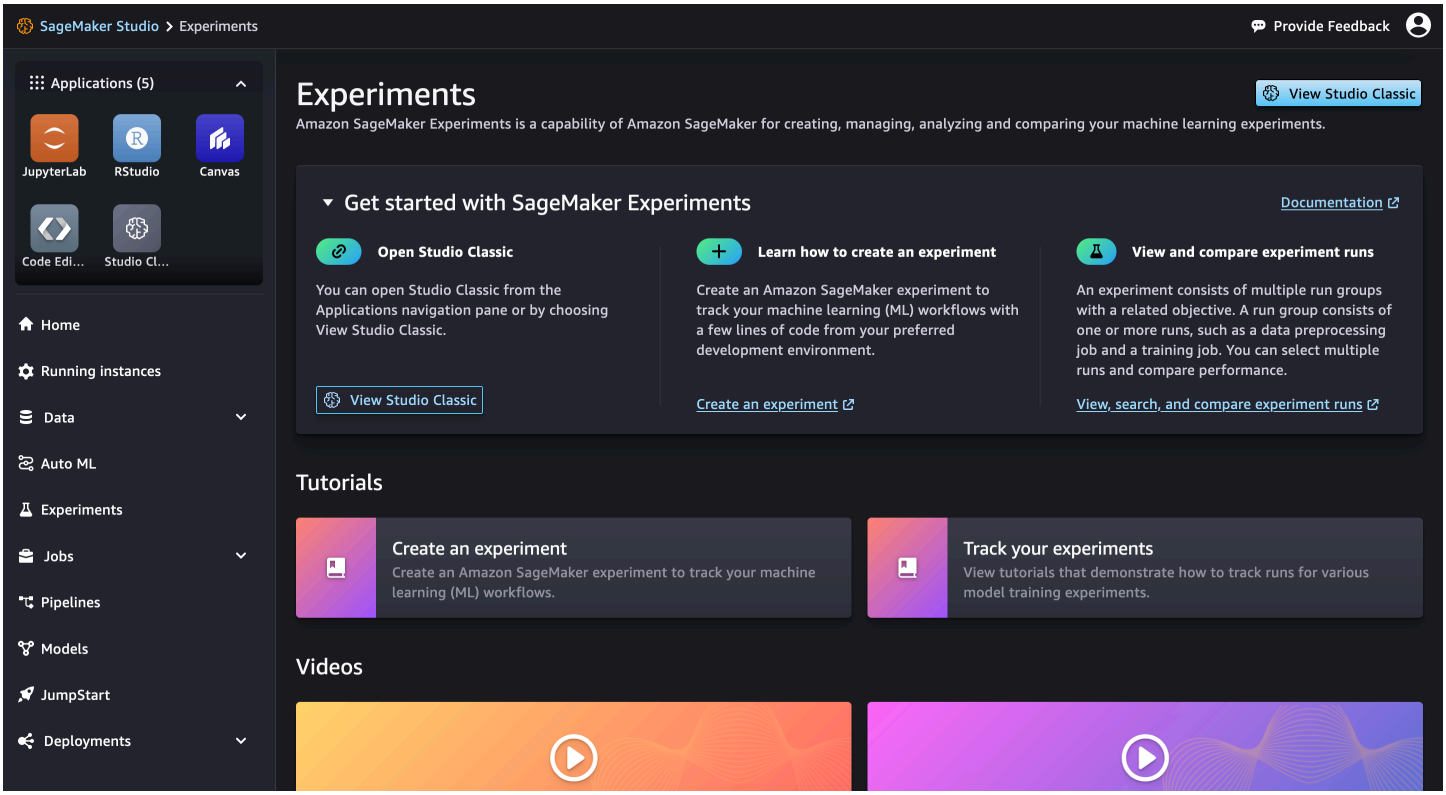
For more information on script mode, see Use script mode in a supported framework. You can also define custom metrics in script mode by specifying a name and regular expression for each metric that a tuning job monitors. See Use a custom algorithm for training for more information.

View your experiment in Studio

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.

To view your experiments, you must do so through Studio Classic, which you can access through the updated Studio experience.

Within Studio, choose **Experiments** on the lefthand navigation pane. Then, choose **View Studio Classic**. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic. For more information on getting started with the updated Studio experience, see Amazon SageMaker Studio.

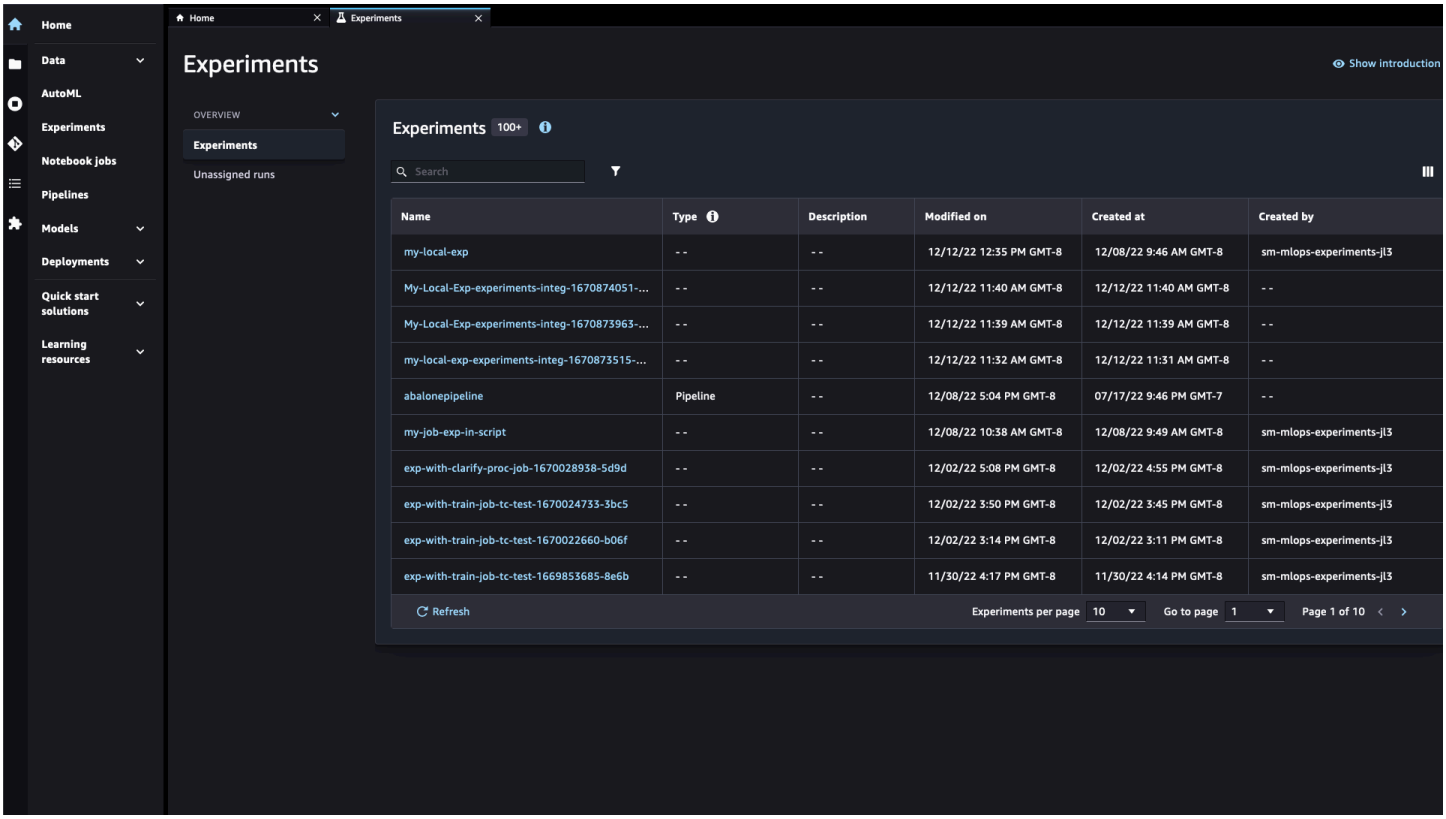


View your experiment in Studio Classic

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see Amazon SageMaker Studio.

To view the experiment in Studio Classic, in the left sidebar, choose **Experiments**.

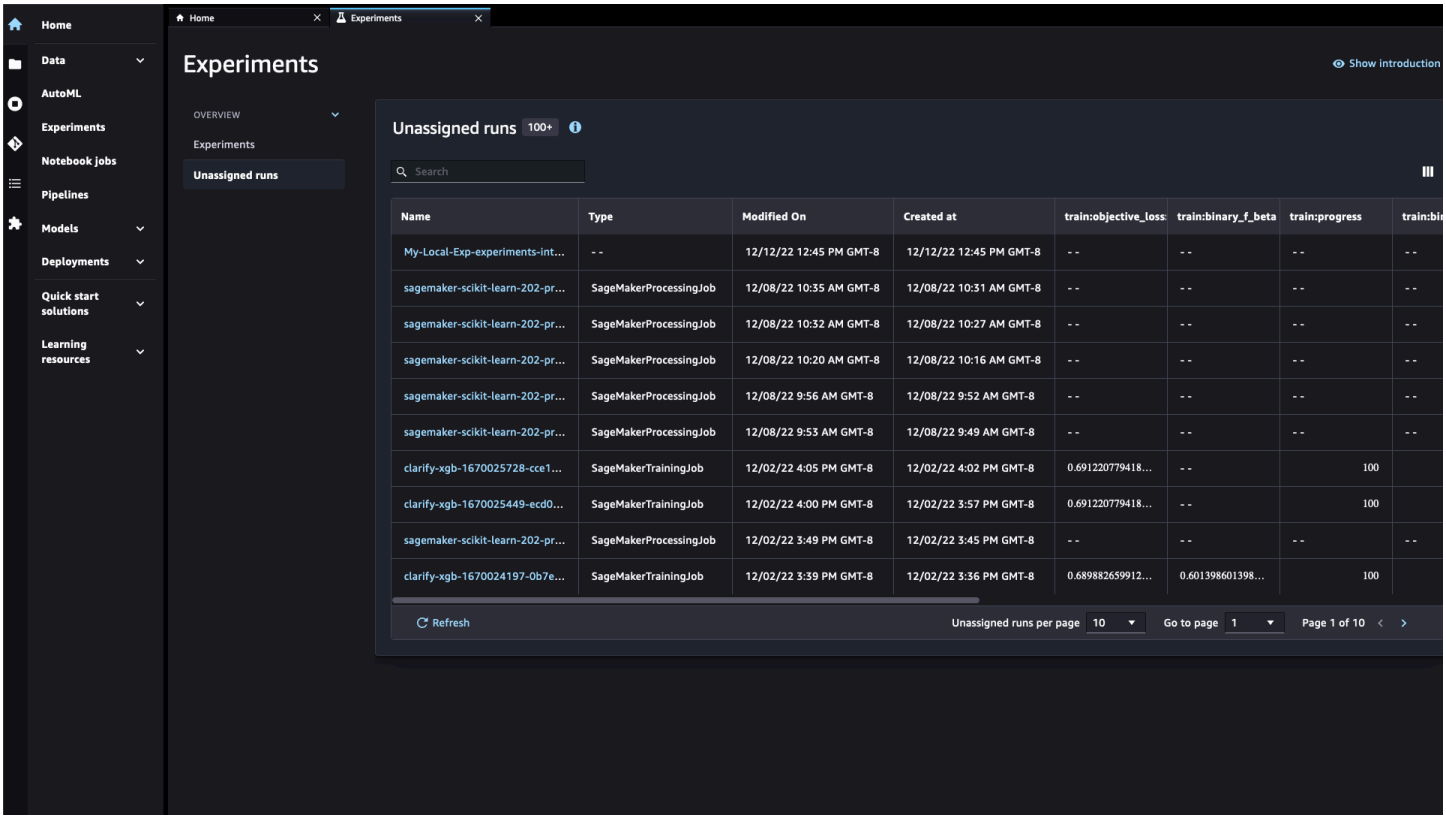
Select the name of the experiment to view all associated runs. It might take a moment for the list to refresh and display a new experiment or experiment run. You can click **Refresh** to update the page. Your experiment list should look similar to the following:



To view the runs that make up your experiment, select the experiment name. For more information, see View, search, and compare experiment runs.

View unassigned runs

All SageMaker jobs, including training jobs, processing jobs, and transform jobs, correspond to runs and create Run objects by default. If you launch these jobs without explicitly associating them with an experiment, the resulting runs are unassigned and can be viewed in the **Unassigned runs** section of the Studio Classic Experiments UI.



To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources.

View, search, and compare experiment runs

An Amazon SageMaker *experiment* consists of multiple *run groups* with a related objective. A run group consists of one or more *runs*, such as a data preprocessing job and a training job.

To view your experiments, you must do so through Studio Classic. For an overview of the Studio Classic user interface, see Amazon SageMaker Studio Classic UI Overview. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see Amazon SageMaker Studio.

View experiments and runs

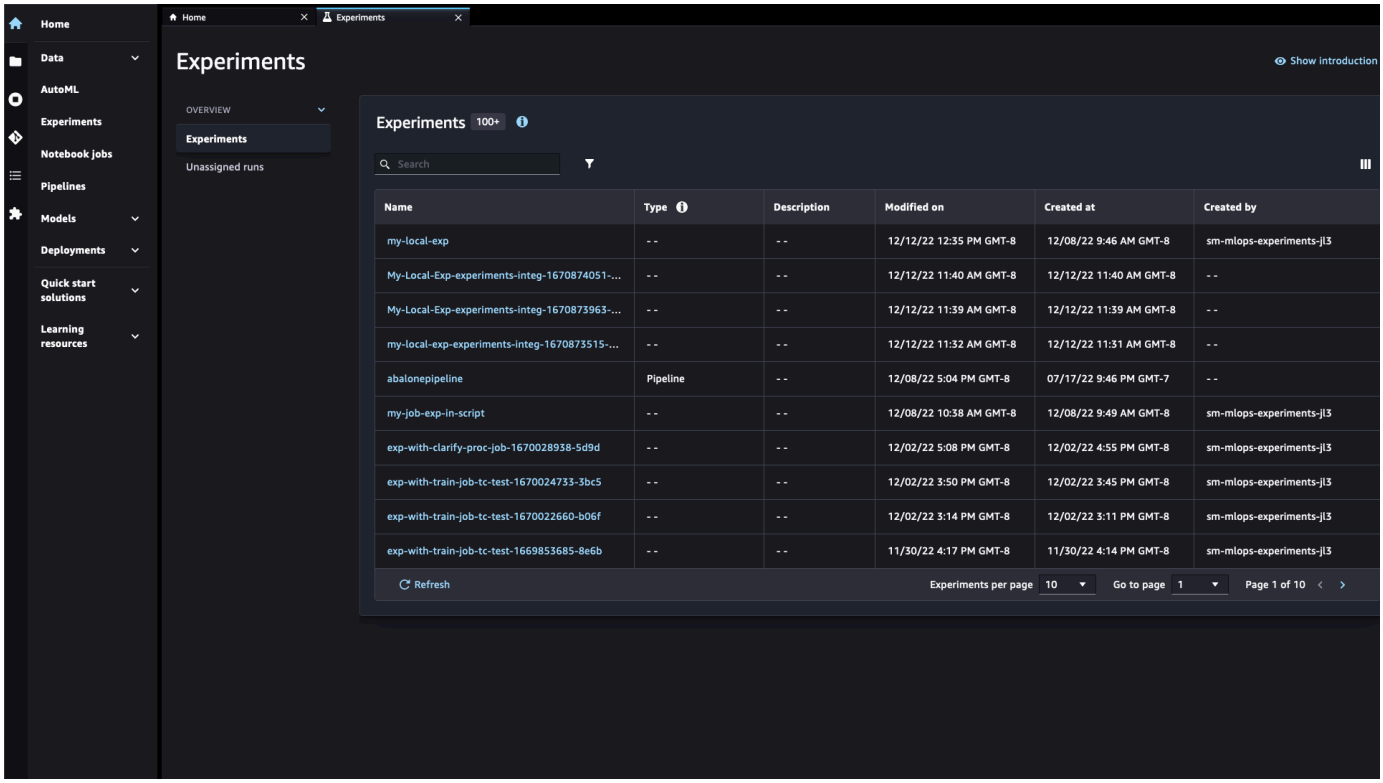
Amazon SageMaker Studio Classic provides an experiments browser that you can use to view lists of experiments and runs. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison. You can filter the list of experiments by entity name, type, and tags.

To view experiments and runs

1. To view the experiment in Studio Classic, in the left sidebar, choose **Experiments**.

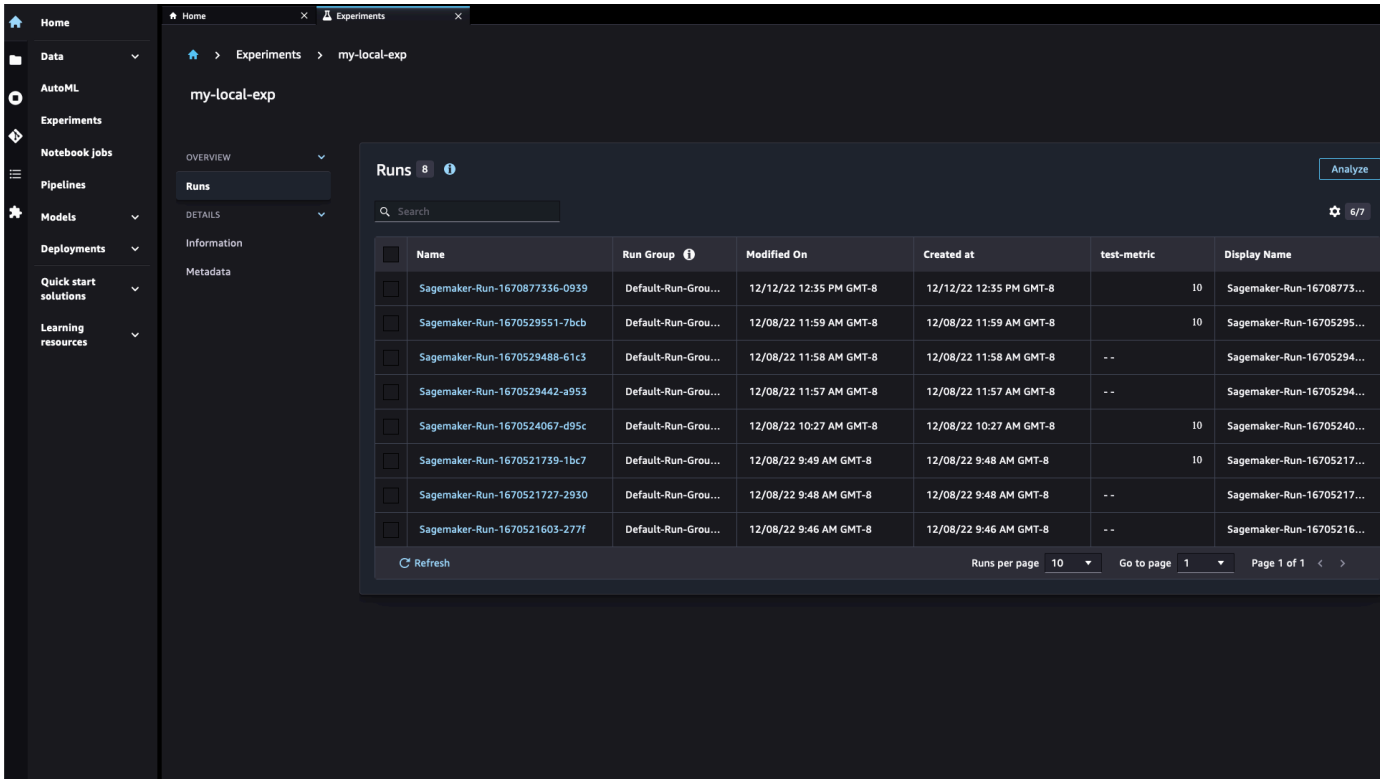
   Select the name of the experiment to view all associated runs. You can search experiments by typing directly into the **Search** bar or filtering for experiment type. You can also choose which columns to display in your experiment or run list.

   It might take a moment for the list to refresh and display a new experiment or experiment run. You can click **Refresh** to update the page. Your experiment list should look similar to the following:



2. In the experiments list, double-click an experiment to display a list of the runs in the experiment.

> **Note**
>
> Experiment runs that are automatically created by SageMaker jobs and containers are visible in the Experiments Studio Classic UI by default. To hide runs created by SageMaker jobs for a given experiment, choose the settings icon ( ) and toggle **Show jobs**.



3. Double-click a run to display information about a specific run.

   In the **Overview** pane, choose any of the following headings to see available information about each run:

   - **Metrics** – Metrics that are logged during a run.
   - **Charts** – Build your own charts to compare runs.
   - **Output artifacts** – Any resulting artifacts of the experiment run and the artifact locations in Amazon S3.
   - **Bias reports** – Pre-training or post-training bias reports generated using Clarify.

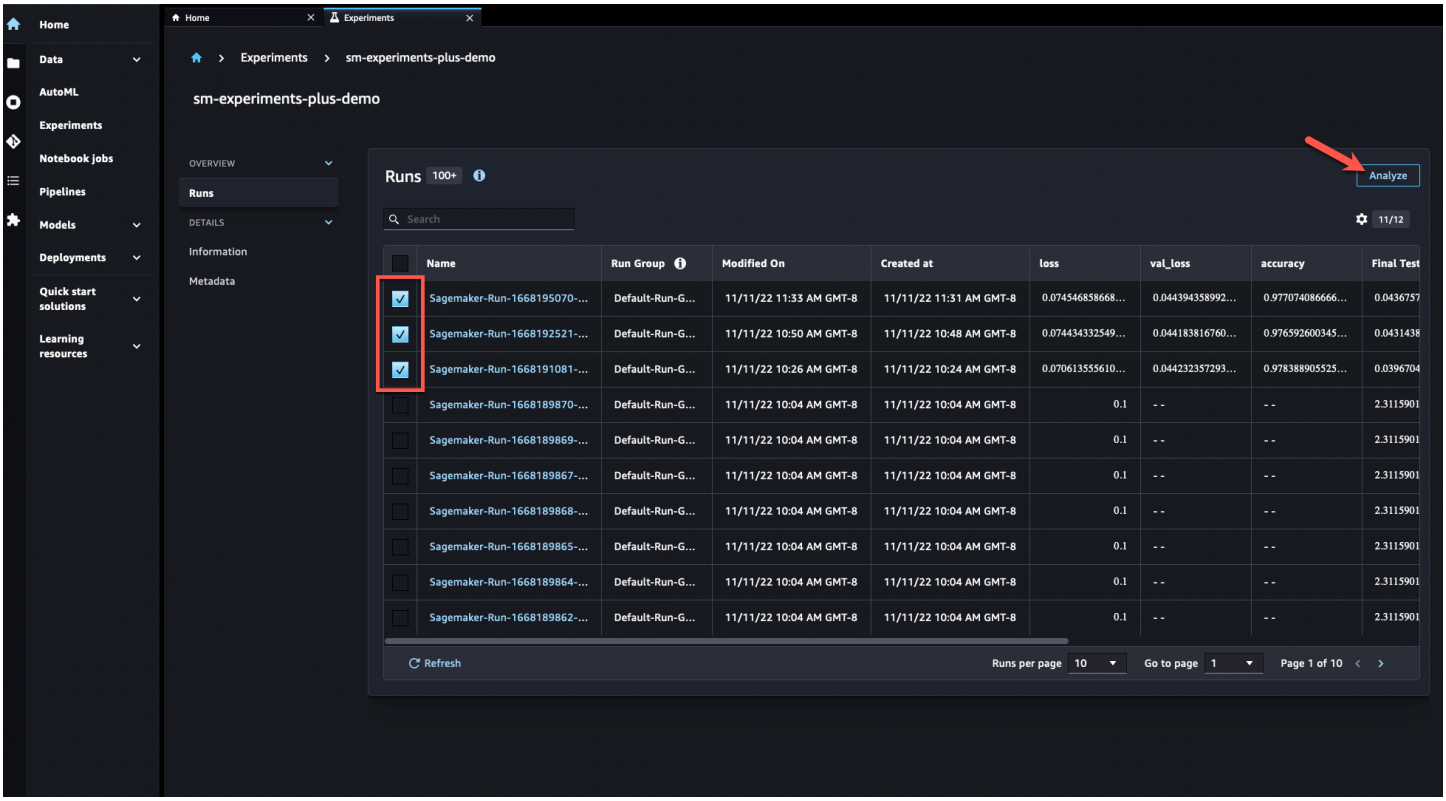
- **Explainability**– Explainability reports generated using Clarify.
- **Debugs** – A list of debugger rules and any issues found.

Compare and analyze runs

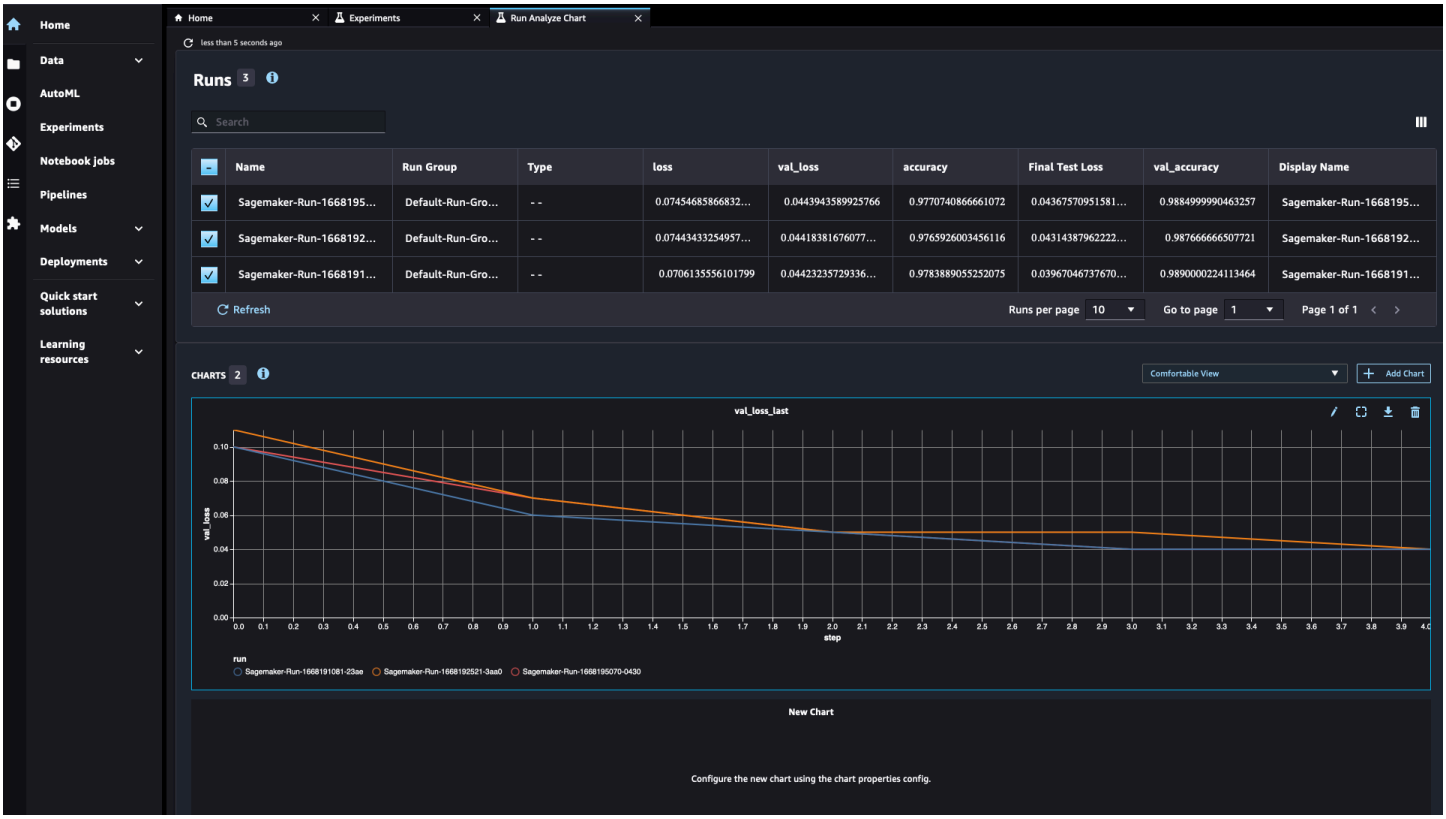
To analyze experiment runs, select the experiment of your choice in the Amazon SageMaker Studio Classic Experiments UI and then select the runs that you want to compare. You must select between 1 and 20 runs. After you have your runs selected, choose **Analyze** in the upper right-hand corner.

To compare experiment runs:

1. After navigating to the experiment of your choice, select all the runs that you want to compare. You must choose more than 1 and less than 20 runs to analyze.
2. Choose **Analyze** in the upper right-hand corner.
3. Visualize the comparative metrics of multiple experiment runs in a histogram, line chart, scatter plot, or bar chart. To add a chart, choose **Add Chart**, select values for your chart axes, and choose **Create**.



You can update, download, or delete existing charts.



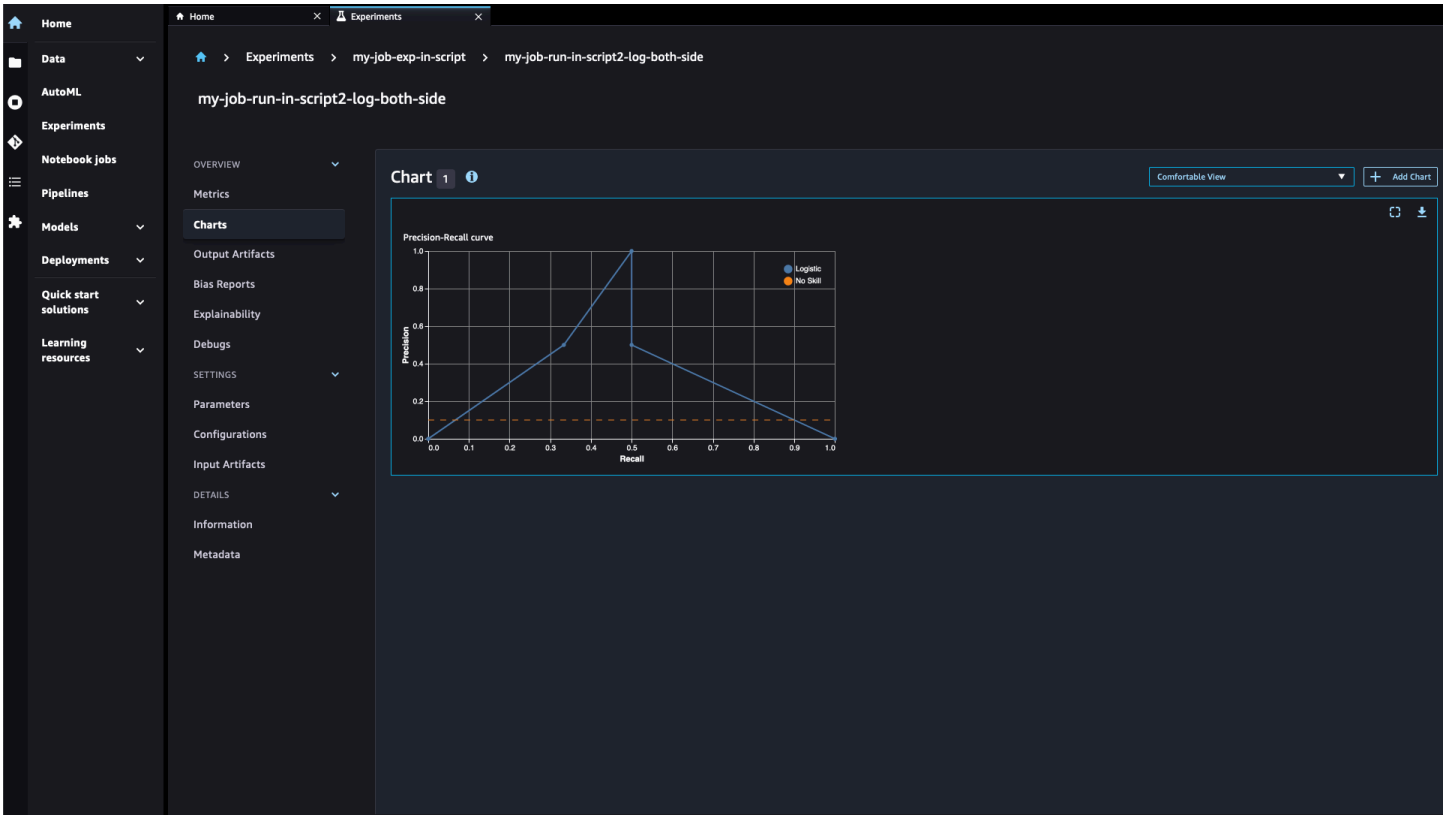
Log charts

Logging charts and visualizations is available for classification models. You can log a confusion matrix, receiver operating characteristics, or precision and recall graphs.

Log and visualize metrics with the following Python SDK methods:

- `log_confusion_matrix`: Records a confusion matrix artifact that you can view in the **Charts** section of the **Run Overview** in Studio Classic.
- `log_roc_curve`: Records a receiver operating characteristic artifact that you can view in the **Charts** section of the **Run Overview** in Studio Classic.
- `log_precision_recall`: Records a precision recall graph that you can view in the **Charts** section of the **Run Overview** in Studio Classic.

An automatically logged precision recall record creates a chart similar to the following:



SageMaker integrations

Amazon SageMaker Experiments is integrated with a number of SageMaker features. Certain SageMaker jobs automatically create experiments. You can view and manage SageMaker Clarify bias reports or SageMaker Debugger output tensors for specific experiment runs directly in the Studio Classic Experiments UI.

- Automatic experiment creation
- Bias and explainability reports
- Debugging

Automatic experiment creation

Amazon SageMaker automatically creates experiments when running Autopilot jobs, hyperparameter optimization (HPO) jobs, or Pipeline executions. You can view these experiments in the Studio Classic Experiments UI.

Autopilot

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for that job as well as runs for each of the different combinations of the available run components, parameters, and artifacts. You can find these runs in the SageMaker Experiments UI by filtering for the run type **Autopilot**. For more information, see Automate model development with Amazon SageMaker Autopilot.

HPO

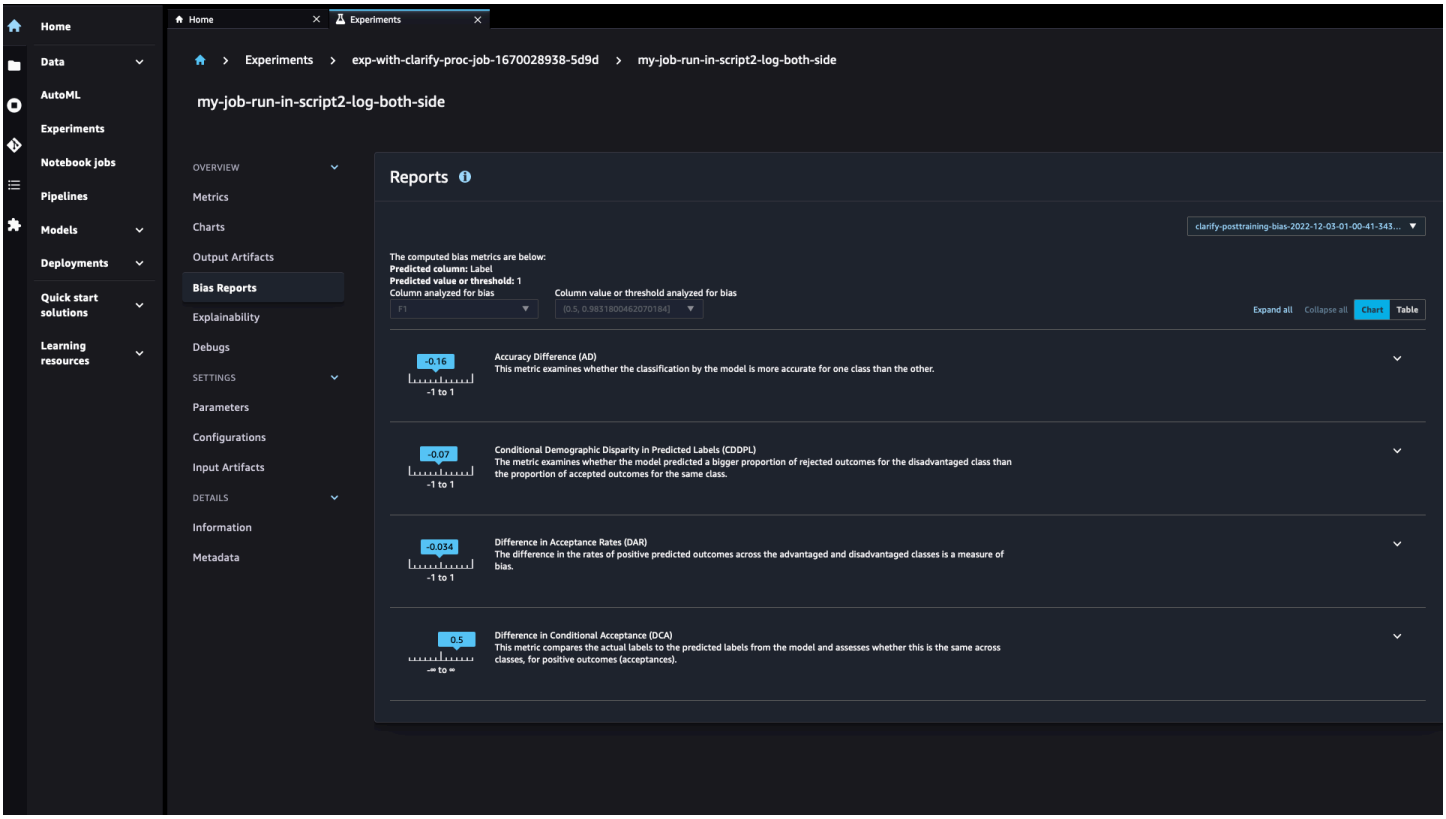
Amazon SageMaker Experiments is integrated with HPO jobs. An HPO job automatically creates Amazon SageMaker experiments, runs, and components for each training job that it completes. You can find these runs in the SageMaker Experiments UI by filtering for the run type **HPO**. For more information, see Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model.

Pipelines

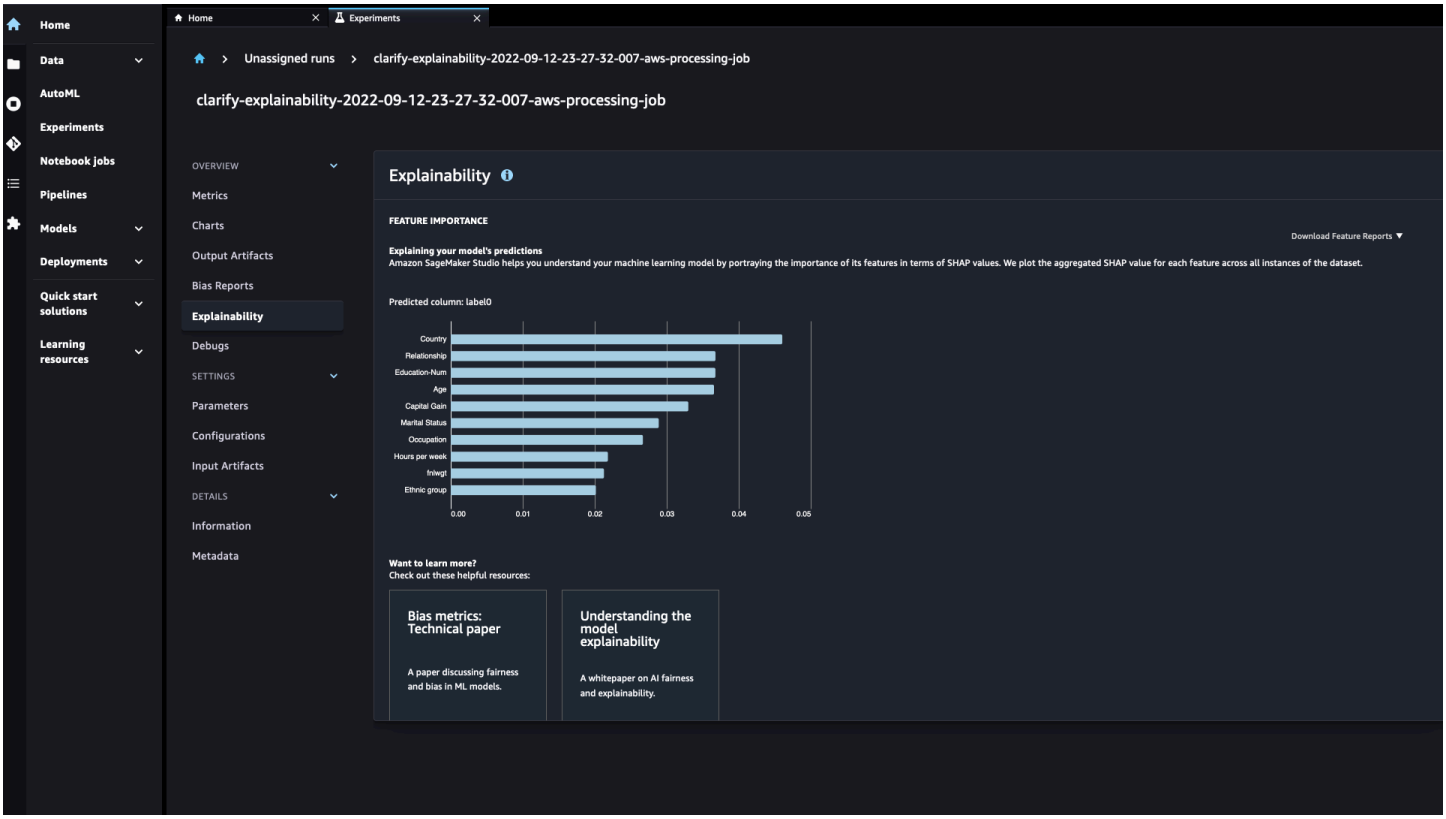
Amazon SageMaker Model Building Pipelines is closely integrated with Amazon SageMaker Experiments. By default, when SageMaker Pipelines creates and executes a pipeline, experiments, runs, and components are created if they do not already exist. You can find these runs in the SageMaker Experiments UI by filtering for the run type **Pipelines**. For more information, see Amazon SageMaker Experiments Integration.

Bias and explainability reports

Manage SageMaker Clarify bias and explainability reports for experiment runs directly through Studio Classic. To view reports, find and select the name of the experiment run of your choice in Studio Classic. Choose **Bias reports** to see any Clarify bias reports associated with the experiment run.



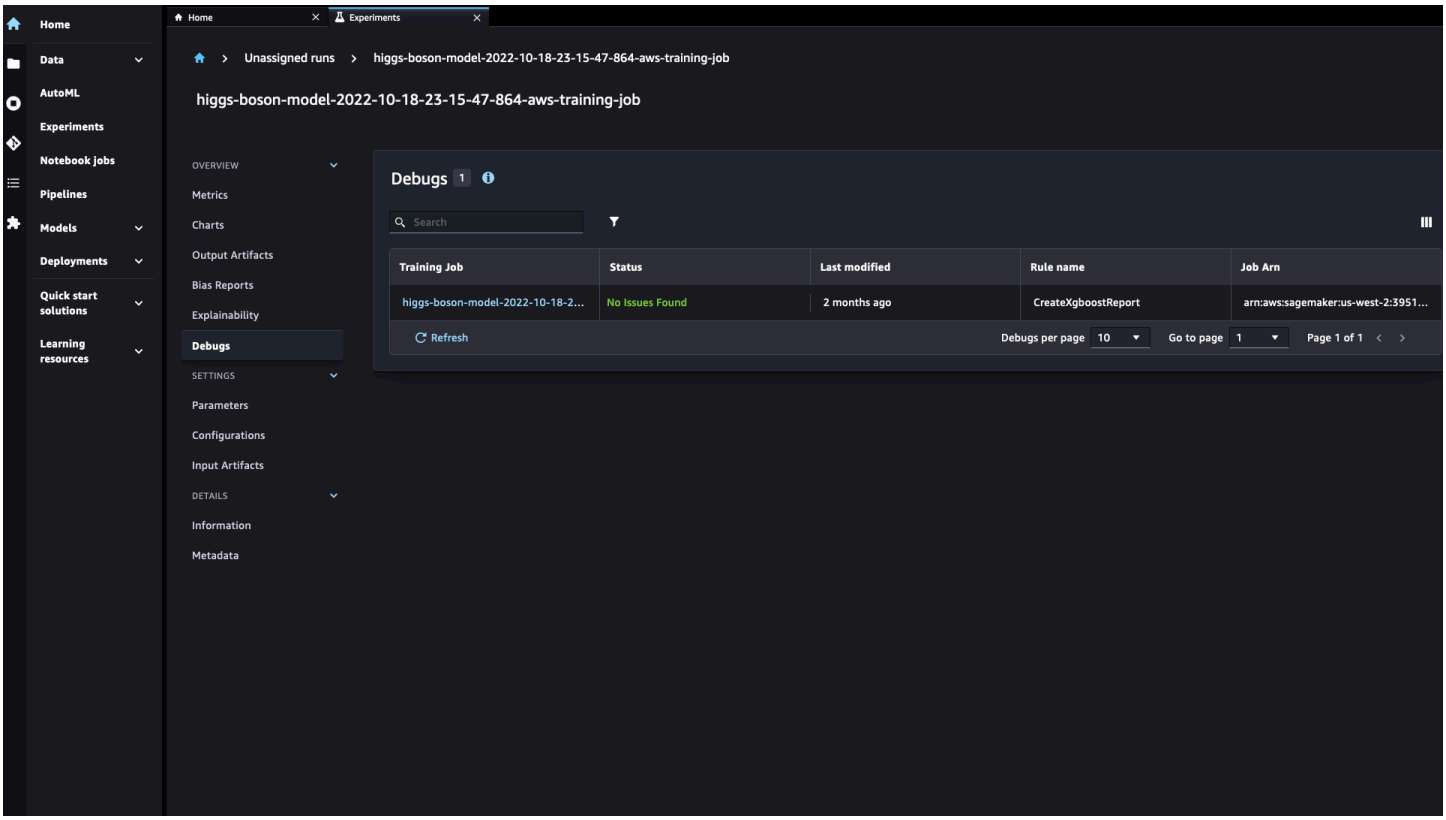
Choose **Explanations** to see any Clarify explainability reports associated with the experiment run.



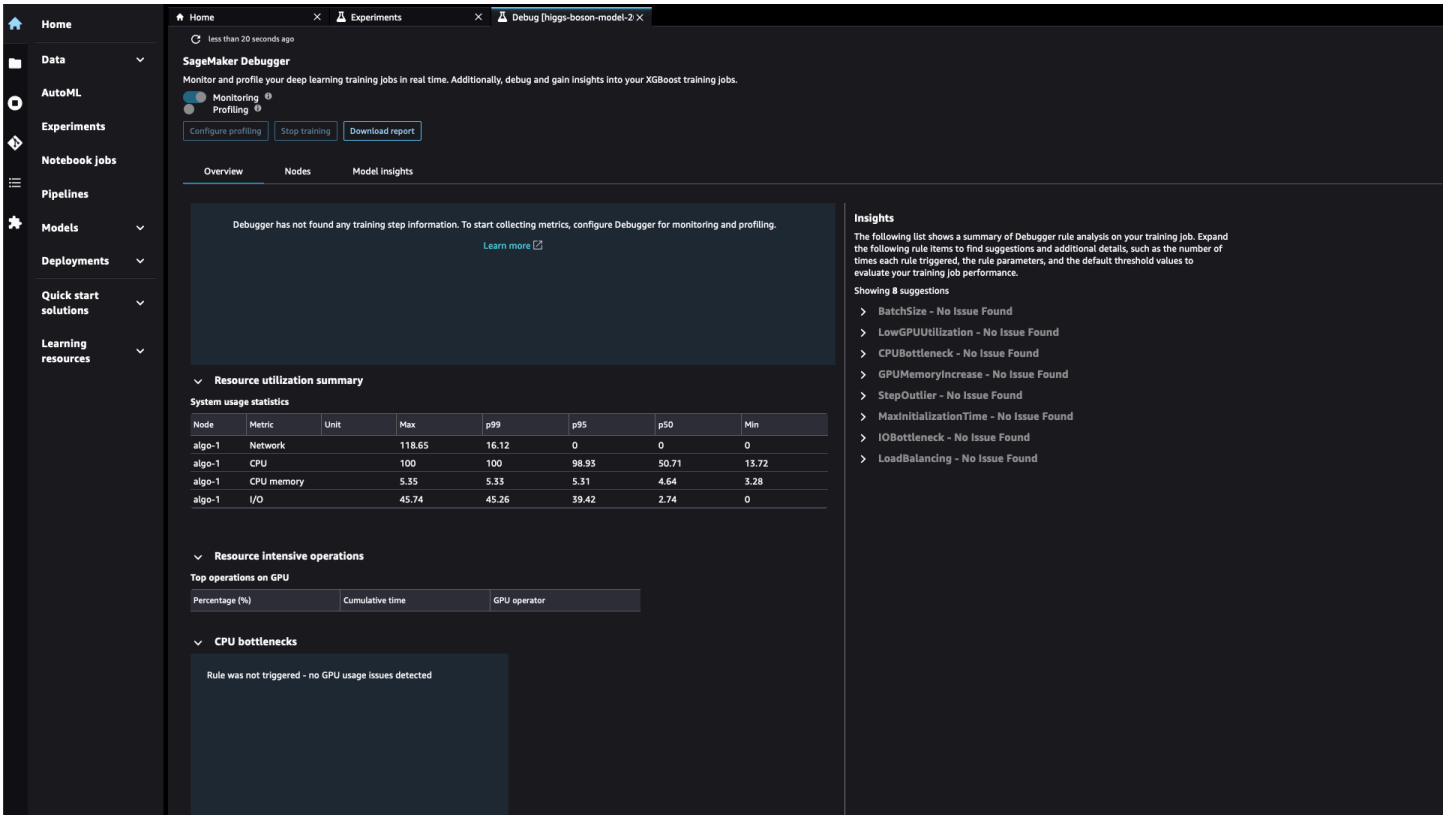
You can generate pre-training or post-training bias reports that analyze bias in datasets or model predictions using labels and bias metrics with SageMaker Clarify. You can also use SageMaker Clarify to generate explainability reports that document model behavior for global or local data samples. For more information, see [Amazon SageMaker Clarify Bias Detection and Model Explainability].

Debugging

You can debug model training progress with Amazon SageMaker Debugger and view debug output tensors in the Studio Classic Experiments UI. Choose the name of the run associated with the Debugger report and choose **Debugger**.



Then, choose the training job name to view the associated Amazon SageMaker Debugger dashboard.



For more information, see Debug Training Jobs Using Amazon SageMaker Debugger.

Example notebooks for Amazon SageMaker Experiments

The following tutorials demonstrate how to track runs for various model training experiments. You can view the resulting experiments in Studio Classic after running the notebooks. To clean up the resources created by a notebook, see Clean Up Amazon SageMaker Experiment Resources. For a tutorial that showcases additional features of Studio, see Amazon SageMaker Studio Classic Tour.

Track experiments in a notebook environment

To learn more about tracking experiments in a notebook environment, see the following example notebooks:

- Track an experiment while training a Keras model locally
- Track an experiment while training a Pytorch model locally or in your notebook

Track bias and explainability for your experiments with SageMaker Clarify

For a step-by-step guide on tracking bias and explainability for your experiments, see the following example notebook:

- Fairness and Explainability with SageMaker Clarify

Track experiments for SageMaker training jobs using script mode

For more information about tracking experiments for SageMaker training jobs, see the following example notebooks:

- Run a SageMaker Experiment with Pytorch Distributed Data Parallel - MNIST Handwritten Digits Classification
- Track an experiment while training a Pytorch model with a SageMaker Training Job
- Train a TensorFlow model with a SageMaker training job and track it using SageMaker Experiments

Monitor experiment training metrics with AWS CloudTrail

The training metrics for Amazon SageMaker Experiments are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for `BatchPutMetrics` as events. SageMaker automatically calls `BatchPutMetrics` when you create an experiment run using the SageMaker SDK for Python. AWS CloudTrail captures data related to calls for resource type `AWS::SageMaker::ExperimentTrialComponent`.

> **Note**
>
> In the Studio Classic Experiments UI, trials are referred to as *run groups* and trial components are referred to as *runs*.

When you create an experiment run, you can also configure the continuous delivery of CloudTrail events to an Amazon S3 bucket. Use CloudTrail to monitor all ingested training metrics for an experiment run, including information such as the metric name, the training step of the recorded metric, the timestamp, and the metric value. CloudTrail events also include the experiment

run ARN, the ID of the account that created the run, and the resource type, which should be `AWS::SageMaker::ExperimentTrialComponent`.

To monitor `BatchPutMetrics` API calls as CloudTrail events, you must first set up the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information. For granular control over which API calls you want to selectively log and pay for, you can filter CloudTrail events by resource type. Specify `AWS::SageMaker::ExperimentTrialComponent` as a resource type to monitor calls to the `BatchPutMetrics` API. For more information, see DataResource in the AWS CloudTrail API reference. To learn more about CloudTrail, see the AWS CloudTrail User Guide.

For an in-depth explanation of how Amazon SageMaker works with AWS CloudTrail, see Log Amazon SageMaker API Calls with AWS CloudTrail.

The following is an example CloudTrail event for a training metric in an experiment run:

```
{
  ...
  "eventTime": "2022-12-14T21:53:41Z",
  "eventSource": "metrics-sagemaker.amazonaws.com",
  "eventName": "BatchPutMetrics",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "aws-cli/2.7.25 Python/3.9.11 Linux/5.4.214-134.408.amzn2int.x86_64 exe/

trial-component-name"
    }
  ],
  ...
}
```

Clean Up Amazon SageMaker Experiment Resources

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio Classic UI. This topic shows you how to clean up these resources using the SageMaker Python SDK, Boto3, and the Experiments SDK.

Topics

Clean Up Using the SageMaker Python SDK (Recommended)

To clean up using the SageMaker Python SDK

```
from sagemaker.experiments.experiment import Experiment

exp = Experiment.load(experiment_name=experiment_name, sagemaker_session=sm_session)
exp._delete_all(action="--force")
```

Clean Up Using the Python SDK (Boto3)

To clean up using Boto 3

```
import boto3
sm = boto3.Session().client('sagemaker')
```

Define cleanup_boto3

```
def cleanup_boto3(experiment_name):
```

```
    trials = sm.list_trials(ExperimentName=experiment_name)['TrialSummaries']
    print('TrialNames:')
    for trial in trials:
        trial_name = trial['TrialName']
        print(f"\n{trial_name}")

        components_in_trial = sm.list_trial_components(TrialName=trial_name)
        print('\tTrialComponentNames:')
        for component in components_in_trial['TrialComponentSummaries']:
            component_name = component['TrialComponentName']
            print(f"\t{component_name}")
            sm.disassociate_trial_component(TrialComponentName=component_name,
 TrialName=trial_name)
            try:
                # comment out to keep trial components
                sm.delete_trial_component(TrialComponentName=component_name)
            except:
                # component is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
        sm.delete_trial(TrialName=trial_name)
    sm.delete_experiment(ExperimentName=experiment_name)
    print(f"\nExperiment {experiment_name} deleted")
```

Call cleanup_boto3

```
# Use experiment name not display name
experiment_name = "experiment-name"
cleanup_boto3(experiment_name)
```

Clean Up Using the Experiments SDK

To clean up using the Experiments SDK

```
import sys
!{sys.executable} -m pip install sagemaker-experiments
```

```
import time

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
```

```
from smexperiments.trial_component import TrialComponent
```

Define cleanup_sme_sdk

```
def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
        trial.delete()
        experiment_name = experiment.experiment_name
    experiment.delete()
    print(f"\nExperiment {experiment_name} deleted")
```

Call cleanup_sme_sdk

```
experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")

cleanup_sme_sdk(experiment_to_cleanup)
```

Additional supported SDK

Important

As of v2.123.0, SageMaker Experiments is now fully integrated with the SageMaker Python SDK and you no longer need to use the separate SageMaker Experiments SDK. We recommend creating an experiment with `sagemaker.experiments.run` rather than the following `smexperiments` module.

The following section describes how to create a SageMaker Experiment with the SageMaker Experiments SDK.

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see Amazon SageMaker Studio.

Create an Amazon SageMaker Experiment with the SageMaker Experiments SDK

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio Classic) describe how to view the experiment in Amazon SageMaker Studio Classic. You don't have to run the experiment in Studio Classic to view the experiment in Studio Classic.

1. Import the `sys` module to install the SDKs.

   ```
   import sys
   ```

2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in Amazon SageMaker Studio Classic. If you plan to run your code outside Studio Classic, install the SageMaker Python SDK.

   ```
   !{sys.executable} -m pip install sagemaker
   ```

3. Install the SageMaker Experiments Python SDK.

   ```
   !{sys.executable} -m pip install sagemaker-experiments
   ```

4. Import modules.

   ```
   import time
   from time import strftime
   ```

```
import sagemaker

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```

5. Get the execution role and create the SageMaker session.

```
role = sagemaker.get_execution_role()
sm_sess = sagemaker.session.Session()
```

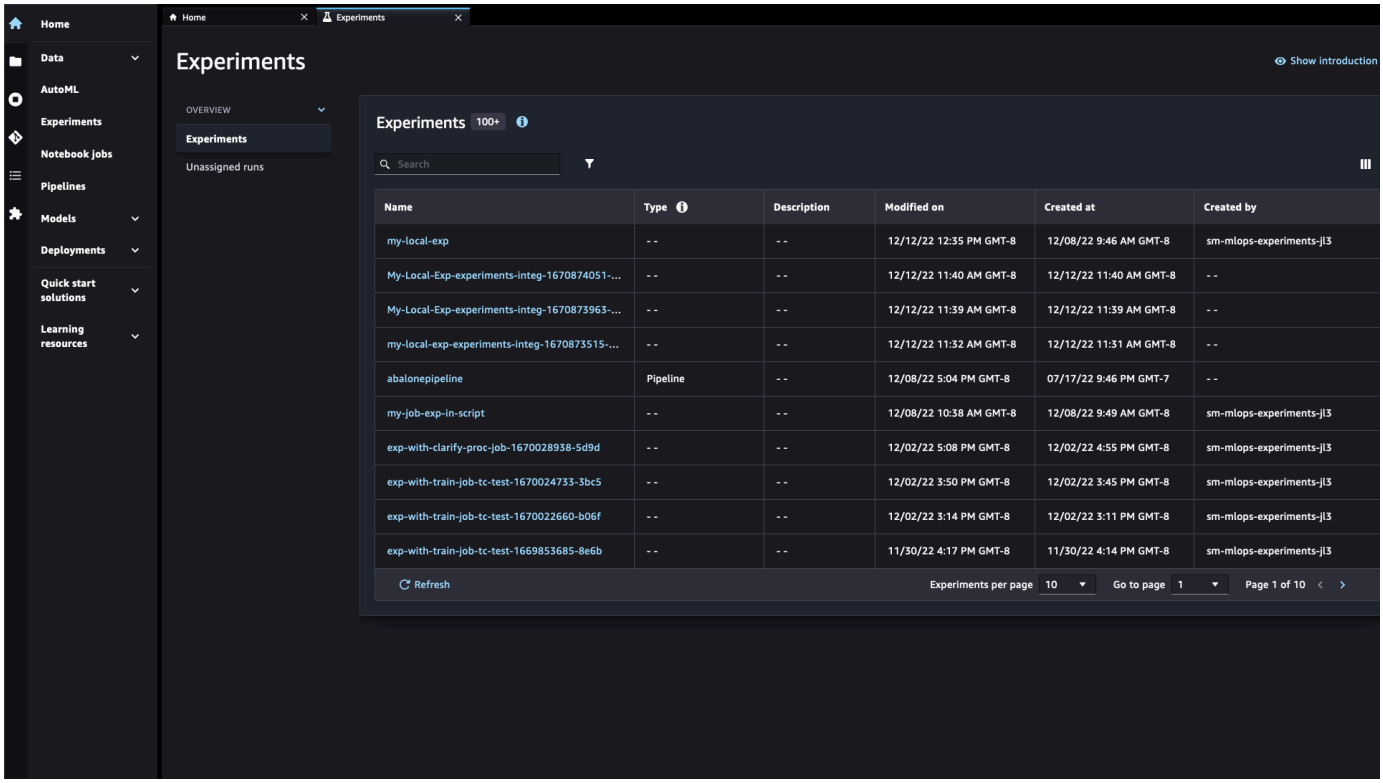
6. Create a SageMaker experiment. The experiment name must be unique in your account.

> **Note**
>
> The `tags` parameter is optional. You can search for the tag using Studio Classic, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components.

```
create_date = strftime("%Y-%m-%d-%H-%M-%S")
demo_experiment = Experiment.create(experiment_name = "DEMO-
{}".format(create_date),
                                    description = "Demo experiment",
                                    tags = [{'Key': 'demo-experiments', 'Value':
 'demo1'}])
```

7. (Studio Classic) To view the experiment in Amazon SageMaker Studio Classic, in the left sidebar, choose the **Experiments**.

   After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:



8. Create a trial for the experiment. The trial name must be unique in your account.

```
demo_trial = Trial.create(trial_name = "DEMO-{}".format(create_date),
                          experiment_name = demo_experiment.experiment_name,
                          tags = [{'Key': 'demo-trials', 'Value': 'demo1'}])
```

9. Create a trial component as part of the trial. The trial component is the SageMaker job.

   Add the ExperimentConfig parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

Job	SageMaker Python SDK method	Boto3 method
Training	Estimator.fit	CreateTrainingJob
Processing	Processor.run	CreateProcessingJob
Transform	Transformer.transform	CreateTransformJob

The following examples are for a training job. The `Tags` parameter adds a tag to the trial component. `ExperimentName` isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

Using the SageMaker Python SDK

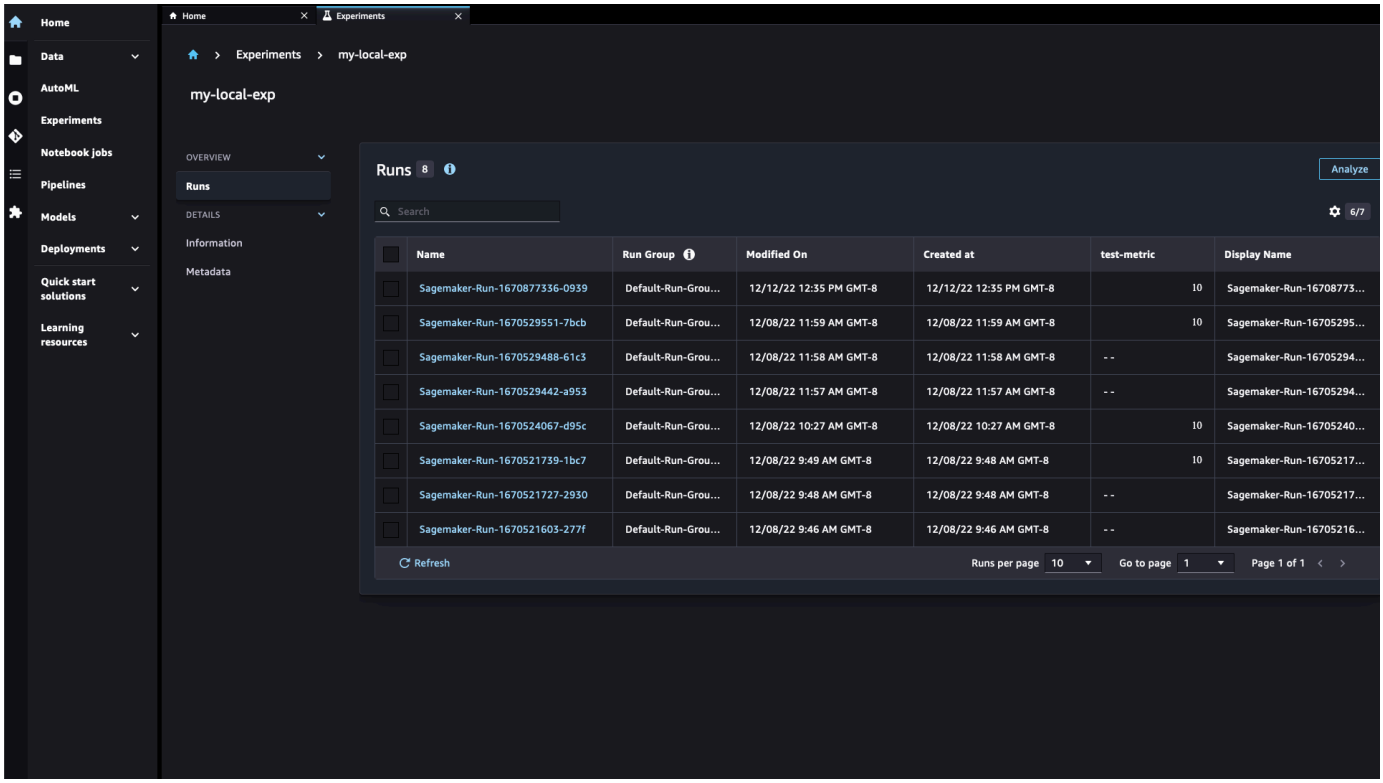
```
sagemaker.estimator.Estimator(
    ...,
    sagemaker_session = sm_sess,
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])

estimator.fit(
    ...,
    experiment_config = {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    })
```

Using Boto3

```
create_training_job(
    ...,
    "ExperimentConfig": {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    },
    "Tags": [{'Key': 'demo-jobs', 'Value': 'demo2'}])
```

10. (Studio Classic) In the experiment list, double-click the experiment to display a list of the trials in the experiment. In the Studio Classic UI, trials are referred to as *run groups* and trial components are referred to as *runs*. Your list should look similar to the following:



11. (Studio Classic) To view information about the experiment, trial, and job (trial component), see View, search, and compare experiment runs.

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources.

Experiments FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Experiments.

Q. What is the recommended method to create an experiment?

A: Experiments are a collection of runs aimed at finding the best model to solve a problem. To initialize a run within an experiment, use the SageMaker Python SDK Run class. For more examples, see Create an Amazon SageMaker Experiment.

Q. Can I create an experiment using SageMaker script mode?

Yes. You can create experiments using SageMaker script mode. In the Jupyter notebook or Python file you are using to define your estimator, initialize a run using the Run class. Within the run, launch an estimator with your custom entry point script. Within that entry point script, use the

`load_run` method to initialize the run you defined within the entry point script and log your metrics. For in-depth examples, see Track experiments for SageMaker training jobs using script mode.

Q. What SageMaker jobs automatically create experiments?

SageMaker Hyperparameter Optimzation (HPO) jobs (also known as tuning jobs) automatically create experiments to track all the training jobs launched during a hyperparameter search. All other SageMaker jobs create unassigned runs unless launched from within an experiment.

Q. What kind of SageMaker jobs can I create an experiment for?

You can use SageMaker Experiments to track metrics from training jobs, processing jobs, and transform jobs.

Q. Why do I see experiments and runs in the Experiments Studio Classic UI that I did not create using the SageMaker Python SDK?

Experiment runs that are automatically created by SageMaker jobs and containers are visible in the Experiments Studio Classic UI by default. To hide runs created by SageMaker jobs for a given experiment, choose the settings icon (⚙) and toggle **Show jobs**.

Q. Is the SageMaker Experiments SDK still supported?

Yes, the SageMaker Experiments SDK is still supported. However, as of v2.123.0, SageMaker Experiments is fully integrated with the SageMaker Python SDK. We recommend using the SageMaker Python SDK to create experiments and runs. For more information, see Create an Amazon SageMaker Experiment.

Q. Can I use distributed training with my experiments?

A: Yes. However, metrics for distributed training can be logged only at the epoch level. Be sure that you only log metrics generated by the leader node, as shown in the following example:

```
...
if rank == 0:
        test_loss, correct, target, pred = test(model, test_loader, device, tracker)
        logger.info(
            "Test Average loss: {:.4f}, Test Accuracy: {:.0f}%;\n".format(
```

```
                test_loss, test_accuracy)
            )
        )
        run.log_metric(name = "train_loss", value = loss.item(), step = epoch)
        run.log_metric(name = "test_loss", value = test_loss, step = epoch)
        run.log_metric(name = "test_accuracy", value = test_accuracy, step = epoch)
        ...
```

For more information, see the Run a SageMaker Experiment with Pytorch Distributed Data Parallel - MNIST Handwritten Digits Classification example notebook.

Q. What are unassigned runs?

A: All jobs in SageMaker (training jobs, processing jobs, transform jobs) correspond to runs. When launching these jobs, `TrialComponents` are created by default. `TrialComponents` map directly to runs. If these jobs are launched without being explicitly associated with an experiment or run, they are created as unassigned runs.

Q. Do I need to pass the experiment run context to the training script when running a SageMaker training job?

A: Yes. You need to load the run context into the training script, along with the SageMaker session information.

```
from sagemaker.session import Session
from sagemaker.experiments.run import load_run

session = Session(boto3.session.Session(region_name=args.region))

with load_run(sagemaker_session=session) as run:
    run.log_parameters(
        {"num_train_samples": len(train_set.data), "num_test_samples":
 len(test_set.data)}
    )
```

Q. How do I add a new run to an experiment analysis?

A: If you already created a comparison for your experiment and want to add a new run to analyze, select all the runs from your previous analysis as well as the new run and choose **Analyze**. If you don't see your new run in the resulting analysis page, then refresh the Studio Classic browser. Note that refreshing your Studio Classic browser may impact your other open tabs.

Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API.

Topics

Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. *Searchable items* include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

Topics

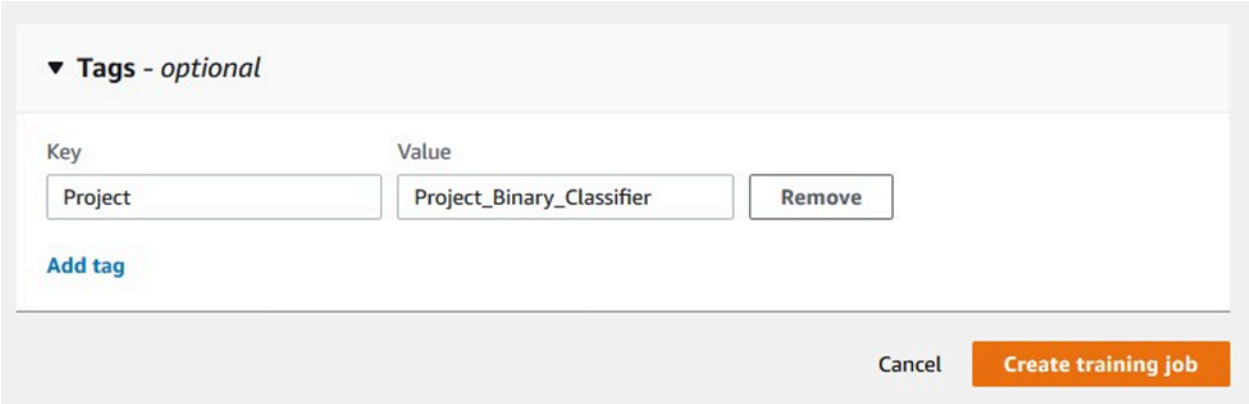
- Evaluate Models (Console)

Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

Add tags to training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Training jobs** and **Create training job**.
3. Scroll to the bottom of the page and enter a key and value for the tag.



4. To add another tag, choose **Add tag**, and add another key-value pair.

Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, **Tags** appears only if you have added a tag for a training job.

To find training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Search**.
3. Add **Parameters**.
    a. In the search box, enter a parameter and choose a parameter type, for example **TrainingJobName**.

b. Choose a conditional operation. For numeric values, use operators such as **is equals to**, **lesser than**, or **or greater than**. For text-based values, use operators such as **equals to** or **contains**.

c. Enter a value for the parameter.

4. (Optional) To refine your search, add additional search criteria. Choose **Add row** and enter the parameter values.

5. Choose **Search**.

Evaluate Models (Console)

To evaluate a model's performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

To evaluate a model (console)

1. Open the Amazon SageMaker console.

2. In the navigation pane, choose **Search** and search for training jobs by specifying relevant parameters. The results are displayed in a table.

Results: Training jobs

1

HyperParameter mini_batch_size	HyperParameter predictor_type	Metric train:binary_f_beta	Metric train:progress	Metric train:objective_loss	Metric train:binary_classification_accuracy
300	binary_classifier	0.966639518737793	100	0.023814236745238304	0.9934399724006653
100	binary_classifier	0.9652714133262634	100	0.023504912853240967	0.993179976940155
200	binary_classifier	0.9647442698478699	100	0.023259807378053665	0.9930800199508667

3. Open the preferences window by choosing the settings icon in the search results table.

4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter** or **Metric** .

5. Make necessary changes, then choose **Update view**.

6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

Find and Evaluate Training Jobs (API)

To the find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the `Search` API.

Topics

Find Training Jobs (API)

To find training jobs, create a search parameter using the `search_params` parameter. Then use the search function in the `smclient` subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the `Search` API to find training jobs.

```
import boto3

search_params={
   "MaxResults": 10,
   "Resource": "TrainingJob",
   "SearchExpression": {
      "Filters": [{
            "Name": "Tags.Project",
            "Operator": "Equals",
            "Value": "Project_Binary_Classifier"
         }]},
  "SortBy": "Metrics.train:binary_classification_accuracy",
  "SortOrder": "Descending"
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

Evaluate Models (API)

To evaluate models, run a search as described in Find Training Jobs (API), review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```
import pandas

headers=["Training Job Name", "Training Job Status", "Batch Size", "Binary
 Classification Accuracy"]
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
    rows.append([trainingJob['TrainingJobName'],
     trainingJob['TrainingJobStatus'],
     trainingJob['HyperParameters']['mini_batch_size'],
     metrics[[x['MetricName'] for x in
     metrics].index('train:binary_classification_accuracy')]['Value']
    ])

df = pandas.DataFrame(data=rows,columns=headers)

from IPython.display import display, HTMLdisplay(HTML(df.to_html()))
```

Get Suggestions for a Search (API)

To get suggestions for a search, use the [GetSearchSuggestions] API.

The following example for AWS SDK for Python (Boto3) is a `get_search_suggestions` request for items containing `linear`.

```
search_suggestion_params={
   "Resource": "TrainingJob",
   "SuggestionQuery": {
      "PropertyNameQuery": {
         "PropertyNameHint": "linear"
      }
   }
}
```

The following is an example response for a `get_search_suggestions` request.

```
{
        'PropertyNameSuggestions': [{'PropertyName':
 'hyperparameters.linear_init_method'},
                    {'PropertyName': 'hyperparameters.linear_init_value'},
                    {'PropertyName': 'hyperparameters.linear_init_sigma'},
```

```
                    {'PropertyName': 'hyperparameters.linear_lr'},
                    {'PropertyName': 'hyperparameters.linear_wd'}]
}
```

After getting search suggestions, you can use one of the property names in a search.

Verify the Datasets Used by Your Training Jobs

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

Trace Model Lineage

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.

Topics

- Trace Model Lineage (Console)
- Trace Model Lineage (API)

Trace Model Lineage (Console)

To trace a model's lineage (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Endpoints**, and choose the relevant endpoint.
3. Scroll to the **Endpoint configuration settings** section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

Trace Model Lineage (API)

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.

```
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
   "MaxResults": 1,
   "Resource": "TrainingJob",
   "SearchExpression": {
      "Filters": [
         {
            "Name": "ModelArtifacts.S3ModelArtifacts",
            "Operator": "Equals",
            "Value": model['PrimaryContainer']['ModelDataUrl']
         }]},
}
results = smclient.search(**search_params)
```

After finding the training job, you can review the resources used to train the model.

Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning (AMT), also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset. To do this, AMT uses the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that creates a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a *binary classification* problem on a marketing dataset. Your goal is to maximize the *area under the curve (AUC)* metric of the algorithm by training an XGBoost Algorithm model. You want to find which values for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters that will train the best model. Specify

a range of values for these hyperparameters. Then, SageMaker hyperparameter tuning searches within these ranges to find a combination of values that creates a training job that creates a model with the highest AUC. To conserve resources or meet a specific model quality expectation, you can also set up completion criteria to stop tuning after the criteria have been met.

You can use SageMaker AMT with built-in algorithms, custom algorithms, or SageMaker pre-built containers for machine learning frameworks.

SageMaker AMT can use an Amazon EC2 Spot instance to optimize costs when running training jobs. For more information, see Use Managed Spot Training in Amazon SageMaker.

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm that you need to train
- A clear understanding of how you measure success

Prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see Setting up Amazon SageMaker.

Topics

How Hyperparameter Tuning Works

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate your productivity by trying many variations of a model. It looks for the best model automatically by focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you must choose the right ranges to explore.

Use the API reference guide to understand how to interact with hyperparameter tuning. The examples on this page can be found in the HyperParameterTuningJobConfig and HyperbandStrategyConfig APIs.

> **Note**
>
> Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer. This can occur even if the best possible combination of values is within the ranges that you choose.

Grid Search

When using grid search, hyperparameter tuning chooses combinations of values from the range of categorical values that you specify when you create the job. Only categorical parameters are supported when using the grid search strategy. You do not need to specify the `MaxNumberOfTrainingJobs`. The number of training jobs created by the tuning job will be automatically calculated to be the total number of distinct categorical combinations possible. If specified, the value of `MaxNumberOfTrainingJobs` should equal the total number of distinct categorical combinations possible.

Random Search

When using random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn't depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the tuning.

For an example notebook that uses random search, see the Random search and hyperparameter scaling with SageMaker XGBoost and Automatic Model Tuning notebook.

Bayesian Optimization

Bayesian optimization treats hyperparameter tuning like a *regression* problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing a set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses an Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not yet well understood. The explore/exploit trade-off is common in many machine learning problems.

Hyperband

Hyperband is a multi-fidelity based tuning strategy that dynamically reallocates resources. Hyperband uses both intermediate and final results of training jobs to re-allocate epochs to well-utilized hyperparameter configurations and automatically stops those that underperform. It also seamlessly scales to using many parallel training jobs. These features can significantly speed up hyperparameter tuning over random search and Bayesian optimization strategies.

Hyperband should only be used to tune iterative algorithms that publish results at different resource levels. For example, Hyperband can be used to tune a neural network for image classification which publishes accuracy metrics after every epoch.

For more information about Hyperband, see the following links:

- Hyperband: A Novel Bandit-Based Approach to Hyperparameter Optimization
- Massively Parallel Hyperparameter Tuning
- BOHB: Robust and Efficient Hyperparameter Optimization at Scale
- Model-based Asynchronous Hyperparameter and Neural Architecture Search

Hyperband with early stopping

Training jobs can be stopped early when they are unlikely to improve the objective metric of the hyperparameter tuning job. This can help reduce compute time and avoid overfitting your model. Hyperband uses an advanced internal mechanism to apply early stopping. Thus, the parameter `TrainingJobEarlyStoppingType` in the `HyperParameterTuningJobConfig` API must be set to `OFF` when using the Hyperband internal early stopping feature.

> **Note**
>
> Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions. As such, it should be considered part of the scientific development process.

Define metrics and environment variables

A tuning job optimizes hyperparameters for training jobs that it launches by using a metric to evaluate performance. This guide shows how to define metrics so that you can use a custom algorithm for training, or use a built-in algorithm from Amazon SageMaker. This guide also shows how to specify environment variables during an Automatic model tuning (AMT) job.

Define metrics

Amazon SageMaker hyperparameter tuning parses your machine learning algorithm's `stdout` and `stderr` streams to find metrics, such as loss or validation-accuracy. The metrics show how well the model is performing on the dataset.

The following sections describe how to use two types of algorithms for training: built-in and custom.

Use a built-in algorithm for training

If you use one of the SageMaker built-in algorithms, metrics are already defined for you. In addition, built-in algorithms automatically send metrics to hyperparameter tuning for optimization. These metrics are also written to Amazon CloudWatch logs. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch.

For the objective metric for the tuning job, choose one of the metrics that the built-in algorithm emits. For a list of available metrics, see the model tuning section for the appropriate algorithm in Use Amazon SageMaker Built-in Algorithms or Pre-trained Models.

You can choose up to 40 metrics to monitor in your tuning job. Select one of those metrics to be the objective metric. The hyperparameter tuning job returns the training job that performed the best against the objective metric.

> **Note**
>
> Hyperparameter tuning automatically sends an additional hyperparameter `_tuning_objective_metric` to pass your objective metric to the tuning job for use during training.

Use a custom algorithm for training

This section shows how to define your own metrics to use your own custom algorithm for training. When doing so, make sure that your algorithm writes at least one metric to `stderr` or `stdout`. Hyperparameter tuning parses these streams to find algorithm metrics that show how well the model is performing on the dataset.

You can define custom metrics by specifying a name and regular expression for each metric that your tuning job monitors. Then, pass these metric definitions to the `CreateHyperParameterTuningJob` API in the `TrainingJobDefinition` parameter in the `MetricDefinitions` field of `AlgorithmSpecification`.

The following shows sample output from a log written to `stderr` or `stdout` by a training algorithm.

```
GAN_loss=0.138318;  Scaled_reg=2.654134; disc:[-0.017371,0.102429] real 93.3% gen 0.0%
 disc-combined=0.000000; disc_train_loss=1.374587;  Loss = 16.020744;  Iteration 0 took
 0.704s;  Elapsed=0s
```

The following code example shows how to use regular expressions in Python (regex). This is used to search the sample log output and capture the numeric values of four different metrics.

```
[
    {
        "Name": "ganloss",
        "Regex": "GAN_loss=(.*?);",
    },
    {
        "Name": "disc-combined",
        "Regex": "disc-combined=(.*?);",
    },
    {
        "Name": "discloss",
```

```
        "Regex": "disc_train_loss=(.*?);",
    },
    {
        "Name": "loss",
        "Regex": "Loss = (.*?);",
    },
]
```

In regular expressions, parenthesis `( )` are used to group parts of the regular expression together.

- For the `loss` metric that is defined in the code example, the expression `(.*?);` captures any character between the exact text `"Loss="` and the first semicolon `(;)` character.
- The character `.` instructs the regular expression to match any character.
- The character `*` means to match zero or more characters.
- The character `?` means capture only until the first instance of the `;` character.

The loss metric defined in the code sample will capture `Loss = 16.020744` from the sample output.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the SageMaker API, specify the value of the `name` key in the `HyperParameterTuningJobObjective` field of the `HyperParameterTuningJobConfig` parameter that you send to the `CreateHyperParameterTuningJob` operation.

Specify environment variables

SageMaker AMT optimizes hyperparameters within a tuning job to find the best parameters for model performance. You can use environment variables to configure your tuning job to change its behavior. You can also use environment variables that you used during training inside your tuning job.

If you want to use an environment variable from your tuning job or specify a new environment variable, input a string value for `Environment` within the SageMaker HyperParameterTrainingJobDefinition API. Pass this training job definition to the CreateHyperParameterTuningJob API.

For example, the environment variable `SM_LOG_LEVEL` can be set to the following values to tailor the output from a Python container.

```
NOTSET=0
DEBUG=10
INFO=20
WARN=30
ERROR=40
CRITICAL=50
```

As an example, to set the log level to 10 to debug your container logs, set the environment variable inside the HyperParameterTrainingJobDefinition, as follows.

```
{
   "HyperParameterTuningJobConfig": {
   ...,
   }
   "TrainingJobDefinition": {
      ...,
      "Environment" : [
          {
            "SM_LOG_LEVEL": 10
          }
      ],
      ...,
   },
   ...,
}
```

Define Hyperparameter Ranges

This guide shows how to use SageMaker APIs to define hyperparameter ranges. It also provides a list of hyperparameter scaling types that you can use.

Choosing hyperparameters and ranges significantly affects the performance of your tuning job. Hyperparameter tuning finds the best hyperparameter values for your model by searching over a range of values that you specify for each tunable hyperparameter. You can also specify up to 100 static hyperparameters that do not change over the course of the tuning job. You can use up to 100 hyperparameters in total (static + tunable). For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning. You can also use autotune to find optimal tuning job settings. For more information, see the following **Autotune** section.

> **Note**
>
> SageMaker Automatic Model Tuning (AMT) may add additional hyperparameters(s) that contribute to the limit of 100 total hyperparameters. Currently, to pass your objective metric to the tuning job for use during training, SageMaker adds `_tuning_objective_metric` automatically.

Static hyperparameters

Use static hyperparameters for the following cases: For example, you can use AMT to tune your model using `param1` (a tunable parameter) and `param2` (a static parameter). If you do, then use a search space for `param1` that lies between two values, and pass `param2` as a static hyperparameter, as follows.

```
param1: ["range_min","range_max"]
param2: "static_value"
```

Static hyperparameters have the following structure:

```
"StaticHyperParameters": {
    "objective" : "reg:squarederror",
    "dropout_rate": "0.3"
}
```

You can use the Amazon SageMaker API to specify key value pairs in the StaticHyperParameters field of the `HyperParameterTrainingJobDefinition` parameter that you pass to the CreateHyperParameterTuningJob operation.

Dynamic hyperparameters

You can use the SageMaker API to define hyperparameter ranges. Specify the names of hyperparameters and ranges of values in the `ParameterRanges` field of the `HyperParameterTuningJobConfig` parameter that you pass to the `CreateHyperParameterTuningJob` operation.

The `ParameterRanges` field has three subfields: categorical, integer, and continuous. You can define up to 30 total (categorical + integer + continuous) tunable hyperparameters to search over.

> **Note**
>
> Each categorical hyperparameter can have at most 30 different values.

Dynamic hyperparameters have the following structure:

```
"ParameterRanges": {
    "CategoricalParameterRanges": [
        {
            "Name": "tree_method",
            "Values": ["auto", "exact", "approx", "hist"]
        }
    ],
    "ContinuousParameterRanges": [
        {
            "Name": "eta",
            "MaxValue" : "0.5",
            "MinValue": "0",
            "ScalingType": "Auto"
        }
    ],
    "IntegerParameterRanges": [
        {
            "Name": "max_depth",
            "MaxValue": "10",
            "MinValue": "1",
            "ScalingType": "Auto"
        }
    ]
}
```

If you create a tuning job with a `Grid` strategy, you can only specify categorical values. You don't need to provide the `MaxNumberofTrainingJobs`. This value is inferred from the total number of configurations that can be produced from your categorical parameters. If specified, the value of `MaxNumberOfTrainingJobs` should be equal to the total number of distinct categorical combinations possible.

Autotune

To save time and resources searching for hyperparameter ranges, resources or objective metrics, autotune can automatically guess optimal values for some hyperparameter fields. Use autotune to find optimal values for the following fields:

- **ParameterRanges** – The names and ranges of hyperparameters that a tuning job can optimize.
- **ResourceLimits** – The maximum resources to be used in a tuning job. These resources can include the maximum number of training jobs, maximum runtime of a tuning job, and the maximum number of training jobs that can be run at the same time.
- **TrainingJobEarlyStoppingType** – A flag that stops a training job if a job is not significantly improving against an objective metric. Defaults to enabled. For more information, see Stop Training Jobs Early.
- **RetryStrategy** – The number of times to retry a training job. Non-zero values for `RetryStrategy` can increase the likelihood that your job will complete successfully.
- **Strategy** – Specifies how hyperparameter tuning chooses the combinations of hyperparameter values to use for the training job that it launches.
- **ConvergenceDetected** – A flag to indicate that Automatic Model Tuning (AMT) has detected model convergence.

To use autotune, do the following:

1. Specify the hyperparameter and an example value in the `AutoParameters` field of the ParameterRanges API.
2. Enable autotune.

AMT will determine if your hyperparameters and example values are eligible for autotune. Hyperparameters that can be used in autotune are automatically assigned to the appropriate parameter range type. Then, AMT uses `ValueHint` to select an optimal range for you. You can use the `DescribeHyperParameterTrainingJob` API to view these ranges.

The following example shows you how to configure a tuning job that uses autotune. In the configuration example, the hyperparameter `max_depth` has `ValueHint` containing an example value of `4`.

```
config = {
```

```
    'Autotune': {'Mode': 'Enabled'},
    'HyperParameterTuningJobName':'my-autotune-job',
    'HyperParameterTuningJobConfig': {
        'HyperParameterTuningJobObjective': {'Type': 'Minimize', 'MetricName':
 'validation:rmse'},
        'ResourceLimits': {'MaxNumberOfTrainingJobs': 5, 'MaxParallelTrainingJobs': 1},
        'ParameterRanges': {
            'AutoParameters': [
                {'Name': 'max_depth', 'ValueHint': '4'}
            ]
        }
    },
    'TrainingJobDefinition': {
    .... }
```

Continuing the previous example, a tuning job is created after the previous configuration is included in a call to the `CreateHyperParameterTuningJob` API. Then, autotune converts the max_depth hyperparameter in AutoParameters to the hyperparameter `IntegerParameterRanges`. The following response from a `DescribeHyperParameterTrainingJob` API shows that the optimal `IntegerParameterRanges` for `max_depth` are between 2 and 8.

```
{
    'HyperParameterTuningJobName':'my_job',
    'HyperParameterTuningJobConfig': {
        'ParameterRanges': {
            'IntegerParameterRanges': [
                {'Name': 'max_depth', 'MinValue': '2', 'MaxValue': '8'},
            ],
        }
    },
    'TrainingJobDefinition': {
        ...
    },
    'Autotune': {'Mode': 'Enabled'}

}
```

Hyperparameter scaling types

For integer and continuous hyperparameter ranges, you can choose the scale that you want hyperparameter tuning to use. For example, to search the range of values, you can specify a value

for the `ScalingType` field of the hyperparameter range. You can choose from the following hyperparameter scaling types:

Auto

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude). Uniformly searching values from the range provides a reasonable exploration of the entire range.

Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have values greater than 0.

Choose logarithmic scaling when you're searching a range that spans several orders of magnitude.

For example, if you're tuning a Tune a linear learner model model, and you specify a range of values between .0001 and 1.0 for the `learning_rate` hyperparameter, consider the following: Searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would. This is because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0. As a result, that leaves only 10 percent of your training budget for the values between .0001 and .1.

`ReverseLogarithmic`

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. Reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

For an example notebook that uses hyperparameter scaling, see these Amazon SageMaker hyperparameter examples on GitHub.

Track and set completion criteria for your tuning job

You can use completion criteria to instruct Automatic model tuning (AMT) to stop your tuning job if certain conditions are met. With these conditions, you can set a minimum model performance or maximum number of training jobs that don't improve when evaluated against the objective metric. You can also track the progress of your tuning job and decide to let it continue or to stop it manually. This guide shows you how to set completion criteria, check the progress of and stop your tuning job manually.

Set completion criteria for your tuning job

During hyperparameter optimization, a tuning job will launch several training jobs inside a loop. The tuning job will do the following.

- Check your training jobs for completion and update statistics accordingly
- Decide what combination of hyperparameters to evaluate next.

AMT will continuously check the training jobs that were launched from your tuning job to update statistics. These statistics include tuning job runtime and best training job. Then, AMT determines whether it should stop the job according to your completion criteria. You can also check these statistics and stop your job manually. For more information about stopping a job manually, see the Stopping your tuning job manually section.

As an example, if your tuning job meets your objective, you can stop tuning early to conserve resources or ensure model quality. AMT checks your job performance against your completion criteria and stops the tuning job if any have been met.

You can specify the following kinds of completion criteria:

- `MaxNumberOfTrainingJobs` – The maximum number of training jobs to be run before tuning is stopped.
- `MaxNumberOfTrainingJobsNotImproving` – The maximum number of training jobs that do not improve performance against the objective metric from the current best training job. As an example, if the best training job returned an objective metric that had an accuracy of `90%`, and `MaxNumberOfTrainingJobsNotImproving` is set to `10`. In this example, tuning will stop after `10` training jobs fail to return an accuracy higher than `90%`.

- `MaxRuntimeInSeconds` – The upper limit of wall clock time in seconds of how long a tuning job can run.
- `TargetObjectiveMetricValue` – The value of the objective metric against which the tuning job is evaluated. Once this value is met, AMT stops the tuning job.
- `CompleteOnConvergence` – A flag to stop tuning after an internal algorithm determines that the tuning job is unlikely to improve more than 1% over the objective metric from the best training job.

Selecting completion criteria

You can choose one or multiple completion criteria to stop your hyperparameter tuning job after a condition has been meet. The following instructions show you how to select completion criteria and how to decide which is the most appropriate for your use case.

- Use `MaxNumberOfTrainingJobs` in the ResourceLimits API to set an upper limit for the number of training jobs that can be run before your tuning job is stopped. Start with a large number and adjust it based on model performance against your tuning job objective. Most users input values of around `50` or more training jobs to find an optimal hyperparameter configuration. Users looking for higher levels of model performance will use `200` or more training jobs.
- Use `MaxNumberOfTrainingJobsNotImproving` in the BestObjectiveNotImproving API field to stop training if model performance fails to improve after a specified number of jobs. Model performance is evaluated against an objective function. After the `MaxNumberOfTrainingJobsNotImproving` is met, AMT will stop the tuning job. Tuning jobs tend to make the most progress in the beginning of the job. Improving model performance against an objective function will require a larger number of training jobs towards the end of tuning. Select a value for `MaxNumberOfTrainingJobsNotImproving` by checking the performance of similar training jobs against your objective metric.
- Use `MaxRuntimeInSeconds` in the ResourceLimits API to set an upper limit for the amount of wall clock time that the tuning job may take. Use this field to meet a deadline by which the tuning job must complete or to limit compute resources.

  To get an estimated total compute time in seconds for a tuning job, use the following formula:

  Estimated max compute time in seconds= `MaxRuntimeInSeconds` * `MaxParallelTrainingJobs` * `MaxInstancesPerTrainingJob`

> **Note**
>
> The actual duration of a tuning job may deviate slightly from the value specified in this field.

- Use `TargetObjectiveMetricValue` in the TuningJobCompletionCriteria API to stop your tuning job. You stop the tuning job after any training job that is launched by the tuning job reaches this objective metric value. Use this field if your use case depends on reaching a specific performance level, rather than spending compute resources to find the best possible model.
- Use `CompleteOnConvergence` in the TuningJobCompletionCriteria API to stop a tuning job after AMT has detected that the tuning job has converged, and is unlikely to make further significant progress. Use this field when it is not clear what values for any of the other completion criteria should be used. AMT determines convergence based on an algorithm developed and tested on a wide range of diverse benchmarks. A tuning job is defined to have converged when none of the training jobs return significant improvement (1% or less). Improvement is measured against the objective metric returned by the highest performing job, so far.

Combining different completion criteria

You can also combine any of the different completion criteria in the same tuning job. AMT will stop the tuning job when any one of the completion criteria is met. For example, if you want to tune your model until it meets an objective metric, but don't want to keep tuning if your job has converged, use the following guidance.

- Specify `TargetObjectiveMetricValue` in the TuningJobCompletionCriteria API to set a target objective metrics value to reach.
- Set CompleteOnConvergence to `Enabled` to stop a tuning job if AMT has determined that model performance is unlikely to improve.

Track tuning job progress

You can use the `DescribeHyperParameterTuningJob` API to track the progress of your tuning job at any time while it is running. You don't have to specify completion criteria to obtain tracking information for your tuning job. Use the following fields to obtain statistics about your tuning job.

- BestTrainingJob – An object that describes the best training job obtained so far, evaluated against your objective metric. Use this field to check your current model performance and the value of the objective metric of this best training job.
- ObjectiveStatusCounters – An object that specifies the total number of training jobs completed in a tuning job. To estimate average duration of a tuning job, use `ObjectiveStatusCounters` and the total runtime of a tuning job. You can use the average duration to estimate how much longer your tuning job will run.
- `ConsumedResources` – The total resources, such as `RunTimeInSeconds`, consumed by your tuning job. Compare `ConsumedResources`, found in the DescribeHyperParameterTuningJob API, against `BestTrainingJob` in the same API. You can also compare `ConsumedResources` against the response from the ListTrainingJobsForHyperParameterTuningJob API to assess if your tuning job is making satisfactory progress given the resources being consumed.
- TuningJobCompletionDetails – Tuning job completion information that includes the following:
  - The timestamp of when convergence is detected if the job has converged.
  - The number of training jobs that have not improved model performance. Model performance is evaluated against the objective metric from the best training job.

  Use the tuning job completion criteria to assess how likely your tuning job is to improve your model performance. Model performance is evaluated against the best objective metric if it ran to completion.

Stopping your tuning job manually

You can determine if you should let the tuning job run until it completes or if you should stop the tuning job manually. To determine this, use the information returned by the parameters in the `DescribeHyperParameterTuningJob` API, as shown in the previous **Tracking tuning job progress** section. As an example, if your model performance does not improve after several training jobs complete, you may choose to stop the tuning job. Model performance is evaluated against the best objective metric.

To stop the tuning job manually, use the StopHyperParameterTuningJob API and provide the name of the tuning job to be stopped.

Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- The **job settings** to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.
- The **training job definition** to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.
- The **tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

Get Started

You can create a new hyperparameter tuning job, clone a job, add, or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

- **In the console**: To create a new job, open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/, choose **Hyperparameter tuning jobs** from the **Training**, menu, and then choose **Create hyperparameter tuning job**. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) topic.

> **Note**
>
> When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API**: For instructions on using the SageMaker API to create a hyperparameter tuning job, see Example: Hyperparameter Tuning Job. When you call `CreateHyperParameterTuningJob` to tune multiple algorithms, you must provide a list of training definitions using `TrainingJobDefinitions` instead of specifying a single TrainingJobDefinition. You must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources that you want to use for the tuning job. Choose only one of these definition types depending on the number of algorithms that are being tuned.

- Manage Hyperparameter Tuning and Training Jobs

Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

This guide shows you how to create a new hyperparameter optimization (HPO) tuning job for one or more algorithms. To create an HPO job, define the settings for the tuning job, and create training job definitions for each algorithm being tuned. Next, configure the resources for and create the tuning job. The following sections provide details about how to complete each step. We provide an example of how to tune multiple algorithms using the SageMaker SDK for Python client at the end of this guide.

Components of a tuning job

An HPO tuning job contains the following three components:

- Tuning job settings
- Training job definitions
- Tuning job configuration

The way that these components are included in your HPO tuning job depends on whether your tuning job contains one or multiple training algorithms. The following guide describes each of the components and gives an example of both types of tuning jobs.

Tuning job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when you're tuning a single algorithm. After you define the job settings, you can create individual training definitions for each algorithm or variation that you want to tune.

Warm start

If you cloned this job, you can use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature, and it's only available when tuning a single algorithm. With the warm start option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

> **Note**
>
> Warm start is compatible only with tuning jobs that were created after October 1, 2018. For more information, see Run a warm start job.

Early stopping

To reduce compute time and avoid overfitting your model, you can stop training jobs early. Early stopping is helpful when the training job is unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it’s disabled by default. For more information about how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see Stop Training Jobs Early.

Tuning strategy

Tuning strategy can be either random, Bayesian, or Hyperband. These selections specify how automatic tuning algorithms search specified hyperparameter ranges that are selected in a later

step. Random search chooses random combinations of values from the specified ranges and can be run sequentially or in parallel. Bayesian optimization chooses values based on what is likely to get the best result according to the known history of previous selections. Hyperband uses a multi-fidelity strategy that dynamically allocates resources toward well-utilized jobs and automatically stops those that underperform. The new configuration that starts after stopping other configurations is chosen randomly.

Hyperband can only be used with iterative algorithms, or algorithms that run steps in iterations, such as XGBoost or Random Cut Forest. Hyperband can't be used with non-iterative algorithms, such as decision trees or k-Nearest Neighbors. For more information about search strategies, see How Hyperparameter Tuning Works.

> **Note**
>
> Hyperband uses an advanced internal mechanism to apply early stopping. Therefore, when you use the Hyperband internal early stopping feature, the parameter `TrainingJobEarlyStoppingType` in the `HyperParameterTuningJobConfig` API must be set to `OFF`.

Tags

To help you manage tuning jobs, you can enter tags as key-value pairs to assign metadata to tuning jobs. Values in the key-value pair are not required. You can use the key without values. To see the keys associated with a job, choose the **Tags** tab on the details page for tuning job. For more information about using tags for tuning jobs, see Manage Hyperparameter Tuning and Training Jobs.

Training job definitions

To create a training job definition, you must configure the algorithm and parameters, define the data input and output, and configure resources. Provide at least one `TrainingJobDefinition` for each HPO tuning job. Each training definition specifies the configuration for an algorithm.

To create several definitions for your training job, you can clone a job definition. Cloning a job can save time because it copies all of the job settings, including data channels and Amazon S3 storage locations for output artifacts. You can edit a cloned job to change what you need for your use case.

Topics

- Configure algorithm and parameters
- Define data input and output
- Configure training job resources
- Add or clone a training job

Configure algorithm and parameters

The following list describes what you need to configure the set of hyperparameter values for each training job.

- A name for your tuning job
- Permission to access services
- Parameters for any algorithm options
- An objective metric
- The range of hyperparameter values, when required

Name

Provide a unique name for the training definition.

Permissions

Amazon SageMaker requires permissions to call other services on your behalf. Choose an AWS Identity and Access Management (IAM) role, or let AWS create a role with the `AmazonSageMakerFullAccess` IAM policy attached.

Optional security settings

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a virtual private cloud (VPC).

> **Note**
>
> Inter-container encryption is only available when you create a job definition from the API.

Algorithm options

You can choose built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

- If you choose a built-in algorithm, it has the Amazon Elastic Container Registry (Amazon ECR) image information pre-populated.
- If you choose your own container, you must specify the (Amazon ECR) image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a CSV file from Amazon S3, you should select the file.

Metrics

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you must define your metrics. You can define up to 20 metrics for your tuning job to monitor. You must choose one metric as the objective metric. For more information about how to define a metric for a tuning job, see Define metrics.

Objective metric

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page. The detail page provides a summary of the best training job that is found using this objective metric.

Hyperparameter configuration

When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm that's being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to **static**. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define data input and output

Each training job definition for a tuning job must configure the channels for data inputs, data output locations, and optionally, any checkpoint storage locations for each training job.

Input data configuration

Input data is defined by channels. Each channel its own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the algorithm that you choose supports multiple input channels, you can specify those, too. For example, when you use the XGBoost churn prediction notebook, you can add two channels: train and validation.

Checkpoint configuration

Checkpoints are periodically generated during training. For the checkpoints to be saved, you must choose an Amazon S3 location. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Use checkpoints in Amazon SageMaker.

Output data configuration

Define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

Configure training job resources

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

Resource configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see Use Managed Spot Training in Amazon SageMaker.

Stopping condition

The stopping condition specifies the maximum duration that's allowed for each training job.

Add or clone a training job

After you create a training job definition for a tuning job, you will return to the **Training Job Definition(s)** panel. This panel is where you can create additional training job definitions to train

additional algorithms. You can select the **Add training job definition** and work through the steps to define a training job again.

Alternatively, to replicate an existing training job definition and edit it for the new algorithm, choose **Clone** from the **Action** menu. The clone option can save time because it copies all of the job's settings, including the data channels and Amazon S3 storage locations. For more information about cloning, see Manage Hyperparameter Tuning and Training Jobs.

Tuning job configuration

Resource Limits

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most). You can also specify the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes that you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

Review the job settings, the training job definitions, and the resource limits. Then select **Create hyperparameter tuning job**.

HPO tuning job example

To run a hyperparameter optimization (HPO) training job, first create a training job definition for each algorithm that's being tuned. Next, define the tuning job settings and configure the resources for the tuning job. Finally, run the tuning job.

If your HPO tuning job contains a single training algorithm, the SageMaker tuning function will call the `HyperparameterTuner` API directly and pass in your parameters. If your HPO tuning job contains multiple training algorithms, your tuning function will call the `create` function of the `HyperparameterTuner` API. The `create` function tells the API to expect a dictionary containing one or more estimators.

In the following section, code examples show how to tune a job containing either a single training algorithm or multiple algorithms using the SageMaker Python SDK.

Create training job definitions

When you create a tuning job that includes multiple training algorithms, your tuning job configuration will include the estimators and metrics and other parameters for your training jobs. Therefore, you need to create the training job definition first, and then configure your tuning job.

The following code example shows how to retrieve two SageMaker containers containing the built-in algorithms XGBoost and Linear Learner. If your tuning job contains only one training algorithm, omit one of the containers and one of the estimators.

```
import sagemaker
from sagemaker import image_uris

from sagemaker.estimator import Estimator

sess = sagemaker.Session()
region = sess.boto_region_name
role = sagemaker.get_execution_role()

bucket = sess.default_bucket()
prefix = "sagemaker/multi-algo-hpo"

# Define the training containers and intialize the estimators
xgb_container = image_uris.retrieve("xgboost", region, "latest")
ll_container = image_uris.retrieve("linear-learner", region, "latest")

xgb_estimator = Estimator(
    xgb_container,
    role=role,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    output_path='s3://{}/{}/xgb_output".format(bucket, prefix)',
    sagemaker_session=sess,
)

ll_estimator = Estimator(
    ll_container,
    role,
    instance_count=1,
    instance_type="ml.c4.xlarge",
    output_path="s3://{}/{}/ll_output".format(bucket, prefix),
    sagemaker_session=sess,
)

# Set static hyperparameters
ll_estimator.set_hyperparameters(predictor_type="binary_classifier")
xgb_estimator.set_hyperparameters(
    eval_metric="auc",
    objective="binary:logistic",
```

```
    num_round=100,
    rate_drop=0.3,
    tweedie_variance_power=1.4,
)
```

Next, define your input data by specifying the training, validation, and testing datasets, as shown in the following code example. This example shows how to tune multiple training algorithms.

```
training_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/{}/train".format(bucket, prefix), content_type="csv"
)
validation_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/{}/validate".format(bucket, prefix), content_type="csv"
)
test_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/{}/test".format(bucket, prefix), content_type="csv"
)

train_inputs = {
    "estimator-1": {
        "train": training_data,
        "validation": validation_data,
        "test": test_data,
    },
    "estimator-2": {
        "train": training_data,
        "validation": validation_data,
        "test": test_data,
    },
}
```

If your tuning algorithm contains only one training algorithm, your `train_inputs` should contain only one estimator.

You must upload the inputs for the training, validation, and training datasets to your Amazon S3 bucket before you use those in an HPO tuning job.

Define resources and settings for your tuning job

This section shows how to initialize a tuner, define resources, and specify job settings for your tuning job. If your tuning job contains multiple training algorithms, these settings are applied to all of the algorithms that are contained inside your tuning job. This section provides two

code examples to define a tuner. The code examples show you how to optimize a single training algorithm followed by an example of how to tune multiple training algorithms.

Tune a single training algorithm

The following code example shows how to initialize a tuner and set hyperparameter ranges for one SageMaker built-in algorithm, XGBoost.

```
from sagemaker.tuner import HyperparameterTuner
from sagemaker.parameter import ContinuousParameter, IntegerParameter

hyperparameter_ranges = {
    "max_depth": IntegerParameter(1, 10),
    "eta": ContinuousParameter(0.1, 0.3),
}

objective_metric_name = "validation:accuracy"

tuner = HyperparameterTuner(
    xgb_estimator,
    objective_metric_name,
    hyperparameter_ranges,
    objective_type="Maximize",
    max_jobs=5,
    max_parallel_jobs=2,
)
```

Tune multiple training algorithms

Each training job requires different configurations, and these are specified using a dictionary. The following code example shows how to initialize a tuner with configurations for two SageMaker built-in algorithms, XGBoost and Linear Learner. The code example also shows how to set a tuning strategy and other job settings, such as the compute resources for the tuning job. The following code example uses `metric_definitions_dict`, which is optional.

```
from sagemaker.tuner import HyperparameterTuner
from sagemaker.parameter import ContinuousParameter, IntegerParameter

# Initialize your tuner
tuner = HyperparameterTuner.create(
    estimator_dict={
        "estimator-1": xgb_estimator,
```

```
        "estimator-2": ll_estimator,
    },
    objective_metric_name_dict={
        "estimator-1": "validation:auc",
        "estimator-2": "test:binary_classification_accuracy",
    },
    hyperparameter_ranges_dict={
        "estimator-1": {"eta": ContinuousParameter(0.1, 0.3)},
        "estimator-2": {"learning_rate": ContinuousParameter(0.1, 0.3)},
    },
    metric_definitions_dict={
        "estimator-1": [
            {"Name": "validation:auc", "Regex": "Overall test accuracy: (.*?);"}
        ],
        "estimator-2": [
            {
                "Name": "test:binary_classification_accuracy",
                "Regex": "Overall test accuracy: (.*?);",
            }
        ],
    },
    strategy="Bayesian",
    max_jobs=10,
    max_parallel_jobs=3,
)
```

Run your HPO tuning job

Now you can run your tuning job by passing your training inputs to the `fit` function of the `HyperparameterTuner` class. The following code example shows how to pass the `train_inputs` parameter, that is defined in a previous code example, to your tuner.

```
tuner.fit(inputs=train_inputs, include_cls_metadata ={}, estimator_kwargs ={})
```

Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/. Select **Hyperparameter tuning job** from the **Training** menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting **Create hyperparameter tuning job**.

To see the training jobs run a part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting **Create Model** or you can clone the training job by selecting **Clone**.

Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in Add or clone a training job step of that procedure.

Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the Components of a tuning job section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes, such as cost allocation or access control. To add tags using the SageMaker SDK, use `AddTags` API. For more information about using tagging for AWS resources, see Tagging AWS resources.

Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level SDK for Python (Boto3) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need

- An AWS account and an administrator user
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker notebook instance

Topics

Create a Notebook Instance

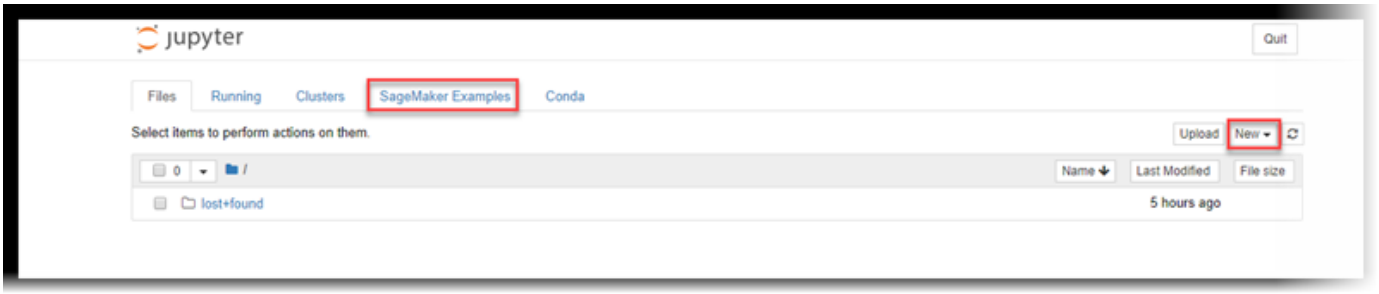
> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide Permissions for Tagging SageMaker Resources.
> AWS Managed Policies for Amazon SageMaker that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.

2. Open a running notebook instance, by choosing **Open** next to its name. The Jupyter notebook server page appears:



3. To create a notebook, choose **Files**, **New**, and **conda_python3**. .
4. Name the notebook.

Next Step

[Get the Amazon SageMaker Boto 3 Client]

Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```
import sagemaker
import boto3

import numpy as np                                # For performing matrix operations
 and numerical processing
import pandas as pd                               # For manipulating tabular data
from time import gmtime, strftime
import os

region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines `region` and `smclient` objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.

Next Step

[Get the SageMaker Execution Role]

Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance.

To find the ARN of the IAM execution role attached to a notebook instance:

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. On the left navigation pane, choose **Notebook** then **Notebook instances**.
3. From the list of notebooks, select the notebook that you want to view.
4. The ARN is in the **Permissions and encryption** section.

Alternatively, Amazon SageMaker Python SDK users can retrieve the ARN of the execution role attached to their user profile or a notebook instance by running the following code:

```
from sagemaker import get_execution_role

role = get_execution_role()
print(role)
```

For more information about using `get_execution_role` in the Amazon SageMaker Python SDK, see Session. For more information about roles, see SageMaker Roles.

Next Step

Use an Amazon S3 bucket for input and output

Use an Amazon S3 bucket for input and output

Set up a S3 bucket to upload training datasets and save training output data for your hyperparameter tuning job.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. `prefix` is the path within the bucket where SageMaker stores the data for the current training job.

```
sess = sagemaker.Session()
bucket = sess.default_bucket() # Set a default S3 bucket
```

```
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

To use a specific S3 bucket (Optional)

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain **`sagemaker`**, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```
bucket = "sagemaker-your-preferred-s3-bucket"

sess = sagemaker.Session(
    default_bucket = bucket
)
```

> **Note**
>
> The name of the bucket doesn't need to contain **`sagemaker`** if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

Next Step

Download, Prepare, and Upload Training Data

Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.

For more information about the dataset and the data transformation that the example performs, see the *hpo_xgboost_direct_marketing_sagemaker_APIs* notebook in the **Hyperparameter Tuning** section of the **SageMaker Examples** tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```
!wget -N https://archive.ics.uci.edu/ml/machine-learning-databases/00222/bank-
additional.zip
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)     # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)         # Keep the output on one page
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)
            # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired',
 'unemployed']), 1, 0)   # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)
            # Convert categorical variables to sets of indicators
model_data
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx',
 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)

train_data, validation_data, test_data = np.split(model_data.sample(frac=1,
 random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])

pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)],
 axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)],
 axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)],
 axis=1).to_csv('test.csv', index=False, header=False)

boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/
train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/
validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job

Configure and Launch a Hyperparameter Tuning Job

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide Permissions for Tagging SageMaker Resources.
> AWS Managed Policies for Amazon SageMaker that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

A hyperparameter is a high-level parameter that influences the learning process during model training. To get the best model predictions, you can optimize a hyperparameter configuration or set hyperparameter values. The process of finding an optimal configuration is called hyperparameter tuning. To configure and launch a hyperparameter tuning job, complete the steps in these guides.

Topics

Settings for the hyperparameter tuning job

To specify settings for the hyperparameter tuning job, define a JSON object when you create the tuning job. Pass this JSON object as the value of the `HyperParameterTuningJobConfig` parameter to the `CreateHyperParameterTuningJob` API.

In this JSON object, specify the following:

In this JSON object, you specify:

- `HyperParameterTuningJobObjective` – The objective metric used to evaluate the performance of the training job launched by the hyperparameter tuning job.
- `ParameterRanges` – The range of values that a tunable hyperparameter can use during optimization. For more information, see Define Hyperparameter Ranges
- `RandomSeed` – A value used to initialize a pseudo-random number generator. Setting a random seed will allow the hyperparameter tuning search strategies to produce more consistent configurations for the same tuning job (optional).
- `ResourceLimits` – The maximum number of training and parallel training jobs that the hyperparameter tuning job can use.

> **Note**
>
> If you use your own algorithm for hyperparameter tuning, rather than a SageMaker built-in algorithm, you must define metrics for your algorithm. For more information, see Define metrics.

The following code example shows how to configure a hyperparameter tuning job using the built-in XGBoost algorithm. The code example shows how to define ranges for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters. For more information about these and other hyperparameters see XGBoost Parameters.

In this code example, the objective metric for the hyperparameter tuning job finds the hyperparameter configuration that maximizes `validation:auc`. SageMaker built-in algorithms automatically write the objective metric to CloudWatch Logs. The following code example also shows how to set a `RandomSeed`.

```
tuning_job_config = {
    "ParameterRanges": {
      "CategoricalParameterRanges": [],
      "ContinuousParameterRanges": [
        {
          "MaxValue": "1",
          "MinValue": "0",
          "Name": "eta"
        },
```

```
        {
          "MaxValue": "2",
          "MinValue": "0",
          "Name": "alpha"
        },
        {
          "MaxValue": "10",
          "MinValue": "1",
          "Name": "min_child_weight"
        }
      ],
      "IntegerParameterRanges": [
        {
          "MaxValue": "10",
          "MinValue": "1",
          "Name": "max_depth"
        }
      ]
    },
    "ResourceLimits": {
      "MaxNumberOfTrainingJobs": 20,
      "MaxParallelTrainingJobs": 3
    },
    "Strategy": "Bayesian",
    "HyperParameterTuningJobObjective": {
      "MetricName": "validation:auc",
      "Type": "Maximize"
    },
    "RandomSeed" : 123
  }
```

Configure the training jobs

The hyperparameter tuning job will launch training jobs to find an optimal configuration of hyperparameters. These training jobs should be configured using the SageMaker `CreateHyperParameterTuningJob` API.

To configure the training jobs, define a JSON object and pass it as the value of the `TrainingJobDefinition` parameter inside `CreateHyperParameterTuningJob`.

In this JSON object, you can specify the following:

- `AlgorithmSpecification` – The registry path of the Docker image containing the training algorithm and related metadata. To specify an algorithm, you can use your own custom built algorithm inside a Docker container or a SageMaker built-in algorithm (required).
- `InputDataConfig` – The input configuration, including the `ChannelName`, `ContentType`, and data source for your training and test data (required).
- `InputDataConfig` – The input configuration, including the `ChannelName`, `ContentType`, and data source for your training and test data (required).
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- `RoleArn` – The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that SageMaker uses to perform tasks. Tasks include reading input data, downloading a Docker image, writing model artifacts to an S3 bucket, writing logs to Amazon CloudWatch Logs, and writing metrics to Amazon CloudWatch (required).
- `StoppingCondition` – The maximum runtime in seconds that a training job can run before being stopped. This value should be greater than the time needed to train your model (required).
- `MetricDefinitions` – The name and regular expression that defines any metrics that the training jobs emit. Define metrics only when you use a custom training algorithm. The example in the following code uses a built-in algorithm, which already has metrics defined. For information about defining metrics (optional), see Define metrics.
- `TrainingImage` – The Dockercontainer image that specifies the training algorithm (optional).
- `StaticHyperParameters` – The name and values of hyperparameters that are not tuned in the tuning job (optional).

The following code example sets static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the XGBoost Algorithm built-in algorithm.

SageMaker Python SDK v1

```
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}/{}/train'.format(bucket, prefix)
s3_input_validation ='s3://{}/{}/validation/'.format(bucket, prefix)

training_job_definition = {
```

```
    "AlgorithmSpecification": {
      "TrainingImage": training_image,
      "TrainingInputMode": "File"
    },
    "InputDataConfig": [
      {
        "ChannelName": "train",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_train
          }
        }
      },
      {
        "ChannelName": "validation",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_validation
          }
        }
      }
    ],
    "OutputDataConfig": {
      "S3OutputPath": "s3://{}/{}/output".format(bucket,prefix)
    },
    "ResourceConfig": {
      "InstanceCount": 2,
      "InstanceType": "ml.c4.2xlarge",
      "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
      "eval_metric": "auc",
      "num_round": "100",
      "objective": "binary:logistic",
      "rate_drop": "0.3",
```

```
      "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
      "MaxRuntimeInSeconds": 43200
    }
}
```

SageMaker Python SDK v2

```
training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')

s3_input_train = 's3://{}/{}/train'.format(bucket, prefix)
s3_input_validation ='s3://{}/{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
      "TrainingImage": training_image,
      "TrainingInputMode": "File"
    },
    "InputDataConfig": [
      {
        "ChannelName": "train",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_train
          }
        }
      },
      {
        "ChannelName": "validation",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
          "S3DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_validation
          }
        }
```

```
      }
    ],
    "OutputDataConfig": {
      "S3OutputPath": "s3://{}/{}/output".format(bucket,prefix)
    },
    "ResourceConfig": {
      "InstanceCount": 2,
      "InstanceType": "ml.c4.2xlarge",
      "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
      "eval_metric": "auc",
      "num_round": "100",
      "objective": "binary:logistic",
      "rate_drop": "0.3",
      "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
      "MaxRuntimeInSeconds": 43200
    }
}
```

Name and launch the hyperparameter tuning job

After you configure the hyperparameter tuning job, you can launch it by calling the `CreateHyperParameterTuningJob` API. The following code example uses `tuning_job_config` and `training_job_definition`. These were defined in the previous two code examples to create a hyperparameter tuning job.

```
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
 tuning_job_name,
                                            HyperParameterTuningJobConfig =
 tuning_job_config,
                                            TrainingJobDefinition =
 training_job_definition)
```

Monitor the Progress of a Hyperparameter Tuning Job

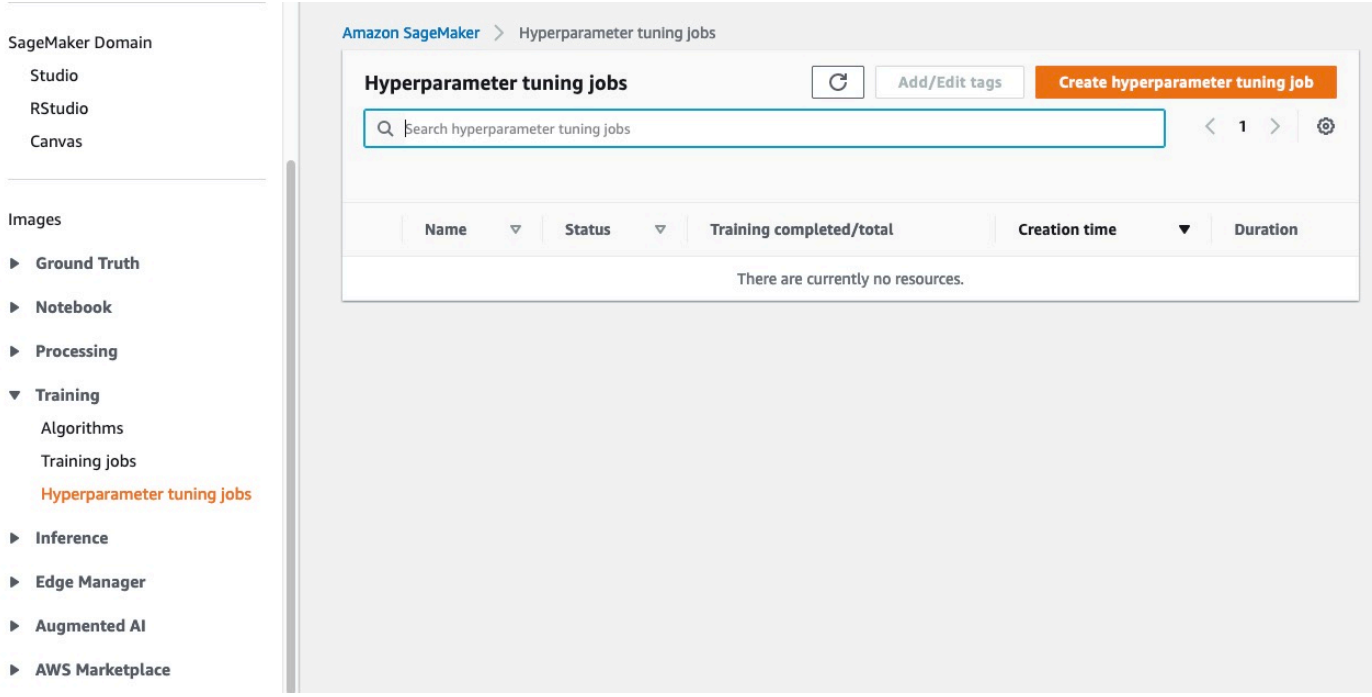
To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

Topics

View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Hyperparameter tuning jobs**.

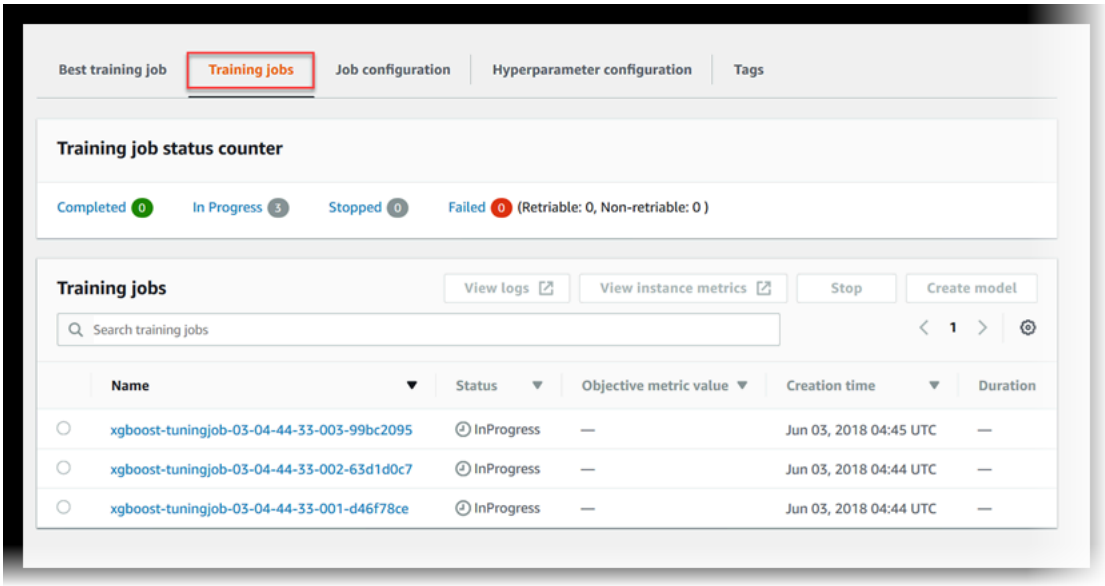


3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:
   - `Completed`—The hyperparameter tuning job successfully completed.
   - `InProgress`—The hyperparameter tuning job is in progress. One or more training jobs are still running.
   - `Failed`—The hyperparameter tuning job failed.
   - `Stopped`—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
   - `Stopping`—The hyperparameter tuning job is in the process of stopping.

View the Status of the Training Jobs

To view the status of the training jobs that the hyperparameter tuning job launched

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.



3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

   A training job can be:

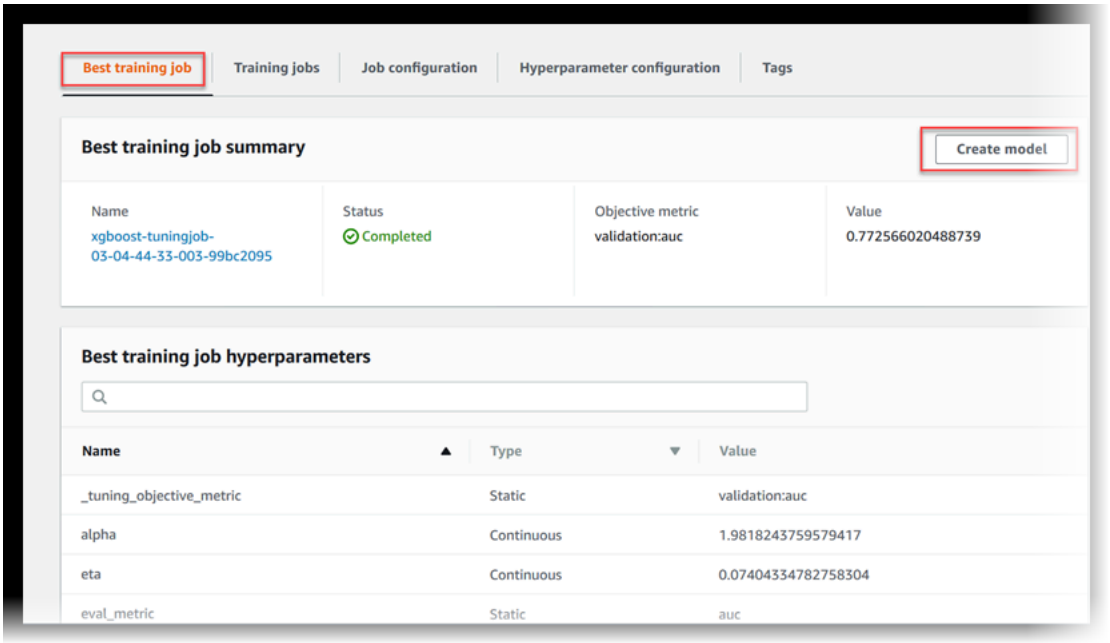
   - `Completed`—The training job successfully completed.
   - `InProgress`—The training job is in progress.
   - `Stopped`—The training job was manually stopped before it completed.
   - `Failed (Retryable)`—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
   - `Failed (Non-retryable)`—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.

> **Note**
>
> Hyperparameter tuning jobs can be stopped and the underlying resources deleted, but the jobs themselves cannot be deleted.

View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.



To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

Next Step

Clean up

Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

> **Note**
>
> If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.
4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with `/aws/sagemaker/`.

Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto3), set the `TrainingJobEarlyStoppingType` field of the `HyperParameterTuningJobConfig` object that you use to configure the tuning job to `AUTO`.
- If you are using the Amazon SageMaker Python SDK, set the `early_stopping_type` parameter of the HyperParameterTuner object to `Auto`.
- In the Amazon SageMaker console, in the **Create hyperparameter tuning job** workflow, under **Early stopping**, choose **Auto**.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the `hpo_image_classification_early_stopping.ipynb` notebook in the **Hyperparameter Tuning** section of the **SageMaker Examples** in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks.

How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- LightGBM
- CatBoost
- AutoGluon-Tabular
- TabTransformer
- Linear Learner Algorithm—Supported only if you use `objective_loss` as the objective metric.
- XGBoost Algorithm
- Image Classification - MXNet
- Object Detection - MXNet
- Sequence-to-Sequence Algorithm
- IP Insights

> **Note**
>
> This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

TensorFlow

Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see the tf.keras.callbacks.ProgbarLogger API.

MXNet

Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see the mxnet.callback APIs.

Chainer

Extend chainer by using the `extensions.Evaluator` class. For information, see the chainer.training.extensions.Evaluator API.

PyTorch and Spark

There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see How Hyperparameter Tuning Works. Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

> **Note**
>
> Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons to consider warm start include the following:

- To gradually increase the number of training jobs over several tuning jobs based on results after each iteration.
- To tune a model using new data that you received.
- To change hyperparameter ranges that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.

Topics

Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

`IDENTICAL_DATA_AND_ALGORITHM`

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not

affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run an warm start tuning job of type `IDENTICAL_DATA_AND_ALGORITHM`, there is an additional field in the response to `DescribeHyperParameterTuningJob` named `OverallBestTrainingJob`. The value of this field is the TrainingJobSummary for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

`TRANSFER_LEARNING`

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (`Completed`, `Stopped`, or `Failed`) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.

- The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. For example, if the parent job has a tunable categorical hyperparameter with the possible values `red` and `blue`, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of `red` in the parent job, and you change the static value to `blue` in the new tuning job, it also counts as 2 changes.
- Warm start tuning is not recursive. For example, if you create `MyTuningJob3` as a warm start tuning job with `MyTuningJob2` as a parent job, and `MyTuningJob2` is itself an warm start tuning job with a parent job `MyTuningJob1`, the information that was learned when running `MyTuningJob1` is not used for `MyTuningJob3`. If you want to use the information from `MyTuningJob1`, you must explicitly add it as a parent for `MyTuningJob3`.
- The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.
- Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Example Notebooks. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the **Hyperparameter tuning** section, and is named `hpo_image_classification_warmstart.ipynb`. To open a notebook, click on its **Use** tab and select **Create copy**.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

Topics

- Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

- Create a Warm Start Tuning Job (SageMaker Python SDK)

Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a `HyperParameterTuningJobWarmStartConfig` object, and pass that as the `WarmStartConfig` field in a call to `CreateHyperParameterTuningJob`.

The following code shows how to create a `HyperParameterTuningJobWarmStartConfig` object and pass it to `CreateHyperParameterTuningJob` job by using the low-level SageMaker API for Python (Boto 3).

Create the `HyperParameterTuningJobWarmStartConfig` object:

```
warm_start_config = {
          "ParentHyperParameterTuningJobs" : [
          {"HyperParameterTuningJobName" : 'MyParentTuningJob'}
          ],
          "WarmStartType" : "IdenticalDataAndAlgorithm"
}
```

Create the warm start tuning job:

```
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
 'MyWarmStartTuningJob',
   HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning
 configuration
   TrainingJobDefinition = training_job_definition, # See notebook for job definition
   WarmStartConfig = warm_start_config)
```

Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a `WarmStartConfig` object.
- Pass the `WarmStartConfig` object as the value of the `warm_start_config` argument of a HyperparameterTuner object.
- Call the `fit` method of the `HyperparameterTuner` object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning.

This example uses an estimator that uses the Image Classification - MXNet algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges.

```
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                         'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a `WarmStartConfig` object.

```
from sagemaker.tuner import WarmStartConfig,WarmStartTypes

parent_tuning_job_name = "MyParentTuningJob"
warm_start_config =
 WarmStartConfig(warm_start_type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
 parents={parent_tuning_job_name})
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```
imageclassification.set_hyperparameters(num_layers=18,
                                        image_shape='3,224,224',
                                        num_classes=257,
                                        num_training_samples=15420,
                                        mini_batch_size=128,
                                        epochs=30,
                                        optimizer='sgd',
                                        top_k='2',
                                        precision_dtype='float32',
                                        augmentation_type='crop')
```

Now create the `HyperparameterTuner` object and pass the `WarmStartConfig` object that you previously created as the `warm_start_config` argument.

```
tuner_warm_start = HyperparameterTuner(imageclassification,
                            'validation:accuracy',
```

```
                                hyperparameter_ranges,
                                objective_type='Maximize',
                                max_jobs=10,
                                max_parallel_jobs=2,
                                base_tuning_job_name='warmstart',
                                warm_start_config=warm_start_config)
```

Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```
tuner_warm_start.fit(
        {'train': s3_input_train, 'validation': s3_input_validation},
        include_cls_metadata=False)
```

Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

Resource	Regions	Default limits	Can be increased to
Number of parallel (concurrent) hyperparameter tuning jobs	All	100	N/A
Number of hyperparameters that can be searched *	All	30	N/A
Number of metrics defined per hyperparameter tuning job	All	20	N/A
Number of parallel training jobs per hyperparameter tuning job	All	10	100

Resource	Regions	Default limits	Can be increased to
[Bayesian optimization] Number of training jobs per hyperparameter tuning job	All	750	N/A
[Random search] Number of training jobs per hyperparameter tuning job	All	750	10000
[Hyperband] Number of training jobs per hyperparameter tuning job	All	750	N/A
[Grid] Number of training jobs per hyperparameter tuning job, either specified explicitly or inferred from the search space	All	750	N/A
Maximum run time for a hyperparameter tuning job	All	30 days	N/A

* Each categorical hyperparameter can have at most 30 different values.

Resource limit example

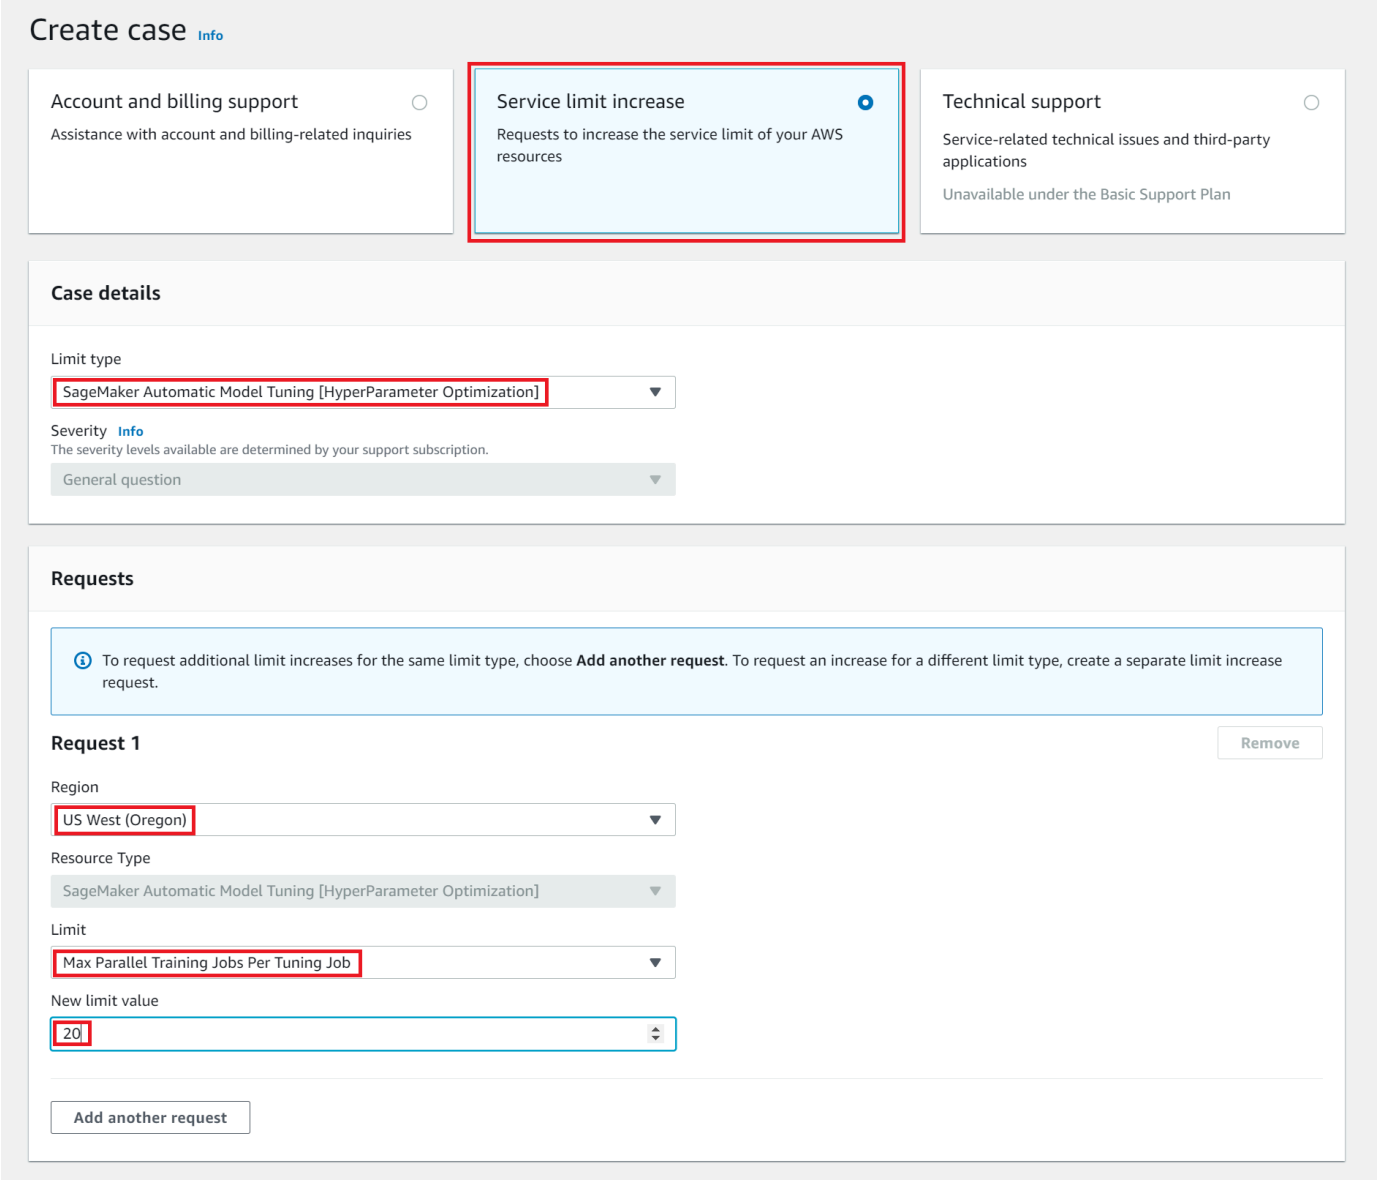
When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see SageMaker Limits. Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you

run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one **ml.m4.xlarge** instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 750.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training **ml.m4.xlarge** instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose **Create case**.
2. On the **Create case** page, choose **Service limit increase**.
3. On the **Case details** panel, select **SageMaker Automatic Model Tuning [Hyperparameter Optimization]** for the **Limit type**
4. On the **Requests** panel for **Request 1**, select the **Region**, the resource **Limit** to increase and the **New Limit value** you are requesting. Select **Add another request** if you have additional requests for quota increases.



5. In the **Case description** panel, provide a description of your use case .
6. In the **Contact options** panel, select your preferred **Contact methods** (**Web**, **Chat** or **Phone**) and then choose **Submit**.

Best Practices for Hyperparameter Tuning

Hyperparameter optimization (HPO) is not a fully-automated process. To improve optimization, follow these best practices for hyperparameter tuning.

Topics

- Choosing a tuning strategy

- Choosing the number of hyperparameters
- Choosing hyperparameter ranges
- Using the correct scales for hyperparameters
- Choosing the best number of parallel training jobs
- Running training jobs on multiple instances
- Using a random seed to reproduce hyperparameter configurations

Choosing a tuning strategy

For large jobs, using the Hyperband tuning strategy can reduce computation time. Hyperband has an early stopping mechanism to stop under-performing jobs. Hyperband can also reallocate resources towards well-utilized hyperparameter configurations and run parallel jobs. For smaller training jobs using less runtime, use either random search or Bayesian optimization.

Use Bayesian optimization to make increasingly informed decisions about improving hyperparameter configurations in the next run. Bayesian optimization uses information gathered from prior runs to improve subsequent runs. Because of its sequential nature, Bayesian optimization cannot massively scale.

Use random search to run a large number of parallel jobs. In random search, subsequent jobs do not depend on the results from prior jobs and can be run independently. Compared to other strategies, random search is able to run the largest number of parallel jobs.

Use grid search to reproduce results of a tuning job, or if simplicity and transparency of the optimization algorithm are important. You can also use grid search to explore the entire hyperparameter search space evenly. Grid search methodically searches through every hyperparameter combination to find optimal hyperparameter values. Unlike grid search, Bayesian optimization, random search and Hyperband all draw hyperparameters randomly from the search space. Because grid search analyzes every combination of hyperparameters, optimal hyperparameter values will be identical between tuning jobs that use the same hyperparameters.

Choosing the number of hyperparameters

During optimization, the computational complexity of a hyperparameter tuning job depends on the following:

- The number of hyperparameters
- The range of values that Amazon SageMaker has to search

Although you can simultaneously specify up to 30 hyperparameters, limiting your search to a smaller number can reduce computation time. Reducing computation time allows SageMaker to converge more quickly to an optimal hyperparameter configuration.

Choosing hyperparameter ranges

The range of values that you choose to search can adversely affect hyperparameter optimization. For example, a range that covers every possible hyperparameter value can lead to large compute times and a model that doesn't generalize well to unseen data. If you know that using a subset of the largest possible range is appropriate for your use case, consider limiting the range to that subset.

Using the correct scales for hyperparameters

During hyperparameter tuning, SageMaker attempts to infer if your hyperparameters are log-scaled or linear-scaled. Initially, SageMaker assumes linear scaling for hyperparameters. If hyperparameters are log-scaled, choosing the correct scale will make your search more efficient. You can also select `Auto` for `ScalingType` in the CreateHyperParameterTuningJob API if you want SageMaker to detect the scale for you.

Choosing the best number of parallel training jobs

You can use the results of previous trials to improve the performance of subsequent trials. Choose the largest number of parallel jobs that would provide a meaningful incremental result that is also within your region and account compute constraints. Use the `MaxParallelTrainingJobs` field to limit the number of training jobs that a hyperparameter tuning job can launch in parallel. For more information, see Running multiple HPO jobs in parallel on Amazon SageMaker.

Running training jobs on multiple instances

When a training job runs on multiple machines in distributed mode, each machine emits an objective metric. HPO can only use one of these emitted objective metrics to evaluate model performance, In distributed mode, HPO uses the objective metric that was reported by the last running job across all instances.

Using a random seed to reproduce hyperparameter configurations

You can specify an integer as a random seed for hyperparameter tuning and use that seed during hyperparameter generation. Later, you can use the same seed to reproduce hyperparameter

configurations that are consistent with your previous results. For random search and Hyperband strategies, using the same random seed can provide up to 100% reproducibility of the previous hyperparameter configuration for the same tuning job. For Bayesian strategy, using the same random seed will improve reproducibility for the same tuning job.

Refine data during training with Amazon SageMaker smart sifting

SageMaker smart sifting is a capability of SageMaker Training that helps improve the efficiency of your training datasets and reduce total training time and cost.

Modern deep learning models such as large language models (LLMs) or vision transformer models often require massive datasets to achieve acceptable accuracy. For example, LLMs often require trillions of tokens or petabytes of data to converge. The growing size of training datasets, along with the size of state-of-the-art models, can increase the compute time and cost of model training.

Invariably, samples in a dataset do not contribute equally to the learning process during model training. A significant proportion of computational resources provisioned during training might be spent on processing easy samples that do not contribute substantially to the overall accuracy of a model. Ideally, training datasets would only include samples that are actually improving the model convergence. Filtering out less helpful data can reduce training time and compute cost. However, identifying less helpful data can be challenging and risky. It is practically difficult to identify which samples are less informative before training, and model accuracy can be impacted if the wrong samples or too many samples are excluded.

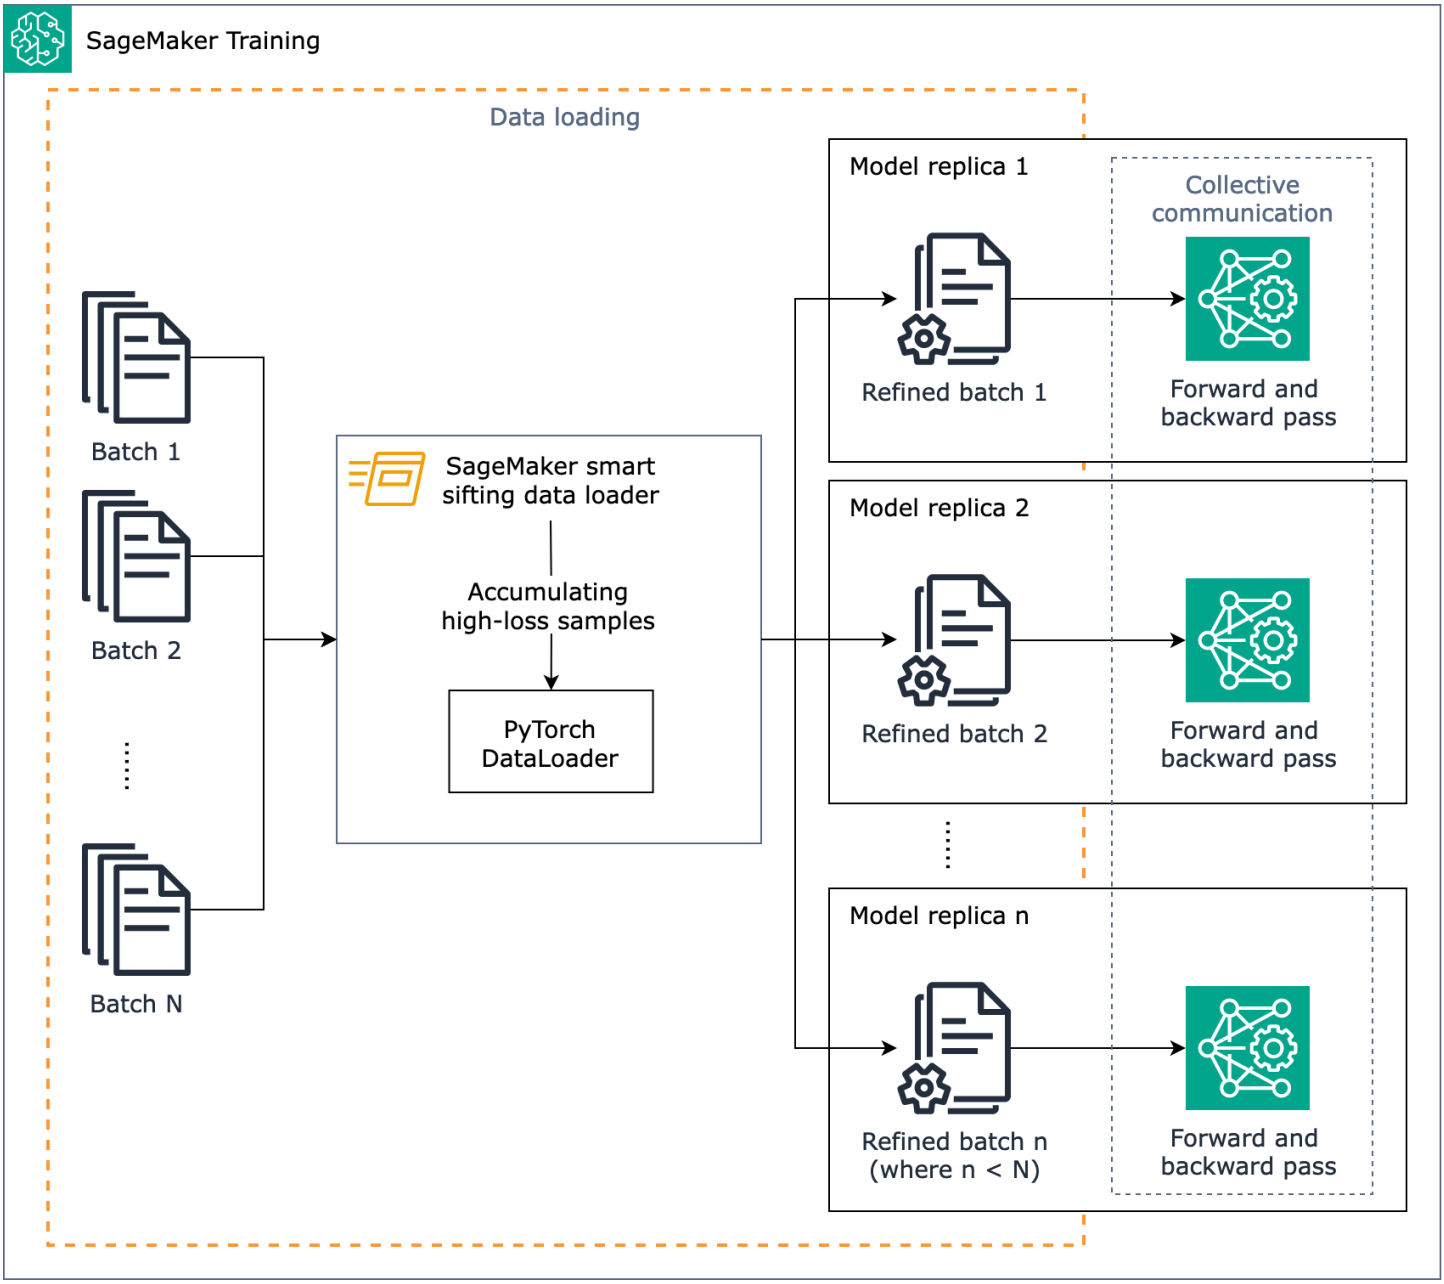
Smart sifting of data with Amazon SageMaker can help reduce training time and cost by improving data efficiency. The SageMaker smart sifting algorithm evaluates the loss value of each data during the data loading stage of a training job and excludes samples which are less informative to the model. By using refined data for training, the total time and cost of training your model is reduced by eliminating unnecessary forward and backward passes on non-improving data. Therefore, there is minimal or no impact on the accuracy of the model.

SageMaker smart sifting is available through SageMaker Training Deep Learning Containers (DLCs) and supports PyTorch workloads via the PyTorch `DataLoader`. Just a few lines of code change are needed to implement SageMaker smart sifting and you do not need to change your existing training or data processing workflows.

How SageMaker smart sifting works

The goal of SageMaker smart sifting is to sift through your training data during the training process and only feed more informative samples to the model. During typical training with PyTorch, data is iteratively sent in batches to the training loop and to accelerator devices (such as GPUs or Trainium chips) by the PyTorch `DataLoader`. SageMaker smart sifting is implemented at this data loading stage and is thus independent of any upstream data pre-processing in your training pipeline. SageMaker smart sifting uses your model and its user-specified loss function to do an evaluative forward pass of each data sample as it is loaded. Samples that return *low-loss* values have less of an impact on the model's learning and are thus excluded from training, because it is already *easy* for the model to make the right prediction about them with high confidence. Meanwhile, those relatively high-loss samples are what the model still needs to learn, so these are kept for training. A key input you can set for SageMaker smart sifting is the proportion of data to exclude. For example, by setting the proportion to 25%, samples distributed in the lowest quartile of the distribution of loss (taken from a user-specified number of previous samples) are excluded from training. High-loss samples are accumulated in a refined data batch. The refined data batch is sent to the training loop (forward and backward pass), and the model learns and trains on the refined data batch.

The following diagram shows an overview of how the SageMaker smart sifting algorithm is designed.



In short, SageMaker smart sifting operates during training as data is loaded. The SageMaker smart sifting algorithm runs loss calculation over the batches, and sifts non-improving data out before the forward and backward pass of each iteration. The refined data batch is then used for the forward and backward pass.

SageMaker smart sifting works for PyTorch-based training jobs with classic distributed data parallelism, which makes model replicas on each GPU worker and performs `AllReduce`. It works with PyTorch DDP and the SageMaker distributed data parallel library.

Supported frameworks and AWS Regions

Before using SageMaker smart sifting data loader, check if your framework of choice is supported, that the instance types are available in your AWS account, and that your AWS account is in one of the supported AWS Regions.

Supported Frameworks

SageMaker smart sifting supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

Topics

PyTorch

Framework	Framework version	Deep Learning Container URI	
PyTorch	2.1.0	*763104351884* .dkr.ecr.*region*.amazonaws.com/pytorch-training:2.1.0-gpu-py310-cu121-ubuntu20.04-sagemaker	

For more information about the pre-built containers, see SageMaker Framework Containers in the *AWS Deep Learning Containers GitHub repository*.

AWS Regions

The containers packaged with the SageMaker smart sifting library are available in the AWS Regions where AWS Deep Learning Containers are in service.

Instance types

You can use SageMaker smart sifting for any PyTorch training jobs on any instance types. We recommend that you use P4d, P4de, or P5 instances.

Apply SageMaker smart sifting to your training script

The SageMaker smart sifting library is packaged in the SageMaker framework DLCs as a complementary library. It provides a filtering logic against training samples that have relatively lower impact on model training, and your model can reach the desired model accuracy with fewer training samples when compared to the model training with full data samples.

PyTorch

These instructions demonstrate how to enable SageMaker smart sifting with your training script.

1. Configure the SageMaker smart sifting interface.

   The SageMaker smart sifting library implements a relative-threshold loss-based sampling technique that helps filter out samples with lower impact on reducing the loss value. The SageMaker smart sifting algorithm calculates the loss value of every input data sample using a forward pass, and calculates its relative percentile against the loss values of preceding data.

   The following two parameters are what you need to specify to the `RelativeProbabilisticSiftConfig` class for creating a sifting configuration object.

   - Specify the proportion of data that should be used for training to the `beta_value` parameter.
   - Specify the number of samples used in the comparison with the `loss_history_length` parameter.

   The following code example demonstrates setting up an object of the `RelativeProbabilisticSiftConfig` class.

   ```
   from smart_sifting.sift_config.sift_configs import (
       RelativeProbabilisticSiftConfig
       LossConfig
       SiftingBaseConfig
   )
   ```

```
sift_config=RelativeProbabilisticSiftConfig(
    beta_value=0.5,
    loss_history_length=500,
    loss_based_sift_config=LossConfig(
         sift_config=SiftingBaseConfig(sift_delay=0)
    )
)
```

For more information about the `loss_based_sift_config` parameter and related classes, see the section called "SageMaker smart sifting configuration modules" in the SageMaker smart sifting Python SDK reference section.

The `sift_config` object in the preceding code example is used in step 4 for setting up the `SiftingDataloader` class.

2. (Optional) Configure a SageMaker smart sifting batch transform class.

   Different training use cases require different training data formats. Given the variety of data formats, the SageMaker smart sifting algorithm needs to identify how to perform sifting on a particular batch. To address this, SageMaker smart sifting provides a batch transform module that helps convert batches into standardized formats that it can efficiently sift.

   a. SageMaker smart sifting handles batch transform of training data in the following formats: Python lists, dictionaries, tuples, and tensors. For these data formats, SageMaker smart sifting automatically handles the batch data format conversion, and you can skip the rest of this step. If you skip this step, in step 4 for configuring `SiftingDataloader`, leave the `batch_transforms` parameter of `SiftingDataloader` to its default value, which is `None`.

   b. If your dataset is not in these format, you should proceed to the rest of this step to create a custom batch transform using `SiftingBatchTransform`.

      In cases in which your dataset isn't in one of the supported formats by SageMaker smart sifting, you might run into errors. Such data format errors can be resolved by adding the `batch_format_index` or `batch_transforms` parameter to the `SiftingDataloader` class, which you set up in step 4. The following shows example errors due to an incompatible data format and resolutions for them.

Error Message	Resolution

Batches of type *{type(batch)}* are not supported by default.	This error indicates the batch format is not supported by default. You should implement a custom batch transform class, and use this by specifying it to the `batch_transforms` parameter of the `SiftingDataloader` class.
Unable to index the batch of type *{type(batch)}*	This error indicates the batch object cannot be indexed normally. User must implement a custom batch transform and pass this using the `batch_transforms` parameter.
Batch size *{batch_size}* does not match dimension 0 or dimension 1 sizes	This error occurs when the provided batch size does not match the 0th or 1st dimensions of the batch. User must implement a custom batch transform and pass this using the `batch_transforms` parameter.
Both dimension 0 and dimension 1 match batch size	This error indicates that since multiple dimensions match the provided batch size, more information is required to sift the batch. The user can provide the `batch_format_index` parameter to indicate if the batch is indexable by sample or feature. Users may also implement a custom batch transform, but this is more work than required.

To resolve the aforementioned issues, you need to create a custom batch transform class using the `SiftingBatchTransform` module. A batch transform class should consist of a pair of transform and reverse-transform functions. The function pair converts your data format to a format that SageMaker smart sifting algorithm can process. After you create a batch transform class, the class returns a `SiftingBatch` object that you'll pass to the `SiftingDataloader` class in step 4.

The following are examples of custom batch transform classes of the `SiftingBatchTransform` module.

- An example of a custom list batch transform implementation with SageMaker smart sifting for cases where the dataloader chunk has inputs, masks, and labels.

```
from typing import Any

import torch

from smart_sifting.data_model.data_model_interface import
 SiftingBatchTransform
from smart_sifting.data_model.list_batch import ListBatch

class ListBatchTransform(SiftingBatchTransform):
    def transform(self, batch: Any):
        inputs = batch[0].tolist()
        labels = batch[-1].tolist()  # assume the last one is the list of
 labels
        return ListBatch(inputs, labels)

    def reverse_transform(self, list_batch: ListBatch):
        a_batch = [torch.tensor(list_batch.inputs),
 torch.tensor(list_batch.labels)]
        return a_batch
```

- An example of a custom list batch transform implementation with SageMaker smart sifting for cases where no labels are needed for reverse transformation.

```
class ListBatchTransformNoLabels(SiftingBatchTransform):
    def transform(self, batch: Any):
        return ListBatch(batch[0].tolist())

    def reverse_transform(self, list_batch: ListBatch):
        a_batch = [torch.tensor(list_batch.inputs)]
        return a_batch
```

- An example of a custom tensor batch implementation with SageMaker smart sifting for cases where the data loader chunk has inputs, masks, and labels.

```
from typing import Any
```

```
from smart_sifting.data_model.data_model_interface import
 SiftingBatchTransform
from smart_sifting.data_model.tensor_batch import TensorBatch

class TensorBatchTransform(SiftingBatchTransform):
    def transform(self, batch: Any):
        a_tensor_batch = TensorBatch(
            batch[0], batch[-1]
        )  # assume the last one is the list of labels
        return a_tensor_batch

    def reverse_transform(self, tensor_batch: TensorBatch):
        a_batch = [tensor_batch.inputs, tensor_batch.labels]
        return a_batch
```

After you create a `SiftingBatchTransform`-implemted batch transform class, you use this class in step 4 for setting up the `SiftingDataloader` class. The rest of this guide assumes that a `ListBatchTransform` class is created. In step 4, this class is passed to the `batch_transforms`.

3. Create a class for implementing the SageMaker smart sifting `Loss` interface. This tutorial assumes that the class is named `SiftingImplementedLoss`. While setting up this class, we recommend that you use the same loss function in the model training loop. Go through the following substeps for creating a SageMaker smart sifting `Loss` implemented class.

   a. SageMaker smart sifting calculates a loss value for each training data sample, as opposed to calculating a single loss value for a batch. To ensure that SageMaker smart sifting uses the same loss calculation logic, create a smart-sifting-implemented loss function using the SageMaker smart sifting `Loss` module that uses your loss function and calculates loss per training sample.

   Tip

   SageMaker smart sifting algorithm runs on every data sample, not on the entire batch, so you should add an initialization function to set the PyTorch loss function without any reduction strategy.

   ```
   class SiftingImplementedLoss(Loss):
       def __init__(self):
   ```

```
        self.loss = torch.nn.CrossEntropyLoss(reduction='none')
```

This is also shown in the following code example.

b. Define a loss function that accepts the `original_batch` (or `transformed_batch` if you have set up a batch transform in step 2) and the PyTorch model. Using the specified loss function with no reduction, SageMaker smart sifting runs a forward pass for each data sample to evaluate its loss value.

The following code is an example of a smart-sifting-implemented `Loss` interface named `SiftingImplementedLoss`.

```
from typing import Any

import torch
import torch.nn as nn
from torch import Tensor

from smart_sifting.data_model.data_model_interface import SiftingBatch
from smart_sifting.loss.abstract_sift_loss_module import Loss

model=... # a PyTorch model based on torch.nn.Module

class SiftingImplementedLoss(Loss):
    # You should add the following initializaztion function
    # to calculate loss per sample, not per batch.
    def __init__(self):
        self.loss_no_reduction = torch.nn.CrossEntropyLoss(reduction='none')

    def loss(
        self,
        model: torch.nn.Module,
        transformed_batch: SiftingBatch,
        original_batch: Any = None,
    ) -> torch.Tensor:
        device = next(model.parameters()).device
        batch = [t.to(device) for t in original_batch] # use this if you use
 original batch and skipped step 2
        # batch = [t.to(device) for t in transformed_batch] # use this if you
 transformed batches in step 2
```

```
        # compute loss
        outputs = model(batch)
        return self.loss_no_reduction(outputs.logits, batch[2])
```

Before the training loop hits the actual forward pass, this sifting loss calculation is done during the data loading phase of fetching a batch in each iteration. The individual loss value is then compared to previous loss values, and its relative percentile is estimated per the object of `RelativeProbabilisticSiftConfig` you have set up in step 1.

4. Wrap the PyTroch data loader by the SageMaker `SiftingDataloader` class.

   Finally, use all the SageMaker smart sifting implemented classes you configured in the previous steps to the SageMaker `SiftingDataloder` configuration class. This class is a wrapper for PyTorch `DataLoader`. By wrapping PyTorch `DataLoader`, SageMaker smart sifting is registered to run as part of data loading in each iteration of a PyTorch training job. The following code example demonstrates implementing SageMaker data sifting to a PyTorch `DataLoader`.

```
from smart_sifting.dataloader.sift_dataloader import SiftingDataloader
from torch.utils.data import DataLoader

train_dataloader = DataLoader(...) # PyTorch data loader

# Wrap the PyTorch data loader by SiftingDataloder
train_dataloader = SiftingDataloader(
    sift_config=sift_config, # config object of RelativeProbabilisticSiftConfig
    orig_dataloader=train_dataloader,
    batch_transforms=ListBatchTransform(), # Optional, this is the custom class
 from step 2
    loss_impl=SiftingImplementedLoss(), # PyTorch loss function wrapped by the
 Sifting Loss interface
    model=model,
    log_batch_data=False
)
```

Hugging Face Transformers

There are two ways to implement the SageMaker smart sifting into the Transformers `Trainer` class.

> **Note**
>
> If you use one of the DLCs for PyTorch with the SageMaker smart sifting package installed, note that you need to install the `transformers` library. You can install additional packages by extending the DLCs or passing `requirements.txt` to the training job launcher class for PyTorch (`sagemaker.pytorch.PyTorch`) in the SageMaker Python SDK.

Simple setup

The simplest way to implement SageMaker smart sifting into the Transformers `Trainer` class is to use the `enable_sifting` function. This function accepts an existing `Trainer` object, and wraps the existing `DataLoader` object with `SiftingDataloader`. You can continue using the same training object. See the following example usage.

```
from smart_sifting.integrations.trainer import enable_sifting
from smart_sifting.loss.abstract_sift_loss_module import Loss
from smart_sifting.sift_config.sift_configs import (
    RelativeProbabilisticSiftConfig
    LossConfig
    SiftingBaseConfig
)

class SiftingImplementedLoss(Loss):
   def loss(self, model, transformed_batch, original_batch):
        loss_fct = MSELoss(reduction="none") # make sure to set reduction to "none"
        logits = model.bert(**original_batch)
        return loss_fct(logits, original_batch.get("labels"))

sift_config = RelativeProbabilisticSiftConfig(
    beta_value=0.5,
    loss_history_length=500,
    loss_based_sift_config=LossConfig(
         sift_config=SiftingBaseConfig(sift_delay=0)
    )
)

trainer = Trainer(...)
enable_sifting(trainer, sift_config, loss=SiftingImplementedLoss()) # updates the
 trainer with Sifting Loss and config
```

```
trainer.train()
```

The `SiftingDataloader` class is an iterable data loader. The exact size of the resulting dataset is not known beforehand due to the random sampling during sifting. As a result, the Hugging Face `Trainer` expects the `max_steps` training argument. Note that this argument overrides the epoch configuration parameter `num_train_epochs`. If your original data loader was also iterable, or your training uses `max_steps` and a single epoch, then the `SiftingDataloader` performs the same as the existing dataloader. If the original dataloader was not iterable or `max_steps` was not provided, the Hugging Face Trainer might throw an error message similar to the following.

```
args.max_steps must be set to a positive value if dataloader does not have a length,
was -1
```

To address this, the `enable_sifting` function provides an optional `set_epochs` parameter. This enables training with epochs, using the number of epochs provided by num_train_epochs argument of the `Trainer` class, and sets `max_steps` to the maximum system integer, allowing training to progress until the specified epochs have completed.

Custom setup

For a custom integration of the SageMaker smart sifting dataloader, you can utilize a custom Hugging Face `Trainer` class. Within any subclass of `Trainer`, the `get_train_dataloader()` function can be overridden to return an object of the `SiftingDataloader` class instead. For cases with existing custom trainers, this approach might be less intrusive but requires code changes than the simple setup option. The following is an example implementation of SageMaker smart sifting into a custom Hugging Face `Trainer` class.

```
from smart_sifting.sift_config.sift_configs import (
    RelativeProbabilisticSiftConfig
    LossConfig
    SiftingBaseConfig
)
from smart_sifting.dataloader.sift_dataloader import SiftingDataloader
from smart_sifting.loss.abstract_sift_loss_module import Loss
from smart_sifting.data_model.data_model_interface import SiftingBatch,
 SiftingBatchTransform
from smart_sifting.data_model.list_batch import ListBatch

class SiftingListBatchTransform(SiftingBatchTransform):
    def transform(self, batch: Any):
```

```
        inputs = batch[0].tolist()
        labels = batch[-1].tolist()  # assume the last one is the list of labels
        return ListBatch(inputs, labels)

    def reverse_transform(self, list_batch: ListBatch):
        a_batch = [torch.tensor(list_batch.inputs), torch.tensor(list_batch.labels)]
        return a_batch

class SiftingImplementedLoss():
    # You should add the following initializaztion function
    # to calculate loss per sample, not per batch.
    def __init__(self):
        self.celoss = torch.nn.CrossEntropyLoss(reduction='none')

    def loss(
        self,
        model: torch.nn.Module,
        transformed_batch: SiftingBatch,
        original_batch: Any = None,
    ) -> torch.Tensor:
        device = next(model.parameters()).device
        batch = [t.to(device) for t in original_batch]

        # compute loss
        outputs = model(batch)
        return self.celoss(outputs.logits, batch[2])

class SiftingImplementedTrainer(Trainer):
    def get_train_dataloader(self):
        dl = super().get_train_dataloader()

        sift_config = RelativeProbabilisticSiftConfig(
            beta_value=0.5,
            loss_history_length=500,
            loss_based_sift_config=LossConfig(
                sift_config=SiftingBaseConfig(sift_delay=0)
            )
        )

        return SiftingDataloader(
                sift_config=sift_config,
                orig_dataloader=dl,
                batch_transforms=SiftingListBatchTransform(),
                loss_impl=SiftingImplementedLoss(),
```

```
                model=self.model
        )
```

Using the wrapped `Trainer` class, create an object of it as follows.

```
trainer = SiftingImplementedTrainer(
    model=model,
    args=training_args,
    train_dataset=small_train_dataset,
    eval_dataset=small_eval_dataset
)

trainer.train()
```

Best practices, considerations, and troubleshooting

Best practices

- Smart sifting of data on SageMaker uses additional forward passes to analyze and filter your training data. In turn, there are fewer backward passes as less impactful data is excluded from your training job. Because of this, models which have long or expensive backward passes see the greatest efficiency gains when using smart sifting. Meanwhile, if your model's forward pass takes longer than its backward pass, overhead could increase total training time. To measure the time spent by each pass, you can run a pilot training job and collect logs that record the time on the processes. Also consider using SageMaker Profiler that provides profiling tools and UI application. To learn more, see Use Amazon SageMaker Profiler to profile activities on AWS compute resources.
- SageMaker smart sifting supports PyTorch model training with traditional data parallelism and distributed data parallelism, which makes model replicas in all GPU workers and uses the `AllReduce` operation. It doesn't work with model parallelism techniques, including sharded data parallelism.
- Because SageMaker smart sifting works for data parallelism jobs, make sure that the model you train fits in each GPU memory.
- SageMaker smart sifting runs on individual data in batches during data loading, so make sure that you set the reduction strategy of the PyTorch loss function to `"none"` for non-reduction. With `reduction` set to `"mean"` or `"sum"`, the loss function returns a single loss value, which leads SageMaker smart sifting not working properly.

Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot the issue. If you need further support, reach out to the SageMaker team at <sm-smart-sifting-feedback@amazon.com>.

Exceptions from the SageMaker smart sifting library

Use the following reference of exceptions raised by the SageMaker smart sifting library to troubleshoot errors and identify causes.

Exception Name	Description
SiftConfigValidationException	Thrown from the SageMaker smart sifting library in case of any missing Config key or unsupported value type for Sift Key
UnsupportedDataFormatException	Thrown from the SageMaker smart sifting library in case of any unsupported DataFormat for Sifting logic
LossImplementationNotProvidedException	Thrown in case of missing or not implement ing Loss interface

Security in SageMaker smart sifting

Because the SageMaker smart sifting library runs processes of removing less valuable training samples, it requires full access to training datasets as they are produced by the data loader. This access is not different than the access already provided to PyTorch in normal training scenario.

SageMaker smart sifting has built-in logging with security implications. By default, SageMaker smart sifting logs are only application-level logs containing metrics, latencies, and user errors or warnings. Users can, however, choose to enable verbose logs, which log full batch data to show which samples were removed from a given batch. These logs are emitted using Python loggers and are not uploaded or stored anywhere by the library. In the case of automatic log uploading to CloudWatch or similar services, please note that using verbose logs may result in sensitive training data being uploaded off of the training instance.

Beyond the aforementioned logging, SageMaker smart sifting does not have any network functionality nor does it interact with the local file system. User data is stored as in-memory objects for the entirety of the time it is used by the library.

SageMaker smart sifting Python SDK reference

This page provides a reference of Python modules you need for applying SageMaker smart sifting to your training script.

SageMaker smart sifting configuration modules

class smart_sifting.sift_config.sift_configs.RelativeProbabilisticSiftConfig()

The SageMaker smart sifting configuration class.

Parameters

- `beta_value` (float) – A beta (constant) value for calculating the probability of selecting a sample for training based on the percentile of the loss in the history of loss values. Lowering the beta value results in a lower percentage of data sifted, and raising it results in a higher percentage of data sifted. There's no minimum or maximum value for the beta value, beside that it must be a positive value. Refer to the following reference table for sifting rates with respect to `beta_value`.

`beta_value`	Proportion of data kept (%)	Proportion of data sifted out (%)
0.1	90.91	9.01
0.25	80	20
0.5	66.67	33.33
1	50	50
2	33.33	66.67
3	25	75

10	9.09	90.92
100	0.99	99.01

- `loss_history_length` (int) – The number of previous training losses to store for the relative threshold loss based sampling.
- `loss_based_sift_config` (dict or a `LossConfig` object) – Specify a `LossConfig` object that returns the SageMaker smart sifting Loss interface configuration.

class smart_sifting.sift_config.sift_configs.LossConfig()

The configuration class for the `loss_based_sift_config` parameter of the `RelativeProbabilisticSiftConfig` class.

Parameters

- `sift_config` (dict or a `SiftingBaseConfig` object) – Specify a `SiftingBaseConfig` object that returns a sifting base configuration dictionary.

class smart_sifting.sift_config.sift_configs.SiftingBaseConfig()

The configuration class for the `sift_config` parameter of `LossConfig`.

Parameters

- `sift_delay` (int) – The number of training steps to wait for before start sifting. We recommend that you start sifting after all the layers in the model has sufficient view of the training data. The default value is `1000`.
- `repeat_delay_per_epoch` (bool) – Specify whether to delay sifting every epoch. The default value is `False`.

SageMaker smart sifting data batch transform modules

class smart_sifting.data_model.data_model_interface.SiftingBatchTransform

A SageMaker smart sifting Python module for defining how to perform batch transform. Using this, you can set up a batch transform class that converts the data format of your training data to `SiftingBatch` format, which SageMaker smart sifting can sift and accumulate into a sifted batch.

class smart_sifting.data_model.data_model_interface.SiftingBatch

An interface to define a batch data type that can be sifted and accumulated.

class smart_sifting.data_model.list_batch.ListBatch

A module for keeping track of a list batch for sifting.

class smart_sifting.data_model.tensor_batch.TensorBatch

A module for keeping track of a tensor batch for sifting.

SageMaker smart sifting loss implementation module

class smart_sifting.loss.abstract_sift_loss_module.Loss

A wrapper module for registering the SageMaker smart sifting interface to the loss function of a PyTorch-based model.

SageMaker smart sifting data loader wrapper module

class smart_sifting.dataloader.sift_dataloader.SiftingDataloader

A wrapper module for registering the SageMaker smart sifting interface to the data loader of a PyTorch-based model.

The Main Sifting Dataloader iterator sifts out training samples from a dataloader based on a sift configuration

Parameters

- `sift_config` (dict or a `RelativeProbabilisticSiftConfig` object) – A `RelativeProbabilisticSiftConfig` object.
- `orig_dataloader` (a PyTorch DataLoader object) – Specify the PyTorch Dataloader object to be wrapped.
- `batch_transforms` (a `SiftingBatchTransform` object) – (Optional) If your data format is not supported by the SageMaker smart sifting library's default transform, you need to create a batch transform class using the `SiftingBatchTransform` module. This parameter is to pass the batch transform class that `SiftingDataloader` can run to convert the data for SageMaker smart sifting algorithm can accept.

- `model` (a PyTorch model object) – The original PyTorch model
- `loss_impl` (a sifting loss function of `smart_sifting.loss.abstract_sift_loss_module.Loss`) – A sifting loss function that is configured with the `Loss` module and wraps the PyTorch loss function.
- `log_batch_data` (bool) – Specify whether to log batch data. If set to `True`, SageMaker smart sifting logs the details of the batches that are kept or sifted. We recommend that you turn it on only for a pilot training job. When logging is on, the samples are loaded to GPU and transferred to CPU, which introduces overhead. The default value is `False`.

SageMaker smart sifting release notes

See the following release notes to track the latest updates for the SageMaker smart sifting capability.

SageMaker smart sifting release notes: November 29, 2023

New Features

- Launched the Amazon SageMaker smart sifting library at AWS re:Invent 2023.

Migration to AWS Deep Learning Containers

- The SageMaker smart sifting library passed integration testing and is available in AWS Deep Learning Containers. To find a complete list of the pre-built containers with the SageMaker smart sifting library, see the section called “Supported frameworks and AWS Regions”.

Debug and improve model performance

The essence of training machine learning models, deep learning neural networks, transformer models is in achieving stable model convergence, and as such, state-of-the-art models have millions, billions, or trillions of model parameters. The number of operations to update the gigantic number of model parameters during each iteration can easily become astronomical. To identify model convergence issues, it is important to be able to access the model parameters, activations, and gradients computed during optimization processes.

Amazon SageMaker provides two debugging tools to help identify such convergence issues and gain visibility into your models.

Amazon SageMaker with TensorBoard

To offer a greater compatiblity with the open-source community tools within the SageMaker Training platform, SageMaker hosts TensorBoard as an application in SageMaker domain. You can bring your training jobs to SageMaker and keep using the TensorBoard summary writer to collect the model output tensors. Because TensorBoard is implemented into SageMaker domain, it also gives you more options to manage user profiles under the SageMaker domain in your AWS account, and provides fine control over the user profiles by granting access to specific actions and resources. To learn more, see the section called "Use TensorBoard".

Amazon SageMaker Debugger

Amazon SageMaker Debugger is a capability of SageMaker that provides tools to register hooks to callbacks to extract model output tensors and save them in Amazon Simple Storage Service. It provides built-in rules for detecting model convergence issues, such as overfitting, saturated activation functions, vanishing gradients, and more. You can also set up the built-in rules with Amazon CloudWatch Events and AWS Lambda for taking automated actions against detected issues, and set up Amazon Simple Notification Service to receive email or text notifications. To learn more, see the section called "Use SageMaker Debugger".

Topics

- Use TensorBoard to debug and analyze training jobs in Amazon SageMaker
- Use Amazon SageMaker Debugger to debug and improve model performance
- Access a training container through AWS Systems Manager for remote debugging
- Release notes for debugging capabilities of Amazon SageMaker

Use TensorBoard to debug and analyze training jobs in Amazon SageMaker

Amazon SageMaker with TensorBoard is a capability of Amazon SageMaker that brings the visualization tools of TensorBoard to SageMaker, integrated with SageMaker Training and domain. It provides options to administer your AWS account and users belonging to the account through SageMaker domain, to give the domain users access to the TensorBoard data with appropriate permissions to Amazon S3, and help the domain users perform model debugging tasks using the TensorBoard visualization plugins. SageMaker with TensorBoard is extended with the SageMaker Data Manager plugin, with which domain users can access a number of training jobs in one place within the TensorBoard application.

> **Note**
>
> This feature is for training and debugging deep learning models using the PyTorch or TensorFlow framework.

For data scientists

Training large models can have scientific problems that require data scientists to debug and resolve them in order to improve model convergence and stabilize gradient descent processes.

When you encounter model training issues, such as loss not converging, or vanishing or exploding weights and gradients, you need to access tensor data to dive deep and analyze the model parameters, scalars, and any custom metrics. Using SageMaker with TensorBoard, you can visualize model output tensors extracted from training jobs. As you experiment with different models, multiple training runs, and model hyperparameters, you can select multiple training jobs in TensorBoard and compare them in one place.

For administrators

Through the TensorBoard landing page in the SageMaker console or SageMaker domain, you can manage TensorBoard application users if you are an administrator of an AWS account or SageMaker domain. Each domain user can access their own TensorBoard application given the granted permissions. As a SageMaker domain administrator and domain user, you can create and delete the TensorBoard application given the permission level you have.

Supported frameworks and AWS Regions

This feature supports the following machine learning frameworks and AWS Regions.

Frameworks

- PyTorch
- TensorFlow
- Hugging Face Transformers

AWS Regions

- US East (N. Virginia) (`us-east-1`)

- US East (Ohio) (`us-east-2`)
- US West (Oregon) (`us-west-2`)
- Europe (Frankfurt) (`eu-central-1`)
- Europe (Ireland) (`eu-west-1`)

> **Note**
>
> Amazon SageMaker with TensorBoard runs the TensorBoard application on an `ml.r5.large` instance and incurs charges after the SageMaker free tier or the free trial period of the feature. For more information, see Amazon SageMaker Pricing.

Prerequisites

The following list shows the prerequisites to start using SageMaker with TensorBoard.

- A SageMaker domain that's set up with Amazon VPC in your AWS account.

  For instructions on setting up a domain, see Onboard to Amazon SageMaker domain using quick setup. You also need to add domain user profiles for individual users to access the TensorBoard on SageMaker. For more information, see Add and remove SageMaker domain user profiles.
- The following list is the minimum set of permissions for using TensorBoard on SageMaker.
  - `sagemaker:CreateApp`
  - `sagemaker:DeleteApp`
  - `sagemaker:DescribeTrainingJob`
  - `sagemaker:Search`
  - `s3:GetObject`
  - `s3:ListBucket`

Prepare a training job with a TensorBoard output data configuration

A typical training job for deep learning in SageMaker consists of two main steps: preparing a training script and configuring a SageMaker Training job launcher. In this section, you can check the required changes to collect TensorBoard-compatible data from SageMaker Training.

Step 1: Modify your training script

Make sure you determine which output tensors and scalars to collect, and modify code lines in your training script using any of the following tools: TensorBoardX, TensorFlow Summary Writer, PyTorch Summary Writer, or SageMaker Debugger.

Also make sure that you specify the TensorBoard data output path as the log directory (`log_dir`) for callback in the training container.

For more information about callbacks per framework, see the following resources.

- For PyTorch, use torch.utils.tensorboard.SummaryWriter. See also the Using TensorBoard in PyTorch and Log scalars sections in the *PyTorch tutorials*. Alternatively, you can use TensorBoardX Summary Writer.

  ```
  LOG_DIR="/opt/ml/output/tensorboard"
  tensorboard_callback=torch.utils.tensorboard.writer.SummaryWriter(log_dir=LOG_DIR)
  ```

- For TensorFlow, use the native callback for TensorBoard, tf.keras.callbacks.TensorBoard.

  ```
  LOG_DIR="/opt/ml/output/tensorboard"
  tensorboard_callback=tf.keras.callbacks.TensorBoard(
      log_dir=LOG_DIR, histogram_freq=1)
  ```

- For Transformers with PyTorch, you can use transformers.integrations.TensorBoardCallback.

  For Transformers with TensorFlow, use the `tf.keras.tensorboard.callback`, and pass that to the keras callback in transformers.

  > **Tip**
  >
  > You can also use a different container local output path. However, in Step 2: Construct a SageMaker training launcher with TensorBoard data configuration, you must map the paths correctly for SageMaker to successfully search the local path and save the TensorBoard data to the S3 output bucket.

- For guidance on modifying training scripts using the SageMaker Debugger Python library, see the section called “Step 1: Adapt Your Training Script to Register a Hook”.

Step 2: Construct a SageMaker training launcher with TensorBoard data configuration

Use the `sagemaker.debugger.TensorBoardOutputConfig` while configuring a SageMaker framework estimator. This configuration API maps the S3 bucket you specify for saving TensorBoard data with the local path in the training container (`/opt/ml/output/tensorboard`). Pass the object of the module to the `tensorboard_output_config` parameter of the estimator class. The following code snippet shows an example of preparing a TensorFlow estimator with the TensorBoard output configuration parameter.

> **Note**
>
> This example assumes that you use the SageMaker Python SDK. If you use the low-level SageMaker API, you should include the following to the request syntax of the CreateTrainingJob API.
>
> ```
> "TensorBoardOutputConfig": {
>   "LocalPath": "/opt/ml/output/tensorboard",
>   "S3OutputPath": "s3_output_bucket"
> }
> ```

```
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import TensorBoardOutputConfig

# Set variables for training job information,
# such as s3_out_bucket and other unique tags.
...

LOG_DIR="/opt/ml/output/tensorboard"

output_path = os.path.join(
    "s3_output_bucket", "sagemaker-output", "date_str", "your-training_job_name"
)

tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path=os.path.join(output_path, 'tensorboard'),
    container_local_output_path=LOG_DIR
)

estimator = TensorFlow(
    entry_point="train.py",
```

```
    source_dir="src",
    role=role,
    image_uri=image_uri,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    base_job_name="your-training_job_name",
    tensorboard_output_config=tensorboard_output_config,
    hyperparameters=hyperparameters
)
```

How to access TensorBoard on SageMaker

You can access TensorBoard by two methods: programmatically using the `sagemaker.interactive_apps.tensorboard` module that generates an unsigned or a presigned URL, or using the TensorBoard landing page in the SageMaker console. After you open TensorBoard, SageMaker runs the TensorBoard plugin and automatically finds all training job output data in TensorBoard-compatible file format.

Topics

- Open TensorBoard using the sagemaker.interactive_apps.tensorboard module
- Open TensorBoard using the get_app_url function as an estimator class method
- Open TensorBoard through the SageMaker console

Open TensorBoard using the `sagemaker.interactive_apps.tensorboard` module

The `sagemaker.interactive_apps.tensorboard` module provides a function called `get_app_url` that generates unsigned or presigned URLs to open the TensorBoard application in any environment in SageMaker or Amazon EC2. This is to provide a unified experience for both Studio Classic and non-Studio Classic users. For the Studio environment, you can open TensorBoard by running the `get_app_url()` function as it is, or you can also specify a job name to start tracking as the TensorBoard application opens. For non-Studio Classic environments, you can open TensorBoard by providing your domain and user profile information to the utility function. With this functionality, regardless of where or how you run training code and launch training jobs, you can directly access TensorBoard by running the `get_app_url` function in your Jupyter notebook or terminal.

> **Note**
>
> This functionality is available in the SageMaker Python SDK v2.184.0 and later. To use this functionality, make sure that you upgrade the SDK by running `pip install sagemaker --upgrade`.

Topics

Option 1: For SageMaker Studio Classic

If you are using SageMaker Studio Classic, you can directly open the TensorBoard application or retrieve an unsigned URL by running the `get_app_url` function as follows. As you are already within the Studio Classic environment and signed in as a domain user, `get_app_url()` generates unsigned URL because it is not necessary to authenticate again.

To open the TensorBoard application

The following code automatically opens the TensorBoard application from the unsigned URL that the `get_app_url()` function returns in the your environment's default web browser.

```
from sagemaker.interactive_apps import tensorboard

region = "us-west-2"
app = tensorboard.TensorBoardApp(region)

app.get_app_url(
    training_job_name="your-training_job_name" # Optional. Specify the job name to
 track a specific training job
)
```

To retrieve an unsigned URL and open the TensorBoard application manually

The following code prints an unsigned URL that you can copy to a web browser and open the TensorBoard application.

```
from sagemaker.interactive_apps import tensorboard
```

```
region = "us-west-2"
app = tensorboard.TensorBoardApp(region)
print("Navigate to the following URL:")
print(
    app.get_app_url(
        training_job_name="your-training_job_name", # Optional. Specify the name of the
 job to track.
        open_in_default_web_browser=False           # Set to False to print the URL to
 terminal.
    )
)
```

Note that if you run the preceding two code samples outside the SageMaker Studio Classic environment, the function will return a URL to the TensorBoard landing page in the SageMaker console, because these do not have sign-in information to your domain and user profile. For creating a presigned URL, see Option 2 in the following section.

Option 2: For non-Studio Classic environments

If you use non-Studio Classic environments, such as SageMaker Notebook instance or Amazon EC2, and want to open TensorBoard directly from the environment you are in, you need to generate a URL presigned with your domain and user profile information. A *presigned* URL is a URL that's signed in to Amazon SageMaker Studio Classic while the URL is being created with your domain and user profile, and therefore granted access to all of the domain applications and files associated with your domain. To open TensorBoard through a presigned URL, use the `get_app_url` function with your domain and user profile name as follows.

Note that this option requires the domain user to have the `sagemaker:CreatePresignedDomainUrl` permission. Without the permission, the domain user will receive an exception error.

> **⚠ Important**
>
> Do not share any presigned URLs. The `get_app_url` function creates presigned URLs, which automatically authenticates with your domain and user profile and gives access to any applications and files associated with your domain.

```
print(
```

```
    app.get_app_url(
        training_job_name="your-training_job_name", # Optional. Specify the name of the
 job to track.
        create_presigned_domain_url=True,           # Reguired to be set to True for
 creating a presigned URL.
        domain_id="your-domain-id",                 # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        user_profile_name="your-user-profile-name", # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        open_in_default_web_browser=False,          # Optional. Set to False to print
 the URL to terminal.
        optional_create_presigned_url_kwargs={}     # Optional. Add any additional args
 for Boto3 create_presigned_domain_url
    )
)
```

Tip

The `get_app_url` function runs the [SageMaker.Client.create_presigned_domain_url] API in the AWS SDK for Python (Boto3) in the backend. As the Boto3 `create_presigned_domain_url` API creates presigned domain URLs that expire in 300 seconds by default, presigned TensorBoard application URLs also expire in 300 seconds. If you want to extend the expiration time, pass the `ExpiresInSeconds` argument to the `optional_create_presigned_url_kwargs` argument of the `get_app_url` function as follows.

```
optional_create_presigned_url_kwargs={"ExpiresInSeconds": 1500}
```

Note

If any of your input passed to the arguments of `get_app_url` is invalid, the function outputs a URL to the TensorBoard landing page instead of opening the TensorBoard application. The output message would be similar to the following.

```
Navigate to the following URL:
https://us-west-2.console.aws.amazon.com/sagemaker/home?region=us-west-2#/
tensor-board-landing
```

Open TensorBoard using the `get_app_url` function as an `estimator` class method

If you are in the process of running a training job using the `estimator` class of the SageMaker Python SDK and have an active object of the `estimator` class, you can also access the `get_app_url` function as a class method of the `estimator` class. Open the TensorBoard application or retrieve an unsigned URL by running the `get_app_url` method as follows. The `get_app_url` class method pulls the training job name from the estimator and opens the TensorBoard application with the specified job.

> **Note**
>
> This functionality is available in the SageMaker Python SDK v2.184.0 and later. To use this functionality, make sure that you upgrade the SDK by running `pip install sagemaker --upgrade`.

Topics

- Option 1: For SageMaker Studio Classic
- Option 2: For non-Studio Classic environments

Option 1: For SageMaker Studio Classic

To open the TensorBoard application

The following code automatically opens the TensorBoard application from the unsigned URL that the `get_app_url()` method returns in the your environment's default web browser.

```
estimator.get_app_url(
    app_type=SupportedInteractiveAppTypes.TENSORBOARD # Required.
)
```

To retrieve an unsigned URL and open the TensorBoard application manually

The following code prints an unsigned URL that you can copy to a web browser and open the TensorBoard application.

```
print(
    estimator.get_app_url(
```

```
        app_type=SupportedInteractiveAppTypes.TENSORBOARD, # Required.
        open_in_default_web_browser=False, # Optional. Set to False to print the URL to
 terminal.
    )
)
```

Note that if you run the preceding two code samples outside the SageMaker Studio Classic environment, the function will return a URL to the TensorBoard landing page in the SageMaker console, because these do not have sign-in information to your domain and user profile. For creating a presigned URL, see Option 2 in the following section.

Option 2: For non-Studio Classic environments

If you use non-Studio Classic environments, such as SageMaker Notebook instance and Amazon EC2, and want to generate a presigned URL to open the TensorBoard application, use the `get_app_url` method with your domain and user profile information as follows.

Note that this option requires the domain user to have the `sagemaker:CreatePresignedDomainUrl` permission. Without the permission, the domain user will receive an exception error.

> **Important**
>
> Do not share any presigned URLs. The `get_app_url` function creates presigned URLs, which automatically authenticates with your domain and user profile and gives access to any applications and files associated with your domain.

```
print(
    estimator.get_app_url(
        app_type=SupportedInteractiveAppTypes.TENSORBOARD, # Required
        create_presigned_domain_url=True,           # Reguired to be set to True for
 creating a presigned URL.
        domain_id="your-domain-id",                 # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        user_profile_name="your-user-profile-name", # Required if creating a presigned
 URL (create_presigned_domain_url=True).
        open_in_default_web_browser=False,            # Optional. Set to False to print
 the URL to terminal.
        optional_create_presigned_url_kwargs={}       # Optional. Add any additional
 args for Boto3 create_presigned_domain_url
```

```
    )
)
```

Open TensorBoard through the SageMaker console

You can also use the SageMaker console UI to open the TensorBoard application. There are two options to open the TensorBoard application through the SageMaker console.

Topics

- Option 1: Launch TensorBoard from the domain details page
- Option 2: Launch TensorBoard from the TensorBoard landing page

Option 1: Launch TensorBoard from the domain details page

Navigate to the domain details page

The following procedure shows how to navigate to the domain details page.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. From the list of domains, select the domain in which you want to launch the TensorBoard application.

Launch a user profile application

The following procedure shows how to launch a Studio Classic application that is scoped to a user profile.

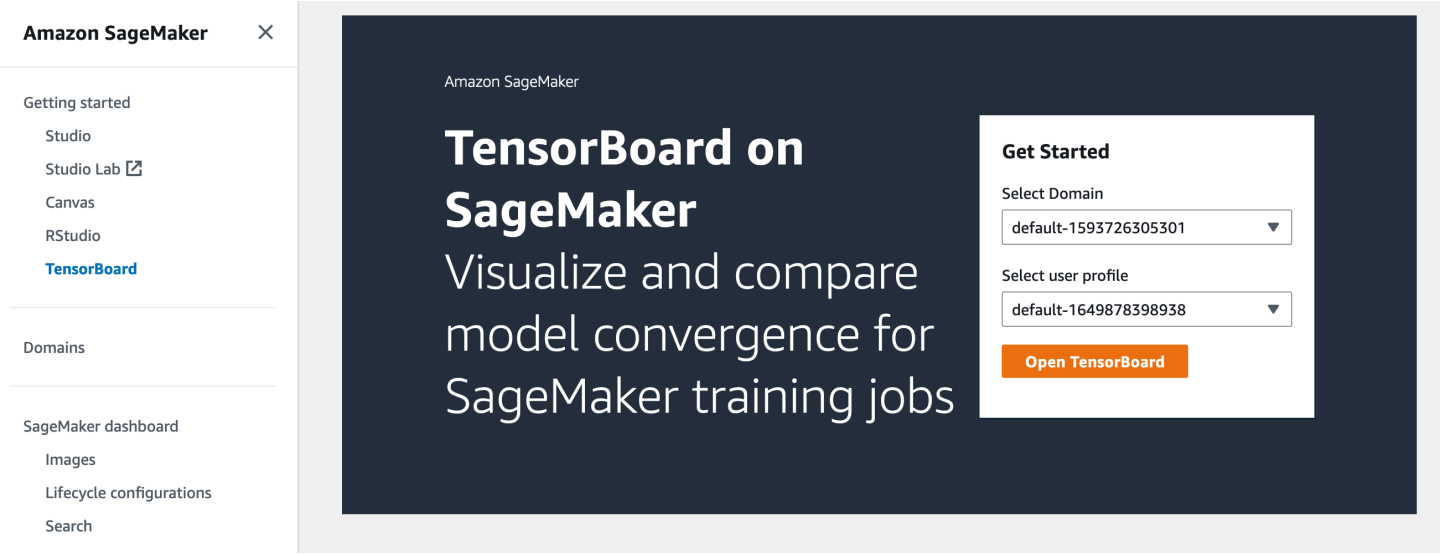
1. On the domain details page, choose the **User profiles** tab.
2. Identify the user profile for which you want to launch the Studio Classic application.
3. Choose **Launch** for your selected user profile, then choose **TensorBoard**.

Option 2: Launch TensorBoard from the TensorBoard landing page

The following procedure describes how to launch a TensorBoard application from the TensorBoard landing page.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **TensorBoard**.
3. Under **Get started**, select the domain in which you want to launch the Studio Classic application. If your user profile only belongs to one domain, you do not see the option for selecting a domain.
4. Select the user profile for which you want to launch the Studio Classic application. If there is no user profile in the domain, choose **Create user profile**. For more information, see Add and Remove User Profiles.
5. Choose **Open TensorBoard**.

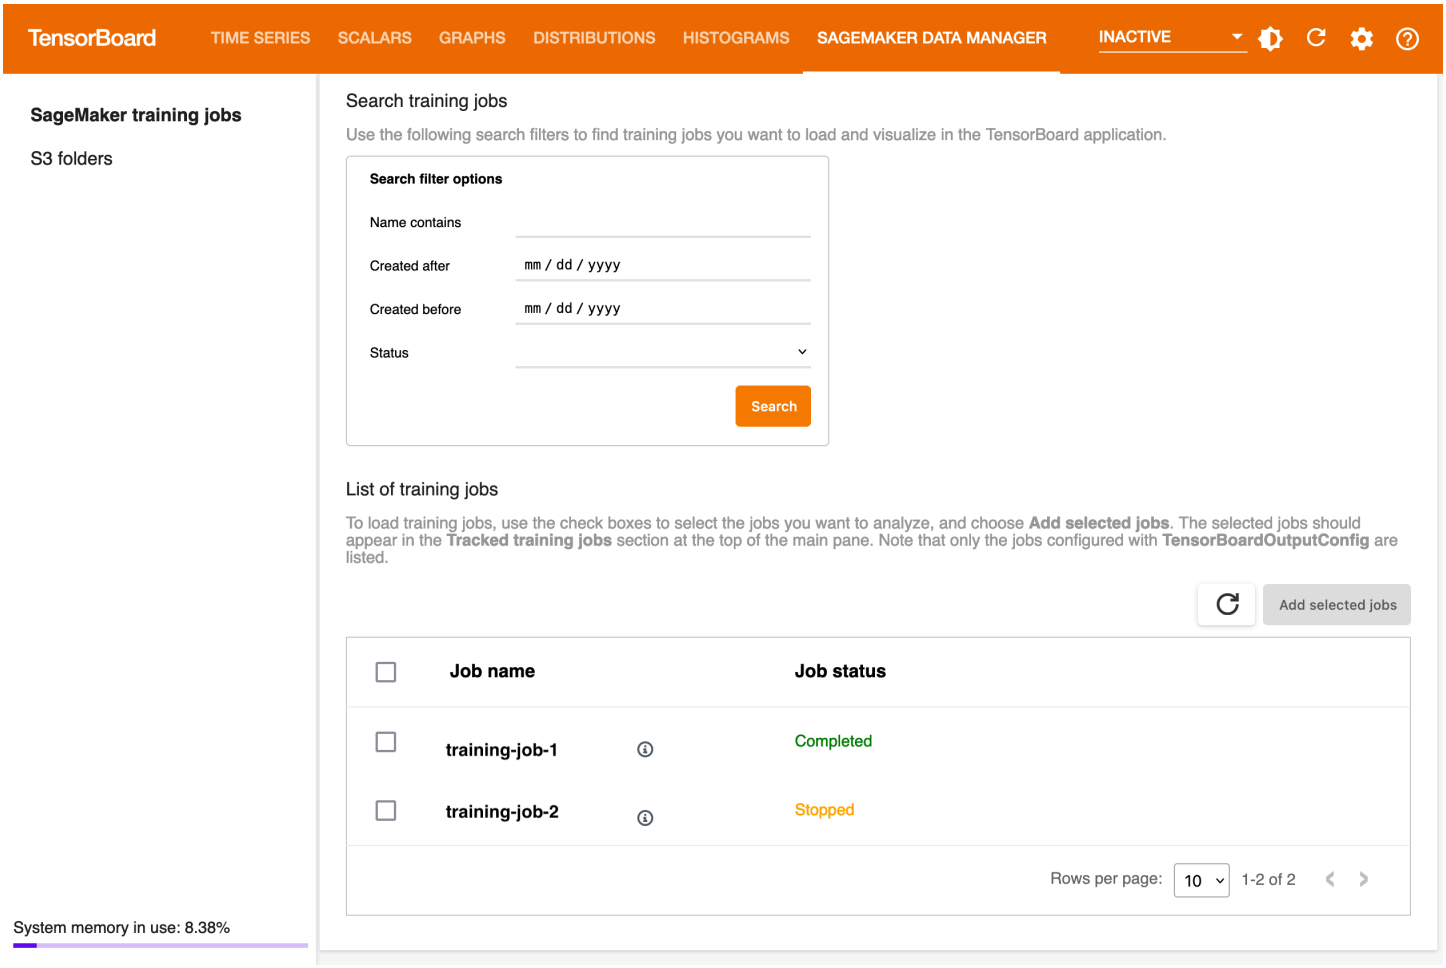
The following screenshot shows the location of TensorBoard in the left navigation pane of the SageMaker console and the SageMaker with TensorBoard landing page in the main pane.



Access and visualize training output data in TensorBoard

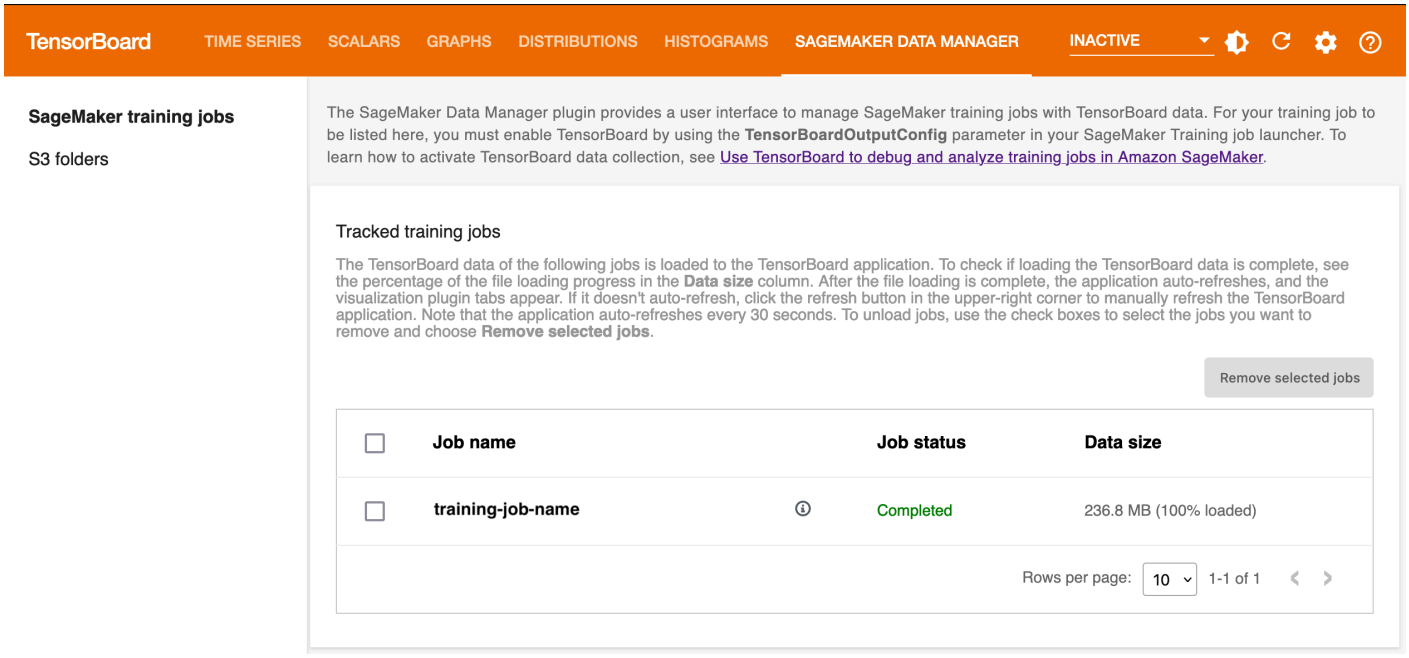
You can conduct an online or offline analysis by loading collected output tensors from S3 buckets paired with training jobs during or after training.

When you open the TensorBoard application, TensorBoard opens with the **SageMaker Data Manager** tab. The following screenshot shows the full view of the SageMaker Data Manager tab in the TensorBoard application.



In the **SageMaker Data Manager** tab, you can select any training job and load TensorBoard-compatible training output data from Amazon S3.

1. In the **Search training jobs** section, use the filters to narrow down the list of training jobs you want to find, load, and visualize.
2. In the **List of training jobs** section, use the check boxes to choose training jobs from which you want to pull data and visualize for debugging.
3. Choose **Add selected jobs**. The selected jobs should appear in the **Tracked training jobs** section, as shown in the following screenshot.



> **Note**
>
> The **SageMaker Data Manager** tab only shows training jobs configured with the `TensorBoardOutputConfig` parameter. Make sure you have configured the SageMaker estimator with this parameter. For more information, see Step 2: Construct a SageMaker training launcher with TensorBoard data configuration.

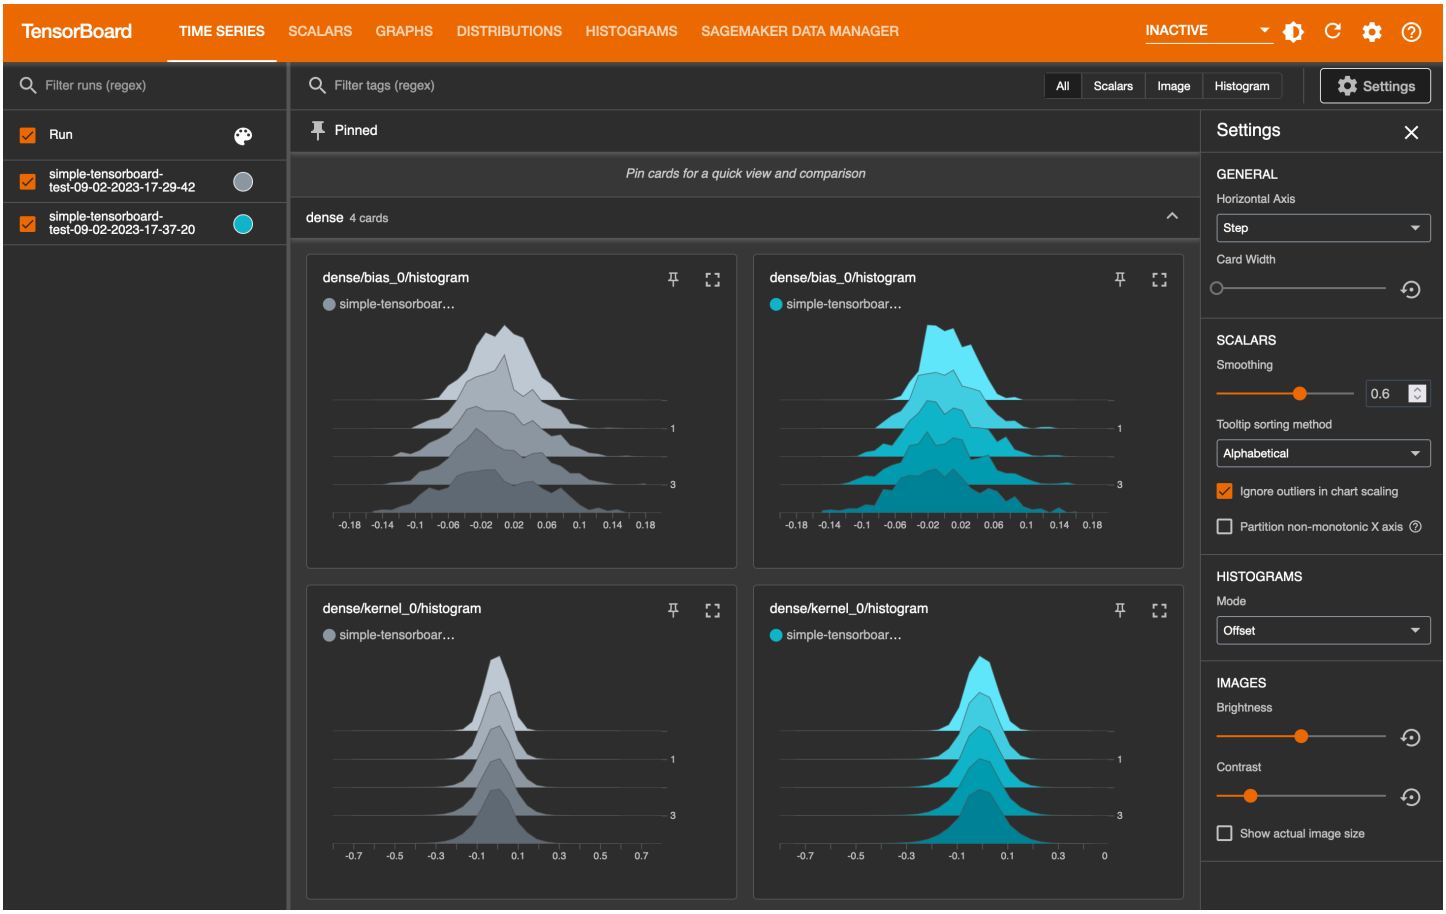
> **Note**
>
> The visualization tabs might not appear if you are using SageMaker with TensorBoard for the first time or no data is loaded from a previous use. After adding training jobs and waiting for a few seconds, refresh the viewer by choosing the clockwise circular arrow on the upper-right corner. The visualization tabs should appear after the job data are successfully loaded. You can also set to auto-refresh using the **Settings** button next to the refresh button in the upper right corner.

Explore training output data visualized in TensorBoard

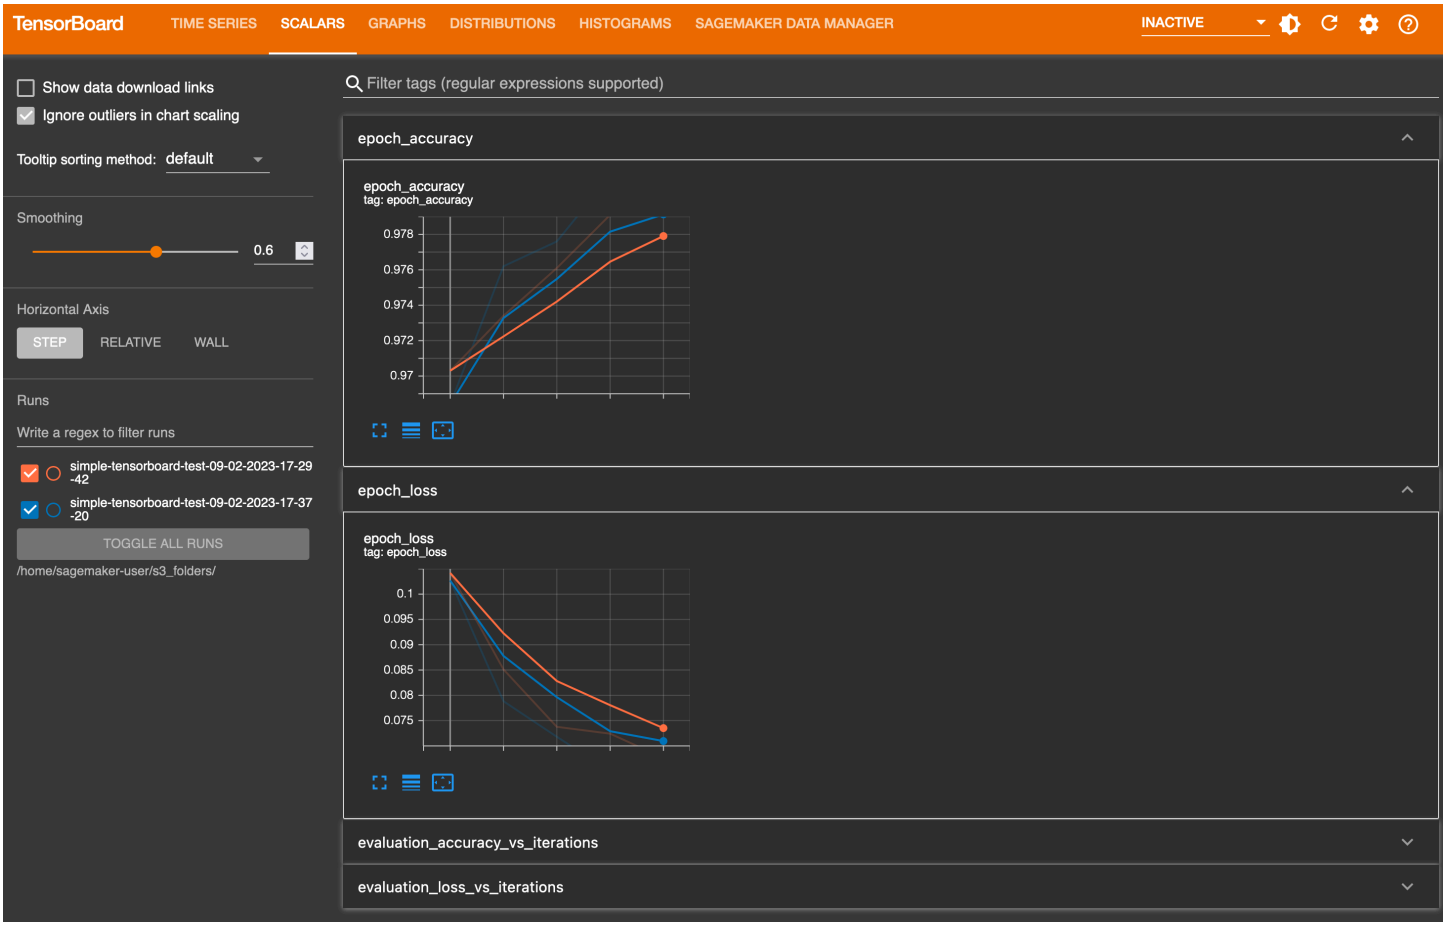
In the graphics tabs, you can see the list of the loaded training jobs in the left pane. You can also use the check boxes of the training jobs to show or hide visualizations. The TensorBoard dynamic

plugins are activated dynamically depending on how you have set your training script to include summary writers and pass callbacks for tensor and scalar collection, and therefore the graphics tabs also appear dynamically. The following screenshots show example views of each tab with visualization of two training jobs that collected metrics for time series, scalar, graph, distribution, and histogram plugins.

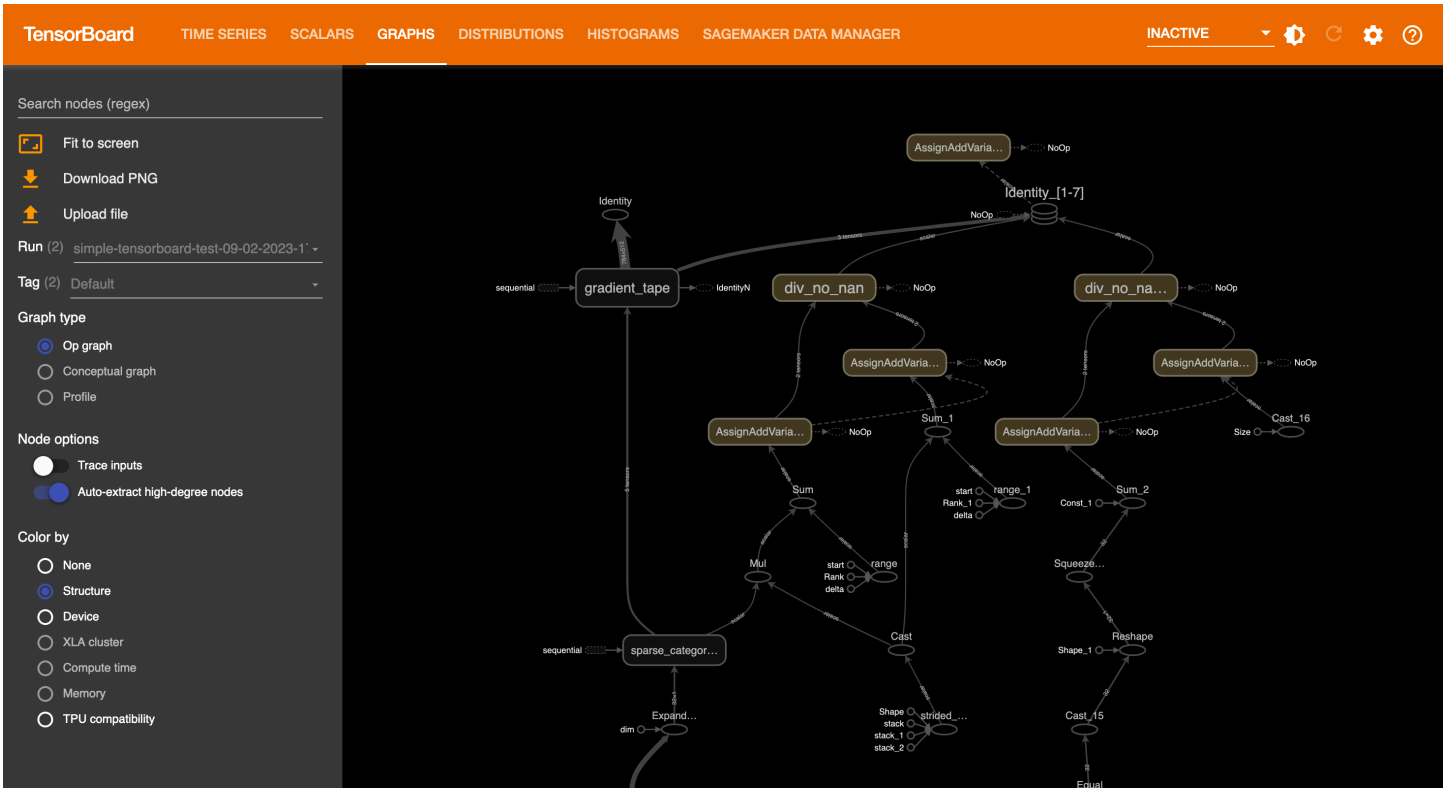
The TIME SERIES tab view



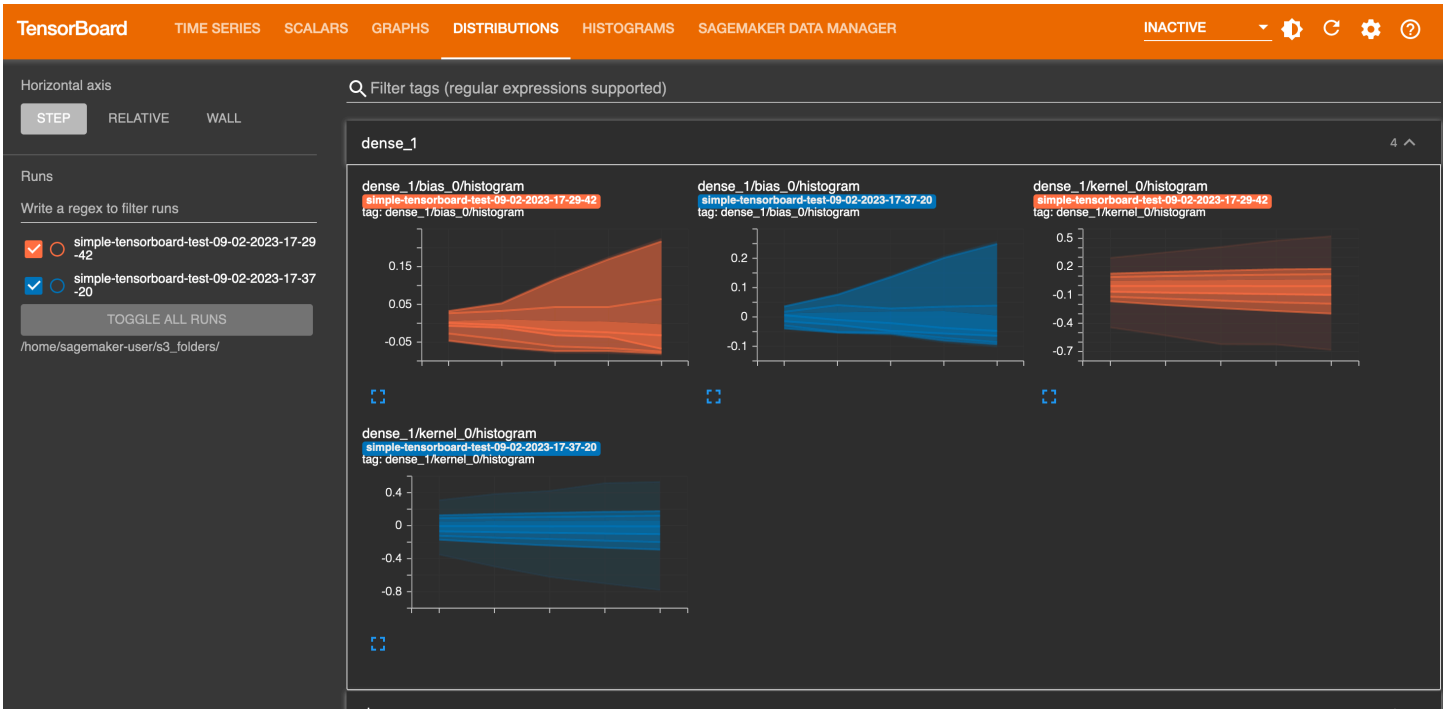
The SCALARS tab view



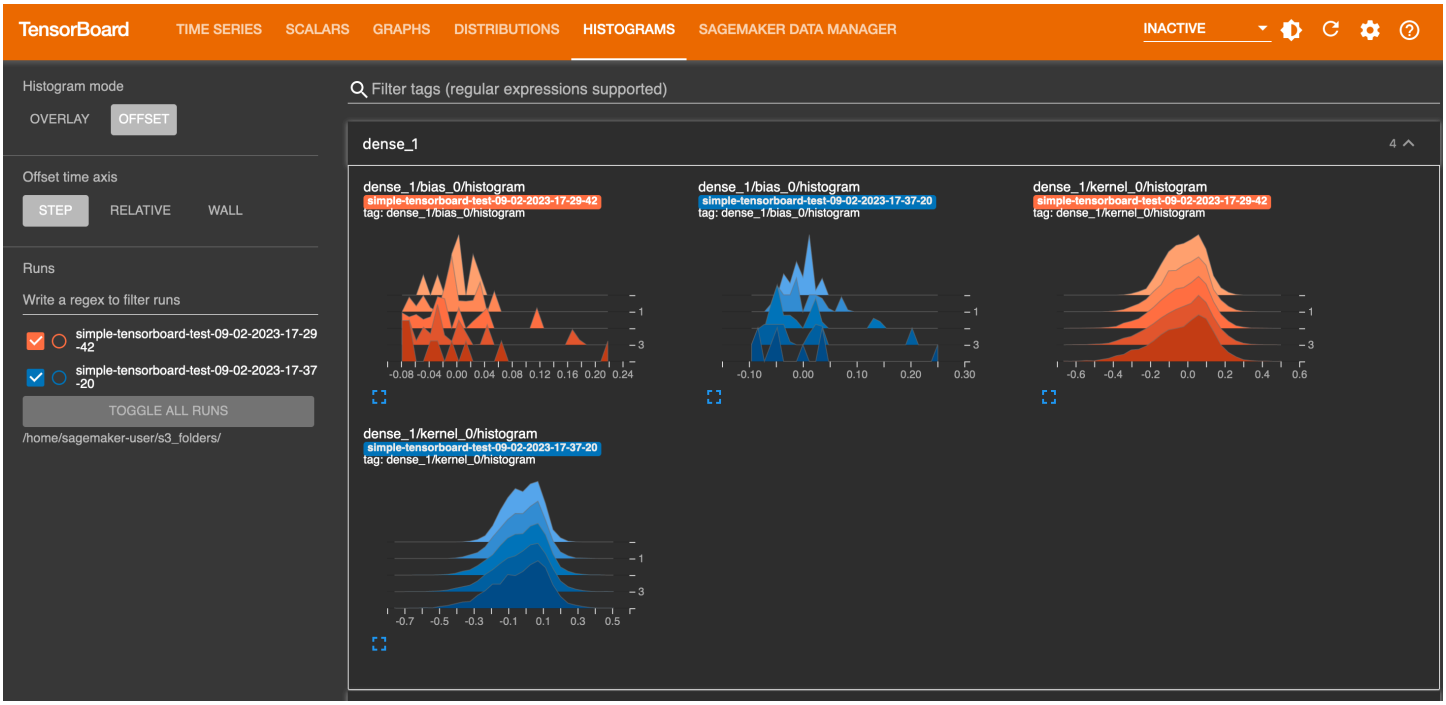
The GRAPHS tab view



The DISTRIBUTIONS tab view



The HISTOGRAMS tab view



Delete unused TensorBoard applications

After you are done with monitoring and experimenting with jobs in TensorBoard, shut the TensorBoard application down.

1. Open the SageMaker console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Choose your domain.
5. Choose your user profile.
6. Under **Apps**, choose **Delete App** for the TensorBoard row.
7. Choose **Yes, delete app**.
8. Type **`delete`** in the text box, then choose **Delete**.
9. A blue message should appear at the top of the screen: **default is being deleted**.

Considerations

Consider the following when using SageMaker with TensorBoard.

- You cannot share the TensorBoard applications for collaboration purposes because SageMaker domain does not allow application sharing among users. Users can share the output tensors saved in an S3 bucket, if they have access to the bucket.
- The visualization plugins might not appear when you first launch the TensorBoard application. After you select training jobs in the SageMaker Data Manager plugin, the TensorBoard application loads the TensorBoard data and populates the visualization plugins.
- The TensorBoard applications automatically shuts down after 1 hour of inactivity. If you want to shut the application down when you are done using it, make sure to manually shut down TensorBoard to avoid paying for the instance hosting it. For instructions on deleting the application, see Delete unused TensorBoard applications.

Use Amazon SageMaker Debugger to debug and improve model performance

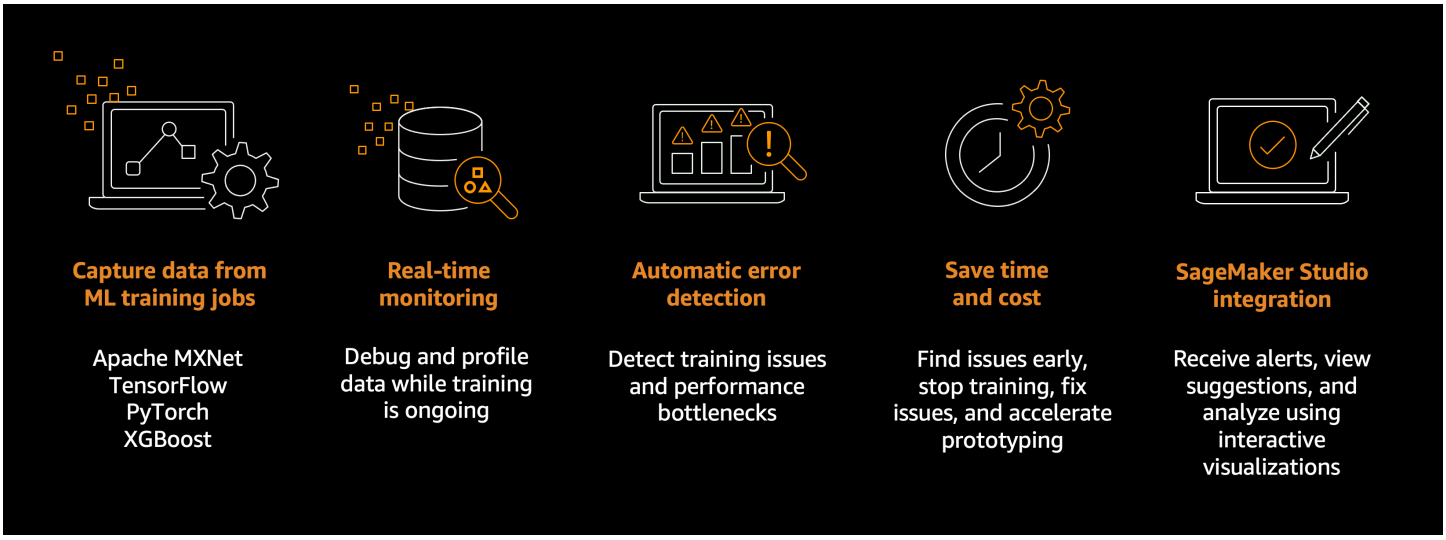
Debug model output tensors from machine learning training jobs in real time and detect non-converging issues using Amazon SageMaker Debugger.

Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger provides tools to debug training jobs and resolve such problems to improve the performance of your model. Debugger also offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.

SageMaker Debugger supports the Apache MXNet, PyTorch, TensorFlow, and XGBoost frameworks. For more information about available frameworks and versions supported by SageMaker Debugger, see Supported Frameworks and Algorithms.



The high-level Debugger workflow is as follows:

1. Modify your training script with the `sagemaker-debugger` Python SDK if needed.
2. Configure a SageMaker training job with SageMaker Debugger.
   - Configure using the SageMaker Estimator API (for Python SDK).
   - Configure using the SageMaker `CreateTrainingJob` request (for Boto3 or CLI).
   - Configure custom training containers with SageMaker Debugger.
3. Start a training job and monitor training issues in real time.
   - List of Debugger Built-in Rules.
4. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules.
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda.
5. Explore deep analysis of the training issues.
   - For debugging model output tensors, see Visualize Debugger Output Tensors in TensorBoard.
6. Fix the issues, consider the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics

- Supported Frameworks and Algorithms

- Amazon SageMaker Debugger Architecture
- Get Started with Debugger Tutorials
- Debug Training Jobs Using Amazon SageMaker Debugger
- List of Debugger Built-in Rules
- Create Debugger Custom Rules for Training Job Analysis
- Use Debugger with Custom Training Containers
- Configure Debugger Using Amazon SageMaker API
- Best Practices for Amazon SageMaker Debugger
- Amazon SageMaker Debugger Advanced Topics and Reference Documentation

Supported Frameworks and Algorithms

The following table shows SageMaker machine learning frameworks and algorithms supported by Debugger.

SageMaker-supported frameworks and algorithms	Debugging output tensors
TensorFlow	AWS TensorFlow deep learning containers 1.15.4 or later
PyTorch	AWS PyTorch deep learning containers 1.5.0 or later
MXNet	AWS MXNet deep learning containers 1.6.0 or later
XGBoost	1.0-1, 1.2-1, 1.3-1
SageMaker generic estimator	Custom training containers (available for TensorFlow, PyTorch, MXNet, and XGBoost with manual hook registration)

- **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.

Important

For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the `tf.keras` modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. For instructions on how to update your training script, see the section called "TensorFlow".

Important

From PyTorch v1.12.0 and later, SageMaker Debugger deprecates the zero code change support for debugging models.
This is due to breaking changes that cause SageMaker Debugger to interfere with the `torch.jit` functionality. For instructions on how to update your training script, see the section called "PyTorch".

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

AWS Regions

Amazon SageMaker Debugger is available in all regions where Amazon SageMaker is in service except the following region.

- Asia Pacific (Jakarta): `ap-southeast-3`

To find if Amazon SageMaker is in service in your AWS Region, see AWS Regional Services.

Use Debugger with Custom Training Containers

Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the `sagemaker-debugger` client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers.

Debugger Open-Source GitHub Repositories

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker CreateTrainingJob and DescribeTrainingJob API operations. The `sagemaker-debugger` client library provides tools to register *hooks* and access the training data through its *trial* feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and `sagemaker-debugger` API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Python SDK - Debugger APIs
- The `sagemaker-debugger` Python SDK documentation for the Amazon SageMaker Debugger open source client library
- The `sagemaker-debugger` PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- Amazon SageMaker Debugger API Operations
- Configure Debugger Using Amazon SageMaker API

Amazon SageMaker Debugger Architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for *performance optimization* to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for *model optimization* is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.

Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include

scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

> **Note**
>
> By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the `ProfilerReport` rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see Process Data and Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

Get Started with Debugger Tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

Debug Models with Amazon SageMaker Debugger in Studio

Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds

This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

Debug Models with Amazon SageMaker Debugger (part 1)

You can find the example notebook in the video in this Studio Demo repository provided by the author. You need to clone the `debugger.ipynb` notebook file and the `mnist_keras_tf.py` training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path `keras_script_path` to the `mnist_keras_tf.py` file inside the `debugger.ipynb` notebook. For example, if you cloned the two files in the same directory, set it as `keras_script_path = "mnist_keras_tf.py"`.

Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor

Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

Debug Models with Debugger (part 2)

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

Debugger Example Notebooks

SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

To find the examples in a SageMaker Notebook instance, follow the instructions at SageMaker Notebook Instance Example Notebooks.

> **Important**
>
> To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.
>
> ```
> import sys
> import IPython
> !{sys.executable} -m pip install -U sagemaker smdebug
> IPython.Application.instance().kernel.do_shutdown(True)
> ```

Debugger Example Notebooks for Profiling Training Jobs

Train and Tune Your Models with Amazon SageMaker Experiments and Debugger

Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds

Train and Prune Models with SageMaker Experiments and Debugger

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as *trials* through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.

SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

```
Pruning iteration: 0
----------------------------------------------------------------
        Layer (type)               Output Shape         Param #

----------------------------------------------------------------
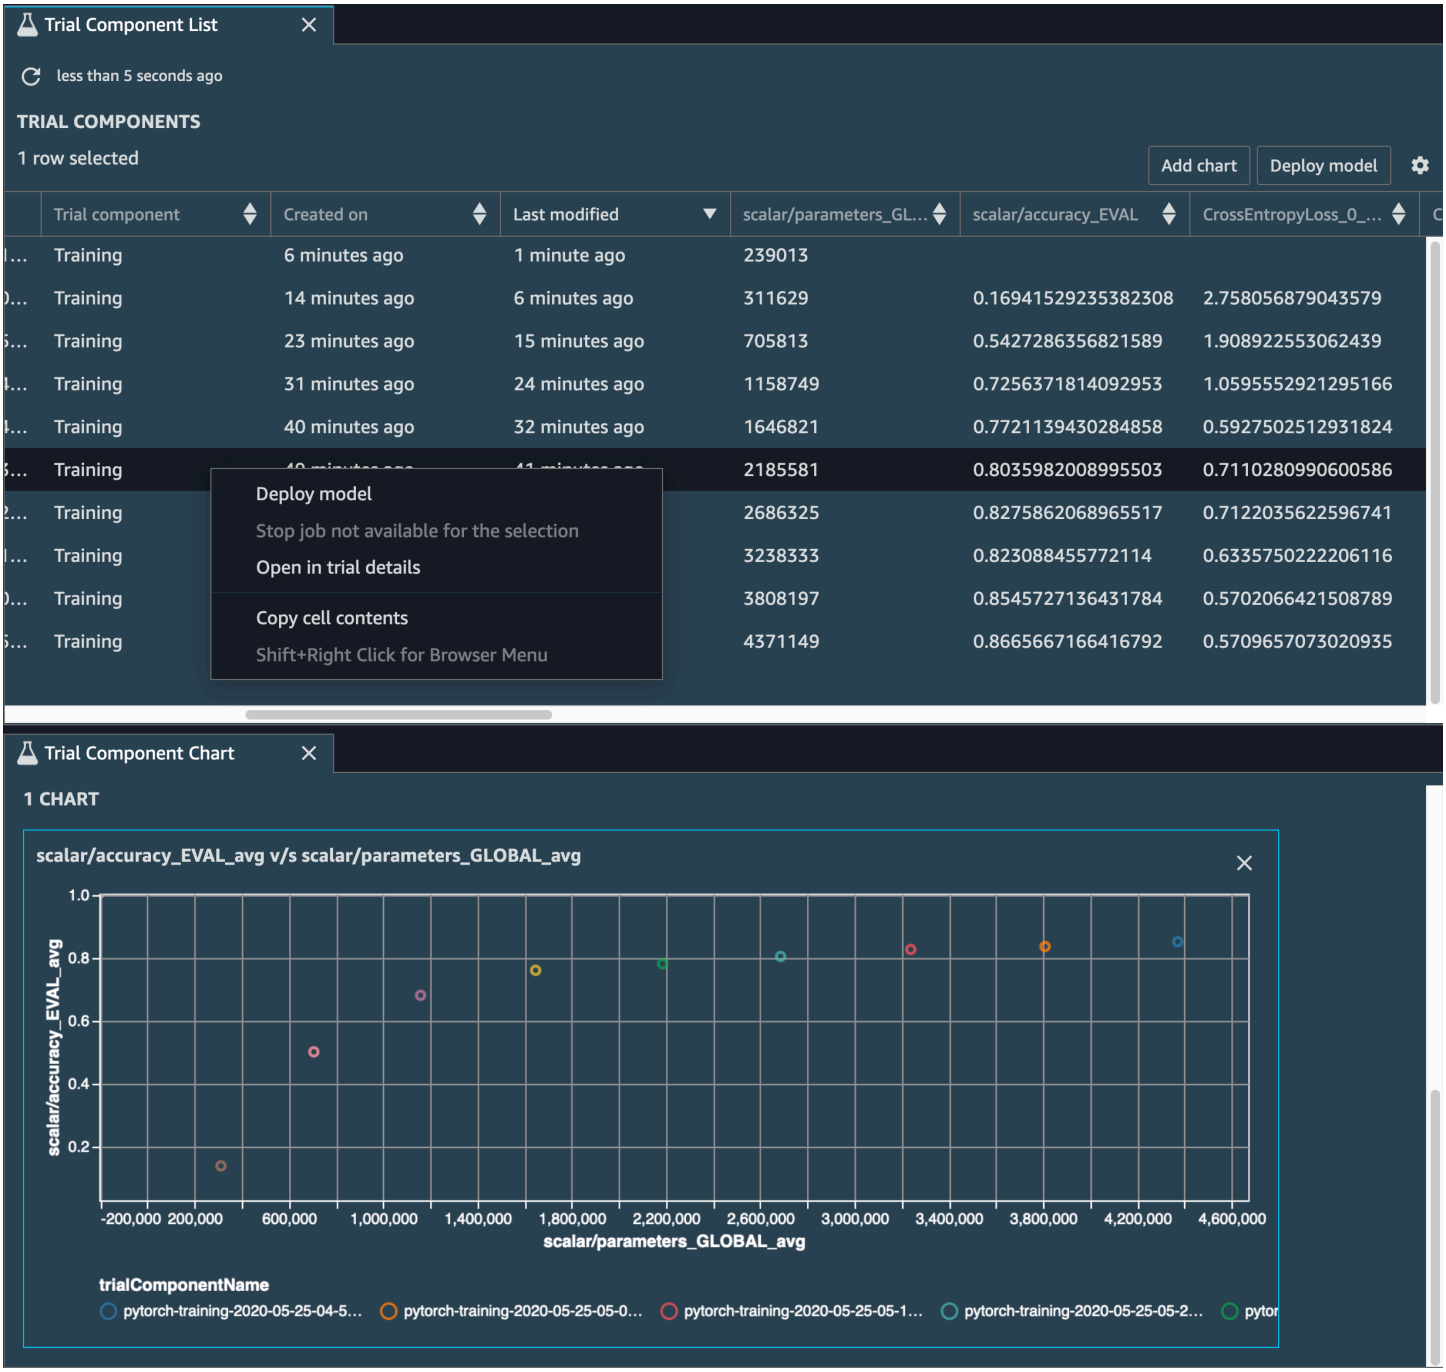
```

You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.



In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

Note

To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
        print('acc:{:.4f}'.format(correct/total))
        hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the
 pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```

Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

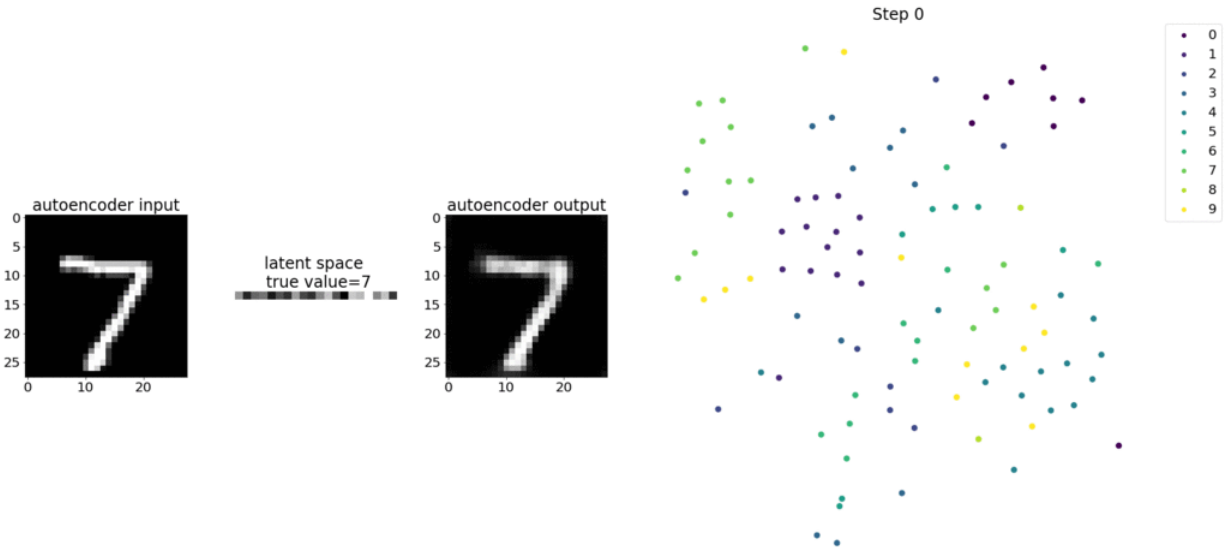
The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two *deconvolutional* layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.



Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on *transfer learning* and the *Transformer model* for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high *attention* to appropriate verb tokens or pronoun tokens from a subject token.

The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called *attention*.

This notebook demonstrates how to use the pre-trained BERT model from the GluonNLP model zoo on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting *attention scores* and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the *attention-head view* in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.

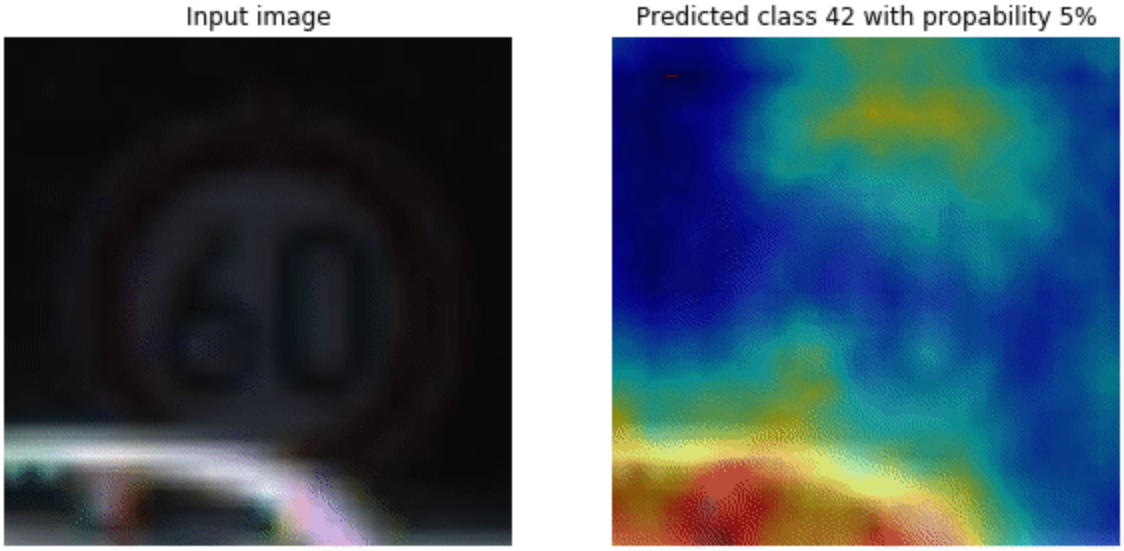
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a *convolutional neural network (CNN or ConvNet)* is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.



During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a *saliency map*) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Debug Training Jobs Using Amazon SageMaker Debugger

To prepare your training script and run training jobs with SageMaker Debugger to debug model training progress, you follow the typical two-step process: modify your training script using the `sagemaker-debugger` Python SDK, and construct a SageMaker estimator using the SageMaker Python SDK. Go through the following topics to learn how to use SageMaker Debugger's debugging functionality.

Topics

Step 1: Adapt Your Training Script to Register a Hook

Amazon SageMaker Debugger comes with a client library called the `sagemaker-debugger` Python SDK. The `sagemaker-debugger` Python SDK provides tools for adapting your training script before training and analysis tools after training. In this page, you'll learn how to adapt your training script using the client library.

The `sagemaker-debugger` Python SDK provides wrapper functions that help register a hook to extract model tensors, without altering your training script. To get started with collecting model output tensors and debug them to find training issues, make the following modifications in your training script.

> **Tip**
>
> While you're following this page, use the `sagemaker-debugger` open source SDK documentation for API references.

Topics

Adapt Your PyTorch Training Script

To start collecting model output tensors and debug training issues, make the following modifications to your PyTorch training script.

For PyTorch 1.12.0

If you bring a PyTorch training script, you can run the training job and extract model output tensors with a few additional code lines in your training script. You need to use the hook APIs in the `sagemaker-debugger` client library. Walk through the following instructions that break down the steps with code examples.

1. Create a hook.

   (Recommended) For training jobs within SageMaker

   ```
   import smdebug.pytorch as smd
   hook=smd.get_hook(create_if_not_exists=True)
   ```

   When you launch a training job in the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK" with any of the DebuggerHookConfig, TensorBoardConfig, or Rules in your estimator, SageMaker adds a JSON configuration file to your training instance that is picked up by the `get_hook` function. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns `None`.

   (Optional) For training jobs outside SageMaker

   If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use `smd.Hook` class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode because the Rules require SageMaker ML training instances and S3 to store outputs from the remote instances in real time. The `smd.get_hook` API returns `None` in this case.

   If you want to create a manual hook to save tensors in local mode, use the following code snippet with the logic to check if the `smd.get_hook` API returns `None` and create a manual hook using the `smd.Hook` class. Note that you can specify any output directory in your local machine.

```
import smdebug.pytorch as smd
hook=smd.get_hook(create_if_not_exists=True)

if hook is None:
    hook=smd.Hook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )
```

2. Wrap your model with the hook's class methods.

   The hook`.register_module()` method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK". The collectable tensors through this hook method are weights, biases, activations, gradients, inputs, and outputs.

   ```
   hook.register_module(model)
   ```

   Tip

   If you collect the entire output tensors from a large deep learning model, the total size of those collections can exponentially grow and might cause bottlenecks. If you want to save specific tensors, you can also use the hook`.save_tensor()` method. This method helps you pick the variable for the specific tensor and save to a custom collection named as you want. For more information, see step 7 of this instruction.

3. Warp the loss function with the hook's class methods.

   The hook`.register_loss` method is to wrap the loss function. It extracts loss values every `save_interval` that you'll set during configuration in the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK", and saves them to the `"losses"` collection.

   ```
   hook.register_loss(loss_function)
   ```

4. Add hook`.set_mode(ModeKeys.TRAIN)` in the train block. This indicates the tensor collection is extracted during the training phase.

```
def train():
    ...
    hook.set_mode(ModeKeys.TRAIN)
```

5. Add `hook.set_mode(ModeKeys.EVAL)` in the validation block. This indicates the tensor collection is extracted during the validation phase.

```
def validation():
    ...
    hook.set_mode(ModeKeys.EVAL)
```

6. Use `hook.save_scalar()` to save custom scalars. You can save scalar values that aren't in your model. For example, if you want to record the accuracy values computed during evaluation, add the following line of code below the line where you calculate accuracy.

```
hook.save_scalar("accuracy", accuracy)
```

   Note that you need to provide a string as the first argument to name the custom scalar collection. This is the name that'll be used for visualizing the scalar values in TensorBoard, and can be any string you want.

7. Use `hook.save_tensor()` to save custom tensors. Similarly to `hook.save_scalar()`, you can save additional tensors, defining your own tensor collection. For example, you can extract input image data that are passed into the model and save as a custom tensor by adding the following code line, where `"images"` is an example name of the custom tensor, `image_inputs` is an example variable for the input image data.

```
hook.save_tensor("images", image_inputs)
```

   Note that you must provide a string to the first argument to name the custom tensor. `hook.save_tensor()` has the third argument `collections_to_write` to specify the tensor collection to save the custom tensor. The default is `collections_to_write="default"`. If you don't explicitely specify the third argument, the custom tensor is saved to the `"default"` tensor collection.

After you have completed adapting your training script, proceed to the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK".

Adapt Your TensorFlow Training Script

To start collecting model output tensors and debug training issues, make the following modifications to your TensorFlow training script.

Create a hook for training jobs within SageMaker

```
import smdebug.tensorflow as smd

hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)
```

This creates a hook when you start a SageMaker training job. When you launch a training job in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” with any of the `DebuggerHookConfig`, `TensorBoardConfig`, or `Rules` in your estimator, SageMaker adds a JSON configuration file to your training instance that is picked up by the `smd.get_hook` method. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns `None`.

(Optional) Create a hook for training jobs outside SageMaker

If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use `smd.Hook` class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode. The `smd.get_hook` method also returns `None` in this case.

If you want to create a manual hook, use the following code snippet with the logic to check if the hook returns `None` and create a manual hook using the `smd.Hook` class.

```
import smdebug.tensorflow as smd

hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)

if hook is None:
    hook=smd.KerasHook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )
```

After adding the hook creation code, proceed to the following topic for TensorFlow Keras.

> **Note**
>
> SageMaker Debugger currently supports TensorFlow Keras only.

Register the hook in your TensorFlow Keras training script

The following precedure walks you through how to use the hook and its methods to collect output scalars and tensors from your model and optimizer.

1. Wrap your Keras model and optimizer with the hook's class methods.

   The hook`.register_model()` method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK". The collectable tensors through this hook method are weights, biases, and activations.

   ```
   model=tf.keras.Model(...)
   hook.register_model(model)
   ```

2. Wrap the optimizer by the hook`.wrap_optimizer()` method.

   ```
   optimizer=tf.keras.optimizers.Adam(...)
   optimizer=hook.wrap_optimizer(optimizer)
   ```

3. Compile the model in eager mode in TensorFlow.

   To collect tensors from the model, such as the input and output tensors of each layer, you must run the training in eager mode. Otherwise, SageMaker Debugger will not be able to collect the tensors. However, other tensors, such as model weights, biases, and the loss, can be collected without explicitly running in eager mode.

   ```
   model.compile(
       loss="categorical_crossentropy",
       optimizer=optimizer,
       metrics=["accuracy"],
       # Required for collecting tensors of each layer
       run_eagerly=True
   )
   ```

4. Register the hook to the `tf.keras.Model.fit()` method.

   To collect the tensors from the hooks that you registered, add `callbacks=[hook]` to the Keras `model.fit()` class method. This will pass the `sagemaker-debugger` hook as a Keras callback.

```
model.fit(
    X_train, Y_train,
    batch_size=batch_size,
    epochs=epoch,
    validation_data=(X_valid, Y_valid),
    shuffle=True,
    callbacks=[hook]
)
```

5. TensorFlow 2.x provides only symbolic gradient variables that do not provide access to their values. To collect gradients, wrap `tf.GradientTape` by the `hook.wrap_tape()` method, which requires you to write your own training step as follows.

```
def training_step(model, dataset):
    with hook.wrap_tape(tf.GradientTape()) as tape:
        pred=model(data)
        loss_value=loss_fn(labels, pred)
    grads=tape.gradient(loss_value, model.trainable_variables)
    optimizer.apply_gradients(zip(grads, model.trainable_variables))
```

   By wrapping the tape, the `sagemaker-debugger` hook can identify output tensors such as gradients, parameters, and losses. Wrapping the tape ensures that the `hook.wrap_tape()` method around functions of the tape object, such as `push_tape()`, `pop_tape()`, `gradient()`, will set up the writers of SageMaker Debugger and save tensors that are provided as input to `gradient()` (trainable variables and loss) and output of `gradient()` (gradients).

   > **Note**
   >
   > To collect with a custom training loop, make sure that you use eager mode. Otherwise, SageMaker Debugger is not able to collect any tensors.

For a full list of actions that the `sagemaker-debugger` hook APIs offer to construct hooks and save tensors, see Hook Methods in the *`sagemaker-debugger` Python SDK documentation*.

After you have completed adapting your training script, proceed to the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK".

Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK

To configure a SageMaker estimator with SageMaker Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters. To fully utilize the debugging functionality, there are three parameters you need to configure: `debugger_hook_config`, `tensorboard_output_config`, and `rules`.

> **Important**
>
> Before constructing and running the estimator fit method to launch a training job, make sure that you adapt your training script following the instructions at the section called "Step 1: Adapt Your Training Script to Register a Hook".

Construct a SageMaker Estimator with Debugger-specific parameters

The code examples in this section show how to construct a SageMaker estimator with the Debugger-specific parameters.

> **Note**
>
> The following code examples are templates for constructing the SageMaker framework estimators and not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

PyTorch

```
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

session=boto3.session.Session()
region=session.region_name
```

```
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.12.0",
    py_version="py37",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

TensorFlow

```
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

session=boto3.session.Session()
region=session.region_name

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
```

```
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

XGBoost

```
# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

Generic estimator

```
# An example of constructing a SageMaker generic estimator using the XGBoost
 algorithm base image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule,
 rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]
```

```
region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

Configure the following parameters to activate SageMaker Debugger:

- `debugger_hook_config` (an object of `DebuggerHookConfig`) – Required to activate the hook in the adapted training script during the section called "Step 1: Adapt Your Training Script to Register a Hook", configure the SageMaker training launcher (estimator) to collect output tensors from your training job, and save the tensors into your secured S3 bucket or local machine. To learn how to configure the `debugger_hook_config` parameter, see Configure SageMaker Debugger to Save Tensors.
- `rules` (a list of `Rule` objects) – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in real time. The built-in rules are logics that automatically debug the training progress of your model and find training issues by analyzing the output tensors saved in your secured S3 bucket. To learn how to configure the `rules` parameter, see Configure Debugger Built-in Rules. To find a complete list of built-in rules for debugging output tensors, see the section called "Debugger Rule". If you want to create your own logic to detect any training issues, see the section called "Create Custom Rules".

> **Note**
>
> The built-in rules are available only through SageMaker training instances. You cannot use them in local mode.

- `tensorboard_output_config` (an object of `TensorBoardOutputConfig`) – Configure SageMaker Debugger to collect output tensors in the TensorBoard-compatible format and save to your S3 output path specified in the `TensorBoardOutputConfig` object. To learn more, see the section called "Visualize Debugger Output Tensors in TensorBoard".

  > **Note**
  >
  > The `tensorboard_output_config` must be configured with the `debugger_hook_config` parameter, which also requires you to adapt your training script by adding the `sagemaker-debugger` hook.

> **Note**
>
> SageMaker Debugger securely saves output tensors in subfolders of your S3 bucket. For example, the format of the default S3 bucket URI in your account is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are two subfolders created by SageMaker Debugger: `debug-output`, and `rule-output`. If you add the `tensorboard_output_config` parameter, you'll also find `tensorboard-output` folder.

See the following topics to find more examples of how to configure the Debugger-specific parameters in detail.

Topics

- Configure SageMaker Debugger to Save Tensors
- Configure Debugger Built-in Rules
- Turn Off Debugger
- Useful SageMaker Estimator Classmethods for Debugger

Configure SageMaker Debugger to Save Tensors

Tensors are data collections of updated parameters from the backward and forward pass of each training iteration. SageMaker Debugger collects the output tensors to analyze the state of a training job. SageMaker Debugger's `CollectionConfig` and `DebuggerHookConfig` API

operations provide methods for grouping tensors into *collections* and saving them to a target S3 bucket.

> **Note**
>
> After properly configured and activated, SageMaker Debugger saves the output tensors in a default S3 bucket, unless otherwise specified. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

While constructing a SageMaker estimator, activate SageMaker Debugger by specifying the `debugger_hook_config` parameter. The following steps include examples of how to set up the `debugger_hook_config` using the `CollectionConfig` and `DebuggerHookConfig` API operations to pull tensors out of your training jobs and save them.

Configure Tensor Collections Using the `CollectionConfig` API

Use the `CollectionConfig` API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default `"save_interval"` value.

For a full list of available Debugger built-in collections, see Debugger Built-in Collections.

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following `CollectionConfig` template to adjust parameters.

```
from sagemaker.debugger import CollectionConfig
```

```
collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see CollectionConfig in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "100",
            "eval.save_interval": "10"
        }
    )
]
```

Tip

This tensor collection configuration object can be used for both DebuggerHookConfig and Rule API operations.

Configure the `DebuggerHookConfig` API to Save Tensors

Use the DebuggerHookConfig API to create a `debugger_hook_config` object using the `collection_configs` object you created in the previous step.

```
from sagemaker.debugger import DebuggerHookConfig
```

```
debugger_hook_config=DebuggerHookConfig(
    collection_configs=collection_configs
)
```

Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```
from sagemaker.debugger import DebuggerHookConfig

debugger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri"
    collection_configs=collection_configs
)
```

For more information, see DebuggerHookConfig in the Amazon SageMaker Python SDK.

Example Notebooks and Code Samples to Configure Debugger Hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

Topics

- Tensor Visualization Example Notebooks
- Save Tensors Using Debugger Built-in Collections
- Save Tensors Using Debugger Modified Built-in Collections
- Save Tensors Using Debugger Custom Collections

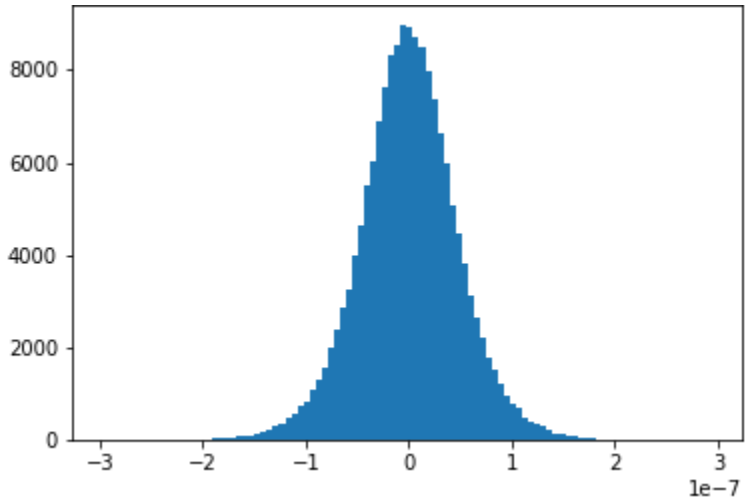
Tensor Visualization Example Notebooks

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training

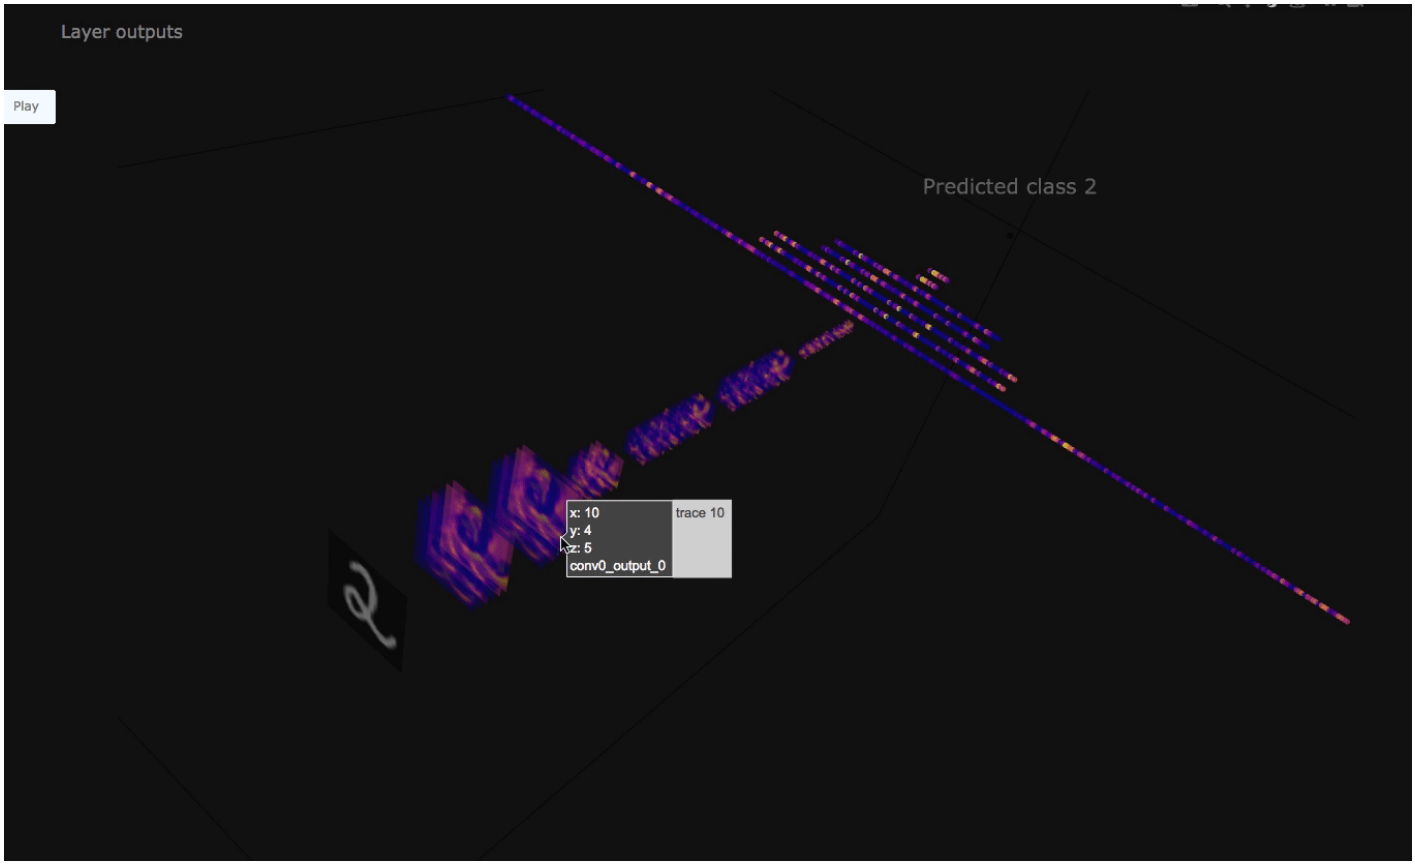
deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.



This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- Visualizing and Debugging Tensors from MXNet Model Training

  This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.



In this notebook, the `TensorPlot` class imported from `tensor_plot.py` is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The `tensor_plot.py` script provided with the notebook retrieves tensors using Debugger and visualizes the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- Real-time Tensor Analysis in a SageMaker Notebook with MXNet

  This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

Save Tensors Using Debugger Built-in Collections

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of

Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

> **Note**
>
> In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:
>
> ```
> "s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
> ```

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
        CollectionConfig(name="weights"),
        CollectionConfig(name="gradients"),
        CollectionConfig(name="losses"),
        CollectionConfig(name="biases")
    ]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
                    format(BUCKET_NAME=BUCKET_NAME,
                           LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
```

```
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the `CollectionConfig` API operation. The following example shows how to tweak the built-in `losses` collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs=[
    CollectionConfig(
                name="losses",
                parameters={"save_interval": "50"})]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
                    format(BUCKET_NAME=BUCKET_NAME,
                           LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
```

```
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of `CollectionConfig` parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection
collection_configs=[
        CollectionConfig(
            name="custom_activations_collection",
            parameters={
                "include_regex": "relu|tanh", # Required
                "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
            })
    ]

# configure Debugger hook
```

```
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
                   format(BUCKET_NAME=BUCKET_NAME,
                          LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of `CollectionConfig` parameters, see Debugger CollectionConfig.

Configure Debugger Built-in Rules

Amazon SageMaker Debugger's built-in rules analyze tensors emitted during the training of a model. SageMaker Debugger offers the `Rule` API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules.

In the following topics, you'll learn how to use the SageMaker Debugger built-in rules.

Topics

- Use Debugger Built-in Rules with the Default Parameter Settings
- Use Debugger Built-in Rules with Custom Parameter Values
- Example Notebooks and Code Samples to Configure Debugger Rules

Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n()),
    ... # You can also append more profiler rules in the
 ProfilerRule.sagemaker(rule_configs.*()) format.
]
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules.

To find the SageMaker Debugger API reference, see `sagemaker.debugger.rule_configs` and `sagemaker.debugger.Rule`.

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration.

```
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.loss_not_decreasing()),
    Rule.sagemaker(rule_configs.overfit()),
    Rule.sagemaker(rule_configs.overtraining()),
    Rule.sagemaker(rule_configs.stalled_training_rule())
]
```

When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger

analyzes the resource utilization to identify if your model is having bottleneck problems. The `loss_not_decreasing`, `overfit`, `overtraining`, and `stalled_training_rule` monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules.

Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` classmethods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. The instruction of how to use the `CollectionConfig` class is provided at Configure Tensor Collections Using the `CollectionConfig` API.

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-in Rules.
- The `collections_to_save` argument takes in a tensor configuration through the `CollectionConfig` API, which requires `name` and `parameters` arguments.
  - To find available tensor collections for `name`, see Debugger Built-in Tensor Collections .
  - For a full list of adjustable `parameters`, see Debugger CollectionConfig API.

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
                "key": "value"
```

```
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules.

Example Notebooks and Code Samples to Configure Debugger Rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

Topics

- Debugger Built-in Rules Example Notebooks
- Debugger Built-in Rules Example Code
- Use Debugger Built-in Rules with Parameter Modifications

Debugger Built-in Rules Example Notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- Using a SageMaker Debugger built-in rule with TensorFlow
- Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet
- Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

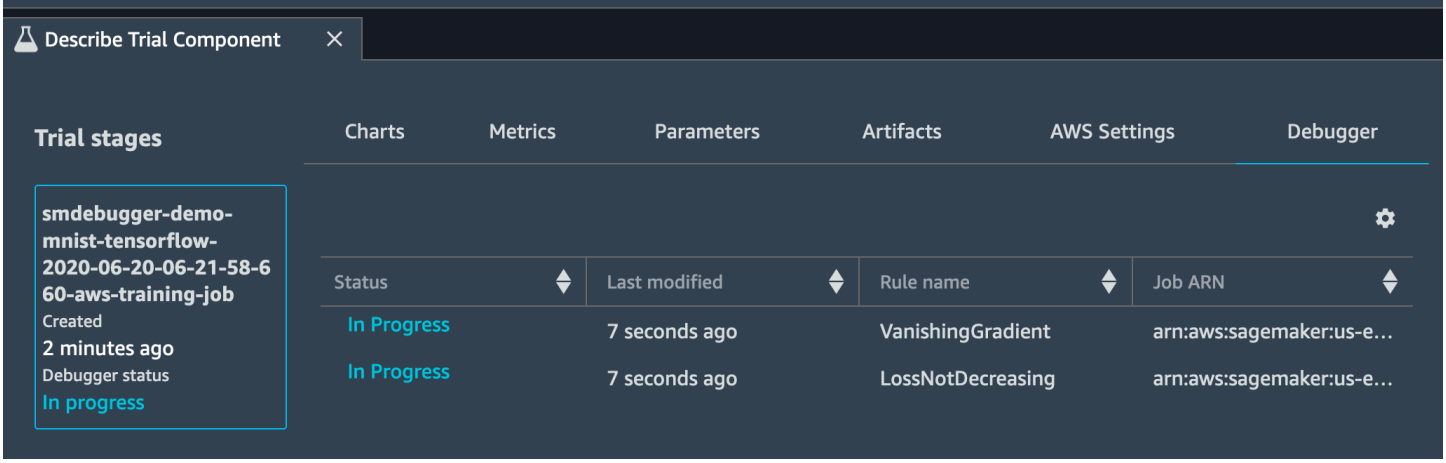
While running the example notebooks in SageMaker Studio, you can find the training job trial created on the **Studio Experiment List** tab. For example, as shown in the following screenshot, you can find and open a **Describe Trial Component** window of your current training job.
On the Debugger tab, you can check if the Debugger rules, `vanishing_gradient()` and

`loss_not_decreasing()`, are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.

```
[29]: rules = [
          Rule.sagemaker(rule_configs.vanishing_gradient()),
          Rule.sagemaker(
              base_config=rule_configs.loss_not_decreasing(),
              collections_to_save=[
                  CollectionConfig(
                      name="losses",
                      parameters={
                            #"save_interval": "50",
                            "train.save_interval": "50",
                            "eval.save_interval": "10"}

                  )
              ]
          )
      ]

      estimator = TensorFlow(
          role=sagemaker.get_execution_role(),
          base_job_name='smdebugger-demo-mnist-tensorflow',
          train_instance_count=1,
          train_instance_type='ml.m4.xlarge',
          train_volume_size=400,
          entry_point=entrypoint_script,
          framework_version='1.15',
          py_version='py3',
          train_max_run=3600,
          script_mode=True,
          hyperparameters=hyperparameters,
          ## New parameter
          rules = rules
      )
```



There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

Debugger Built-in Rules Example Code

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see List of Debugger Built-in Rules.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules=[
            Rule.sagemaker(rule_configs.vanishing_gradient())
            Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific arguments below
    rules=built_in_rules
)
sagemaker_estimator.fit()
```

> **Note**
>
> The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger Built-in Rules with Parameter Modifications section.

Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example, the `stalled_training_rule` collects the `losses` tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the `stalled_training_rule` stops the training job.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

built_in_rules_modified=[
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                'threshold': '120',
                'training_job_name_prefix': base_job_name_prefix,
                'stop_training_on_fire' : 'True'
        }
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                      "train.save_interval": "50"
                      "eval.save_interval": "10"
                }
            )
        ]
    )
]

# construct a SageMaker estimator with the modified Debugger built-in rule
```

```
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # debugger-specific arguments below
    rules=built_in_rules_modified
)
sagemaker_estimator.fit()
```

For an advanced configuration of the Debugger built-in rules using the `CreateTrainingJob` API, see Configure Debugger Using Amazon SageMaker API.

Turn Off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To stop both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

  > **Warning**
  >
  > If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To stop debugging, set the `debugger_hook_config` parameter to `False`.

  > **Warning**
  >
  > If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```
estimator=Estimator(
```

```
    ...
    disable_profiler=True
    debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the estimator.disable_profiling and estimator.update_profiler classmethods in the Amazon SageMaker Python SDK documentation.

Useful SageMaker Estimator Classmethods for Debugger

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.

- To check the base S3 bucket URI of a SageMaker training job:

  ```
  estimator.output_path
  ```

- To check the base job name of a SageMaker training job:

  ```
  estimator.latest_training_job.job_name
  ```

- To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:

```
estimator.latest_training_job.describe()
```

- To check a full list of the Debugger rules while a SageMaker training job is running:

```
estimator.latest_training_job.rule_job_summary()
```

- To check the S3 bucket URI where the model parameter data (output tensors) are saved:

```
estimator.latest_job_debugger_artifacts_path()
```

- To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:

```
estimator.latest_job_profiler_artifacts_path()
```

- To check the Debugger rule configuration for debugging output tensors:

```
estimator.debugger_rule_configs
```

- To check the list of the Debugger rules for debugging while a SageMaker training job is running:

```
estimator.debugger_rules
```

- To check the Debugger rule configuration for monitoring and profiling system and framework metrics:

```
estimator.profiler_rule_configs
```

- To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

```
estimator.profiler_rules
```

For more information about the SageMaker estimator class and its methods, see Estimator API in the Amazon SageMaker Python SDK.

SageMaker Debugger Interactive Report for XGBoost

Receive training reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance.

> **Note**
>
> You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

> **Important**
>
> In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger CreateXgboostReport rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the CreateXgboostReport rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and gain insights into the training results.

Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule

The CreateXgboostReport rule collects the following output tensors from your training job:

- `hyperparameters` – Saves at the first step.
- `metrics` – Saves loss and accuracy every 5 steps.
- `feature_importance` – Saves every 5 steps.
- `predictions` – Saves every 5 steps.
- `labels` – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`.

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

Using the SageMaker generic estimator

```
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
```

```
    # Add the Debugger XGBoost report rule
    rules=rules
)

estimator.fit(wait=False)
```

Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Download using the SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

   ```
   estimator.output_path
   ```

2. Check the current job name.

   ```
   estimator.latest_training_job.job_name
   ```

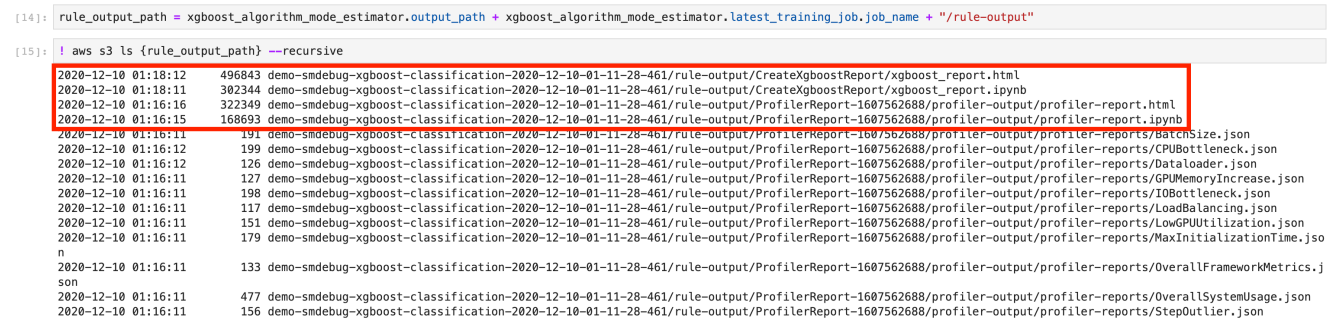
3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/<training-job-name>/rule-output`. Configure the rule output path as follows:

   ```
   rule_output_path = estimator.output_path + "/" +
    estimator.latest_training_job.job_name + "/rule-output"
   ```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

   ```
   ! aws s3 ls {rule_output_path} --recursive
   ```

   This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger profiling report.



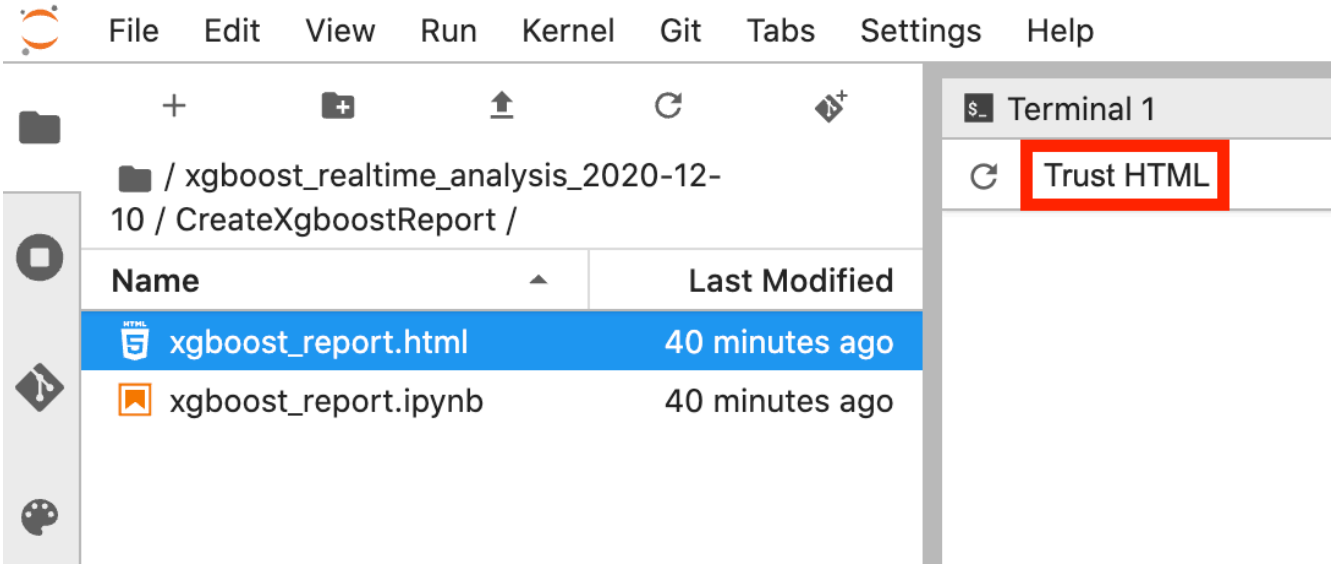
The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

> **Tip**
>
> If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

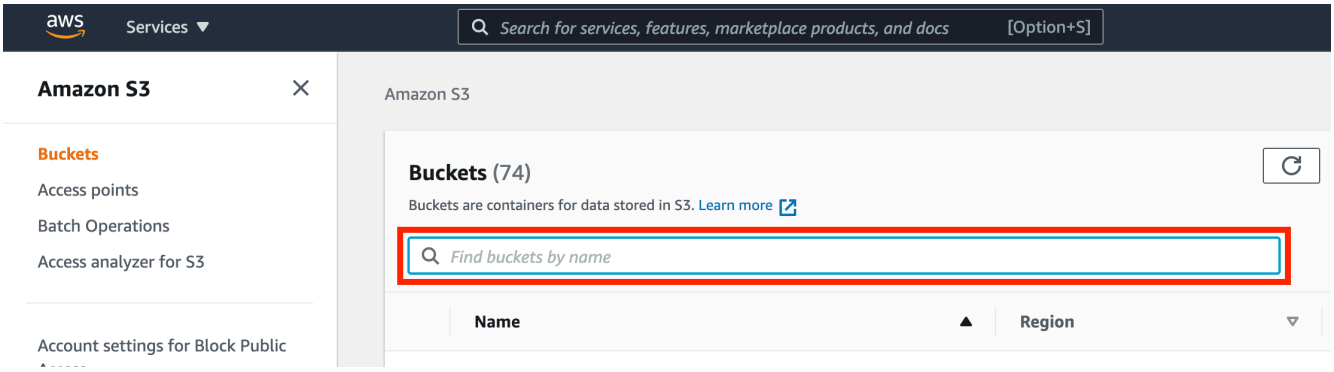
6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger training report.



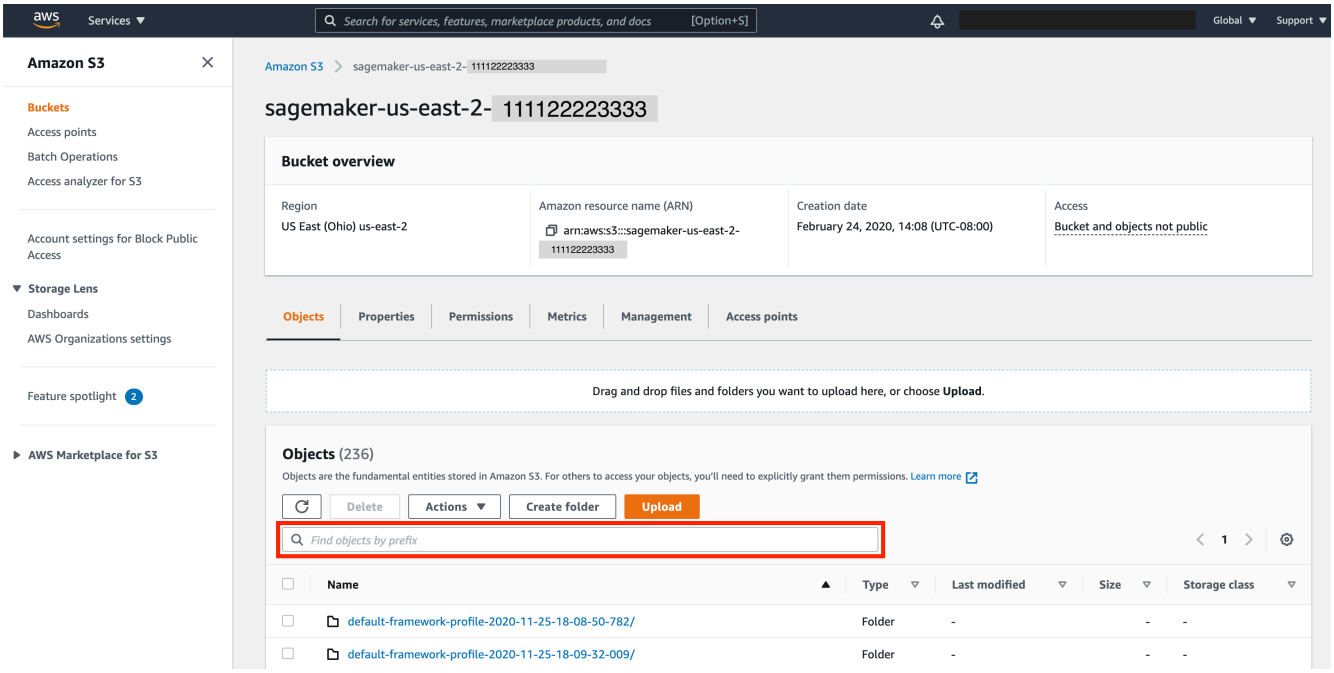
7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

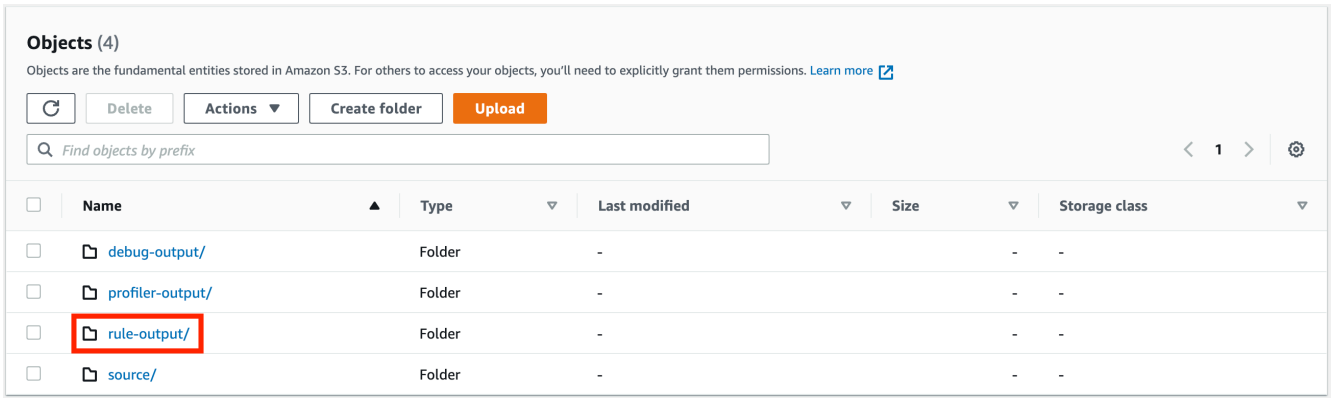
1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the **Find bucket by name** field.



3. In the base S3 bucket, look up the training job name by entering your job name prefix in **Find objects by prefix** and then choosing the training job name.



4. In the training job's S3 bucket, choose **rule-output/** subfolder. There must be three subfolders for training data collected by Debugger: **debug-output/**, **profiler-output/**, and **rule-output/**.



5. In the **rule-output/** folder, choose the **CreateXgboostReport/** folder. The folder contains **xbgoost_report.html** (the autogenerated report in html) and **xbgoost_report.ipynb** (a Jupyter notebook with scripts that are used for generating the report).
6. Choose the **xbgoost_report.html** file, choose **Download actions**, and then choose **Download**.

Debugger XGBoost Training Report Walkthrough

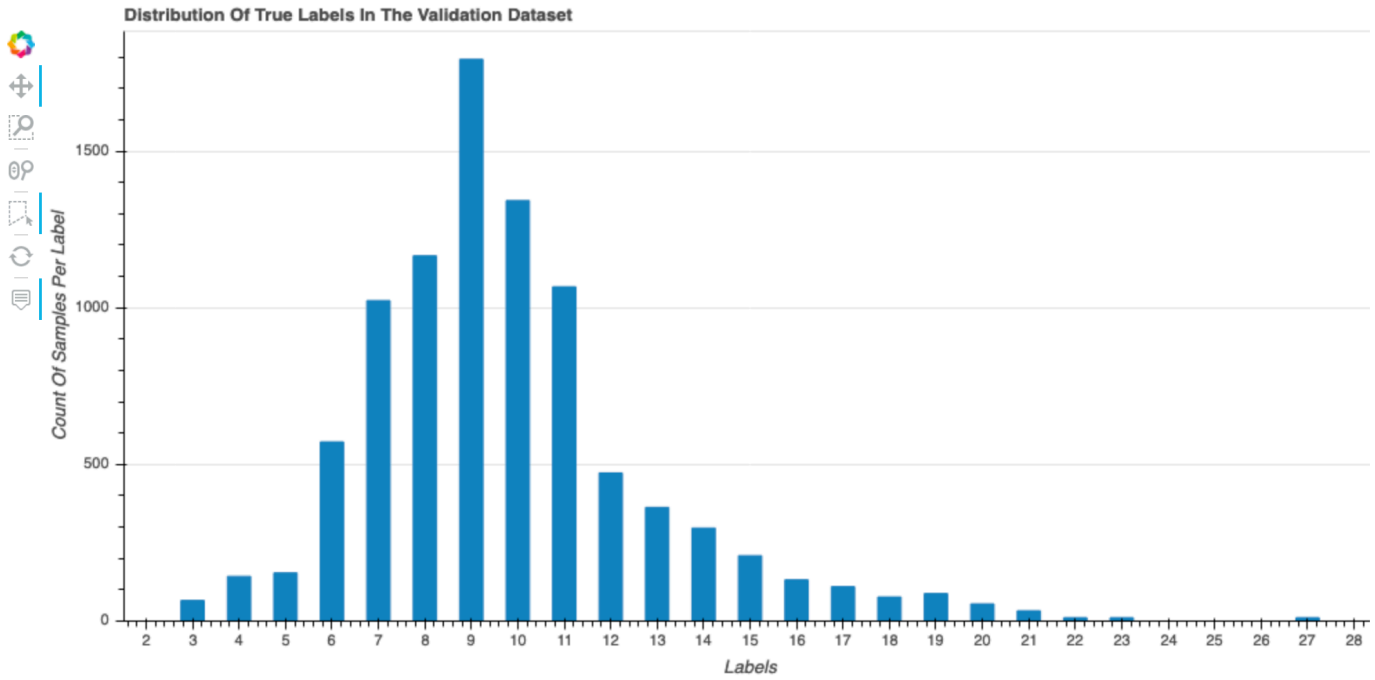
This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.

> **Important**
>
> In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics

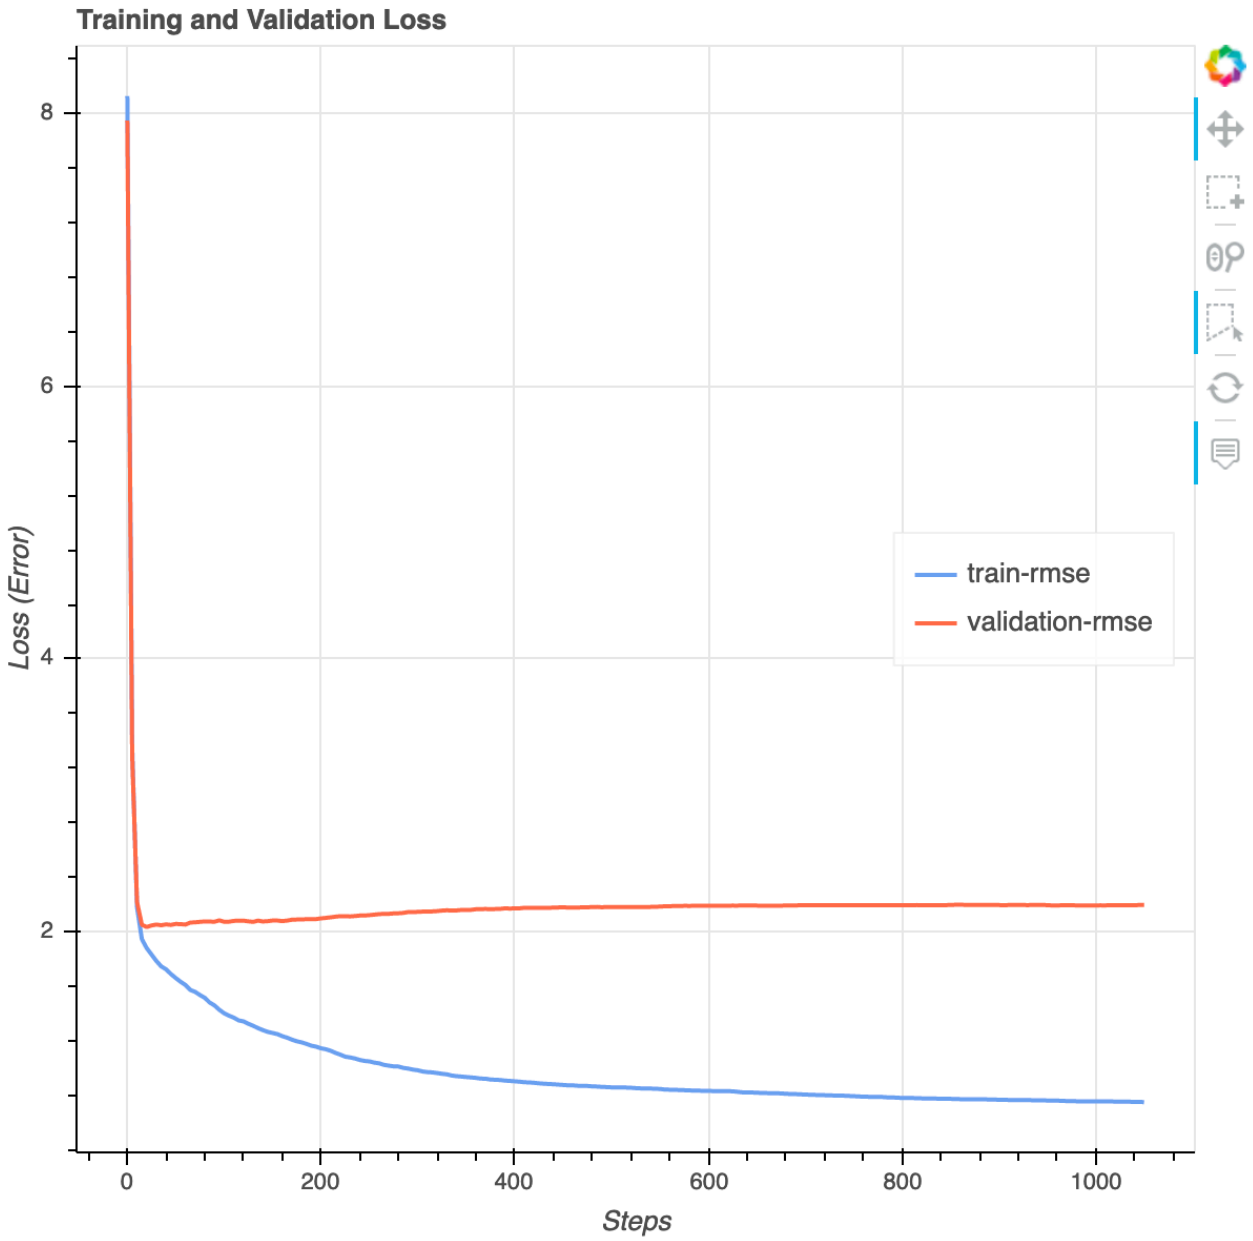
Distribution of True Labels of the Dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.



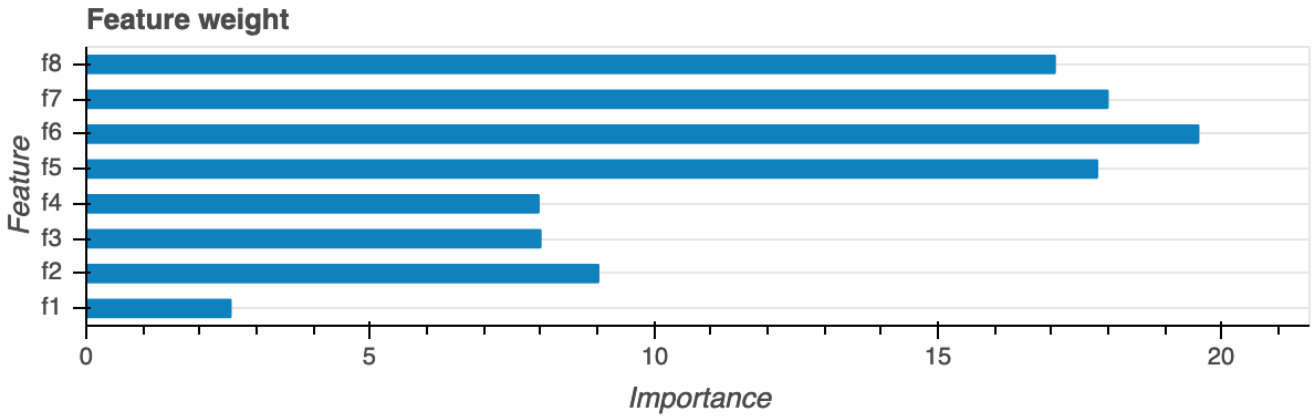
Loss versus Step Graph

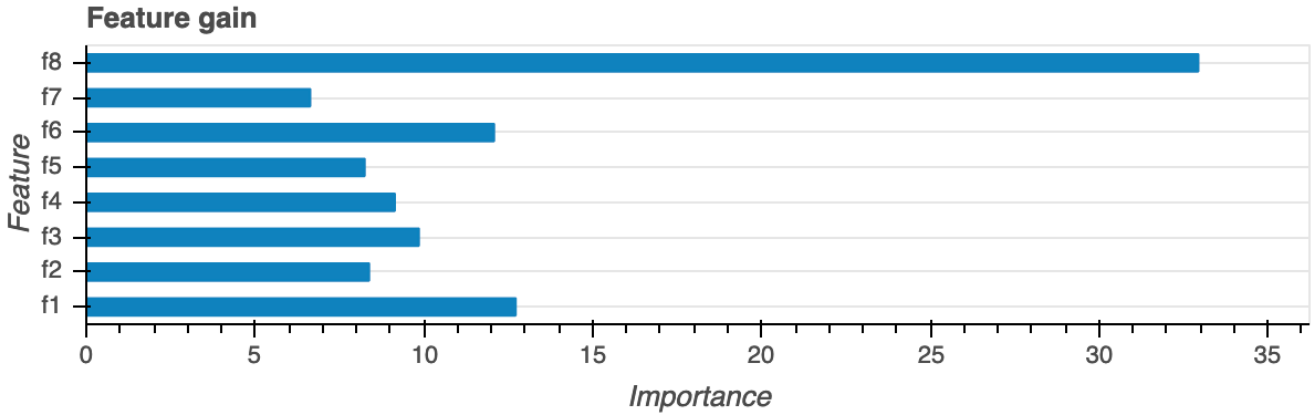
This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.

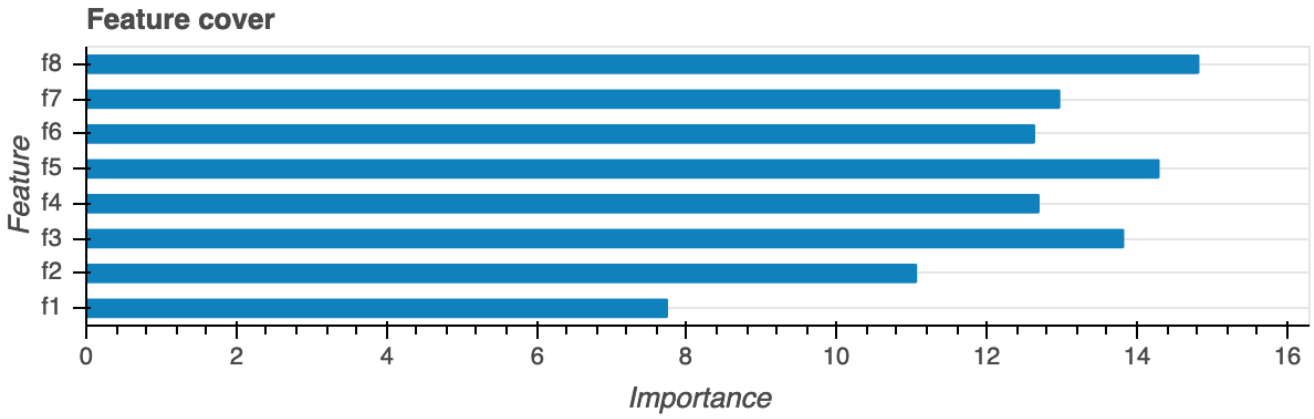


Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.



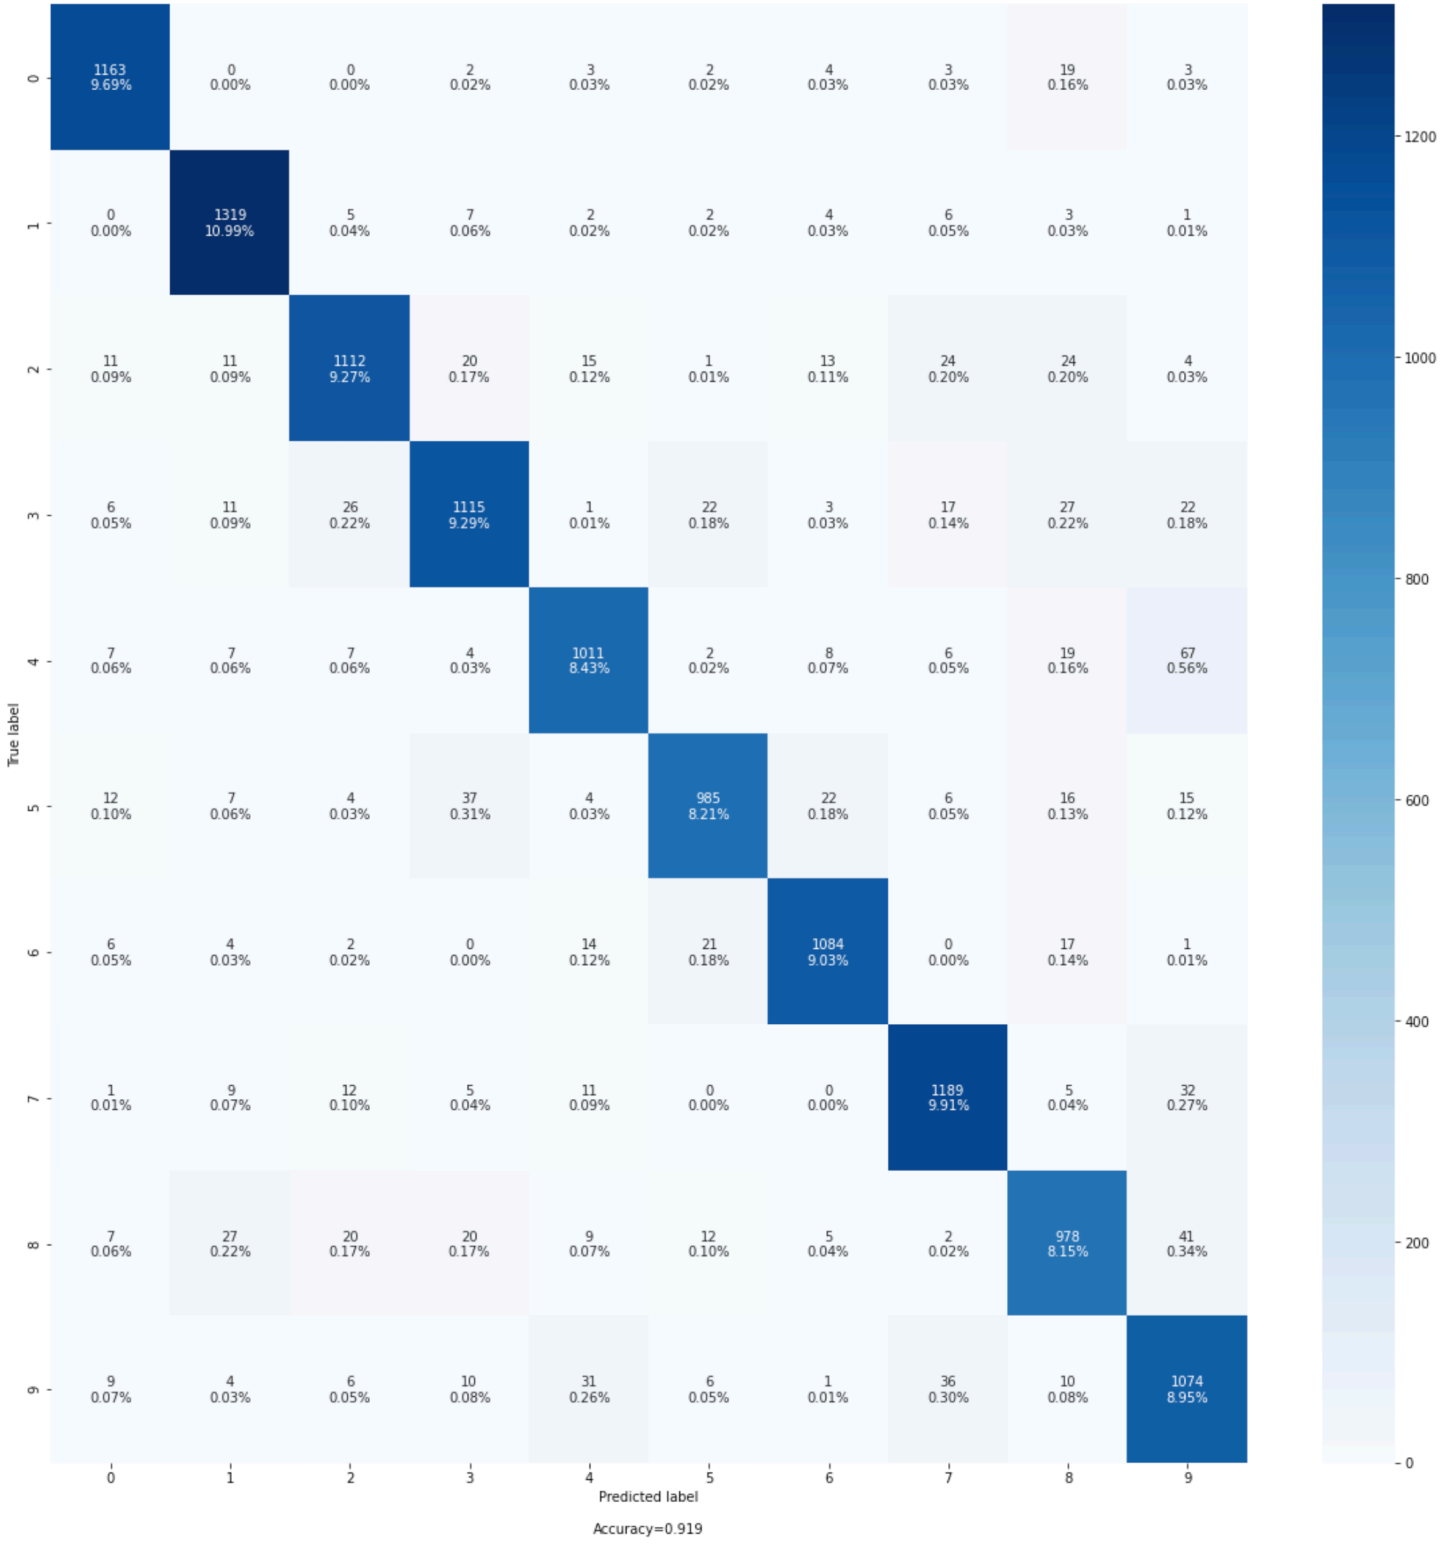




Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it's also important to know the false positive rate and false

negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.



Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.

Overall Accuracy

```
    Overall Accuracy: 0.919
```

Micro Performance Metrics

```
    Performance metrics calculated globally by counting the total true positives, false negatives, and false positive
s.

    Micro Precision: 0.919
    Micro Recall: 0.919
    Micro F1-score: 0.919
```

Macro Performance Metrics

```
    Performance metrics calculated for each label, and find their unweighted mean.
    This does not take the class imbalance problem into account.

    Macro Precision: 0.919
    Macro Recall: 0.918
    Macro F1-score: 0.918
```

Weighted Performance Metrics

```
    Performance metrics calculated for each label and their average weighted by support
    (the number of true instances for each label).
    This extends the macro option to take the class imbalance into account.
    It might result in an F-score that is not between precision and recall.

    Weighted Precision: 0.92
    Weighted Recall: 0.919
    Weighted F1-score: 0.919
```

Classification Report

```
        The summary of the precision, recall, and F1-score for each class.

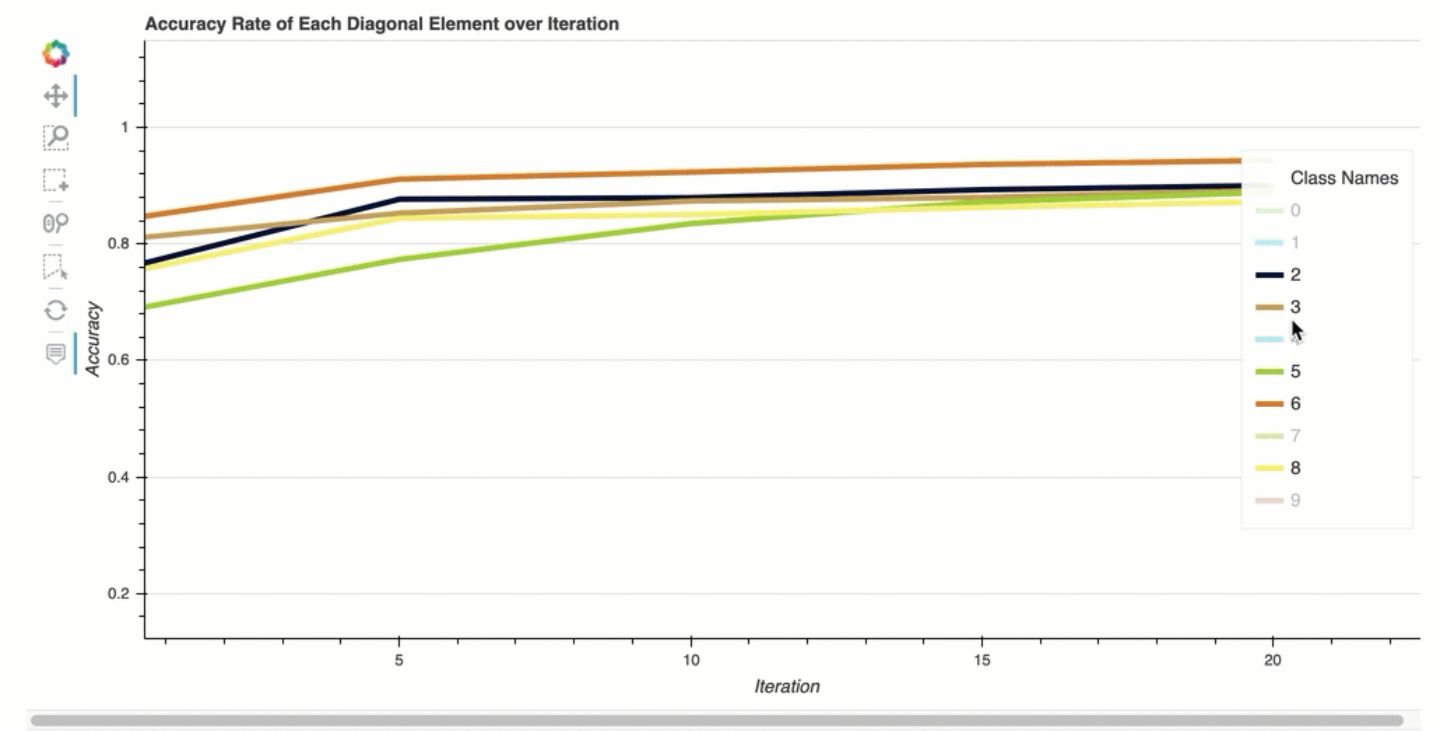
              precision    recall  f1-score   support

         0.0       0.95      0.97      0.96      1199
         1.0       0.94      0.98      0.96      1349
         2.0       0.93      0.90      0.92      1235
         3.0       0.91      0.89      0.90      1250
         4.0       0.92      0.89      0.90      1138
         5.0       0.94      0.89      0.91      1108
         6.0       0.95      0.94      0.95      1149
         7.0       0.92      0.94      0.93      1264
         8.0       0.87      0.87      0.87      1121
         9.0       0.85      0.90      0.88      1187

    accuracy                           0.92     12000
   macro avg       0.92      0.92      0.92     12000
weighted avg       0.92      0.92      0.92     12000
```

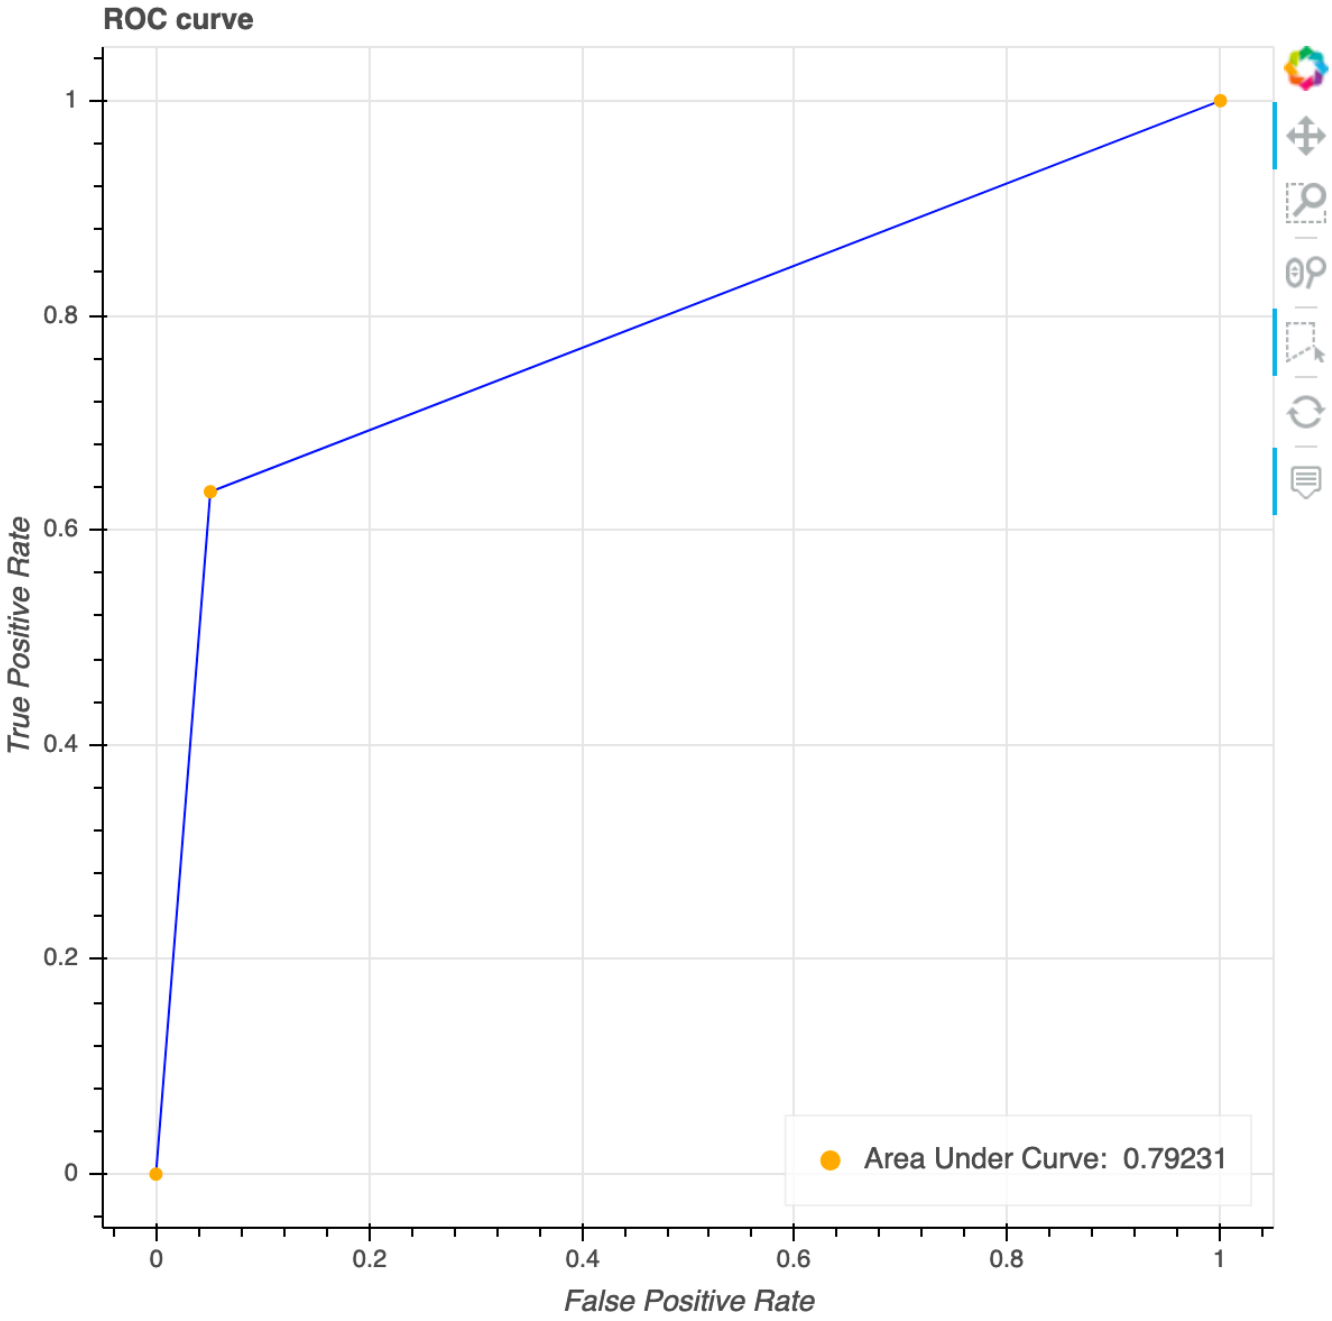
Accuracy Rate of Each Diagonal Element Over Iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.



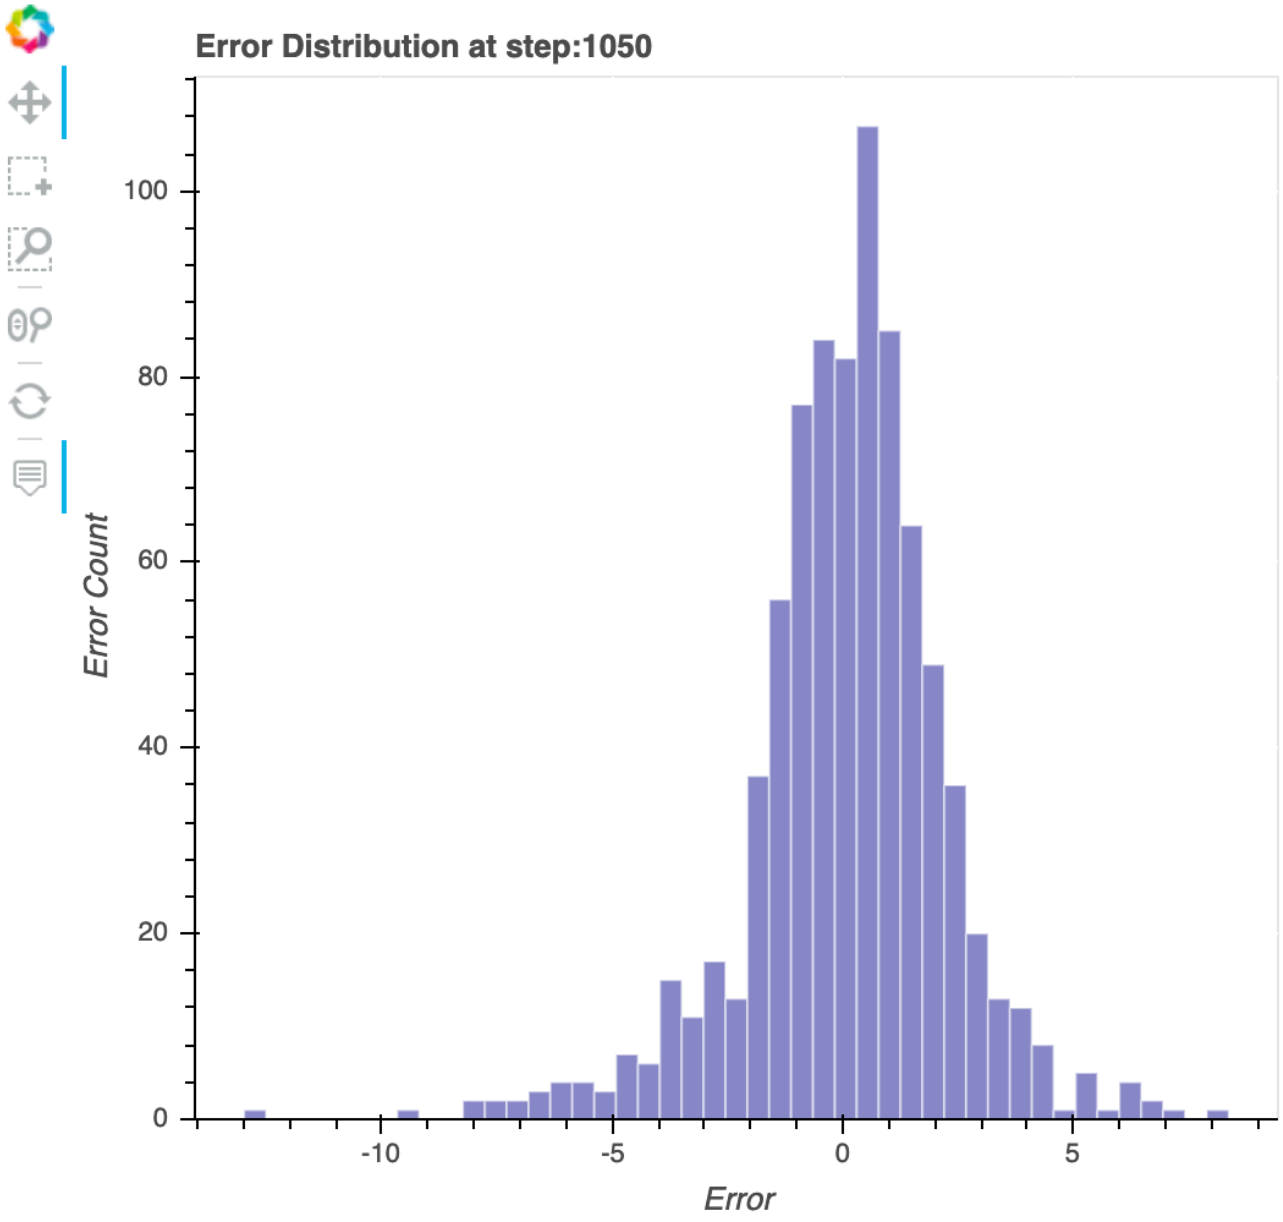
Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).



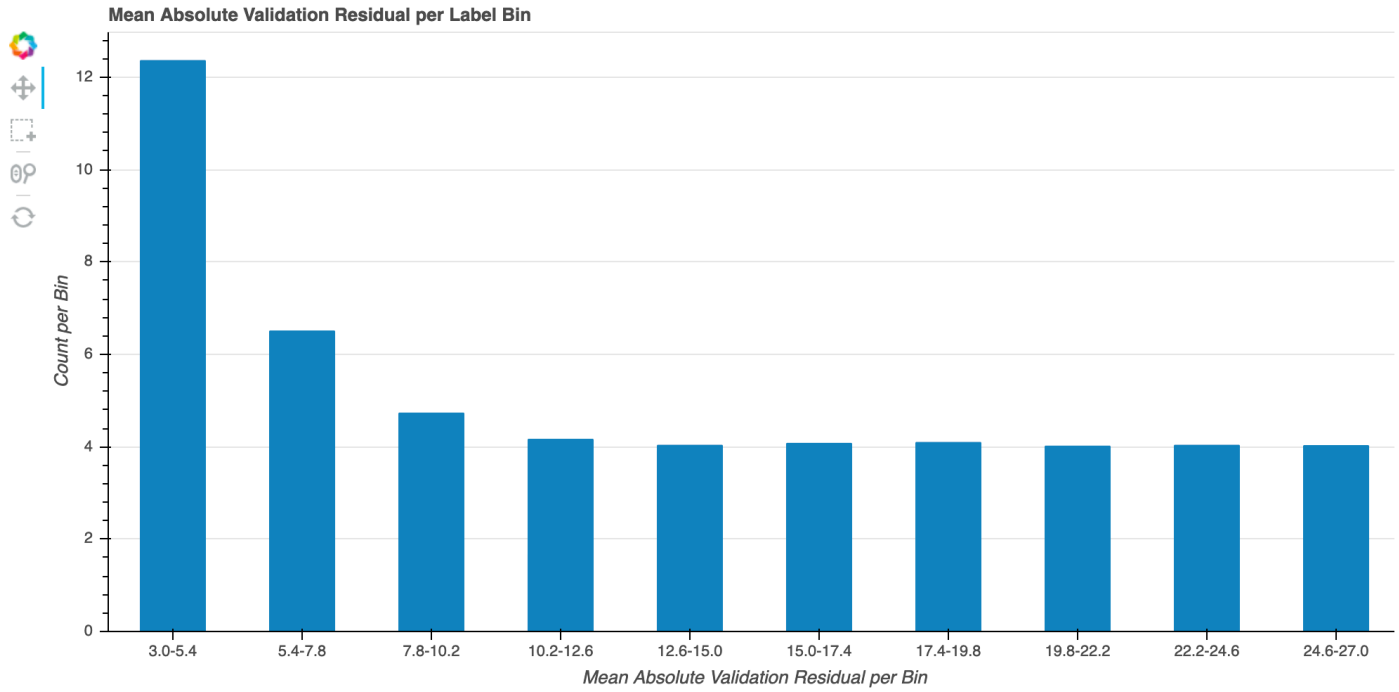
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that's centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.



Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.



Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

Topics

- Debugger Built-in Actions for Rules
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Debugger Built-in Actions for Rules

Use Debugger built-in actions to respond to issues found by Debugger Rule. The Debugger `rule_configs` class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic

This section walks you through how to set up an Amazon SNS **`SMDebugRules`** topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

> **Note**
>
> For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

To create a SMDebugRules topic

1. Sign in to the AWS Management Console and open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the left navigation pane, choose **Topics**.
3. On the **Topics** page, choose **Create topic**.
4. On the **Create topic** page, in the **Details** section, do the following:
   a. For **Type**, choose **Standard** for topic type.
   b. In **Name**, enter **`SMDebugRules`**.
5. Skip all other optional settings and choose **Create topic**. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

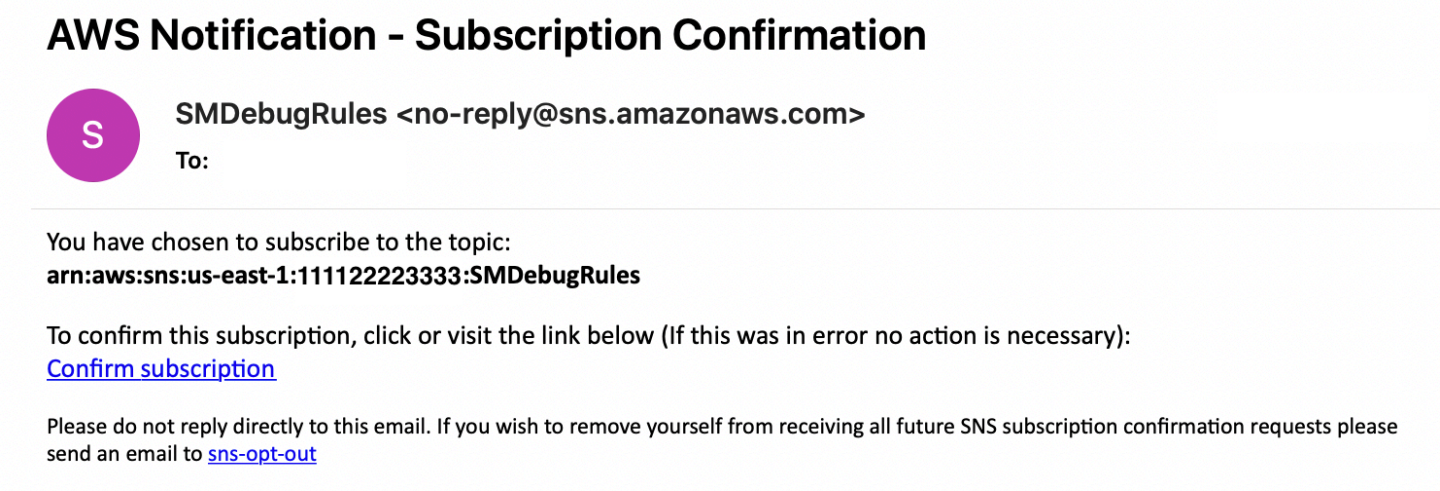
To subscribe to the SMDebugRules topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the left navigation pane, choose **Subscriptions**.
3. On the **Subscriptions** page, choose **Create subscription**.
4. On the **Create subscription** page, in the **Details** section, do the following:
   a. For **Topic ARN**, choose the **SMDebugRules** topic ARN. The ARN should be in format of `arn:aws:sns:<region-id>:111122223333:SMDebugRules`.
   b. For **Protocol**, choose **Email** or **SMS**.
   c. For **Endpoint**, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

> **Note**
>
> Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as **+12223334444**.

5. Skip all other optional settings and choose **Create subscription**. If you want to learn more about the optional settings, see Subscribing to an Amazon SNS topic.

After you subscribe to the **SMDebugRules** topic, you receive the following confirmation message in email or by phone:



For more information about Amazon SNS, see Mobile text messaging (SMS) and Email notifications in the *Amazon SNS Developer Guide*.

Step 2: Set Up Your IAM Role to Attach Required Policies

In this step, you add the required policies to your IAM role.

To add the required policies to your IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**, and choose **Create policy**.
3. On the **Create policy** page, do the following to create a new sns-access policy:

a. Choose the **JSON** tab.

b. Paste the JSON strings formatted in bold in the following code into the `"Statement"`, replacing the 12-digit AWS account ID with your AWS account ID.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "sns:Publish",
                "sns:CreateTopic",
                "sns:Subscribe"
            ],
            "Resource": "arn:aws:sns:*:111122223333:SMDebugRules"
        }
    ]
}
```

c. At the bottom of the page, choose **Review policy**.

d. On the **Review policy** page, for **Name**, enter **`sns-access`**.

e. At the bottom of the page, choose **Create policy**.

4. Go back to the IAM console, and choose **Roles** in the left navigation pane.
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the **Permissions** tab of the **Summary** page, choose **Attach policies**.
7. Search for the **sns-access** policy, select the check box next to the policy, and then choose **Attach policy**.

For more examples of setting up IAM policies for Amazon SNS, see Example cases for Amazon SNS access control.

Step 3: Configure Debugger Rules with the Built-in Actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the `actions` list object. The `rule_configs`

is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` – Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

> **Note**
>
> Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as **+12223334444**.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

To add all of the three built-in actions to a single rule

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
```

```
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),          # Required
        rule_parameters={"paramter_key": value },         # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
    rules = rules
)

estimator.fit(wait=False)
```

To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' `name` attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule to take two different actions: send an email to `abc@abc.com` when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```
from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls
 for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
```

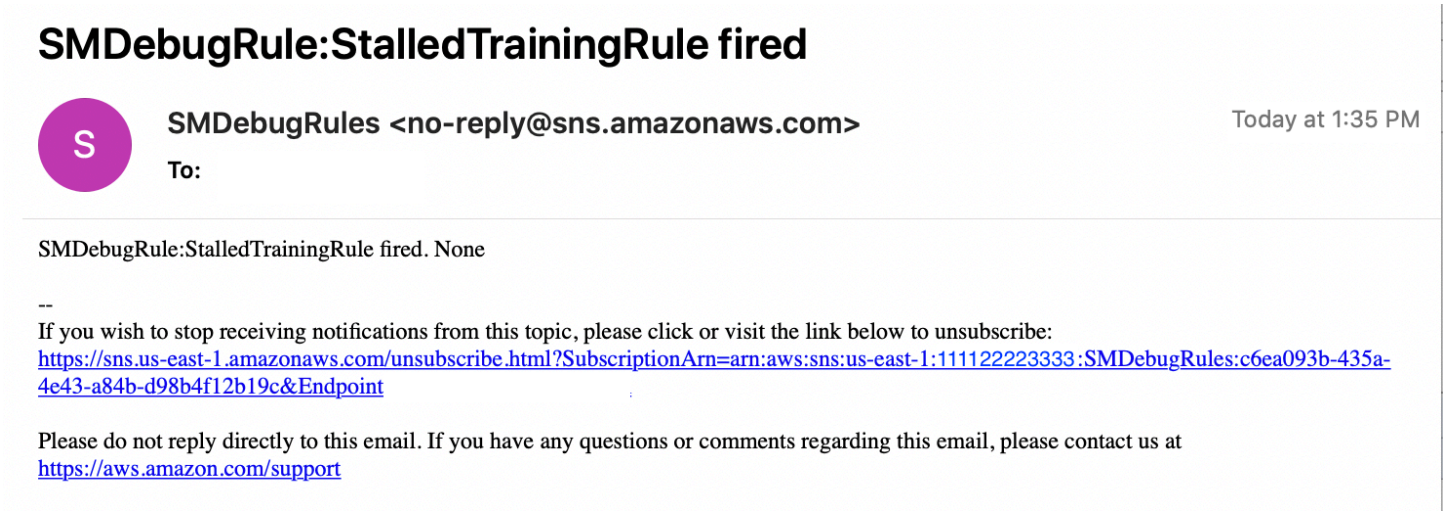
```
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                "threshold": "60",
                "training_job_name_prefix": base_job_name_prefix
        },
        actions=action_email
)
stalled_training_job_rule_text.name="StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job
 stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                "threshold": "120",
                "training_job_name_prefix": base_job_name_prefix
        },
        actions=action_stop_training
)
stalled_training_job_rule.name="StalledTrainingJobRuleStopTraining"

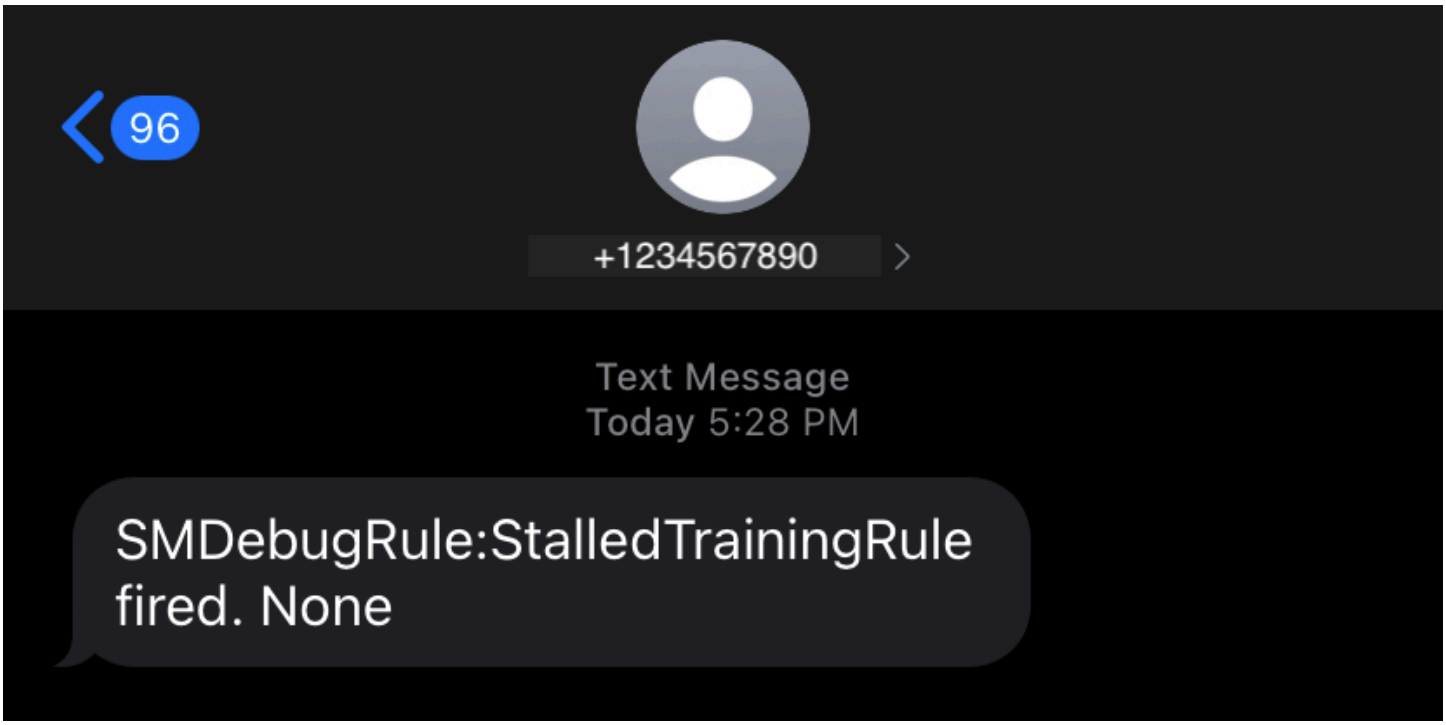
estimator = Estimator(
    ...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)

estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.



The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.



Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Profiler rules.
- The built-in actions cannot be used on training jobs with spot training interruptions.

- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

CloudWatch Logs for Debugger Rules and Training Jobs

To find training job logs and Debugger rule job logs

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane under the **Log** node, choose **Log Groups**.
3. In the log groups list, do the following:
   - Choose **/aws/sagemaker/TrainingJobs** for training job logs.
   - Choose **/aws/sagemaker/ProcessingJobs** for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker.

Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

Step 1: Create a Lambda Function

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions** and then choose **Create function**.
3. On the **Create function** page, choose **Author from scratch** option.

4. In the **Basic information** section, enter a **Function name** (for example, **debugger-rule-stop-training-job**).
5. For **Runtime**, choose **Python 3.7**.
6. For **Permissions**, expand the drop down option, and choose **Change default execution role**.
7. For **Execution role**, choose **Use an existing role** and choose the IAM role that you use for training jobs on SageMaker.

   > **Note**
   >
   > Make sure you use the execution role with `AmazonSageMakerFullAccess` and `AWSLambdaBasicExecutionRole` attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:
   >
   > ```
   > import sagemaker
   > sagemaker.get_execution_role()
   > ```

8. At the bottom of the page, choose **Create function**.

The following figure shows an example of the **Create function** page with the input fields and selections completed.

Create function Info

Choose one of the following options to create your function.

Author from scratch (selected)
Start with a simple Hello World example.

Use a blueprint
Build a Lambda application from sample code and configuration presets for common use cases.

Container image
Select a container image to deploy for your function.

Browse serverless app repository
Deploy a sample Lambda application from the AWS Serverless Application Repository.

Basic information

Function name
Enter a name that describes the purpose of your function.

debugger-rule-stop-training-job

Use only letters, numbers, hyphens, or underscores with no spaces.

Runtime Info
Choose the language to use to write your function. Note that the console code editor supports only Node.js, Python, and Ruby.

Python 3.7

Permissions Info

By default, Lambda will create an execution role with permissions to upload logs to Amazon CloudWatch Logs. You can customize this default role later when adding triggers.

▼ Change default execution role

Execution role
Choose a role that defines the permissions of your function. To create a custom role, go to the **IAM console**.

- ○ Create a new role with basic Lambda permissions
- ◉ Use an existing role
- ○ Create a new role from AWS policy templates

Existing role
Choose an existing role that you've created to be used with this Lambda function. The role must have permission to upload logs to Amazon CloudWatch Logs.

service-role/AmazonSageMaker-ExecutionRole-20200611T110452

View the AmazonSageMaker-ExecutionRole-20200611T110452 role on the IAM console.

▶ Advanced settings

Cancel **Create function**

Step 2: Configure the Lambda function

To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) `client` for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f'Evaluating Debugger rules for training job:
 {training_job_name}')
    eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)

    if eval_statuses is None or len(eval_statuses) == 0:
        logging.info("Couldn't find any debug rule statuses, skipping...")
        return {
            'statusCode': 200,
            'body': json.dumps('Nothing to do')
        }

    # should only attempt stopping jobs with InProgress status
    training_job_status = event.get("detail").get("TrainingJobStatus", None)
    if training_job_status != 'InProgress':
        logging.debug(f"Current Training job status({training_job_status}) is not
 'InProgress'. Exiting")
        return {
            'statusCode': 200,
            'body': json.dumps('Nothing to do')
        }

    client = boto3.client('sagemaker')

    for status in eval_statuses:
```

```
        logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus='
+ str(status))
        if status.get("RuleEvaluationStatus") == "IssuesFound":
            secondary_status = event.get("detail").get("SecondaryStatus", None)
            logging.info(
                f'About to stop training job, since evaluation of rule
configuration {status.get("RuleConfigurationName")} resulted in "IssuesFound". ' +
                f'\ntraining job "{training_job_name}" status is
"{training_job_status}", secondary status is "{secondary_status}"' +
                f'\nAttempting to stop training job "{training_job_name}"'
            )
            try:
                client.stop_training_job(
                    TrainingJobName=training_job_name
                )
            except Exception as e:
                logging.error(
                    "Encountered error while trying to "
                    "stop training job {}: {}".format(
                        training_job_name, str(e)
                    )
                )
                raise e
    return None
```

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose **Save** at the top of the configuration page.

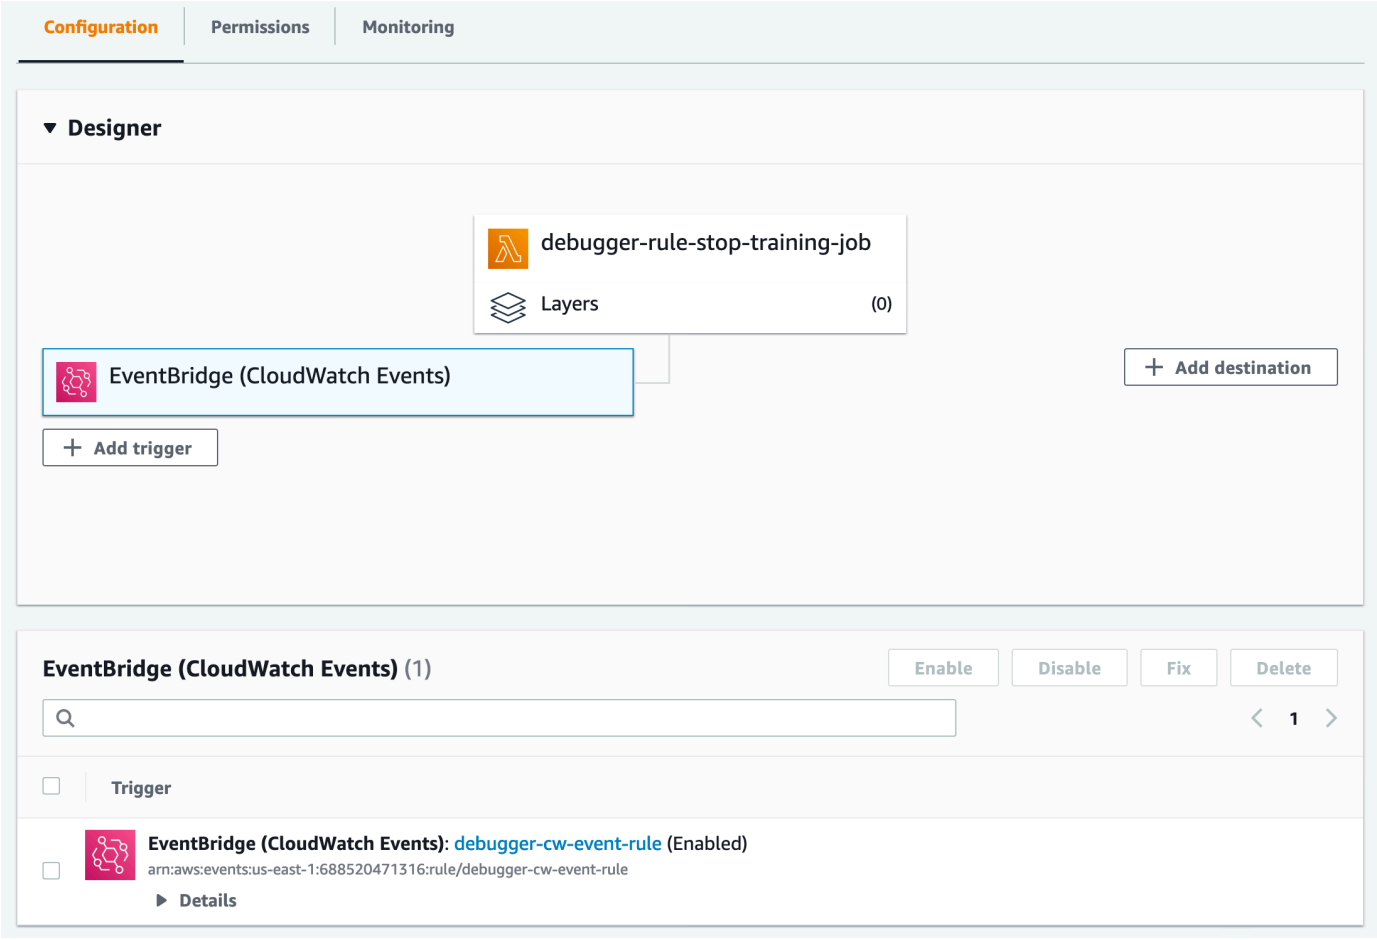
Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger

To create a CloudWatch Events rule and link to the Lambda function for Debugger

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Rules** under the **Events** node.
3. Choose **Create rule**.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```
{
    "source": [
        "aws.sagemaker"
    ],
    "detail-type": [
        "SageMaker Training Job State Change"
    ]
}
```

5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.
6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.
7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.
8. Choose **Create rule** to finish.
9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:



Run Example Notebooks to Test Automated Training Job Termination

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- Amazon SageMaker Debugger - Reacting to CloudWatch Events from Rules

  This example notebook runs a training job that has a vanishing gradient issue. The Debugger VanishingGradient built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.

- Detect Stalled Training and Invoke Actions Using SageMaker Debugger Rule

  This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule built-in rule invokes issues and stops the training job.

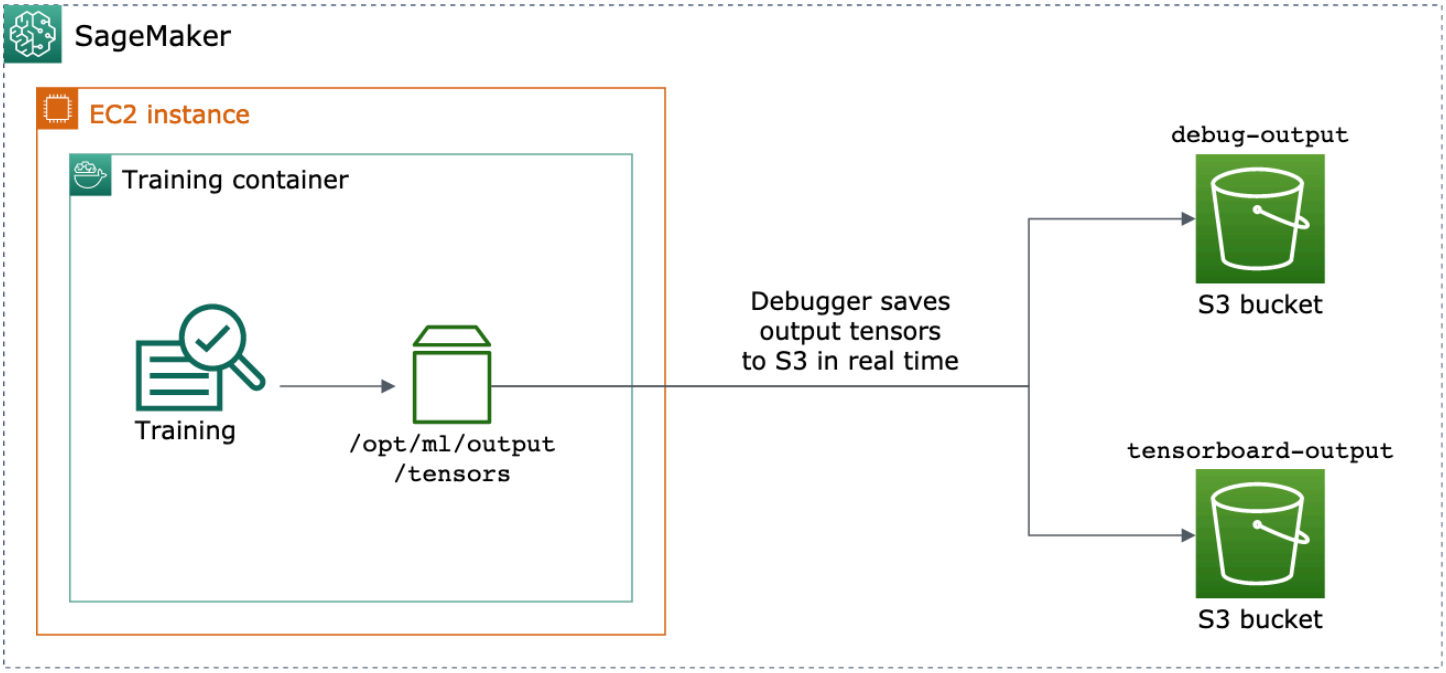
Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda **Designer** panel, choose the **EventBridge (CloudWatch Events)** block linked to the Lambda function. This shows an **EventBridge** panel below the **Designer** panel (for example, see the previous screen shot). Select the check box next to **EventBridge (CloudWatch Events): debugger-cw-event-rule**, and then choose **Disable**. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard

> **Important**
>
> This page is deprecated in favor of Amazon SageMaker with TensoBoard, which provides a comprehensive TensorBoard experience integrated with SageMaker Training and the access control functionalities of SageMaker domain. To learn more, see Use TensorBoard to debug and analyze training jobs in Amazon SageMaker.

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.



You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an `estimator`.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

To save TensorBoard compatible output tensor files using Debugger

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the `container_local_output_path` parameter; instead, it is set to the default local path `/opt/ml/output/tensors`.

   ```
   import sagemaker
   from sagemaker.debugger import TensorBoardOutputConfig

   bucket = sagemaker.Session().default_bucket()
   tensorboard_output_config = TensorBoardOutputConfig(
       s3_output_path='s3://{}'.format(bucket)
   )
   ```

   For additional information, see the Debugger `TensorBoardOutputConfig` API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the `weights` parameters every 500 steps (the default `save_interval` value for saving tensor collections is 500), and the `bias` parameters every 10 global steps until the global step reaches 500.

   ```
   from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

   hook_config = DebuggerHookConfig(
       hook_parameters={
           "train.save_interval": "100",
           "eval.save_interval": "10"
       },
       collection_configs=[
   ```

```
        CollectionConfig("weights"),
        CollectionConfig(
            name="biases",
            parameters={
                "save_interval": "10",
                "end_step": "500",
                "save_histogram": "True"
            }
        ),
    ]
)
```

For more information about the Debugger configuration APIs, see the Debugger `CollectionConfig` and `DebuggerHookConfig` APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are `TensorFlow`, `PyTorch`, and `MXNet`.

```
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
    debugger_hook_config=hook_config,
    tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```

The `estimator.fit()` method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use `estimator.latest_job_debugger_artifacts_path()`.
- For the TensorBoard S3 output path, use `estimator.latest_job_tensorboard_artifacts_path()`.

4. After the training has completed, check the names of saved output tensors:

```
from smdebug.trials import create_trial
trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()
```

5. Check the TensorBoard output data in Amazon S3:

```
tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
print(tensorboard_output_path)
!aws s3 ls {tensorboard_output_path}/
```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to `/logs/fit` under the current working directory of your notebook instance.

```
!aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
```

7. Compress the file directory to a TAR file to download to your local machine.

```
!tar -cf logs.tar logs
```

8. Download and extract the Tensorboard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

```
!tar -xf logs.tar
%load_ext tensorboard
%tensorboard --logdir logs/fit
```

List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze metrics and tensors collected while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. There's no additional cost for using the built-in rules. For more information about billing, see the Amazon SageMaker Pricing page.

Note

The maximum numbers of built-in rules that you can attach to a training job is 20. SageMaker Debugger fully manages the built-in rules and analyzes your training job synchronously.

Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Debugger Rule

The following rules are the Debugger built-in rules that are callable using the `Rule.sagemaker` classmethod.

Debugger built-in rules for generating training reports

Scope of Validity	Built-in Rules
Training Report for SageMaker XGboost training job	• create_xgboost_report

Debugger built-in rules for debugging model training data (output tensors)

Scope of Validity	Built-in Rules
Deep learning frameworks (TensorFlow, MXNet, and PyTorch)	• dead_relu • exploding_tensor

Scope of Validity	Built-in Rules
	• poor_weight_initialization • saturated_activation • vanishing_gradient • weight_update_ratio
Deep learning frameworks (TensorFlow, MXNet, and PyTorch) and the XGBoost algorithm	• all_zero • class_imbalance • loss_not_decreasing • overfit • overtraining • similar_across_runs • stalled_training_rule • tensor_variance • unchanged_tensor
Deep learning applications	• check_input_images • nlp_sequence_ratio
XGBoost algorithm	• confusion • feature_importance_overweight • tree_depth

To use the built-in rules with default parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```

To use the built-in rules with customizing the parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
                "key": "value"
        }
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code.
- For a full instruction on using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API.

CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- `hyperparameters` – Saves at the first step

- `metrics` – Saves loss and accuracy every 5 steps
- `feature_importance` – Saves every 5 steps
- `predictions` – Saves every 5 steps
- `labels` – Saves every 5 steps

Parameter Descriptions for the CreateXgboostReport Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String

```
rules=[
    Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )
]
```

DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns `True`.

Parameter Descriptions for the DeadRelu Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.

Parameter Name	Description
	Required Valid values: String
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: `".*relu_output"`
`threshold_inactivity`	Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the `threshold _inactivity` , it is considered to be dead. **Optional** Valid values: Float Default values: `1.0` (in percentage)

Parameter Name	Description
`threshold_layer`	Returns `True` if the percentage of inactive ReLUs in a layer is greater than `threshold_layer` . Returns `False` if the percentage of inactive ReLUs in a layer is less than `threshold_layer` . **Optional** Valid values: Float Default values: `50.0` (in percentage)

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.dead_relu(),
        rule_parameters={
                "tensor_regex": ".*relu_output|.*ReLU_output",
                "threshold_inactivity": "1.0",
                "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex: ".*relu_output|.*ReLU_output",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns `True`.

Parameter Descriptions for the ExplodingTensor Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: String Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional**

Parameter Name	Description
	Valid values: String Default value: None
only_nan	True to monitor the base_trial tensors only for NaN values and not for infinity. False to treat both NaN and infinity as exploding values and to monitor for both. **Optional** Default value: False

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
                "tensor_regex": ".*gradient",
                "only_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

PoorWeightInitialization

This rule detects if your model parameters have been poorly initialized.

Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

Parameter Descriptions for the PoorWeightInitialization Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`activation_inputs_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: String Default value: `".*relu_input"`
`threshold`	If the ratio between minimum and maximum variance of weights per layer exceeds the `threshold` at a step, the rule returns `True`.

Parameter Name	Description
	Optional Valid values: Float Default value: `10.0`
`distribution_range`	If the minimum difference between 5th and 95th percentiles of the gradient distribution is less than the `distribution_range` , the rule returns `True`. **Optional** Valid values: Float Default value: `0.001`
`patience`	The number of steps to wait until the loss is considered to be no longer decreasing. **Optional** Valid values: Integer Default value: 5
`steps`	The number of steps this rule analyzes. You typically need to check only the first few iterations. **Optional** Valid values: Float Default value: `10`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.poor_weight_initialization(),
```

```
        rule_parameters={
                "activation_inputs_regex": ".*relu_input|.*ReLU_input",
                "threshold": "10.0",
                "distribution_range": "0.001",
                "patience": "5",
                "steps": "10"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex": ".*relu_input|.*ReLU_input",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

SaturatedActivation

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective `min_threshold` and `max_thresholds` values. If the activity of a node drops below the `threshold_inactivity` percentage, it is considered saturated. If more than a `threshold_layer` percent of the nodes are saturated, the rule returns `True`.

Parameter Descriptions for the SaturatedActivation Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: String Default value: `".*tanh_input|.*si gmoid_input".`
`threshold_tanh_min`	The minimum and maximum thresholds that define the extremes of the input for a tanh activation function, defined as: `(min_thre shold, max_threshold)` . The default

Parameter Name	Description
	values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `-9.4999`
`threshold_tanh_max`	The minimum and maximum thresholds that define the extremes of the input for a tanh activation function, defined as: `(min_threshold, max_threshold)` . The default values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `9.4999`
`threshold_sigmoid_min`	The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: `(min_threshold, max_threshold)` . The default values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `-23`

Parameter Name	Description
`threshold_sigmoid_max`	The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: `(min_threshold, max_threshold)` . The default values are determined based on a vanishing gradient threshold of 0.0000001. **Optional** Valid values: Float Default values: `16.99999`
`threshold_inactivity`	The percentage of inactivity below which the activation layer is considered to be saturated. The activation might be active in the beginning of a trial and then slowly become less active during the training process. **Optional** Valid values: Float Default values: `1.0`
`threshold_layer`	Returns `True` if the number of saturated activations in a layer is greater than the `threshold_layer` percentage. Returns `False` if the number of saturated activations in a layer is less than the `threshold_layer` percentage. **Optional** Valid values: Float Default values: `50.0`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.saturated_activation(),
        rule_parameters={
                "tensor_regex": ".*tanh_input|.*sigmoid_input",
                "threshold_tanh_min": "-9.4999",
                "threshold_tanh_max": "9.4999",
                "threshold_sigmoid_min": "-23",
                "threshold_sigmoid_max": "16.99999",
                "threshold_inactivity": "1.0",
                "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_activations_collection",
                parameters={
                    "include_regex": ".*tanh_input|.*sigmoid_input"
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

VanishingGradient

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified `threshold`, the rule returns `True`.

Parameters Descriptions for the VanishingGradient Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	The value at which the gradient is determined to be vanishing. **Optional** Valid values: Float Default value: `0.0000001` .

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
                "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the `large_threshold value` or if this ratio is smaller than `small_threshold`, the rule returns `True`.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and `train.save_interval` needs to be set equal to `num_steps`.

Parameter Descriptions for the WeightUpdateRatio Rule

Parameter Name,	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`num_steps`	The number of steps across which the rule checks to determine if the tensor has changed. The number of steps across which you want to compare the weight ratios. If you pass no value, the rule runs by default against the current step and the immediately previous saved step. If you override the default by passing a value for this parameter, the comparison is done between weights at step `s` and at a step `>= s - num_steps` .

Parameter Name,	Description
	Optional Valid values: Integer Default value: None
`large_threshold`	The maximum value that the ratio of updates to weight can take before the rule returns `True`. **Optional** Valid values: Float Default value: `10.0`
`small_threshold`	The minimum value that the ratio of updates to weight can take, below which the rule returns `True`. **Optional** Valid values: Float Default value: `0.00000001`
`epsilon`	A small constant used to ensure that Debugger does not divide by zero when computing the ratio updates to weigh. **Optional** Valid values: Float Default value: `0.000000001`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.weight_update_ratio(),
```

```
        rule_parameters={
                "num_steps": "100",
                "large_threshold": "10.0",
                "small_threshold": "0.00000001",
                "epsilon": "0.000000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="weights",
                parameters={
                    "train.save_interval": "100"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> This rule is not available for the XGBoost algorithm.

AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameters Descriptions for the AllZero Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`threshold`	Specifies the percentage of values in the tensor that needs to be zero for this rule to be invoked.

Parameter Name	Description
	Optional Valid values: Float Default value: 100 (in percentage)

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.all_zero(),
        rule_parameters={
                "tensor_regex": ".*",
                "threshold": "100"
        },
        collections_to_save=[
            CollectionConfig(
                name="all",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the `threshold_imbalance`, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but

low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above `threshold_misprediction`, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the ClassImbalance Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold_imbalance`	The acceptable imbalance between the number of samples in the smallest class and in the largest class. Exceeding this threshold value throws an error. **Optional** Valid values: Float Default value: `10`
`threshold_misprediction`	A limit on the fraction of mispredictions allowed for each class. Exceeding this threshold throws an error. The underrepr esented classes are most at risk of crossing this threshold. **Optional** Valid values: Float

Parameter Name	Description
	Default value: `0.7`
`samples`	The number of labels that have to be processed before an imbalance is evaluated . The rule might not be triggered until it has seen sufficient samples across several steps. The more classes that your dataset contains, the larger this `sample` number should be. **Optional** Valid values: Integer Default value: `500` (assuming a dataset like MNIST with 10 classes)
`argmax`	If `True`, np.argmax is applied to the predictio n tensor. Required when you have a vector of probabilities for each class. It is used to determine which class has the highest probability. **Conditional** Valid values: Boolean Default value: `False`
`labels_regex`	The name of the tensor that contains the labels. **Optional** Valid values: String Default value: `".*labels"`

Parameter Name	Description
`predictions_regex`	The name of the tensor that contains the predictions. **Optional** Valid values: String Default value: `".*predictions"`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.class_imbalance(),
        rule_parameters={
                "threshold_imbalance": "10",
                "threshold_misprediction": "0.7",
                "samples": "500",
                "argmax": "False",
                "labels_regex": ".*labels",
                "predictions_regex": ".*predictions"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_output_collection",
                parameters={
                    "include_regex": ".*labels|.*predictions",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the

`collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the LossNotDecreasing Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns that is used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string

Parameter Name	Description
	Default value: None
use_losses_collection	If set to True, looks for losses in the collection named "losses" when the collection is present. **Optional** Valid values: Boolean Default value: True
num_steps	The minimum number of steps after which the rule checks if the loss has decreased. Rule evaluation happens every num_steps . The rule compares the loss for this step with the loss at a step which is at least num_steps behind the current step. For example, suppose that the loss is being saved every three steps, but num_steps is set to 10. At step 21, loss for step 21 is compared with loss for step 9. The next step at which loss is checked is step 33, because ten steps after step 21 is step 31, and at step 31 and step 32 loss is not saved. **Optional** Valid values: Integer Default value: 10

Parameter Name	Description
`diff_percent`	The minimum percentage difference by which the loss should decrease between `num_steps` . **Optional** Valid values: `0.0` < float < `100` Default value: `0.1` (in percentage)
`increase_threshold_percent`	The maximum threshold percent that loss is allowed to increase in case loss has been increasing **Optional** Valid values: `0` < float < `100` Default value: 5 (in percentage)
`mode`	The name of the Debugger mode to query tensor values for rule checking. If this is not passed, the rule checks in order by default for the `mode.EVAL` , then `mode.TRAIN` , and then `mode.GLOBAL` . **Optional** Valid values: String (`EVAL`, `TRAIN`, or `GLOBAL`) Default value: `GLOBAL`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.loss_not_decreasing(),
        rule_parameters={
                "tensor_regex": ".*",
                "use_losses_collection": "True",
```

```
                "num_steps": "10",
                "diff_percent": "0.1",
                "increase_threshold_percent": "5",
                "mode": "GLOBAL"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> A standard way to prevent overfitting is to regularize your model.

Parameter Descriptions for the Overfit Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**

Parameter Name	Description
	Valid values: String
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`start_step`	The step from which to start comparing the validation and training loss. **Optional** Valid values: Integer Default value: `0`
`patience`	The number of steps for which the `ratio_threshold` is allowed to exceed the value set before the model is considered to be overfit. **Optional** Valid values: Integer Default value: 1

Parameter Name	Description
`ratio_threshold`	The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a `patience` number of steps, the model is being overfit and the rule returns `True`. **Optional** Valid values: Float Default value: `0.1`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
                "tensor_regex": ".*",
                "start_step": "0",
                "patience": "1",
                "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]
```

Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum

of the loss function and does not improve anymore. If the model continues training it can happen that validation loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

> **Note**
>
> Overtraining can be avoided by early stopping. For information on early stopping, see Stop Training Jobs Early. For an example that shows how to use spot training with Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

Parameter Descriptions for the Overtraining Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`patience_train`	The number of steps to wait before the training loss is considered to not to be improving anymore. **Optional** Valid values: Integer Default value: 5

Parameter Name	Description
patience_validation	The number of steps to wait before the validation loss is considered to not to be improving anymore. **Optional** Valid values: Integer Default value: 10
delta	The minimum threshold by how much the error should improve before it is considered as a new optimum. **Optional** Valid values: Float Default value: 0.01

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overtraining(),
        rule_parameters={
                "patience_train": "5",
                "patience_validation": "10",
                "delta": "0.01"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

SimilarAcrossRuns

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the SimilarAcrossRuns Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`other_trials`	A completed training job name whose tensors you want to compare to those tensors gathered from the current `base_trial` . **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors.

Parameter Name	Description
	The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.similar_across_runs(),
        rule_parameters={
                "other_trials": "<specify-another-job-name>",
                "collection_names": "losses",
                "tensor_regex": ".*"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

StalledTrainingRule

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its `threshold` parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

Parameter Descriptions for the StalledTrainingRule Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds. **Optional** Valid values: Integer Default value: `1800`
`stop_training_on_fire`	If set to `True`, watches if the base training job outputs tensors in "`threshold `" seconds. **Optional** Valid values: Boolean Default value: `False`
`training_job_name_prefix`	The prefix of base training job name. If `stop_training_on_fire` is true, the rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a `StopTrainingJob` action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job.

Parameter Name	Description
	Optional Valid values: String

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
                "threshold": "1800",
                "stop_training_on_fire": "True",
                "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

TensorVariance

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the TensorVariance Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`max_threshold`	The threshold for the upper bound of tensor variance. **Optional**

Parameter Name	Description
	Valid values: Float Default value: None
`min_threshold`	The threshold for the lower bound of tensor variance. **Optional** Valid values: Float Default value: None

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tensor_variance(),
        rule_parameters={
                "collection_names": "weights",
                "max_threshold": "10",
                "min_threshold": "0.00001",
        },
        collections_to_save=[
            CollectionConfig(
                name="weights",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the numpy.allclose method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the

`collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the UnchangedTensor Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`collection_names`	The list of collection names whose tensors the rule inspects. **Optional** Valid values: List of strings or a comma-sep arated string Default value: None
`tensor_regex`	A list of regex patternsused to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional** Valid values: List of strings or a comma-sep arated string

Parameter Name	Description
	Default value: None
num_steps	The number of steps across which the rule checks to determine if the tensor has changed. This checks the last num_steps that are available. They don't need to be consecutive. If num_steps is 2, at step s it doesn't necessarily check for s-1 and s. If s-1 isn't available, it checks the last available step along with s. In that case, it checks the last available step with the current step. **Optional** Valid values: Integer Default value: 3
rtol	The relative tolerance parameter to be passed to the numpy.allclose method. **Optional** Valid values: Float Default value: 1e-05
atol	The absolute tolerance parameter to be passed to the numpy.allclose method. **Optional** Valid values: Float Default value: 1e-08

Parameter Name	Description
equal_nan	Whether to compare NaNs as equal. If True, NaNs in input array a are considered equal to NaNs in input array b in the output array. This parameter is passed to the numpy.allclose method. **Optional** Valid values: Boolean Default value: False

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.unchanged_tensor(),
        rule_parameters={
                "collection_names": "losses",
                "tensor_regex": "",
                "num_steps": "3",
                "rtol": "1e-05",
                "atol": "1e-08",
                "equal_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the CheckInputImages Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold_mean`	A threshold that defines by how much mean of the input data can differ from 0. **Optional** Valid values: Float Default value: `0.2`
`threshold_samples`	The number of images that have to be sampled before an error can be thrown. If the value is too low, the estimation of the dataset mean will be inaccurate. **Optional** Valid values: Integer Default value: `500`

Parameter Name	Description
`regex`	The name of the input data tensor. **Optional** Valid values: String Default value: `".*hybridsequential0_input_0"` (the name of the input tensor for Apache MXNet models using HybridSequential)
`channel`	The position of the color channel in the input tensor shape array. **Optional** Valid values: Integer Default value: 1 (for example, MXNet expects input data in the form of (batch_size, channel, height, width))

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
                "threshold_mean": "0.2",
                "threshold_samples": "500",
                "regex": ".*hybridsequential0_input_0",
                "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*hybridsequential0_input_0",
                    "save_interval": "500"
                }
```

```
            )
        ]
    )
]
```

NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the NLPSequenceRatio Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`tensor_regex`	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. **Optional**

Parameter Name	Description
	Valid values: List of strings or a comma-separated string Default value: `".*embedding0_input_0"` (assuming an embedding as the initial layer of the network)
`token_values`	A string of a list of the numerical values of the tokens. For example, "3, 0". **Optional** Valid values: Comma-separated string of numerical values Default value: `0`
`token_thresholds_percent`	A string of a list of thresholds (in percentages) that correspond to each of the `token_values` . For example,"50.0, 50.0". **Optional** Valid values: Comma-separated string of floats Default value: `"50"`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.nlp_sequence_ratio(),
        rule_parameters={
                "tensor_regex": ".*embedding0_input_0",
                "token_values": "0",
                "token_thresholds_percent": "50"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
```

```
                    "include_regex": ".*embedding0_input_0"
                }
            )
        ]
    )
]
```

Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size `category_no*category_no` and populates it with data coming from (`labels`, `predictions`) pairs. For each (`labels`, `predictions`) pair, the count in `confusion[labels][predictions]` is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: `confusion[i][i]/sum_j(confusion[j][j])>=min_diag`
- For elements off the diagonal: `confusion[j][i])/sum_j(confusion[j][i])<=max_off_diag`

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the Confusion Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`category_no`	The number of categories. **Optional**

Parameter Name	Description
	Valid values: Integer ≥2 Default value: `"None"`
`labels`	The `labels` tensor collection or an 1-d vector of true labels. **Optional** Valid values: String Default value: `"labels"`
`predictions`	The `predictions` tensor collection or an 1-d vector of estimated labels. **Optional** Valid values: String Default value: `"predictions"`
`labels_collection`	The rule inspects the tensors in this collection for `labels`. **Optional** Valid values: String Default value: `"labels"`
`predictions_collection`	The rule inspects the tensors in this collection for `predictions` . **Optional** Valid values: String Default value: `"predictions"`

Parameter Name	Description
`min_diag`	The minimum threshold for the ratio of data on the diagonal. **Optional** Valid values: `0`≤float≤`1` Default value: `0.9`
`max_off_diag`	The maximum threshold for the ratio of data off the diagonal. **Optional** Valid values: `0`≤float≤`1` Default value: `0.1`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.confusion(),
        rule_parameters={
                "category_no": "10",
                "labels": "labels",
                "predictions": "predictions",
                "labels_collection": "labels",
                "predictions_collection": "predictions",
                "min_diag": "0.9",
                "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="labels",
                parameters={
                    "save_interval": "500"
                }
            ),
            CollectionConfig(
                name="predictions",
```

```
                parameters={
                    "include_regex": "500"
                }
            )
        ]
    )
]
```

> **Note**
>
> This rule infers default values for the optional parameters if their values aren't specified.

FeatureImportanceOverweight

This rule accumulates the weights of the n largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the FeatureImportanceOverweight Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold for the proportion of the cumulative sum of the n largest features. The number n is defined by the `nfeatures` parameter. **Optional**

Parameter Name	Description
	Valid values: Float Default value: `0.8`
`nfeatures`	The number of largest features. **Optional** Valid values: Integer Default value: 3
`tensor_regex`	Regular expression (regex) of tensor names the rule to analyze. **Optional** Valid values: String Default value: `".*feature_importance/weight"`

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.feature_importance_overweight(),
        rule_parameters={
                "threshold": "0.8",
                "nfeatures": "3",
                "tensor_regex": ".*feature_importance/weight"
        },
        collections_to_save=[
            CollectionConfig(
                name="feature_importance",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
```

```
]
```

TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the `depth` parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules.

Parameter Descriptions for the TreeDepth Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`depth`	The depth of the tree. The depth of the tree is obtained by computing the base 2 logarithm of the largest node ID. **Optional** Valid values: Float Default value: 4

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tree_depth(),
        rule_parameters={
                "depth": "4"
        },
```

```
        collections_to_save=[
            CollectionConfig(
                name="tree",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Topics

- Prerequisites for Creating Debugger Custom Rules
- Use the Debugger Client Library smdebug to Create a Custom Rule Python Script
- Use the Debugger APIs to Run Your Own Custom Rules

Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule.custom API
- The open source smdebug Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators

Use the Debugger Client Library `smdebug` to Create a Custom Rule Python Script

The `smdebug` Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, `CustomGradientRule`. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```
from smdebug.rules.rule import Rule
```

```
class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at '*path/to/my_custom_rule.py*'.

```
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-
evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)
```

The following list explains the Debugger `Rule.custom` API arguments.

- `name` (str): Specify a custom rule name as you want.
- `image_uri` (str): This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job.

You can find the list of open source SageMaker rule evaluator images from Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators.

- `instance_type` (str): You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- `source` (str): This is the local path or the Amazon S3 URI to your custom rule script.
- `rule_to_invoke` (str): This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- `collections_to_save` (str): This specifies which tensor collections you will save for the rule to run.
- `rule_parameters` (dictionary): This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
                role=sagemaker.get_execution_role(),
                base_job_name='smdebug-custom-rule-demo-tf-keras',
                entry_point='path/to/your_training_script.py'
                train_instance_type='ml.p2.xlarge'
                ...

                # debugger-specific arguments below
                rules = [custom_rule]
)

estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.

- Monitor your training job with Amazon SageMaker Debugger custom rules
- PyTorch iterative model pruning of ResNet and AlexNet

- Trigger Amazon CloudWatch Events using Debugger Rules to Take an Action Based on Training Status with TensorFlow

Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker `Estimator` API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script.

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

> **Tip**
>
> This custom container with Debugger guide is an extension of the Adapting your own training container guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```
### debugger_custom_container_test_notebook.ipynb      # a notebook to run python
 snippet codes
```

```
### debugger_custom_container_test_folder             # this is a docker folder
    ###  your-training-script.py                      # your training script with
 Debugger hook
    ###  Dockerfile                                   # a Dockerfile to build your own
 container
```

Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

> **Note**
>
> This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimater.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.

```
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):

    ...
    model.fit(X_train, Y_train,
              batch_size=batch_size,
              epochs=epoch,
              validation_data=(X_valid, Y_valid),
              shuffle=True,

              # smdebug modification: Pass the Debugger hook in the main() as a Keras
 callback
              callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")
```

```
    # hyperparameter settings
    parser.add_argument(...)

    args = parser.parse_args()

    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

    # Add the following line to register the Debugger hook for Keras.
    hook=smd.KerasHook.create_from_json_file()

    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

if __name__ == "__main__":
    main()
```

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

  To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.

  In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, TensorFlow Keras ResNet training script in script mode. The training script imports the `smdebug` library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the `smdebug` hook functionality by adding the

`callbacks=[hook]` argument inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

- Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode

  This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

  The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

  This notebook shows detailed steps to change the original PyTorch training script to a modified version to enable Debugger. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and `Dockerfile`. The following code example is a `Dockerfile` that includes essential docker build commends. Paste the following code into the `Dockerfile` text file and save it. Upload your training script to the same folder.

```
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug
CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'

region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(account_id, region, uri_suffix,
 ecr_repository + tag)

!docker build -t $ecr_repository docker
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)
!aws ecr create-repository --repository-name $ecr_repository
!docker tag {ecr_repository + tag} $byoc_image_uri
!docker push $byoc_image_uri
```

Tip

If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

```
! aws ecr get-login-password --region {region} | docker login --username AWS --
password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
```

Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the `smdebug` core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point="./debugger_custom_container_test_folder/your-training-script.py"
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test',
    instance_count=1,
    instance_type='ml.p3.2xlarge',

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

# start training
estimator.fit()
```

Configure Debugger Using Amazon SageMaker API

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-

level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this section covers how to configure the following low-level API operations.

Topics

- JSON (AWS CLI)
- AWS Boto3

JSON (AWS CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the DebugHookConfig, DebugRuleConfiguration, ProfilerConfig, and ProfilerRuleConfiguration objects through the SageMaker CreateTrainingJob API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request CreateTrainingJob.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as `debugger-training-job-cli.json`.

> **Note**
>
> Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules.

```
{
   "TrainingJobName": "debugger-aws-cli-test",
   "RoleArn": "arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-
ExecutionRole-YYYYMMDDT123456",
   "AlgorithmSpecification": {
      // Specify a training Docker container image URI (Deep Learning Container or your
 own training container) to TrainingImage.
      "TrainingImage": "763104351884.dkr.ecr.us-west-2.amazonaws.com/tensorflow-
training:2.4.1-gpu-py37-cu110-ubuntu18.04",
```

      "ProfilingParameters": {
          "DataloaderProfilingConfig": "{\"StartStep\": 5, \"NumSteps\": 3,
 \"MetricsRegex\": \".*\", }",
          "DetailedProfilingConfig": "{\"StartStep\": 5, \"NumSteps\": 3, }",
          "PythonProfilingConfig": "{\"StartStep\": 5, \"NumSteps\": 3, \"ProfilerName
\": \"cprofile\", \"cProfileTimer\": \"total_time\"}",
          "LocalPath": "/opt/ml/output/profiler/"
      }
```

```
   },
   "ProfilerRuleConfigurations": [
      {
         "RuleConfigurationName": "ProfilerReport",
         "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest",
         "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
      }
   ],
   "ResourceConfig": {
      "InstanceType": "ml.p3.8xlarge",
      "InstanceCount": 1,
      "VolumeSizeInGB": 30
   },

   "StoppingCondition": {
      "MaxRuntimeInSeconds": 86400
   }
}
```

After saving the JSON file, run the following command in your terminal. (Use ! at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-
cli.json
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in `VanishingGradient` rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "gradients",
            "CollectionParameters" : {
                "save_interval": "500"
```

```
            }
        }
    ]
}
```

This will make the training job save the tensor collection, `gradients`, every `save_interval` of 500 steps. To find available `CollectionName` values, see Debugger Built-in Collections in the *SMDebug client library documentation*. To find available `CollectionParameters` parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the *SageMaker Python SDK documentation*.

To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in `VanishingGradient` rule on the saved `gradients` collection.

```
"DebugRuleConfigurations": [
    {
        "RuleConfigurationName": "VanishingGradient",
        "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "VanishingGradient",
            "threshold": "20.0"
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the `VanishingGradient` rule on the collection of `gradients` tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules. To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules.

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3,
 \"MetricsRegex\": \".*\" }",
        "DetailedProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu,
 total_time
        "PythonProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3,
 \"ProfilerName\": \"cProfile\", \"cProfileTimer\": \"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

Target Time Duration

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
 \"DurationInSeconds\": 10, \"MetricsRegex\": \".*\" }",
        "DetailedProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
 \"DurationInSeconds\": 10 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu,
 total_time
        "PythonProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
 \"DurationInSeconds\": 10, \"ProfilerName\": \"cProfile\", \"cProfileTimer\":
 \"total_time\" }",
```

```
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the `ProfilerReport` rule.

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport",
        "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "CPUBottleneck_cpu_threshold": "90",
            "IOBottleneck_threshold": "90"
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules. To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules.

Update Debugger Profiling Configuration Using the `UpdateTrainingJob` API Operation

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the `TrainingJobName` parameter.

```
{
    "ProfilerConfig": {
        "DisableProfiler": boolean,
        "ProfilingIntervalInMilliseconds": number,
        "ProfilingParameters": {
            "string" : "string"
        }
    },
    "ProfilerRuleConfigurations": [
        {
```

```
            "RuleConfigurationName": "string",
            "RuleEvaluatorImage": "string",
            "RuleParameters": {
                "string" : "string"
            }
        }
    ],
    "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}
```

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects in the CreateTrainingJob API operation. The following code sample shows how to configure a custom `ImproperActivation` rule written with the *smdebug* library using this SageMaker API operation. This example assumes that you've written the custom rule in *custom_rules.py* file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators. You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "relu_activations",
            "CollectionParameters": {
                "include_regex": "relu",
                "save_interval": "500",
                "end_step": "5000"
            }
        }
    ]
},
"DebugRulesConfigurations": [
    {
        "RuleConfigurationName": "improper_activation_job",
        "RuleEvaluatorImage": "552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rule-evaluator:latest",
        "InstanceType": "ml.c4.xlarge",
        "VolumeSizeInGB": 400,
        "RuleParameters": {
```

```
            "source_s3_uri": "s3://bucket/custom_rules.py",
            "rule_to_invoke": "ImproperActivation",
            "collection_names": "relu_activations"
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules. To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules.

AWS Boto3

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in `us-west-2`, assuming that a training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

> **Note**
>
> Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules.

```
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()
```

```
# Upload a training script to a default Amazon S3 bucket of the current SageMaker
 session
source = 'source.tar.gz'
project = 'debugger-boto3-test'

tar = tarfile.open(source, 'w:gz')
tar.add ('entry_point/train.py') # Specify the directory and name of your training
 script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-
%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training scrip file location and
 name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        # Specify a training Docker container image URI (Deep Learning Container or
 your own training container) to TrainingImage.
        'TrainingImage': '763104351884.dkr.ecr.us-west-2.amazonaws.com/tensorflow-
training:2.4.1-gpu-py37-cu110-ubuntu18.04',

            'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for
 profiling outputs
        }
    },
    ProfilerRuleConfigurations=[
        {
            'RuleConfigurationName': 'ProfilerReport',
            'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest',
            'RuleParameters': {'rule_to_invoke': 'ProfilerReport'}
        }
    ]
)
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in `VanishingGradient` rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'gradients',
            'CollectionParameters' : {
                'train.save_interval': '500',
                'eval.save_interval': '50'
            }
        }
    ]
}
```

This will make the training job save a tensor collection, `gradients`, every `save_interval` of 500 steps. To find available `CollectionName` values, see Debugger Built-in Collections in the *SMDebug client library documentation*. To find available `CollectionParameters` parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the *SageMaker Python SDK documentation*.

To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in `VanishingGradient` rule on the saved `gradients` collection.

```
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
```

```
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the `VanishingGradient` rule on the collection of `gradients` tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules. To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules.

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', #
 Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        }',
        'PythonProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time"  # Include only when using cprofile.
 Available options: cpu, off_cpu, total_time
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
 outputs
```

```
    }
}
```

Target Time Duration

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', #
 Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10
        }',
        'PythonProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time"  # Include only when using cprofile.
 Available options: cpu, off_cpu, total_time
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
 outputs
    }
}
```

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the `ProfilerReport` rule.

```
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest',
```

```
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules. To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules.

Update Debugger Profiling Configuration Using the `UpdateTrainingJob` API Operation

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the AWS Boto3 SageMaker client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the `TrainingJobName` parameter.

```
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string' : 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string' : 'string'
        }
    }
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'
```

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects using the AWS Boto3 SageMaker client's `create_training_job()` function. The following code sample shows how to configure a

custom `ImproperActivation` rule written with the *smdebug* library using this SageMaker API operation. This example assumes that you've written the custom rule in *custom_rules.py* file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators. You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
                'include_regex': 'relu',
                'save_interval': '500',
                'end_step': '5000'
            }
        }
    ]
},
DebugRulesConfigurations=[
    {
        'RuleConfigurationName': 'improper_activation_job',
        'RuleEvaluatorImage': '552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-
debugger-rule-evaluator:latest',
        'InstanceType': 'ml.c4.xlarge',
        'VolumeSizeInGB': 400,
        'RuleParameters': {
           'source_s3_uri': 's3://bucket/custom_rules.py',
           'rule_to_invoke': 'ImproperActivation',
           'collection_names': 'relu_activations'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules. To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules.

Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

Topics

Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers.

Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see Amazon SageMaker Debugger UI in Amazon SageMaker Studio Classic Experiments.

Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job.

You can find more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger interactive report.

Capture Data from Your Training Job and Save Data to Amazon S3

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure SageMaker Debugger to Save Tensors.

Analyze the Data with a Fleet of Debugger Built-in Rules

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules. If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis.

Take Actions Based on the Built-in Rule Status

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an `"IssuesFound"` evaluation status, CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda.

Dive Deep into the Data Using the SMDebug Client Library

You can use the SMDebug tools to access and analyze training data collected by Debugger. The `TrainingJob` and `create_trial` classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework

metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see Analyze data using the Debugger Python client library.

Monitor and Analyze Training Job Metrics

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the *Amazon CloudWatch API Reference*.

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors).

SageMaker Debugger also provides visualizations through Studio Classic and its profiling report. Unlike CloudWatch metrics, which accumulates resource utilization rates of CPU and GPU cores and averages those out across multiple instances, Debugger tracks the utilization rate of each core. This enables you to identify unbalanced usage of hardware resources as you scale up to larger compute clusters. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

Monitoring System Utilization and Detect Bottlenecks

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules and then Configure settings for basic profiling of system resource utilization.

For a full list of available built-in rules for monitoring, see Debugger built-in rules for profiling hardware system resource utilization (system metrics).

Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules and then Configure for framework profiling.

For a complete list of available built-in rules for profiling, see Debugger built-in rules for profiling framework metrics.

Debugging Model Output Tensors

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.

To learn how to configure Debugger for debugging output tensors, see Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK and then Configure SageMaker Debugger to Save Tensors.

For a full list of available built-in rules for debugging, see Debugger built-in rules for debugging model training data (output tensors).

Amazon SageMaker Debugger Advanced Topics and Reference Documentation

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

Topics

- Amazon SageMaker Debugger API Operations
- Use Debugger Docker Images for Built-in or Custom Rules
- Amazon SageMaker Debugger Exceptions
- Considerations for Amazon SageMaker Debugger
- Amazon SageMaker Debugger Usage Statistics

Amazon SageMaker Debugger API Operations

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source `sagemaker-debugger` Python SDK that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the `SMDebug` Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- `CreateTrainingJob` and `UpdateTrainingJob` use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - `CollectionConfiguration`
  - `DebugHookConfig`
  - `DebugRuleConfiguration`

- `TensorBoardOutputConfig`
- `ProfilerConfig`
- `ProfilerRuleConfiguration`

- `DescribeTrainingJob` provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `DebugRuleEvaluationStatus`
  - `ProfilerConfig`
  - `ProfilerRuleConfiguration`
  - `ProfilerRuleEvaluationStatus`

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see Process data.

Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the `ConfigureTrainingJob`API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the `CreateTrainingJob` API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

Topics

Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

ECR Repository Name: sagemaker-debugger-rules

Tag: latest

Example of a full registry URL:

`904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest`

Account IDs for Built-in Rules Container Images by AWS Region

Region	account_id
af-south-1	314341159256
ap-east-1	199566480951
ap-northeast-1	430734990657
ap-northeast-2	578805364391
ap-south-1	904829902805
ap-southeast-1	972752614525
ap-southeast-2	184798709955

Amazon SageMaker Debugger Exceptions

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the smdebug.exceptions module. You can import them as follows:

```
from smdebug.exceptions import *
```

The following exceptions are available:

- `TensorUnavailableForStep` – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.
- `TensorUnavailable` – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.
- `StepUnavailable` – The step was not saved and Debugger has no data from the step.
- `StepNotYetAvailable` – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
- `NoMoreData` – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
- `IndexReaderException` – The index reader is not valid.
- `InvalidWorker` – A worker was invoked that was not valid.

- `RuleEvaluationConditionMet` – Evaluation of the rule at the step resulted in the condition being met.
- `InsufficientInformationForRuleInvocation` – Insufficient information was provided to invoke the rule.

Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

  Scope of validity of using Debugger for training jobs with Horovod

Deep Learning Framework	Apache MXNet	TensorFlow 1.x	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Monitoring system bottlenecks	Yes	Yes	Yes	Yes	Yes
Profiling framework operations	No	No	No	Yes	Yes
Debugging model output tensors	Yes	Yes	Yes	Yes	Yes

- **SageMaker distributed data parallel**

Scope of validity of using Debugger for training jobs with SageMaker distributed data parallel

Deep Learning Framework	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Monitoring system bottlenecks	Yes	Yes	Yes
Profiling framework operations	No*	No**	Yes
Debugging model output tensors	Yes	Yes	Yes

* Debugger does not support framework profiling for TensorFlow 2.x.

** SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.
- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing
 Enabled
```

  To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see Using SageMaker distributed data parallel with Amazon SageMaker Debugger and checkpoints and Saving Checkpoints.
- **Parameter Server** – Debugger does not support parameter server-based distributed training.
- Profiling distributed training framework operations, such as the `AllReduced` operation of SageMaker distributed data parallel and Horovod operations, is not available.

Considerations for Monitoring System Bottlenecks and Profiling Framework Operations

- For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in `"/"`. For example:

```
FrameworkProfile(local_path="/opt/ml/output/profiler/")
```

- For AWS TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.
- For AWS TensorFlow, a `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.
- Python profiling and detailed profiling are only supported for Keras API.
- To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:
  - For TensorFlow

```
image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-
training:2.3.1-gpu-py37-cu110-ubuntu18.04"
```

  - For PyTorch

```
image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-
gpu-py36-cu110-ubuntu18.04"
```

Considerations for Debugging Model Output Tensors

- Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.
  - Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.
  - Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLu activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```
import mxnet as mx
from mxnet.gluon import HybridBlock, nn

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))

model = Model()
model.initialize(ctx=mx.cpu(0))
model.hybridize()
model(mx.nd.zeros((10, 10), ctx=mx.cpu(0)))
```

Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

Debugger Profiling Report Usage

For all SageMaker training jobs, Amazon SageMaker Debugger runs the ProfilerReport rule and autogenerates a SageMaker Debugger profiling report. The `ProfilerReport` rule provides a Jupyter notebook file (`profiler-report.ipynb`) that generates a corresponding HTML file (`profiler-report.html`).

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final `profiler-report.html` file.

Debugger only collects information about whether a user opens the final HTML report. It **DOES NOT** collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using either of the following options.

(Recommended) Option 1: Opt Out before Running a Training Job

To opt out, you need to add the following Debugger `ProfilerReport` rule configuration to your training job request.

SageMaker Python SDK

```
estimator=sagemaker.estimator.Estimator(
    ...

    rules=ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport()
        rule_parameters={"opt_out_telemetry": "True"}
    )
)
```

AWS CLI

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport-1234567890",
        "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "opt_out_telemetry": "True"
        }
    }
]
```

AWS SDK for Python (Boto3)

```
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport-1234567890',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/
sagemaker-debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'opt_out_telemetry': 'True'
        }
    }
```

```
]
```

Option 2: Opt Out after a Training Job Has Completed

To opt out after training has completed, you need to modify the `profiler-report.ipynb` file.

> **Note**
>
> HTML reports autogenerated without **Option 1** already added to your training job request still report the usage statistics even after you opt out using **Option 2**.

1. Follow the instructions on downloading the Debugger profiling report files in the Download the SageMaker Debugger profiling report page.
2. In the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.ipynb`.
3. Add **`opt_out=True`** to the `setup_profiler_report()` function in the fifth code cell as shown in the following example code:

```
setup_profiler_report(processing_job_arn, opt_out=True)
```

4. Run the code cell to finish opting out.

Access a training container through AWS Systems Manager for remote debugging

You can securely connect to SageMaker training containers through AWS Systems Manager (SSM). This gives you a shell-level access to debug training jobs that are running within the container. You can also log commands and responses that are streamed to Amazon CloudWatch. If you use your own Amazon Virtual Private Cloud (VPC) to train a model, you can use AWS PrivateLink to set up a VPC endpoint for SSM and connect to containers privately through SSM.

You can connect to SageMaker Framework Containers or connect to your own training container set up with the SageMaker Training environment.

Set up IAM permissions

To enable SSM in your SageMaker training container, you need to set up an IAM role for the container. For you or users in your AWS account to access the training containers through SSM, you need to set up IAM users with permissions to use SSM.

IAM role

For a SageMaker training container to start with the SSM agent, provide an IAM role with SSM permissions.

To enable remote debugging for your training job, SageMaker needs to start the SSM agent in the training container when the training job starts. To allow the SSM agent to communicate with the SSM service, add the following policy to the IAM role that you use to run your training job.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": "*"
        }
    ]
 }
```

IAM user

Add the following policy to provide an IAM user with SSM session permissions to connect to an SSM target. In this case, the SSM target is a SageMaker training container.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "ssm:StartSession",
                "ssm:TerminateSession"
            ],
            "Resource": "*"
        }
    ]
}
```

You can restrict IAM users to connect only to containers for specific training jobs by adding the `Condition` key, as shown in the following policy sample.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/aws:ssmmessages:target-id": [
                        "sagemaker-training-job:*"
                    ]
                }
            }
        }
    ]
}
```

You can also explicitly use the `sagemaker:EnableRemoteDebug` condition key to restrict remote debugging. The following is an example policy for IAM users to restrict remote debugging.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyRemoteDebugInTrainingJob",
```

```
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:UpdateTrainingJob"
            ],
            "Resource": "*",
            "Condition": {
                "BoolIfExists": {
                    "sagemaker:EnableRemoteDebug": false
                }
            }
        }
    ]
}
```

For more information, see Condition keys for Amazon SageMaker in the *AWS Service Authorization Reference*.

How to enable remote debugging for a SageMaker training job

In this section, learn how to enable remote debugging when starting or updating a training job in Amazon SageMaker.

SageMaker Python SDK

Using the estimator class in the SageMaker Python SDK, you can turn remote debugging on or off using the `enable_remote_debug` parameter or the `enable_remote_debug()` and `disable_remote_debug()` methods.

To enable remote debugging when you create a training job

To enable remote debugging when you create a new training job, set the `enable_remote_debug` parameter to `True`. The default value is `False`, so if you don't set this parameter at all, or you explicitly set it to `False`, remote debugging functionality is disabled.

```
import sagemaker

session = sagemaker.Session()

estimator = sagemaker.estimator.Estimator(
    ...,
    sagemaker_session=session,
```

```
    image_uri="<your_image_uri>", #must be owned by your organization or Amazon
 DLCs
    role=role,
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=output_path,
    max_run=1800,
    enable_remote_debug=True
)
```

To enable remote debugging by updating a training job

Using the following estimator class methods, you can enable or disable remote debugging while a training job is running when the `SecondaryStatus` of the job is `Downloading` or `Training`.

```
# Enable RemoteDebug
estimator.enable_remote_debug()

# Disable RemoteDebug
estimator.disable_remote_debug()
```

AWS SDK for Python (Boto3)

To enable remote debugging when you create a training job

To enable remote debugging when you create a new training job, set the value for the `EnableRemoteDebug` key to `True` in the `RemoteDebugConfig` parameter.

```
import boto3

sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    ...,
    TrainingJobName=job_name,
    AlgorithmSpecification={
        // Specify a training Docker container image URI
        // (Deep Learning Container or your own training container) to
 TrainingImage.
        "TrainingImage": "<your_image_uri>",
```

```
        "TrainingInputMode": "File"
    },
    RoleArn=iam_role_arn,
    OutputDataConfig=output_path,
    ResourceConfig={
        "InstanceType": "ml.m5.xlarge",
        "InstanceCount": 1,
        "VolumeSizeInGB": 30
    },
    StoppingCondition={
        "MaxRuntimeInSeconds": 86400
    },
    RemoteDebugConfig={
        "EnableRemoteDebug": True
    }
)
```

To enable remote debugging by updating a training job

Using the `update_traing_job` API, you can enable or disable remote debugging while a training job is running when the `SecondaryStatus` of the job is `Downloading` or `Training`.

```
# Update a training job
sm.update_training_job(
    TrainingJobName=job_name,
    RemoteDebugConfig={
        "EnableRemoteDebug": True     # True | False
    }
)
```

AWS Command Line Interface (CLI)

To enable remote debugging when you create a training job

Prepare a `CreateTrainingJob` request file in JSON format, as follows.

```
// train-with-remote-debug.json
{
    "TrainingJobName": job_name,
    "RoleArn": iam_role_arn,
    "AlgorithmSpecification": {
        // Specify a training Docker container image URI (Deep Learning Container or
 your own training container) to TrainingImage.
```

```
        "TrainingImage": "<your_image_uri>",
        "TrainingInputMode": "File"
    },
    "OutputDataConfig": {
        "S3OutputPath": output_path
    },
    "ResourceConfig": {
        "InstanceType": "ml.m5.xlarge",
        "InstanceCount": 1,
        "VolumeSizeInGB": 30
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 86400
    },
    "RemoteDebugConfig": {
        "EnableRemoteDebug": True
    }
}
```

After saving the JSON file, run the following command in the terminal where you submit the training job. The following example command assumes that the JSON file is named `train-with-remote-debug.json`. If you run it from a Jupyter notebook, add an exclamation point (`!`) to the beginning of the line.

```
aws sagemaker create-training-job \
    --cli-input-json file://train-with-remote-debug.json
```

To enable remote debugging by updating a training job

Prepare an `UpdateTrainingJob` request file in JSON format, as follows.

```
// update-training-job-with-remote-debug-config.json
{
    "TrainingJobName": job_name,
    "RemoteDebugConfig": {
        "EnableRemoteDebug": True
    }
}
```

After saving the JSON file, run the following command in the terminal where you submit the training job. The following example command assumes that the JSON file is named `train-`

`with-remote-debug.json`. If you run it from a Jupyter notebook, add an exclamation point (`!`) to the beginning of the line.

```
aws sagemaker update-training-job \
    --cli-input-json file://update-training-job-with-remote-debug-config.json
```

Access your training container

You can access a training container when the `SecondaryStatus` of the corresponding training job is `Training`. The following code examples demonstrate how to check the status of your training job using the `DescribeTrainingJob` API, how to check the training job logs in CloudWatch, and how to log in to the training container.

To check the status of a training job

SageMaker Python SDK

To check the `SecondaryStatus` of a training job, run the following SageMaker Python SDK code.

```
import sagemaker

session = sagemaker.Session()

# Describe the job status
training_job_info = session.describe_training_job(job_name)
print(training_job_info)
```

AWS SDK for Python (Boto3)

To check the `SecondaryStatus` of a training job, run the following SDK for Python (Boto3) code.

```
import boto3

session = boto3.session.Session()
region = session.region_name
sm = boto3.Session(region_name=region).client("sagemaker")

# Describe the job status
```

```
sm.describe_training_job(TrainingJobName=job_name)
```

AWS Command Line Interface (CLI)

To check the `SecondaryStatus` of a training job, run the following AWS CLI command for SageMaker.

```
aws sagemaker describe-training-job \
    --training-job-name job_name
```

To find the host name of a training container

To connect to the training container through SSM, use this format for the target ID: `sagemaker-training-job:<training-job-name>_algo-<n>`, where `algo-<n>` is the name of the container host. If your job is running on a single instance, the host is always `algo-1`. If you run a distributed training job on multiple instances, SageMaker creates an equal number of hosts and log streams. For example, if you use 4 instances, SageMaker creates `algo-1`, `algo-2`, `algo-3`, and `algo-4`. You must determine which log stream you want to debug, and its host number. To access log streams that are associated with a training job, do the following.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Training**, then choose **Training jobs**.
3. From the **Training jobs** list, choose the training job that you want to debug. The training job details page opens.
4. In the **Monitor** section, choose **View logs**. The related training job log stream list opens in the CloudWatch console.
5. Log stream names appear in `<training-job-name>/algo-<n>-<time-stamp>` format, with `algo-<n>` representing the host name.

To learn more about how SageMaker manages configuration information for multi-instance distributed training, see Distributed Training Configuration.

To access the training container

Use the following command in terminal to start the SSM session (`aws ssm start-session`) and connect to the training container.

```
aws ssm start-session --target sagemaker-training-job:<training-job-name>_algo-<n>
```

For example, if the training job name is `training-job-test-remote-debug` and the host name is `algo-1`, the target ID becomes `sagemaker-training-job:training-job-test-remote-debug_algo-1`. If the output of this command is similar to `Starting session with SessionId:xxxxx`, the connection is successful.

SSM access with AWS PrivateLink

If your training containers run within a Amazon Virtual Private Cloud that is not connected to the public internet, you can use AWS PrivateLink to enable SSM. AWS PrivateLink restricts all network traffic between your endpoint instances, SSM, and Amazon EC2 to the Amazon network. For more information on how to setup SSM access with AWS PrivateLink, see Set up an Amazon VPC endpoint for Session Manager.

Log SSM session commands and results

After following the instructions at Create a Session Manager preferences document (command line), you can create SSM documents that define your preferences for SSM sessions. You can use SSM documents to configure session options, including data encryption, session duration, and logging. For example, you can specify whether to store session log data in an Amazon Simple Storage Service (Amazon S3) bucket or in an Amazon CloudWatch Logs group. You can create documents that define general preferences for all sessions for an AWS account and AWS Region, or documents that define preferences for individual sessions.

Troubleshooting issues by checking error logs from SSM

Amazon SageMaker uploads errors from the SSM agent to your CloudWatch Logs in the `/aws/sagemaker/TrainingJobs` log group. SSM agent log streams are named in this format: `<job-name>/algo-<n>-<timestamp>/ssm`. For example, if you create a two-node training job named `training-job-test-remote-debug`, the training job log `training-job-test-remote-debug/algo-<n>-<timestamp>` and multiple SSM agent error logs `training-job-test-remote-debug/algo-<n>-<timestamp>/ssm` are uploaded to your CloudWatch Logs. In this example, you can review the `*/ssm` log streams to troubleshoot SSM issues.

```
training-job-test-remote-debug/algo-1-1680535238
training-job-test-remote-debug/algo-2-1680535238
training-job-test-remote-debug/algo-1-1680535238/ssm
```

```
training-job-test-remote-debug/algo-2-1680535238/ssm
```

Considerations

Consider the following when using SageMaker remote debugging.

- Remote debugging isn't supported for SageMaker algorithm containers or containers from SageMaker on AWS Marketplace.
- You can't start an SSM session for containers that have network isolation enabled because the isolation prevents outbound network calls.

Release notes for debugging capabilities of Amazon SageMaker

See the following release notes to track the latest updates for debugging capabilities of Amazon SageMaker.

December 21, 2023

New features

Released a remote debugging functionality, a new debugging capability of SageMaker that gives you a shell-level access to training containers. With this release, you can debug training jobs by logging into the job containers running on SageMaker ML instances. To learn more, see the section called “Access a training container through SSM for remote debugging”.

September 7, 2023

New features

Added a new utility module `sagemaker.interactive_apps.tensorboard.TensorBoardApp` that provides a function called `get_app_url()`. The `get_app_url()` function generates unsigned or presigned URLs to open the TensorBoard application in any environment in SageMaker or Amazon EC2. This is to provide a unified experience for both Studio Classic and non-Studio Classic users. For the Studio Classic environment, you can open TensorBoard by running the `get_app_url()` function as it is, or you can also specify a job name to start tracking as the TensorBoard application opens. For non-Studio Classic environments, you can open TensorBoard by providing your domain information to the utility function. With this functionality, regardless of where or how you run training code and launch training jobs, you can directly access TensorBoard

by running the `get_app_url` function in your Jupyter notebook or terminal. This functionality is available in the SageMaker Python SDK v2.184.0 and later. For more information, see the section called "How to access TensorBoard on SageMaker".

April 4, 2023

New features

Released SageMaker with TensorBoard, a capability that hosts TensorBoard on SageMaker. TensorBoard is available as an application through SageMaker domain, and the SageMaker Training platform supports TensorBoard output data collection to S3 and loading them automatically to the hosted TensorBoard on SageMaker. With this capability, you can run training jobs set up with TensorBoard summary writers in SageMaker, save the TensorBoard output files in Amazon S3, open the TensorBoard application directly from the SageMaker console, and load the output files using SageMaker Data Manager plugin implemented to the hosted TensorBoard interface. You don't need to install TensorBoard manually and host locally on the SageMaker IDEs or local machine. To learn more, see the section called "Use TensorBoard".

March 16, 2023

Deprecation notes

SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

With the deprecation, SageMaker Debugger also discontinues support for the following three `ProfilerRules` for framework profiling.

- MaxInitializationTime
- OverallFrameworkMetrics
- StepOutlier

February 21, 2023

Other changes

- The XGBoost report tab has been removed from the SageMaker Debugger's profiler dashboard. You can still access the XGBoost report by downloading it as a Jupyter notebook or a HTML file. For more information, see SageMaker Debugger XGBoost Training Report.
- Starting from this release, the built-in profiler rules are not activated by default. To use the SageMaker Debugger profiler rules to detect certain computational problems, you need to add the rules when you configure a SageMaker training job launcher.

December 1, 2020

Amazon SageMaker Debugger launched deep profiling features at re:Invent 2020.

December 3, 2019

Amazon SageMaker Debugger initially launched at re:Invent 2019.

Profile and optimize computational performance

When training state-of-the-art deep learning models that rapidly grow in size, scaling the training job of such models to a large GPU cluster and identifying computational performance issues from billions and trillions of operations and communications in every iteration of the gradient descent process become a challenge.

SageMaker provides profiling tools to visualize and diagnose such complex computation issues arising from running training jobs on AWS cloud computing resources. There are two profiling options that SageMaker offers: Amazon SageMaker Profiler and a resource utilzation monitor in Amazon SageMaker Studio Classic. See the following introductions of the two functionalities to gain quick insights and learn which one to use depending on your needs.

Amazon SageMaker Profiler

Amazon SageMaker Profiler is a profiling capability of SageMaker with which you can deep dive into compute resources provisioned while training deep learning models, and gain visibility into operation-level details. SageMaker Profiler provides Python modules for adding annotations throughout PyTorch or TensorFlow training scripts and activating SageMaker Profiler. You can access the modules through the SageMaker Python SDK and AWS Deep Learning Containers.

With SageMaker Profiler, you can track all activities on CPUs and GPUs, such as CPU and GPU utilizations, kernel runs on GPUs, kernel launches on CPUs, sync operations, memory operations across CPUs and GPUs, latencies between kernel launches and corresponding runs, and data transfer between CPUs and GPUs.

SageMaker Profiler also offers a user interface (UI) that visualizes the *profile*, a statistical summary of profiled events, and the timeline of a training job for tracking and understanding the time relationship of the events between GPUs and CPUs.

To learn more about SageMaker Profiler, see the section called “Use SageMaker Profiler”.

Monitoring AWS compute resources in Amazon SageMaker Studio Classic

SageMaker also provides a user interface in Studio Classic for monitoring resource utilization at high level, but with more granularity compared to the default utilization metrics collected from SageMaker to CloudWatch.

For any training job you run in SageMaker using the SageMaker Python SDK, SageMaker starts profiling basic resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, network, and I/O wait time. It collects these resource utilization metrics every 500 milliseconds.

Compared to Amazon CloudWatch metrics, which collect metrics at intervals of 1 second, the monitoring functionality of SageMaker provides finer granularity into the resource utilization metrics down to 100-millisecond (0.1 second) intervals, so you can dive deep into the metrics at the level of an operation or a step.

To access the dashboard for monitoring the resource utilization metrics of a training job, see the SageMaker Debugger UI in SageMaker Studio Experiments.

Topics

Use Amazon SageMaker Profiler to profile activities on AWS compute resources

Amazon SageMaker Profiler is currently in preview release and available at no cost in supported AWS Regions. The generally available version of Amazon SageMaker Profiler (if any) may include features and pricing that are different than those offered in preview.

Amazon SageMaker Profiler is a capability of Amazon SageMaker that provides a detailed view into the AWS compute resources provisioned during training deep learning models on SageMaker. It focuses on profiling the CPU and GPU usage, kernel runs on GPUs, kernel launches on CPUs, sync operations, memory operations across CPUs and GPUs, latencies between kernel launches and corresponding runs, and data transfer between CPUs and GPUs. SageMaker Profiler also offers a user interface (UI) that visualizes the *profile*, a statistical summary of profiled events, and the timeline of a training job for tracking and understanding the time relationship of the events between GPUs and CPUs.

Note

SageMaker Profiler supports PyTorch and TensorFlow and is available in AWS Deep Learning Containers for SageMaker. To learn more, see the section called "Supported framework images, AWS Regions, and instance types".

For data scientists

Training deep learning models on a large compute cluster often has computational optimization problems, such as bottlenecks, kernel launch latencies, memory limit, and low resource utilization.

To identify such computational performance issues, you need to profile deeper into the compute resources to understand which kernels introduce latencies and which operations cause bottlenecks. Data scientists can take the benefit from using the SageMaker Profiler UI for visualizing the detailed profile of training jobs. The UI provides a dashboard furnished with summary charts and a timeline interface to track every event on the compute resources. Data scientists can also add custom annotations to track certain parts of the training job using the SageMaker Profiler Python modules.

For administrators

Through the Profiler landing page in the SageMaker console or SageMaker domain, you can manage the Profiler application users if you are an administrator of an AWS account or SageMaker domain. Each domain user can access their own Profiler application given the granted permissions. As a SageMaker domain administrator and domain user, you can create and delete the Profiler application given the permission level you have.

Supported framework images, AWS Regions, and instance types

This feature supports the following machine learning frameworks and AWS Regions.

> **Note**
>
> To use this feature, make sure that you have at least version 2.180.0 of the SageMaker Python SDK installed.

SageMaker framework images pre-installed with SageMaker Profiler

SageMaker Profiler is pre-installed in the following AWS Deep Learning Containers for SageMaker.

PyTorch images

PyTorch versions	AWS DLC image URI
2.2.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.2.0-gpu-py310-cu121-ubuntu20.04-sagemaker
2.1.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.1.0-gpu-py310-cu121-ubuntu20.04-sagemaker
2.0.1	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.0.1-gpu-py310-cu118-ubuntu20.04-sagemaker *763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:2.0.1-gpu-py310-cu121-ubuntu20.04-sagemaker

PyTorch versions	AWS DLC image URI
1.13.1	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/pytorch-training:1.13.1-gpu-py39-cu117-ubuntu20.04-sagemaker

TensorFlow images

TensorFlow versions	AWS DLC image URI
2.13.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/tensorflow-training:2.13.0-gpu-py310-cu118-ubuntu20.04-sagemaker
2.12.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/tensorflow-training:2.12.0-gpu-py310-cu118-ubuntu20.04-sagemaker
2.11.0	*763104351884* .dkr.ecr.*<region>*.amazonaws.com/tensorflow-training:2.11.0-gpu-py39-cu112-ubuntu20.04-sagemaker

Important

Distribution and maintenance of the framework containers in the preceding tables are under the Framework Support Policy managed by the AWS Deep Learning Containers service. We highly recommend you to upgrade to the currently supported framework versions, if you are using prior framework versions that are no longer supported.

Note

If you want to use SageMaker Profiler for other framework images or your own Docker images, you can install SageMaker Profiler using the SageMaker Profiler Python package binary files provided in the following section.

SageMaker Profiler Python package binary files

If you want to configure your own Docker container, use SageMaker Profiler in other pre-built containers for PyTorch and TensorFlow, or install the SageMaker Profiler Python package locally, use one the following binary files. Depending on the Python and CUDA versions in your environment, choose one of the following.

PyTorch

- Python3.8, CUDA 11.3: https://smppy.s3.amazonaws.com/pytorch/cu113/smprof-0.3.334-cp38-cp38-linux_x86_64.whl
- Python3.9, CUDA 11.7: https://smppy.s3.amazonaws.com/pytorch/cu117/smprof-0.3.334-cp39-cp39-linux_x86_64.whl
- Python3.10, CUDA 11.8: https://smppy.s3.amazonaws.com/pytorch/cu118/smprof-0.3.334-cp310-cp310-linux_x86_64.whl
- Python3.10, CUDA 12.1: https://smppy.s3.amazonaws.com/pytorch/cu121/smprof-0.3.334-cp310-cp310-linux_x86_64.whl

TensorFlow

- Python3.9, CUDA 11.2: https://smppy.s3.amazonaws.com/tensorflow/cu112/smprof-0.3.334-cp39-cp39-linux_x86_64.whl
- Python3.10, CUDA 11.8: https://smppy.s3.amazonaws.com/tensorflow/cu118/smprof-0.3.334-cp310-cp310-linux_x86_64.whl

For more information about how to install SageMaker Profiler using the binary files, see the section called “(Optional) Install the SageMaker Profiler Python package”.

Supported AWS Regions

SageMaker Profiler is available in the following AWS Regions.

- US East (N. Virginia) (`us-east-1`)
- US East (Ohio) (`us-east-2`)
- US West (Oregon) (`us-west-2`)
- Europe (Frankfurt) (`eu-central-1`)
- Europe (Ireland) (`eu-west-1`)

Supported instance types

SageMaker Profiler supports profiling of training jobs on the following instance types.

CPU and GPU profiling

- `ml.g4dn.12xlarge`
- `ml.g5.24xlarge`
- `ml.g5.48xlarge`
- `ml.p3dn.24xlarge`
- `ml.p4de.24xlarge`
- `ml.p4d.24xlarge`
- `ml.p5.48xlarge`

GPU profiling only

- `ml.g5.2xlarge`
- `ml.g5.4xlarge`
- `ml.g5.8xlarge`
- `ml.g5.16.xlarge`

Prerequisites

The following list shows the prerequisites to start using SageMaker Profiler.

- A SageMaker domain set up with Amazon VPC in your AWS account.

  For instructions on setting up a domain, see Onboard to Amazon SageMaker domain using quick setup. You also need to add domain user profiles for individual users to access the Profiler UI application. For more information, see Add and remove SageMaker domain user profiles.
- The following list is the minimum set of permissions for using the Profiler UI application.
  - `sagemaker:CreateApp`
  - `sagemaker:DeleteApp`
  - `sagemaker:DescribeTrainingJob`
  - `sagemaker:Search`

- `s3:GetObject`
- `s3:ListBucket`

Prepare and run a training job with SageMaker Profiler

Setting up to running a training job with the SageMaker Profiler consists of two steps: adapting the training script and configuring the SageMaker training job launcher.

Topics

Step 1: Adapt your training script using the SageMaker Profiler Python modules

To start capturing kernel runs on GPUs while the training job is running, modify your training script using the SageMaker Profiler Python modules. Import the library and add the `start_profiling()` and `stop_profiling()` methods to define the beginning and the end of profiling. You can also use optional custom annotations to add markers in the training script to visualize hardware activities during particular operations in each step.

Note that the annotators extract operations from GPUs. For profiling operations in CPUs, you don't need to add any additional annotations. CPU profiling is also activated when you specify the profiling configuration, which you'll practice in the section called "Step 2: Create a SageMaker framework estimator and activate SageMaker Profiler".

> **Note**
>
> Profiling an entire training job is not the most efficient use of resources. We recommend profiling at most 300 steps of a training job.

> **Important**
>
> The release on December 14, 2023 involves a breaking change. The SageMaker Profiler Python package name is changed from `smppy` to `smprof`. This is effective in the SageMaker Framework Containers for TensorFlow v2.12 and later.

If you use one of the previous versions of the SageMaker Framework Containers such TensorFlow v2.11.0, the SageMaker Profiler Python package is still available as `smppy`. If you are uncertain about which version or the package name you should use, replace the import statement of the SageMaker Profiler package with the following code snippet.

```
try:
    import smprof
except ImportError:
    # backward-compatability for TF 2.11 and PT 1.13.1 images
    import smppy as smprof
```

Approach 1. Use the context manager `smprof.annotate` to annotate full functions

You can wrap full functions with the `smprof.annotate()` context manager. This wrapper is recommended if you want to profile by functions instead of code lines. The following example script shows how to implement the context manager to wrap the training loop and full functions in each iteration.

```
import smprof

SMProf = smprof.SMProfiler.instance()
config = smprof.Config()
config.profiler = {
    "EnableCuda": "1",
}
SMProf.configure(config)
SMProf.start_profiling()

for epoch in range(args.epochs):
    if world_size > 1:
        sampler.set_epoch(epoch)
    tstart = time.perf_counter()
    for i, data in enumerate(trainloader, 0):
        with smprof.annotate("step_"+str(i)):
            inputs, labels = data
            inputs = inputs.to("cuda", non_blocking=True)
            labels = labels.to("cuda", non_blocking=True)

            optimizer.zero_grad()
```

```
            with smprof.annotate("Forward"):
                outputs = net(inputs)
            with smprof.annotate("Loss"):
                loss = criterion(outputs, labels)
            with smprof.annotate("Backward"):
                loss.backward()
            with smprof.annotate("Optimizer"):
                optimizer.step()

SMProf.stop_profiling()
```

Approach 2. Use `smprof.annotation_begin()` and `smprof.annotation_end()` to annotate specific code line in functions

You can also define annotations to profile specific code lines. You can set the exact starting point and end point of profiling at the level of individual code lines, not by the functions. For example, in the following script, the `step_annotator` is defined at the beginning of each iteration and ends at the end of the iteration. Meanwhile, other detailed annotators for each operations are defined and wrap around the target operations throughout each iteration.

```
import smprof

SMProf = smprof.SMProfiler.instance()
config = smprof.Config()
config.profiler = {
    "EnableCuda": "1",
}
SMProf.configure(config)
SMProf.start_profiling()

for epoch in range(args.epochs):
    if world_size > 1:
        sampler.set_epoch(epoch)
    tstart = time.perf_counter()
    for i, data in enumerate(trainloader, 0):
        step_annotator = smprof.annotation_begin("step_" + str(i))

        inputs, labels = data
        inputs = inputs.to("cuda", non_blocking=True)
        labels = labels.to("cuda", non_blocking=True)
        optimizer.zero_grad()

        forward_annotator = smprof.annotation_begin("Forward")
```

```
        outputs = net(inputs)
        smprof.annotation_end(forward_annotator)

        loss_annotator = smprof.annotation_begin("Loss")
        loss = criterion(outputs, labels)
        smprof.annotation_end(loss_annotator)

        backward_annotator = smprof.annotation_begin("Backward")
        loss.backward()
        smprof.annotation_end(backward_annotator)

        optimizer_annotator = smprof.annotation_begin("Optimizer")
        optimizer.step()
        smprof.annotation_end(optimizer_annotator)

        smprof.annotation_end(step_annotator)

SMProf.stop_profiling()
```

After annotating and setting up the profiler initiation modules, save the script to submit using a SageMaker training job launcher in the following Step 2. The sample launcher assumes that the training script is named `train_with_profiler_demo.py`.

Step 2: Create a SageMaker framework estimator and activate SageMaker Profiler

The following procedure shows how to prepare a SageMaker framework estimator for training using the SageMaker Python SDK.

1. Set up a `profiler_config` object using the `ProfilerConfig` and `Profiler` modules as follows.

   ```
   from sagemaker import ProfilerConfig, Profiler
   profiler_config = ProfilerConfig(
       profile_params = Profiler(cpu_profiling_duration=3600)
   )
   ```

   The following is the description of the `Profiler` module and its argument.

   - `Profiler`: The module for activating SageMaker Profiler with the training job.
     - `cpu_profiling_duration` (int): Specify the time duration in seconds for profiling on CPUs. Default is 3600 seconds.

2. Create a SageMaker framework estimator with the `profiler_config` object created in the previous step. The following code shows an example of creating a PyTorch estimator. If you want to create a TensorFlow estimator, import `sagemaker.tensorflow.TensorFlow` instead, and specify one of the TensorFlow versions supported by SageMaker Profiler. For more information about supported frameworks and instance types, see the section called "SageMaker framework images pre-installed with SageMaker Profiler".

```
import sagemaker
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    framework_version="2.0.0",
    role=sagemaker.get_execution_role(),
    entry_point="train_with_profiler_demo.py", # your training job entry point
    source_dir=source_dir, # source directory for your training script
    output_path=output_path,
    base_job_name="sagemaker-profiler-demo",
    hyperparameters=hyperparameters, # if any
    instance_count=1, # Recommended to test with < 8
    instance_type=ml.p4d.24xlarge,
    profiler_config=profiler_config
)
```

3. Start the training job by running the `fit` method. With `wait=False`, you can silence the training job logs and let it run in the background.

```
estimator.fit(wait=False)
```

While running the training job or after the job has completed, you can go to the next topic at the section called "Open the SageMaker Profiler UI application" and start exploring and visualizing the saved profiles.

If you want to directly access the profile data saved in the Amazon S3 bucket, use the following script to retrieve the S3 URI.

```
import os
# This is an ad-hoc function to get the S3 URI
# to where the profile output data is saved
def get_detailed_profiler_output_uri(estimator):
    config_name = None
```

```
    for processing in estimator.profiler_rule_configs:
        params = processing.get("RuleParameters", dict())
        rule = config_name = params.get("rule_to_invoke", "")
        if rule == "DetailedProfilerProcessing":
            config_name = processing.get("RuleConfigurationName")
            break
    return os.path.join(
        estimator.output_path,
        estimator.latest_training_job.name,
        "rule-output",
        config_name,
    )

print(
    f"Profiler output S3 bucket: ",
    get_detailed_profiler_output_uri(estimator)
)
```

(Optional) Install the SageMaker Profiler Python package

To use SageMaker Profiler on PyTorch or TensorFlow framework images not listed in the section called "SageMaker framework images pre-installed with SageMaker Profiler", or on your own custom Docker container for training, you can install SageMaker Profiler by using one of the the section called "SageMaker Profiler Python package binary files".

Option 1: Install the SageMaker Profiler package while launching a training job

If you want to use SageMaker Profiler for training jobs using PyTorch or TensorFlow images not listed in the section called "SageMaker framework images pre-installed with SageMaker Profiler", create a `requirements.txt` file and locate it under the path you specify to the `source_dir` parameter of the SageMaker framework estimator in Step 2. For more information about setting up a `requirements.txt` file in general, see Using third-party libraries in the *SageMaker Python SDK documentation*. In the `requirements.txt` file, add one of the S3 bucket paths for the the section called "SageMaker Profiler Python package binary files".

```
# requirements.txt
https://smppy.s3.amazonaws.com/tensorflow/cu112/smprof-0.3.332-cp39-cp39-
linux_x86_64.whl
```

Option 2: Install the SageMaker Profiler package in your custom Docker containers

If you use a custom Docker container for training, add one of the the section called "SageMaker Profiler Python package binary files" to your Dockerfile.

```
# Install the smprof package version compatible with your CUDA version
RUN pip install https://smppy.s3.amazonaws.com/tensorflow/cu112/smprof-0.3.332-cp39-cp39-linux_x86_64.whl
```

For guidance on running a custom Docker container for training on SageMaker in general, see Adapting your own training container.

Open the SageMaker Profiler UI application

You can access the SageMaker Profiler UI application through the following options.

Topics

Option 1: Launch the SageMaker Profiler UI from the domain details page

If you have access to the SageMaker console, you can take this option.

Navigate to the domain details page

The following procedure shows how to navigate to the domain details page.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **domains**.
3. From the list of domains, select the domain in which you want to launch the SageMaker Profiler application.

Launch the SageMaker Profiler UI application

The following procedure shows how to launch the SageMaker Profiler application that is scoped to a user profile.

1. On the domain details page, choose the **User profiles** tab.

2. Identify the user profile for which you want to launch the SageMaker Profiler UI application.
3. Choose **Launch** for the selected user profile, and choose **Profiler**.

Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker console

The following procedure describes how to launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker console. If you have access to the SageMaker console, you can take this option.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose **Profiler**.
3. Under **Get started**, select the domain in which you want to launch the Studio Classic application. If your user profile only belongs to one domain, you do not see the option for selecting a domain.
4. Select the user profile for which you want to launch the SageMaker Profiler UI application. If there is no user profile in the domain, choose **Create user profile**. For more information about creating a new user profile, see Add and Remove User Profiles.
5. Choose **Open Profiler**.

Option 3: Use the application launcher function in the SageMaker Python SDK

If you are a SageMaker domain user and have access only to SageMaker Studio, you can access the SageMaker Profiler UI application through SageMaker Studio Classic by running the `sagemaker.interactive_apps.detail_profiler_app.DetailProfilerApp` function.

Note that SageMaker Studio Classic is the previous Studio UI experience before re:Invent 2023, and is migrated as an application into a newly designed Studio UI at re:Invent 2023. The SageMaker Profiler UI application is available at SageMaker domain level, and thus requires your domain ID and user profile name. Currently, the `DetailedProfilerApp` function only works within the SageMaker Studio Classic application; the function properly takes in the domain and user profile information from SageMaker Studio Classic.

For domain, domain users, and Studio created before re:Invent 2023, Studio Classic would be the default experience unless you have updated it following the instructions at Migrating from Amazon SageMaker Studio Classic. If this is your case, there's no further action needed, and you can directly launch the SageMaker Profiler UI application by running the `DetailProfilerApp` funciton.

If you created a new domain and Studio after re:Invent 2023, launch the Studio Classic application within the Studio UI and then run the `DetailProfilerApp` function to launch the SageMaker Profiler UI application.

Note that the `DetailedProfilerApp` function doesn't work in other SageMaker machine learning IDEs, such as the SageMaker Studio JupyterLab application, the SageMaker Studio Code Editor application, and SageMaker Notebook instances. If you run the `DetailedProfilerApp` function in those IDEs, it returns a URL to the Profiler landing page in the SageMaker console, instead of a direct link to open the Profiler UI application.

Explore the profile output data visualized in the SageMaker Profiler UI

This section walks through the SageMaker Profiler UI and provides tips for how to use and gain insights from it.

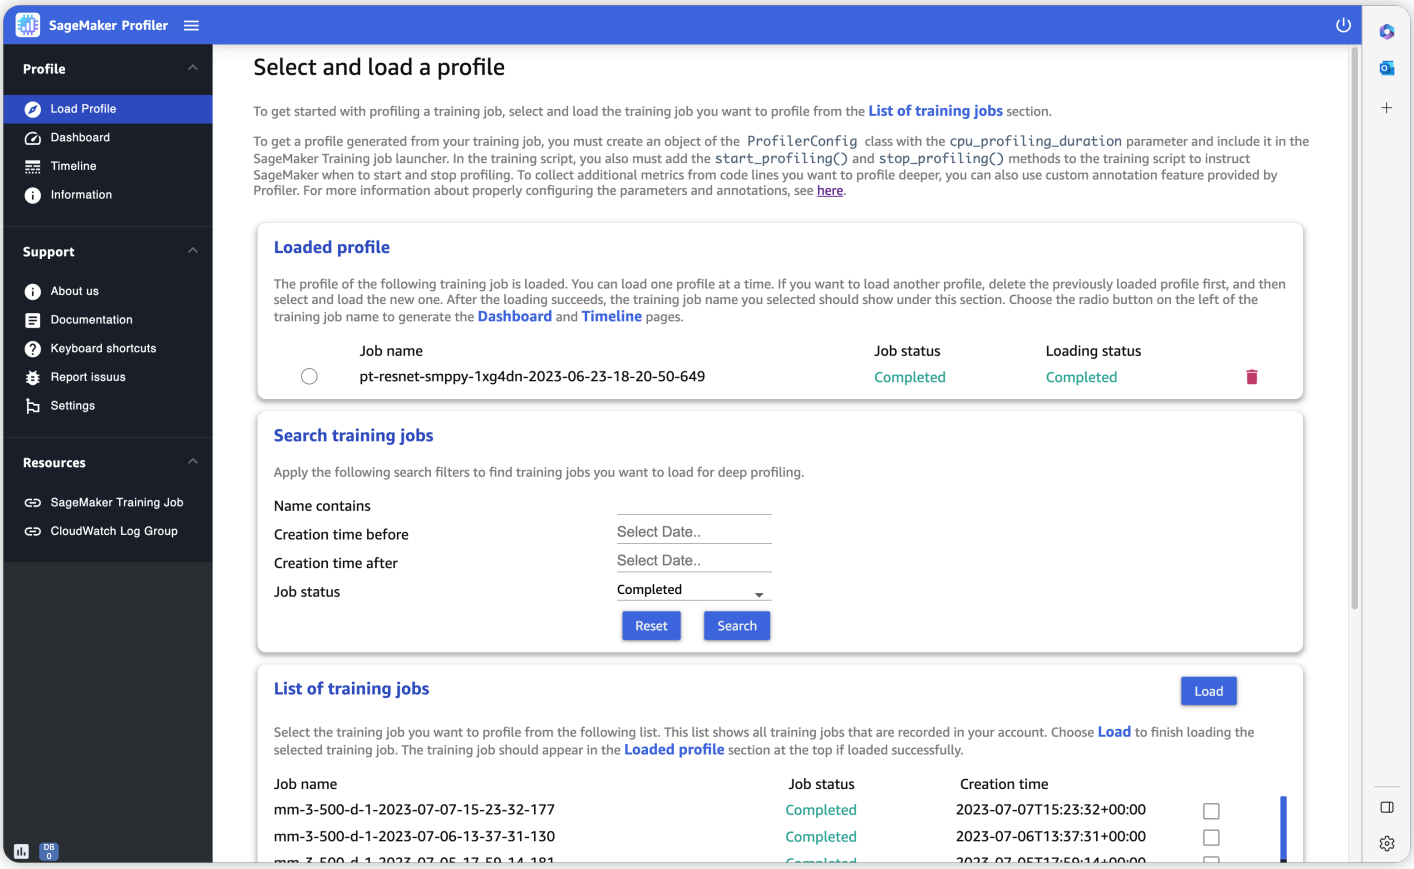
Load profile

When you open the SageMaker Profiler UI, the **Load profile** page opens up. To load and generate the **Dashboard** and **Timeline**, go through the following procedure.

To load the profile of a training job

1. From the **List of training jobs** section, use the check box to choose the training job for which you want to load the profile.
2. Choose **Load**. The job name should appear in the **Loaded profile** section at the top.
3. Choose the radio button on the left of the **Job name** to generate the **Dashboard** and **Timeline**. Note that when you choose the radio button, the UI automatically opens the **Dashboard**. Note also that if you generate the visualizations while the job status and loading status still appear to be in progress, the SageMaker Profiler UI generates **Dashboard** plots and a **Timeline** up to the most recent profile data collected from the ongoing training job or the partially loaded profile data.

> **Tip**
>
> You can load and visualize one profile at a time. To load another profile, you must first unload the previously loaded profile. To unload a profile, use the trash bin icon on the right end of the profile in the **Loaded profile** section.



Dashboard

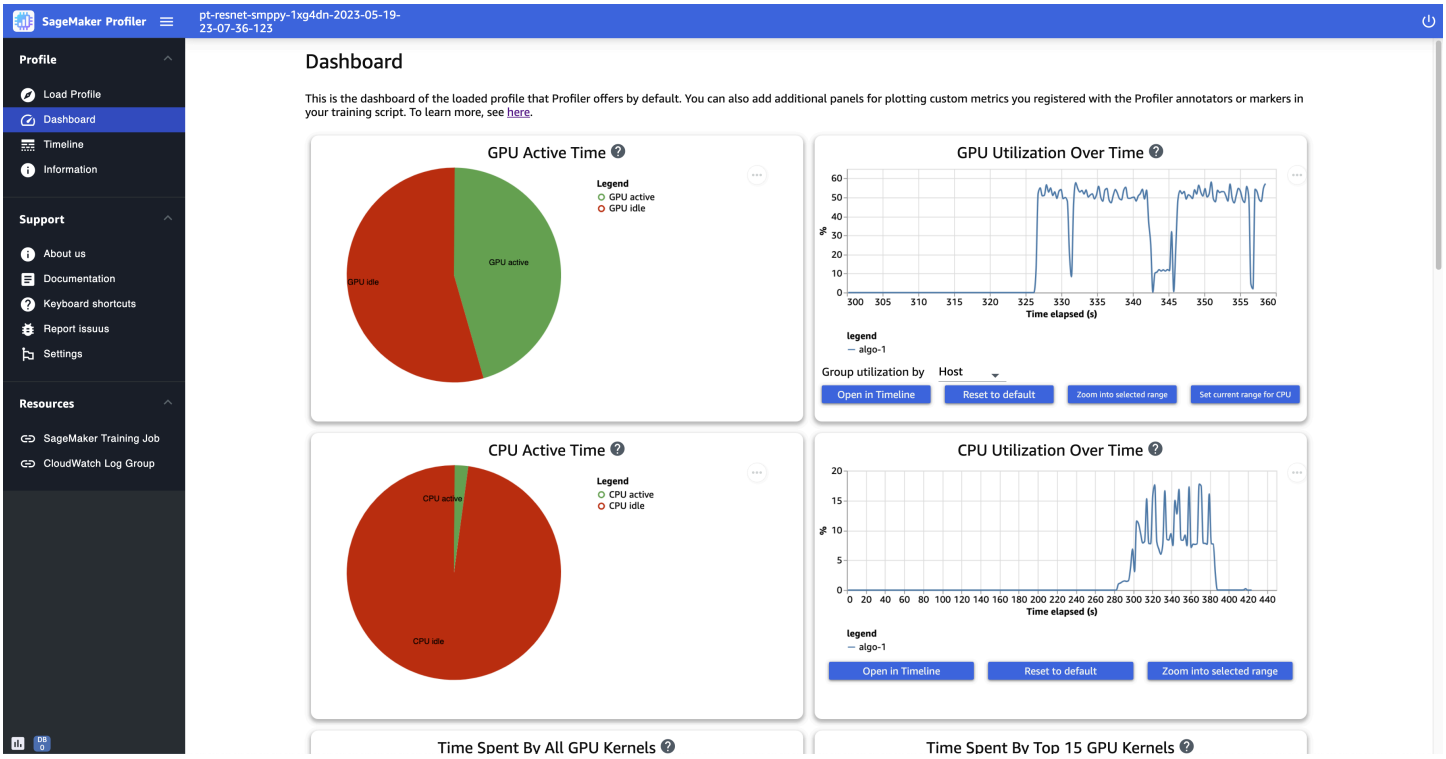
After you finish loading and selecting the training job, the UI opens the **Dashboard** page furnished with the following panels by default.

- **GPU active time** – This pie chart shows the percentage of GPU active time versus GPU idle time. You can check if your GPUs are more active than idle throughout the entire training job. GPU active time is based on the profile data points with a utilization rate greater than 0%, whereas GPU idle time is the profiled data points with 0% utilization.
- **GPU utilization over time** – This timeline graph shows the average GPU utilization rate over time per node, aggregating all of the nodes in a single chart. You can check if the GPUs have an unbalanced workload, under-utilization issues, bottlenecks, or idle issues during certain time intervals. To track the utilization rate at the individual GPU level and related kernel runs, use the the section called “Timeline interface”. Note that the GPU activity collection starts from where you added the profiler starter function `SMProf.start_profiling()` in your training script, and stops at `SMProf.stop_profiling()`.

- **CPU active time** – This pie chart shows the percentage of CPU active time versus CPU idle time. You can check if your CPUs are more active than idle throughout the entire training job. CPU active time is based on the profiled data points with a utilization rate greater than 0%, whereas CPU idle time is the profiled data points with 0% utilization.
- **CPU utilization over time** – This timeline graph shows the average CPU utilization rate over time per node, aggregating all of the nodes in a single chart. You can check if the CPUs are bottlenecked or underutilized during certain time intervals. To track the utilization rate of the CPUs aligned with the individual GPU utilization and kernel runs, use the the section called "Timeline interface". Note that the utilization metrics start from the start from the job initialization.
- **Time spent by all GPU kernels** – This pie chart shows all GPU kernels operated throughout the training job. It shows the top 15 GPU kernels by default as individual sectors and all other kernels in one sector. Hover over the sectors to see more detailed information. The value shows the total time of the GPU kernels operated in seconds, and the percentage is based on the entire time of the profile.
- **Time spent by top 15 GPU kernels** – This pie chart shows all GPU kernels operated throughout the training job. It shows the top 15 GPU kernels as individual sectors. Hover over the sectors to see more detailed information. The value shows the total time of the GPU kernels operated in seconds, and the percentage is based on the entire time of the profile.
- **Launch counts of all GPU kernels** – This pie chart shows the number of counts for every GPU kernel launched throughout the training job. It shows the top 15 GPU kernels as individual sectors and all other kernels in one sector. Hover over the sectors to see more detailed information. The value shows the total count of the launched GPU kernels, and the percentage is based on the entire count of all kernels.
- **Launch counts of top 15 GPU kernels** – This pie chart shows the number of counts of every GPU kernel launched throughout the training job. It shows the top 15 GPU kernels. Hover over the sectors to see more detailed information. The value shows the total count of the launched GPU kernels, and the percentage is based on the entire count of all kernels.
- **Step time distribution** – This histogram shows the distribution of step durations on GPUs. This plot is generated only after you add the step annotator in your training script.
- **Kernel precision distribution** – This pie chart shows the percentage of time spent on running kernels in different data types such as FP32, FP16, INT32, and INT8.
- **GPU activity distribution** – This pie chart shows the percentage of time spent on GPU activities, such as running kernels, memory (`memcpy` and `memset`), and synchronization (`sync`).

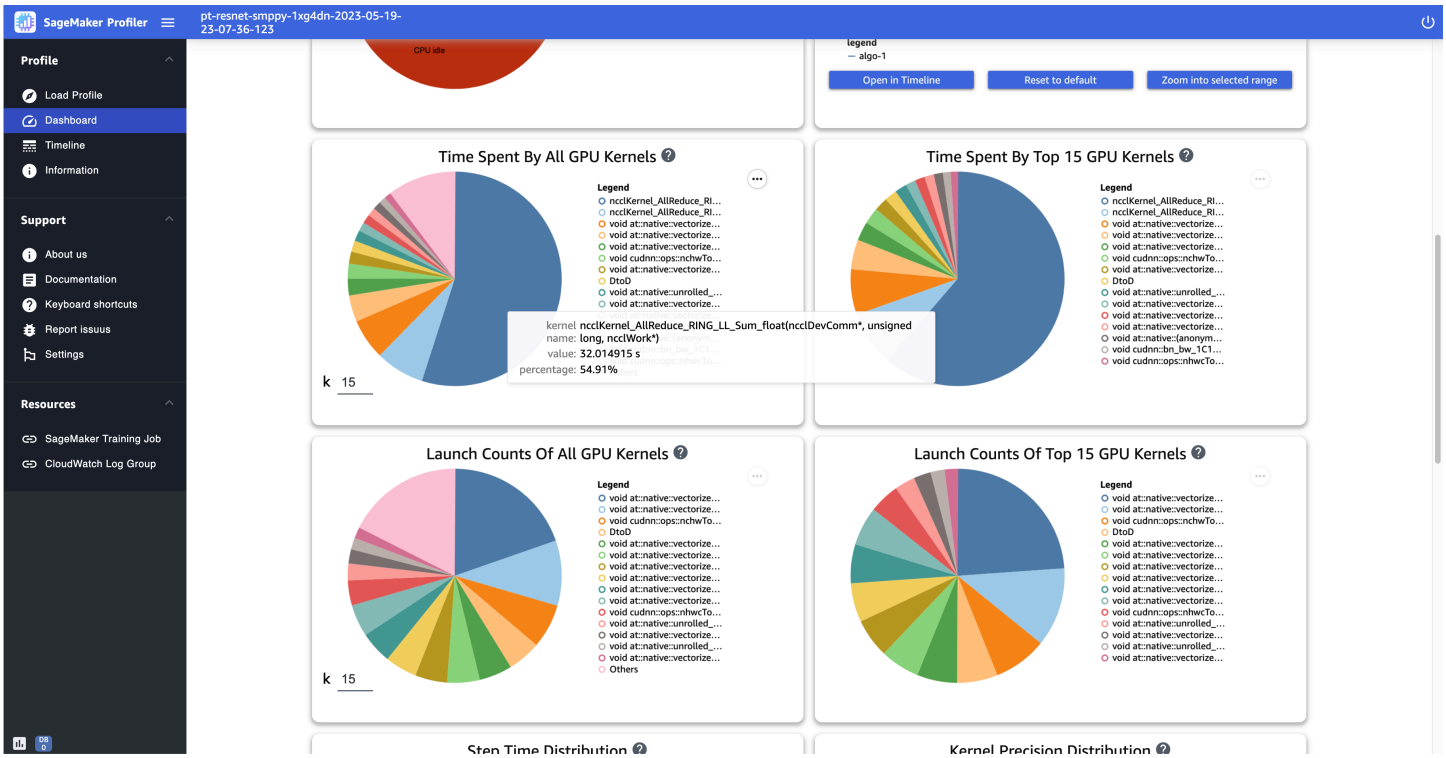
- **GPU memory operations distribution** – This pie chart shows the percentage of time spent on GPU memory operations. This visualizes the `memcopy` activities and helps identify if your training job is spending excessive time on certain memory operations.
- **Create a new histogram** – Create a new diagram of a custom metric you annotated manually during the section called “Step 1: Adapt your training script using the SageMaker Profiler Python modules”. When adding a custom annotation to a new histogram, select or type the name of the annotation you added in the training script. For example, in the demo training script in Step 1, `step`, `Forward`, `Backward`, `Optimize`, and `Loss` are the custom annotations. While creating a new histogram, these annotation names should appear in the drop-down menu for metric selection. If you choose `Backward`, the UI adds the histogram of the time spent on backward passes throughout the profiled time to the **Dashboard**. This type of histogram is useful for checking if there are outliers taking abnormally longer time and causing bottleneck problems.

The following screenshots show the GPU and CPU active time ratio and the average GPU and CPU utilization rate with respect to time per compute node.

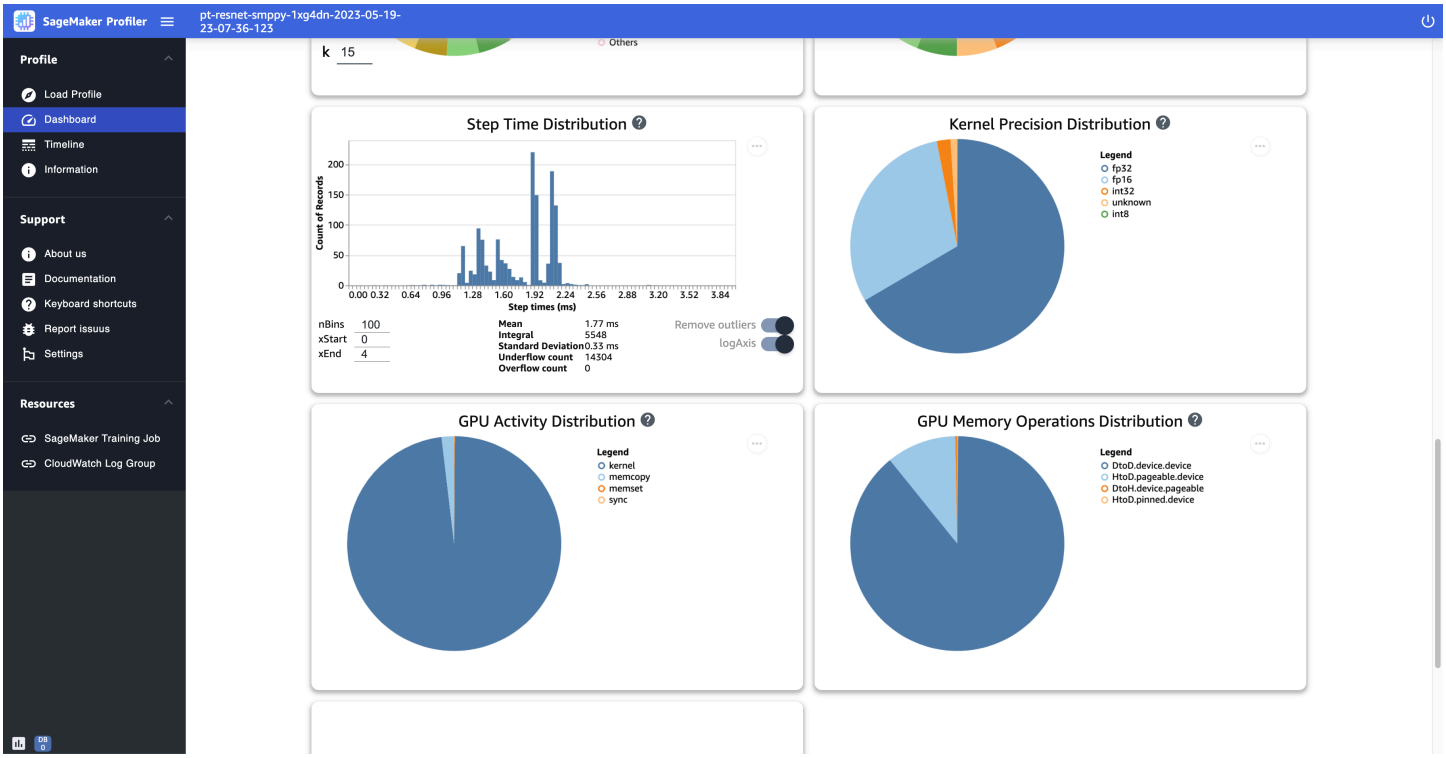


The following screenshot shows an example of pie charts for comparing how many times the GPU kernels are launched and measuring the time spent on running them. In the **Time spent by all GPU kernels** and **Launch counts of all GPU kernels** panels, you can also specify an integer to the input

field for *k* to adjust the number of legend to show in the plots. For example, if you specify 10, the plots show the top 10 most run and launched kernels respectively.



The following screenshot shows an example of step time duration histogram, and pie charts for the kernel precision distribution, GPU activity distribution, and GPU memory operation distribution.



Timeline interface

To gain a detailed view into the compute resources at the level of operations and kernels scheduled on the CPUs and run on the GPUs, use the **Timeline** interface.

You can zoom in and out and pan left or right in the timeline interface using your mouse, the `[w, a, s, d]` keys, or the four arrow keys on the keyboard.

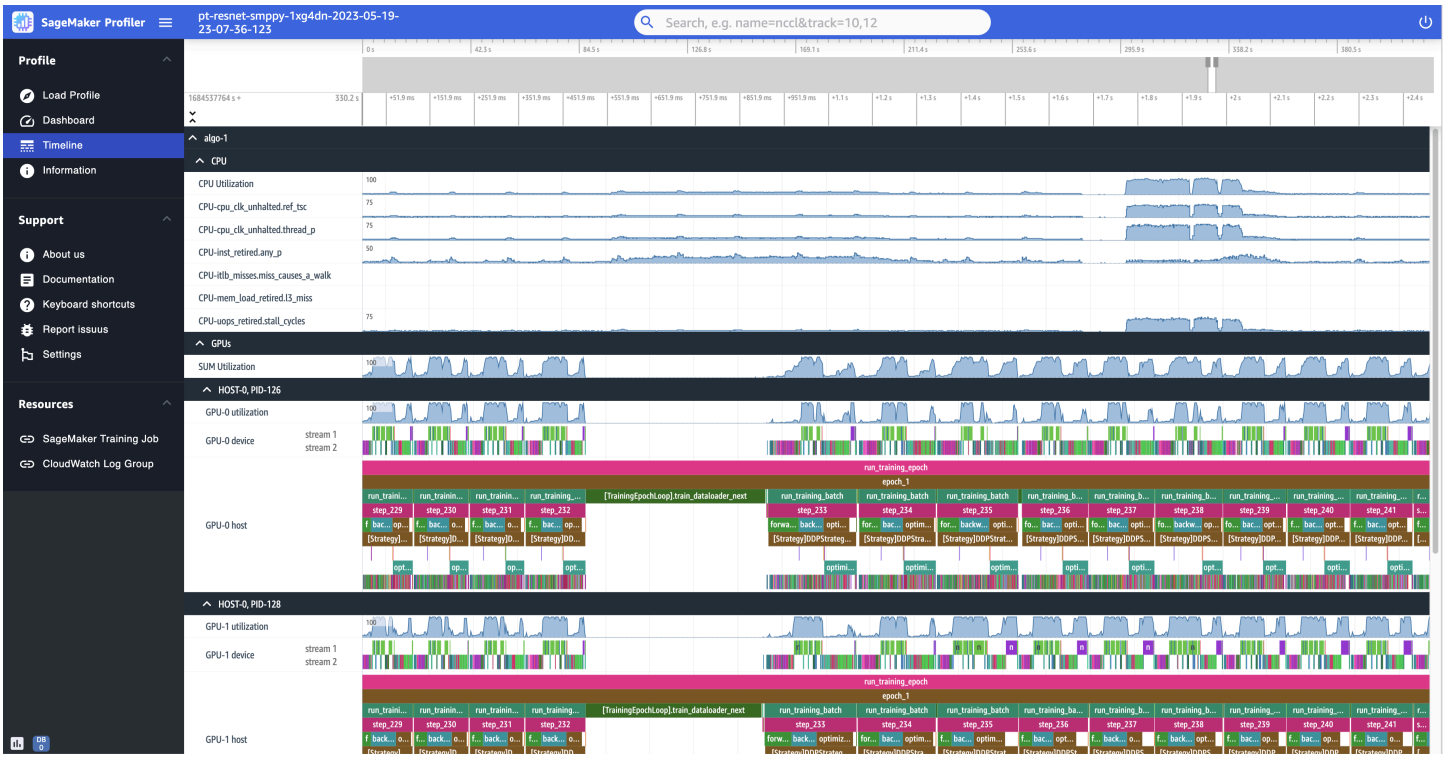
> **Tip**
>
> For more tips on the keyboard shortcuts to interact with the **Timeline** interface, choose **Keyboard shortcuts** in the left pane.

The timeline tracks are organized in a tree structure, giving you information from the host level to the device level. For example, if you run `N` instances with eight GPUs in each, the timeline structure of each instance would be as follows.

- **algo-i_{node}** – This is what SageMaker tags to assign jobs to provisioned instances. The digit i_{node} is randomly assigned. For example, if you use 4 instances, this section expands from **algo-1** to **algo-4**.
  - **CPU** – In this section, you can check the average CPU utilization rate and performance counters.
  - **GPUs** – In this section, you can check the average GPU utilization rate, individual GPU utilization rate, and kernels.
    - **SUM Utilization** – The average GPU utilization rates per instance.
    - **HOST-0 PID-123** – A unique name assigned to each process track. The acronym PID is the process ID, and the number appended to it is the process ID number that's recorded during data capture from the process. This section shows the following information from the process.
      - **GPU-i_{num_gpu} utilization** – The utilization rate of the i_{num_gpu}-th GPU over time.
      - **GPU-i_{num_gpu} device** – The kernel runs on the i_{num_gpu}-th GPU device.
        - **stream i_{cuda_stream}** – CUDA streams showing kernel runs on the GPU device. To learn more about CUDA streams, see the slides in PDF at CUDA C/C++ Streams and Concurrency provided by NVIDIA.
      - **GPU-i_{num_gpu} host** – The kernel launches on the i_{num_gpu}-th GPU host.

The following several screenshots show the **Timeline** of the profile of a training job run on `ml.p4d.24xlarge` instances, which are equipped with 8 NVIDIA A100 Tensor Core GPUs in each.

The following is a zoomed-out view of the profile, printing a dozen of steps including an intermittent data loader between `step_232` and `step_233` for fetching the next data batch.



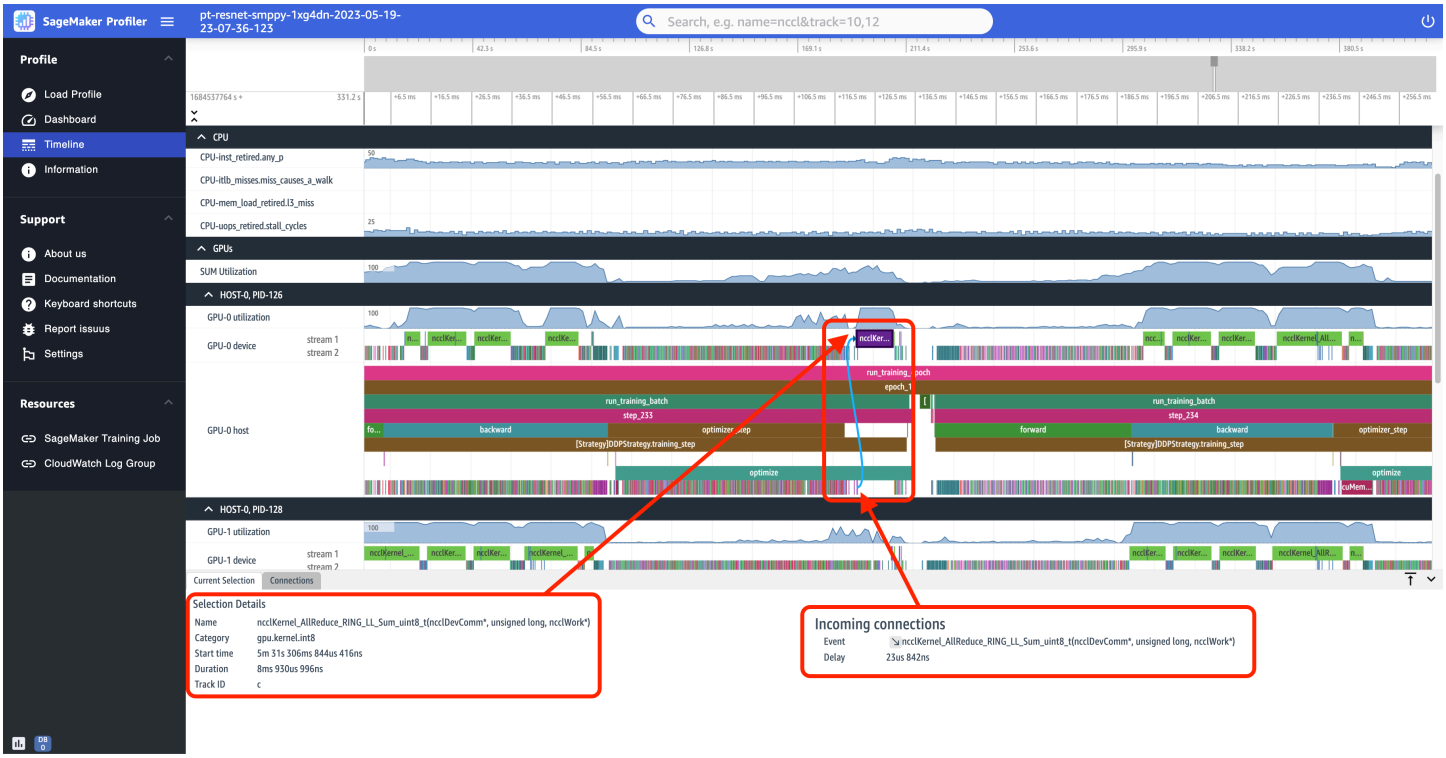
For each CPU, you can track the CPU utilization and performance counters, such as `"clk_unhalted_ref.tsc"` and `"itlb_misses.miss_causes_a_walk"`, which are indicative of instructions run on the CPU.

For each GPU, you can see a host timeline and a device timeline. Kernel launches are on the host timeline and kernel runs are on the device timeline. You can also see annotations (such as forward, backward, and optimize) if you have added in training script in the GPU host timeline.

In the timeline view, you can also track kernel launch-and-run pairs. This helps you understand how a kernel launch scheduled on a host (CPU) is run on the corresponding GPU device.

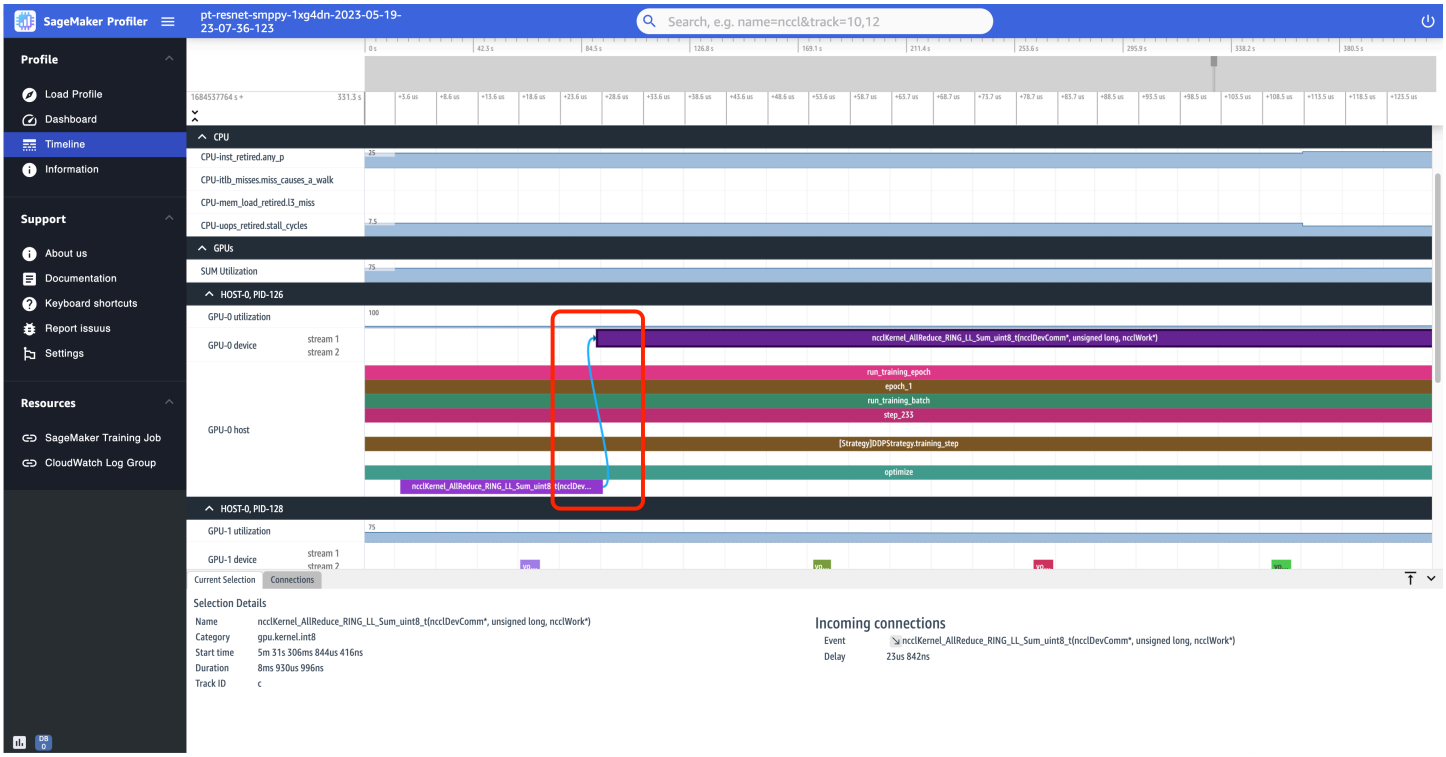
> **Tip**
>
> Press the `f` key to zoom into the selected kernel.

The following screenshot is a zoomed-in view into `step_233` and `step_234` from the previous screenshot. The timeline interval selected in the following screenshot is the `AllReduce` operation, an essential communication and synchronization step in distributed training, run on the GPU-0 device. In the screenshot, note that the kernel launch in the GPU-0 host connects to the kernel run in the GPU-0 device stream 1, indicated with the arrow in cyan color.



Also two information tabs appear in the bottom pane of the UI when you select a timeline interval, as shown in the previous screenshot. The **Current Selection** tab shows the details of the selected kernel and the connected kernel launch from the host. The connection direction is always from host (CPU) to device (GPU) since each GPU kernel is always called from a CPU. The **Connections** tab shows the chosen kernel launch and run pair. You can select either of them to move it to the center of the **Timeline** view.

The following screenshot zooms in further into the `AllReduce` operation launch and run pair.



Information

In **Information**, you can access information about the loaded training job, such as the instance type, Amazon Resource Names (ARNs) of compute resources provisioned for the job, node names, and hyperparameters.

Settings

The SageMaker Profiler UI application instance is configured to shut down after 2 hours of idle time by default. In **Settings**, use the following settings to adjust the auto shutdown timer.

- **Enable app auto shutdown** – Choose and set to **Enabled** to let the application automatically shut down after the specified number of hours of idle time. To turn off the auto-shutdown functionality, choose **Disabled**.
- **Auto shutdown threshold in hours** – If you choose **Enabled** for **Enable app auto shutdown**, you can set the threshold time in hours for the application to shut down automatically. This is set to 2 by default.

Frequently asked questions about using SageMaker Profiler

Use the following frequently asked questions to find answers about using SageMaker Profiler.

Q. I'm getting an error message, `ModuleNotFoundError: No module named 'smppy'`

Since December 2023, the name of the SageMaker Profiler Python package has changed from `smppy` to `smprof` to resolve a duplicate package name issue; `smppy` is already used by an open source package.

Therefore, if you have been using `smppy` since before December 2023 and experiencing this `ModuleNotFoundError` issue, it might be due to the outdated package name in your training script while having the latested `smprof` package installed or using one of the latest the section called "SageMaker framework images pre-installed with SageMaker Profiler". In this case, make sure that you replace all mentions of `smppy` with `smprof` throughout your training script.

While updating the SageMaker Profiler Python package name in your training scripts, to avoid confusion around which version of the package name you should use, consider using a conditional import statement as shown in the following code snippet.

```
try:
    import smprof
except ImportError:
    # backward-compatability for TF 2.11 and PT 1.13.1 images
    import smppy as smprof
```

Also note that if you have been using `smppy` while upgrading to the latest PyTorch or TensorFlow versions, make sure that you install the latest `smprof` package by following instructions at the section called "(Optional) Install the SageMaker Profiler Python package".

Q. I'm getting an error message, `ModuleNotFoundError: No module named 'smprof'`

First, make sure that you use one of the officially supported SageMaker Framework Containers. If you don't use one of those, you can install the `smprof` package by following instructions at the section called "(Optional) Install the SageMaker Profiler Python package".

Q. I'm not able to import `ProfilerConfig`

If you are unable to import `ProfilerConfig` in your job launcher script using the SageMaker Python SDK, your local environment or the Jupyter kernel might have a significantly outdated version of the SageMaker Python SDK. Make sure that you upgrade the SDK to the latest version.

```
$ pip install --upgrade sagemaker
```

Q. I'm getting an error message, `aborted: core dumped when importing smprof into my training script`

In an earlier version of `smprof`, this issue occurs with PyTorch 2.0+ and PyTorch Lightning. To resolve this issue, also install the latest `smprof` package by following instructions at the section called "(Optional) Install the SageMaker Profiler Python package".

Q. I cannot find the SageMaker Profiler UI from SageMaker Studio. How can I find it?

If you have access to the SageMaker console, choose one of the following options.

- the section called "Option 1: Launch the SageMaker Profiler UI from the domain details page"
- the section called "Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker console"

If you are a domain user and don't have access to the SageMaker console, you can access the application through SageMaker Studio Classic. If this is your case, choose the following option.

- the section called "Option 3: Use the application launcher function in the SageMaker Python SDK"

Considerations

Consider the following when using SageMaker Profiler.

- SageMaker Profiler is not compatible with SageMaker managed warm pools.

Monitor AWS compute resource utilization in Amazon SageMaker Studio Classic

To track compute resource utilization of your training job, use the monitoring tools offered by Amazon SageMaker Debugger.

For any training job you run in SageMaker using the SageMaker Python SDK, Debugger collects basic resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, network, and I/O wait time every 500 milliseconds. To see the dashbard of the resource utilization metrics of your training job, simply use the SageMaker Debugger UI in SageMaker Studio Experiments.

Deep learning operations and steps might operate in intervals of milliseconds. Compared to Amazon CloudWatch metrics, which collect metrics at intervals of 1 second, Debugger provides finer granularity into the resource utilization metrics down to 100-millisecond (0.1 second) intervals so you can dive deep into the metrics at the level of an operation or a step.

If you want to change the metric collection time interval, you can add a paramter for profiling configuration to your training job launcher. For example, if you're using the SageMaker Python SDK, you need to pass the `profiler_config` parameter when you create an estimator object. To learn how to adjust the resource utilization metric collection interval, see the section called "Code template for configuring a SageMaker estimator object with the SageMaker Debugger Python modules in the SageMaker Python SDK" and then the section called "Configure settings for basic profiling of system resource utilization".

Additionally, you can add issue detecting tools called *built-in profiling rules* provided by SageMaker Debugger. The built-in profiling rules run analysis against the resource utilization metrics and detect computational performance issues. For more information, see the section called "Configure built-in profiler rules". You can receive rule analysis results through the SageMaker Debugger UI in SageMaker Studio Experiments or the SageMaker Debugger Profiling Report. You can also create custom profiling rules using the SageMaker Python SDK.

To learn more about monitoring functionalities provided by SageMaker Debugger, see the following topics.

Topics

- Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules
- Configure built-in profiler rules managed by Amazon SageMaker Debugger
- List of Debugger built-in profiler rules
- Amazon SageMaker Debugger UI in Amazon SageMaker Studio Classic Experiments
- SageMaker Debugger interactive report
- Analyze data using the Debugger Python client library

Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules

By default, SageMaker Debugger basic profiling is on by default and monitors resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, Network, and I/O

wait time, of all SageMaker training jobs submitted using the Amazon SageMaker Python SDK. SageMaker Debugger collects these resource utilization metrics every 500 milliseconds. You don't need to make any additional changes in your code, training script, or the job launcher for tracking basic resource utilization. If you want to access the resource utilization metrics dashboard of your training job in SageMaker Studio, you can jump onto the Amazon SageMaker Debugger UI in Amazon SageMaker Studio Classic Experiments.

If you want to change the metric collection interval for basic profiling, you can specify Debugger-specific parameters while creating a SageMaker training job launcher using the SageMaker Python SDK, AWS SDK for Python (Boto3), or AWS Command Line Interface (CLI). In this guide, we focus on how to change profiling options using the Amazon SageMaker Python SDK.

If you want to activate the rules that detect system resource utilization problems automatically, you can add the `rules` parameter in the estimator object for activating the rules.

Important

To use the latest SageMaker Debugger features, you need to upgrade the SageMaker Python SDK and the `SMDebug` client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Code template for configuring a SageMaker estimator object with the SageMaker Debugger Python modules in the SageMaker Python SDK

To adjust the basic profiling configuration (`profiler_config`) or add the profiler rules (`rules`), choose one of the tabs to get the template for setting up a SageMaker estimator. In the subsequent pages, you can find more information about how to configure the two parameters.

> **Note**
>
> The following code examples are not directly executable. Proceed to the next sections to learn how to configure each parameter.

PyTorch

```
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.12.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

TensorFlow

```
# An example of constructing a SageMaker TensorFlow estimator
import boto3
```

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.8.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
```

```
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

> **Note**
>
> For MXNet, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

XGBoost

```
# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
```

```
)

estimator.fit(wait=False)
```

> **Note**
>
> For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

Generic estimator

```
# An example of constructing a SageMaker generic estimator using the XGBoost
 algorithm base image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule,
 ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
)
```

```
estimator.fit(wait=False)
```

The following provides brief descriptions of the parameters.

- `profiler_config` – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. You can set how frequently or loosely collect the system metrics. To learn how to configure the `profiler_config` parameter, see Configure settings for basic profiling of system resource utilization and Configure for framework profiling.
- `rules` – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in parallel. Make sure that your training job has access to this S3 bucket. The rules runs on processing containers and automatically analyze your training job to find computational and operational performance issues. The ProfilerReport rule is the most integrated rule that runs all built-in profiling rules and saves the profiling results as a report into your secured S3 bucket. To learn how to configure the `rules` parameter, see Configure built-in profiler rules managed by Amazon SageMaker Debugger.

> **Note**
>
> Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are three subfolders created by Debugger: `debug-output`, `profiler-output`, and `rule-output`. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods.

See the following topics to find out how to configure the Debugger-specific parameters in detail.

Topics

- Configure settings for basic profiling of system resource utilization
- Configure for framework profiling
- Updating Debugger system monitoring and framework profiling configuration while a training job is running
- Turn off Debugger

Configure settings for basic profiling of system resource utilization

To adjust the time interval for collecting the utilization metrics, use the `ProfilerConfig` API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

> **Note**
>
> By default, for all SageMaker training jobs, Debugger collects resource utilization metrics from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators.
> Debugger saves the system metrics in the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following code example shows how to set up the `profiler_config` parameter with a system monitoring time interval of 1000 milliseconds.

```
from sagemaker.debugger import ProfilerConfig

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open the Amazon SageMaker Debugger Insights dashboard.

Configure for framework profiling

> **Warning**
>
> In favor of Amazon SageMaker Profiler, SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

See also March 16, 2023.

To enable Debugger framework profiling, configure the `framework_profile_params` parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the `FrameworkProfile` class, you can configure custom framework profiling options.

Note

Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported Frameworks and Algorithms.
Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

Start a training job with the default framework profiling

The following example code is the simplest `profiler_config` parameter setting to start the default system monitoring and the default framework profiling. The `FrameworkProfile` class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile()
)
```

With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a training job with the default system monitoring and customized framework profiling with different profiling options and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the `FrameworkProfile` class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

Start a training job with the default system monitoring and customized framework profiling for target steps or a target time range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile

  profiler_config=ProfilerConfig(
  ```

```
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
)
```

- **For a target time range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
 duration=600)
)
```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
 duration=600)
)
```

  The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

Start a training job with the default system monitoring and customized framework profiling with different profiling options

You can use the following profiling configuration classes to manage the framework profiling options:

- DetailedProfilingConfig – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  > **Note**
  >
  > Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- DataloaderProfilingConfig – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

  > **Note**
  >
  > Data loader profiling might lower the training performance while collecting information from data loaders. We don't recommend enabling data loader profiling for more than a couple of steps.
  > Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- PythonProfilingConfig – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

- *cProfile* – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.
- *Pyinstrument* – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

> **Note**
>
> Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```
import time
from sagemaker.debugger import (ProfilerConfig,
                                FrameworkProfile,
                                DetailedProfilingConfig,
                                DataloaderProfilingConfig,
                                PythonProfilingConfig,
                                PythonProfiler, cProfileTimer)
```

```
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see DetailedProfilingConfig, DataloaderProfilingConfig, and PythonProfilingConfig in the Amazon SageMaker Python SDK.

Updating Debugger system monitoring and framework profiling configuration while a training job is running

If you want to activate or update the Debugger monitoring configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To activate Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

  ```
  estimator.enable_default_profiling()
  ```

  When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

  For more information, see estimator.enable_default_profiling in the Amazon SageMaker Python SDK.

- To update system monitoring configuration, use the following:

```
estimator.update_profiler(
    system_monitor_interval_millis=500
)
```

For more information, see estimator.update_profiler in the Amazon SageMaker Python SDK.

Turn off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To turn off profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

  > **Warning**
  >
  > If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To turn off debugging, set the `debugger_hook_config` parameter to `False`.

  > **Warning**
  >
  > If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```
estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the estimator.disable_profiling and estimator.update_profiler classmethods in the Amazon SageMaker Python SDK documentation.

Configure built-in profiler rules managed by Amazon SageMaker Debugger

The Amazon SageMaker Debugger built-in profiler rules analyze system metrics and framework operations collected during the training of a model. Debugger offers the `ProfilerRule` API operation that helps configure the rules to monitor training compute resources and operations and to detect anomalies. For example, the profiling rules can help you detect whether there are computational problems such as CPU bottlenecks, excessive I/O wait time, imbalanced workload across GPU workers, and compute resource underutilization. To see a full list of available built-in profiling rules, see List of Debugger built-in profiler rules.

> **Note**
>
> The built-in rules are provided through Amazon SageMaker processing containers and fully managed by SageMaker Debugger at no additional cost. For more information about billing, see the Amazon SageMaker Pricing page.

In the following topics, learn how to use the Debugger built-in rules.

Topics

- Use SageMaker Debugger built-in profiler rules with their default parameter settings

- Use Debugger built-in profiler rules with custom parameter values

Use SageMaker Debugger built-in profiler rules with their default parameter settings

To add SageMaker Debugger built-in rules in your estimator, you need to configure a `rules` list object. The following example code shows the basic structure of listing the SageMaker Debugger built-in rules.

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_n()),
    ... # You can also append more debugging rules in the
 Rule.sagemaker(rule_configs.*()) format.
]

estimator=Estimator(
    ...
    rules=rules
)
```

For a complete list of available built-in rules, see List of Debugger built-in profiler rules.

To use the profiling rules and inspect the computational performance and progress of your training job, add the `ProfilerReport` rule of SageMaker Debugger. This rule activates all built-in rules under the Debugger ProfilerRule `ProfilerRule` family. Furthermore, this rule generates an aggregated profiling report. For more information, see Profiling Report Generated Using SageMaker Debugger. You can use the following code to add the profiling report rule to your training estimator.

```
from sagemaker.debugger import Rule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.ProfilerReport())
]
```

When you start the training job with the `ProfilerReport` rule, Debugger collects resource utilization data every 500 milliseconds. Debugger analyzes the resource utilization to identify

if your model is having bottleneck problems. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules.

Use Debugger built-in profiler rules with custom parameter values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` class methods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. For instruction on how to use the `CollectionConfig` class, see Configure Tensor Collections Using the `CollectionConfig` API.

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be initiated.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in List of Debugger built-in profiler rules.

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInProfilerRuleName(),
        rule_parameters={
                "key": "value"
        }
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at List of Debugger built-in profiler rules.

For a low-level JSON configuration of the Debugger built-in rules using the `CreateTrainingJob` API, see Configure Debugger Using Amazon SageMaker API.

List of Debugger built-in profiler rules

Use the Debugger built-in profiler rules provided by Amazon SageMaker Debugger and analyze metrics collected while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of running a performant training job. You can call the built-in profiler rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. There's no additional cost for using the built-in rules. For more information about billing, see the Amazon SageMaker Pricing page.

Note

The maximum numbers of built-in profiler rules that you can attach to a training job is 20. SageMaker Debugger fully manages the built-in rules and analyzes your training job synchronously.

Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Profiler rules

The following rules are the Debugger built-in rules that are callable using the `ProfilerRule.sagemaker` classmethod.

Debugger built-in rule for generating the profiling report

Scope of Validity	Built-in Rules
Profiling Report for any SageMaker training job	• ProfilerReport

Debugger built-in rules for profiling hardware system resource utilization (system metrics)

Scope of Validity	Built-in Rules
Generic system monitoring rules for any SageMaker training job	• BatchSize • CPUBottleneck • GPUMemoryIncrease • IOBottleneck • LoadBalancing • LowGPUUtilization • OverallSystemUsage

Debugger built-in rules for profiling framework metrics

Scope of Validity	Built-in Rules
Profiling rules for deep learning frameworks (TensorFlow and PyTorch)	• MaxInitializationTime • OverallFrameworkMetrics • StepOutlier

Warning

In favor of Amazon SageMaker Profiler, SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0

- TensorFlow >= v2.3.1, < v2.11

See also March 16, 2023.

To use the built-in rules with default parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_n())
]
```

To use the built-in rules with customizing the parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInRuleName(),
        rule_parameters={
                "key": "value"
        }
    )
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code.
- For a full instruction on using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API.

ProfilerReport

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>_<parameter_name> = value
        )
    )
]
```

If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's `cpu_threshold` parameter and the IOBottleneck rule's `threshold` parameter.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

To explore what's in the profiler report, see SageMaker Debugger Profiling Report. Also, because this rule activates all of the profiling rules, you can also check the rule analysis status using the SageMaker Debugger UI in SageMaker Studio Experiments.

Parameter Descriptions for the OverallSystemUsage Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`<BuiltInRuleName>_<parameter_name>`	Customizable parameter to adjust thresholds of other built-in monitoring and profiling rules. **Optional** Default value: None

BatchSize

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

Parameter Descriptions for the BatchSize Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**

Parameter Name	Description
	Valid values: String
`cpu_threshold_p95`	Defines the threshold for 95th quantile of CPU utilization in percentage. **Optional** Valid values: Integer Default value: `70` (in percentage)
`gpu_threshold_p95`	Defines the threshold for 95th quantile of GPU utilization in percentage. **Optional** Valid values: Integer Default value: `70` (in percentage)
`gpu_memory_threshold_p95`	Defines the threshold for 95th quantile of GPU memory utilization in percentage. **Optional** Valid values: Integer Default values: `70` (in percentage)

Parameter Name	Description
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `100`
`window`	Window size for computing quantiles. **Optional** Valid values: Integer Default values: `500`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

CPUBottleneck

The CPUBottleneck rule helps detect if GPU is underutilized due to CPU bottlenecks. Rule returns True if number of CPU bottlenecks exceeds a predefined threshold.

Parameter Descriptions for the CPUBottleneck Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold for proportion of bottlenecked time to the total training time. If the proportion exceeds the percentage specified to the threshold parameter, the rule switches the rule status to True. **Optional** Valid values: Integer Default value: `50` (in percentage)
`gpu_threshold`	A threshold that defines low GPU utilization. **Optional** Valid values: Integer Default value: `10` (in percentage)
`cpu_threshold`	A threshold that defines high CPU utilization. **Optional** Valid values: Integer Default values: `90` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first

Parameter Name	Description
	several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `100`
`scan_interval_us`	Time interval with which timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

GPUMemoryIncrease

The GPUMemoryIncrease rule helps detect a large increase in memory usage on GPUs.

Parameter Descriptions for the GPUMemoryIncrease Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`increase`	Defines the threshold for absolute memory increase.

Parameter Name	Description
	Optional Valid values: Integer Default value: `10` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `100`
`window`	Window size for computing quantiles. **Optional** Valid values: Integer Default values: `500`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

IOBottleneck

This rule helps to detect if GPU is underutilized due to data IO bottlenecks. Rule returns True if number of IO bottlenecks exceeds a predefined threshold.

Parameter Descriptions for the IOBottleneck Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold when Rule to return True. **Optional** Valid values: Integer Default value: `50` (in percentage)
`gpu_threshold`	A threshold that defines when GPU is considered underutilized. **Optional** Valid values: Integer Default value: `70` (in percentage)
`io_threshold`	A threshold that defines high IO wait time. **Optional** Valid values: Integer Default values: `50` (in percentage)

Parameter Name	Description
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `1000`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

LoadBalancing

The LoadBalancing rule helps detect issues in workload balancing among multiple GPUs.

Parameter Descriptions for the LoadBalancing Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the workload percentage.

Parameter Name	Description
	Optional Valid values: Integer Default value: `0.5` (unitless proportion)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer Default values: `10`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

LowGPUUtilization

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.

Parameter Descriptions for the LowGPUUtilization Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold_p95`	A threshold for 95th quantile below which GPU is considered to be underutilized. **Optional** Valid values: Integer Default value: `70` (in percentage)
`threshold_p5`	A threshold for 5th quantile. Default is 10 percent. **Optional** Valid values: Integer Default values: `10` (in percentage)
`patience`	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter. **Optional** Valid values: Integer

Parameter Name	Description
	Default values: `1000`
`window`	Window size for computing quantiles. **Optional** Valid values: Integer Default values: `500`
`scan_interval_us`	Time interval that timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

OverallSystemUsage

The OverallSystemUsage rule measures overall system usage per worker node. The rule currently only aggregates values per node and computes their percentiles.

Parameter Descriptions for the OverallSystemUsage Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`scan_interval_us`	Time interval to scan timeline files. **Optional** Valid values: Integer

Parameter Name	Description
	Default values: `60000000` (in microseconds)

MaxInitializationTime

The MaxInitializationTime rule helps detect if the training initialization is taking too much time. The rule waits until the first step is available.

Parameter Descriptions for the MaxInitializationTime Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`threshold`	Defines the threshold in minutes to wait for the first step to become available. **Optional** Valid values: Integer Default value: `20` (in minutes)
`scan_interval_us`	Time interval with which timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

OverallFrameworkMetrics

The OverallFrameworkMetrics rule summarizes the time spent on framework metrics, such as forward and backward pass, and data loading.

Parameter Descriptions for the OverallFrameworkMetrics Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String
`scan_interval_us`	Time interval to scan timeline files. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

StepOutlier

The StepOutlier rule helps detect outliers in step durations. This rule returns `True` if there are outliers with step durations larger than `stddev` sigmas of the entire step durations in a time range.

Parameter Descriptions for the StepOutlier Rule

Parameter Name	Description
`base_trial`	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required** Valid values: String

Parameter Name	Description
`stddev`	Defines a factor by which to multiply the standard deviation. For example, the rule is invoked by default when a step duration is larger or smaller than 5 times the standard deviation. **Optional** Valid values: Integer Default value: 5 (in minutes)
`mode`	Mode under which steps have been saved and on which Rule should run on. Per default rule will run on steps from EVAL and TRAIN phase **Optional** Valid values: Integer Default value: 5 (in minutes)
`n_outliers`	How many outliers to ignore before rule returns True **Optional** Valid values: Integer Default value: `10`
`scan_interval_us`	Time interval with which timeline files are scanned. **Optional** Valid values: Integer Default values: `60000000` (in microseconds)

Amazon SageMaker Debugger UI in Amazon SageMaker Studio Classic Experiments

Use the Amazon SageMaker Debugger Insights dashboard in Amazon SageMaker Studio Classic Experiments to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud (Amazon EC2) instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, GPU memory, network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio Classic UI or using the Amazon SageMaker Python SDK.

Important

If you're using an existing Studio Classic app, delete the app and restart to use the latest Studio Classic features. For instructions on how to restart and update your Studio Classic environment, see Update Amazon SageMaker Studio Classic.

Topics

Open the Amazon SageMaker Debugger Insights dashboard

In the SageMaker Debugger Insights dashboard in Studio Classic, you can see the compute resource utilization, resource utilization, and system bottleneck information of your training job that runs on Amazon EC2 instances in real time and after trainings

Note

The SageMaker Debugger Insights dashboard runs a Studio Classic application on an `ml.m5.4xlarge` instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio Classic kernel session. Multiple kernel sessions for

multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio Classic application remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important

When you are done using the SageMaker Debugger Insights dashboard, you must shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance.

To open the SageMaker Debugger Insights dashboard

1. On the Studio Classic **Home** page, choose **Experiments** in the left navigation pane.
2. Search your training job in the **Experiments** page. If your training job is set up with an Experiments run, the job should appear in the **Experiments** tab; if you didn't set up an Experiments run, the job should appear in the **Unassigned runs** tab.
3. Choose (click) the link of the training job name to see the job details.
4. Under the **OVERVIEW** menu, choose **Debuggger**. This should show the following two sections.
   - In the **Debugger rules** section, you can browse the status of the Debugger built-in rules associated with the training job.
   - In the **Debugger insights** section, you can find links to open SageMaker Debugger Insights on the dashboard.
5. In the **SageMaker Debugger Insights** section, choose the link of the training job name to open the SageMaker Debugger Insights dashboard. This opens a **Debug [your-training-job-name]** window. In this window, Debugger provides an overview of the computational performance of your training job on Amazon EC2 instances and helps you identify issues in compute resource utilization.

You can also download an aggregated profiling report by adding the built-in ProfilerReport rule of SageMaker Debugger. For more information, see Configure Built-in Profiler Rules and Profiling Report Generated Using SageMaker Debugger.

Amazon SageMaker Debugger Insights dashboard controller

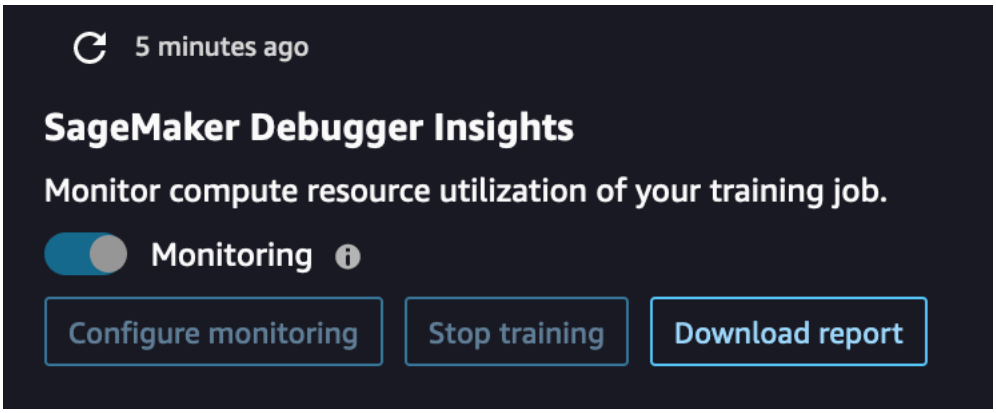
There are different components of the Debugger controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

> **Note**
>
> The SageMaker Debugger Insights dashboard runs a Studio Classic app on an `ml.m5.4xlarge` instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio Classic kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio Classic app remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

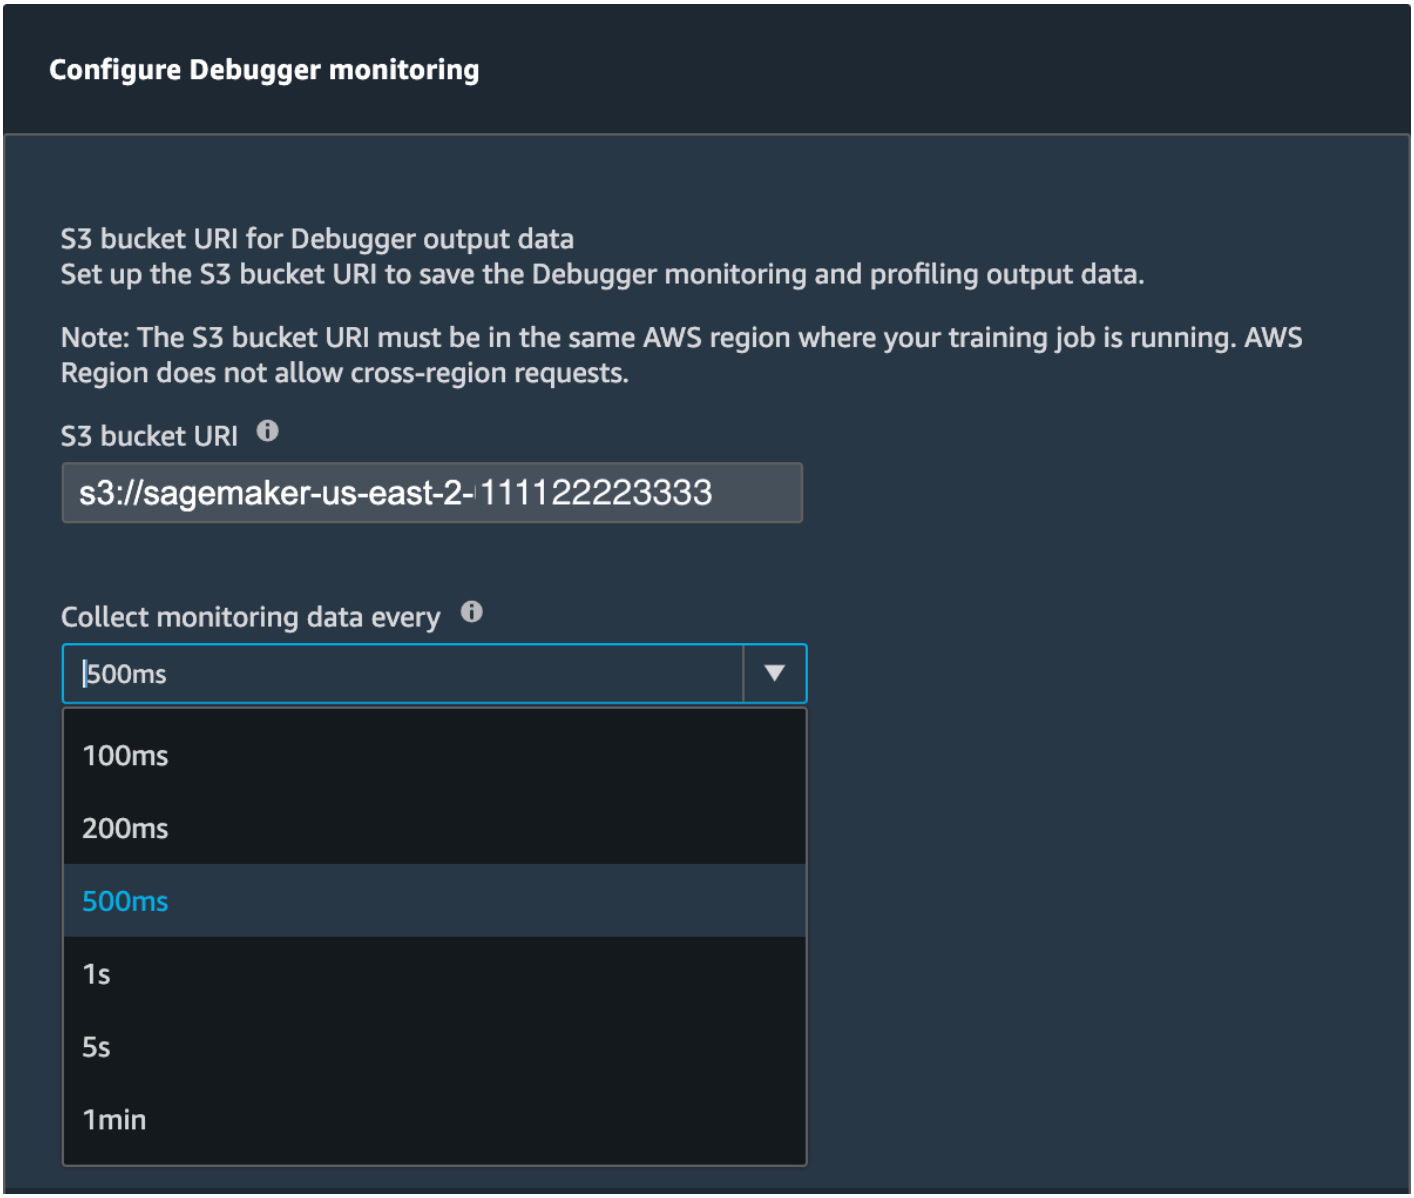
> **Important**
>
> When you are done using the SageMaker Debugger Insights dashboard, shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance.

SageMaker Debugger Insights controller UI

Using the Debugger controller located at the upper-left corner of the Insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics, stop a training job, and download a Debugger profiling report.



- If you want to manually refresh the dashboard, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- The **Monitoring** toggle button is on by default for any SageMaker training job initiated using the SageMaker Python SDK. If not activated, you can use the toggle button to start monitoring. During monitoring, Debugger only collects resource utilization metrics to detect computational problems such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see Debugger built-in rules for profiling hardware system resource utilization (system metrics).
- The **Configure monitoring** button opens a pop-up window that you can use to set or update the data collection frequency and the S3 path to save the data.



You can specify values for the following fields.

- **S3 bucket URI**: Specify the base S3 bucket URI.
- **Collect monitoring data every**: Select a time interval to collect system metrics. You can choose one of the monitoring intervals from the dropdown list. Available intervals are 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.

> **Note**
>
> If you choose one of the lower time intervals, you increase the granularity of resource utilization metrics, so you can capture spikes and anomalies with a higher time resolution. However, higher the resolution, larger the size of system metrics to process. This might introduce additional overhead and impact the overall training and processing time.

- Using the **Stop training** button, you can stop the training job when you find anomalies in resource utilization.
- Using the **Download report** button, you can download an aggregated profiling report by using the built-in ProfilerReport rule of SageMaker Debugger. The button is activated when you add the built-in ProfilerReport rule to the estimator. For more information, see Configure Built-in Profiler Rules and Profiling Report Generated Using SageMaker Debugger.

Explore the Amazon SageMaker Debugger Insights dashboard

When you initiate a SageMaker training job, SageMaker Debugger starts monitoring the resource utilization of the Amazon EC2 instances by default. You can track the system utilization rates, statistics overview, and built-in rule analysis through the Insights dashboard. This guide walks you through the content of the SageMaker Debugger Insights dashboard under the following tabs: **System Metrics** and **Rules**.

> **Note**
>
> The SageMaker Debugger Insights dashboard runs a Studio Classic application on an `ml.m5.4xlarge` instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio Classic kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The

Studio Classic application remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important

When you are done using the SageMaker Debugger Insights dashboard, shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance.

System metrics

In the **System Metrics** tab, you can use the summary table and timeseries plots to understand resource utilization.

Resource utilization summary

This summary table shows the statistics of compute resource utilization metrics of all nodes (denoted as algo-*n*). The resource utilization metrics include the total CPU utilization, the total GPU utilization, the total CPU memory utilization, the total GPU memory utilization, the total I/O wait time, and the total network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.

System Metrics Rules

Resource utilization summary

System usage statistics

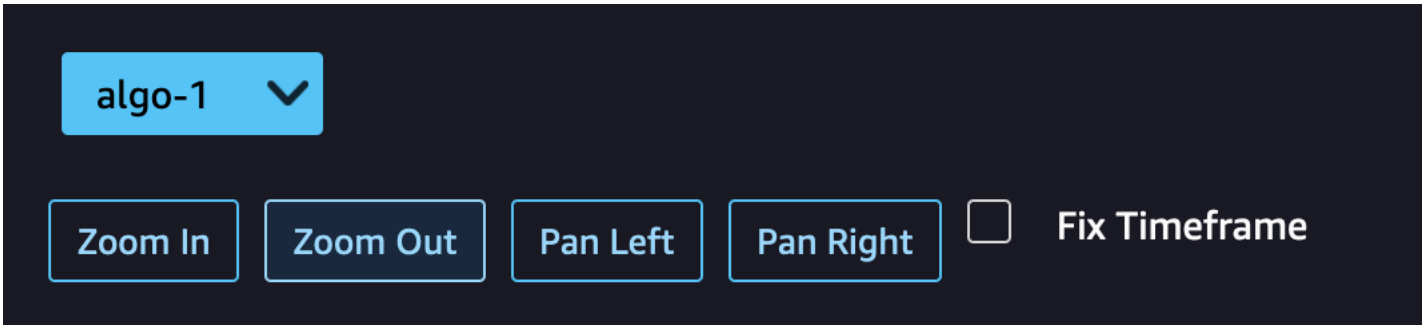
Node	Metric	Unit	Max	p99	p95	p50	Min
algo-1	Network	MB/s	37.82	33.68	32.83	12.39	0
algo-2	Network	MB/s	37.51	33.51	32.69	9.54	0
algo-1	GPU	%	69	20.61	18.27	6.81	0
algo-2	GPU	%	70	20.89	18.68	6.53	0
algo-1	CPU	%	100	94.58	78.95	51.71	0
algo-2	CPU	%	100	94.76	78.48	49.72	0
algo-1	CPU memory	%	5	4.98	4.92	4.16	1
algo-2	CPU memory	%	5	4.98	4.91	4.15	1
algo-1	GPU memory	%	32	9.6	7.71	2.27	0
algo-2	GPU memory	%	33	9.59	7.76	2.21	0
algo-1	I/O	%	100	20.41	0	0	0
algo-2	I/O	%	92	19.45	0	0	0

Resource utilization time series plots

Use the time series graphs to see more details of resource utilization and identify at what time interval each instance shows any undesired utilization rate, such as low GPU utilization and CPU bottlenecks that can cause a waste of the expensive instance.

The time series graph controller UI

The following screenshot shows the UI controller for adjusting the time series graphs.

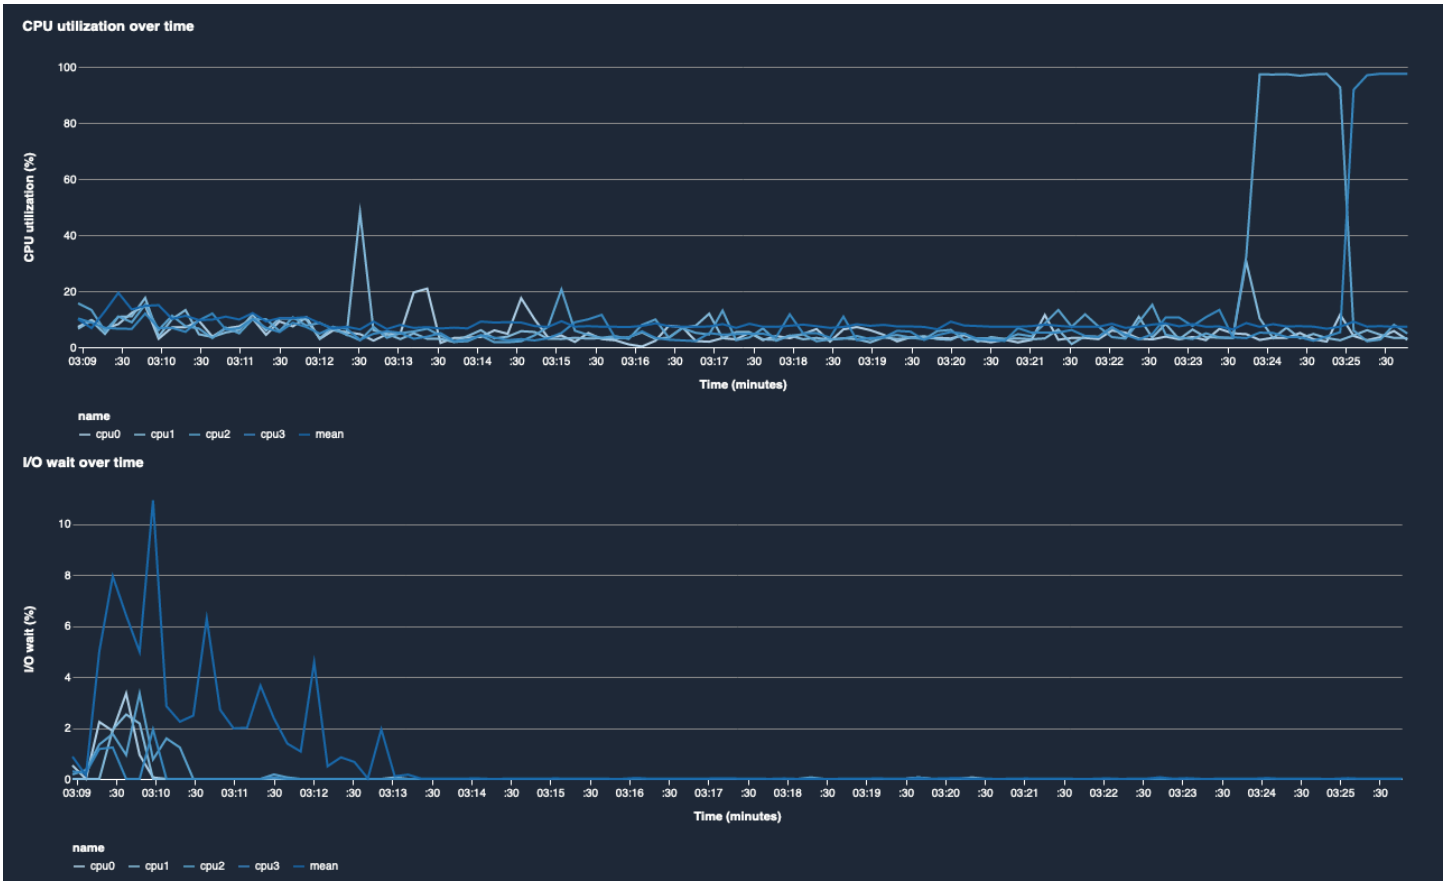


- **algo-1**: Use this dropdown menu to choose the node that you want to look into.
- **Zoom In**: Use this button to zoom in the time series graphs and view shorter time intervals.
- **Zoom Out**: Use this button to zoom out the time series graphs and view wider time intervals.
- **Pan Left**: Move the time series graphs to an earlier time interval.

- **Pan Right**: Move the time series graphs to a later time interval.
- **Fix Timeframe**: Use this check box to fix or bring back the time series graphs to show the whole view from the first data point to the last data point.

CPU utilization and I/O wait time

The first two graphs show CPU utilization and I/O wait time over time. By default, the graphs show the average of CPU utilization rate and I/O wait time spent on the CPU cores. You can select one or more CPU cores by selecting the labels to graph them on single chart and compare utilization across cores. You can drag and zoom in and out to have a closer look at specific time intervals.



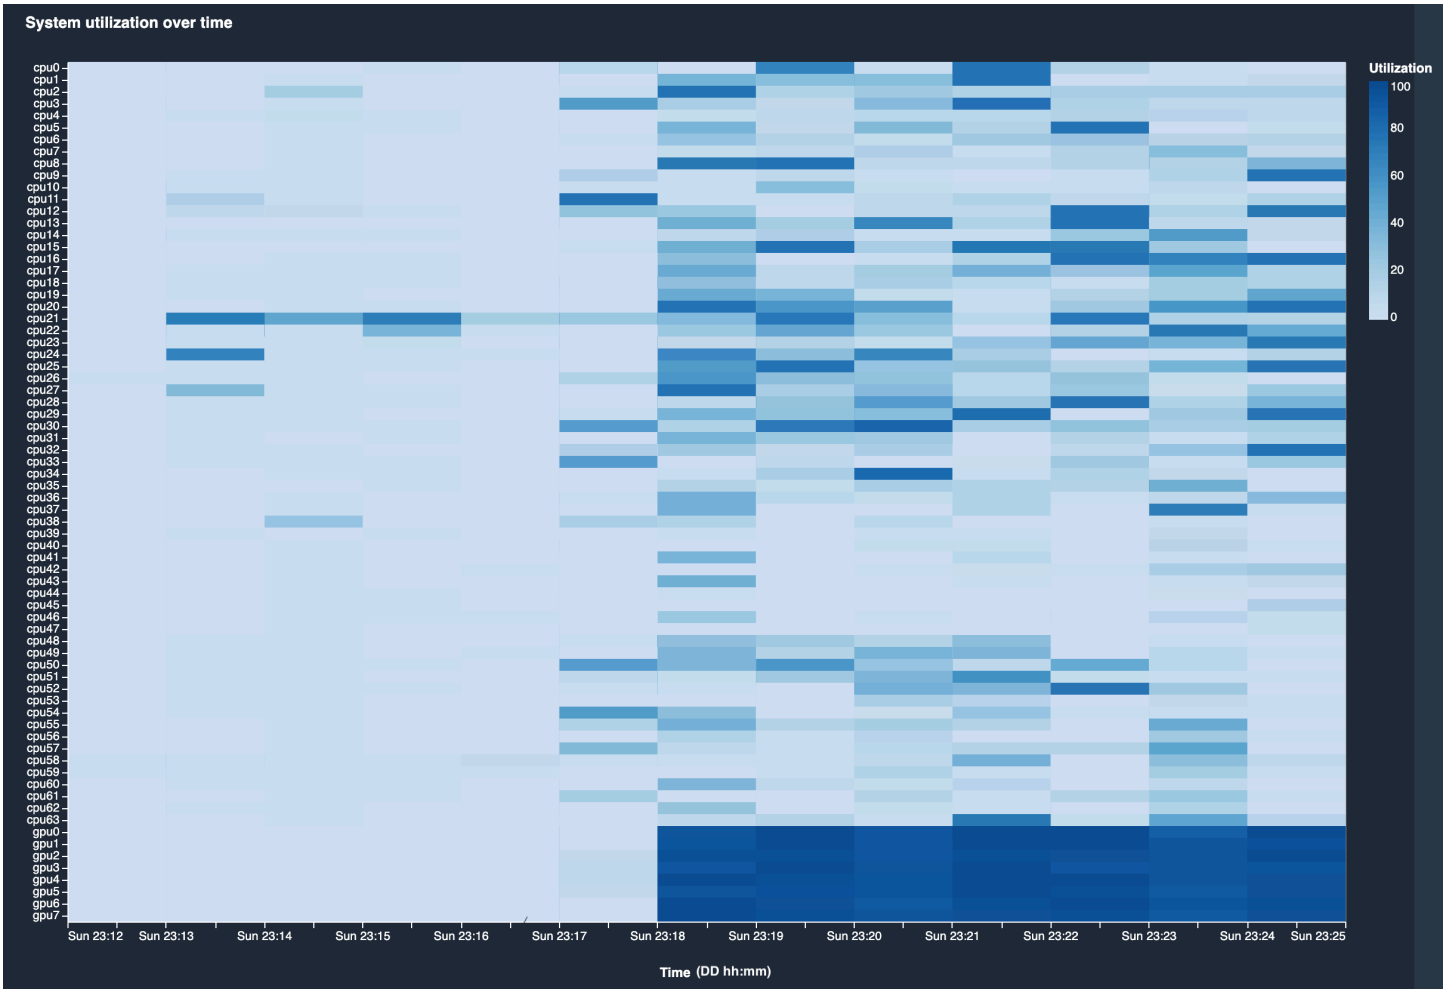
GPU utilization and GPU memory utilization

The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of an Amazon EC2 instance. The

following figure shows an example training job on an `ml.p3.16xlarge` instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.

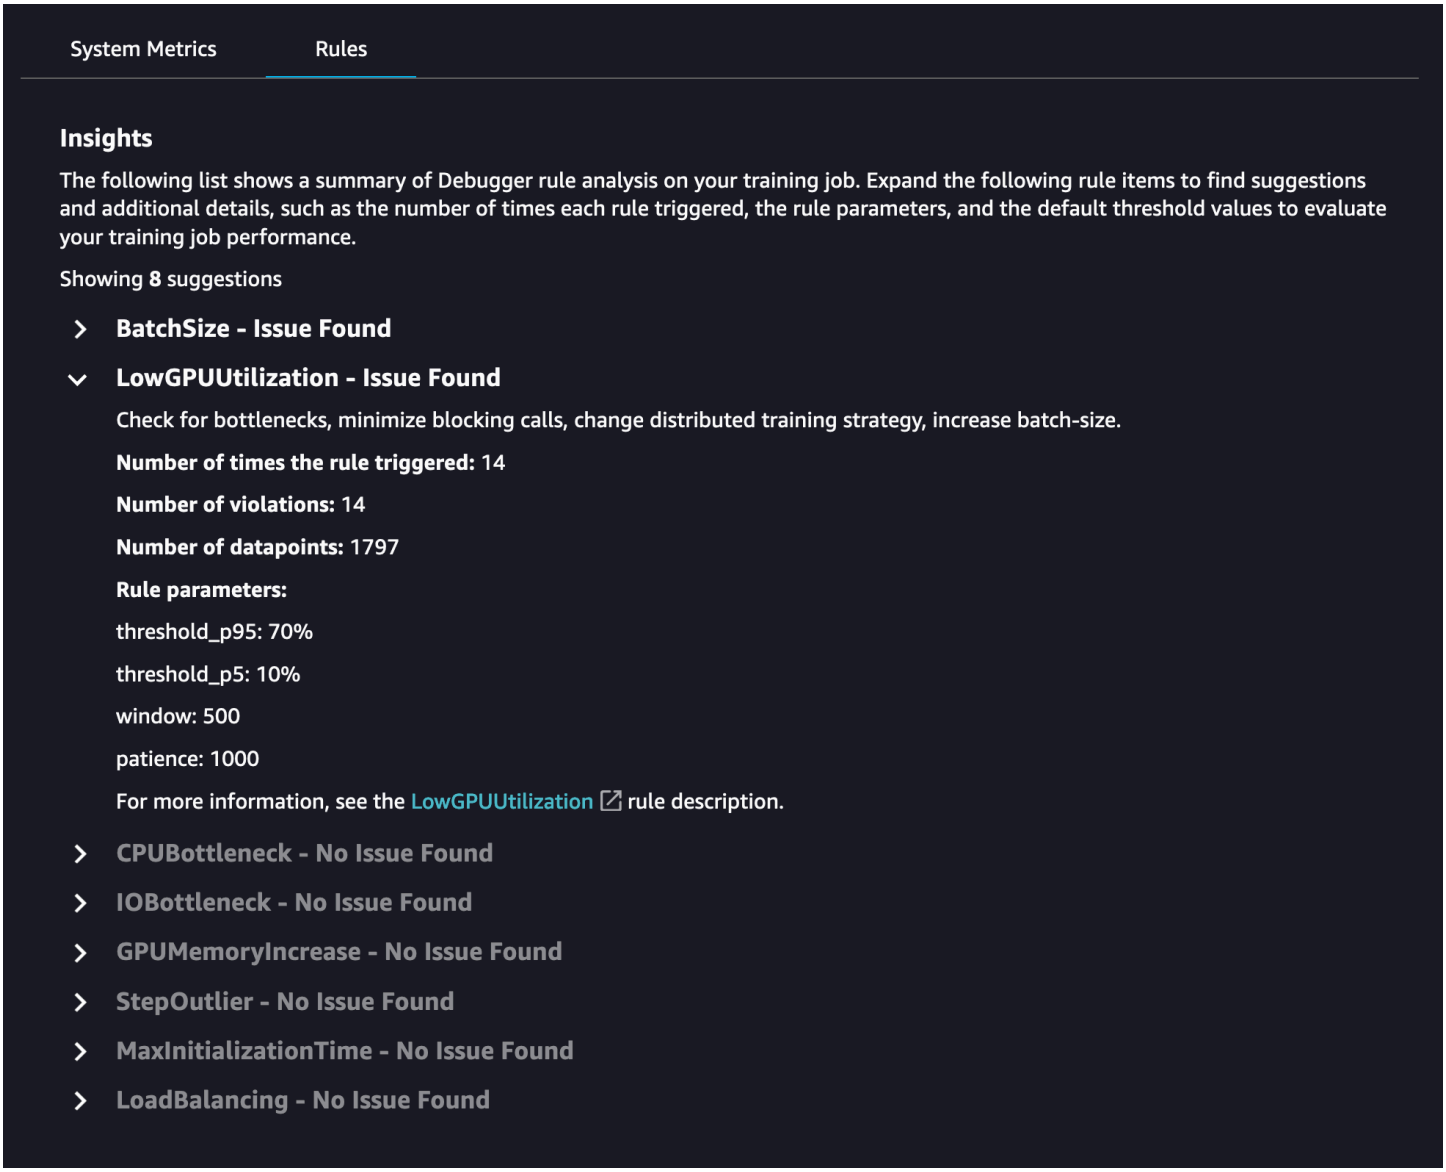
Overall system utilization over time

The following heatmap shows an example of the entire system utilization of an `ml.p3.16xlarge` instance over time, projected onto the two-dimensional plot. Every CPU and GPU core is listed in the vertical axis, and the utilization is recorded over time with a color scheme, where the bright colors represent low utilization and the darker colors represent high utilization. See the labeled color bar on the right side of the plot to find out which color level corresponds to which utilization rate.



Rules

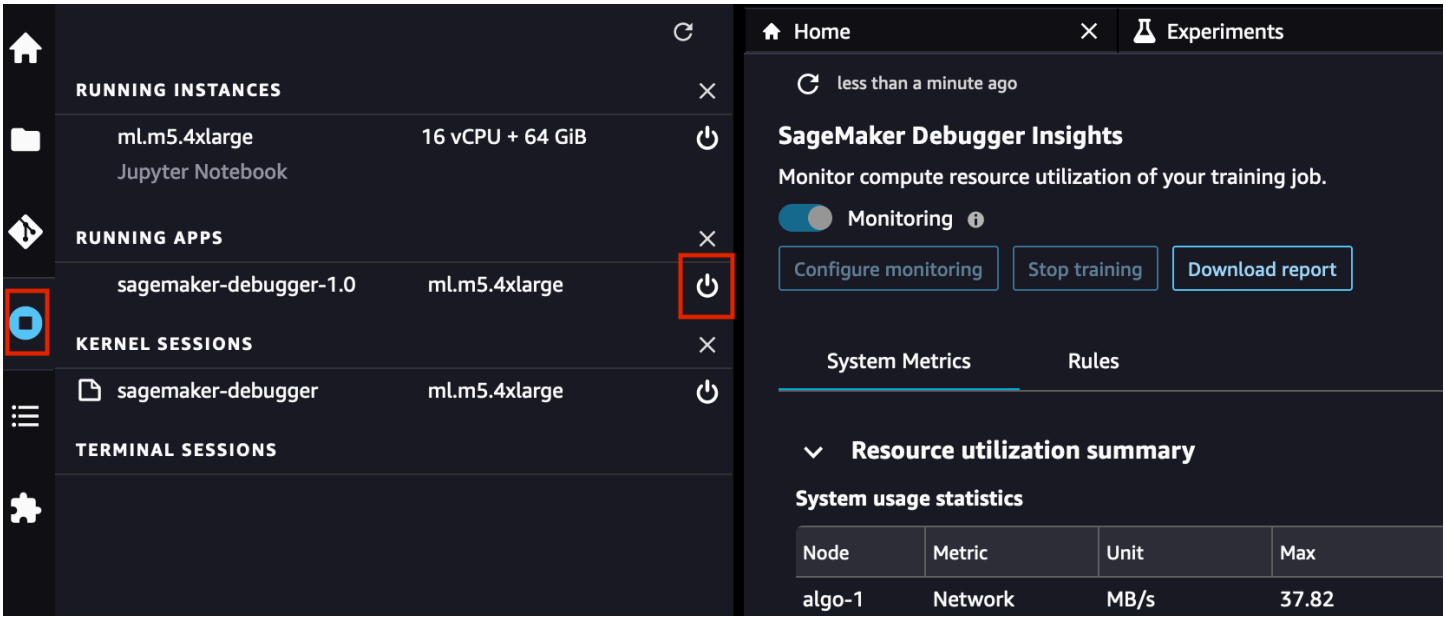
Use the **Rules** tab to find a summary of the profiling rule analysis on your training job. If the profiling rule is activated with the training job, the text appears highlighted with the solid white text. Inactive rules are dimmed in gray text. To activate these rules, follow instructions at the section called “Configure built-in profiler rules”.



Shut down the Amazon SageMaker Debugger Insights instance

When you are not using the SageMaker Debugger Insights dashboard, you should shut down the app instance to avoid incurring additional fees.

To shut down the SageMaker Debugger Insights app instance in Studio Classic



1. In Studio Classic, select the **Running Instances and Kernels** icon ( ).
2. Under the **RUNNING APPS** list, look for the **sagemaker-debugger-1.0** app. Select the shutdown icon ( ) next to the app. The SageMaker Debugger Insights dashboards run on an `ml.m5.4xlarge` instance. This instance also disappears from the **RUNNING INSTANCES** when you shut down the **sagemaker-debugger-1.0** app.

SageMaker Debugger interactive report

Receive profiling reports autogenerated by Debugger. The Debugger report provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger profiling report.

> **Note**
>
> You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the

current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

Important

In the reports, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

SageMaker Debugger profiling report

For any SageMaker training jobs, the SageMaker Debugger ProfilerReport rule invokes all of the monitoring and profiling rules and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the Amazon SageMaker Python SDK or the S3 console, and learn what you can interpret from the profiling results.

Important

In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Download the SageMaker Debugger profiling report

Download the SageMaker Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Note

To get the profiling report generated by SageMaker Debugger, you must use the built-in ProfilerReport rule offered by SageMaker Debugger. To activate the rule with your training job, see Configure Built-in Profiler Rules.

Tip

You can also download the report with a single click in the SageMaker Studio Debugger insights dashboard. This doesn't require any additional scripting to download the report. To find out how to download the report from Studio, see Open the Amazon SageMaker Debugger Insights dashboard.

Download using SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

```
estimator.output_path
```

2. Check the current job name.

```
estimator.latest_training_job.job_name
```

3. The Debugger profiling report is stored under `<default-s3-output-base-uri>/<training-job-name>/rule-output`. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path +
 estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under an autogenerated folder that's named as `ProfilerReport-1234567890`. The folder name is a combination of strings: `ProfilerReport` and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.

2020-11-28 07:26:03        575 sagemaker-debugger-mnist-byoc-tf2-2020-11-28-06-32-33-097/rule-output/ProfilerReport-1606545153/profiler-output/profiler-reports/OverallSystemUsage.json
2020-11-28 07:26:03       2208 sagemaker-debugger-mnist-byoc-tf2-2020-11-28-06-32-33-097/rule-output/ProfilerReport-1606545153/profiler-output/profiler-reports/StepOutlier.json
```

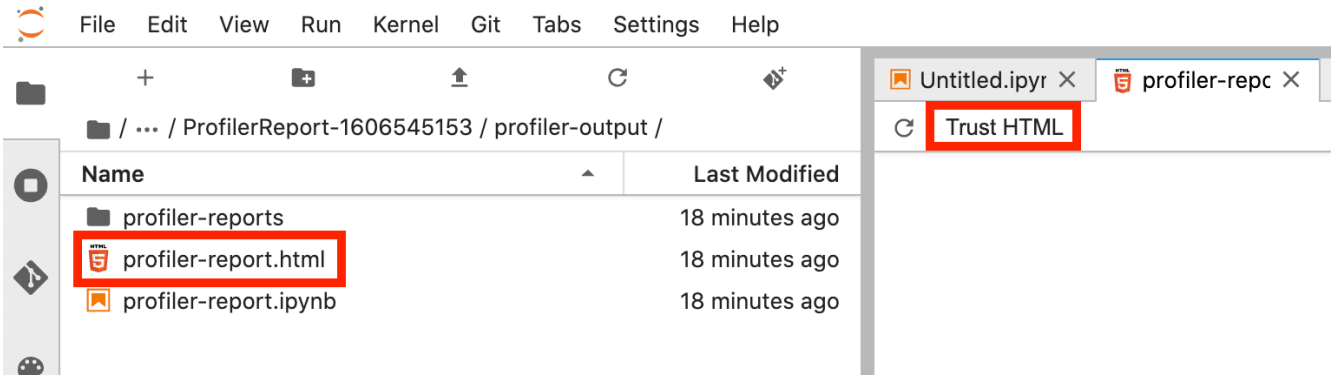
The `profiler-report.html` is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

> **Tip**
>
> If using a Jupyter notebook server, run `!pwd` to double check the current working directory.

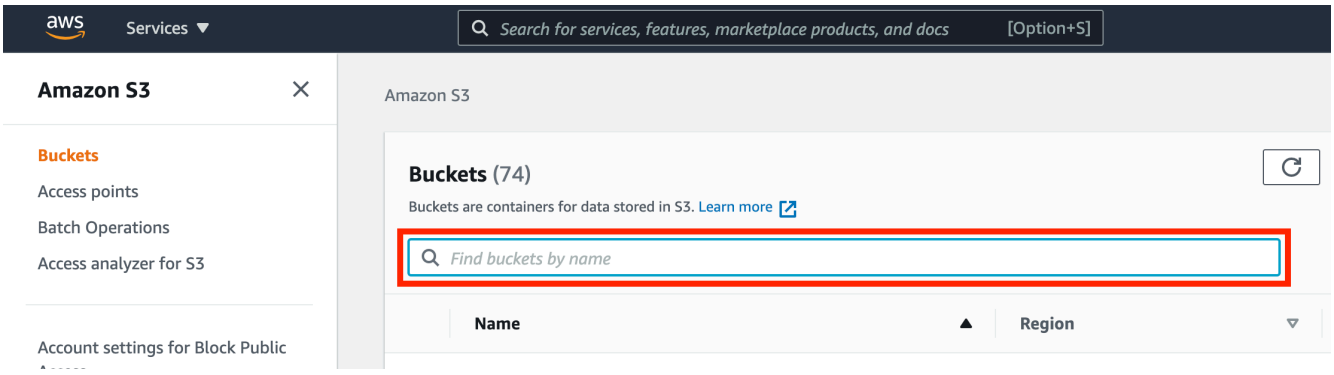
6. Under the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.html`. If using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger profiling report.



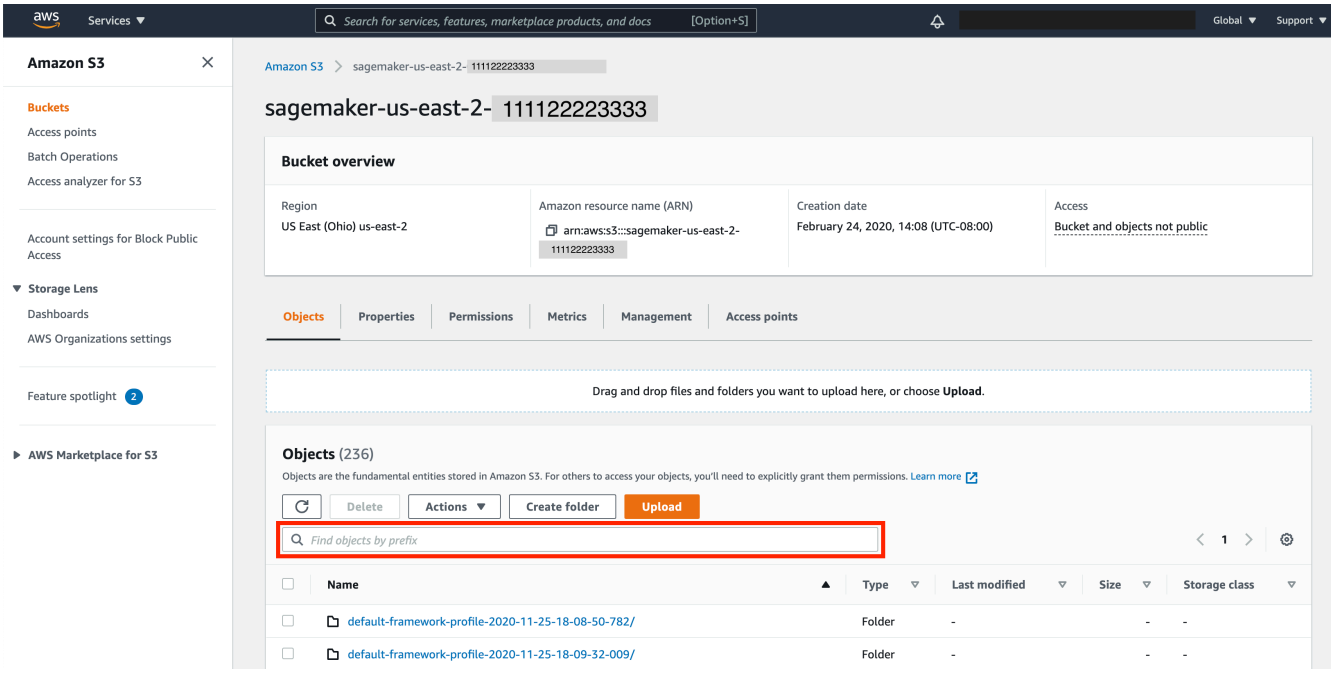
7. Open the `profiler-report.ipynb` file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

Download using Amazon S3 Console

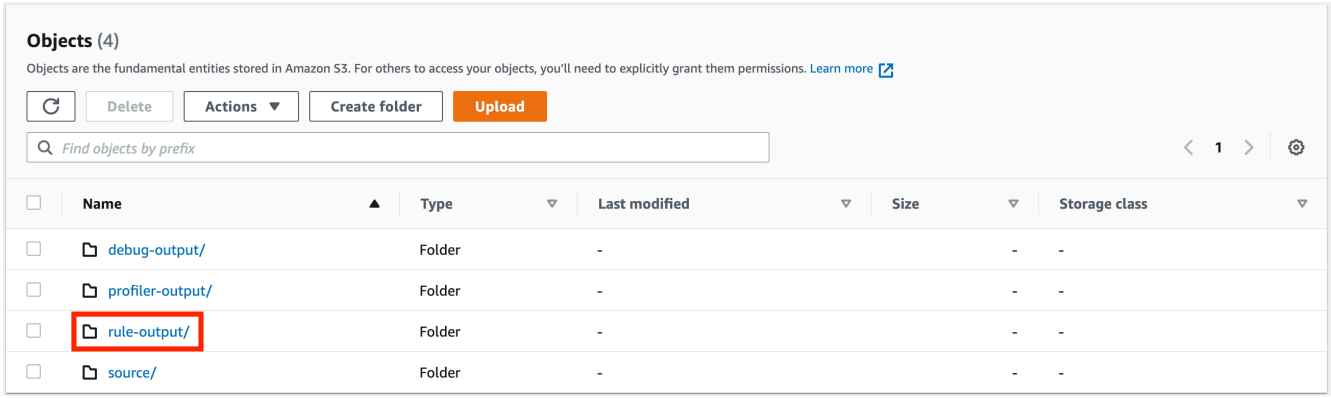
1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the *Find bucket by name* field.



3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the *Find objects by prefix* input field. Choose the training job name.



4. In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: **debug-output/**, **profiler-output/**, and **rule-output/**. Choose **rule-output/**.



5. In the **rule-output/** folder, choose **ProfilerReport-1234567890**, and choose **profiler-output/** folder. The **profiler-output/** folder contains **profiler-report.html** (the autogenerated profiling report in html), **profiler-report.ipynb** (a Jupyter notebook with scripts that are used for generating the report), and a **profiler-report/** folder (contains rule analysis JSON files that are used as components of the report).
6. Select the **profiler-report.html** file, choose **Actions**, and **Download**.

> **Note**
>
> If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker estimators. To learn how to configure the `profiler_config` parameter before starting a training job, see Configure for framework profiling.
> To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration.

Debugger profiling report walkthrough

This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

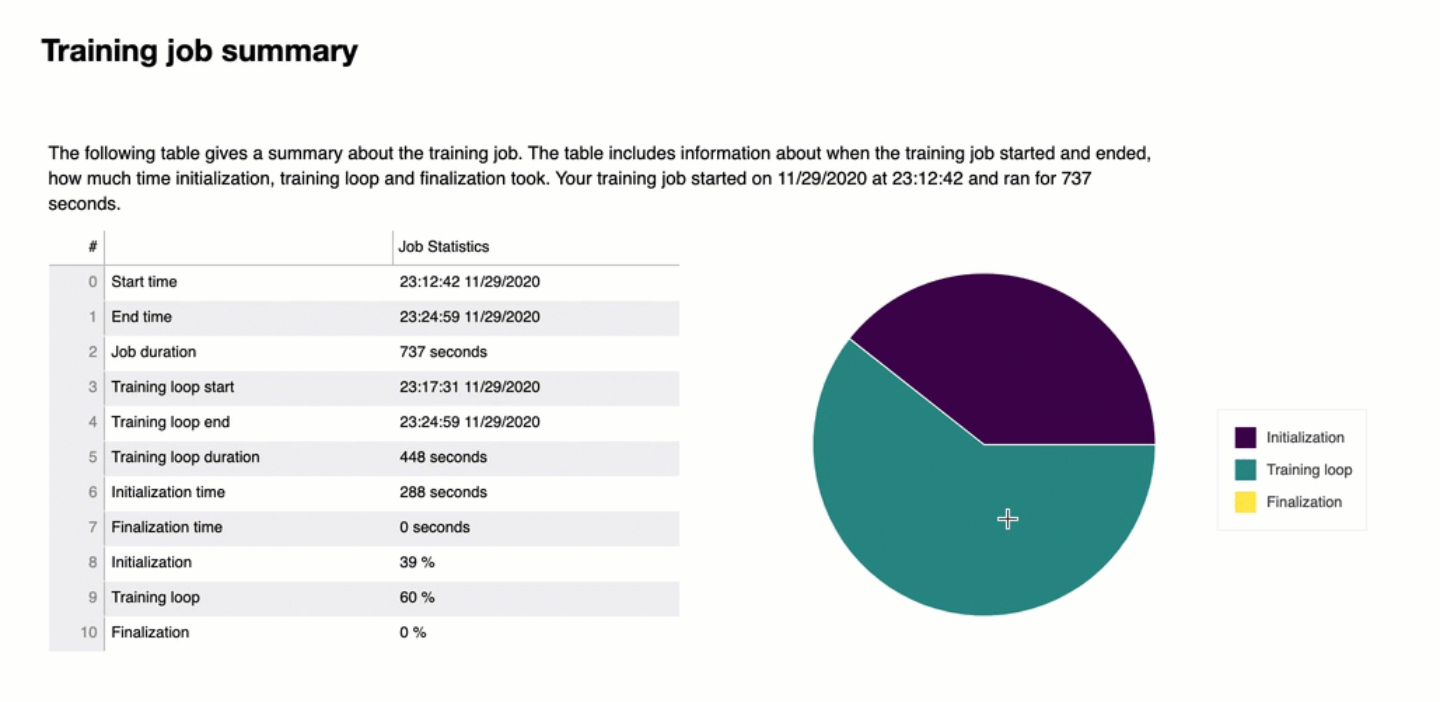
> **Important**
>
> In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics

- Batch size
- CPU bottlenecks
- I/O bottlenecks
- Load balancing in multi-GPU training
- GPU memory analysis

Training job summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.



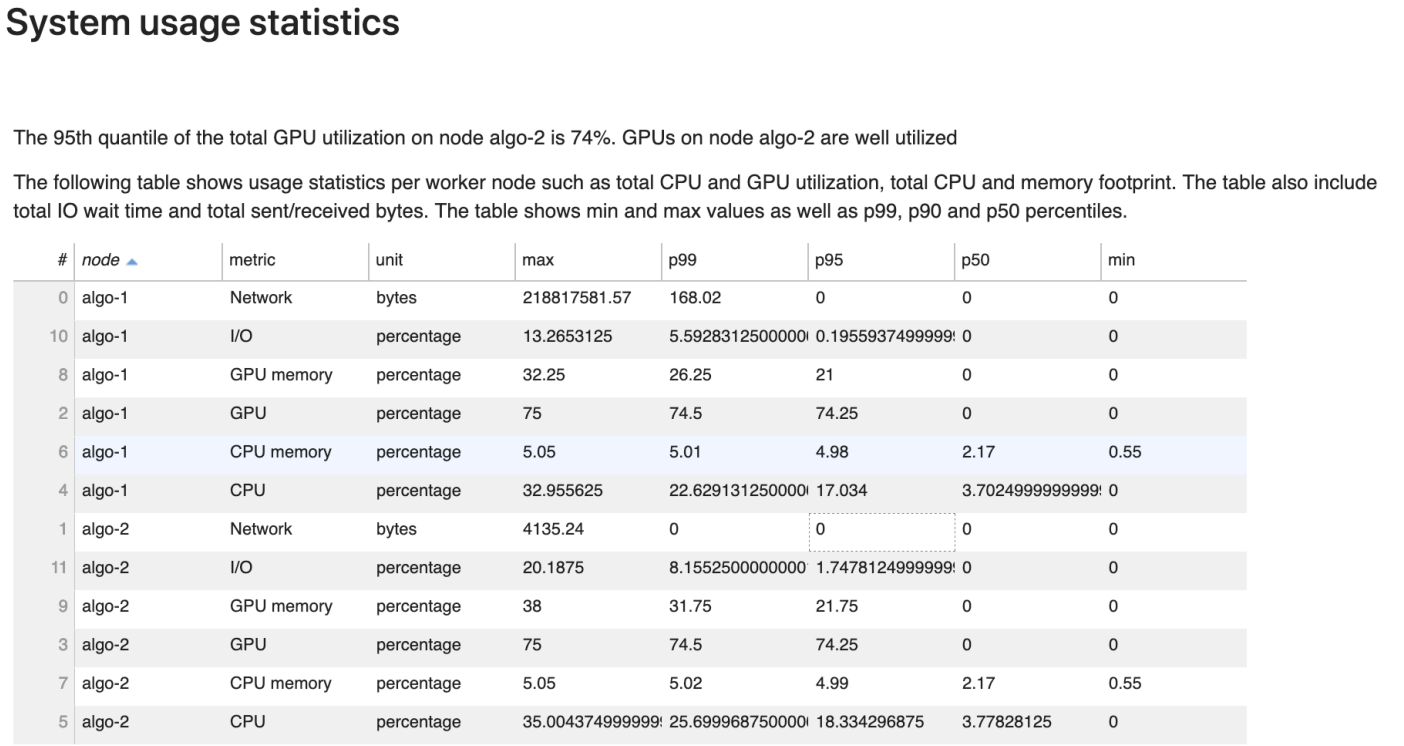
The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the **start_time** to the **end_time**.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.

- **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the **start_time** to the **training_loop_start** time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the **training_loop_end** time to the **end_time**.
- **initialization (%)** – The percentage of time spent on **initialization** over the total **job_duration_in_seconds**.
- **training loop (%)** – The percentage of time spent on **training loop** over the total **job_duration_in_seconds**.
- **finalization (%)** – The percentage of time spent on **finalization** over the total **job_duration_in_seconds**.

System usage statistics

In this section, you can see an overview of system utilization statistics.



System usage statistics

The 95th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also include total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p90 and p50 percentiles.

#	node	metric	unit	max	p99	p95	p50	min
0	algo-1	Network	bytes	218817581.57	168.02	0	0	0
10	algo-1	I/O	percentage	13.2653125	5.5928312500000	0.1955937499999	0	0
8	algo-1	GPU memory	percentage	32.25	26.25	21	0	0
2	algo-1	GPU	percentage	75	74.5	74.25	0	0
6	algo-1	CPU memory	percentage	5.05	5.01	4.98	2.17	0.55
4	algo-1	CPU	percentage	32.955625	22.629131250000	17.034	3.7024999999999	0
1	algo-2	Network	bytes	4135.24	0	0	0	0
11	algo-2	I/O	percentage	20.1875	8.1552500000000	1.7478124999999	0	0
9	algo-2	GPU memory	percentage	38	31.75	21.75	0	0
3	algo-2	GPU	percentage	75	74.5	74.25	0	0
7	algo-2	CPU memory	percentage	5.05	5.02	4.99	2.17	0.55
5	algo-2	CPU	percentage	35.004374999999	25.699968750000	18.334296875	3.77828125	0

The Debugger profiling report includes the following information:

- **node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of `algo-n`.
- **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **unit** – The unit of the system metrics.
- **max** – The maximum value of each system metric.
- **p99** – The 99th percentile of each system utilization.
- **p95** – The 95th percentile of each system utilization.
- **p50** – The 50th percentile (median) of each system utilization.
- **min** – The minimum value of each system metric.

Framework metrics summary

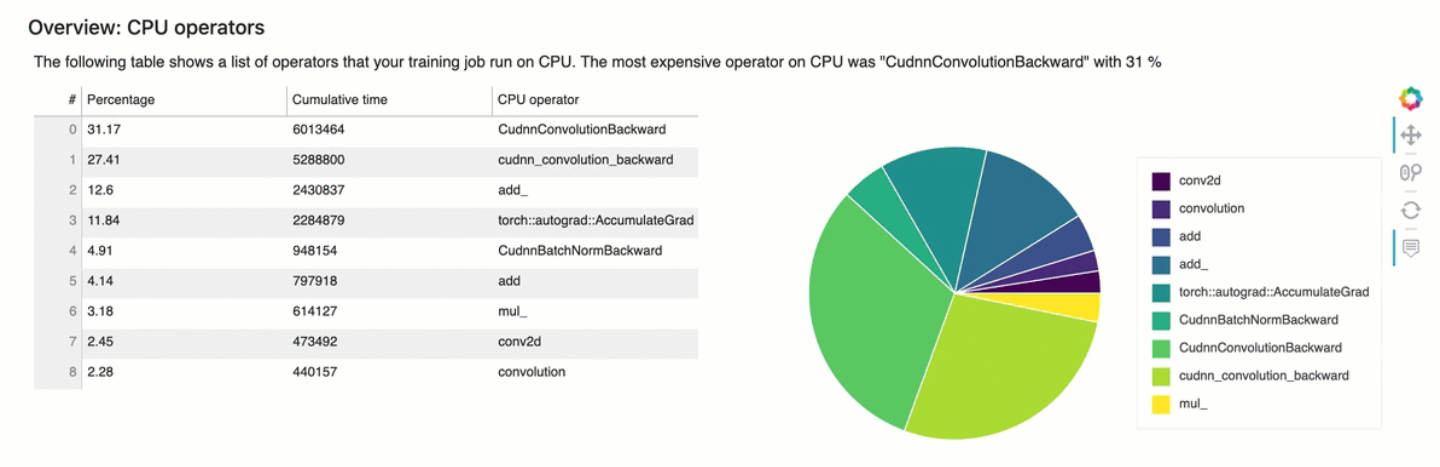
In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.

Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

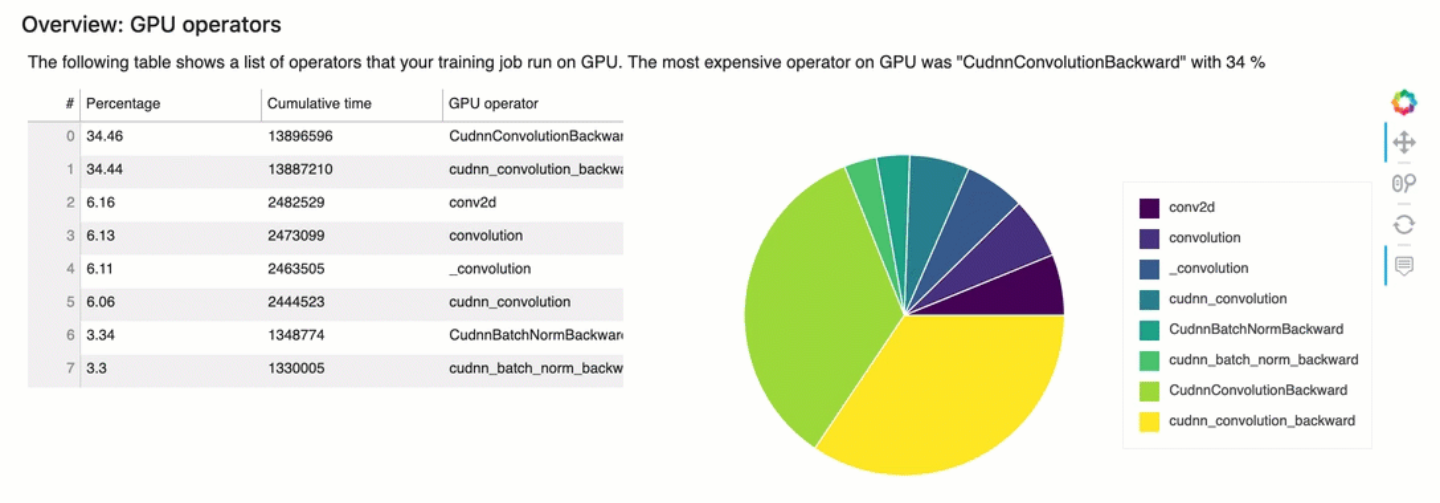
Overview: CPU Operators

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.



Overview: GPU operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.



Rules summary

In this section, Debugger aggregates all of the rule evaluation results, analysis, rule descriptions, and suggestions.

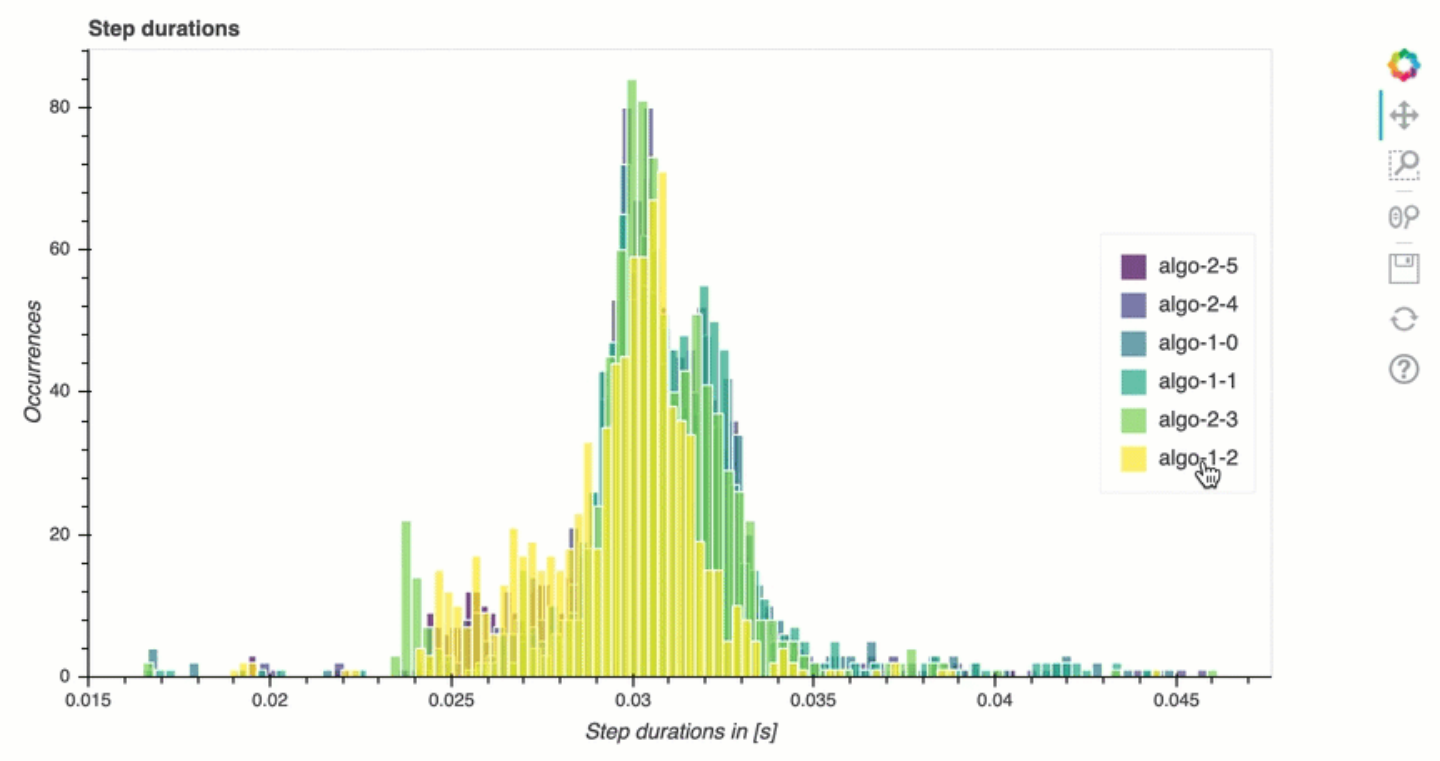
Rules summary

The following table shows a summary of the executed profiler rules. The table is sorted by the rules that triggered most frequently. In your training job this was the case for rule LoadBalancing. It has processed 5467 datapoints and triggered 263 times.

	Description	Recommendation	Number of times rule triggered	Number of datapoints	Rule parameters
LoadBalancing	Detect issues in workload balancing between multiple GPUs. Workload imbalance can for instance occur in data parallel training when gradients are accumulated on primary GPU so this GPU will be overused with regards to other GPUs limiting the effect of parallelization.	Choose different distributed training strategy or different distributed training framework	263	5467	threshold:0.2 patience:1000
LowGPUUtilization	Checks if GPU utilization is low or suffers from fluctuations. This can happen if there are bottlenecks, many blocking calls due to synchronizations or batch size too small.	Check for bottlenecks, minimize blocking calls, change distributed training strategy, increase batch-size.	244	5467	threshold_p95:70 threshold_p5:10 window:500 patience:1000
BatchSize	Checks if GPU is under-utilized because of the batch size being too small. To detect this the rule analyzes the average GPU memory footprint, CPU and GPU utilization.	Run on a smaller instance type or increase batch size	211	5466	cpu_threshold_p95:70 gpu_threshold_p95:70 gpu_memory_threshold_p95:70 patience:1000 window:500
GPUMemoryIncrease	If model and/or batch size is too large then training will run out of memory and crash.	Choose a larger instance type with more memory (if it is not a memory leak) or apply model parallelism (Rubik)	25	5467	increase:5 patience:1000 window:10
CPUBottleneck	Checks if CPU usage is high but GPU usage is low at the same time, it may indicate a CPU bottleneck where GPU is waiting for data to arrive from CPU. The rule triggers if number of CPU bottlenecks exceeds a predefined threshold.	CPU bottlenecks can happen when data preprocessing is very compute intensive. You should consider increasing the number of data-loader processes or apply pre-fetching.	18	10938	threshold:50 cpu_threshold:90 gpu_threshold:10 patience:1000
IOBottleneck	If IO wait time is high but at the same time GPU usage is low, it may indicate an IO bottleneck where GPU is waiting for data to arrive from disk. The rule triggers if number of IO bottlenecks exceeds a predefined threshold.	Pre-fetch data or choose different file formats such as binary formats which improves read performance.	0	10938	threshold:50 io_threshold:50 gpu_threshold:10 patience:1000
StepOutlier	Detect outliers in step duration. Time for forward and backward pass should be roughly the same throughout the training. If there are significant outliers it would indicate an issue due to a system stall or a bottleneck.	Check for bottlenecks	0	4803	threshold:3 mode:None n_outliers:10 stddev:3
MaxInitializationTime	Checks if the training initialization is taking too much time. The rule waits until first step is available. This can happen if you are running in File mode and a lot of data needs to be downloaded from Amazon S3.	Switch from File to Pipe mode	0	4803	threshold:20

Analyzing the training loop – step durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.



GPU utilization analysis

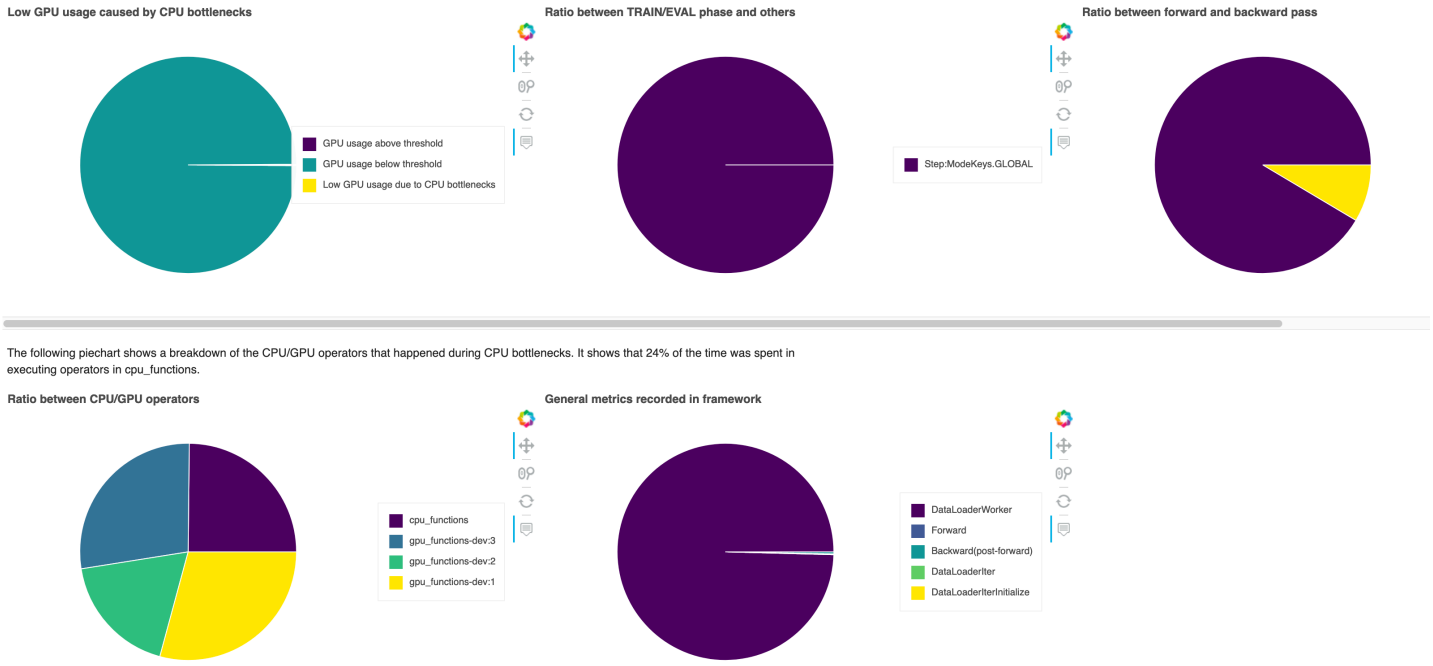
This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

CPU bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above `cpu_threshold` (90% by default) and also if the GPU utilization is below `gpu_threshold` (10% by default).



The pie charts show the following information:

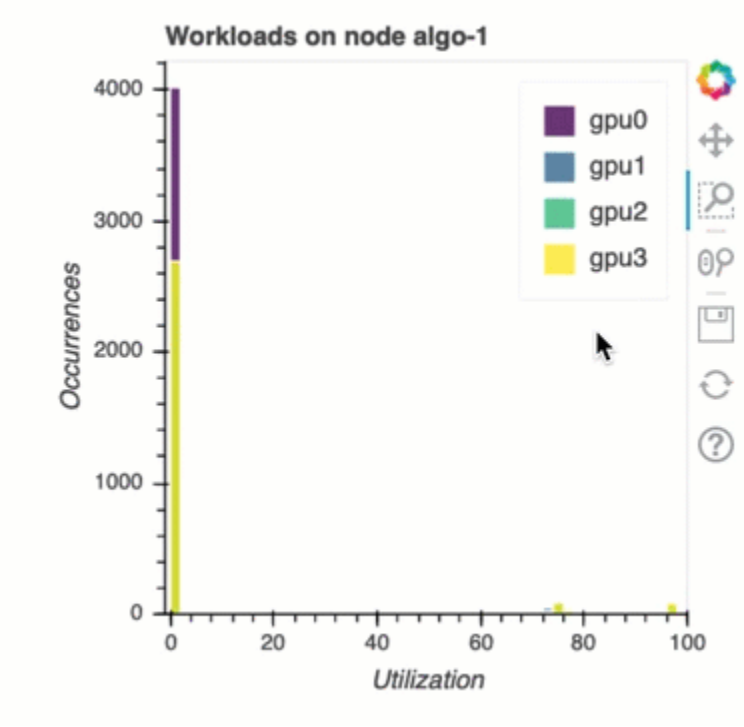
- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.
- **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

I/O bottlenecks

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

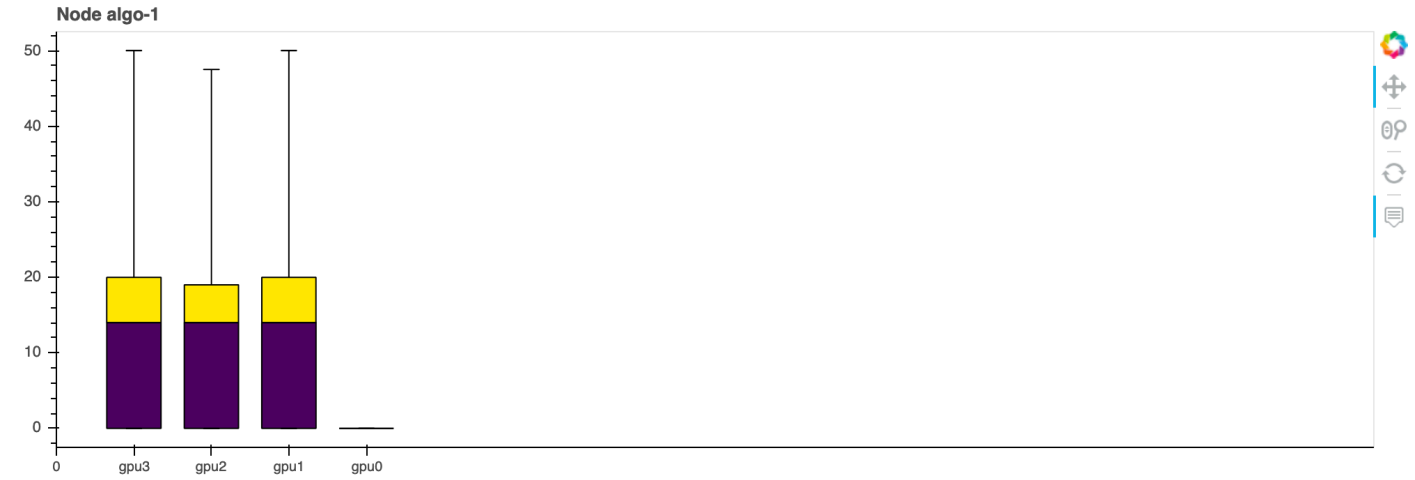
Load balancing in multi-GPU training

In this section, you can identify workload balancing issue across GPUs.



GPU memory analysis

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.



Analyze data using the Debugger Python client library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The Debugger Python client library provides analysis and visualization tools that enable you to drill down into your training job data.

To install the library and use its analysis tools (in a JupyterLab notebook or an iPython kernel)

```
! pip install -U smdebug
```

The following topics walk you through how to use the Debugger Python tools to visualize and analyze the training data collected by Debugger.

Analyze system and framework metrics

- Access the profile data
- Plot the system metrics and framework metrics data
- Access the profiling data using the pandas data parsing tool
- Access the Python profiling stats data
- Merge timelines of multiple profile trace files
- Profiling data loaders

Access the profile data

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

To set up a `TrainingJob` object and retrieve profiling event files of a training job

```
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

> **Tip**
>
> You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

Note

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.

- If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see Configure SageMaker Debugger Framework Profiling.
- If you use Studio Classic, turn on profiling using the **Profiling** toggle button in the Debugger insights dashboard. To learn more, see SageMaker Debugger Insights Dashboard Controller.

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

To check if the system and framework metrics are available from the S3 URI

```
tj.wait_for_sys_profiling_data_to_be_available()
```

```
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

Plot the system metrics and framework metrics data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

> **Note**
>
> To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=["GPU"]`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=["total"]`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- The `MetricsHistogram` class

```
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import
 MetricsHistogram

metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
```

```
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"]                  # optional
)
```

- The `StepTimelineChart` class

```
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import
 StepTimelineChart

view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

- The `StepHistogram` class

```
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram

step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)
```

- The `TimelineCharts` class

```
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts

view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"]                  # optional
)

view_timeline_charts.plot_detailed_profiler_data([700,710])
```

- The `Heatmap` class

```
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap

view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
```

```
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"],                 # optional
    plot_height=450
)
```

Access the profiling data using the pandas data parsing tool

The following `PandasFrame` class provides tools to convert the collected profiling data to Pandas data frame.

```
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame
```

The `PandasFrame` class takes the `tj` object's S3 bucket output path, and its methods `get_all_system_metrics()` `get_all_framework_metrics()` return system metrics and framework metrics in the Pandas data format.

```
pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics(
    selected_framework_metrics=[
        'Step:ModeKeys.TRAIN',
        'Step:ModeKeys.GLOBAL'
    ]
)
```

Access the Python profiling stats data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- `PythonProfileModes.TRAIN` – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- `PythonProfileModes.EVAL` – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- `PythonProfileModes.PREDICT` – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- `PythonProfileModes.GLOBAL` – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- `PythonProfileModes.PRE_STEP_ZERO` – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- `PythonProfileModes.POST_HOOK_CLOSE` – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- `StepPhase.START` – Use to specify the start point of the initialization phase.
- `StepPhase.STEP_START` – Use to specify the start step of the training phase.
- `StepPhase.FORWARD_PASS_END` – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- `StepPhase.STEP_END` – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- `StepPhase.END` – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

Python Profiling Analysis Tools

Debugger supports the Python profiling with two profiling tools:

- cProfile – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.
- Pyinstrument – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see Start a training job with the default system monitoring and customized framework profiling with different profiling options.

The following methods of the `PythonProfileAnalysis`, `cProfileAnalysis`, `PyinstrumentAnalysis` classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis,
 cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the cProfileAnalysis or PyinstrumentAnalysis classes as shown in the following example code. It shows how to set a `cProfileAnalysis` object, and if you want to use `PyinstrumentAnalysis`, replace the class name.

```
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the `cProfileAnalysis` and `PyinstrumentAnalysis` classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_se end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled `step` satisfies `start_step <= step < end_step`.

- `start_step` and `end_step` (str) – Specify the start step and end step to fetch the Python profiling stats data.
- `mode` (str) – Specify the mode of training job using the `PythonProfileModes` enumerator class. The default is `PythonProfileModes.TRAIN`. Available options are provided in the Training Modes and Phases for Python Profiling section.
- `start_phase` (str) – Specify the start phase in the target step(s) using the `StepPhase` enumerator class. This parameter enables profiling between different phases of training. The default is `StepPhase.STEP_START`. Available options are provided in the Training Modes and Phases for Python Profiling section.
- `end_phase` (str) – Specify the end phase in the target step(s) using the `StepPhase` enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the `start_phase` parameter. The default is `StepPhase.STEP_END`. Available options are provided in the Training Modes and Phases for Python Profiling section.

- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches stats from the Python profiling between the start and end modes.
- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.
- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.
- `python_analysis.list_profile_stats()` – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).
- `python_analysis.list_available_node_ids()` – Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

- `fetch_profile_stats_by_training_phase()` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are `(PRE_STEP_ZERO, TRAIN)`, `(TRAIN, TRAIN)`, `(TRAIN, EVAL)`, `(EVAL, EVAL)`, and `(EVAL, POST_HOOK_CLOSE)`. All stats files within each of these combinations are aggregated.

- `fetch_profile_stats_by_job_phase()` – Fetches and aggregates the Python profiling stats by job phase. The job phases are `initialization` (profiling until step 0), `training_loop` (training and validation), and `finalization` (profiling after the hook is closed).

Merge timelines of multiple profile trace files

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

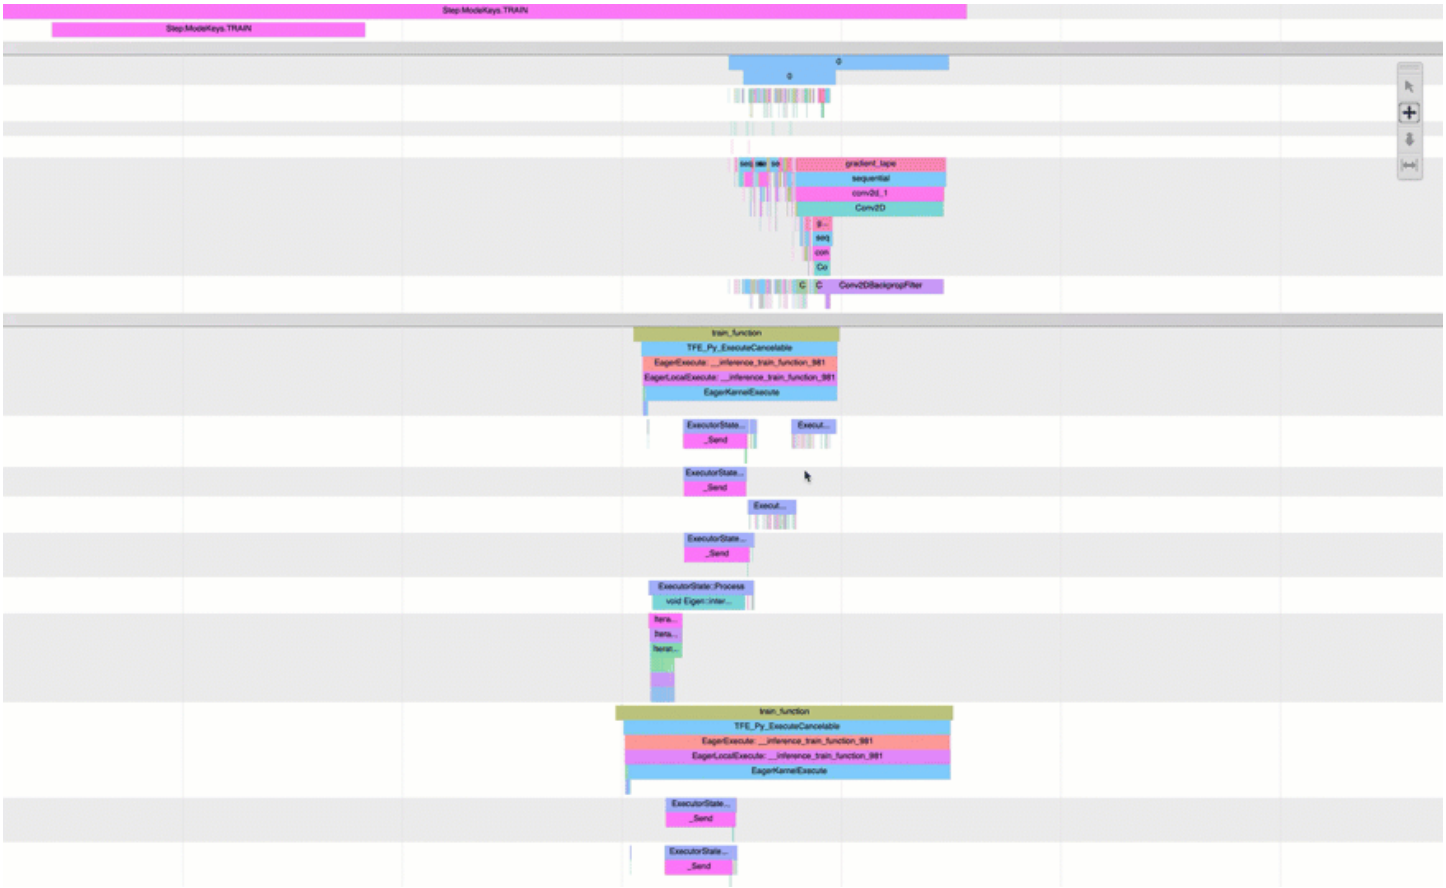
> **Tip**
>
> Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the profile data.

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- Tensorflow profiler saves events in a `*trace.json.gz` file.

> **Tip**
>
> If you want to list all of the JSON trace files, use the following AWS CLI command:
>
> ```
> ! aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
> ```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.



Tip

To interact with the merged timeline on the traicing app using a keyboard, use the `W` key for zooming in, the `A` key for shifting to the left, the `S` key for zooming out, and the `D` key for shifiting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following `MergedTimeline` API operation and class method from the `smdebug.profiler.analysis.utils.merge_timelines` module.

```
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The `MergedTimeline` API operation passes the following parameters:

- `path` (str) – Specify a root folder (`/profiler-output`) that contains system and framework profiling trace files. You can locate the `profiler-output` using the SageMaker estimator classmethod or the TrainingJob object. For example, `estimator.latest_job_profiler_artifacts_path()` or `tj.profiler_s3_output_path`.
- `file_suffix_filter` (list) – Specify a list of file suffix filters to merge timelines. Available suffiex filters are `["model_timeline.json", "pythontimeline.json", "trace.json.gz"]`. If this parameter is not manually specified, all of the trace files are merged by default.
- `output_directory` (str) – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the `path` parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- `start` (int) – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- end (int) – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
- `unit` (str) – Choose between `"time"` and `"step"`. The default is `"time"`.

Using the following example codes, execute the `merge_timeline()` method and download the merged JSON file.

- Merge timeline with the `"time"` unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

- Merge timeline with the `"step"` unit option. The following example code merges all available timelines between step 3 and step 9.

```
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at `chrome://tracing` on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

Profiling data loaders

In PyTorch, data loader iterators, such as `SingleProcessingDataLoaderIter` and `MultiProcessingDataLoaderIter`, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import
 PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the profiling data using the pandas data parsing tool section:

```
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The SMDebug `S3SystemMetricsReader` class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

- `pt_analysis.analyze_dataloaderIter_initialization()`

  The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.

  The following list shows what analysis is available from this class method:

  - Which type of data loader iterators were initialized.

  - The number of workers per iterator.
  - Inspect whether the iterator was initialized with or without pin_memory.
  - Number of times the iterators were initialized during training.
- `pt_analysis.analyze_dataloaderWorkers()`

  The following list shows what analysis is available from this class method:

  - The number of worker processes that were spun off during the entire training.
  - Median and maximum duration for the worker processes.
  - Start and end time for the worker processes that are outliers.
- `pt_analysis.analyze_dataloader_getnext()`

  The following list shows what analysis is available from this class method:

  - Number of GetNext calls made during the training.
  - Median and maximum duration in microseconds for GetNext calls.
  - Start time, End time, duration and worker id for the outlier GetNext call duration.
- `pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=[".*"], select_dimensions=[".*"])`

  Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

  The following list shows what analysis is available from this class method:

  - Profile time spent on each data batch, `BatchTime_in_seconds`, by finding the difference between start times of current and subsequent GetNext calls.
  - Find the outliers in `BatchTime_in_seconds` and start and end time for those outliers.
  - Obtain the system and framework metrics during those `BatchTime_in_seconds` timestamps. This indicates where the time was spent.
- `pt_analysis.plot_the_window()`

  Plots a timeline charts between a start timestamp and the end timestamp.

Release notes for profiling capabilities of Amazon SageMaker

See the following release notes to track the latest updates for profiling capabilities of Amazon SageMaker.

March 21, 2024

Currency updates

SageMaker Profiler has added support for PyTorch v2.2.0, v2.1.0, and v2.0.1.

AWS Deep Learning Containers pre-installed with SageMaker Profiler

SageMaker Profiler is packaged in the following AWS Deep Learning Containers.

- SageMaker Framework Container for PyTorch v2.2.0
- SageMaker Framework Container for PyTorch v2.1.0
- SageMaker Framework Container for PyTorch v2.0.1

December 14, 2023

Currency updates

SageMaker Profiler has added support for TensorFlow v2.13.0.

Breaking changes

This release involves a breaking change. The SageMaker Profiler Python package name is changed from `smppy` to `smprof`. If you have been using the previous version of the package while you have started using the latest SageMaker Framework Containers for TensorFlow listed in the following section, make sure that you update the package name from `smppy` to `smprof` in the import statement in your training script.

AWS Deep Learning Containers pre-installed with SageMaker Profiler

SageMaker Profiler is packaged in the following AWS Deep Learning Containers.

- SageMaker Framework Container for TensorFlow v2.13.0
- SageMaker Framework Container for TensorFlow v2.12.0

If you use the previous versions of the framework containers such TensorFlow v2.11.0, the SageMaker Profiler Python package is still available as `smppy`. If you are uncertain which version or the package name you should use, replace the import statement of the SageMaker Profiler package with the following code snippet.

```
try:
    import smprof
except ImportError:
    # backward-compatability for TF 2.11 and PT 1.13.1 images
    import smppy as smprof
```

August 24, 2023

New features

Released Amazon SageMaker Profiler, a profiling and visualization capability of SageMaker to deep dive into compute resources provisioned while training deep learning models and gain visibility into operation-level details. SageMaker Profiler provides Python modules (`smppy`) for adding annotations throughout PyTorch or TensorFlow training scripts and activating SageMaker Profiler. You can access the modules through the SageMaker Python SDK and AWS Deep Learning Containers. For any jobs run with the SageMaker Profiler Python modules, you can load the profile data in the SageMaker Profiler UI application that provides a summary dashboard and a detailed timeline. To learn more, see Use Amazon SageMaker Profiler to profile activities on AWS compute resources.

This release of the SageMaker Profiler Python package is integrated into the following SageMaker Framework Containers for PyTorch and TensorFlow.

- PyTorch v2.0.0
- PyTorch v1.13.1
- TensorFlow v2.12.0
- TensorFlow v2.11.0

Distributed training in Amazon SageMaker

SageMaker provides distributed training libraries and supports various distributed training options for deep learning tasks such as computer vision (CV) and natural language processing (NLP). With

SageMaker's distributed training libraries, you can run highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs. You can also use other distributed training frameworks and packages such as PyTorch DistributedDataParallel (DDP), `torchrun`, MPI (`mpirun`), and parameter server. Throughout the documentation, instructions and examples focus on how to set up the distributed training options for deep learning tasks using the SageMaker Python SDK.

> **Tip**
>
> To learn best practices for distributed computing of machine learning (ML) training and processing jobs in general, see Distributed computing with SageMaker best practices.

Before you get started

SageMaker Training supports distributed training on a single instance as well as multiple instances, so you can run any size of training at scale. We recommend you to use the framework estimator classes such as PyTorch and TensorFlow in the SageMaker Python SDK, which are the training job launchers with various distributed training options. When you create an estimator object, the object sets up distributed training infrastructure, runs the `CreateTrainingJob` API in the backend, finds the Region where your current session is running, and pulls one of the pre-built AWS deep learning container prepackaged with a number of libraries including deep learning frameworks, distributed training frameworks, and the EFA driver. If you want to mount an FSx file system to the training instances, you need to pass your VPC subnet and security group ID to the estimator. Before running your distributed training job in SageMaker, read the following general guidance on the basic infrastructure setup.

Availability zones and network backplane

When using multiple instances (also called*nodes*), it's important to understand the network that connects the instances, how they read the training data, and how they share information between themselves. For example, when you run a distributed data-parallel training job, a number of factors, such as communication between the nodes of a compute cluster for running the `AllReduce` operation and data transfer between the nodes and data storage in Amazon Simple Storage Service or Amazon FSx for Lustre, play a crucial role to achieve an optimal use of compute resources and a faster training speed. To reduce communication overhead, make sure that you configure instances, VPC subnet, and data storage in the same AWS Region and Availability Zone.

GPU instances with faster network and high-throughput storage

You can technically use any instances for distributed training. For cases where you need to run multi-node distributed training jobs for training large models, such as large language models (LLMs) and diffusion models, which require faster inter-node commutation, we recommend EFA-enabled GPU instances supported by SageMaker. Especially, to achieve the most performant distributed training job in SageMaker, we recommend P4d and P4de instances equipped with NVIDIA A100 GPUs. These are also equipped with high-throughput low-latency local instance storage and faster intra-node network. For data storage, we recommend Amazon FSx for Lustre that provides high throughput for storing training datasets and model checkpoints.

Get started with distributed training in Amazon SageMaker

If you're already familiar with distributed training, choose one of the following options that matches your preferred strategy or framework to get started. If you want to learn about distributed training in general, see the section called "Basic distributed training concepts".

The SageMaker distributed training libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker, and improve training speed and throughput. The libraries offer both data parallel and model parallel training strategies. They combine software and hardware technologies to improve inter-GPU and inter-node communications, and extend SageMaker's training capabilities with built-in options that require minimal code changes to your training scripts.

Use the SageMaker distributed data parallelism (SMDDP) library

The SMDDP library improves communication between nodes with implementations of `AllReduce` and `AllGather` collective communication operations that are optimized for AWS network infrastructure and Amazon SageMaker ML instance topology. You can use the SMDDP library as the backend of PyTorch-based distributed training packages: PyTorch distributed data parallel (DDP), PyTorch fully sharded data parallelism (FSDP), DeepSpeed, and Megatron-DeepSpeed. The following code example shows how to set a `PyTorch` estimator for launching a distributed training job on two `ml.p4d.24xlarge` instances.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...,
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
```

```
    # Activate distributed training with SMDDP
    distribution={ "pytorchddp": { "enabled": True } }  # mpirun, activates SMDDP
 AllReduce OR AllGather
    # distribution={ "torch_distributed": { "enabled": True } }  # torchrun, activates
 SMDDP AllGather
    # distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }  #
 mpirun, activates SMDDP AllReduce OR AllGather
)
```

To learn how to prepare your training script and launch a distributed data-parallel training job on SageMaker, see the section called “SageMaker distributed data parallelism library”.

Use the SageMaker model parallelism library (SMP)

SageMaker provides the SMP library and supports various distributed training techniques, such as sharded data parallelism, pipelining, tensor parallelism, optimizer state sharding, and more. To learn more about what the SMP library offers, see the section called “Core Features”.

To use SageMaker's model parallelism library, configure the `distribution` parameter of the SageMaker framework estimators. Supported framework estimators are PyTorch and TensorFlow. The following code example shows how to construct a framework estimator for distributed training with the model parallelism library on two `ml.p4d.24xlarge` instances.

```
from sagemaker.framework import Framework

distribution={
    "smdistributed": {
        "modelparallel": {
            "enabled":True,
            "parameters": {
                ...   # enter parameter key-value pairs here
            }
        },
    },
    "mpi": {
        "enabled" : True,
        ...           # enter parameter key-value pairs here
    }
}

estimator = Framework(
    ...,
    instance_count=2,
```

```
    instance_type="ml.p4d.24xlarge",
    distribution=distribution
)
```

To learn how to adapt your training script, configure distribution parameters in the `estimator` class, and launch a distributed training job, see SageMaker's model parallelism library (see also Distributed Training APIs in the *SageMaker Python SDK documentation*).

Use open source distributed training frameworks

SageMaker also supports the following options to operate `mpirun` and `torchrun` in the backend.

- To use PyTorch DistributedDataParallel (DDP) in SageMaker with the `mpirun` backend, add `distribution={"pytorchddp": {"enabled": True}}` to your PyTorch estimator. For more information, see also PyTorch Distributed Training and SageMaker PyTorch Estimator's `distribution` argument in the *SageMaker Python SDK documentation*.

  > **Note**
  >
  > This option is available for PyTorch 1.12.0 and later.

  ```
  from sagemaker.pytorch import PyTorch

  estimator = PyTorch(
      ...,
      instance_count=2,
      instance_type="ml.p4d.24xlarge",
      distribution={"pytorchddp": {"enabled": True}}  # runs mpirun in the backend
  )
  ```

- SageMaker supports the PyTorch `torchrun` launcher for distributed training on GPU-based Amazon EC2 instances, such as P3 and P4, as well as Trn1 powered by the AWS Trainium device.

  To use PyTorch DistributedDataParallel (DDP) in SageMaker with the `torchrun` backend, add `distribution={"torch_distributed": {"enabled": True}}` to the PyTorch estimator.

  > **Note**
  >
  > This option is available for PyTorch 1.13.0 and later.

The following code snippet shows an example of constructing a SageMaker PyTorch estimator to run distributed training on two `ml.p4d.24xlarge` instances with the `torch_distributed` distribution option.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...,
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution={"torch_distributed": {"enabled": True}}   # runs torchrun in the
 backend
)
```

For more information, see Distributed PyTorch Training and SageMaker PyTorch Estimator's `distribution` argument in the *SageMaker Python SDK documentation*.

Notes for distributed training on Trn1

A Trn1 instance consists of up to 16 Trainium devices, and each Trainium device consists of two NeuronCores. For specs of the AWS Trainium devices, see Trainium Architecture in the *AWS Neuron Documentation*.

To train on the Trainium-powered instances, you only need to specify the Trn1 instance code, `ml.trn1.*`, in string to the `instance_type` argument of the SageMaker PyTorch estimator class. To find available Trn1 instance types, see AWS Trn1 Architecture in the *AWS Neuron documentation*.

> **Note**
>
> SageMaker Training on Amazon EC2 Trn1 instances is currently available only for the PyTorch framework in the AWS Deep Learning Containers for PyTorch Neuron starting v1.11.0. To find a complete list of supported versions of PyTorch Neuron, see Neuron Containers in the *AWS Deep Learning Containers GitHub repository*.

When you launch a training job on Trn1 instances using the SageMaker Python SDK, SageMaker automatically picks up and runs the right container from Neuron Containers provided by AWS

Deep Learning Containers. The Neuron Containers are prepackaged with training environment settings and dependencies for easier adaptation of your training job to the SageMaker Training platform and Amazon EC2 Trn1 instances.

> **Note**
>
> To run your PyTorch training job on Trn1 instances with SageMaker, you should modify your training script to initialize process groups with the `xla` backend and use PyTorch/XLA. To support the XLA adoption process, the AWS Neuron SDK provides PyTorch Neuron that uses XLA to make conversion of PyTorch operations to Trainium instructions. To learn how to modify your training script, see Developer Guide for Training with PyTorch Neuron (`torch-neuronx`) in the *AWS Neuron Documentation*.

For more information, see Distributed Training with PyTorch Neuron on Trn1 instances and SageMaker PyTorch Estimator's `distribution` argument in the *SageMaker Python SDK documentation*.

- To use MPI in SageMaker, add `distribution={"mpi": {"enabled": True}}` to your estimator. The MPI distribution option is available for the following frameworks: MXNet, PyTorch, and TensorFlow.
- To use a parameter server in SageMaker, add `distribution={"parameter_server": {"enabled": True}}` to your estimator. The parameter server option is available for the following frameworks: MXNet, PyTorch, and TensorFlow.

> **Tip**
>
> For more information about using the MPI and parameter server options per framework, use the following links to the *SageMaker Python SDK documentation*.
>
> - MXNet Distributed Training and SageMaker MXNet Estimator's `distribution` argument
> - PyTorch Distributed Training and SageMaker PyTorch Estimator's `distribution` argument
> - TensorFlow Distributed Training and SageMaker TensorFlow Estimator's `distribution` argument.

Basic distributed training concepts

SageMaker's distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.
- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: `global batch size = (the number of model replicas) * (per-replica batch size)`. A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
- **Per-replica batch size:** When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used , it is a subset of the per-replica sized batch . When you use SageMaker's distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an execution schedule defined by the library's runtime.

Training

- **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.
- **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.
- **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

Instances and GPUs

- **Instances**: An AWS machine learning compute instance. These are also referred to as *nodes*.
- **Cluster size**: When using SageMaker's distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between Amazon EC2 ML compute instances, leading to higher device utilization and faster training times.

Distributed Training Solutions

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple GPUs in a compute cluster, which consists of multiple Amazon EC2 ML Instances. Each GPU contains a *replica* of the model, receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.
- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple GPUs in a compute cluster, which consists of multiple Amazon EC2 ML Instances. The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single instance. Each GPU carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.
- **Pipeline Execution Schedule** (**Pipelining**): The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

Advanced concepts

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: *scaling model size* and *scaling training data*. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well because they need to ingest all the training data *in memory* for training. They only scale vertically, and to bigger and bigger instance types. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called *mini-batches*. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an *epoch*. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called *data parallel distributed training*, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called *allreduce* that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware subtracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, such as a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called *model-parallel distributed training*.

Strategies

Distributed training is usually split by two approaches: data parallel and model parallel. *Data parallel* is the most common approach to distributed training: You have a lot of data, batch it up,

and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A *model parallel* approach is used with large models that won't fit in a node's memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms *network* and *model* are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you're also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker's distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

Train with data parallel and model parallel

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (FP16, INT8):

- On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and memory consumption reduction.
- SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level

modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the *NVIDIA Deep Learning Performance documentation*
- Frameworks - TensorFlow in the *NVIDIA Deep Learning Performance documentation*
- Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the *PyTorch Blog*
- TensorFlow mixed precision APIs in the *TensorFlow documentation*

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

- Your model does not fit on a single device.
- Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:

- Run distributed training with the SageMaker distributed data parallelism library
- (Archived) SageMaker model parallelism library v1.x

Optimize distributed training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework's distributed training documentation.

- Apache MXNet distributed training
- PyTorch distributed training
- TensorFlow distributed training

Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

> **Tip**
>
> Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-batch size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.

Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer that you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a `p3.16xlarge` that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on `p3.2xlarge` with one GPU.

Instance type	GPUs
p3.2xlarge	1
p3.8xlarge	4
p3.16xlarge	8
p3dn.24xlarge	8

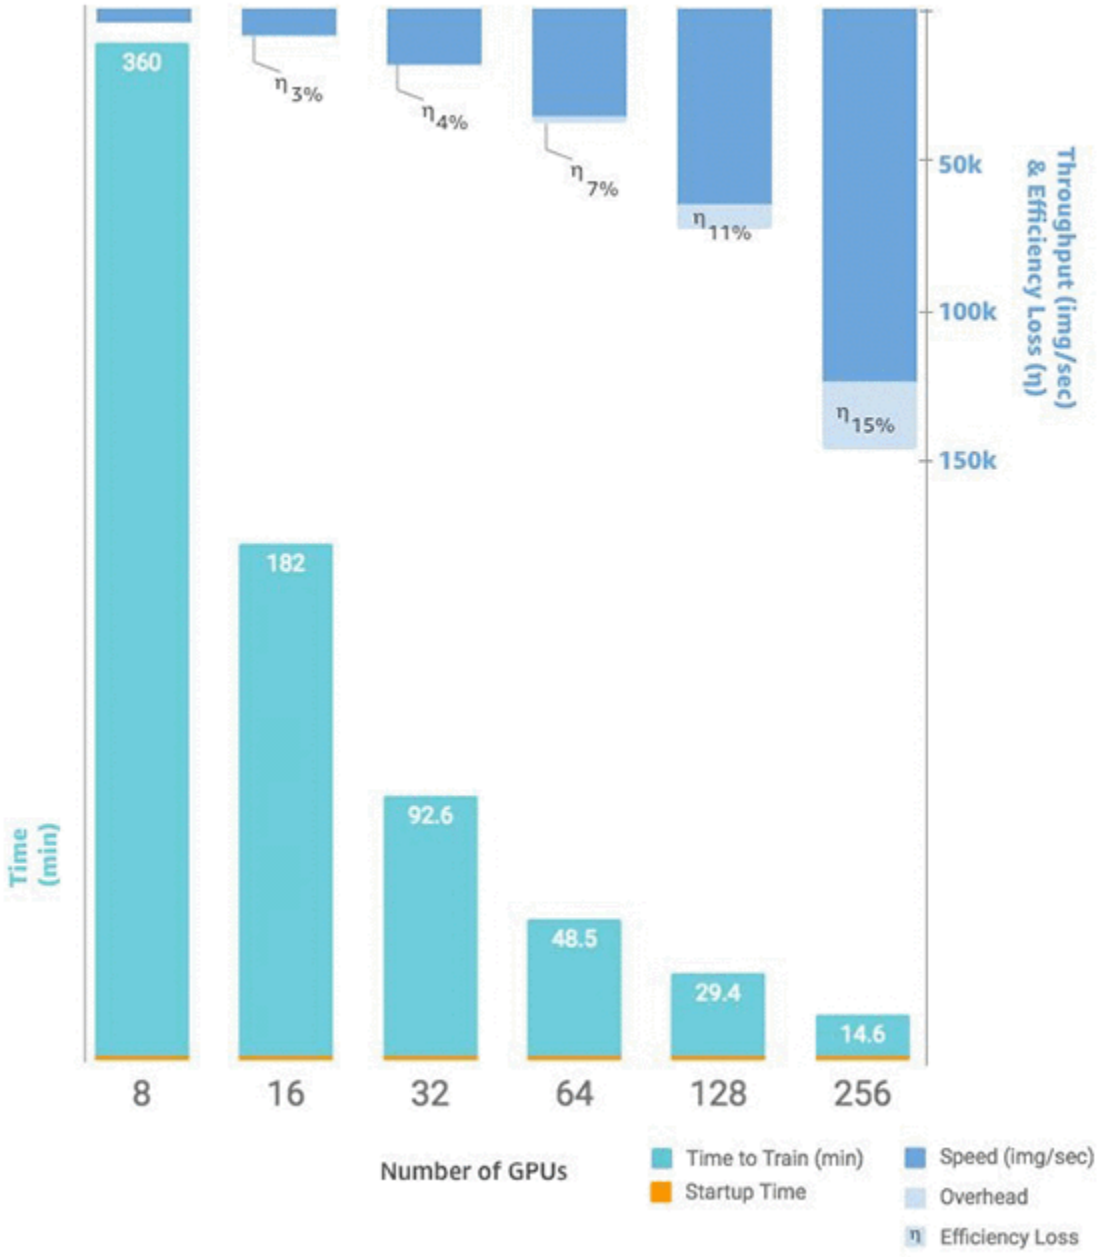
> **Note**
>
> The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, `ml.p3.8xlarge` has the same number of GPUs as `p3.8xlarge` - 4.

Scaling from a single instance to multiple instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a `p3.2xlarge` to four GPUs on a `p3.8xlarge`, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a `p3.16xlarge` before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK `estimator` function by setting your `instance_count`. For example, you can set `instance_type = p3.16xlarge` and `instance_count = 2`. Instead of the eight GPUs on a single `p3.16xlarge`, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.



Custom training scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker's container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

Run distributed training with the SageMaker distributed data parallelism library

The SageMaker distributed data parallelism (SMDDP) library extends SageMaker training capabilities on deep learning models with near-linear scaling efficiency by providing implementations of collective communication operations optimized for AWS infrastructure.

When training large machine learning (ML) models, such as large language models (LLM) and diffusion models, on a huge training dataset, ML practitioners use clusters of accelerators and distributed training techniques to reduce the time to train or resolve memory constraints for models that cannot fit in each GPU memory. ML practitioners often start with multiple accelerators on a single instance and then scale to clusters of instances as their workload requirements increase. As the cluster size increases, so does the communication overhead between multiple nodes, which leads to drop in overall computational performance.

To address such overhead and memory problems, the SMDDP library offers the following.

- The SMDDP library optimizes training jobs for AWS network infrastructure and Amazon SageMaker ML instance topology.
- The SMDDP library improves communication between nodes with implementations of `AllReduce` and `AllGather` collective communication operations that are optimized for AWS infrastructure.

To learn more about the details of the SMDDP library offerings, proceed to the section called "Introduction to the SMDDP library".

For more information about training with the model-parallel strategy offered by SageMaker, see also (Archived) SageMaker model parallelism library v1.x.

Introduction to the SageMaker distributed data parallelism library

The SageMaker distributed data parallelism (SMDDP) library is a collective communication library that improves compute performance of distributed data parallel training. The SMDDP library addresses communications overhead of the key collective communication operations by offering the following.

1. The library offers `AllReduce` optimized for AWS. `AllReduce` is a key operation used for synchronizing gradients across GPUs at the end of each training iteration during distributed data training.
2. The library offers `AllGather` optimized for AWS. `AllGather` is another key operation used in sharded data parallel training, which is a memory-efficient data parallelism technique offered by popular libraries such as the SageMaker model parallelism (SMP) library, DeepSpeed Zero Redundancy Optimizer (ZeRO), and PyTorch Fully Sharded Data Parallelism (FSDP).
3. The library performs optimized node-to-node communication by fully utilizing AWS network infrastructure and the Amazon EC2 instance topology.

The SMDDP library can increase training speed by offering performance improvement as you scale your training cluster, with near-linear scaling efficiency.

> **Note**
>
> The SageMaker distributed training libraries are available through the AWS deep learning containers for PyTorch and Hugging Face within the SageMaker Training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

SMDDP collective communication operations optimized for AWS compute resources and network infrastructure

The SMDDP library provides implementations of the `AllReduce` and `AllGather` collective operations that are optimized for AWS compute resources and network infrastructure.

SMDDP `AllReduce` collective operation

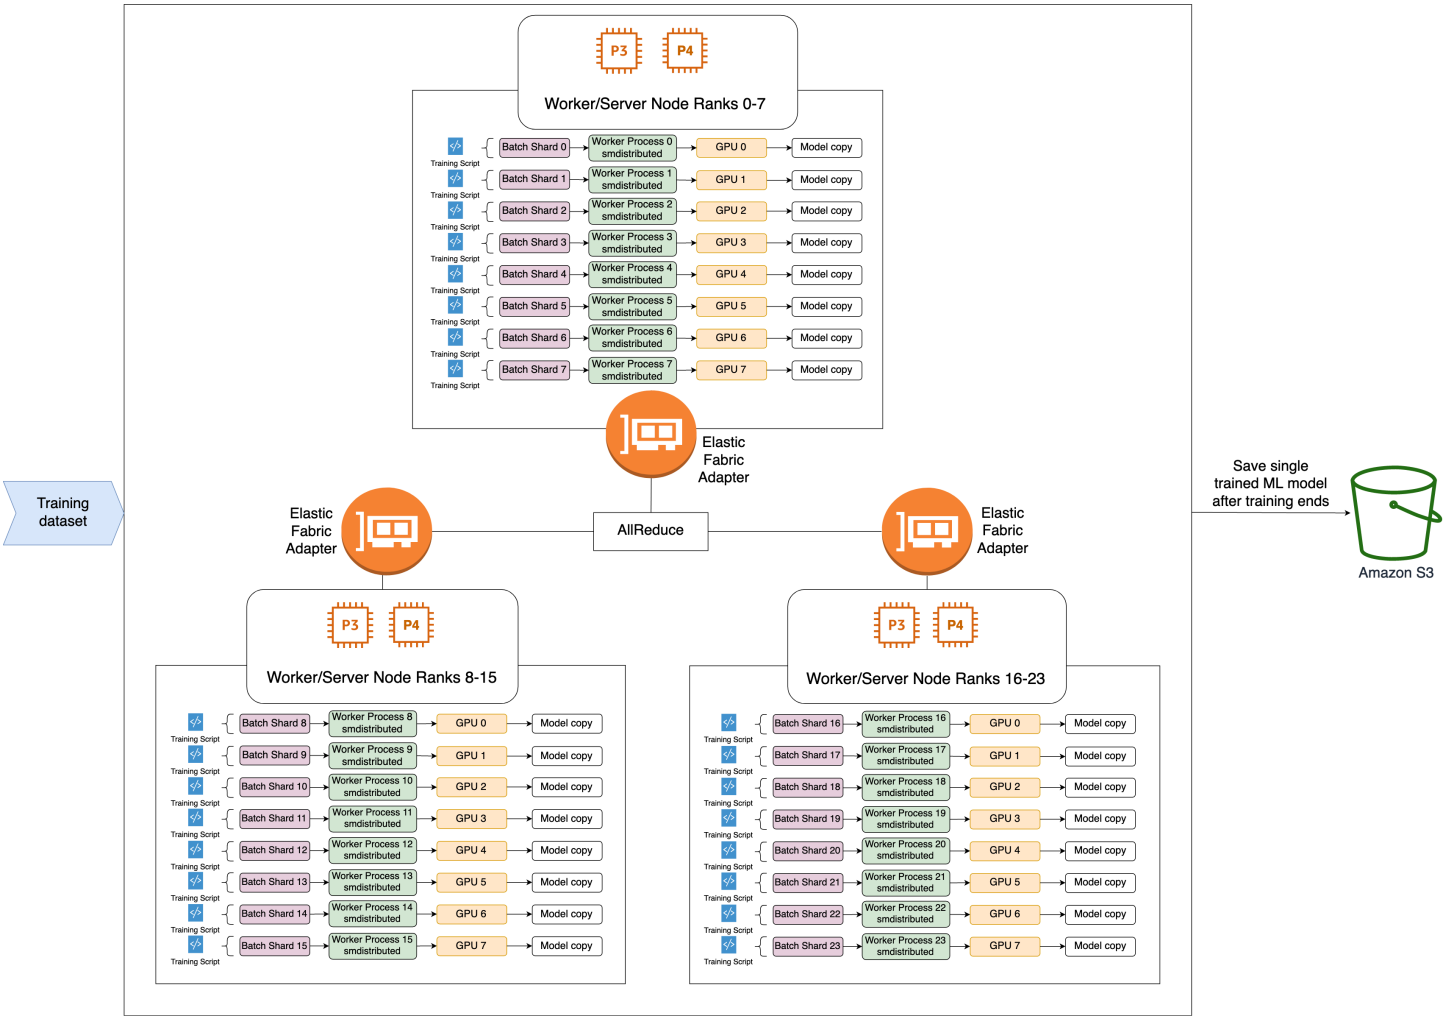
The SMDDP library achieves optimal overlapping of the `AllReduce` operation with the backward pass, significantly improving GPU utilization. It achieves near-linear scaling efficiency and faster training speed by optimizing kernel operations between CPUs and GPUs. The library performs `AllReduce` in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library to achieve faster training.

- *Leverages CPUs*: The library uses CPUs to `AllReduce` gradients, offloading this task from the GPUs.
- *Improved GPU usage*: The cluster's GPUs focus on computing gradients, improving their utilization throughout training.

The following is the high-level workflow of the SMDDP `AllReduce` operation.

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
   - The size of the global batch is `(number of nodes in a cluster) * (number of GPUs per node) * (per batch shard)`.
   - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.



SMDDP `AllGather` collective operation

`AllGather` is a collective operation where each worker starts with an input buffer, and then concatenates or *gathers* the input buffers from all other workers into an output buffer.

> **Note**
>
> The SMDDP `AllGather` collective operation is available in `smdistributed-dataparallel>=2.0.1` and AWS Deep Learning Containers (DLC) for PyTorch v2.0.1 and later.

`AllGather` is heavily used in distributed training techniques such as sharded data parallelism where each individual worker holds a fraction of a model, or a sharded layer. The workers call `AllGather` before forward and backward passes to reconstruct the sharded layers. The forward

and backward passes continue onward after the parameters are *all gathered*. During the backward pass, each worker also calls `ReduceScatter` to collect (reduce) gradients and break (scatter) them into gradient shards to update the corresponding sharded layer. For more details on the role of these collective operations in sharded data parallelism, see the SMP library's implementati on of sharded data parallelism, ZeRO in the DeepSpeed documentation, and the blog about PyTorch Fully Sharded Data Parallelism.

Because collective operations like AllGather are called in every iteration, they are the main contributors to GPU communication overhead. Faster computation of these collective operations directly translates to a shorter training time with no side effects on convergence. To achieve this, the SMDDP library offers `AllGather` optimized for P4d instances.

SMDDP `AllGather` uses the following techniques to improve computational performance on P4d instances.

1. It transfers data between instances (inter-node) through the Elastic Fabric Adapter (EFA) network with a mesh topology. EFA is the AWS low-latency and high-throughput network solution. A mesh topology for inter-node network communication is more tailored to the characteristics of EFA and AWS network infrastructure. Compared to the NCCL ring or tree topology that involves multiple packet hops, SMDDP avoids accumulating latency from multiple hops as it only needs one hop. SMDDP implements a network rate control algorithm that balances the workload to each communication peer in a mesh topology and achieves a higher global network throughput.
2. It adopts low-latency GPU memory copy library based on NVIDIA GPUDirect RDMA technology (GDRCopy) to coordinate local NVLink and EFA network traffic. GDRCopy, a low-latency GPU memory copy library offered by NVIDIA, provides low-latency communication between CPU processes and GPU CUDA kernels. With this technology, the SMDDP library is able to pipeline the intra-node and inter-node data movement.
3. It reduces the usage of GPU streaming multiprocessors to increase compute power for running model kernels. P4d and P4de instances are equipped with NVIDIA A100 GPUs, which each have 108 streaming multiprocessors. While NCCL takes up to 24 streaming multiprocessors to run collective operations, SMDDP uses fewer than 9 streaming multiprocessors. Model compute kernels pick up the saved streaming multiprocessors for faster computation.

Supported frameworks, AWS Regions, and instances types

Before using the SageMaker distributed data parallelism (SMDDP) library, check what are the supported ML frameworks and instance types and if there are enough quotas in your AWS account and AWS Region.

Supported frameworks

The following tables show the deep learning frameworks and their versions that SageMaker and SMDDP support. The SMDDP library is available in SageMaker Framework Containers, integrated in Docker containers distributed by the SageMaker model parallelism (SMP) library v2, or downloadable as a binary file.

> **Note**
>
> To check the latest updates and release notes of the SMDDP library, see the the section called "Release notes".

** The URLs of the binary files are for installing the SMDDP library in custom containers. For more information, see Create your own Docker container with the SageMaker distributed data parallel library.

Note

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the PyTorch DLCs. When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide `requirements.txt` to install `pytorch-lightning` and `lightning-bolts` in the SageMaker PyTorch training container.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the *Amazon SageMaker Python SDK documentation*.

Hugging Face Transformers

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

TensorFlow (deprecated)

Important

The SMDDP library discontinued support for TensorFlow and is no longer available in DLCs for TensorFlow later than v2.11.0. The following table lists previous DLCs for TensorFlow with the SMDDP library installed.

TensorFlow version	SMDDP library version
2.9.1, 2.10.1, 2.11.0	`smdistributed-dataparallel==v1.4.1`
2.8.3	`smdistributed-dataparallel==v1.3.0`

AWS Regions

The SMDDP library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker and the SMP Docker images are in service.

Supported instance types

The SMDDP library requires one of the following instance types.

Instance type		
ml.p3dn.24xlarge *		
ml.p4d.24xlarge		
ml.p4de.24xlarge		

Tip

To properly run distributed training on the EFA-enabled instance types, you should enable traffic between the instances by setting up the security group of your VPC to allow all inbound and outbound traffic to and from the security group itself. To learn how to set up the security group rules, see Step 1: Prepare an EFA-enabled security group in the *Amazon EC2 User Guide*.

Important

* The SMDDP library has discontinued support for optimizing its collective communication operations on P3 instances. While you can still utilize the SMDDP optimized `AllReduce` collective on `ml.p3dn.24xlarge` instances, there will be no further development support to enhance performance on this instance type. Note that the SMDDP optimized `AllGather` collective is only available for P4 instances.

For specs of the instance types, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
for training job usage' is 0 Instances, with current utilization of 0 Instances
and a request delta of 1 Instances.
Please contact AWS support to request an increase for this limit.
```

How to run a distributed training job with the SageMaker distributed data parallelism library

The SageMaker distributed data parallelism (SMDDP) library is designed for ease of use and to provide seamless integration with PyTorch.

When training a deep learning model with the SMDDP library on SageMaker, you can focus on writing your training script and model training.

To get started, import the SMDDP library to use its collective operations optimized for AWS. The following topics provide instructions on what to add to your training script depending on which collective operation you want to optimize.

Topics

Step 1: Adapt your training script to use the SMDDP collective operations

The training script examples provided in this section are simplified and highlight only the required changes to enable the SageMaker distributed data parallelism (SMDDP) library in your training script. For end-to-end Jupyter notebook examples that demonstrate how to run a distributed training job with the SMDDP library, see Amazon SageMaker data parallelism library examples.

Topics

Use the SMDDP library in your PyTorch training script

Starting from the SageMaker distributed data parallelism (SMDDP) library v1.4.0, you can use the library as a backend option for the PyTorch distributed package. To use the SMDDP `AllReduce` and `AllGather` collective operations, you only need to import the SMDDP library at the beginning of your training script and set SMDDP as the the backend of PyTorch distributed modules during process group initialization. With the single line of backend specification, you can keep all the native PyTorch distributed modules and the entire training script unchanged. The following code

snippets show how to use the SMDDP library as the backend of PyTorch-based distributed training packages: PyTorch distributed data parallel (DDP), PyTorch fully sharded data parallelism (FSDP), DeepSpeed, and Megatron-DeepSpeed.

For PyTorch DDP or FSDP

Initialize the process group as follows.

```
import torch.distributed as dist
import smdistributed.dataparallel.torch.torch_smddp

dist.init_process_group(backend="smddp")
```

> **Note**
>
> (For PyTorch DDP jobs only) The `smddp` backend currently does not support creating subprocess groups with the `torch.distributed.new_group()` API. You also cannot use the `smddp` backend concurrently with other process group backends such as `NCCL` and `Gloo`.

For DeepSpeed or Megatron-DeepSpeed

Initialize the process group as follows.

```
import deepspeed
import smdistributed.dataparallel.torch.torch_smddp

deepspeed.init_distributed(dist_backend="smddp")
```

> **Note**
>
> To use SMDDP `AllGather` with the `mpirun`-based launchers (`smdistributed` and `pytorchddp`) in the section called "Step 2: Launch a distributed training job", you also need to set the following environment variable in your training script.
>
> ```
> export SMDATAPARALLEL_OPTIMIZE_SDP=true
> ```

For general guidance on writing a PyTorch FSDP training script, see Advanced Model Training with Fully Sharded Data Parallel (FSDP) in the PyTorch documentation.

For general guidance on writing a PyTorch DDP training script, see Getting started with distributed data parallel in the PyTorch documentation.

After you have completed adapting your training script, proceed to Step 2: Launch a distributed training job using the SageMaker Python SDK.

Use the SMDDP library in your PyTorch Lightning training script

If you want to bring your PyTorch Lightning training script and run a distributed data parallel training job in SageMaker, you can run the training job with minimal changes in your training script. The necessary changes include the following: import the `smdistributed.dataparallel` library's PyTorch modules, set up the environment variables for PyTorch Lightning to accept the SageMaker environment variables that are preset by the SageMaker training toolkit, and activate the SMDDP library by setting the process group backend to `"smddp"`. To learn more, walk through the following instructions that break down the steps with code examples.

> **Note**
>
> The PyTorch Lightning support is available in the SageMaker data parallel library v1.5.0 and later.

PyTorch Lightning == v2.1.0 and PyTorch == 2.0.1

1. Import the `pytorch_lightning` library and the `smdistributed.dataparallel.torch` modules.

```
import lightning as pl
import smdistributed.dataparallel.torch.torch_smddp
```

2. Instantiate the LightningEnvironment.

```
from lightning.fabric.plugins.environments.lightning import LightningEnvironment

env = LightningEnvironment()
env.world_size = lambda: int(os.environ["WORLD_SIZE"])
env.global_rank = lambda: int(os.environ["RANK"])
```

3. **For PyTorch DDP** – Create an object of the DDPStrategy class with `"smddp"` for `process_group_backend` and `"gpu"` for `accelerator`, and pass that to the Trainer class.

```
import lightning as pl
from lightning.pytorch.strategies import DDPStrategy

ddp = DDPStrategy(
    cluster_environment=env,
    process_group_backend="smddp",
    accelerator="gpu"
)

trainer = pl.Trainer(
    max_epochs=200,
    strategy=ddp,
    devices=num_gpus,
    num_nodes=num_nodes
)
```

For PyTorch FSDP – Create an object of the FSDPStrategy class (with wrapping policy of choice) with `"smddp"` for `process_group_backend` and `"gpu"` for `accelerator`, and pass that to the Trainer class.

```
import lightning as pl
from lightning.pytorch.strategies import FSDPStrategy

from functools import partial
from torch.distributed.fsdp.wrap import size_based_auto_wrap_policy

policy = partial(
    size_based_auto_wrap_policy,
    min_num_params=10000
)

fsdp = FSDPStrategy(
    auto_wrap_policy=policy,
    process_group_backend="smddp",
    cluster_environment=env
)

trainer = pl.Trainer(
    max_epochs=200,
```

```
    strategy=fsdp,
    devices=num_gpus,
    num_nodes=num_nodes
)
```

After you have completed adapting your training script, proceed to Step 2: Launch a distributed training job using the SageMaker Python SDK.

Note

When you construct a SageMaker PyTorch estimator and submit a training job request in the section called "Step 2: Launch a distributed training job", you need to provide `requirements.txt` to install `pytorch-lightning` and `lightning-bolts` in the SageMaker PyTorch training container.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the *Amazon SageMaker Python SDK documentation*.

Use the SMDDP library in your TensorFlow training script (deprecated)

Important

The SMDDP library discontinued support for TensorFlow and is no longer available in DLCs for TensorFlow later than v2.11.0. To find previous TensorFlow DLCs with the SMDDP library installed, see the section called "Supported frameworks".

The following steps show you how to modify a TensorFlow training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. For additional details on each API that the library offers for TensorFlow, see the SageMaker distributed data parallel TensorFlow API documentation.

> **Note**
>
> SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of `tf` core modules except `tf.keras` modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.

> **Note**
>
> The SageMaker distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:
>
> - Frameworks - TensorFlow in the *NVIDIA Deep Learning Performance documentation*
> - Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
> - TensorFlow mixed precision APIs in the *TensorFlow documentation*

1. Import the library's TensorFlow client and initialize it.

```
import smdistributed.dataparallel.tensorflow as sdp
sdp.init()
```

2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you with the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the following code block as `sdp.local_rank()`. `set_memory_growth` is not directly related to SageMaker distributed, but must be set for distributed training with TensorFlow.

```
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
```

```
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the following code block as `sdp.size()`.

```
learning_rate = learning_rate * sdp.size()
```

4. Use the library's `DistributedGradientTape` to optimize `AllReduce` operations during training. This wraps `tf.GradientTape`.

```
with tf.GradientTape() as tape:
      output = model(input)
      loss_value = loss(label, output)

# SageMaker data parallel: Wrap tf.GradientTape with the library's
 DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
```

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. Use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the following code block as `sdp.broadcast_variables()`.

```
sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

```
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

The following is an example TensorFlow training script for distributed training with the library.

```
import tensorflow as tf
```

```
# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp

# SageMaker data parallel: Initialize the library
sdp.init()

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

    # SageMaker data parallel: Wrap tf.GradientTape with the library's
 DistributedGradientTape
    tape = sdp.DistributedGradientTape(tape)

    grads = tape.gradient(loss_value, mnist_model.trainable_variables)
    opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

    if first_batch:
       # SageMaker data parallel: Broadcast model and optimizer variables
       sdp.broadcast_variables(mnist_model.variables, root_rank=0)
       sdp.broadcast_variables(opt.variables(), root_rank=0)

    return loss_value
```

```
...

# SageMaker data parallel: Save checkpoints only from master node.
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

After you have completed adapting your training script, move on to Step 2: Launch a distributed training job using the SageMaker Python SDK.

Step 2: Launch a distributed training job using the SageMaker Python SDK

To run a distributed training job with your adapted script from the section called "Step 1: Adapt your training script to use the SMDDP collective operations", use the SageMaker Python SDK's framework or generic estimators by specifying the prepared training script as an entry point script and the distributed training configuration.

This page walks you through how to use the SageMaker Python SDK in two ways.

- If you want to achieve a quick adoption of your distributed training job in SageMaker, configure a SageMaker PyTorch or TensorFlow framework estimator class. The framework estimator picks up your training script and automatically matches the right image URI of the pre-built PyTorch or TensorFlow Deep Learning Containers (DLC), given the value specified to the `framework_version` parameter.
- If you want to extend one of the pre-built containers or build a custom container to create your own ML environment with SageMaker, use the SageMaker generic `Estimator` class and specify the image URI of the custom Docker container hosted in your Amazon Elastic Container Registry (Amazon ECR).

Your training datasets should be stored in Amazon S3 or Amazon FSx for Lustre in the AWS Region in which you are launching your training job. If you use Jupyter notebooks, you should have a SageMaker notebook instance or a SageMaker Studio Classic app running in the same AWS Region. For more information about storing your training data, see the SageMaker Python SDK data inputs documentation.

Tip

We recommend that you use Amazon FSx for Lustre instead of Amazon S3 to improve training performance. Amazon FSx has higher throughput and lower latency than Amazon S3.

Tip

To properly run distributed training on the EFA-enabled instance types, you should enables traffic between the instances by setting up the security group of your VPC to allow all inbound and outbound traffic to and from the security group itself. To learn how to set up the security group rules, see Step 1: Prepare an EFA-enabled security group in the *Amazon EC2 User Guide*.

Choose one of the following topics for instructions on how to run a distributed training job of your training script. After you launch a training job, you can monitor system utilization and model performance using Use Amazon SageMaker Debugger to debug and improve model performance or Amazon CloudWatch.

While you follow instructions in the following topics to learn more about technical details, we also recommend that you try the Amazon SageMaker data parallelism library examples to get started.

Topics

- Using framework estimators in the SageMaker Python SDK
- Using the SageMaker generic estimator to extend prebuilt containers
- Create your own Docker container with the SageMaker distributed data parallel library

Using framework estimators in the SageMaker Python SDK

You can launch distributed training by adding the `distribution` argument to the SageMaker framework estimators, `PyTorch` or `TensorFlow`. For more details, choose one of the frameworks supported by the SageMaker distributed data parallelism (SMDDP) library from the following selections.

PyTorch

The following launcher options are available for launching PyTorch distributed training.

- `pytorchddp` – This option runs `mpirun` and sets up environment variables needed for running PyTorch distributed training on SageMaker. To use this option, pass the following dictionary to the `distribution` parameter.

```
{ "pytorchddp": { "enabled": True } }
```

- `torch_distributed` – This option runs `torchrun` and sets up environment variables needed for running PyTorch distributed training on SageMaker. To use this option, pass the following dictionary to the `distribution` parameter.

```
{ "torch_distributed": { "enabled": True } }
```

- `smdistributed` – This option also runs `mpirun` but with `smddprun` that sets up environment variables needed for running PyTorch distributed training on SageMaker.

```
{ "smdistributed": { "dataparallel": { "enabled": True } } }
```

If you chose to replace NCCL `AllGather` to SMDDP `AllGather`, you can use all three options. Choose one option that fits with your use case.

If you chose to replace NCCL `AllReduce` with SMDDP `AllReduce`, you should choose one of the `mpirun`-based options: `smdistributed` or `pytorchddp`. You can also add additional MPI options as follows.

```
{
    "pytorchddp": {
        "enabled": True,
        "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
    }
}
```

```
{
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
```

```
        }
    }
}
```

The following code sample shows the basic structure of a PyTorch estimator with distributed training options.

```
from sagemaker.pytorch import PyTorch

pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    source_dir="subdirectory-to-your-code",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    py_version="py310",
    framework_version="2.0.1",

    # For running a multi-node distributed training job, specify a value greater
 than 1
    # Example: 2,3,4,..8
    instance_count=2,

    # Instance types supported by the SageMaker data parallel library:
    # ml.p4d.24xlarge, ml.p4de.24xlarge
    instance_type="ml.p4d.24xlarge",

    # Activate distributed training with SMDDP
    distribution={ "pytorchddp": { "enabled": True } }  # mpirun, activates SMDDP
 AllReduce OR AllGather
    # distribution={ "torch_distributed": { "enabled": True } }  # torchrun,
 activates SMDDP AllGather
    # distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }  #
 mpirun, activates SMDDP AllReduce OR AllGather
)

pt_estimator.fit("s3://bucket/path/to/training/data")
```

Note

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the SageMaker PyTorch DLCs. Create the following `requirements.txt` file and save in the source directory where you save the training script.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For example, the tree-structured directory should look like the following.

```
### pytorch_training_launcher_jupyter_notebook.ipynb
### sub-folder-for-your-code
    ###  adapted-training-script.py
    ###  requirements.txt
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the *Amazon SageMaker Python SDK documentation*.

Considerations for activating SMDDP collective operations and using the right distributed training launcher options

- SMDDP `AllReduce` and SMDDP `AllGather` are not mutually compatible at present.
- SMDDP `AllReduce` is activated by default when using `smdistributed` or `pytorchddp`, which are `mpirun`-based launchers, and NCCL `AllGather` is used.
- SMDDP `AllGather` is activated by default when using `torch_distributed` launcher, and `AllReduce` falls back to NCCL.
- SMDDP `AllGather` can also be activated when using the `mpirun`-based launchers with an additional environment variable set as follows.

```
export SMDATAPARALLEL_OPTIMIZE_SDP=true
```

TensorFlow

> **Important**
>
> The SMDDP library discontinued support for TensorFlow and is no longer available in DLCs for TensorFlow later than v2.11.0. To find previous TensorFlow DLCs with the SMDDP library installed, see the section called "TensorFlow (deprecated)".

```
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    framework_version="2.11.0",
    py_version="py38",

    # For running a multi-node distributed training job, specify a value greater
 than 1
    # Example: 2,3,4,..8
    instance_count=2,

    # Instance types supported by the SageMaker data parallel library:
    # ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
    instance_type="ml.p3.16xlarge",

    # Training using the SageMaker data parallel distributed training strategy
    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

tf_estimator.fit("s3://bucket/path/to/training/data")
```

Using the SageMaker generic estimator to extend prebuilt containers

You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a prebuilt container or adapt your own container to use the library, you must use one of the images listed in Supported frameworks.

> **Note**
>
> From TensorFlow 2.4.1 and PyTorch 1.8.1, SageMaker framework DLCs supports EFA-enabled instance types. We recommend that you use the DLC images that contain TensorFlow 2.4.1 or later and PyTorch 1.8.1 or later.

For example, if you use PyTorch, your Dockerfile should contain a `FROM` statement similar to the following:

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/pytorch-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our
 user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory
 to store your user code.
COPY train.py /opt/ml/code/train.py

# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM train.py
```

You can further customize your own Docker container to work with SageMaker using the SageMaker Training toolkit and the binary file of the SageMaker distributed data parallel library. To learn more, see the instructions in the following section.

Create your own Docker container with the SageMaker distributed data parallel library

To build your own Docker container for training and use the SageMaker data parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides instructions on how to create a complete Dockerfile with the minimum set of dependencies for distributed training in SageMaker using the data parallel library.

> **Note**
>
> This custom Docker option with the SageMaker data parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the data parallel library

1. Start with a Docker image from NVIDIA CUDA. Use the cuDNN developer versions that contain CUDA runtime and development tools (headers and libraries) to build from the PyTorch source code.

   ```
   FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
   ```

   > **Tip**
   >
   > The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   To use versions of the third party libraries other than the ones provided in the following code example, we recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find versions that are tested, compatible, and suitable for your application.

   To find URLs for the `SMDATAPARALLEL_BINARY` argument, see the lookup tables at Supported frameworks.

   ```
   ARG PYTORCH_VERSION=1.10.2
   ARG PYTHON_SHORT_VERSION=3.8
   ARG EFA_VERSION=1.14.1
   ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/
   ${PYTORCH_VERSION}/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-
   linux_x86_64.whl
   ```

```
ARG PT_S3_WHL_GPU=https://aws-s3-plugin.s3.us-west-2.amazonaws.com/
binaries/0.0.1/1c3e69e/awsio-0.0.1-cp38-cp38-manylinux1_x86_64.whl
ARG CONDA_PREFIX="/opt/conda"
ARG BRANCH_OFI=1.1.3-aws
```

3. Set the following environment variables to properly build SageMaker training components and run the data parallel library. You use these variables for the components in the subsequent steps.

```
# Set ENV variables required to build PyTorch
ENV TORCH_CUDA_ARCH_LIST="7.0+PTX 8.0"
ENV TORCH_NVCC_FLAGS="-Xfatbin -compress-all"
ENV NCCL_VERSION=2.10.3

# Add OpenMPI to the path.
ENV PATH /opt/amazon/openmpi/bin:$PATH

# Add Conda to path
ENV PATH $CONDA_PREFIX/bin:$PATH

# Set this enviroment variable for SageMaker to launch SMDDP correctly.
ENV SAGEMAKER_TRAINING_MODULE=sagemaker_pytorch_container.training:main

# Add enviroment variable for processes to be able to call fork()
ENV RDMAV_FORK_SAFE=1

# Indicate the container type
ENV DLC_CONTAINER_TYPE=training

# Add EFA and SMDDP to LD library path
ENV LD_LIBRARY_PATH="/opt/conda/lib/python${PYTHON_SHORT_VERSION}/site-packages/
smdistributed/dataparallel/lib:$LD_LIBRARY_PATH"
ENV LD_LIBRARY_PATH=/opt/amazon/efa/lib/:$LD_LIBRARY_PATH
```

4. Install or update `curl`, `wget`, and `git` to download and build packages in the subsequent steps.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
    apt-get update && apt-get install -y  --no-install-recommends \
        curl \
        wget \
        git \
    && rm -rf /var/lib/apt/lists/*
```

5. Install Elastic Fabric Adapter (EFA) software for Amazon EC2 network communication.

```
RUN DEBIAN_FRONTEND=noninteractive apt-get update
RUN mkdir /tmp/efa \
    && cd /tmp/efa \
    && curl --silent -O https://efa-installer.amazonaws.com/aws-efa-installer-
${EFA_VERSION}.tar.gz \
    && tar -xf aws-efa-installer-${EFA_VERSION}.tar.gz \
    && cd aws-efa-installer \
    && ./efa_installer.sh -y --skip-kmod -g \
    && rm -rf /tmp/efa
```

6. Install Conda to handle package management.

```
RUN curl -fsSL -v -o ~/miniconda.sh -O  https://repo.anaconda.com/miniconda/
Miniconda3-latest-Linux-x86_64.sh  && \
    chmod +x ~/miniconda.sh && \
    ~/miniconda.sh -b -p $CONDA_PREFIX && \
    rm ~/miniconda.sh && \
    $CONDA_PREFIX/bin/conda install -y python=${PYTHON_SHORT_VERSION} conda-build
 pyyaml numpy ipython && \
    $CONDA_PREFIX/bin/conda clean -ya
```

7. Get, build, and install PyTorch and its dependencies. We build PyTorch from the source code because we need to have control of the NCCL version to guarantee compatibility with the AWS OFI NCCL plug-in.

   a. Following the steps in the PyTorch official dockerfile, install build dependencies and set up ccache to speed up recompilation.

```
RUN DEBIAN_FRONTEND=noninteractive \
    apt-get install -y --no-install-recommends \
        build-essential \
        ca-certificates \
        ccache \
        cmake \
        git \
        libjpeg-dev \
        libpng-dev \
    && rm -rf /var/lib/apt/lists/*

# Setup ccache
RUN /usr/sbin/update-ccache-symlinks
```

```
RUN mkdir /opt/ccache && ccache --set-config=cache_dir=/opt/ccache
```

b. Install PyTorch's common and Linux dependencies.

```
# Common dependencies for PyTorch
RUN conda install astunparse numpy ninja pyyaml mkl mkl-include setuptools cmake
 cffi typing_extensions future six requests dataclasses

# Linux specific dependency for PyTorch
RUN conda install -c pytorch magma-cuda113
```

c. Clone the PyTorch GitHub repository.

```
RUN --mount=type=cache,target=/opt/ccache \
    cd / \
    && git clone --recursive https://github.com/pytorch/pytorch -b v
${PYTORCH_VERSION}
```

d. Install and build a specific NCCL version. To do this, replace the content in the PyTorch's default NCCL folder (`/pytorch/third_party/nccl`) with the specific NCCL version from the NVIDIA repository. The NCCL version was set in the step 3 of this guide.

```
RUN cd /pytorch/third_party/nccl \
    && rm -rf nccl \
    && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \
    && cd nccl \
    && make -j64 src.build CUDA_HOME=/usr/local/cuda NVCC_GENCODE="-
gencode=arch=compute_70,code=sm_70 -gencode=arch=compute_80,code=sm_80" \
    && make pkg.txz.build \
    && tar -xvf build/pkg/txz/nccl_*.txz -C $CONDA_PREFIX --strip-components=1
```

e. Build and install PyTorch. This process usually takes slightly more than 1 hour to complete. It is built using the NCCL version downloaded in a previous step.

```
RUN cd /pytorch \
    && CMAKE_PREFIX_PATH="$(dirname $(which conda))/../" \
    python setup.py install \
    && rm -rf /pytorch
```

8. Build and install AWS OFI NCCL plugin. This enables libfabric support for the SageMaker data parallel library.

```
RUN DEBIAN_FRONTEND=noninteractive apt-get update \
    && apt-get install -y --no-install-recommends \
        autoconf \
        automake \
        libtool
RUN mkdir /tmp/efa-ofi-nccl \
    && cd /tmp/efa-ofi-nccl \
    && git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \
    && cd aws-ofi-nccl \
    && ./autogen.sh \
    && ./configure --with-libfabric=/opt/amazon/efa \
    --with-mpi=/opt/amazon/openmpi \
    --with-cuda=/usr/local/cuda \
    --with-nccl=$CONDA_PREFIX \
    && make \
    && make install \
    && rm -rf /tmp/efa-ofi-nccl
```

9. Build and install TorchVision.

```
RUN pip install --no-cache-dir -U \
    packaging \
    mpi4py==3.0.3
RUN cd /tmp \
    && git clone https://github.com/pytorch/vision.git -b v0.9.1 \
    && cd vision \
    && BUILD_VERSION="0.9.1+cu111" python setup.py install \
    && cd /tmp \
    && rm -rf vision
```

10. Install and configure OpenSSH. OpenSSH is required for MPI to communicate between containers. Allow OpenSSH to talk to containers without asking for confirmation.

```
RUN apt-get update \
    && apt-get install -y  --allow-downgrades --allow-change-held-packages --no-
install-recommends \
    && apt-get install -y --no-install-recommends openssh-client openssh-server \
    && mkdir -p /var/run/sshd \
    && cat /etc/ssh/ssh_config | grep -v StrictHostKeyChecking > /etc/ssh/
ssh_config.new \
    && echo "    StrictHostKeyChecking no" >> /etc/ssh/ssh_config.new \
    && mv /etc/ssh/ssh_config.new /etc/ssh/ssh_config \
```

```
    && rm -rf /var/lib/apt/lists/*

# Configure OpenSSH so that nodes can communicate with each other
RUN mkdir -p /var/run/sshd && \
 sed 's@session\s*required\s*pam_loginuid.so@session optional pam_loginuid.so@g' -i /
etc/pam.d/sshd
RUN rm -rf /root/.ssh/ && \
 mkdir -p /root/.ssh/ && \
 ssh-keygen -q -t rsa -N '' -f /root/.ssh/id_rsa && \
 cp /root/.ssh/id_rsa.pub /root/.ssh/authorized_keys \
 && printf "Host *\n StrictHostKeyChecking no\n" >> /root/.ssh/config
```

11 Install the PT S3 plug-in to efficiently access datasets in Amazon S3.

```
RUN pip install --no-cache-dir -U ${PT_S3_WHL_GPU}
RUN mkdir -p /etc/pki/tls/certs && cp /etc/ssl/certs/ca-certificates.crt /etc/pki/
tls/certs/ca-bundle.crt
```

12 Install the libboost library. This package is needed for networking the asynchronous IO functionality of the SageMaker data parallel library.

```
WORKDIR /
RUN wget https://sourceforge.net/projects/boost/files/boost/1.73.0/
boost_1_73_0.tar.gz/download -O boost_1_73_0.tar.gz \
    && tar -xzf boost_1_73_0.tar.gz \
    && cd boost_1_73_0 \
    && ./bootstrap.sh \
    && ./b2 threading=multi --prefix=${CONDA_PREFIX} -j 64 cxxflags=-fPIC cflags=-
fPIC install || true \
    && cd .. \
    && rm -rf boost_1_73_0.tar.gz \
    && rm -rf boost_1_73_0 \
    && cd ${CONDA_PREFIX}/include/boost
```

13 Install the following SageMaker tools for PyTorch training.

```
WORKDIR /root
RUN pip install --no-cache-dir -U \
    smclarify \
    "sagemaker>=2,<3" \
    sagemaker-experiments==0.* \
    sagemaker-pytorch-training
```

14Finally, install the SageMaker data parallel binary and the remaining dependencies.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
  apt-get update && apt-get install -y  --no-install-recommends \
  jq \
  libhwloc-dev \
  libnuma1 \
  libnuma-dev \
  libssl1.1 \
  libtool \
  hwloc \
  && rm -rf /var/lib/apt/lists/*

RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

15After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container, host it in Amazon ECR, and run a training job using the SageMaker Python SDK.

The following example code shows a complete Dockerfile after combining all the previous code blocks.

```
# This file creates a docker image with minimum dependencies to run SageMaker data
 parallel training

Tip

For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

Tip

If you want to extend the custom Dockerfile to incorporate the SageMaker model parallel library, see Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library.

Amazon SageMaker data parallelism library examples

This page provides Jupyter notebooks that present examples of implementing the SageMaker distributed data parallelism (SMDDP) library to run distributed training jobs on SageMaker.

Blogs and Case Studies

The following blogs discuss case studies about using the SMDDP library.

SMDDP v2 blogs

- Enable faster training with Amazon SageMaker data parallel library, *AWS Machine Learning Blog* (December 05, 2023)

SMDDP v1 blogs

- How I trained 10TB for Stable Diffusion on SageMaker in *Medium* (November 29, 2022)
- Run PyTorch Lightning and native PyTorch DDP on Amazon SageMaker Training, featuring Amazon Search , *AWS Machine Learning Blog* (August 18, 2022)
- Training YOLOv5 on AWS with PyTorch and the SageMaker distributed data parallel library, *Medium* (May 6, 2022)
- Speed up EfficientNet model training on SageMaker with PyTorch and the SageMaker distributed data parallel library, *Medium* (March 21, 2022)
- Speed up EfficientNet training on AWS with the SageMaker distributed data parallel library, *Towards Data Science* (January 12, 2022)
- Hyundai reduces ML model training time for autonomous driving models using Amazon SageMaker, *AWS Machine Learning Blog* (June 25, 2021)
- Distributed Training: Train BART/T5 for Summarization using Transformers and Amazon SageMaker, the *Hugging Face website* (April 8, 2021)

Example notebooks

Example notebooks are provided in the SageMaker examples GitHub repository. To download the examples, run the following command to clone the repository and go to `training/distributed_training/pytorch/data_parallel`.

Note

Clone and run the example notebooks in the following SageMaker ML IDEs.

- SageMaker JupyterLab (available in Studio created after December 2023)
- SageMaker Code Editor (available in Studio created after December 2023)
- Studio Classic (available as an application in Studio created after December 2023)
- SageMaker Notebook Instances

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
cd amazon-sagemaker-examples/training/distributed_training/pytorch/data_parallel
```

SMDDP v2 examples

- Train Llama 2 using the SageMaker distributed data parallel library (SMDDP) and DeepSpeed
- Train Falcon using the SageMaker distributed data parallel library (SMDDP) and PyTorch Fully Sharded Data Parallelism (FSDP)

SMDDP v1 examples

- CNN with PyTorch and the SageMaker data parallelism library
- BERT with PyTorch and the SageMaker data parallelism library
- CNN with TensorFlow 2.3.1 and the SageMaker data parallelism library
- BERT with TensorFlow 2.3.1 and the SageMaker data parallelism library

- HuggingFace Distributed Data Parallel Training in PyTorch on SageMaker - Distributed Text Summarization
- HuggingFace Distributed Data Parallel Training in TensorFlow on SageMaker

Configuration tips for the SageMaker distributed data parallelism library

Review the following tips before using the SageMaker distributed data parallelism (SMDDP) library. This list includes tips that are applicable across frameworks.

Topics

Data preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for `AllReduce` operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

Single versus multiple nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library's `AllReduce` operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node `AllReduce` efficiency.

Debug scaling efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational performance issues, such as `CPUBottleneck`, `LoadBalancing`, and `LowGPUUtilization`. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS SDK for Python (Boto3) for training on SageMaker, you can enable Debugger as shown in Configure SageMaker Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.

Batch size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a *Linear Scaling Rule* where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Sections 2 and 3.

Custom MPI options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch `Estimator`, the respective container sets up the MPI environment and executes the `mpirun` command to start jobs on the cluster nodes.

You can set custom MPI operations using the `custom_mpi_options` parameter in the `Estimator`. Any `mpirun` flags passed in this field are added to the `mpirun` command and executed by SageMaker for training. For example, you may define the `distribution` parameter of an `Estimator` using the following to use the NCCL_DEBUG variable to print the NCCL version at the start of the program:

```
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options":
 "-verbose -x NCCL_DEBUG=VERSION"}}}
```

Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the **SCRATCH_2** deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the SRATCH_2 type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that's optimized to the cluster, assume that the model can complete one epoch in about 30 seconds. In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the *Amazon FSx for Lustre documentation*:

- How to increase storage capacity
- Aggregate file system performance

Amazon SageMaker distributed data parallelism library FAQ

Use the following to find answers to commonly asked questions about the SMDDP library.

Q: When using the library, how are the `allreduce`-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the SMDDP library?

The SMDDP library only supports GPU instances, more specificcally, P4d and P4de instances with NVIDIA A100 GPUs and EFA. No additional C5 or CPU instances are launched; if your SageMaker

training job is on an 8-node P4d cluster, only 8 `ml.p4d.24xlarge` instances are used. No additional instances are provisioned.

Q: I have a training job taking 5 days on a single `ml.p3.24xlarge` instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is using SageMaker's data parallelism library and a five-time bigger cluster enough to achieve an approximate five-time speedup? Or do I have to revisit its training hyperparameters after activating the SMDDP library?

The library changes the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

Q: Does the SMDDP library support Spot?

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You save and restore checkpoints in their training script as mentioned in the last steps of the section called "TensorFlow (deprecated)" and the section called "PyTorch".

Q: Is the SMDDP library relevant in a single-host, multi-device setup?

The library can be used in single-host multi-device training but the library offers performance improvements only in multi-host training.

Q: Where should the training dataset be stored?

The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input file systems for a training job.

Q: When using the SMDDP library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?

We generally recommend you use Amazon FSx because of its lower latency and higher throughput. If you prefer, you can use Amazon EFS or Amazon S3.

Q: Can the library be used with CPU nodes?

No. To find instance types supported by the SMDDP library, see the section called "Supported instance types".

Q: What frameworks and framework versions are currently supported by the SMDDP library at launch?

the SMDDP library currently supports PyTorch v1.6.0 or later and TensorFlow v2.3.0 or later. It doesn't support TensorFlow 1.x. For more information about which version of the SMDDP library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, the SMDDP library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to use AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the *NVIDIA Deep Learning Performace documentation*
- Frameworks - TensorFlow in the *NVIDIA Deep Learning Performace documentation*
- Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the *PyTorch Blog*
- TensorFlow mixed precision APIs in the *TensorFlow documentation*

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput requirement and more complex network topology). For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the *FSx for Lustre User Guide*.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

We highly recommend that you use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up an optimal storage and throughput capacity.

Q: (For the library v1.4.0 or later) How do I resolve the `Invalid backend` error while initializing process group.

If you encounter the error message `ValueError: Invalid backend: 'smddp'` when calling `init_process_group`, this is due to the breaking change in the SMDDP library v1.4.0 and later. You must import the PyTorch client of the library, `smdistributed.dataparallel.torch.torch_smddp`, which registers `smddp` as a backend for PyTorch. To learn more, see the section called "PyTorch".

Q: (For the SMDDP library v1.4.0 or later) I would like to call the collective primitives of the `torch.distributed` interface. Which primitives does the `smddp` backend support?

In v1.4.0, the SMDDP library supports `all_reduce`, `broadcast`, `reduce`, `all_gather`, and `barrier` of of the `torch.distributed` interface.

Q: (For the SMDDP library v1.4.0 or later) Does this new API work with other custom DDP classes or libraries like Apex DDP?

The SMDDP library is tested with other third-party distributed data parallel libraries and framework implementations that use the `torch.distribtued` modules. Using the SMDDP library with custom DDP classes works as long as the collective operations used by the custom DDP classes are supported by the SMDDP library. See the preceding question for a list of supported collectives. If you have these use cases and need further support, reach out to the SageMaker team through the AWS Support Center or AWS Developer Forums for Amazon SageMaker.

Q: Does the SMDDP library support the bring-your-own-container (BYOC) option? If so, how do I install the library and run a distributed training job by writing a custom Dockerfile?

If you want to integrate the SMDDP library and its minimum dependencies into your own Docker container, BYOC is the right approach. You can build your own container using the binary file of the library. The recommended process is to write a custom Dockerfile with the library and its dependencies, build the Docker container, host it in Amazon ECR, and use the ECR image URI to launch a training job using the SageMaker generic estimator class. For more instructions on how to prepare a custom Dockerfile for distributed training in SageMaker with the SMDDP library, see Create your own Docker container with the SageMaker distributed data parallel library.

Troubleshooting for distributed training in Amazon SageMaker

If you have problems in running a training job when you use the library, use the following list to try to troubleshoot. If you need further support, reach out to the SageMaker team through AWS Support Center or AWS Developer Forums for Amazon Amazon SageMaker.

Topics

- Using SageMaker distributed data parallel with Amazon SageMaker Debugger and checkpoints
- An unexpected prefix attached to model parameter keys
- SageMaker distributed training job stalling during initialization
- SageMaker distributed training job stalling at the end of training
- Observing scaling efficiency degradation due to Amazon FSx throughput bottlenecks
- SageMaker distributed training job with PyTorch returns deprecation warnings

Using SageMaker distributed data parallel with Amazon SageMaker Debugger and checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, use Amazon SageMaker Debugger.

However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following example.

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker distributed data parallel.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework `estimator` example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name,
 checkpoint_in_bucket)

estimator = TensorFlow(
    ...

    distribution={"smdistributed": {"dataparallel": { "enabled": True }}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
```

```
)
```

- If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the `checkpoint_s3_uri` and `checkpoint_local_path` parameters from the estimator. For more information about setting up manual checkpointing in a training script, see Saving Checkpoints.

An unexpected prefix attached to model parameter keys

For PyTorch distributed training jobs, an unexpected prefix (`model` for example) might be attached to `state_dict` keys (model parameters). The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the `state_dict` to go over the network, prepending the prefix. If you encounter any model failure problem due to different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script.

```
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```

This takes each `state_dict` key as a string value, separates the string at the first occurrence of `'model.'`, and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the *PyTorch discussion forum*.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the *PyTorch documentation*.

SageMaker distributed training job stalling during initialization

If your SageMaker distributed data parallel training job stalls during initialization when using EFA-enabled instances, this might be due to a misconfiguration in the security group of the VPC subnet that's used for the training job. EFA requires a proper security group configuration to enable traffic between the nodes.

To configure inbound and outbound rules for the security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Security Groups** in the left navigation pane.
3. Select the security group that's tied to the VPC subnet you use for training.
4. In the **Details** section, copy the **Security group ID**.
5. On the **Inbound rules** tab, choose **Edit inbound rules**.
6. On the **Edit inbound rules** page, do the following:
   a. Choose **Add rule**.
   b. For **Type**, choose **All traffic**.
   c. For **Source**, choose **Custom**, paste the security group ID into the search box, and select the security group that pops up.
7. Choose **Save rules** to finish configuring the inbound rule for the security group.
8. On the **Outbound rules** tab, choose **Edit outbound rules**.
9. Repeat the step 6 and 7 to add the same rule as an outbound rule.

After you complete the preceding steps for configuring the security group with the inbound and outbound rules, re-run the training job and verify if the stalling issue is resolved.

For more information about configuring security groups for VPC and EFA, see Security groups for your VPC and Elastic Fabric Adapter.

SageMaker distributed training job stalling at the end of training

One of the root causes of stalling issues at the end of training is a mismatch in the number of batches that are processed per epoch across different ranks. All workers (GPUs) synchronize their local gradients in the backward pass to ensure they all have the same copy of the model at the end of the batch iteration. If the batch sizes are unevenly assigned to different worker groups during the final epoch of training, the training job stalls. For example, while a group of workers (group A) finishes processing all batches and exits the training loop, another group of workers (group B) starts processing another batch and still expects communication from group A to synchronize the gradients. This causes group B to wait for group A, which already completed training and does not have any gradients to synchronize.

Therefore, when setting up your training dataset, it is important that each worker gets the same number of data samples so that each worker goes through the same number of batches while training. Make sure each rank gets the same number of batches to avoid this stalling issue.

Observing scaling efficiency degradation due to Amazon FSx throughput bottlenecks

One potential cause of lowered scaling efficiency is the FSx throughput limit. If you observe a sudden drop in scaling efficiency when you switch to a larger training cluster, try using a larger FSx for Lustre file system with a higher throughput limit. For more information, see Aggregate file system performance and Managing storage and throughput capacity in the *Amazon FSx for Lustre User Guide*.

SageMaker distributed training job with PyTorch returns deprecation warnings

Since v1.4.0, the SageMaker distributed data parallelism library works as a backend of PyTorch distributed. Because of the breaking change of using the library with PyTorch, you might encounter a warning message that the `smdistributed` APIs for the PyTorch distributed package are deprecated. The warning message should be similar to the following:

```
smdistributed.dataparallel.torch.dist is deprecated in the SageMaker distributed data
 parallel library v1.4.0+.
Please use torch.distributed and specify 'smddp' as a backend when initializing process
 group as follows:
torch.distributed.init_process_group(backend='smddp')
For more information, see the library's API documentation at
https://docs.aws.amazon.com/sagemaker/latest/dg/data-parallel-modify-sdp-pt.html
```

In v1.4.0 and later, the library only needs to be imported once at the top of your training script and set as the backend during the PyTorch distributed initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. See Use the SMDDP library in your PyTorch training script to learn about the breaking changes and the new way to use the library with PyTorch.

SageMaker data parallelism library release notes

See the following release notes to track the latest updates for the SageMaker distributed data parallelism (SMDDP) library.

The SageMaker distributed data parallelism library v2.2.0

Date: March 4, 2024

New features

- Added support for PyTorch v2.2.0 with CUDA v12.1.

Integration into Docker containers distributed by the SageMaker model parallelism (SMP) library

This version of the SMDDP library is migrated to the section called "SMP v2.2.0".

```
658645717510.dkr.ecr.<region>.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-
py310-cu121
```

For Regions where the SMP Docker images are available, see the section called "AWS Regions".

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.2.0/cu121/2024-03-04/
smdistributed_dataparallel-2.2.0-cp310-cp310-linux_x86_64.whl
```

The SageMaker distributed data parallelism library v2.1.0

Date: March 1, 2024

New features

- Added support for PyTorch v2.1.0 with CUDA v12.1.

Bug fixes

- Fixed the CPU memory leak issue in SMDDP v2.0.1.

Integration into SageMaker Framework Containers

This version of the SMDDP library passed benchmark testing and is migrated to the following SageMaker Framework Container.

- PyTorch v2.1.0

```
763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-training:2.1.0-gpu-py310-cu121-
ubuntu20.04-sagemaker
```

Integration into Docker containers distributed by the SageMaker model parallelism (SMP) library

This version of the SMDDP library is migrated to the section called "SMP v2.1.0".

```
658645717510.dkr.ecr.<region>.amazonaws.com/smdistributed-modelparallel:2.1.2-gpu-
py310-cu121
```

For Regions where the SMP Docker images are available, see the section called "AWS Regions".

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.1.0/cu121/2024-02-04/
smdistributed_dataparallel-2.1.0-cp310-cp310-linux_x86_64.whl
```

The SageMaker distributed data parallelism library v2.0.1

Date: December 7, 2023

New features

- Added a new SMDDP-implementation of `AllGather` collective operation optimized for AWS compute resources and network infrastructure. To learn more, see the section called "SMDDP `AllGather` collective operation".
- The SMDDP `AllGather` collective operation is compatible with PyTorch FSDP and DeepSpeed. To learn more, see the section called "PyTorch".
- Added support for PyTorch v2.0.1

Known issues

- There's a CPU memory leak issue from a gradual CPU memory increase while training with SMDDP `AllReduce` in DDP mode.

Integration into SageMaker Framework Containers

This version of the SMDDP library passed benchmark testing and is migrated to the following SageMaker Framework Container.

- PyTorch v2.0.1

```
763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-training:2.0.1-gpu-py310-cu118-ubuntu20.04-sagemaker
```

Binary file of this release

You can download or install the library using the following URL.

```
https://smdataparallel.s3.amazonaws.com/binary/pytorch/2.0.1/cu118/2023-12-07/smdistributed_dataparallel-2.0.2-cp310-cp310-linux_x86_64.whl
```

Other changes

- Starting from this release, documentation for the SMDDP library is fully available in this *Amazon SageMaker Developer Guide*. In favor of the complete developer guide for SMDDP v2 housed in the *Amazon SageMaker Developer Guide*, documentation for the additional reference for SMDDP v1.x in the *SageMaker Python SDK documentation* is no longer supported. If you still need SMP v1.x documentation, see the following snapshot of the documentation at SageMaker Python SDK v2.212.0 documentation.

SageMaker model parallelism library v2

> **Note**
>
> Since the release of the SageMaker model parallelism (SMP) library v2.0.0 on December 19, 2023, this documentation is renewed for the SMP library v2. For previous versions of the SMP library, see the section called "(Archived) SageMaker model parallelism library v1.x".

The Amazon SageMaker model parallelism library is a capability of SageMaker that enables high performance and optimized large scale training on SageMaker accelerate compute instances. The the section called "Core features of SMP v2" include techniques and optimizations to accelerate

and simplify large model training, such as hybrid sharded data parallelism, tensor parallelism, activation checkpointing, and activation offloading. You can use the SMP library to accelerate the training and fine-tuning of large language models (LLMs), large vision models (LVMs), and foundation models (FMs) with hundreds of billions of parameters.

The SageMaker model parallelism library v2 (SMP v2) aligns the library's APIs and methods with open source PyTorch Fully Sharded Data Parallelism (FSDP), which gives you the benefit of SMP performance optimizations with minimal code changes. With SMP v2, you can improve the computational performance of training a state-of-the-art large model on SageMaker by bringing your PyTorch FSDP training scripts to SageMaker.

You can use SMP v2 for the general SageMaker Training jobs and distributed training workloads on the section called "SageMaker HyperPod" clusters.

Topics

Introduction to model parallelism

Model parallelism is a distributed training method in which the deep learning (DL) model is partitioned across multiple GPUs and instances. The SageMaker model parallel library v2 (SMP v2) is compatible with the native PyTorch APIs and capabilities. This makes it convenient for you to adapt your PyTorch Fully Sharded Data Parallel (FSDP) training script to the SageMaker Training platform and take advantage of the performance improvement that SMP v2 provides.

This introduction page provides a high-level overview about model parallelism and a description of how it can help overcome issues that arise when training deep learning (DL) models that are

typically very large in size. It also provides examples of what the SageMaker model parallel library offers to help manage model parallel strategies and memory consumption.

What is model parallelism?

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model that you can train, because the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.

To overcome the limitations associated with training a model on a single GPU, SageMaker provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve optimized distributed training using EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

Estimate memory requirements before using model parallelism

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses automatic mixed precision such as `float16` (FP16) or `bfloat16` (BF16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 or BF16 parameter ~ 2 bytes
- An FP16 or BF16 gradient ~ 2 bytes
- An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
- An FP32 copy of parameter ~ 4 bytes (needed for the `optimizer apply` (OA) operation)
- An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with

40GB/80GB memory) available on a single GPU. On top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P4 and P5 instances that have NVIDIA A100 and H100 Tensor Core GPUs respectively. For more details about specifications such as CPU cores, RAM, attached storage volume, and network bandwidth, see the *Accelerated Computing* section in the Amazon EC2 Instance Types page. For instance types that SMP v2 supports, see the section called "Supported instance types".

Even with the accelerated computing instances, models with about 10 billion parameters such as Megatron-LM and T5, and even larger models with hundreds of billions of parameters such as GPT-3, cannot fit model replicas in each GPU device.

How the library employs model parallelism and memory saving techniques

The library consists of various types of model parallelism features and memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models that consist of hundreds of billions of parameters.

Topics

- Sharded data parallelism
- Expert parallelism
- Tensor parallelism
- Activation checkpointing and offloading
- Choosing the right techniques for your model

Sharded data parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs within a data-parallel group.

SMP v2 implements sharded data parallelism through FSDP, and extends it to implement the scale aware hybrid sharding strategy discussed in the blog post Near-linear scaling of gigantic-model training on AWS.

You can apply sharded data parallelism to your model as a standalone strategy. Furthermore, if you are using the most performant GPU instances equipped with NVIDIA A100 Tensor Core GPUs, `ml.p4d.24xlarge` and `ml.p4de.24xlarge`, you can take the advantage of improved training speed from the `AllGather` operation offered by the SageMaker data parallelism (SMDDP) library.

To dive deep into sharded data parallelism and learn how to set it up or use a combination of sharded data parallelism with other techniques like tensor parallelism and mixed precision training, see the section called "Hybrid sharded data parallelism".

Expert parallelism

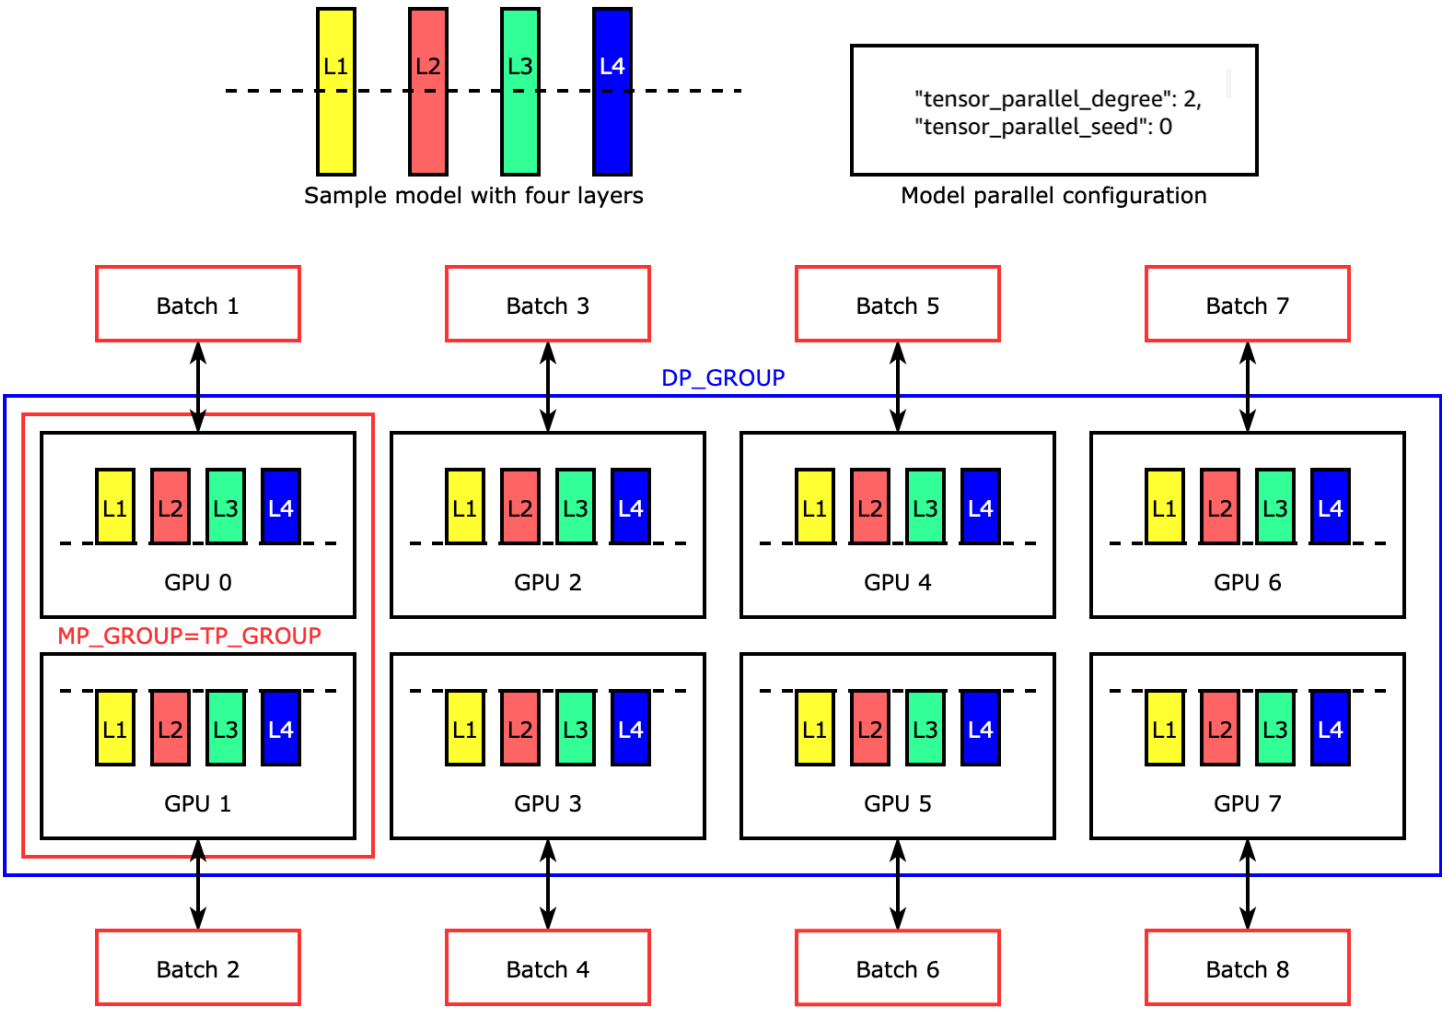
SMP v2 integrates with NVIDIA Megatron for implementing *expert parallelism* on top of its support for the native PyTorch FSDP APIs. You can keep your PyTorch FSDP training code as is and apply SMP expert parallelism for training *Mixture of Experts* (MoE) models within SageMaker.

An MoE model is a type of transformer model that consists of multiple *experts*, each consisting of a neural network, typically a feed-forward network (FFN). A gate network called *router* determines which tokens are sent to which expert. These experts specialize in processing specific aspects of the input data, enabling the model to train faster, reduce compute cost, while achieving the same performance quality as its counterpart dense model. And *expert parallelism* is a parallelism technique that handles splitting experts of an MoE model across GPU devices.

To learn how to train MoE models with SMP v2, see the section called "Expert parallelism".

Tensor parallelism

Tensor parallelism splits individual layers, or `nn.Modules`, across devices to run in parallel. The following figure shows the simplest example of how the SMP library splits a model with four layers to achieve two-way tensor parallelism (`"tensor_parallel_degree": 2`). In the following figure, the notations for model parallel group, tensor parallel group, and data parallel group are `MP_GROUP`, `TP_GROUP`, and `DP_GROUP` respectively. The layers of each model replica are bisected and distributed into two GPUs. The library manages communication across the tensor-distributed model replicas.



To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of the core features, see the section called "Tensor parallelism".

Activation checkpointing and offloading

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, with activation offloading, it offloads the stored activations to CPU memory and fetches them back to GPU during the backward pass to further reduce the activation memory footprint. For more information about how to use these features, see the section called "Activation checkpointing" and the section called "Activation offloading".

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see the section called “Best practices”.

Supported frameworks and AWS Regions

Before using the SageMaker model parallelism library v2 (SMP v2), check the supported frameworks and instance types and determine if there are enough quotas in your AWS account and AWS Region.

> **Note**
>
> To check the latest updates and release notes of the library, see the section called “Release notes”.

Supported frameworks

SMP v2 supports the following deep learning frameworks and available through SMP Docker containers and an SMP Conda channel. When you use the framework estimator classes in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use SMP v2, we recommend that you always keep the SageMaker Python SDK up to date in your development environment.

PyTorch versions that the SageMaker model parallelism library supports

PyTorch version	SageMaker model parallelism library version	SMP Docker image URI
v2.2.0	`smdistributed-modelparallel==v2.3.0`	`658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121`

PyTorch version	SageMaker model parallelism library version	SMP Docker image URI
	`smdistributed-modelparallel==v2.2.0`	Not available. Use the image of SMP v2.3.0, which is backward compatible.
v2.1.2	`smdistributed-modelparallel==v2.1.0`	`658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.1.2-gpu-py310-cu121`
v2.0.1	`smdistributed-modelparallel==v2.0.0`	`658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.0.1-gpu-py310-cu121`

SMP Conda channel

The following S3 bucket is a public Conda channel hosted by the SMP service team. If you want to install the SMP v2 library in an environment such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

```
https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/
```

For more information about Conda channels in general, see Channels in the *Conda documentation*.

> **Note**
>
> To find previous versions of the SMP library v1.x and pre-packaged DLCs, see the section called "Supported Frameworks" in the *SMP v1 documentation*.

Use SMP v2 with open source libraries

The SMP v2 library works with other PyTorch-based open source libraries such as PyTorch Lightning, Hugging Face Transformers, and Hugging Face Accelerate, because SMP v2 is compatible with the PyTorch FSDP APIs. If you have further questions on using the SMP library with other third party libraries, contact the SMP service team at `sm-model-parallel-feedback@amazon.com`.

AWS Regions

SMP v2 is available in the following AWS Regions. If you'd like to use the SMP Docker image URIs or the SMP Conda channel, check the following list and choose the AWS Region matching with yours, and update the image URI or the channel URL accordingly.

- ap-northeast-1
- ap-northeast-2
- ap-northeast-3
- ap-south-1
- ap-southeast-1
- ap-southeast-2
- ca-central-1
- eu-central-1
- eu-north-1
- eu-west-1
- eu-west-2
- eu-west-3
- sa-east-1
- us-east-1
- us-east-2
- us-west-1
- us-west-2

Supported instance types

SMP v2 requires one of the following ML instance types.

Instance type
ml.p4d.24xlarge
ml.p4de.24xlarge
ml.p5.48xlarge

Tip

Starting from SMP v2.2.0 supporting PyTorch v2.2.0 and later, the section called "Mixed precision training with FP8 on P5 instances using Transformer Engine" is available.

For specs of the SageMaker machine learning instance types in general, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Requesting a quota increase in the *AWS Service Quotas User Guide*.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
    the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
    for training job usage' is 0 Instances, with current utilization of 0 Instances
    and a request delta of 1 Instances.
    Please contact AWS support to request an increase for this limit.
```

Get started with the SageMaker model parallelism library v2

On this page, you'll learn how to use the SageMaker model parallelism library v2 APIs and get started with running a PyTorch Fully Sharded Data Parallel (FSDP) training job in the SageMaker Training platform or on a SageMaker HyperPod cluster.

There are various scenarios for running a PyTorch training job with SMP v2.

1. For SageMaker training, use one of the pre-built SageMaker Framework Containers for PyTorch v2.0.1 and later, which are pre-packaged with SMP v2.

2. Use the SMP v2 binary file to set up a Conda environment for running a distributed training workload on a SageMaker HyperPod cluster.
3. Extend the pre-built SageMaker Framework Containers for PyTorch v2.0.1 and later to install any additional functional requirements for your use case. To learn how to extend a pre-built container, see Extend a Pre-built Container.
4. You can also bring your own Docker container and manually set up all SageMaker Training environment using the SageMaker Training toolkit and install the SMP v2 binary file. This is the least recommended option due to the complexity of dependencies. To learn how to run your own Docker container, see Adapting Your Own Training Container.

This getting started guide covers the first two scenarios.

Topics

- Step 1: Adapt your PyTorch FSDP training script
- Step 2: Launch a training job

Step 1: Adapt your PyTorch FSDP training script

To activate and configure the SMP v2 library, start with importing and adding the `torch.sagemaker.init()` module at the top of the script. This module takes in the SMP configuration dictionary of the section called "SMP v2 core feature configuration parameters" that you'll prepare in the section called "Step 2: Launch a training job". Also, for using the various core features offered by SMP v2, you might need to make few more changes to adapt your training script. More detailed instructions on adapting your training script for using the SMP v2 core features are provided at the section called "Core features of SMP v2".

SageMaker Training

In your training script, add the following two lines of code, which is the minimal requirement to start training with SMP v2. In the section called "Step 2: Launch a training job", you'll set up an object of the SageMaker `PyTorch` estimator class with an SMP configuration dictionary through the `distribution` argument of the estimator class.

```
import torch.sagemaker as tsm
tsm.init()
```

> **Note**
>
> You can also directly pass a configuration dictionary of the the section called "SMP v2 core feature configuration parameters" to the `torch.sagemaker.init()` module. However, the parameters passed to the PyTorch estimator in the section called "Step 2: Launch a training job" take priority and override the ones specified to the `torch.sagemaker.init()` module.

SageMaker HyperPod

In your training script, add the following two lines of code. In the section called "Step 2: Launch a training job", you'll set up a `smp_config.json` file for setting up SMP configurations in JSON format, and upload it to a storage or a file system mapped with your SageMaker HyperPod cluster. We recommend that you keep the configuration file under the same directory where you upload your training script.

```
import torch.sagemaker as tsm
tsm.init("/dir_to_training_files/smp_config.json")
```

> **Note**
>
> You can also directly pass a configuration dictionary of the the section called "SMP v2 core feature configuration parameters" into the `torch.sagemaker.init()` module.

Step 2: Launch a training job

Learn how to configure SMP distribution options for launching a PyTorch FSDP training job with SMP core features.

SageMaker Training

When you set up a training job launcher object of the PyTorch framework estimator class in the SageMaker Python SDK, configure the section called "SMP v2 core feature configuration parameters" through `distribution` argument as follows.

> **Note**
>
> The `distribution` configuration for SMP v2 is integrated in the SageMaker Python SDK starting from v2.200. Make sure that you use the SageMaker Python SDK v2.200 or later.

> **Note**
>
> In SMP v2, you should configure `smdistributed` with `torch_distributed` for the `distribution` argument of the SageMaker `PyTorch` estimator. With `torch_distributed`, SageMaker runs `torchrun`, which is the default multi-node job launcher of PyTorch Distributed.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    framework_version=2.2.0,
    py_version="310"
    # image_uri="<smp-docker-image-uri>" # For using prior versions, specify the SMP
 image URI directly.
    entry_point="your-training-script.py", # Pass the training script you adapted
 with SMP from Step 1.
    ... # Configure other required and optional parameters
    distribution={
        "torch_distributed": { "enabled": True },
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    "hybrid_shard_degree": Integer,
                    "sm_activation_offloading": Boolean,
                    "activation_loading_horizon": Integer,
                    "fsdp_cache_flush_warnings": Boolean,
                    "allow_empty_shards": Boolean,
                    "tensor_parallel_degree": Integer,
                    "expert_parallel_degree": Integer,
                    "random_seed": Integer
                }
            }
```

```
        }
    }
)
```

Important

For using one of the prior versions of PyTorch or SMP instead of the latest, you need to specify the SMP Docker image directly using the `image_uri` argument instead of the `framework_version` and `py_version` pair. The following is an example of

```
estimator = PyTorch(
    ...,
    image_uri="658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-
modelparallel:2.2.0-gpu-py310-cu121"
)
```

To find SMP Docker image URIs, see the section called "Supported frameworks".

SageMaker HyperPod

Before you start, make sure if the following prerequisites are met.

- An Amazon FSx shared directory mounted (`/fsx`) to your HyperPod cluster.
- Conda installed in the FSx shared directory. To learn how to install Conda, use the instructions at Installing on Linux in the *Conda User Guide*.
- `cuda11.8` or `cuda12.1` installed on the head and compute nodes of your HyperPod cluster.

If the prerequisites are all met, proceed to the following instructions on launching a workload with SMP v2 on a HyperPod cluster.

1. Prepare an `smp_config.json` file that contains a dictionary of the section called "SMP v2 core feature configuration parameters". Make sure that you upload this JSON file to where you store your training script, or the path you specified to the `torch.sagemaker.init()` module in Step 1. If you've already passed the configuration dictionary to the `torch.sagemaker.init()` module in the training script in Step 1, you can skip this step.

```
// smp_config.json
{
    "hybrid_shard_degree": Integer,
    "sm_activation_offloading": Boolean,
    "activation_loading_horizon": Integer,
    "fsdp_cache_flush_warnings": Boolean,
    "allow_empty_shards": Boolean,
    "tensor_parallel_degree": Integer,
    "expert_parallel_degree": Integer,
    "random_seed": Integer
}
```

2. Upload the `smp_config.json` file to a directory in your file system. The directory path must match with the path you specified in Step 1. If you've already passed the configuration dictionary to the `torch.sagemaker.init()` module in the training script, you can skip this step.
3. On the compute nodes of your cluster, start a terminal session with the following command.

```
sudo su -l ubuntu
```

4. Create a Conda environment on the compute nodes. The following code is an example script of creating a Conda environment and installing SMP, SMDDP, CUDA, and other dependencies.

```
# Run on compute nodes
SMP_CUDA_VER=<11.8 or 12.1>

source /fsx/<path_to_miniconda>/miniconda3/bin/activate

export ENV_PATH=/fsx/<path to miniconda>/miniconda3/envs/<ENV_NAME>
conda create -p ${ENV_PATH} python=3.10

conda activate ${ENV_PATH}

# Verify aws-cli is installed: Expect something like "aws-cli/2.15.0*"
aws --version
# Install aws-cli if not already installed
# https://docs.aws.amazon.com/cli/latest/userguide/getting-started-
install.html#cliv2-linux-install

# Install the SMP library
```

```
conda install pytorch="2.0.1=sm_py3.10_cuda${SMP_CUDA_VER}*" packaging --override-
channels \
  -c https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/
smp-2.0.0-pt-2.0.1/2023-12-11/smp-v2/ \
  -c pytorch -c numba/label/dev \
  -c nvidia -c conda-forge

# Install dependencies of the script as below
python -m pip install packaging transformers==4.31.0 accelerate ninja tensorboard
 h5py datasets \
    && python -m pip install expecttest hypothesis \
    && python -m pip install "flash-attn>=2.0.4" --no-build-isolation

python -m pip install --no-build-isolation git+https://github.com/NVIDIA/
TransformerEngine.git@v1.0
```

5. Run a test training job.

   a. In the shared file system (`/fsx`), clone the Awsome Distributed Training GitHub repository, and go to the `3.test_cases/11.modelparallel` folder.

   ```
   git clone https://github.com/aws-samples/awsome-distributed-training/
   cd awsome-distributed-training/3.test_cases/11.modelparallel
   ```

   b. Submit a job using `sbatch` as follows.

   ```
   conda activate <ENV_PATH>
   sbatch -N 16 conda_launch.sh
   ```

   If the job submission is successful, the output message of this `sbatch` command should be similar to `Submitted batch job ABCDEF`.

   c. Check the log file in the current directory under `logs/`.

   ```
   tail -f ./logs/fsdp_smp_ABCDEF.out
   ```

Core features of the SageMaker model parallelism library v2

The Amazon SageMaker model parallelism library v2 (SMP v2) offers distribution strategies and memory-saving techniques, such as sharded data parallelism, tensor parallelism, and checkpointing. The model parallelism strategies and techniques offered by SMP v2 help distribute

large models across multiple devices while optimizing training speed and memory consumption. SMP v2 also provides a Python package `torch.sagemaker` to help adapt your training script with few lines of code change.

This guide follows the basic two-step flow introduced in the section called "Get started with SMP v2". To dive deep into the core features of SMP v2 and how to use them, see the following topics.

> **Note**
>
> These core features are available in SMP v2.0.0 and later and the SageMaker Python SDK v2.200.0 and later, and works for PyTorch v2.0.1 and later. To check the versions of the packages, see the section called "Supported frameworks and AWS Regions".

Topics

Hybrid sharded data parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across devices. This helps you fit a larger model or increase the batch size using the freed-up GPU memory. The SMP library offers a capability of running sharded data parallelism with PyTorch Fully Sharded Data Parallel (FSDP). PyTorch FSDP by default shards across the whole set of GPUs being used. In SMP v2, the library offers this sharded data parallelism on top of PyTorch FSDP by extending PyTorch hybrid sharding

(HYBRID_SHARD), which is one of the sharding strategies provided by PyTorch FSDP: FULL_SHARD, SHARD_GRAD_OP, HYBRID_SHARD, _HYBRID_SHARD_ZERO2. Extending hybrid sharding in this manner helps implement scale-aware-sharding as described in the blog Near-linear scaling of gigantic-model training on AWS for PyTorch FSDP.

The SMP library makes it easy to use HYBRID_SHARD and _HYBRID_SHARD_ZERO2 across any configurable number of GPUs, extending the native PyTorch FSDP that supports sharding across a single node (HYBRID_SHARD) or all GPUs (FULL_SHARD). PyTorch FSDP calls can stay as is, and you only need to add the `hybrid_shard_degree` argument to the SMP configuration, as shown in the following code example. You don't need to change the value of the `sharding_strategy` argument in the PyTorch FSDP wrapper around your PyTorch model. You can pass `ShardingStrategy.HYBRID_SHARD` as the value. Alternatively, the SMP library overrides the strategy in the script and sets it to `ShardingStrategy.HYBRID_SHARD` if you specify a value equal to or greater than 2 to the `hybrid_shard_degree` parameter.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Get started with SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `hybrid_shard_degree` parameter, see the section called "SMP v2 core feature configuration parameters".

SMP configuration dictionary

```
{ "hybrid_shard_degree": 16 }
```

In training script

```
import torch.sagemaker as tsm
tsm.init()

# Set up a PyTorch model
model = ...

# Wrap the PyTorch model using the PyTorch FSDP module
model = FSDP(
    model,
    ...
)
```

```
# Optimizer needs to be created after FSDP wrapper
optimizer = ...
```

Expert parallelism

A *Mixture of Experts* (MoE) model is a type of transformer model that employs a *sparse* approach, making it lighter for training compared to training traditional dense models. In this MoE neural network architecture, only a subset of the model's components called *experts* are utilized for each input. This approach offers several advantages, including more efficient training and faster inference, even with a larger model size. In other words, with the same compute budget for training a full dense model, you can fit a larger model or dataset when using MoE.

An MoE model consists of multiple *experts*, each consisting of a neural network, typically a feed-forward network (FFN). A gate network called *router* determines which tokens are sent to which expert. These experts specialize in processing specific aspects of the input data, enabling the model to train faster, reduce compute cost, while achieving the same performance quality as its counterpart dense model. To learn more about Mixture of Experts in general, refer to the blog Applying Mixture of Experts in LLM Architectures in the *NVIDIA developer website*.

Expert parallelism is a type of parallelism that handles splitting experts of an MoE model across GPU devices.

SMP v2 integrates with NVIDIA Megatron for implementing expert parallelism to support training MoE models, and runs on top of PyTorch FSDP APIs. You keep using your PyTorch FSDP training code as is and activate SMP expert parallelism for training MoE models.

Hugging Face Transformer models compatible with SMP expert parallelism

SMP v2 expert parallelism supports the following Hugging Face Transformer model.

- Mixtral

Configure expert parallelism

For `expert_parallel_degree`, you select a value for the degree of expert parallelism. The value must evenly divide the number of GPUs in your cluster. For example, to shard your model while using an instance with 8 GPUs, choose 2, 4, or 8. We recommend that you start with a small number, and gradually increase it until the model fits in the GPU memory.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration

dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Get started with SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `expert_parallel_degree` parameter, see the section called "SMP v2 core feature configuration parameters".

> **Note**
>
> You can use expert parallelism with the section called "Hybrid sharded data parallelism". Note that expert parallelism is currently not compatible with tensor parallelism.

> **Note**
>
> This expert parallelism training feature is available in the following combination of libraries of SageMaker and the PyTorch library:
>
> - SMP v2.3.0 and later
> - The SageMaker Python SDK v2.214.4 and later
> - PyTorch v2.2.0 and later

In your training script

As part of Step 1, initialize your script with `torch.sagemaker.init()` to activate SMP v2 and wrap your model with the the section called "`torch.sagemaker.transform`" API, adding the `config` parameter to the API to activate MoE. The following code snippet shows how to activate SMP MoE for the generic model class `AutoModelForCausalLM` pulling an MoE transformer model configuration using the `from_config` method for training from scratch, or the `from_pretrained` method for fine-tuning. To learn more about the SMP `MoEConfig` class, see the section called "`torch.sagemaker.moe.moe_config.MoEConfig`".

```
# Import the torch.sagemaker.transform API and initialize.
import torch.sagemaker as tsm
tsm.init()

# Import transformers AutoModelForCausalLM class.
from transformers import AutoModelForCausalLM
```

```
# Import the SMP-implementation of MoE configuration class.
from torch.sagemaker.moe.moe_config import MoEConfig

# Define a transformer model with an MoE model configuration
model = AutoModelForCausalLM.from_config(MoEModelConfig)

# Wrap it by torch.sagemaker.transform with the SMP MoE configuration.
model = tsm.transform(
    model,
    config=MoEConfig(
        smp_moe=True,
        random_seed=12345,
        moe_load_balancing="sinkhorn",
        global_token_shuffle=False,
        moe_all_to_all_dispatcher=True,
        moe_aux_loss_coeff=0.001,
        moe_z_loss_coeff=0.001
    )
)
```

SMP configuration

As part of Step 2, add the following parameter to the SMP configuration dictionary for the SageMaker PyTorch estimator.

```
{
    ..., # other SMP config parameters
    "expert_parallel_degree": 8
}
```

Compatibility with the SMDDP library optimized for AWS infrastructure

You can use the SageMaker model parallelism library v2 (SMP v2) in conjunction with the SageMaker distributed data parallelism (SMDDP) library that offers the `AllGather` collective communication operation optimized for AWS infrastructure. In distributed training, collective communication operations are designed for synchronizing multiple GPU workers and exchange information between them. `AllGather` is one of the core collective communication operations typically used in sharded data parallelism. To learn more about the SMDDP `AllGather` operation, see the section called "SMDDP `AllGather` collective operation" Optimizing such collective communication operations would directly contribute to a faster end-to-end training without side effects on convergence.

> **Note**
>
> The SMDDP library supports P4 and P4de instances (see also the section called "Supported frameworks, AWS Regions, and instances types" by the SMDDP library).

The SMDDP library integrates natively with PyTorch through the process group layer. To use the SMDDP library, you only need to add two lines of code to your training script. It supports any training frameworks such as SageMaker Model Parallelism Library, PyTorch FSDP, and DeepSpeed.

To activate SMDDP and use its `AllGather` operation, you need to add two lines of code to your training script as part of the section called "Step 1: Adapt your PyTorch FSDP training script". Note that you need to initialize PyTorch Distributed with the SMDDP backend first, and then run the SMP initialization.

```
import torch.distributed as dist

# Initialize with SMDDP
import smdistributed.dataparallel.torch.torch_smddp
dist.init_process_group(backend="smddp") # Replacing "nccl"

 # Initialize with SMP
import torch.sagemaker as tsm
tsm.init()
```

SageMaker Framework Containers for PyTorch (see also the section called "Supported frameworks and AWS Regions" by SMP v2 and the section called "Supported frameworks, AWS Regions, and instances types" by the SMDDP library) are pre-packaged with the SMP binary and the SMDDP binary. To learn more about the SMDDP library, see the section called "SageMaker distributed data parallelism library".

Mixed precision training

The SageMaker model parallelism (SMP) library v2 supports mixed precision training out of the box by integrating with open source frameworks such as PyTorch FSDP and Transformer Engine. To learn more, see the following topics.

Topics

- Mixed precision training with FP8 on P5 instances using Transformer Engine

- Mixed precision training with half-precision data types using PyTorch FSDP

Mixed precision training with FP8 on P5 instances using Transformer Engine

Starting from the SageMaker model parallelism (SMP) library v2.2.0, the SMP library integrates with Transformer Engine and supports FP8 mixed precision training out of the box, keeping compatibility with PyTorch FSDP `MixedPrecision`. This means that you can use both PyTorch FSDP for mixed precision training and Transformer Engine for FP8 training. For model layers not supported by Transformer Engine's FP8 training feature, those layers fall back to PyTorch FSDP mixed precision.

> **Note**
>
> SMP v2 offers FP8 support for the following Hugging Face Transformer models:
>
> - GPT-NeoX
> - Llama 2

> **Note**
>
> This FP8 training on the P5 feature is available in the following combination of libraries of SageMaker and the PyTorch library:
>
> - SMP v2.2.0 and later
> - the SageMaker Python SDK v2.212.0 and later
> - PyTorch v2.2.0 and later

FP8 (8-bit floating point precision) is a data type that has emerged as another paradigm to accelerate deep learning training of LLM models. With the release of NVIDIA H100 GPUs supporting FP8 data types, you can benefit from the advantages from the performance improvements on P5 instances equipped with the H100 GPUs, while accelerating distributed training with FP8 mixed precision training.

The FP8 data type further branches down to E4M3 and E5M2 formats. *E4M3* offers a better precision, has a limited dynamic range, and is ideal for the forward pass in model training. *E5M2* has a broader dynamic range, but reduced precision, and is better suited for the backward

pass, where precision is less critical and a wider dynamic range becomes beneficial. Hence, we recommend that you use the hybrid FP8 strategy recipe to leverage these characteristics effectively.

For half-precision data types (FP16 and BF16), global loss-scaling techniques such as static loss-scaling or dynamic loss-scaling handle convergence issues that arise from information loss due to rounding gradients in half-precision. However, the dynamic range of FP8 is even narrower, and the global loss scaling techniques are not sufficient. At this point, we need a finer-grained per-tensor scaling technique. *Delayed scaling* is a strategy that selects a scaling factor based on the maximum absolute values observed in a number of tensors form previous iterations. There's a trade-off in this strategy; it uses the full performance benefits of FP8 computation but requires memory for keeping the maximum value history of tensors. To learn more about the delayed scaling strategy in general, see the paper *FP8 Formats for Deep Learning*.

In practice, using FP8 is helpful in all training scenarios on P5 instances. We strongly recommend enabling FP8 whenever possible for enhancing training performance.

SMP v2 supports Transformer Engine out of the box. Therefore, when running FP8 training with SMP v2 on P5 instances of SageMaker (`ml.p5.48xlarge`), the only thing you need to do is to import `torch.sagemaker` in your training script and keep using the native Transformer Engine Python package. To learn more about using Transformer Engine for FP8 training in general, see Using FP8 with Transformer Engine in the *NVIDIA Transformer Engine documentation*. The following code snippet shows how the code lines for importing the SMP library and setting up FP8 in your training script should look.

```
import torch.sagemaker as tsm
import transformer_engine.pytorch as te
from transformer_engine.common.recipe import DelayedScaling, Format

# Initialize the SMP torch.sagemaker API.
tsm.init()

# Define a transformer model and wrap it with the torch.sagemaker.transform API.
from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_config(ModelConfig)
model = tsm.transform(model)

# Enable E4M3 during forward pass, E5M2 during backward pass.
fp8_format = Format.HYBRID

# Create an FP8 recipe.
```

```
fp8_recipe = DelayedScaling(fp8_format=fp8_format, amax_history_len=32,
 amax_compute_algo="max")

# Enable FP8 autocasting.
with te.fp8_autocast(enabled=True, fp8_recipe=fp8_recipe,
 fp8_group=tsm.state.world_process_group):
    out = model(inp)

loss = out.sum()
loss.backward()
```

To find a practical example of FP8 training with SMP v2 on P5 instances, see the example notebook at Accelerate SageMaker PyTorch FSDP Training of Llama-v2 (or GPT-NeoX) with FP8 on P5 instances.

Mixed precision training with half-precision data types using PyTorch FSDP

SMP v2 supports PyTorch FSDP `MixedPrecision` for training jobs on P4 and P5 instances. PyTorch FSDP provides various configurations for mixed precision for both performance improvement and memory reduction.

> **Note**
>
> This mixed precision training with the PyTorch FSDP feature is available in the following combination of libraries of SageMaker and the PyTorch library.
>
> - SMP v2.0.0 and later
> - the SageMaker Python SDK v2.200.0 and later
> - PyTorch v2.0.1 and later

The standard way to configure a model for mixed precision is to create the model in `float32`, and then allow FSDP to cast the parameters to `float16` or `bfloat16` on the fly by passing a `MixedPrecision` policy, as shown in the following code snippet. For more information about options to change the `dtype` for parameters, reduction, or buffers for mixed precision in PyTorch, see PyTorch FSDP `MixedPrecision` API in the *PyTorch documentation*.

```
# Native PyTorch API
from torch.distributed.fsdp import MixedPrecision
```

```
dtype = torch.bfloat16
mixed_precision_policy = MixedPrecision(
    param_dtype=dtype, reduce_dtype=dtype, buffer_dtype=dtype
)

model = FSDP(
    model,
    ...,
    mixed_precision=mixed_precision_policy
)
```

Note that certain models (such as the Hugging Face Transformers Llama model) expect buffers as `float32`. To use `float32`, replace `torch.bfloat16` with `torch.float32` in the line defining the `dtype` object.

Delayed parameter initialization

Initialization of a large model for training is not always possible with the limited GPU memory. To resolve this problem of insufficient GPU memory, you can initialize the model on CPU memory. However, for larger models with more than 20 or 40 billion parameters, even CPU memory might not be enough. For such case, we recommend that you initialize the model on what PyTorch calls a *meta device*, which allows the creation of tensors without any data attached to them. A tensor on a meta device only needs the shape information, and this allows to create a large model with its parameters on meta devices. Hugging Face Accelerate provides the context manager `init_empty_weights` to help create such model on meta devices while initializing the buffers on a regular device. Before training starts, PyTorch FSDP initializes the model parameters. This delayed parameter initialization feature of SMP v2 delays this creation of model parameters to happen after PyTorch FSDP performs parameter sharding. PyTorch FSDP accepts a parameter initialization function (`param_init_fn`) when sharding the modules, and it calls `param_init_fn` for each module. The `param_init_fn` API takes a module as an argument and initializes all the parameters in it, not including the parameters of any child module. Note that this behavior *differs* from the native PyTorch v2.0.1 which has a bug causing the parameters to be initialized multiple times.

SMP v2 provides the the section called “`torch.sagemaker.delayed_param.DelayedParamIniter`” API for applying delayed parameter initialization.

The following code snippets show how to apply the `torch.sagemaker.delayed_param.DelayedParamIniter` API to your training script.

Assume that you have a PyTorch FSDP training script as follows.

```
# Creation of model on meta device
from accelerate import init_empty_weights
with init_empty_weights():
    model = create_model()

# Define a param init fn, below is an example for Hugging Face GPTNeoX.
def init_weights(module):
    d = torch.cuda.current_device()
    # Note that below doesn't work if you have buffers in the model
    # buffers will need to reinitialized after this call
    module.to_empty(device=d, recurse=False)
    if isinstance(module, (nn.Linear, Conv1D)):
        module.weight.data.normal_(mean=0.0, std=args.initializer_range)
        if module.bias:
            module.bias.data.zero_()
    elif isinstance(module, nn.Embedding):
        module.weight.data.normal_(mean=0.0, std=args.initializer_range)
        if module.padding_idx:
            module.weight.data[module.padding_idx].zero_()
    elif isinstance(module, nn.LayerNorm):
        module.bias.data.zero_()
        module.weight.data.fill_(1.0)

# Changes to FSDP wrapper.
model = FSDP(
    model,
    ...,
    param_init_fn=init_weights
)

# At this point model is initialized and sharded for sharded data parallelism.
```

Note that the delayed parameter initialization approach is not model agnostic. To resolve this issue, you need to write an `init_weights` function as shown in the preceding example to match the initialization in the original model definition, and it should cover all the parameters of the model. To simplify this process of preparing such `init_weights` function, SMP v2 implements this initialization function for the following models: GPT-2, GPT-J, GPT-NeoX, and Llama from Hugging Face Transformers. The `torch.sagemaker.delayed_param.DelayedParamIniter` API also works with the SMP tensor parallel implementation,

`torch.sagemaker.tensor_parallel.transformer.TransformerLMHead` model, that you can call after the the section called "`torch.sagemaker.transform`" API call.

Using the `torch.sagemaker.delayed_param.DelayedParamIniter` API, you can adapt your PyTorch FSDP script as follows. After creating a model with empty weights, register the `torch.sagemaker.delayed_param.DelayedParamIniter` API to the model, and define an object of it. Pass the object to the `param_init_fn` of the PyTorch FSDP class.

```
from torch.sagemaker.delayed_param import DelayedParamIniter
from accelerate import init_empty_weights

with init_empty_weights():
    model = create_model()

delayed_initer = DelayedParamIniter(model)

with delayed_initer.validate_params_and_buffers_inited():
    model = FSDP(
        model,
        ...,
        param_init_fn=delayed_initer.get_param_init_fn()
    )
```

Notes on tied weights

When training models with tied weights, we need to take special care to tie the weights after initializing the weights with delayed parameter initialization. PyTorch FSDP does not have a mechanism to tie the weights after initializing them using `param_init_fn` as above. To address such cases we added API to allow a `post_init_hook_fn`, which can be used to tie the weights. You can pass any function in there which accepts the module as argument, but we also have a predefined `post_param_init_fn` defined in `DelayedParamIniter` which calls `tie_weights` method of the module if it exists. Note that it's safe to always pass in `post_param_init_fn` even if there's no `tie_weights` method for the module.

```
with delayed_initer.validate_params_and_buffers_inited():
    model = FSDP(
        model,
        ...,
        param_init_fn=delayed_initer.get_param_init_fn(),
        post_param_init_fn=delayed_initer.get_post_param_init_fn()
    )
```

Activation checkpointing

Activation checkpointing is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during the backward pass. Effectively, this trades extra computation time for reducing memory usage. If a module is checkpointed, at the end of a forward pass, only the initial inputs to the module and final outputs from the module stay in memory. PyTorch releases any intermediate tensors that are part of the computation inside that module during the forward pass. During the backward pass of the checkpointed modules, PyTorch recomputes these tensors. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing becomes lower.

SMP v2 supports the PyTorch activation checkpointing module, `apply_activation_checkpointing`. The following are examples of activation checkpointing of the Hugging Face GPT-NeoX model.

Checkpointing Transformer layers of the Hugging Face GPT-NeoX model

```
from transformers.models.gpt_neox import GPTNeoXLayer
from torch.distributed.algorithms._checkpoint.checkpoint_wrapper import (
    apply_activation_checkpointing
)

# check_fn receives a module as the arg,
# and it needs to return whether the module is to be checkpointed
def is_transformer_layer(module):
    from transformers.models.gpt_neox import GPTNeoXLayer
    return isinstance(submodule, GPTNeoXLayer)

apply_activation_checkpointing(model, check_fn=is_transformer_layer)
```

Checkpointing every other Transformer layer of the Hugging Face GPT-NeoX model

```
# check_fn receives a module as arg,
# and it needs to return whether the module is to be checkpointed
# here we define that function based on global variable (transformer_layers)
from transformers.models.gpt_neox import GPTNeoXLayer
from torch.distributed.algorithms._checkpoint.checkpoint_wrapper import (
    apply_activation_checkpointing
)

transformer_layers = [
```

```
    m for m model.modules() if isinstance(m, GPTNeoXLayer)
]

def is_odd_transformer_layer(module):
    return transformer_layers.index(module) % 2 == 0

apply_activation_checkpointing(model, check_fn=is_odd_transformer_layer)
```

Alternatively, PyTorch also has the `torch.utils.checkpoint` module for checkpointing, which is used by a subset of Hugging Face Transformers models. This module also works with SMP v2. However, it requires you to have access to the model definition for adding the checkpoint wrapper. Therefore, we recommend you to use the `apply_activation_checkpointing` method.

Activation offloading

> **Important**
>
> In SMP v2.2.0, the activation offloading functionality of the SMP library doesn't work. Use the native PyTorch activation offloading instead.

Typically, the forward pass computes activations at each layer and keeps them in GPU memory until the backward pass for the corresponding layer finishes. Offloading these tensors to CPU memory after the forward pass and fetching them back to GPU when they are needed for the backward pass of the layer can save substantial GPU memory usage. PyTorch supports offloading activations, but the implementation causes GPUs to be idle while activations are fetched back from CPU during backward pass. This causes a major performance degradation when using activation offloading.

SMP v2 improves this activation offloading, and it pre-fetches activations ahead of time before the activations are needed for the GPU to start backward pass on those activations. This pre-fetching feature helps training progresses be more efficiently run without idle GPUs, which results in offering benefits from lower memory usage without a performance degradation.

You can keep the native PyTorch modules for offloading activations in your training script. The following is an example structure of applying the SMP activation offloading feature in your script. Note that activation offloading is applicable *only* when used together with the section called "Activation checkpointing". To learn more about the native PyTorch checkpoint tools for activation offloading, see also the checkpoint_wrapper.py in the *PyTorch GitHub repository* and Activation

Checkpointing in the PyTorch blog *Scaling Multi-modal Foundation Models in TorchMultimodal with PyTorch Distributed*.

To apply the SMP activation offloading feature on PyTorch activation checkpointing, add the `sm_activation_offloading` and `activation_loading_horizon` parameters to the SMP configuration dictionary during the section called "Step 2: Launch a training job".

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Get started with SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `sm_activation_offloading` and `activation_loading_horizon` parameters, see the section called "SMP v2 core feature configuration parameters".

SMP configuration

```
{
    "activation_loading_horizon": 2,
    "sm_activation_offloading": True
}
```

In training script

> **Note**
>
> While activating the SMP activation offloading feature, make sure that you also use the PyTorch `offload_wrapper` function and apply it to the root module. The SMP activation offloading feature uses the root module to determine when forward pass is done to start pre-fetching.

```
import torch.sagemaker as tsm
tsm.init()

# Native PyTorch module for activation offloading
from torch.distributed.algorithms._checkpoint.checkpoint_wrapper import (
    apply_activation_checkpointing,
    offload_wrapper,
)
```

```
model = FSDP(...)

# Activation offloading requires activation checkpointing.
apply_activation_checkpointing(
    model,
    check_fn=checkpoint_transformer_layers_policy,
)

model = offload_wrapper(model)
```

Tensor parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the *set* of weights, gradients, or optimizer across devices, tensor parallelism shards *individual* weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

SMP v2 integrates with Transformer Engine for the implementation for tensor parallelism, and runs on top of PyTorch FSDP APIs. You can enable PyTorch FSDP and SMP tensor parallelism simultaneously, and determine the best model parallelism for best performance.

In practice, tensor parallelism is especially helpful in the following scenarios.

- When training with long context lengths as that leads to high activation memory with FSDP alone.
- When training with really large clusters on which the global batch size exceeds desired limits.

Hugging Face Transformer models compatible with the SMP tensor parallelism

SMP v2 currently offers tensor parallelism support for the following Hugging Face transformer models.

- GPT-NeoX

- Llama 2

For reference configuration for applying tensor parallelism on these models, see the section called "Configuration tips".

Configure tensor parallelism

For `tensor_parallel_degree`, you select a value for the degree of tensor parallelism. The value must evenly divide the number of GPUs in your cluster. For example, to shard your model while using an instance with 8 GPUs, choose 2, 4, or 8. We recommend that you start with a small number, and gradually increase it until the model fits in the GPU memory.

The following code snippets show how to add the SMP initialization module `torch.sagemaker.init()` to your training script and set up the SMP configuration dictionary in JSON format for training job launcher while following the two-step process introduced in the section called "Get started with SMP v2". You don't need to make any changes to your PyTorch model or PyTorch FSDP configuration. For more information about the `tensor_parallel_degree` and `random_seed` parameters, see the section called "SMP v2 core feature configuration parameters".

SMP configuration

```
{
    "tensor_parallel_degree": 8,
    "random_seed": 0
}
```

In your training script

Initialize with `torch.sagemaker.init()` to activate SMP v2 and wrap your model with the the section called "`torch.sagemaker.transform`" API.

```
import torch.sagemaker as tsm
tsm.init()

from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_config(..)
model = tsm.transform(model)
```

Saving and loading Hugging Face Transformer checkpoints

After the SMP library transforms a model, it changes the state dictionary (`state_dict`) of the model. This means that the model becomes incompatible with the original Hugging Face Transformer checkpointing functionalities. To handle this, the SMP library provides APIs to save checkpoints from a transformed model in Hugging Face Transformer representation, and the `torch.sagemaker.transform` API to load a Hugging Face Transformer model checkpoint for fine-tuning.

For more information about saving checkpoints while using the tensor parallelism feature of SMP v2, see the section called "Save and load checkpoints while using SMP".

For more information about fine-tuning a model applying the tensor parallelism feature of SMP v2, see the section called "Fine-tuning".

Fine-tuning

Fine-tuning is a process of continuously training pre-trained models to improve performance for specific use cases.

Fine-tuning small models that fit fully on a single GPU, or those that fit 8 copies of model fully on CPUs is straightforward. It requires no special change to regular FSDP training. In the realm of models larger than this, you need to consider using the delayed parameter initialization functionality, which can be tricky.

To address this, the SMP library loads the full model on one of the ranks while the rest of the ranks create models with empty weights on a meta device. Then, PyTorch FSDP initializes the weights on non-zero ranks using the `init_weights` function, and synchronizes the weights on all ranks to the weights on the 0th rank with `sync_module_states` set to `True`. The following code snippet shows how you should set it up in your training script.

```
import torch.distributed as dist
from transformers import AutoModelForCasalLM
from accelerate import init_empty_weights
from torch.sagemaker.delayed_param import DelayedParamIniter

if dist.get_rank() == 0:
    model = AutoModelForCasalLM.from_pretrained(..., low_cpu_mem_usage=True)
else:
    with init_empty_weights():
```

```
        model = AutoModelForCasalLM.from_config(AutoConfig.from_pretrained(...))
    delayed_initer = DelayedParamIniter(model)

model = FSDP(
    model,
    ...,
    sync_module_states=True,
    param_init_fn=delayed_initer.get_param_init_fn() if dist.get_rank() > 0 else None
)
```

Fine-tuning a pre-trained Hugging Face Transformer model with SMP tensor parallelism

This section discusses loading Transformer models for two use cases: fine-tuning small Transformer models and fine-tuning large Transformer models. For smaller models without delayed parameter initialization, wrap the model with the `torch.sagemaker.transform` API before wrapping it with PyTorch FSDP.

```
import functools
from transformers import AutoModelForCausalLM
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.distributed.fsdp.wrap import transformer_auto_wrap_policy
from torch.sagemaker import transform

model = AutoModelForCausalLM.from_pretrained("meta-llama/Llama-2-7b-hf",
 low_cpu_mem_usage=True)

# Transform model while loading state dictionary from rank 0.
tp_model = transform(model, load_state_dict_from_rank0=True)

# Wrap with FSDP.
model = FSDP(
    tp_model,
    ...
    sync_module_states=True,
)
```

For larger models, the preceding approach causes to run out of CPU memory. We recommend that you use delayed parameter initialization to avoid such CPU memory issues. In this case, you can apply the `torch.sagemaker.transform` API and the `torch.sagemaker.delayed_param.DelayedParamIniter` API as shown in the following code example.

```
from transformers import AutoModelForCausalLM
from torch.sagemaker import transform
from torch.sagemaker.delayed_param import DelayedParamIniter

# Create one instance of model without delayed param
# on CPU, on one rank.
if dist.get_rank() == 0:
    model = AutoModelForCasalLM.from_pretrained(...,low_cpu_mem_usage=True)
else:
    with init_empty_weights():
        model = AutoModelForCasalLM.from_config(AutoConfig.from_pretrained(...))

# Transform model while loading state dictionary from rank 0
model = transform(model, load_state_dict_from_rank0=True)

if dist.get_rank() != 0: # For fine-tuning, delayed parameter on non-zero ranks
    delayed_initer = DelayedParamIniter(model)
else:
    delayed_initer = None

with (
    delayed_initer.validate_params_and_buffers_inited() if delayed_initer else
 nullcontext()
):
    # Wrap the model with FSDP
    model = FSDP(
        model,
        ...,
        sync_module_states=True,
        param_init_fn=delayed_initer.get_param_init_fn() if delayed_initer else None
    )
```

FlashAttention

SMP v2 supports FlashAttention kernels and makes it easy to apply them to various scenarios for Hugging Face Transformer models. Note that if you use FlashAttention package v2.0 or later, SMP uses FlashAttention v2; however, the Triton flash attention defaults to the flash attention kernel in FlashAttention v1.x, making it exclusively supported in FlashAttention v1.

The module (`nn.Module`) is a low level API that defines the attention layers of a model. It should be applied right after model creation, from the `AutoModelForCausalLM.from_config()` API for example, and before the model is being transformed or wrapped with FSDP.

Use FlashAttention kernels for self attention

The following code snippet shows how to use the the section called "torch.sagemaker.nn.attn.FlashSelfAttention" API provided by SMP v2.

```
def new_attn(self, q, k, v, attention_mask=None, head_mask=None):
    return (
        self.flashmod((q, k, v), causal=True, cast_dtype=torch.bfloat16, layout="b h s
 d"),
        None,
    )

for layer in model.gpt_neox.layers:
    layer.attention.flash_mod = torch.sagemaker.nn.attn.FlashSelfAttention()
    layer.attention._attn = functools.partial(new_attn, layer.attention)
```

Use FlashAttention kernels for grouped-query attention

SMP v2 also supports FlashAttention kernels for grouped-query attention (GQA) and makes it easy to apply them to various scenarios for Hugging Face Transformer models. Different from original attention architecture, GQA equally partitions query heads into groups, and query heads in the same group share the same key and value heads. Therefore, q and kv heads are passed into forward call separately. Note: The number of q heads needs to be divisible by the number of kv heads.

Example of using FlashGroupedQueryAttention

The following code snippet shows how to use the the section called "torch.sagemaker.nn.attn.FlashGroupedQueryAttention" API provided by SMP v2.

```
from transformers.models.llama.modeling_llama import LlamaAttention
from torch.sagemaker.nn.attn import FlashGroupedQueryAttention

class LlamaFlashAttention(LlamaAttention):
    def __init__(self, config: LlamaConfig):
        super().__init__(config)

        self.flash_attn = FlashGroupedQueryAttention(
            attention_dropout_prob=0.0,
        )
```

```
    def forward(
        self,
        hidden_states: torch.Tensor,
        attention_mask: Optional[torch.Tensor] = None,
        position_ids: Optional[torch.LongTensor] = None,
        ...
    ):
        query_states = self.q_proj(hidden_states)
        key_states = self.k_proj(hidden_states)
        value_states = self.v_proj(hidden_states)
        ...
        kv = (key_states, value_states)
        attn_output = self.flash_attn(
            query_states,
            kv,
            attn_mask=attention_mask,
            causal=True,
            layout="b h s d",
        )
        ...
        attn_output = self.o_proj(attn_output)
        ...
        return attn_output
```

The SMP library also provides the section called "`torch.sagemaker.nn.huggingface.llama_flashattn.LlamaFlashAttention`", which uses the the section called "`torch.sagemaker.nn.attn.FlashGroupedQueryAttention`" API at low level. Hugging Face Transformers has a similar implementation called `LlamaFlashAttention2` from v4.36.0. The following code snippet shows how to use the SMP v2 `LlamaFlashAttention` API or the Transformers `LlamaFlashAttention2` API to replace the attention layers of an existing Llama model.

```
from torch.sagemaker.nn.huggingface.llama_flashattn import LlamaFlashAttention
from transformers.models.llama.modeling_llama import LlamaFlashAttention2

flash_attn_class = LlamaFlashAttention # or flash_attn_class = LlamaFlashAttention2

attn_name = "self_attn"
for layer in model.model.layers:
    prev_layer = getattr(layer, attn_name)
    setattr(layer, attn_name, flash_attn_class(model.config))
```

Save and load checkpoints while using SMP

The SMP library supports PyTorch APIs for checkpoints, and provides APIs that help checkpoint properly while using the SMP library.

PyTorch FSDP supports three types of checkpoints: full, sharded and local. These serve different purposes. Full checkpoint should ideally be used only when exporting the model after training finishes, because it's expensive to generate a full checkpoint. Sharded checkpoint is the recommended approach for saving and loading checkpoints during training. Using sharded checkpoints you can also change the cluster size when resuming training. Local checkpoints are more restrictive. With local checkpoints, you need to resume training with same number of GPUs and currently it's not supported when using tensor parallelism with SMP. Note that checkpoints by FSDP require writing to a shared network file system, such as FSx.

Sharded checkpoints

The following procedure highlights what you need to do to adapt your training script to save and load sharded checkpoints with or without the SMP tensor parallelism feature.

1. Import the SMP `torch.sagemaker` package.

```
import torch.sagemaker as tsm
```

2. Set up auxiliary variables to save and load checkpoints.
   a. Set up a coordinator rank for performing communicative collective operations such as `AllReduce`.

```
coordinator_rank: int = min(dist.get_process_group_ranks(model.process_group))
```

   b. Using the `torch.sagemaker.state` enumerations, set up the action rank to determine whether to let the ranks take part in checkpointing. And add an if statement for saving checkpoints depending on the usage of SMP v2 tensor parallelism.

```
action_rank: bool = global_rank < (tsm.state.hybrid_shard_degree *
 tsm.state.tp_size)

if tsm.state.tp_size > 1:
    # Tensor parallel groups will have their own sub directories.
    sub_dir = f"tp{tsm.state.tp_size}-{tsm.state.tp_rank}"
else:
```

```
    sub_dir = ""
```

3. Keep using the PyTorch FSDP checkpoint APIs as is.

The following code example shows a full PyTorch FSDP training script with the FSDP checkpoint APIs.

```
import torch.distributed as dist
from torch.distributed.checkpoint.optimizer import (
    load_sharded_optimizer_state_dict
)
from torch.distributed.fsdp import (
    FullyShardedDataParallel as FSDP,
    StateDictType
)
import torch.sagemaker as tsm

sharding_strategy, state_dict_type = ..., ...
global_rank = dist.get_rank()

# 0. Auxiliary variables to save and load checkpoints.

# Used when performing comm collectives such as allreduce.
coordinator_rank: int = min(dist.get_process_group_ranks(model.process_group))

# To determine whether to take part in checkpointing.
action_rank: bool = global_rank < (tsm.state.hybrid_shard_degree * tsm.state.tp_size)

if tsm.state.tp_size > 1:
    # Tensor parallel groups will have their own sub directories.
    sub_dir = f"tp{tsm.state.tp_size}-{tsm.state.tp_rank}"
else:
    sub_dir = ""

# 1. Save checkpoints.
with FSDP.state_dict_type(model, StateDictType.SHARDED_STATE_DICT):
    state_dict = {
       "model": model.state_dict(),
       "optimizer": FSDP.optim_state_dict(model, optimizer),
        # Potentially add more customized state dicts.
    }

 # Save from one single replication group.
```

```
 if action_rank:
    dist.checkpoint.save_state_dict(
        state_dict=state_dict,
        storage_writer=dist.checkpoint.FileSystemWriter(os.path.join(save_dir,
 sub_dir)),
        process_group=model.process_group,
        coordinator_rank=coordinator_rank,
    )

# 2. Load checkpoints.
with FSDP.state_dict_type(model, StateDictType.SHARDED_STATE_DICT):
    # 2.1 Load model and everything else except the optimizer.
    state_dict = {
        # All states except optimizer state can be passed here.
        "model": model.state_dict()
    }

    dist.checkpoint.load_state_dict(
        state_dict=state_dict,
        storage_reader=dist.checkpoint.FileSystemReader(os.path.join(load_dir,
 sub_dir)),
        process_group=model.process_group,
        coordinator_rank=coordinator_rank,
    )
    model.load_state_dict(state_dict["model"])
    # Potentially process more customized and non-optimizer dict states.

    # 2.2 Load optimizer.
    optim_state = load_sharded_optimizer_state_dict(
        model_state_dict=state_dict["model"],
        optimizer_key="optimizer",
        storage_reader=dist.checkpoint.FileSystemReader(os.path.join(load_dir,
 sub_dir)),
        process_group=model.process_group,
    )
    flattened_optimizer_state = FSDP.optim_state_dict_to_load(
        optim_state["optimizer"], model, optimizer, group=model.process_group,
    )
    optimizer.load_state_dict(flattened_optimizer_state)
```

Full model checkpoints

At the end of training, you can save a full checkpoint that combines all shards of a model into a single model checkpoint file. The SMP library fully supports the PyTorch full model checkpoints API, so you don't need to make any changes.

Note that if you use the SMP the section called “Tensor parallelism”, the SMP library transforms the model. When checkpointing the full model in this case, the SMP library translates the model back to the Hugging Face Transformers checkpoint format by default.

In cases where you train with the SMP tensor parallelism and turn off the SMP translation process, you can use the `translate_on_save` argument of the PyTorch `FullStateDictConfig` API to switch the SMP auto-translation on or off as needed. For example, if you are focusing on training a model, you don’t need to add the translation process which adds overhead. In that case, we recommend you to set `translate_on_save=False`. Also, if you plan to keep using the SMP translation of the model for further training in future, you can switch it off to save the SMP translation of the model for later use. Translating the model back to the Hugging Face Transformers model checkpoint format is needed when you wrap up the training of your model and use that for inference.

```
from torch.distributed.fsdp import FullyShardedDataParallel as FSDP
from torch.distributed.fsdp import FullStateDictConfig
import torch.sagemaker as tsm

# Save checkpoints.
with FSDP.state_dict_type(
    model,
    StateDictType.FULL_STATE_DICT,
    FullStateDictConfig(
        rank0_only=True, offload_to_cpu=True,
        # Default value is to translate back to Hugging Face Transformers format,
        # when saving full checkpoints for models trained with SMP tensor parallelism.
        # translate_on_save=True
    ),
):
    state_dict = model.state_dict()
    if dist.get_rank() == 0:
        logger.info("Processed state dict to save. Starting write to disk now.")
        os.makedirs(save_dir, exist_ok=True)
        # This name is needed for HF from_pretrained API to work.
        torch.save(state_dict, os.path.join(save_dir, "pytorch_model.bin"))
```

```
        hf_model_config.save_pretrained(save_dir)
    dist.barrier()
```

Note that the option `FullStateDictConfig(rank0_only=True, offload_to_cpu=True)` is to gather the model on the CPU of the 0th rank device to save memory when training large models.

To load the model back for inference, you do so as shown in the following code example. Note that the class `AutoModelForCausalLM` might change to other factor builder classes in Hugging Face Transformers, such as `AutoModelForSeq2SeqLM`, depending on your model. For more information, see Hugging Face Transformers documentation.

```
from transformers import AutoModelForCausalLM
model = AutoModelForCausalLM.from_pretrained(save_dir)
```

Amazon SageMaker model parallelism library v2 examples

This page provides a list of blogs and Jupyter notebooks that present practical examples of implementing the SageMaker model parallelism (SMP) library v2 to run distributed training jobs on SageMaker.

Blogs and Case Studies

The following blogs discuss case studies about using SMP v2.

- Amazon SageMaker model parallel library now accelerates PyTorch FSDP workloads by up to 20%

PyTorch example notebooks

Example notebooks are provided in the SageMaker examples GitHub repository. To download the examples, run the following command to clone the repository and go to `training/distributed_training/pytorch/model_parallel_v2`.

> **Note**
>
> Clone and run the example notebooks in the following SageMaker ML IDEs.
>
> - SageMaker JupyterLab (available in Studio created after December 2023)

- SageMaker Code Editor (available in Studio created after December 2023)
- Studio Classic (available as an application in Studio created after December 2023)
- SageMaker Notebook Instances

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
cd amazon-sagemaker-examples/training/distributed_training/pytorch/model_parallel_v2
```

SMP v2 example notebooks

- Accelerate training of Llama v2 with SMP v2, PyTorch FSDP, and Transformer Engine by running FP8 training on P5 instances
- Fine-tune Llama v2 with SMP v2 and PyTorch FSDP at large-scale using tensor parallelism, hybrid sharding, and activation offloading
- Train GPT-NeoX with SMP v2 and PyTorch FSDP at large scale
- Fine-tune GPT-NeoX with SMP v2 and PyTorch FSDP at large-scale using tensor parallelism, hybrid sharding, and activation offloading

SageMaker distributed model parallelism best practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library v2 (SMP v2).

Setting up the right configuration for distributed training

To estimate and find the best starting point to apply distributed training techniques that SMP v2 provides, review the following list. Each list item discusses the advantage of using the the section called “Core features of SMP v2” along with potential tradeoffs.

Configuration tips

This section provides guidelines on how to decide on the best model configurations for optimal throughput with global batch size requirements.

First, we recommend the following setups regardless of the size of your model.

1. Use the most powerful instance type that you can use.

2. Turn on mixed precision all the time, as it provides substantial benefits for performance and memory reduction. We recommend you to use `bfloat16` as it's more precise than `float16`.
3. Turn on the SageMaker distributed data parallelism library (instead of using NCCL) whenever it's applicable, as shown in the section called "Compatibility with the SMDDP library". One exception is for tensor-parallelism-only use cases (`hybrid_shard_degree = 1` and `tensor_paralle_degree > 1`).
4. If your model has more than about 60 billion parameters, we recommend using the section called "Delayed parameter initialization". You can also use delayed parameter initialization to speed up the initialization for any model.
5. We recommend you to enable the section called "Activation checkpointing".

Depending on the size of you model, we recommend that you start with the following guidance.

1. Use sharded data parallelism.
   a. Depending on the batch size you intend to fit in the GPU memory, choose the appropriate sharded data parallel degree. Normally, you should start with the lowest degree to fit your model in the GPU memory while minimizing overhead from network communication. If you see a warning that cache flushes are happening, we recommend that you increase the sharding degree.
   b. Determine `world_size` based on the maximum local batch size and required global batch size, if any.
   c. You can experiment with activation offloading. Depending on scenarios, it can address your memory needs without having to increase the sharding degree, which means less communication.
2. Use sharded data parallelism of PyTorch FSDP and tensor parallelism of SMP v2 simultaneously, as introduced in the section called "Tensor parallelism".
   a. When training on large clusters, with FSDP alone the global batch size can become too large, causing convergence issues for the model. Typically, most research work keeps the batch size under 4 million tokens. In this case, you can resolve the problem by composing PyTorch FSDP with tensor parallelism of SMP v2 to reduce the batch size.

      For example, if you have 256 nodes and sequence length 4096, even a batch size of 1 per GPU leads to global batch size of 8M tokens. However, when you use tensor parallelism with degree 2 and batch size of 1 per tensor parallel group, this becomes 1/2 batch size per GPU, which translates to 4 million tokens.

b. When training with long context lengths such as 8k, 16k activation memory can become very high. FSDP doesn't shard activations, and activations can cause GPUs to go out of memory. In such scenarios, you can train efficiently by composing PyTorch FSDP with tensor parallelism of SMP v2.

Reference configurations

The SageMaker model parallelism training team provides the following reference points based on experiments with the Llama 2 model transformed to the SMP transformer model using the section called "`torch.sagemaker.transform`", and trained on `ml.p4d.24xlarge` instance(s) with sequence length 4096 and mixed precision (FP16 or BF16).

Model	Model size (the number of model parameters)	The number of instances	Sharded data parallel degree	Tensor parallel degree	Activation checkpointing	Activation offloading	Batch size
Llama 2	7B	1	8	1	TRUE	FALSE	4
	70B	32	256	1	TRUE	FALSE	2
	175B	64	128	4	TRUE	TRUE	6

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn't fit, try increasing the degree of tensor parallelism.

Monitoring and logging a training job using the SageMaker console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker console.

1. In the left navigation pane, choose **Training**.
2. Choose **Training jobs**.

3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the **Monitor** section to see the automated visualization.
5. To see training job logs, choose **View logs** in the **Monitor** section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of **algo-n-1234567890**. The **algo-1** log stream tracks training logs from the main (0th) node.

For more information, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics.

Permissions

To run a SageMaker training job with model parallelism, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add `AmazonFSxFullAccess`.
- To use Amazon S3 as a data channel, add `AmazonS3FullAccess`.
- To use Docker, build your own container, and push it to Amazon ECR, add `AmazonEC2ContainerRegistryFullAccess`.
- To have a full access to use the entire suite of SageMaker features, add `AmazonSageMakerFullAccess`.

The SageMaker model parallel library v2 reference

The following are references for the SageMaker model parallel library v2 (SMP v2).

Topics

- SMP v2 core feature configuration parameters
- Reference for the SMP v2 torch.sagemaker package
- Upgrade from SMP v1 to SMP v2

SMP v2 core feature configuration parameters

The following is a complete list of parameters to activate and configure the the section called "Core features of SMP v2". These must be written in JSON format and passed to the PyTorch estimator in the SageMaker Python SDK or saved as a JSON file for SageMaker HyperPod.

```
{
    "hybrid_shard_degree": Integer,
    "sm_activation_offloading": Boolean,
    "activation_loading_horizon": Integer,
    "fsdp_cache_flush_warnings": Boolean,
    "allow_empty_shards": Boolean,
    "tensor_parallel_degree": Integer,
    "expert_parallel_degree": Integer,
    "random_seed": Integer
}
```

- `hybrid_shard_degree` (Integer) – Specifies a sharded parallelism degree. The value must be an integer between `0` and `world_size`. The default value is `0`.
  - If set to `0`, it falls back to the native PyTorch implementation and API in the script when `tensor_parallel_degree` is 1. Otherwise, it computes the largest possible `hybrid_shard_degree` based on `tensor_parallel_degree` and `world_size`. When falling back to the native PyTorch FSDP use cases, if `FULL_SHARD` is the strategy you use, it shards across the whole cluster of GPUs. If `HYBRID_SHARD` or `_HYBRID_SHARD_ZERO2` was the strategy, it is equivalent to `hybrid_shard_degree` of 8. When tensor parallelism is enabled, it shards based on the revised `hybrid_shard_degree`.
  - If set to 1, it falls back to the native PyTorch implementation and API for `NO_SHARD` in the script when `tensor_parallel_degree` is 1. Otherwise, it's equivalent to `NO_SHARD` within any given tensor parallel groups.
  - If set to an integer between 2 and `world_size`, sharding happens across the specified number of GPUs. If you don't set up `sharding_strategy` in the FSDP script, it gets overridden to `HYBRID_SHARD`. If you set `_HYBRID_SHARD_ZERO2`, the `sharding_strategy` you specify is used.
- `sm_activation_offloading` (Boolean) – Specifies whether to enable the SMP activation offloading implementation. If `False`, offloading uses the native PyTorch implementation. If `True`, it uses the SMP activation offloading implementation. You also need to use the PyTorch activation offload wrapper (`torch.distributed.algorithms._checkpoint.checkpoint_wrapper.offload_wrapper`) in your script. To learn more, see the section called “Activation offloading”. The default value is `True`.
- `activation_loading_horizon` (Integer) – An integer specifying the activation offloading horizon type for FSDP. This is the maximum number of checkpointed or offloaded layers

whose inputs can be in the GPU memory simultaneously. To learn more, see the section called "Activation offloading". The input value must be a positive integer. The default value is 2.

- `fsdp_cache_flush_warnings` (Boolean) – Detects and warns if cache flushes happen in the PyTorch memory manager, because they can degrade computational performance. The default value is `True`.
- `allow_empty_shards` (Boolean) – Whether to allow empty shards when sharding tensors if tensor is not divisible. This is an experimental fix for crash during checkpointing in certain scenarios. Disabling this falls back to the original PyTorch behavior. The default value is `False`.
- `tensor_parallel_degree` (Integer) – Specifies a tensor parallelism degree. The value must be between 1 and `world_size`. The default value is 1. Passing a value greater than 1 does not enable tensor parallelism automatically. You also need to use the the section called "`torch.sagemaker.transform`" API to wrap the model in your training script. To learn more, see the section called "Tensor parallelism".
- `expert_parallel_degree` (Integer) – Specifies a expert parallelism degree. The value must be between 1 and `world_size`. The default value is 1. Passing a value greater than 1 does not enable expert parallelism automatically; make sure that you wrap the MoE model with the the section called "`torch.sagemaker.transform`" API in your training script.
- `random_seed` (Integer) – A seed number for the random operations in distributed modules by SMP tensor parallelism or expert parallelism. This seed will be added to tensor-parallel or expert-parallel ranks to set the actual seed for each rank. It is unique for each tensor-parallel and expert-parallel rank. SMP v2 makes sure that the random number generated across tensor-parallel and expert-parallel ranks matches the non-tensor-parallelism and non-expert-parallelism cases respectively.

Reference for the SMP v2 `torch.sagemaker` package

This section is a reference for the `torch.sagemaker` package provided by SMP v2.

`torch.sagemaker.delayed_param.DelayedParamIniter`

An API for applying the section called "Delayed parameter initialization" to a PyTorch model.

```
class torch.sagemaker.delayed_param.DelayedParamIniter(
    model: nn.Module,
    init_method_using_config : Callable = None,
    verbose: bool = False,
)
```

Parameters

- `model` (`nn.Module`) – A PyTorch model to wrap and apply the delayed parameter initialization functionality of SMP v2.
- `init_method_using_config` (Callable) – If you use the tensor parallel implementation of SMP v2 or supported the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism", keep this parameter at the default value, which is `None`. By default, the `DelayedParamIniter` API finds out how to initialize the given model correctly. For any other models, you need to create a custom parameter initialization function and add it to your script. The following code snippet is the default `init_method_using_config` function that SMP v2 implemented for the the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism". Use the following code snippet as a reference for creating your own initialization configuration function, adding it to your script, and passing it to the `init_method_using_config` parameter of the SMP `DelayedParamIniter` API.

  ```
  from torch.sagemaker.utils.module_utils import empty_module_params,
   move_buffers_to_device

  # Define a custom init config function.
  def custom_init_method_using_config(module):
      d = torch.cuda.current_device()
      empty_module_params(module, device=d)
      if isinstance(module, (nn.Linear, Conv1D)):
          module.weight.data.normal_(mean=0.0, std=config.initializer_range)
          if module.bias is not None:
              module.bias.data.zero_()
      elif isinstance(module, nn.Embedding):
          module.weight.data.normal_(mean=0.0, std=config.initializer_range)
  ```

```
        if module.padding_idx is not None:
            module.weight.data[module.padding_idx].zero_()
    elif isinstance(module, nn.LayerNorm):
        module.weight.data.fill_(1.0)
        module.bias.data.zero_()
    elif isinstance(module, LlamaRMSNorm):
        module.weight.data.fill_(1.0)
    move_buffers_to_device(module, device=d)

delayed_initer = DelayedParamIniter(model,
 init_method_using_config=custom_init_method_using_config)
```

For more information about the `torch.sagemaker.module_util` functions in the preceding code snippet, see the section called "`torch.sagemaker` util functions and properties".

- `verbose` (Boolean) – Whether to enable more detailed logging during initialization and validation. The default value is `False`.

Methods

- `get_param_init_fn()` – Returns the parameter initialization function that you can pass to the `param_init_fn` argument of the PyTorch FSDP wrapper class.
- `get_post_param_init_fn()` – Returns the parameter initialization function that you can pass to the `post_param_init_fn` argument of the PyTorch FSDP wrapper class. This is needed when you have tied weights in the model. The model must implement the method `tie_weights`. For more information, see the **Notes on tied weight** in the section called "Delayed parameter initialization".
- `count_num_params` (`module: nn.Module, *args: Tuple[nn.Parameter]`) – Tracks how many parameters are being initialized by the parameter initialization function. This helps implement the following `validate_params_and_buffers_inited` method. You usually don't need to call this function explicitly, because the `validate_params_and_buffers_inited` method implicitly calls this method in the backend.
- `validate_params_and_buffers_inited` (`enabled: bool=True`) – This is a context manager that helps validate that the number of parameters initialized matches the total number of parameters in the model. It also validates that all parameters and buffers are now on GPU devices instead of meta devices. It raises `AssertionErrors` if these conditions are not met. This context manager is only optional and you're not required to use this context manager to initialize parameters.

`torch.sagemaker.moe.moe_config.MoEConfig`

A configuration class for setting up the SMP-implementation of Mixture-of-Experts (MoE). You can specify MoE configuration values through this class and pass it to the `torch.sagemaker.transform` API call. To learn more about the usage of this class for training MoE models, see the section called "Expert parallelism".

```
class torch.sagemaker.moe.moe_config.MoEConfig(
    smp_moe=True,
    random_seed=12345,
    moe_load_balancing="sinkhorn",
    global_token_shuffle=False,
    moe_all_to_all_dispatcher=True,
    moe_aux_loss_coeff=0.001,
    moe_z_loss_coeff=0.001
)
```

- `smp_moe` (Boolean) - Whether to use the SMP-implementation of MoE. The default value is `True`.
- `random_seed` (Integer) - A seed number for the random operations in expert-parallel distributed modules. This seed will be added to the expert parallel rank to set the actual seed for each rank. It is unique for each expert parallel rank. The default value is `12345`.
- `moe_load_balancing` (String) - Specify the load balancing type of the MoE router. Valid options are `aux_loss`, `sinkhorn`, `balanced`, and none. The default value is `sinkhorn`.
- `global_token_shuffle` (Boolean) - Whether to shuffle tokens across EP ranks within the same EP group. The default value is `False`.
- `moe_all_to_all_dispatcher` (Boolean) - Whether to use all-to-all dispatcher for the communications in MoE. The default value is `True`.
- `moe_aux_loss_coeff` (Float) - A coefficient for auxiliary load balancing loss. The default value is `0.001`.
- `moe_z_loss_coeff` (Float) - Coefficient for z-loss. The default value is `0.001`.

`torch.sagemaker.nn.attn.FlashSelfAttention`

An API for using the section called "FlashAttention" with SMP v2.

```
class torch.sagemaker.nn.attn.FlashSelfAttention(
   attention_dropout_prob: float = 0.0,
```

```
    scale: Optional[float] = None,
    triton_flash_attention: bool = False,
    use_alibi: bool = False,
)
```

Parameters

- `attention_dropout_prob` (float) – The dropout probability to apply to attention. The default value is `0.0`.
- `scale` (float) – If passed, this scale factor will be applied for softmax. If set to `None` (which is also the default value), the scale factor is `1 / sqrt(attention_head_size)`. The default value is `None`.
- `triton_flash_attention` (bool) – If passed, Triton implementation of flash attention will be used. This is necessary to supports Attention with Linear Biases (ALiBi) (see the following `use_alibi` parameter). This version of the kernel doesn't support dropout. The default value is `False`.
- `use_alibi` (bool) – If passed, it enables Attention with Linear Biases (ALiBi) using the mask provided. When using ALiBi, it needs an attention mask prepared as follows. The default value is `False`.

```
def generate_alibi_attn_mask(attention_mask, batch_size, seq_length,
    num_attention_heads, alibi_bias_max=8):
    device, dtype = attention_mask.device, attention_mask.dtype
    alibi_attention_mask = torch.zeros(
        1, num_attention_heads, 1, seq_length, dtype=dtype, device=device
    )

    alibi_bias = torch.arange(1 - seq_length, 1, dtype=dtype, device=device).view(
        1, 1, 1, seq_length
    )
    m = torch.arange(1, num_attention_heads + 1, dtype=dtype, device=device)
    m.mul_(alibi_bias_max / num_attention_heads)
    alibi_bias = alibi_bias * (1.0 / (2 ** m.view(1, num_attention_heads, 1, 1)))

    alibi_attention_mask.add_(alibi_bias)
    alibi_attention_mask = alibi_attention_mask[..., :seq_length, :seq_length]
    if attention_mask is not None and attention_mask.bool().any():
        alibi_attention_mask.masked_fill(
            attention_mask.bool().view(batch_size, 1, 1, seq_length), float("-inf")
        )
```

```
    return alibi_attention_mask
```

Methods

- `forward(self, qkv, attn_mask=None, causal=False, cast_dtype=None, layout="b h s d")` – A regular PyTorch module function. When a `module(x)` is called, SMP runs this function automatically.
  - `qkv` – `torch.Tensor` of the following form: `(batch_size x seqlen x (3 x num_heads) x head_size)` or `(batch_size, (3 x num_heads) x seqlen x head_size)`, a tuple of `torch.Tensors` each of which might be of shape `(batch_size x seqlen x num_heads x head_size)`, or `(batch_size x num_heads x seqlen x head_size)`. An appropriate layout arg must be passed based on the shape.
  - `attn_mask` – `torch.Tensor` of the following form `(batch_size x 1 x 1 x seqlen)`. To enable this attention mask parameter, it requires `triton_flash_attention=True` and `use_alibi=True`. To learn how to generate an attention mask using this method, see the code examples at the section called "FlashAttention". The default value is `None`.
  - `causal` – When set to `False`, which is the default value of the argument, no mask is applied. When set to `True`, the `forward` method uses the standard lower triangular mask. The default value is `False`.
  - `cast_dtype` – When set to a particular `dtype`, it casts the `qkv` tensors to that `dtype` before `attn`. This is useful for implementations such as the Hugging Face Transformer GPT-NeoX model, which has `q` and `k` with `fp32` after rotary embeddings. If set to `None`, no cast is applied. The default value is `None`.
  - `layout` (string) – Available values are `b h s d` or `b s h d`. This should be set to the layout of `qkv` tensors passed, so appropriate transformations can be applied for `attn`. The default value is `b h s d`.

Returns

A single `torch.Tensor` with shape `(batch_size x num_heads x seq_len x head_size)`.

`torch.sagemaker.nn.attn.FlashGroupedQueryAttention`

An API for using `FlashGroupedQueryAttention` with SMP v2. To learn more about the usage of this API, see the section called "Use FlashAttention kernels for grouped-query attention".

```
class torch.sagemaker.nn.attn.FlashGroupedQueryAttention(
    attention_dropout_prob: float = 0.0,
    scale: Optional[float] = None,
)
```

Parameters

- `attention_dropout_prob` (float) – The dropout probability to apply to attention. The default value is `0.0`.
- `scale` (float) – If passed, this scale factor is applied for softmax. If set to None, `1 / sqrt(attention_head_size)` is used as the scale factor. The default value is None.

Methods

- `forward(self, q, kv, causal=False, cast_dtype=None, layout="b s h d")` – A regular PyTorch module function. When a `module(x)` is called, SMP runs this function automatically.
  - `q` – `torch.Tensor` of the following form `(batch_size x seqlen x num_heads x head_size)` or `(batch_size x num_heads x seqlen x head_size)`. Appropriate layout arg must be passed based on the shape.
  - `kv` – `torch.Tensor` of the following form `(batch_size x seqlen x (2 x num_heads) x head_size)` or `(batch_size, (2 x num_heads) x seqlen x head_size)`, or a tuple of two `torch.Tensors`, each of which might be of shape `(batch_size x seqlen x num_heads x head_size)` or `(batch_size x num_heads x seqlen x head_size)`. Appropriate `layout` argument must also be passed based on the shape.
  - `causal` – When set to `False`, which is the default value of the argument, no mask is applied. When set to `True`, the `forward` method uses the standard lower triangular mask. The default value is `False`.
  - `cast_dtype` – When set to a particular dtype, it casts the `qkv` tensors to that dtype before `attn`. This is useful for implementations such as Hugging Face Transformers GPT-NeoX, which has `q,k` with `fp32` after rotary embeddings. If set to None, no cast is applied. The default value is None.
  - layout (string) – Available values are `"b h s d"` or `"b s h d"`. This should be set to the layout of `qkv` tensors passed, so appropriate transformations can be applied for `attn`. The default value is `"b h s d"`.

Returns

Returns a single `torch.Tensor (batch_size x num_heads x seq_len x head_size)` that represents the output of attention computation.

`torch.sagemaker.nn.huggingface.llama_flashattn.LlamaFlashAttention`

An API that supports FlashAttention for the Llama model. This API uses the the section called "`torch.sagemaker.nn.attn.FlashGroupedQueryAttention`" API at low level. To learn how to use this, see the section called "Use FlashAttention kernels for grouped-query attention".

```
class torch.sagemaker.nn.huggingface.llama_flashattn.LlamaFlashAttention(
    config: LlamaConfig
)
```

Parameters

- `config` – A FlashAttention configuration for the Llama model.

Methods

- `forward(self, hidden_states, attention_mask, position_ids, past_key_value, output_attentions, use_cache)`
  - `hidden_states` (`torch.Tensor`) – Hidden states of a tensor in form of `(batch_size x seq_len x num_heads x head_size)`.
  - `attention_mask` (`torch.LongTensor`) – Mask to avoid performing attention on padding token indices in form of `(batch_size x seqlen)`. The default value is None.
  - `position_ids` (`torch.LongTensor`) – When not being None, it is in form of `(batch_size x seqlen)`, indicating the indices of positions of each input sequence token in the position embeddings. The default value is None.
  - `past_key_value` (Cache) – Pre-computed hidden-states (key and values in the self-attention blocks and in the cross-attention blocks). The default value is None.
  - `output_attentions` (bool) – Indicates whether to return the attentions tensors of all attention layers. The default value is `False`.
  - `use_cache` (bool) – Indicates whether to return `past_key_values` key value states. The default value is `False`.

Returns

Returns a single `torch.Tensor (batch_size x num_heads x seq_len x head_size)` that represents the output of attention computation.

`torch.sagemaker.transform`

SMP v2 provides this `torch.sagemaker.transform()` API for transforming Hugging Face Transformer models to SMP model implementations and enabling the SMP tensor parallelism.

```
torch.sagemaker.transform(
    model: nn.Module,
    device: Optional[torch.device] = None,
    dtype: Optional[torch.dtype] = None,
    config: Optional[Dict] = None,
    load_state_dict_from_rank0: bool = False
)
```

SMP v2 maintains transformation policies for the the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism" by converting the configuration of the Hugging Face Transformer models to the SMP transformer configuration.

Parameters

- `model` (`torch.nn.Module`) – A model from the section called "Hugging Face Transformer models compatible with the SMP tensor parallelism" to transform and apply the tensor parallelism feature of the SMP library.
- `device` (`torch.device`) – If passed, a new model is created on this device. If the original module has any parameter on meta device (see the section called "Delayed parameter initialization"), then the transformed module will also be created on meta device, ignoring the argument passed here. The default value is `None`.
- `dtype` (`torch.dtype`) – If passed, sets this as the dtype context manager for the creation of the model and creates a model with this dtype. This is typically unnecessary, as we want to create the model with `fp32` when using `MixedPrecision`, and `fp32` is the default dtype in PyTorch. The default value is `None`.
- `config` (dict) – This is a dictionary for configuring the SMP transformer. The default value is `None`.
- `load_state_dict_from_rank0` (Boolean) – By default, this module creates a new instance of the model with new weights. When this argument is set to `True`, SMP tries to load the state

dictionary of the original PyTorch model from the 0th rank into transformed model for the tensor parallel group that the 0th rank is part of. When this is set to `True`, rank 0 can't have any parameters on meta device. Only the first tensor parallel group populates the weights from the 0th rank after this transform call. You need to set `sync_module_states` to `True` in the FSDP wrapper to get these weights from the first tensor parallel group to all other processes. With this activated, the SMP library loads the state dictionary from the original model. The SMP library takes the `state_dict` of the model before transform, converts it to match the structure of the transformed model, shards it for each tensor parallel rank, communicates this state from the 0th rank to other ranks in the tensor parallel group that the 0th rank is part of, and loads it. The default value is `False`.

Returns

Returns a transformed model that you can wrap with PyTorch FSDP. When `load_state_dict_from_rank0` is set to `True`, the tensor parallel group that involves rank 0 has weights loaded from the original state dictionary on rank 0. When using the section called "Delayed parameter initialization" on the original model, only these ranks have the actual tensors on CPUs for the parameters and buffers of the transformed model. The rest of the ranks continue to have the parameters and buffers on the meta device to save memory.

`torch.sagemaker` util functions and properties

torch.sagemaker util functions

- `torch.sagemaker.init(config: Optional[Union[str, Dict[str, Any]]] = None) -> None` – Initializes the PyTorch training job with SMP.
- `torch.sagemaker.is_initialized() -> bool` – Checks whether the training job is initialized with SMP. When falling back to the native PyTorch while the job is initialized with SMP, some of the properties are not relevant and become None, as indicated in the following **Properties** list.
- `torch.sagemaker.utils.module_utils.empty_module_params(module: nn.Module, device: Optional[torch.device] = None, recurse: bool = False) -> nn.Module` – Creates empty parameters on the given `device` if any, and it can be recursive for all nested modules if specified.
- `torch.sagemaker.utils.module_utils.move_buffers_to_device(module: nn.Module, device: torch.device, recurse: bool = False) -> nn.Module` –

Moves module buffers to the given `device`, and it can be recursive for all nested modules if specified.

Properties

`torch.sagemaker.state` holds multiple useful properties after the initialization of SMP with `torch.sagemaker.init`.

- `torch.sagemaker.state.hybrid_shard_degree` (int) – The sharded data parallelism degree, a copy from user input in the SMP configuration passed to `torch.sagemaker.init()`. To learn more, see the section called "Get started with SMP v2".
- `torch.sagemaker.state.rank` (int) – The global rank for the device, in the range of `[0, world_size)`.
- `torch.sagemaker.state.rep_rank_process_group` (`torch.distributed.ProcessGroup`) – The process group including all devices with the same replication rank. Note the subtle but fundamental difference with `torch.sagemaker.state.tp_process_group`. When falling back to native PyTorch, it returns None.
- `torch.sagemaker.state.tensor_parallel_degree` (int) – The tensor parallelism degree, a copy from user input in the SMP configuration passed to `torch.sagemaker.init()`. To learn more, see the section called "Get started with SMP v2".
- `torch.sagemaker.state.tp_size` (int) – An alias to `torch.sagemaker.state.tensor_parallel_degree`.
- `torch.sagemaker.state.tp_rank` (int) – The tensor parallelism rank for the device in the range of `[0, tp_size)`, determined by the tensor parallelism degree and the ranking mechanism.
- `torch.sagemaker.state.tp_process_group` (`torch.distributed.ProcessGroup`) – The tensor parallel process group including all devices with the same rank in other dimensions (for example, sharded data parallelism and replication) but unique tensor parallel ranks. When falling back to native PyTorch, it returns None.
- `torch.sagemaker.state.world_size` (int) – The total number of devices used in training.

Upgrade from SMP v1 to SMP v2

To move from SMP v1 to SMP v2, you must make script changes to remove the SMP v1 APIs and apply the SMP v2 APIs. Instead of starting from your SMP v1 script, we recommend you start from a PyTorch FSDP script, and follow the instructions at the section called "Get started with SMP v2".

To bring SMP v1 *models* to SMP v2, in SMP v1 you must collect the full model state dictionary and apply the translation functions on the model state dictionary to convert it into the Hugging Face Transformers model checkpoint format. Then in SMP v2, as discussed in the section called "Save and load checkpoints while using SMP", you can load the Hugging Face Transformers model checkpoints, and then continue with using the PyTorch checkpoint APIs with SMP v2. To use SMP with your PyTorch FSDP model, make sure that you move to SMP v2 and make changes to your training script to use PyTorch FSDP and other latest features.

```
import smdistributed.modelparallel.torch as smp

# Create model
model = ...
model = smp.DistributedModel(model)

# Run training
...

# Save v1 full checkpoint
if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True) # save the full model
    # Get the corresponding translation function in smp v1 and translate
    if model_type == "gpt_neox":
        from smdistributed.modelparallel.torch.nn.huggingface.gptneox import
 translate_state_dict_to_hf_gptneox
        translated_state_dict = translate_state_dict_to_hf_gptneox(state_dict,
 max_seq_len=None)

    # Save the checkpoint
    checkpoint_path = "checkpoint.pt"
    if smp.rank() == 0:
        smp.save(
            {"model_state_dict": translated_state_dict},
            checkpoint_path,
            partial=False,
        )
```

To find available translation functions in SMP v1, see the section called "Support for Hugging Face Transformer Models".

For instruction on model checkpoints saving and loading in SMP v2, see the section called "Save and load checkpoints while using SMP".

Release notes for the SageMaker model parallelism library

See the following release notes to track the latest updates for the SageMaker model parallelism (SMP) library. If you have further questions about the SMP library, contact the SMP service team at `sm-model-parallel-feedback@amazon.com`.

The SageMaker model parallelism library v2.3.1

Date: May 9, 2024

Bug fixes

- Fixed an `ImportError` issue when using `moe_load_balancing=balanced` in the section called "`torch.sagemaker.moe.moe_config.MoEConfig`" for expert parallelism.
- Fixed a fine-tuning issue where the the section called "`torch.sagemaker.transform`" call raised `KeyError` when `load_state_dict_from_rank0` is enabled.
- Fixed an out-of-memory (OOM) error raised when loading large Mixture of Experts (MoE) models, such as Mixtral 8x22B, for fine-tuning.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. This release incorporates the aforementioned bug fixes into the following SMP Docker image.

- SMP Docker container for PyTorch v2.2.0 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121
```

The SageMaker model parallelism library v2.3.0

Date: April 11, 2024

New features

- Added a new core feature, *expert parallelism*, to support Mixture of Experts transformer models. To learn more, see the section called "Expert parallelism".

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.214.4 or later.

- SMP Docker container for PyTorch v2.2.0 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-
py310-cu121
```

  - Pre-installed packages in this Docker container
    - The SMDDP library v2.2.0
    - CUDNN v8.9.5.29
    - FlashAttention v2.3.3
    - TransformerEngine v1.2.1
    - Hugging Face Transformers v4.37.1
    - Hugging Face Datasets library v2.16.1
    - Megatron-core 0.5.0
    - EFA v1.30.0
    - NCCL v2.19.4

The SageMaker model parallelism library v2.2.0

Date: March 7, 2024

New Features

- Added support for FP8 training of the following Hugging Face transformer models on P5 instances with Transformer Engine integration:

- GPT-NeoX
- Llama 2

Bug Fixes

- Fixed a bug where tensors were not guaranteed to be contiguous before the `AllGather` collective call during tensor parallelism training.

Currency Updates

- Added support for PyTorch v2.2.0.
- Upgraded the SMDDP library to v2.2.0.
- Upgraded the FlashAttention library to v2.3.3.
- Upgraded the NCCL library to v2.19.4.

Deprecation

- Discontinued support for Transformer Engine versions before v1.2.0.

Known issues

- The SMP the section called “Activation offloading” feature currently does not work. Use the native PyTorch activation offloading instead.

Other changes

- Included a patch to fix the performance regression discussed in the issue thread at https://github.com/pytorch/pytorch/issues/117748 in the PyTorch GitHub repository.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.212.0 or later.

- SMP Docker container for PyTorch v2.2.0 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.2.0-gpu-py310-cu121
```

  - Available for P4d, P4de, and P5 instances
  - Pre-installed packages in this Docker container
    - The SMDDP library v2.2.0
    - CUDNN v8.9.5.29
    - FlashAttention v2.3.3
    - TransformerEngine v1.2.1
    - Hugging Face Transformers v4.37.1
    - Hugging Face Datasets library v2.16.1
    - EFA v1.30.0
    - NCCL v2.19.4

The SageMaker model parallelism library v2.1.0

Date: February 6, 2024

Currency Updates

- Added support for PyTorch v2.1.2.

Deprecation

- Discontinued support for Hugging Face Transformers v4.31.0.

Known issues

- An issue is discovered that fine-tuning of the Hugging Face Llama 2 model with `attn_implementation=flash_attention_2` and FSDP causes the model to diverge. For reference, see the issue ticket in the *Hugging Face Transformers GitHub repository*. To avoid the divergence issue, use `attn_implementation=sdpa`. Alternatively, use the SMP transformer model implementation by setting up `use_smp_implementation=True`.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.207.0 or later.

- SMP Docker container for PyTorch v2.1.2 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.1.2-gpu-py310-cu121
```

  - Available for P4d, P4de, and P5 instances
  - Pre-installed packages in this Docker container
    - The SMDDP library v2.1.0
    - CUDNN v8.9.5.29
    - FlashAttention v2.3.3
    - TransformerEngine v1.2.1
    - Hugging Face Transformers v4.37.1
    - Hugging Face Datasets library v2.16.1
    - EFA v1.30.0

SMP Conda channel

The following S3 bucket is a public Conda channel hosted by the SMP service team. If you want to install the SMP v2 library in an environment of highly customizable compute resources such as SageMaker HyperPod clusters, use this Conda channel to properly install the SMP library.

- `https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/smp-v2/`

For more information about Conda channels in general, see Channels in the *Conda documentation*.

The SageMaker model parallelism library v2.0.0

Date: December 19, 2023

New features

Released the SageMaker model parallelism (SMP) library v2.0.0 with the following new offerings.

- A new `torch.sagemaker` package, entirely revamped from the previous `smdistributed.modelparallel.torch` package in SMP v1.x.
- Support for PyTorch 2.0.1.
- Support for PyTorch FSDP.
- Tensor parallelism implementation by integrating with the Transformer Engine library.
- Support for both SageMaker Training and SageMaker HyperPod.

Breaking changes

- SMP v2 revamped the APIs entirely and provides the `torch.sagemaker` package. Mostly, you only need to initialize with the `torch.sagemaker.init()` module and pass model parallel configuration parameters. With this new package, you can significantly simplify code modifications in your training script. To learn more about adapting your training script to use SMP v2, see the section called "Get started with SMP v2".
- If you've used SMP v1 for training Hugging Face Transformer models and want to reuse the models in SMP v2, see the section called "Upgrade from SMP v1 to SMP v2".
- For PyTorch FSDP training, you should use SMP v2.

Known issues

- Activation checkpointing currently only works with the following wrapping policies with FSDP.
  - `auto_wrap_policy = functools.partial(transformer_auto_wrap_policy, ...)`
- To use the section called "Activation offloading", FSDP activation checkpointing type must be REENTRANT.
- When running with tensor parallel enabled with the sharded data parallel degree set to 1, you must use `backend = nccl`. The `smddp` backend option is not supported in this scenario.
- Transformer Engine is required to use PyTorch with the SMP library even when not using tensor parallelism.

Other changes

- Starting from this release, the documentation for the SageMaker model parallelism library is fully available in this *Amazon SageMaker Developer Guide*. In favor of this complete developer guide for SMP v2 in the *Amazon SageMaker Developer Guide*, the additional reference for SMP v1.x in the *SageMaker Python SDK documentation* is deprecated. If you still need the documentation for SMP v1.x, the developer guide for SMP v1.x is available at the section called "(Archived) SageMaker model parallelism library v1.x", and the SMP Python library v1.x reference is available in the SageMaker Python SDK v2.199.0 documentation.

Deprecations

- Discontinued support for TensorFlow.
- There is no pipeline parallelism support in SMP v2.
- There is no support for the DeepSpeed library in favor of native PyTorch FSDP.

SMP Docker container

The SMP library team distributes Docker containers in replacement of the SageMaker PyTorch framework containers. If you use the PyTorch estimator class in the SageMaker Python SDK and specify distribution configuration to use SMP v2, SageMaker automatically picks up the SMP Docker containers. To use this release of SMP v2, upgrade your SageMaker Python SDK to v2.207.0 or later.

- SMP Docker container for PyTorch v2.0.1 with CUDA v12.1

```
658645717510.dkr.ecr.us-west-2.amazonaws.com/smdistributed-modelparallel:2.0.1-gpu-
py310-cu121
```

(Archived) SageMaker model parallelism library v1.x

> **Important**
>
> As of December 19, 2023, the SageMaker model parallelism (SMP) library v2 is released. In favor of the SMP library v2, the SMP v1 capabilites are no longer supported in future releases. The following section and topics are archived and specific to using the SMP library v1. For information about using the SMP library v2, see the section called "SageMaker model parallelism library v2".

Use Amazon SageMaker's model parallel library to train large deep learning (DL) models that are difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances. Using the library, you can achieve a target prediction accuracy faster by efficiently training larger DL models with billions or trillions of parameters.

You can use the library to automatically partition your own TensorFlow and PyTorch models across multiple GPUs and multiple nodes with minimal code changes. You can access the library's API through the SageMaker Python SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located at Distributed Training APIs in the *SageMaker Python SDK v2.199.0 documentation*.

Topics

Introduction to Model Parallelism

Model parallelism is a distributed training method in which the deep learning model is partitioned across multiple devices, within or across instances. This introduction page provides a high-level overview about model parallelism, a description of how it can help overcome issues that arise when training DL models that are typically very large in size, and examples of what the SageMaker model parallel library offers to help manage model parallel strategies as well as memory consumption.

What is Model Parallelism?

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit

to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model you can train, since the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.

To overcome the limitations associated with training a model on a single GPU, SageMaker provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve most optimized distributed training using EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

Estimate Memory Requirements Before Using Model Parallelism

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses AMP (FP16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 parameter ~ 2 bytes
- An FP16 gradient ~ 2 bytes
- An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
- An FP32 copy of parameter ~ 4 bytes (needed for the `optimizer apply` (OA) operation)
- An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with 40GB/80GB memory and V100 with 16/32 GB) available on a single GPU. Note that on top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P3 and P4 instances that have NVIDIA V100 and A100 Tensor Core GPUs respectively. For more details about specifications

such as CPU cores, RAM, attached storage volume, and network bandwidth, see the *Accelerated Computing* section in the Amazon EC2 Instance Types page.

Even with the accelerated computing instances, it is obvious that models with about 10 billion parameters such as Megatron-LM and T5 and even larger models with hundreds of billions of parameters such as GPT-3 cannot fit model replicas in each GPU device.

How the Library Employs Model Parallelism and Memory Saving Techniques

The library consists of various types of model parallelism features and memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models that consist of hundreds of billions of parameters.

Topics

- Sharded data parallelism (available for PyTorch)
- Pipeline parallelism (available for PyTorch and TensorFlow)
- Tensor parallelism (available for PyTorch)
- Optimizer state sharding (available for PyTorch)
- Activation offloading and checkpointing (available for PyTorch)
- Choosing the right techniques for your model

Sharded data parallelism (available for PyTorch)

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs within a data-parallel group.

SageMaker implements sharded data parallelism through the implementation of MiCS, which is a library that **mi**nimizes **c**ommunication **s**cale and discussed in the blog post Near-linear scaling of gigantic-model training on AWS.

You can apply sharded data parallelism to your model as a stand-alone strategy. Furthermore, if you are using the most performant GPU instances equipped with NVIDIA A100 Tensor Core GPUs, `ml.p4d.24xlarge`, you can take the advantage of improved training speed from the `AllGather` operation offered by SMDDP Collectives.

To dive deep into sharded data parallelism and learn how to set it up or use a combination of sharded data parallelism with other techniques like tensor parallelism and FP16 training, see the section called “Sharded Data Parallelism”.

Pipeline parallelism (available for PyTorch and TensorFlow)

Pipeline parallelism partitions the set of layers or operations across the set of devices, leaving each operation intact. When you specify a value for the number of model partitions (`pipeline_parallel_degree`), the total number of GPUs (`processes_per_host`) must be divisible by the number of the model partitions. To set this up properly, you have to specify the correct values for the `pipeline_parallel_degree` and `processes_per_host` parameters. The simple math is as follows:

```
(pipeline_parallel_degree) x (data_parallel_degree) = processes_per_host
```

The library takes care of calculating the number of model replicas (also called `data_parallel_degree`) given the two input parameters you provide.

For example, if you set `"pipeline_parallel_degree": 2` and `"processes_per_host": 8` to use an ML instance with eight GPU workers such as `ml.p3.16xlarge`, the library automatically sets up the distributed model across the GPUs and four-way data parallelism. The following image illustrates how a model is distributed across the eight GPUs achieving four-way data parallelism and two-way pipeline parallelism. Each model replica, where we define it as a *pipeline parallel group* and label it as PP_GROUP, is partitioned across two GPUs. Each partition of the model is assigned to four GPUs, where the four partition replicas are in a *data parallel group* and labeled as DP_GROUP. Without tensor parallelism, the pipeline parallel group is essentially the model parallel group.

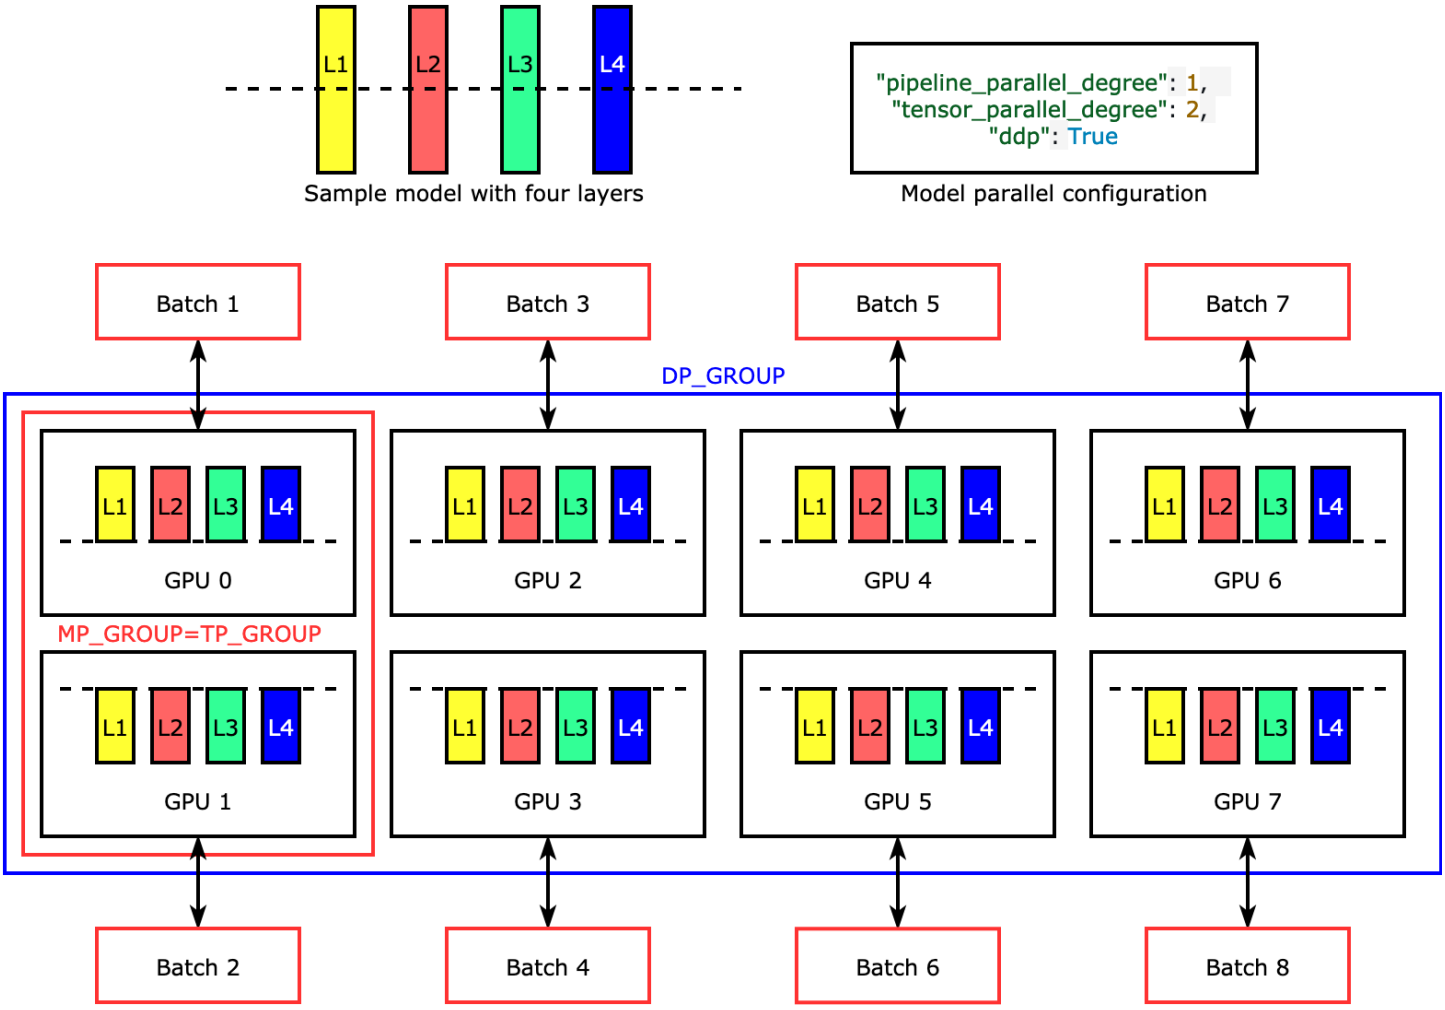
To dive deep into pipeline parallelism, see Core Features of the SageMaker Model Parallelism Library.

To get started with running your model using pipeline parallelism, see Run a SageMaker Distributed Training Job with the SageMaker Model Parallel Library.

Tensor parallelism (available for PyTorch)

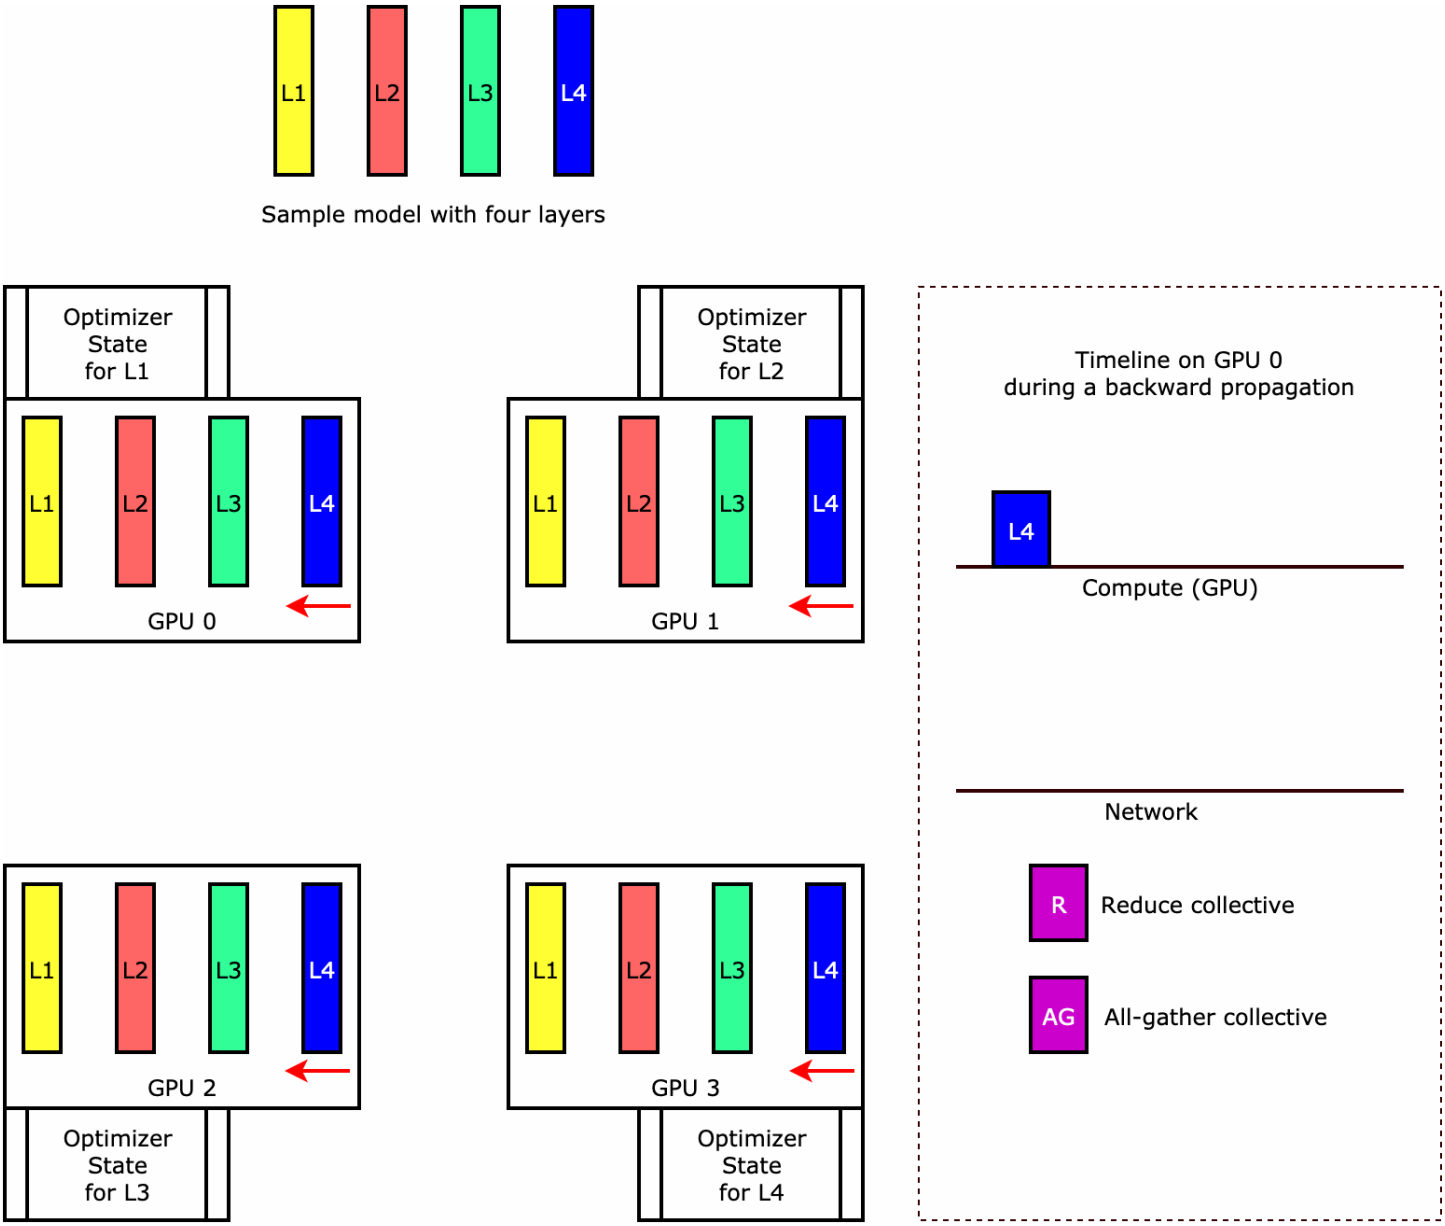
Tensor parallelism splits individual layers, or nn.Modules, across devices, to be run in parallel. The following figure shows the simplest example of how the library splits a model with four layers to achieve two-way tensor parallelism (`"tensor_parallel_degree": 2`). The layers of each model replica are bisected and distributed into two GPUs. In this example case, the model parallel configuration also includes `"pipeline_parallel_degree": 1` and `"ddp": True` (uses PyTorch DistributedDataParallel package in the background), so the degree of data parallelism becomes eight. The library manages communication across the tensor-distributed model replicas.



The usefulness of this feature is in the fact that you can select specific layers or a subset of layers to apply tensor parallelism. To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of pipeline and tensor parallelism, see Tensor Parallelism.

Optimizer state sharding (available for PyTorch)

To understand how the library performs *optimizer state sharding*, consider a simple example model with four layers. The key idea in optimizing state sharding is you don't need to replicate your optimizer state in all of your GPUs. Instead, a single replica of the optimizer state is sharded across data-parallel ranks, with no redundancy across devices. For example, GPU 0 holds the optimizer state for layer one, the next GPU 1 holds the optimizer state for L2, and so on. The following animated figure shows a backward propagation with the optimizer state sharding technique. At the end of the backward propagation, there's compute and network time for the `optimizer apply` (OA) operation to update optimizer states and the `all-gather` (AG) operation to update the model parameters for the next iteration. Most importantly, the `reduce` operation can overlap with the compute on GPU 0, resulting in a more memory-efficient and faster backward propagation. In the current implementation, AG and OA operations do not overlap with `compute`. It can result in an extended computation during the AG operation, so there might be a tradeoff.



For more information about how to use this feature, see Optimizer State Sharding.

Activation offloading and checkpointing (available for PyTorch)

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, the activation offloading feature offloads the stored activations to CPU memory and fetches back to GPU during the backward pass to further reduce activation memory footprint. For more information about how to use these features, see Activation Checkpointing and Activation Offloading.

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see SageMaker Distributed Model Parallel Best Practices and Configuration Tips and Pitfalls.

Supported Frameworks and AWS Regions

Before using the SageMaker model parallelism library, check the supported frameworks and instance types, and determine if there are enough quotas in your AWS account and AWS Region.

> **Note**
>
> To check the latest updates and release notes of the library, see the SageMaker Model Parallel Release Notes in the *SageMaker Python SDK documentation*.

Supported Frameworks

The SageMaker model parallelism library supports the following deep learning frameworks and is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

PyTorch versions supported by SageMaker and the SageMaker model parallelism library

PyTorch version	SageMaker model parallelism library version	`smdistributed-modelparallel` integrated DLC image URI	URL of the binary file**
v2.0.0	`smdistributed-modelparallel==v1.15.0`	`763104351884.dkr.ecr.<region>.amazonaws.com/pytorch-training:2.0.0-gpu-py310-cu118-ubuntu20.04-sagemaker`	https://sagemaker-distributed-model-parallel.s3.us-west-2.amazonaws.com/pytorch-2.0.0/build-artifacts/2023-04-14-20-14/smdistributed_modelparallel-1.15.0-cp310-cp310-linux_x86_64.whl

Note

The SageMaker model parallelism library v1.6.0 and later provides extended features for PyTorch. For more information, see Core Features of the SageMaker Model Parallelism Library.

** The URLs of the binary files are for installing the SageMaker model parallelism library in custom containers. For more information, see the section called "Create Your Own Docker Container with the Library".

TensorFlow versions supported by SageMaker and the SageMaker model parallelism library

TensorFlow version	SageMaker model parallelism library version	`smdistributed-modelparallel` integrated DLC image URI
v2.6.0	`smdistributed-modelparallel==v1.4.0`	`763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.6.0-gpu-py38-cu112-ubuntu20.04`
v2.5.1	`smdistributed-modelparallel==v1.4.0`	`763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.5.1-gpu-py37-cu112-ubuntu18.04`

Hugging Face Transformers versions supported by SageMaker and the SageMaker distributed data parallel library

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

AWS Regions

The SageMaker data parallel library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

Supported Instance Types

The SageMaker model parallelism library requires one of the following ML instance types.

Instance type
ml.g4dn.12xlarge
ml.p3.16xlarge
ml.p3dn.24xlarge
ml.p4d.24xlarge
ml.p4de.24xlarge

For specs of the instance types, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
    the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
    for training job usage' is 0 Instances, with current utilization of 0 Instances
    and a request delta of 1 Instances.
    Please contact AWS support to request an increase for this limit.
```

Core Features of the SageMaker Model Parallelism Library

Amazon SageMaker's model parallelism library offers distribution strategies and memory-saving techniques, such as sharded data parallelism, tensor parallelism, model partitioning by layers for pipeline scheduling, and checkpointing. The model parallelism strategies and techniques help distribute large models across multiple devices while optimizing training speed and memory consumption. The library also provides Python helper functions, context managers, and wrapper functions to adapt your training script for automated or manual partitioning of your model.

When you implement model parallelism to your training job, you keep the same two-step workflow shown in the Run a SageMaker Distributed Training Job with Model Parallelism section. For adapting your training script, you'll add zero or few additional code lines to your training script. For launching a training job of the adapted training script, you'll need to set the distribution configuration parameters to activate the memory-saving features or to pass values for the degree of parallelism.

To get started with examples, see the following Jupyter notebooks that demonstrate how to use the SageMaker model parallelism library.

- PyTorch example notebooks
- TensorFlow example notebooks

To dive deep into the core features of the library, see the following topics.

> **Note**
>
> The SageMaker distributed training libraries are available through the AWS deep learning containers for PyTorch, Hugging Face, and TensorFlow within the SageMaker Training platform. To utilize the features of the distributed training libraries, we recommend that you use the SageMaker Python SDK. You can also manually configure in JSON request syntax if you use SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

> **Important**
>
> The SageMaker model parallelism library supports all the core features for PyTorch, and supports pipeline parallelism for TensorFlow.

Topics

- Sharded Data Parallelism
- Pipelining a Model
- Tensor Parallelism
- Optimizer State Sharding
- Activation Checkpointing
- Activation Offloading
- FP16 Training with Model Parallelism
- Support for FlashAttention

Sharded Data Parallelism

Sharded data parallelism is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs in a data parallel group.

> **Note**
>
> Sharded data parallelism is available for PyTorch in the SageMaker model parallelism library v1.11.0 and later.

When scaling up your training job to a large GPU cluster, you can reduce the per-GPU memory footprint of the model by sharding the training state of the model over multiple GPUs. This returns two benefits: you can fit larger models, which would otherwise run out of memory with standard data parallelism, or you can increase the batch size using the freed-up GPU memory.

The standard data parallelism technique replicates the training states across the GPUs in the data parallel group, and performs gradient aggregation based on the `AllReduce` operation. Sharded data parallelism modifies the standard data-parallel distributed training procedure to account for the sharded nature of the optimizer states. A group of ranks over which the model and optimizer states are sharded is called a *sharding group*. The sharded data parallelism technique shards the trainable parameters of a model and corresponding gradients and optimizer states across the GPUs in the *sharding group*.

SageMaker achieves sharded data parallelism through the implementation of MiCS, which is discussed in the AWS blog post Near-linear scaling of gigantic-model training on AWS. In this implementation, you can set the sharding degree as a configurable parameter, which must be less than the data parallelism degree. During each forward and backward pass, MiCS temporarily recombines the model parameters in all GPUs through the `AllGather` operation. After the forward or backward pass of each layer, MiCS shards the parameters again to save GPU memory. During the backward pass, MiCS reduces gradients and simultaneously shards them across GPUs through the `ReduceScatter` operation. Finally, MiCS applies the local reduced and sharded gradients to their corresponding local parameter shards, using the local shards of optimizer states. To bring down communication overhead, the SageMaker model parallelism library prefetches the upcoming layers in the forward or backward pass, and overlaps the network communication with the computation.

The training state of the model is replicated across the sharding groups. This means that before gradients are applied to the parameters, the `AllReduce` operation must take place across the

sharding groups, in addition to the `ReduceScatter` operation that takes place within the sharding group.

In effect, sharded data parallelism introduces a tradeoff between the communication overhead and GPU memory efficiency. Using sharded data parallelism increases the communication cost, but the memory footprint per GPU (excluding the memory usage due to activations) is divided by the sharded data parallelism degree, thus larger models can be fit in the GPU cluster.

Selecting the degree of sharded data parallelism

When you select a value for the degree of sharded data parallelism, the value must evenly divide the degree of data parallelism. For example, for an 8-way data parallelism job, choose 2, 4, or 8 for the sharded data parallelism degree. While choosing the sharded data parallelism degree, we recommend that you start with a small number, and gradually increase it until the model fits in the memory together with the desired batch size.

Selecting the batch size

After setting up sharded data parallelism, make sure you find the most optimal training configuration that can successfully run on the GPU cluster. For training large language models (LLM), start from the batch size 1, and gradually increase it until you reach the point to receive the out-of-memory (OOM) error. If you encounter the OOM error even with the smallest batch size, apply a higher degree of sharded data parallelism or a combination of sharded data parallelism and tensor parallelism.

Topics

How to apply sharded data parallelism to your training job

To get started with sharded data parallelism, apply required modifications to your training script, and set up the SageMaker PyTorch estimator with the sharded-data-parallelism-specific parameters. Also consider to take reference values and example notebooks as a starting point.

Adapt your PyTorch training script

Follow the instructions at Step 1: Modify a PyTorch Training Script to wrap the model and optimizer objects with the `smdistributed.modelparallel.torch` wrappers of the `torch.nn.parallel` and `torch.distributed` modules.

(Optional) Additional modification to register external model parameters

If your model is built with `torch.nn.Module` and uses parameters that is not defined within the module class, you should register them to the module manually for SMP to gather the full parameters while . To register parameters to a module, use `smp.register_parameter(module, parameter)`.

```
class Module(torch.nn.Module):
    def __init__(self, *args):
        super().__init__(self, *args)
        self.layer1 = Layer1()
        self.layer2 = Layer2()
        smp.register_parameter(self, self.layer1.weight)

    def forward(self, input):
        x = self.layer1(input)
        # self.layer1.weight is required by self.layer2.forward
        y = self.layer2(x, self.layer1.weight)
        return y
```

Set up the SageMaker PyTorch estimator

When configuring a SageMaker PyTorch estimator in the section called “Step 2: Launch a Training Job”, add the parameters for sharded data parallelism.

To turn on sharded data parallelism, add the `sharded_data_parallel_degree` parameter to the SageMaker PyTorch Estimator. This parameter specifies the number of GPUs over which the training state is sharded. The value for `sharded_data_parallel_degree` must be an integer between one and the data parallelism degree and must evenly divide the data parallelism degree. Note that the library automatically detects the number of GPUs so thus the data parallel degree. The following additional parameters are available for configuring sharded data parallelism.

- `"sdp_reduce_bucket_size"` *(int, default: 5e8)* – Specifies the size of PyTorch DDP gradient buckets in number of elements of the default dtype.

- `"sdp_param_persistence_threshold"` *(int, default: 1e6)* – Specifies the size of a parameter tensor in number of elements that can persist at each GPU. Sharded data parallelism splits each parameter tensor across GPUs of a data parallel group. If the number of elements in the parameter tensor is smaller than this threshold, the parameter tensor is not split; this helps reduce communication overhead because the parameter tensor is replicated across data-parallel GPUs.
- `"sdp_max_live_parameters"` *(int, default: 1e9)* – Specifies the maximum number of parameters that can simultaneously be in a recombined training state during the forward and backward pass. Parameter fetching with the `AllGather` operation pauses when the number of active parameters reaches the given threshold. Note that increasing this parameter increases the memory footprint.
- `"sdp_hierarchical_allgather"` *(bool, default: True)* – If set to `True`, the `AllGather` operation runs hierarchically: it runs within each node first, and then runs across nodes. For multi-node distributed training jobs, the hierarchical `AllGather` operation is automatically activated.
- `"sdp_gradient_clipping"` *(float, default: 1.0)* – Specifies a threshold for gradient clipping the L2 norm of the gradients before propagating them backward through the model parameters. When sharded data parallelism is activated, gradient clipping is also activated. The default threshold is `1.0`. Adjust this parameter if you have the exploding gradients problem.

The following code shows an example of how to configure sharded data parallelism.

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        # "pipeline_parallel_degree": 1,    # Optional, default is 1
        # "tensor_parallel_degree": 1,      # Optional, default is 1
        "ddp": True,
        # parameters for sharded data parallelism
        "sharded_data_parallel_degree": 2,              # Add this to activate sharded
 data parallelism
        "sdp_reduce_bucket_size": int(5e8),             # Optional
        "sdp_param_persistence_threshold": int(1e6),    # Optional
        "sdp_max_live_parameters": int(1e9),            # Optional
        "sdp_hierarchical_allgather": True,             # Optional
```

```
        "sdp_gradient_clipping": 1.0                    # Optional
    }
}

mpi_options = {
    "enabled" : True,                       # Required
    "processes_per_host" : 8                # Required
}

smp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-job"
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Reference configurations

The SageMaker distributed training team provides the following reference configurations that you can use as a starting point. You can extrapolate from the following configurations to experiment and estimate the GPU memory usage for your model configuration.

Sharded data parallelism with SMDDP Collectives

Model/the number of parameters	Num instances	Instance type	Sequence length	Global batch size	Mini batch size	Sharded data parallel degree
GPT-NEOX-20B	2	ml.p4d.24xlarge	2048	64	4	16

Model/the number of parameters	Num instances	Instance type	Sequence length	Global batch size	Mini batch size	Sharded data parallel degree
GPT-NEOX-20B	8	ml.p4d.24xlarge	2048	768	12	32

For example, if you increase the sequence length for a 20-billion-parameter model or increase the size of the model to 65 billion parameters, you need to try reducing the batch size first. If the model still doesn't fit with the smallest batch size (the batch size of 1), try increasing the degree of model parallelism.

Sharded data parallelism with tensor parallelism and NCCL Collectives

Model/the number of parameters	Num instances	Instance type	Sequence length	Global batch size	Mini batch size	Sharded data parallel degree	Tensor parallel degree	Activation offloading
GPT-NEOX-65B	64	ml.p4d.24xlarge	2048	512	8	16	8	Y
GPT-NEOX-65B	64	ml.p4d.24xlarge	4096	512	2	64	2	Y

The combined usage of sharded data parallelism and tensor parallelism is useful when you want to fit a large language model (LLM) into a large-scale cluster while using text data with a longer sequence length, which leads to use a smaller batch size, and consequently handling the GPU memory usage to train LLMs against longer text sequences. To learn more, see the section called "Sharded data parallelism with tensor parallelism".

For case studies, benchmarks, and more configuration examples, see the blog post New performance improvements in Amazon SageMaker model parallel library.

Sharded data parallelism with SMDDP Collectives

The SageMaker data parallelism library offers collective communication primitives (SMDDP collectives) optimized for the AWS infrastructure. It achieves optimization by adopting an all-to-all-type communication pattern by making use of Elastic Fabric Adapter (EFA), resulting in high-throughput and less latency-sensitive collectives, offloading the communication-related processing to the CPU, and freeing up GPU cycles for computation. On large clusters, SMDDP Collectives can offer improvements in distributed training performance by up to 40% compared to NCCL. For case studies and benchmark results, see the blog New performance improvements in the Amazon SageMaker model parallelism library.

> **Note**
>
> Sharded data parallelism with SMDDP Collectives is available in the SageMaker model parallelism library v1.13.0 and later, and the SageMaker data parallelism library v1.6.0 and later. See also Supported configurations to use sharded data parallelism with SMDDP Collectives.

In sharded data parallelism, which is a commonly used technique in large-scale distributed training, the `AllGather` collective is used to reconstitute the sharded layer parameters for forward and backward pass computations, in parallel with GPU computation. For large models, performing the `AllGather` operation efficiently is critical to avoid GPU bottleneck problems and slowing down training speed. When sharded data parallelism is activated, SMDDP Collectives drops into these performance-critical `AllGather` collectives, improving training throughput.

Train with SMDDP Collectives

When your training job has sharded data parallelism activated and meets the Supported configurations, SMDDP Collectives are automatically activated. Internally, SMDDP Collectives optimize the `AllGather` collective to be performant on the AWS infrastructure and falls back to NCCL for all other collectives. Furthermore, under unsupported configurations, all collectives, including `AllGather`, automatically use the NCCL backend.

Since the SageMaker model parallelism library version 1.13.0, the `"ddp_dist_backend"` parameter is added to the `modelparallel` options. The default value for this configuration

parameter is "auto", which uses SMDDP Collectives whenever possible, and falls back to NCCL otherwise. To force the library to always use NCCL, specify "nccl" to the "ddp_dist_backend" configuration parameter.

The following code example shows how to set up a PyTorch estimator using the sharded data parallelism with the "ddp_dist_backend" parameter, which is set to "auto" by default and, therefore, optional to add.

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled":True,
    "parameters": {
        "partitions": 1,
        "ddp": True,
        "sharded_data_parallel_degree": 64
        "bf16": True,
        "ddp_dist_backend": "auto"  # Specify "nccl" to force to use NCCL.
    }
}

mpi_options = {
    "enabled" : True,                       # Required
    "processes_per_host" : 8                # Required
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo",
)
```

```
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Supported configurations

The `AllGather` operation with SMDDP Collectives are activated in training jobs when all the following configuration requirements are met.

- The sharded data parallelism degree greater than 1
- `Instance_count` greater than 1
- `Instance_type` equal to `ml.p4d.24xlarge`
- SageMaker training container for PyTorch v1.12.1 or later
- The SageMaker data parallelism library v1.6.0 or later
- The SageMaker model parallelism library v1.13.0 or later

Performance and memory tuning

SMDDP Collectives utilize additional GPU memory. There are two environment variables to configure the GPU memory usage depending on different model training use cases.

- `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` – During the SMDDP `AllGather` operation, the `AllGather` input buffer is copied into a temporary buffer for inter-node communication. The `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` variable controls the size (in bytes) of this temporary buffer. If the size of the temporary buffer is smaller than the `AllGather` input buffer size, the `AllGather` collective falls back to use NCCL.
  - Default value: 16 * 1024 * 1024 (16 MB)
  - Acceptable values: any multiple of 8192

- `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` – The `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` variable is to size the temporary buffer (in bytes) to hold data gathered from inter-node communication. If the size of this temporary buffer is smaller than `1/8 * sharded_data_parallel_degree * AllGather input size`, the `AllGather` collective falls back to use NCCL.
  - Default value: 128 * 1024 * 1024 (128 MB)
  - Acceptable values: any multiple of 8192

Tuning guidance on the buffer size variables

The default values for the environment variables should work well for most use cases. We recommend tuning these variables only if training runs into the out-of-memory (OOM) error.

The following list discusses some tuning tips to reduce the GPU memory footprint of SMDDP Collectives while retaining the performance gain from them.

- Tuning `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES`
  - The `AllGather` input buffer size is smaller for smaller models. Hence, the required size for `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` can be smaller for models with fewer parameters.
  - The `AllGather` input buffer size decreases as `sharded_data_parallel_degree` increases, because the model gets sharded across more GPUs. Hence, the required size for `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` can be smaller for training jobs with large values for `sharded_data_parallel_degree`.
- Tuning `SMDDP_AG_SORT_BUFFER_SIZE_BYTES`
  - The amount of data gathered from inter-node communication is less for models with fewer parameters. Hence, the required size for `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` can be smaller for such models with fewer number of parameters.

Some collectives might fall back to use NCCL; hence, you might not get the performance gain from the optimized SMDDP collectives. If additional GPU memory is available for use, you can consider increasing the values of `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` and `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` to benefit from the performance gain.

The following code shows how you can configure the environment variables by appending them to `mpi_options` in the distribution parameter for the PyTorch estimator.

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    .... # All modelparallel configuration options go here
}

mpi_options = {
    "enabled" : True,                       # Required
    "processes_per_host" : 8                # Required
```

```
}

# Use the following two lines to tune values of the environment variables for buffer
mpioptions += " -x SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES=8192"
mpioptions += " -x SMDDP_AG_SORT_BUFFER_SIZE_BYTES=8192"

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo-with-tuning",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Mixed precision training with sharded data parallelism

To further save GPU memory with half-precision floating point numbers and sharded data parallelism, you can activate 16-bit floating point format (FP16) or Brain floating point format (BF16) by adding one additional parameter to the distributed training configuration.

> **Note**
>
> Mixed precision training with sharded data parallelism is available in the SageMaker model parallelism library v1.11.0 and later.

For FP16 Training with Sharded Data Parallelism

To run FP16 training with sharded data parallelism, add `"fp16": True` to the `smp_options` configuration dictionary. In your training script, you can choose between the static and dynamic loss scaling options through the `smp.DistributedOptimizer` module. For more information, see the section called “FP16 Training with Model Parallelism”.

```
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "fp16": True
    }
}
```

For BF16 Training with Sharded Data Parallelism

The sharded data parallelism feature of SageMaker supports training in BF16 data type. The BF16 data type uses 8 bits to represent the exponent of a floating point number, while the FP16 data type uses 5 bits. Preserving the 8 bits for the exponent allows to keep the same representation of the exponent of a 32-bit single precision floating point (FP32) number. This makes the conversion between FP32 and BF16 simpler and significantly less prone to cause overflow and underflow issues that arise often in FP16 training, especially when training larger models. While both data types use 16 bits in total, this increased representation range for the exponent in the BF16 format comes at the expense of reduced precision. For training large models, this reduced precision is often considered an acceptable trade-off for the range and training stability.

> **Note**
>
> Currently, BF16 training works only when sharded data parallelism is activated.

To run BF16 training with sharded data parallelism, add `"bf16": True` to the `smp_options` configuration dictionary.

```
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "bf16": True
    }
}
```

Sharded data parallelism with tensor parallelism

If you use sharded data parallelism and also need to reduce the global batch size, consider using tensor parallelism with sharded data parallelism. When training a large model with sharded data parallelism on a very large compute cluster (typically 128 nodes or beyond), even a small batch size per GPU results in a very large global batch size. It might lead to convergence issues or low computational performance issues. Reducing the batch size per GPU sometimes is not possible with sharded data parallelism alone when a single batch is already large and cannot be reduced further. In such cases, using sharded data parallelism in combination with tensor parallelism helps reduce the global batch size.

Choosing the optimal sharded data parallel and tensor parallel degrees depends on the scale of the model, the instance type, and the global batch size that is reasonable for the model to converge. We recommend that you start from a low tensor parallel degree to fit the global batch size into the compute cluster to resolve CUDA out-of-memory errors and achieve the best performance. See the following two example cases to learn how the combination of tensor parallelism and sharded data parallelism helps you adjust the global batch size by grouping GPUs for model parallelism, resulting in a lower number of model replicas and a smaller global batch size.

> **Note**
>
> This feature is available from the SageMaker model parallelism library v1.15, and supports PyTorch v1.13.1.

> **Note**
>
> This feature is available for the supported models by the tensor parallelism functionality of the library. To find the list of the supported models, see Support for Hugging Face Transformer Models. Also note that you need to pass `tensor_parallelism=True` to the `smp.model_creation` argument while modifying your training script. To learn more, see the training script `train_gpt_simple.py` in the *SageMaker Examples GitHub repository*.

Example 1

Assume that we want to train a model over a cluster of 1536 GPUs (192 nodes with 8 GPUs in each), setting the degree of sharded data parallelism to 32

(`sharded_data_parallel_degree=32`) and the batch size per GPU to 1, where each batch has a sequence length of 4096 tokens. In this case, there are 1536 model replicas, the global batch size becomes 1536, and each global batch contains about 6 million tokens.

```
(1536 GPUs) * (1 batch per GPU) = (1536 global batches)
(1536 batches) * (4096 tokens per batch) = (6,291,456 tokens)
```

Adding tensor parallelism to it can lower the global batch size. One configuration example can be setting the tensor parallel degree to 8 and the batch size per GPU to 4. This forms 192 tensor parallel groups or 192 model replicas, where each model replica is distributed across 8 GPUs. The batch size of 4 is the amount of training data per iteration and per tensor parallel group; that is, each model replica consumes 4 batches per iteration. In this case, the global batch size becomes 768, and each global batch contains about 3 million tokens. Hence, the global batch size is reduced by half compared to the previous case with sharded data parallelism only.

```
(1536 GPUs) / (8 tensor parallel degree) = (192 tensor parallelism groups)
(192 tensor parallelism groups) * (4 batches per tensor parallelism group) = (768
 global batches)
(768 batches) * (4096 tokens per batch) = (3,145,728 tokens)
```

Example 2

When both sharded data parallelism and tensor parallelism are activated, the library first applies tensor parallelism and shards the model across this dimension. For each tensor parallel rank, the data parallelism is applied as per `sharded_data_parallel_degree`.

For example, assume that we want to set 32 GPUs with a tensor parallel degree of 4 (forming groups of 4 GPUs), a sharded data parallel degree of 4, ending up with a replication degree of 2. The assignment creates eight GPU groups based on the tensor parallel degree as follows: `(0,1,2,3)`, `(4,5,6,7)`, `(8,9,10,11)`, `(12,13,14,15)`, `(16,17,18,19)`, `(20,21,22,23)`, `(24,25,26,27)`, `(28,29,30,31)`. That is, four GPUs form one tensor parallel group. In this case, the reduced data parallel group for the 0th rank GPUs of the tensor parallel groups would be `(0,4,8,12,16,20,24,28)`. The reduced data parallel group is sharded based on the sharded data parallel degree of 4, resulting in two replication groups for data parallelism. GPUs `(0,4,8,12)` form one sharding group, which collectively hold a complete copy of all parameters for the 0th tensor parallel rank, and GPUs `(16,20,24,28)` form another such group. Other tensor parallel ranks also have similar sharding and replication groups.

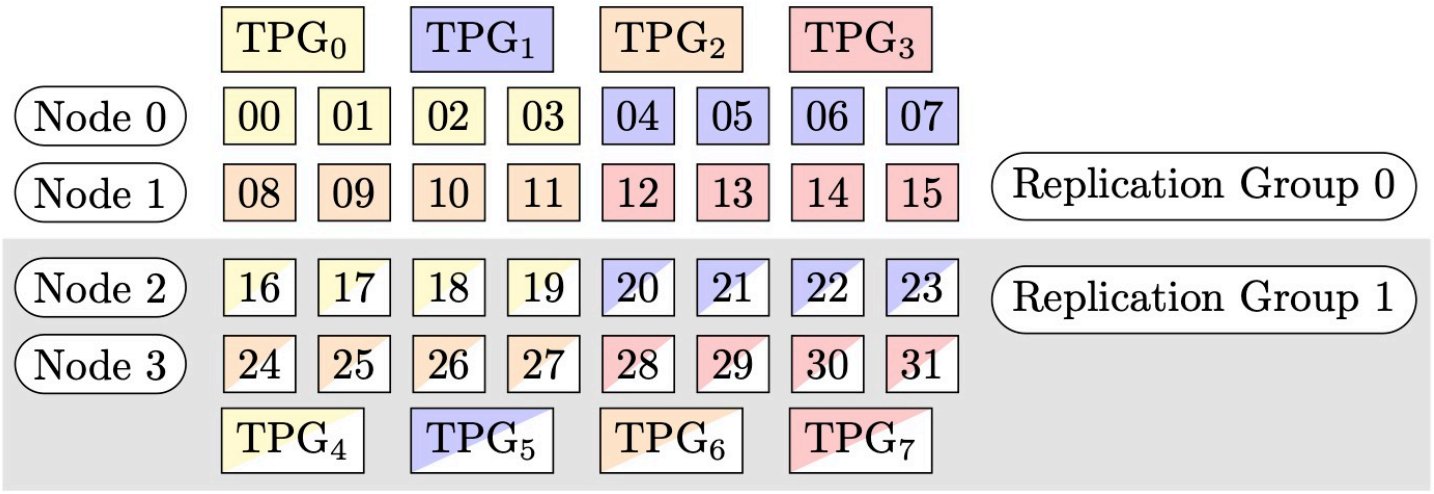

Figure 1: Tensor parallelism groups for (nodes, sharded data parallel degree, tensor parallel degree) = (4, 4, 4), where each rectangle represents a GPU with indices from 0 to 31. The GPUs form tensor parallelism groups from TPG_0 to TPG_7. Replication groups are ({TPG_0, TPG_4}, {TPG_1, TPG_5}, {TPG_2, TPG_6} and {TPG_3, TPG_7}); each replication group pair shares the same color but filled differently.

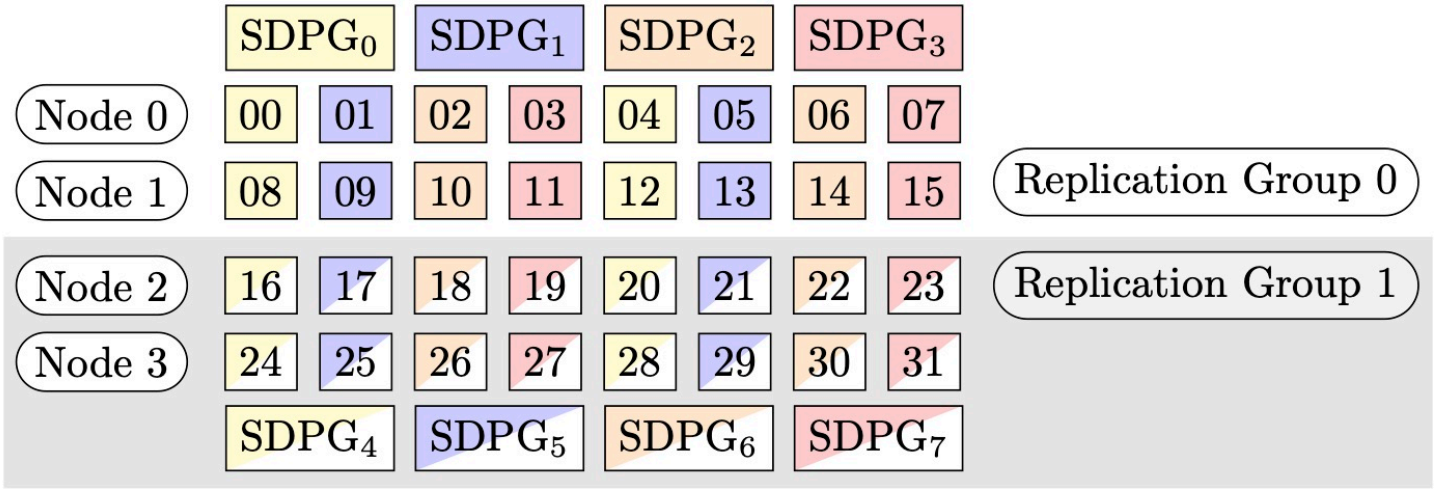

Figure 2: Sharded data parallelism groups for (nodes, sharded data parallel degree, tensor parallel degree) = (4, 4, 4), where each rectangle represents a GPU with indices from 0 to 31. The GPUs form sharded data parallelism groups from $SDPG_0$ to $SDPG_7$. Replication groups are ({$SDPG_0$, $SDPG_4$}, {$SDPG_1$, $SDPG_5$}, {$SDPG_2$, $SDPG_6$} and {$SDPG_3$, $SDPG_7$}); each replication group pair shares the same color but filled differently.

How to activate sharded data parallelism with tensor parallelism

To use sharded data parallelism with tensor parallelism, you need to set both `sharded_data_parallel_degree` and `tensor_parallel_degree` in the configuration for `distribution` while creating an object of the SageMaker PyTorch estimator class.

You also need to activate `prescaled_batch`. This means that, instead of each GPU reading its own batch of data, each tensor parallel group collectively reads a combined batch of the chosen batch size. Effectively, instead of dividing the dataset into parts equal to the number of GPUs (or data parallel size, `smp.dp_size()`), it divides into parts equal to the number of GPUs divided by `tensor_parallel_degree` (also called reduced data parallel size, `smp.rdp_size()`). For more details on prescaled batch, see Prescaled Batch in the *SageMaker Python SDK documentation*. See also the example training script `train_gpt_simple.py` for GPT-2 in the *SageMaker Examples GitHub repository*.

The following code snippet shows an example of creating a PyTorch estimator object based on the aforementioned scenario in the section called "Example 2".

```
mpi_options = "-verbose --mca orte_base_help_aggregate 0 "
smp_parameters = {
    "ddp": True,
    "fp16": True,
    "prescaled_batch": True,
    "sharded_data_parallel_degree": 4,
    "tensor_parallel_degree": 4
}

pytorch_estimator = PyTorch(
    entry_point="your_training_script.py",
    role=role,
    instance_type="ml.p4d.24xlarge",
    volume_size=200,
    instance_count=4,
    sagemaker_session=sagemaker_session,
    py_version="py3",
    framework_version="1.13.1",
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": smp_parameters,
            }
        },
        "mpi": {
            "enabled": True,
            "processes_per_host": 8,
            "custom_mpi_options": mpi_options,
        },
```

```
    },
    source_dir="source_directory_of_your_code",
    output_path=s3_output_location
)
```

Tips and considerations for using sharded data parallelism

Consider the following when using the SageMaker model parallelism library's sharded data parallelism.

- Sharded data parallelism is compatible with FP16 training. To run FP16 training, see the the section called "FP16 Training with Model Parallelism" section.
- Sharded data parallelism is compatible with tensor parallelism. The following items are what you might need to consider for using sharded data parallelism with tensor parallelism.
  - When using sharded data parallelism with tensor parallelism, the embedding layers are also automatically distributed across the tensor parallel group. In other words, the `distribute_embedding` parameter is automatically set to `True`. For more information about tensor parallelism, see the section called "Tensor Parallelism".
  - Note that sharded data parallelism with tensor parallelism currently uses the NCCL collectives as the backend of the distributed training strategy.

  To learn more, see the the section called "Sharded data parallelism with tensor parallelism" section.
- Sharded data parallelism currently is not compatible with pipeline parallelism or optimizer state sharding. To activate sharded data parallelism, turn off optimizer state sharding and set the pipeline parallel degree to 1.
- The activation checkpointing and activation offloading features are compatible with sharded data parallelism.
- To use sharded data parallelism with gradient accumulation, set the `backward_passes_per_step` argument to the number of accumulation steps while wrapping your model with the `smdistributed.modelparallel.torch.DistributedModel` module. This ensures that the gradient `AllReduce` operation across the model replication groups (sharding groups) takes place at the boundary of gradient accumulation.
- You can checkpoint your models trained with sharded data parallelism using the library's checkpointing APIs, `smp.save_checkpoint` and `smp.resume_from_checkpoint`. For more information, see the section called "Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)".

- The behavior of the `delayed_parameter_initialization` configuration parameter changes under sharded data parallelism. When these two features are simultaneously turned on, parameters are immediately initialized upon model creation in a sharded manner instead of delaying the parameter initialization, so that each rank initializes and stores its own shard of parameters.
- When sharded data parallelism is activated, the library performs gradient clipping internally when the `optimizer.step()` call runs. You don't need to use utility APIs for gradient clipping, such as `torch.nn.utils.clip_grad_norm_()`. To adjust the threshold value for gradient clipping, you can set it through the `sdp_gradient_clipping` parameter for the distribution parameter configuration when you construct the SageMaker PyTorch estimator, as shown in the the section called “How to apply sharded data parallelism to your training job” section.

Pipelining a Model

One of the core features of SageMaker's model parallelism library is *pipeline parallelism*, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation. When you use pipeline parallelism, training job is executed in a pipelined fashion over microbatches to maximize GPU usage.

> **Note**
>
> Pipeline parallelism, also called model partitioning, is available for both PyTorch and TensorFlow. For supported versions of the frameworks, see the section called “Supported Frameworks and AWS Regions”.

Pipeline Execution Schedule

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A *microbatch* is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

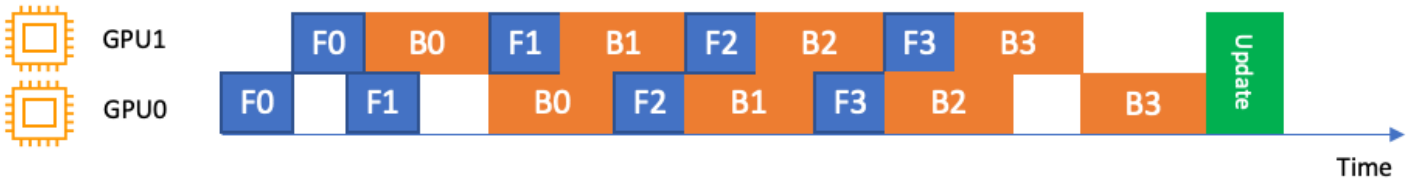
For example, depending on the pipeline schedule and the model partition, GPU `i` might perform (forward or backward) computation on microbatch b while GPU `i+1` performs computation on

microbatch b+1, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, *simple* and *interleaved*, which can be configured using the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

Interleaved Pipeline

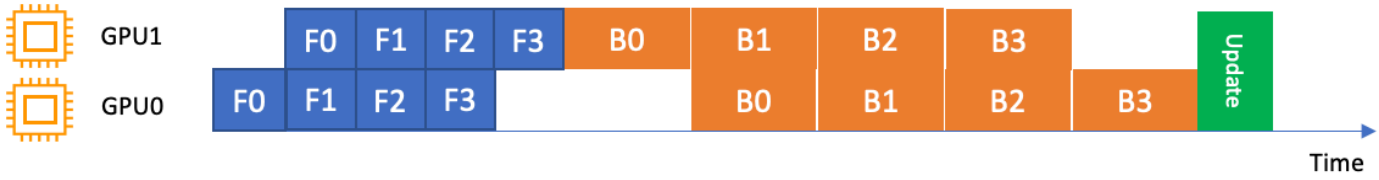
In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.



The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. **Update** represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

Simple Pipeline

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

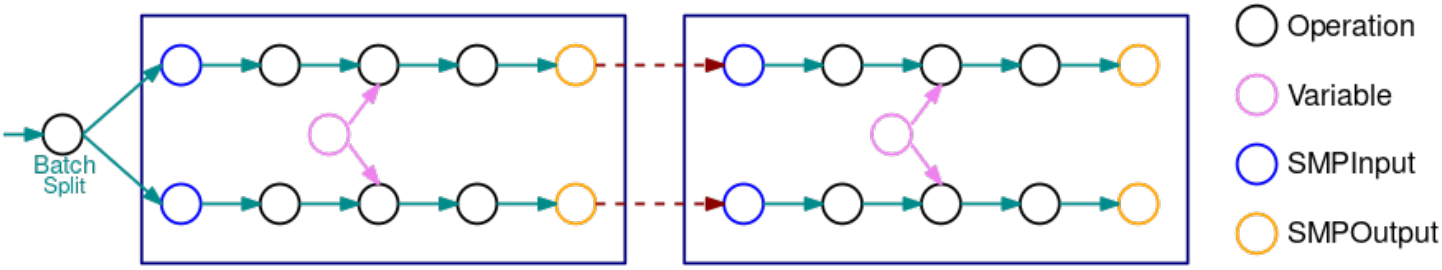


Pipelining Execution in Specific Frameworks

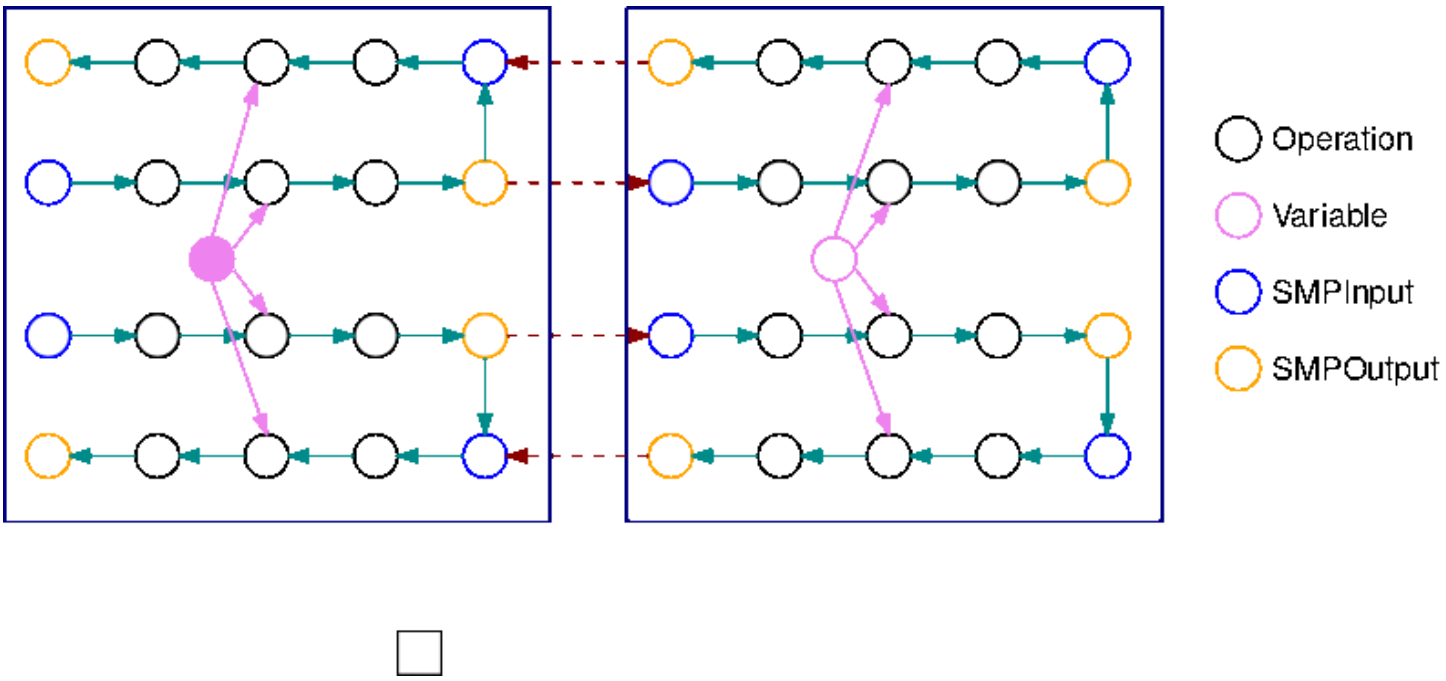
Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's model parallelism library makes for TensorFlow and PyTorch.

Pipeline Execution with TensorFlow

The following image is an example of a TensorFlow graph partitioned by the model parallelism library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An `SMPInput` operation is inserted at each input of a subgraph, and an `SMPOutput` operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.



The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a `SMPInput` op is a `SMPOutput` op, and vice versa. This enables the gradients to flow backwards during back-propagation.



This GIF demonstrates an example interleaved pipeline execution schedule with B=2 microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As B grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue `SMPInput` operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

Pipeline Execution with PyTorch

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallelism library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch

which the current device can actively work on. The prioritization of microbatches is determined by the chosen pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

Tensor Parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the *set* of weights, tensor parallelism splits individual weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

Tensor parallelism is also useful for extremely large models in which a pure pipelining is simply not enough. For example, with GPT-3-scale models that require partitioning over tens of instances, a pure microbatch pipelining is inefficient because the pipeline depth becomes too high and the overhead becomes prohibitively large.

> **Note**
>
> Tensor parallelism is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

Topics

- How Tensor Parallelism Works
- Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism
- Support for Hugging Face Transformer Models
- Ranking Mechanism when Using a Combination of Pipeline Parallelism and Tensor Parallelism

How Tensor Parallelism Works

Tensor parallelism takes place at the level of `nn.Modules`; it partitions specific modules in the model across tensor parallel ranks. This is in addition to the existing partition of the *set of modules* used in pipeline parallelism.

When a module is partitioned through tensor parallelism, its forward and backward propagation are distributed. The library handles the necessary communication across devices to implement the distributed execution of these modules. The modules are partitioned across multiple data parallel ranks. Contrary to the traditional distribution of workloads, each data parallel rank does **not** have the complete model replica when the library's tensor parallelism is used. Instead, each data parallel rank may have only a partition of the distributed modules, in addition to the entirety of the modules that are not distributed.

Example: Consider tensor parallelism across data parallel ranks, where the degree of data parallelism is 4 and the degree of tensor parallelism is 2. Assume that you have a data parallel group that holds the following module tree, after partitioning the set of modules.

```
A
### B
|   ### E
|   ### F
### C
### D
    ### G
    ### H
```

Assume that tensor parallelism is supported for the modules B, G, and H. One possible outcome of tensor parallel partition of this model could be:

```
dp_rank 0 (tensor parallel rank 0): A, B:0, C, D, G:0, H
dp_rank 1 (tensor parallel rank 1): A, B:1, C, D, G:1, H
dp_rank 2 (tensor parallel rank 0): A, B:0, C, D, G:0, H
dp_rank 3 (tensor parallel rank 1): A, B:1, C, D, G:1, H
```

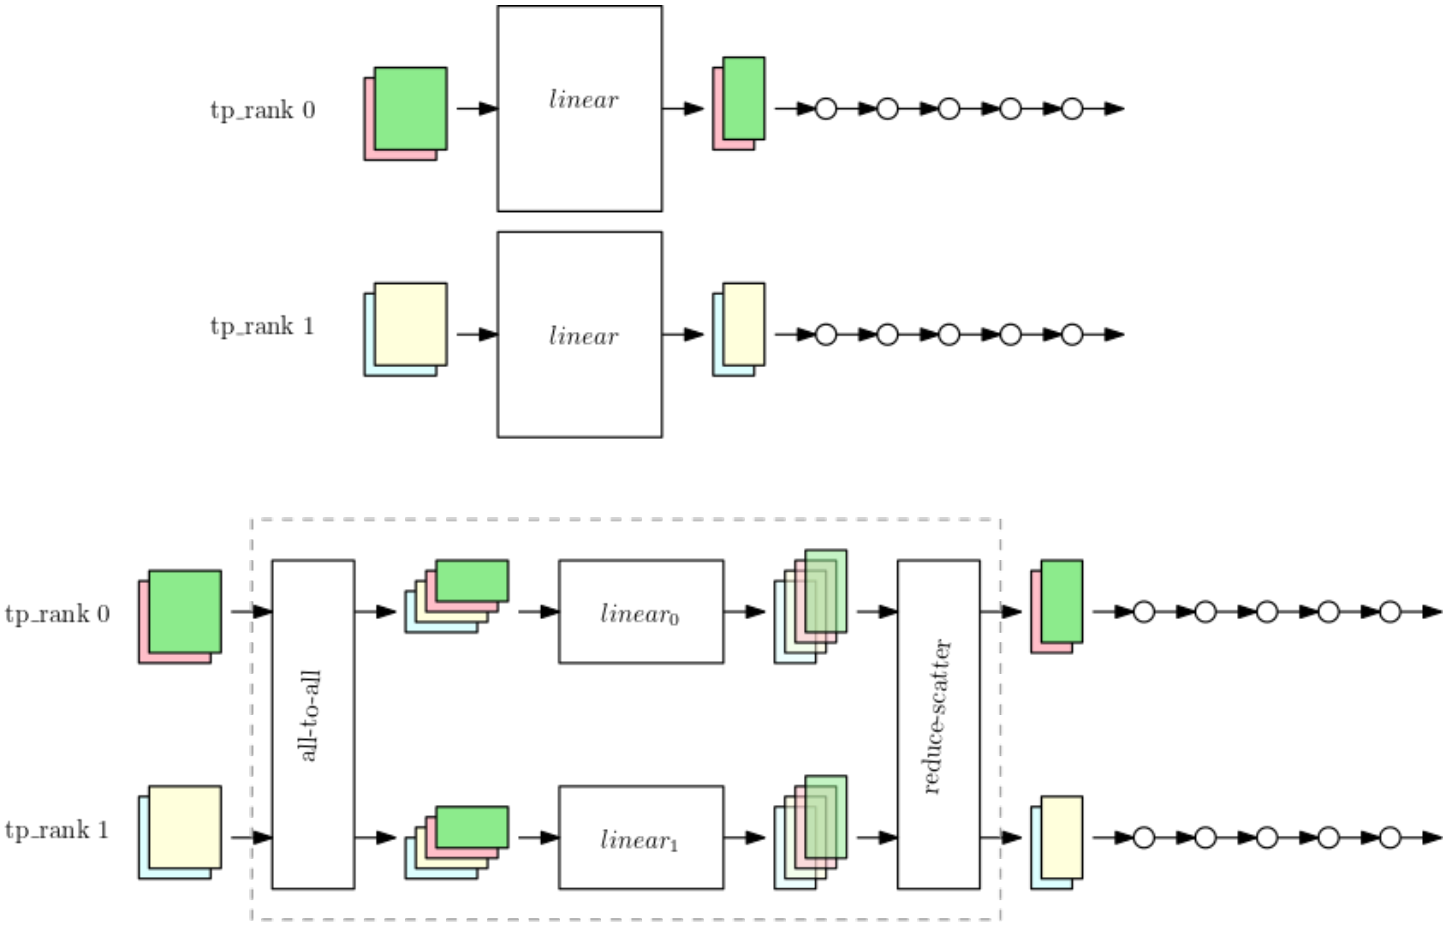
Each line represents the set of modules stored in that dp_rank, and the notation X:y represents the yth fraction of the module X. Note the following:

1. Partitioning takes place across subsets of data parallel ranks, which we call TP_GROUP, not the entire DP_GROUP, so that the exact model partition is replicated across dp_rank 0 and dp_rank 2, and similarly across dp_rank 1 and dp_rank 3.
2. The modules E and F are no longer part of the model, since their parent module B is partitioned, and any execution that is normally a part of E and F takes place within the (partitioned) B module.

3. Even though `H` is supported for tensor parallelism, in this example it is not partitioned, which highlights that whether to partition a module depends on user input. The fact that a module is supported for tensor parallelism does not necessarily mean it is partitioned.

How the library adapts tensor parallelism to PyTorch `nn.Linear` module

When tensor parallelism is performed over data parallel ranks, a subset of the parameters, gradients, and optimizer states are partitioned across the tensor parallel devices *for the modules that are partitioned*. For the rest of the modules, the tensor parallel devices operate in a regular data parallel manner. To execute the partitioned module, a device first collects the necessary parts of *all data samples* across peer devices in the same tensor parallelism group. The device then runs the local fraction of the module on all these data samples, followed by another round of synchronization which both combines the parts of the output for each data sample and returns the combined data samples to the GPUs from which the data sample first originated. The following figure shows an example of this process over a partitioned `nn.Linear` module.



The first figure shows a small model with a large nn.Linear module with data parallelism over the two tensor parallelism ranks. The nn.Linear module is replicated into the two parallel ranks.

The second figure shows tensor parallelism applied on a larger model while splitting the nn.Linear module. Each tp_rank holds half the linear module, and the entirety of the rest of the operations. While the linear module runs, each tp_rank collects the relevant half of all data samples and passes it through their half of the nn.Linear module. The result needs to be reduce-scattered (with summation as the reduction operation) so that each rank has the final linear output for their own data samples. The rest of the model runs in the typical data parallel manner.

Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism

In this section, you learn:

- How to configure a SageMaker PyTorch estimator and the SageMaker model parallelism option to use tensor parallelism.
- How to adapt your training script using the extended smdistributed.modelparallel modules for tensor parallelism.

To learn more about the smdistributed.modelparallel modules, see the SageMaker model parallel APIs in the *SageMaker Python SDK documentation*.

Topics

Tensor parallelism alone

The following is an example of a distributed training option to activate tensor parallelism alone, without pipeline parallelism. Configure the mpi_options and smp_options dictionaries to specify distributed training options to the SageMaker PyTorch estimator.

> **Note**
>
> Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "pipeline_parallel_degree": 1,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 4,      # tp over 4 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py', # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.13.1',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Tip

To find a complete list of parameters for `distribution`, see Configuration Parameters for Model Parallelism in the SageMaker Python SDK documentation.

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. In this example, it is assumed that the script is named `your_training_script.py`.

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        loss.backward()
```

```
        optimizer.step()

# smdistributed: Initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
if smp.local_rank() == 0:
    dataset = datasets.MNIST("../data", train=True, download=False)
smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

train_loader = torch.utils.data.DataLoader(dataset, batch_size=64)

# smdistributed: Enable tensor parallelism for all supported modules in the model
# i.e., nn.Linear in this case. Alternatively, we can use
# smp.set_tensor_parallelism(model.fc1, True)
# to enable it only for model.fc1
with smp.tensor_parallelism():
    model = Net()

# smdistributed: Use the DistributedModel wrapper to distribute the
# modules for which tensor parallelism is enabled
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Tensor parallelism combined with pipeline parallelism

The following is an example of a distributed training option that enables tensor parallelism combined with pipeline parallelism. Set up the `mpi_options` and `smp_options` parameters to specify model parallel options with tensor parallelism when you configure a SageMaker `PyTorch` estimator.

> **Note**
>
> Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
    "microbatches": 4,
        "pipeline_parallel_degree": 2,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,      # tp over 2 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py', # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.13.1',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
```

```
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. Note that the training script now includes the `smp.step` decorator:

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

# smdistributed: Define smp.step. Return any tensors needed outside.
```

```
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: Initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
if smp.local_rank() == 0:
    dataset = datasets.MNIST("../data", train=True, download=False)
smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
```

```
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = Net()

# smdistributed: enable tensor parallelism only for model.fc1
smp.set_tensor_parallelism(model.fc1, True)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Support for Hugging Face Transformer Models

The SageMaker model parallelism library's tensor parallelism offers out-of-the-box support for the following Hugging Face Transformer models:

- GPT-2, BERT, and RoBERTa (Available in the SageMaker model parallelism library v1.7.0 and later)
- GPT-J (Available in the SageMaker model parallelism library v1.8.0 and later)
- GPT-Neo (Available in the SageMaker model parallelism library v1.10.0 and later)

> **Note**
>
> For any other Transformers models, you need to use the smdistributed.modelparallel.torch.tp_register_with_module() API to apply tensor parallelism.

> **Note**
>
> To use tensor parallelism for training Hugging Face Transformer models, make sure you use Hugging Face Deep Learning Containers for PyTorch that has the SageMaker model

parallelism library v1.7.0 and later. For more information, see the SageMaker model parallelism library release notes.

Supported Models Out of the Box

For the Hugging Face transformer models supported by the library out of the box, you don't need to manually implement hooks to translate Transformer APIs to `smdistributed` transformer layers. You can activate tensor parallelism by using the context manager smdistributed.modelparallel.torch.tensor_parallelism() and wrapping the model by smdistributed.modelparallel.torch.DistributedModel(). You don't need to manually register hooks for tensor parallelism using the `smp.tp_register` API.

The `state_dict` translation functions between Hugging Face Transformers and `smdistributed.modelparallel` can be accessed as follows.

- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_state_dict_to_h`
  `max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_hf_state_dict_t`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_state_dict_to_h`
  `max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_hf_state_dict_t`
- `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_state_dict_t`
  `max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_hf_state_dic`
- `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_state_dict_to_h`
  `max_seq_len=None)` (Available in the SageMaker model parallelism library v1.8.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_hf_gptj_state_d`
  (Available in the SageMaker model parallelism library v1.8.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_state_dict_to`
  `max_seq_len=None)` (Available in the SageMaker model parallelism library v1.10.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_hf_state_dict`
  (Available in the SageMaker model parallelism library v1.10.0 and later)

Example usage of the GPT-2 translation function

Start with wrapping the model as shown in the following code.

```
from transformers import AutoModelForCausalLM

with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)

model = smp.DistributedModel(model)
```

Given a `state_dict` from the `DistributedModel` object, you can load the weights into the original Hugging Face GPT-2 model using the `translate_state_dict_to_hf_gpt2` function as shown in the following code.

```
from smdistributed.modelparallel.torch.nn.huggingface.gpt2 \
                                        import translate_state_dict_to_hf_gpt2
max_seq_len = 1024

# [... code block for training ...]

if smp.rdp_rank() == 0:
    state_dict = dist_model.state_dict()
    hf_state_dict = translate_state_dict_to_hf_gpt2(state_dict, max_seq_len)

    # can now call model.load_state_dict(hf_state_dict) to the original HF model
```

Example usage of the RoBERTa translation function

Similarly, given a supported HuggingFace model `state_dict`, you can use the `translate_hf_state_dict_to_smdistributed` function to convert it to a format readable by `smp.DistributedModel`. This can be useful in transfer learning use cases, where a pre-trained model is loaded into a `smp.DistributedModel` for model-parallel fine-tuning:

```
from smdistributed.modelparallel.torch.nn.huggingface.roberta \
                                        import translate_state_dict_to_smdistributed

model = AutoModelForMaskedLM.from_config(roberta_config)
model = smp.DistributedModel(model)

pretrained_model = AutoModelForMaskedLM.from_pretrained("roberta-large")
translated_state_dict =
        translate_state_dict_to_smdistributed(pretrained_model.state_dict())
```

```
# load the translated pretrained weights into the smp.DistributedModel
model.load_state_dict(translated_state_dict)

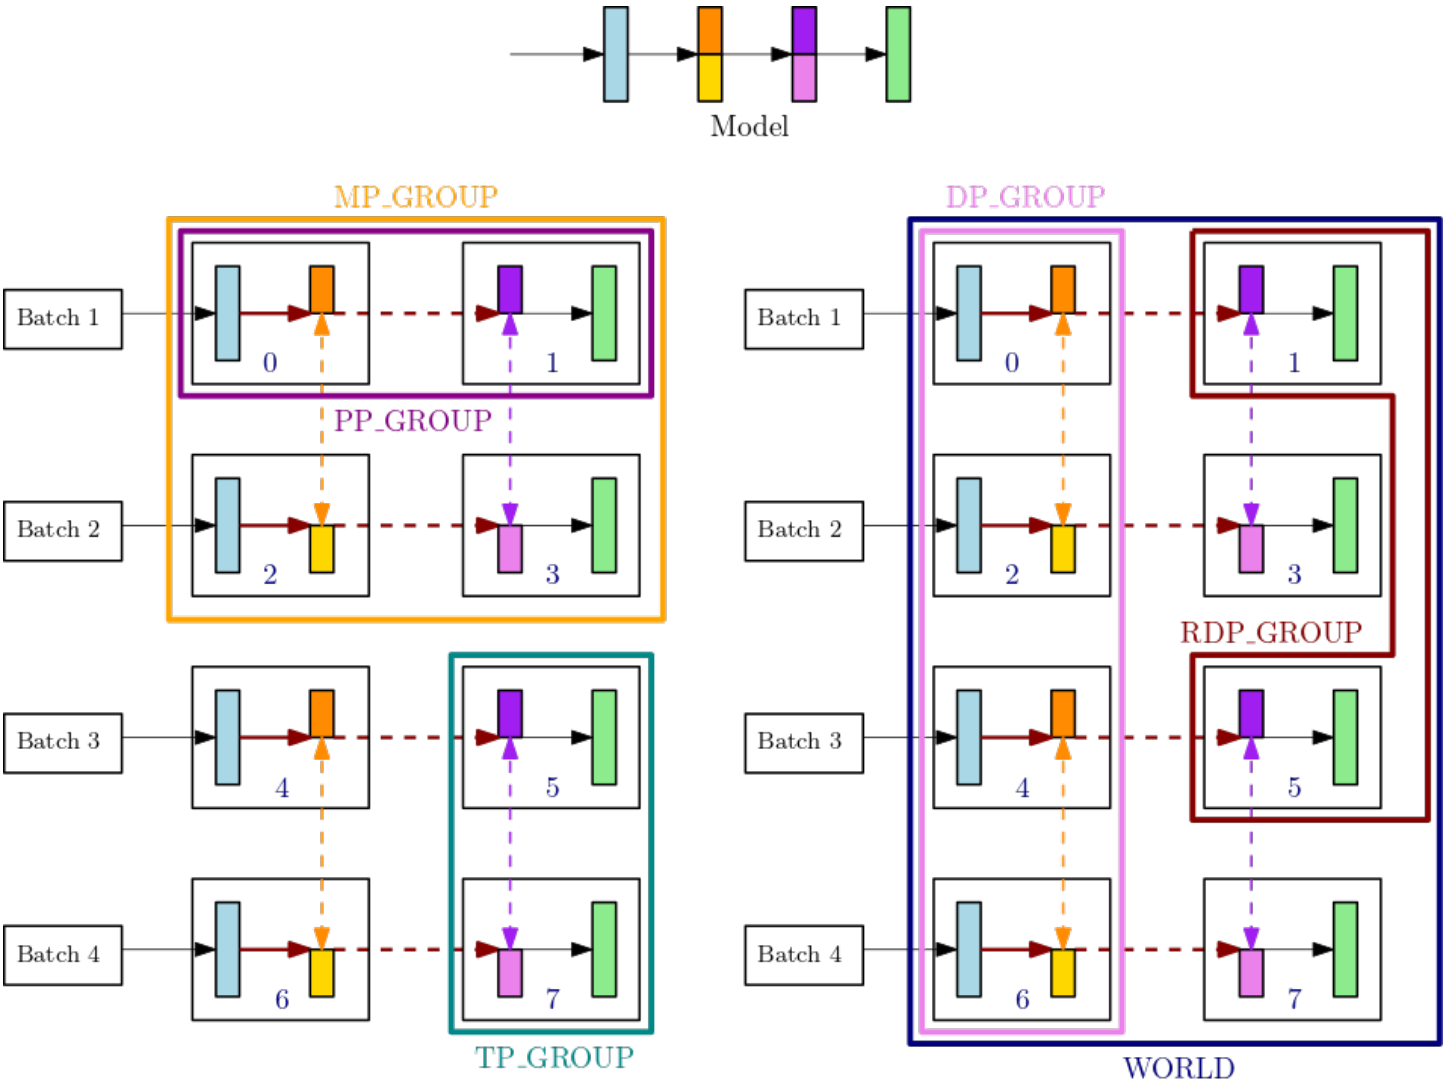
# start fine-tuning...
```

Ranking Mechanism when Using a Combination of Pipeline Parallelism and Tensor Parallelism

This section explains how the ranking mechanism of model parallelism works with tensor parallelism. This is extended from the Ranking Basics for Core Features of the SageMaker Model Parallelism Library. With tensor parallelism, the library introduces three types of ranking and process group APIs: `smp.tp_rank()` for tensor parallel rank, `smp.pp_rank()` for pipeline parallel rank, and `smp.rdp_rank()` for reduced-data parallel rank. The corresponding communication process groups are tensor parallel group (`TP_GROUP`), pipeline parallel group (`PP_GROUP`), and reduced-data parallel group (`RDP_GROUP`). These groups are defined as follows:

- A *tensor parallel group* (`TP_GROUP`) is an evenly divisible subset of the data parallel group, over which tensor parallel distribution of modules takes place. When the degree of pipeline parallelism is 1, `TP_GROUP` is the same as *model parallel group* (`MP_GROUP`).
- A *pipeline parallel group* (`PP_GROUP`) is the group of processes over which pipeline parallelism takes place. When the tensor parallelism degree is 1, `PP_GROUP` is the same as `MP_GROUP`.
- A *reduced-data parallel group* (`RDP_GROUP`) is a set of processes that hold both the same pipeline parallelism partitions and the same tensor parallel partitions, and perform data parallelism among themselves. This is called the reduced data parallel group because it is a subset of the entire data parallelism group, `DP_GROUP`. For the model parameters that are distributed within the `TP_GROUP` , the gradient `allreduce` operation is performed only for reduced-data parallel group, while for the parameters that are not distributed, the gradient `allreduce` takes place over the entire `DP_GROUP`.
- A model parallel group (`MP_GROUP`) refers to a group of processes that collectively store the entire model. It consists of the union of the `PP_GROUP`s of all the ranks that are in the `TP_GROUP` of the current process. When the degree of tensor parallelism is 1, `MP_GROUP` is equivalent to `PP_GROUP`. It is also consistent with the existing definition of `MP_GROUP` from previous `smdistributed` releases. Note that the current `TP_GROUP` is a subset of both the current `DP_GROUP` and the current `MP_GROUP`.

To learn more about the communication process APIs in the SageMaker model parallelism library, see the Common API and the PyTorch-specific APIs in the *SageMaker Python SDK documentation*.



This figure shows ranking mechanism, parameter distribution, and associated AllReduce operations of tensor parallelism.

For example, consider process groups for a single node with 8 GPUs, where the degree of tensor parallelism is 2, the degree of pipeline parallelism is 2, and the degree of data parallelism is 4. The upper center part of the preceding figure shows an example of a model with 4 layers. The lower left and lower right parts of figure illustrate the 4-layer model distributed across 4 GPUs using both pipeline parallelism and tensor parallelism, where tensor parallelism is used for the middle two layers. These two lower figures are simple copies to illustrate different group boundary lines. The partitioned model is replicated for data parallelism across GPUs 0-3 and 4-7. The lower left figure shows the definitions of `MP_GROUP`, `PP_GROUP`, and `TP_GROUP`. The lower right figure shows `RDP_GROUP`, `DP_GROUP`, and `WORLD` over the same set of GPUs. The gradients for the layers and layer slices that have the same color are `allreduced` together for data parallelism. For example, the first layer (light blue) gets the `allreduce` operations across `DP_GROUP`, whereas the dark

orange slice in the second layer only gets the `allreduce` operations within the RDP_GROUP of its process. The bold dark red arrows represent tensors with the batch of its entire TP_GROUP.

```
GPU0: pp_rank 0, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 0
GPU1: pp_rank 1, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 1
GPU2: pp_rank 0, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 2
GPU3: pp_rank 1, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 3
GPU4: pp_rank 0, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 0
GPU5: pp_rank 1, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 1
GPU6: pp_rank 0, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 2
GPU7: pp_rank 1, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 3
```

In this example, pipeline parallelism occurs across the GPU pairs (0,1); (2,3); (4,5) and (6,7). In addition, data parallelism (`allreduce`) takes place across GPUs 0, 2, 4, 6, and independently over GPUs 1, 3, 5, 7. Tensor parallelism happens over subsets of DP_GROUPs, across the GPU pairs (0,2); (1,3); (4,6) and (5,7).

Optimizer State Sharding

Optimizer state sharding is a useful memory-saving technique that shards the optimizer state (the set of weights that describes the state of optimizer) across data parallel device groups. You can use optimizer state sharding whenever you use a stateful optimizer (such as Adam) or an FP16 optimizer (which stores both FP16 and FP32 copies of the parameters).

> **Note**
>
> Optimizer state sharding is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Optimizer State Sharding

You can turn on *optimizer state sharding* by setting `"shard_optimizer_state": True` in the `modelparallel` configuration.

When this feature is turned on, the library partitions the set of model parameters based on the data parallelism degree. The gradients corresponding to the `i`th partition get reduced only at the `i`th data parallel rank. At the end of the first call to an `smp.step` decorator function, the optimizer wrapped by `smp.DistributedOptimizer` redefines its parameters to be only

limited to those parameters corresponding to the partition of the current data parallel rank. The redefined parameters are called *virtual parameters* and share underlying storage with the original parameters. During the first call to `optimizer.step`, the optimizer states are created based on these redefined parameters, which are sharded because of the original partition. After the optimizer update, the AllGather operation (as part of the `optimizer.step` call) runs across the data parallel ranks to achieve consistent parameter states.

> **Tip**
>
> Optimizer state sharding can be useful when the degree of data parallelism is greater than 1 and the model has more than a billion parameters.
> The degree of data parallelism is calculated by `(processes_per_host * instance_count / pipeline_parallel_degree)`, and the `smp.dp_size()` function handles the sizing in the background.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,      # tp over 2 devices
        "ddp": True,
        "shard_optimizer_state": True
    }
}
```

Adapt your PyTorch training script

See Adapt your PyTorch training script in the *Tensor parallelism combined with pipeline parallelism* section. There's no additional modification required for the script.

Activation Checkpointing

Activation checkpointing (or *gradient checkpointing*) is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during a backward pass. Effectively, this trades extra computation time for reduced memory usage. If a module is checkpointed, at the end of a forward pass, the inputs to and outputs from the module stay in memory. Any intermediate tensors that would have been part of the computation inside that module are freed up during the forward pass. During the backward pass of checkpointed modules, these tensors are recomputed. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing can be lower.

> **Note**
>
> This feature is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Activation Checkpointing

With `smdistributed.modelparallel`, you can use activation checkpointing at the granularity of a module. For all `torch.nn` modules except `torch.nn.Sequential`, you can only checkpoint a module tree if it lies within one partition from the perspective of pipeline parallelism. In case of the `torch.nn.Sequential` module, each module tree inside the sequential module must lie completely within one partition for activation checkpointing to work. When you use manual partitioning, be aware of these restrictions.

When you use automated model partitioning, you can find the partitioning assignment logs starting with `Partition assignments:` in the training job logs. If a module is partitioned across multiple ranks (for example, with one descendant on one rank and another descendant on a different rank), the library ignores the attempt to checkpoint the module and raises a warning message that the module won't be checkpointed.

> **Note**
>
> The SageMaker model parallelism library supports both overlapping and non-overlapping `allreduce` operation in combination with checkpointing.

> **Note**
>
> PyTorch's native checkpointing API is not compatible with `smdistributed.modelparallel`.

Example 1: The following sample code shows how to use activation checkpointing when you have a model definition in your script.

```
import torch.nn as nn
import torch.nn.functional as F

from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = self.conv2(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        # This call of fc1 will be checkpointed
        x = checkpoint(self.fc1, x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)
```

Example 2: The following sample code shows how to use activation checkpointing when you have a sequential model in your script.

```
import torch.nn as nn
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint_sequential

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
```

```
        self.seq = nn.Sequential(
            nn.Conv2d(1,20,5),
            nn.ReLU(),
            nn.Conv2d(20,64,5),
            nn.ReLU()
        )

    def forward(self, x):
        # This call of self.seq will be checkpointed
        x = checkpoint_sequential(self.seq, x)
        return F.log_softmax(x, 1)
```

Example 3: The following sample code shows how to use activation checkpointing when you import a prebuilt model from a library, such as PyTorch and Hugging Face Transformers. Whether you checkpoint sequential modules or not, do the following:

1. Wrap the model by `smp.DistributedModel()`.
2. Define an object for sequential layers.
3. Wrap the sequential layer object by `smp.set_activation_checkpointig()`.

```
import smdistributed.modelparallel.torch as smp
from transformers import AutoModelForCausalLM

smp.init()
model = AutoModelForCausalLM(*args, **kwargs)
model = smp.DistributedModel(model)

# Call set_activation_checkpointing API
transformer_layers = model.module.module.module.transformer.seq_layers
smp.set_activation_checkpointing(
    transformer_layers, pack_args_as_tuple=True, strategy='each')
```

Activation Offloading

When activation checkpointing and pipeline parallelism are turned on and the number of microbatches is greater than one, *activation offloading* is an additional feature that can further reduce memory usage. Activation offloading asynchronously moves the checkpointed activations corresponding to their microbatches that are not currently running in the CPU. Right before the GPU needs the activations for the microbatch's backward pass, this functionality prefetches the offloaded activations back from the CPU.

> **Note**
>
> This feature is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Activation Offloading

Use activation offloading to reduce memory usage when **the number of microbatches is greater than 1, and activation checkpointing is turned on** (see Activation Checkpointing). When the activation checkpointing is not used, activation offloading has no effect. When it is used with only one microbatch, it does not save memory.

To use activation offloading, set `"offload_activations": True` in the `modelparallel` configuration.

Activation offloading moves the checkpointed activations in `nn.Sequential` modules to CPU asynchronously. The data transfer over the PCIe link overlaps with GPU computation. The offloading happens immediately, as soon as the forward pass for a particular checkpointed layer is computed. The activations are loaded back to the GPU shortly before they are needed for the backward pass of a particular microbatch. The CPU-GPU transfer similarly overlaps with computation.

To adjust how early the activations are loaded back into the GPU, you can use the configuration parameter `"activation_loading_horizon"` (default is set to 4, must be `int` larger than 0). A larger activation loading horizon would cause the activations to be loaded back to the GPU earlier. If the horizon is too large, the memory-saving impact of activation offloading might be diminished. If the horizon is too small, the activations may not be loaded back in time, reducing the amount of overlap and degrading performance.

> **Tip**
>
> Activation offloading can be useful for large models with over a hundred billion parameters.

Configure a SageMaker PyTorch estimator

```
mpi_options = {
```

```
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,    # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,      # tp over 2 devices
        "ddp": True,
        "offload_activations": True,
        "activation_loading_horizon": 4   # optional. default is 4.
    }
}
```

FP16 Training with Model Parallelism

For FP16 training, apply the following modifications to your training script and estimator.

> **Note**
>
> This feature is available for PyTorch in the SageMaker model parallelism library v1.10.0 and later.

Adapt your PyTorch training script

1. Wrap your model using the smdistributed.modelparallel.torch.model_creation() context manager.

```
# fp16_training_script.py

import torch
import smdistributed.modelparallel.torch as smp

with smp.model_creation(
    dtype=torch.float16 if args.fp16 else torch.get_default_dtype()
):
    model = ...
```

Tip

If you are using tensor parallelism, add `tensor_parallelism=smp.tp_size() > 1` to the `smp.model_creation` context manager. Adding this line also helps automatically detect whether tensor parallelism is activated or not.

```
with smp.model_creation(
    ... ,
    tensor_parallelism=smp.tp_size() > 1
):
    model = ...
```

2. When you wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`, set either the `static_loss_scaling` or `dynamic_loss_scaling` argument. By default, `static_loss_scaling` is set to `1.0`, and `dynamic_loss_scaling` is set to `False`. If you set `dynamic_loss_scale=True`, you can feed dynamic loss scaling options as a dictionary through the `dynamic_loss_args` argument. In most cases, we recommend you use dynamic loss scaling with the default options. For more information, options, and examples of the optimizer wrapper function, see the smdistributed.modelparallel.torch.DistributedOptimizer API.

   The following code is an example of wrapping an `Adadelta` optimizer object with dynamic loss scaling for FP16 training.

```
optimizer = torch.optim.Adadelta(...)
optimizer = smp.DistributedOptimizer(
    optimizer,
    static_loss_scale=None,
    dynamic_loss_scale=True,
    dynamic_loss_args={
        "scale_window": 1000,
        "min_scale": 1,
        "delayed_shift": 2
    }
)
```

Configure a SageMaker PyTorch estimator

Add the FP16 parameter ("fp16") to the distribution configuration for model parallelism when creating a SageMaker PyTorch estimator object. For a complete list of the configuration parameters for model parallelism, see Parameters for smdistributed.

```
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters":  {
        "microbatches":  4,
        "pipeline_parallel_degree":  2,
        "tensor_parallel_degree":  2,
        ...,

        "fp16": True
    }
}

fp16_estimator = PyTorch(
    entry_point="fp16_training_script.py", # Specify your train script
    ...,

    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": {...}
    }
)

fp16_estimator.fit(...)
```

When FP16 training starts, the model and the optimizer are wrapped by FP16_Module and FP16_Optimizer respectively, which are modified smdistributed versions of the Apex utils. FP16_Module converts the model to FP16 dtype and deals with the forward pass in FP16.

Tip

You can apply gradient clipping by calling clip_master_grads before optimizer.step.

```
optimizer.clip_master_grads(max_norm)     # max_norm(float or int): max norm of
 the gradients
```

Tip

When using `torch.optim.lr_scheduler` and FP16 training, you need to pass `optimizer.optimizer` to the LR scheduler rather than the optimizer. See the following example code.

```
from torch.optim.lr_scheduler import StepLR

scheduler = StepLR(
    optimizer.optimizer if smp.state.cfg.fp16 else optimizer,
    step_size=1,
    gamma=args.gamma
)
```

Support for FlashAttention

Support for FlashAttention is a feature of the library only applicable for the *distributed transformer* model, which is a Transformer model wrapped by `smp.DistributedModel()` for model-parallel training. This feature is also compatible with the section called "Tensor Parallelism".

The FlashAttention library only supports models when `attention_head_size` is set to a value that's a multiple of 8 and less than 128. Therefore, when you train a distributed transformer and make sure that FlashAttention works properly, you should adjust parameters to make the attention head size comply the requirements. For more information, see also Installation and features in the *FlashAttention GitHub repository*.

For example, assume that you configure a Transformer model with `hidden_width=864` and `num_heads=48`. The head size of FlashAttention is calculated as `attention_head_size = hidden_width / num_heads = 864 / 48 = 18`. To enable FlashAttention, you need to adjust the `num_heads` parameter to 54, so that `attention_head_size = hidden_width / num_heads = 864 / 54 = 16`, which is a multiple of 8.

Run a SageMaker Distributed Training Job with Model Parallelism

Learn how to run a model-parallel training job of your own training script using the SageMaker Python SDK with the SageMaker model parallelism library.

There are three use-case scenarios for running a SageMaker training job.

1. You can use one of the pre-built AWS Deep Learning Container for TensorFlow and PyTorch. This option is recommended if it is the first time for you to use the model parallel library. To find a tutorial for how to run a SageMaker model parallel training job, see the example notebooks at PyTorch training with Amazon SageMaker's model parallelism library.
2. You can extend the pre-built containers to handle any additional functional requirements for your algorithm or model that the pre-built SageMaker Docker image doesn't support. To find an example of how you can extend a pre-built container, see Extend a Pre-built Container.
3. You can adapt your own Docker container to work with SageMaker using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

For options 2 and 3 in the preceding list, refer to Extend a Pre-built Docker Container that Contains SageMaker's Distributed Model Parallel Library to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your training job configuring a SageMaker `TensorFlow` or `PyTorch` estimator to activate the library. To learn more, see the following topics.

Topics

- Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library
- Step 2: Launch a Training Job Using the SageMaker Python SDK

Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker model parallelism library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the SageMaker model parallel library APIs in the *SageMaker Python SDK documentation*.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker model parallelism library, see Amazon SageMaker model parallelism library v2 examples.

Topics

- Split the model of your training script using the SageMaker model parallelism library
- Modify a TensorFlow training script

- Modify a PyTorch Training Script

Split the model of your training script using the SageMaker model parallelism library

There are two ways to modify your training script to set up model splitting: automated splitting or manual splitting.

Automated model splitting

When you use SageMaker's model parallelism library, you can take advantage of *automated model splitting*, also referred to as *automated model partitioning*. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

How it works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.

Automated model splitting with PyTorch

During the first training step, the model parallelism library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After

this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameters`, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

For instructions on how to register the `smp.step` decorator to your PyTorch training script, see the section called "Automated splitting with PyTorch".

Automated model splitting with TensorFlow

The model parallelism library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed` for `optimize` (in the model parallelism parameters in the Python SDK), the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

For instructions on how to register the `smp.step` decorator to your PyTorch training script, see the section called "Automated splitting with TensorFlow".

Comparison of automated model splitting between frameworks

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operations`, and therefore the model parallelism library partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how to partition your model across devices, use the `smp.partition` context manager. For instructions on how to set the context manager for manual partitioning, see the following pages.

- the section called “Manual splitting with TensorFlow”
- the section called “Manual splitting with PyTorch”

To use this option after making modifications, in Step 2, you'll need to set `auto_partition` to `False`, and define a `default_partition` in the framework estimator class of the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallelism library creates a pipelined execution schedule automatically.

Modify a TensorFlow training script

In this section, you learn how to modify TensorFlow training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism.

> **Note**
>
> To find which TensorFlow versions are supported by the library, see the section called “Supported Frameworks and AWS Regions”.

The required modifications you must make to your training script to use the library are listed in Automated splitting with TensorFlow.

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism.

If you want to use manual partitioning, also review Manual splitting with TensorFlow.

The following topics show examples of training scripts that you can use to configure SageMaker's model parallelism library for auto-partitioning and manual partitioning TensorFlow models.

> **Note**
>
> Auto-partitioning is enabled by default. Unless otherwise specified, the example scripts use auto-partitioning.

Topics

- Automated splitting with TensorFlow
- Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism
- Manual splitting with TensorFlow
- Unsupported framework features

Automated splitting with TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's model parallelism library:

1. Import and initialize the library with `smp.init()`.
2. Define a Keras model by inheriting from `smp.DistributedModel` instead of the Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.

4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.
7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput` API.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

The following Python script is an example of a training script after the changes are made.

```
import tensorflow as tf

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]

```

```
    accuracy = train_accuracy.result()
```

If you are done preparing your training script, proceed to Step 2: Launch a Training Job Using the SageMaker Python SDK. If you want to run a hybrid model and data parallel training job, continue to the next section.

Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism

You can use the SageMaker model parallelism library with Horovod for hybrid model and data parallelism. To read more about how the library splits a model for hybrid parallelism, see Pipeline parallelism (available for PyTorch and TensorFlow).

In this step, we focus on how to modify your training script to adapt the SageMaker model parallelism library.

To properly set up your training script to pick up the hybrid parallelism configuration that you'll set in Step 2: Launch a Training Job Using the SageMaker Python SDK, use the library's helper functions, `smp.dp_rank()` and `smp.mp_rank()`, which automatically detect the data parallel rank and model parallel rank respectively.

To find all MPI primitives the library supports, see MPI Basics in the SageMaker Python SDK documentation.

The required changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

> **Note**
>
> When you use Horovod, you must not directly call `hvd.init` in your training script. Instead, you'll have to set `"horovod"` to `True` in the SageMaker Python SDK `modelparallel` parameters in Step 2: Launch a Training Job Using the SageMaker Python SDK. This allows the library to internally initialize Horovod based on the device assignments of model partitions. Calling `hvd.init()` directly in your training script can cause problems.

Note

Using the `hvd.DistributedOptimizer` API directly in your training script might result in a poor training performance and speed, because the API implicitly places the `AllReduce` operation inside `smp.step`. We recommend you to use the model parallelism library with Horovod by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as will be shown in the following example.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```
import tensorflow as tf
import horovod.tensorflow as hvd

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
```

```
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: AllReduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)

    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()
```

```
for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()

    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))
```

Manual splitting with TensorFlow

Use `smp.partition` context managers to place operations in specific partition. Any operation not placed in any `smp.partition` contexts is placed in the `default_partition`. To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```
import tensorflow as tf

# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
         # define layers
```

```
    def call(self, x):
        with smp.partition(0):
            x = self.layer0(x)
        with smp.partition(1):
            return self.layer1(x)

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
    accuracy = train_accuracy.result()
```

Unsupported framework features

The following TensorFlow features are not supported by the library:

- `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.
- The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

Modify a PyTorch Training Script

In this section, you learn how to modify PyTorch training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning.

> **Note**
>
> To find which PyTorch versions are supported by the library, see the section called "Supported Frameworks and AWS Regions".

> **Tip**
>
> For end-to-end notebook examples that demonstrate how to use a PyTorch training script with the SageMaker model parallelism library, see Amazon SageMaker model parallelism library v1 examples.

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

Topics

Automated splitting with PyTorch

The following training script changes are required to run a PyTorch training script with SageMaker's model parallelism library:

1. Import and initialize the library with `smdistributed.modelparallel.torch.init()`.
2. Wrap the model with `smdistributed.modelparallel.torch.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

   > **Note**
   >
   > For FP16 training, you need to use the smdistributed.modelparallel.torch.model_creation() context manager to wrap the model. For more information, see FP16 Training with Model Parallelism.

3. Wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`.

   > **Note**
   >
   > For FP16 training, you need to set up static or dynamic loss scaling. For more information, see FP16 Training with Model Parallelism.

4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smdistributed.modelparallel.torch.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
8. Replace `torch.Tensor.backward` and `torch.autograd.backward` with `DistributedModel.backward`.
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.

10 If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput` API.

11 Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
```

```
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Manual splitting with PyTorch

Use `smp.partition` context managers to place modules in specific devices. Any module not placed in any `smp.partition` contexts is placed in the `default_partition`. The `default_partition` needs to be provided if `auto_partition` is set to `False`. The modules that are created within a specific `smp.partition` context are placed on the corresponding partition.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        with smp.partition(0):
            # define child modules on device 0
        with smp.partition(1):
            # define child modules on device 1

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
```

```
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
```

```
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)
```

Considerations

When you configure a PyTorch training script using SageMaker's model parallelism library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library's communication basic data types to do this.
- All `torch.Tensor` arguments to the forward methods of the `nn.Modules` in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.
- The argument to the `smp.DistributedModel.backward()` call must depend on all model outputs. In other words, there cannot be an output from the `smp.DistributedModel.forward` call that is not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.
- If there are `torch.cuda.synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.
- Since the library places `nn.Modules` on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.
- You don't need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first `smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallelism library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.
- The weight update (`optimizer.step()`) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, AllReduce of gradients is also guaranteed to finish.
- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that AllReduce does not hang waiting for a rank which is not participating in the step.
- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```
dataloader = torch.utils.data.DataLoader(
            data,
            batch_size=batch_size,
            num_workers=0,
            pin_memory=True,
            drop_last=True,
            shuffle=shuffle,
        )
```

- The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

  For example, if you define a `DataLoader` as follows:

```
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

  You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...
```

```
@smp.step
def train_step(model, data, target):
    ...
    return output, loss
```

- The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

  For example, you may define the `train` function as follows. This function adds `data` and `target` to the current device using `.to()` API before using those input tensors to call `train_step`.

```
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current
 process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()
```

  The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does *not* need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

Unsupported framework features

The following PyTorch features are unsupported by SageMaker's model parallelism library:

- If you use data parallelism with the native PyTorch DDP, the `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library. The library internally manages integrating with PyTorch DDP, including parameter broadcast and gradient AllReduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers that need to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.
- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in torch.
- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.
- `apex` : `FusedLayerNorm`, `FusedAdam`, `FusedLAMB`, and `FusedNovoGrad` from `apex` are not supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn` APIs instead.

Step 2: Launch a Training Job Using the SageMaker Python SDK

The SageMaker Python SDK supports managed training of models with ML frameworks such as TensorFlow and PyTorch. To launch a training job using one of these frameworks, you define a SageMaker TensorFlow estimator, a SageMaker PyTorch estimator, or a SageMaker generic Estimator to use the modified training script and model parallelism configuration.

Topics

- Using the SageMaker TensorFlow and PyTorch Estimators
- Extend a Pre-built Docker Container that Contains SageMaker's Distributed Model Parallel Library
- Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

Using the SageMaker TensorFlow and PyTorch Estimators

The TensorFlow and PyTorch estimator classes contain the `distribution` parameter, which you can use to specify configuration parameters for using distributed training frameworks. The

SageMaker model parallel library internally uses MPI for hybrid data and model parallelism, so you must use the MPI option with the library.

The following template of a TensorFlow or PyTorch estimator shows how to configure the `distribution` parameter for using the SageMaker model parallel library with MPI.

Using the SageMaker TensorFlow estimator

```
import sagemaker
from sagemaker.tensorflow import TensorFlow

smp_options = {
    "enabled":True,              # Required
    "parameters": {
        "partitions": 2,         # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "horovod": True,         # Use this for hybrid model and data parallelism
    }
}

mpi_options = {
    "enabled" : True,            # Required
    "processes_per_host" : 8,    # Required
    # "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = TensorFlow(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```

```
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Using the SageMaker PyTorch estimator

```
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled":True,
    "parameters": {                        # Required
        "pipeline_parallel_degree": 2,     # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "ddp": True,
    }
}

mpi_options = {
    "enabled" : True,                      # Required
    "processes_per_host" : 8,              # Required
    # "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.13.1',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

To enable the library, you need to pass configuration dictionaries to the `"smdistributed"` and `"mpi"` keys through the `distribution` argument of the SageMaker estimator constructors.

Configuration parameters for SageMaker model parallelism

- For the `"smdistributed"` key, pass a dictionary with the `"modelparallel"` key and the following inner dictionaries.

  > **Note**
  >
  > Using `"modelparallel"` and `"dataparallel"` in one training job is not supported.

  - `"enabled"` – Required. To enable model parallelism, set `"enabled": True`.
  - `"parameters"` – Required. Specify a set of parameters for SageMaker model parallelism.
    - For a complete list of common parameters, see Parameters for `smdistributed` in the *SageMaker Python SDK documentation*.

      For TensorFlow, see TensorFlow-specific Parameters.

      For PyTorch, see PyTorch-specific Parameters.
    - `"pipeline_parallel_degree"` (or `"partitions"` in `smdistributed-modelparallel<v1.6.0`) – Required. Among the parameters for `smdistributed`, this parameter is required to specify how many model partitions you want to split into.

      > **Important**
      >
      > There is a breaking change in the parameter name. The `"pipeline_parallel_degree"` parameter replaces the `"partitions"` since `smdistributed-modelparallel` v1.6.0. For more information, see Common Parameters for SageMaker model parallelism configuration and SageMaker Distributed Model Parallel Release Notes in the *SageMaker Python SDK documentation*.

- For the `"mpi"` key, pass a dictionary that contains the following:
  - `"enabled"` – Required. Set `True` to launch the distributed training job with MPI.
  - `"processes_per_host"` – Required. Specify the number of processes MPI should launch on each host. In SageMaker, a host is a single Amazon EC2 ML instance. The SageMaker Python

SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`. To learn more, see Automated splitting with PyTorch.

> **Important**
>
> `process_per_host` *must* not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

- `"custom_mpi_options"` (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

```
--mca btl_vader_single_copy_mechanism none
```

> **Note**
>
> You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:
>
> ```
> The following MCA parameter has been listed multiple times on the command
>  line:
> MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed
>  once
> on a command line to ensure there is no ambiguity as to its value.
> Please correct the situation and try again.
> ```

> **Tip**
>
> If you launch a training job using an EFA-enabled instance type, such as `ml.p4d.24xlarge` and `ml.p3dn.24xlarge`, use the following flag for best performance:

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
```

To launch the training job using the estimator and your SageMaker model parallel configured training script, run the `estimator.fit()` function.

Use the following resources to learn more about using the model parallelism features in the SageMaker Python SDK:

- Use TensorFlow with the SageMaker Python SDK
- Use PyTorch with the SageMaker Python SDK

- We recommend you use a SageMaker notebook instance if you are new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Amazon SageMaker model parallelism library v2 examples.
- You can also submit a distributed training job from your machine using AWS CLI. To set up AWS CLI on your machine, see set up your AWS credentials and Region for development.

Extend a Pre-built Docker Container that Contains SageMaker's Distributed Model Parallel Library

To extend a pre-built container and use SageMaker's model parallelism library, you must use one of the available AWS Deep Learning Containers (DLC) images for PyTorch or TensorFlow. The SageMaker model parallelism library is included in the TensorFlow (2.3.0 and later) and PyTorch (1.6.0 and later) DLC images with CUDA (`cuxyz`). For a complete list of DLC images, see Available Deep Learning Containers Images in the *AWS Deep Learning Containers GitHub repository*.

> **Tip**
>
> We recommend that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up-to-date version of the SageMaker model parallelism library.

For example, your Dockerfile should contain a `FROM` statement similar to the following:

```
# Use the SageMaker DLC image URI for TensorFlow or PyTorch
```

```
FROM aws-dlc-account-id.dkr.ecr.aws-region.amazonaws.com/framework-training:{framework-version-tag}

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker container to determine our user
 code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the `entry_point` for your training script. This should be the same path identified with `ENV SAGEMAKER_SUBMIT_DIRECTORY` in your Dockerfile.

> **Tip**
>
> You must push this Docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (`image_uri`) to define a SageMaker estimator for training. For more information, see Extend a Pre-built Container.

After you finish hosting the Docker container and retrieving the image URI of the container, create a SageMaker `PyTorch` estimator object as follows. This example assumes that you have already defined `smp_options` and `mpi_options`.

```
smd_mp_estimator = Estimator(
    entry_point="your_training_script.py",
    role=sagemaker.get_execution_role(),
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='your_aws_account_id.dkr.ecr.region.amazonaws.com/name:tag'
    instance_count=1,
    distribution={
        "smdistributed": smp_options,
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```

```
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

To build your own Docker container for training and use the SageMaker model parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides the minimum set of code blocks you must include to properly prepare a SageMaker training environment and the model parallel library in your own Docker container.

> **Note**
>
> This custom Docker option with the SageMaker model parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the model parallel library

1. Start with one of the NVIDIA CUDA base images.

   ```
   FROM <cuda-cudnn-base-image>
   ```

   > **Tip**
   >
   > The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. We recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find which versions of the libraries you need to install and how to configure them. The official Dockerfiles are complete, benchmark tested, and managed by the SageMaker and Deep Learning Container service teams. In the provided link, choose the PyTorch version you use, choose the CUDA (`cuxyz`) folder, and choose the Dockerfile ending with `.gpu` or `.sagemaker.gpu`.

2. To set up a distributed training environment, you need to install software for communication and network devices, such as Elastic Fabric Adapter (EFA), NVIDIA Collective Communications Library (NCCL), and Open MPI. Depending on the PyTorch and CUDA versions you choose, you must install compatible versions of the libraries.

> **Important**
>
> Because the SageMaker model parallel library requires the SageMaker data parallel library in the subsequent steps, we highly recommend that you follow the instructions at Create your own Docker container with the SageMaker distributed data parallel library to properly set up a SageMaker training environment for distributed training.

For more information about setting up EFA with NCCL and Open MPI, see Get started with EFA and MPI and Get started with EFA and NCCL.

3. Add the following arguments to specify the URLs of the SageMaker distributed training packages for PyTorch. The SageMaker model parallel library requires the SageMaker data parallel library to use the cross-node Remote Direct Memory Access (RDMA).

```
ARG SMD_MODEL_PARALLEL_URL=https://sagemaker-distributed-model-parallel.s3.us-
west-2.amazonaws.com/pytorch-1.10.0/build-artifacts/2022-02-21-19-26/
smdistributed_modelparallel-1.7.0-cp38-cp38-linux_x86_64.whl
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/
pytorch/1.10.2/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-
linux_x86_64.whl
```

4. Install dependencies that the SageMaker model parallel library requires.

   a. Install the METIS library.

```
ARG METIS=metis-5.1.0

RUN rm /etc/apt/sources.list.d/* \
  && wget -nv http://glaros.dtc.umn.edu/gkhome/fetch/sw/metis/${METIS}.tar.gz \
  && gunzip -f ${METIS}.tar.gz \
  && tar -xvf ${METIS}.tar \
  && cd ${METIS} \
  && apt-get update \
  && make config shared=1 \
  && make install \
  && cd .. \
  && rm -rf ${METIS}.tar* \
  && rm -rf ${METIS} \
  && rm -rf /var/lib/apt/lists/* \
  && apt-get clean
```

b. Install the RAPIDS Memory Manager library. This requires CMake 3.14 or later.

```
ARG RMM_VERSION=0.15.0

RUN  wget -nv https://github.com/rapidsai/rmm/archive/v${RMM_VERSION}.tar.gz \
  && tar -xvf v${RMM_VERSION}.tar.gz \
  && cd rmm-${RMM_VERSION} \
  && INSTALL_PREFIX=/usr/local ./build.sh librmm \
  && cd .. \
  && rm -rf v${RMM_VERSION}.tar* \
  && rm -rf rmm-${RMM_VERSION}
```

5. Install the SageMaker model parallel library.

```
RUN pip install --no-cache-dir -U ${SMD_MODEL_PARALLEL_URL}
```

6. Install the SageMaker data parallel library.

```
RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

7. Install the sagemaker-training toolkit. The toolkit contains the common functionality that's necessary to create a container compatible with the SageMaker training platform and the SageMaker Python SDK.

```
RUN pip install sagemaker-training
```

8. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container and host it in Amazon ECR.

> **Tip**
>
> For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

Checkpointing and Fine-Tuning a Model with Model Parallelism

The SageMaker model parallelism library provides checkpointing APIs to save the model state and the optimizer state split by the various model parallelism strategies, and to load checkpoints for

continuous training from where you want to restart training and fine-tune. The APIs also support options to save the model and optimizer states partially or fully.

Topics

Checkpointing a distributed model

Choose one of the following topics depending on the framework between PyTorch and TensorFlow and the version of the SageMaker model parallelism library you use.

Topics

Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)

The SageMaker model parallelism library provides checkpoint APIs to save and load full or partial checkpoints of the distributed model state and its optimizer state.

> **Note**
>
> This checkpointing method is recommended if you use PyTorch and the SageMaker model parallelism library v1.10.0 or later.

Partial checkpointing

To save checkpoints of a model trained with model parallelism, use the `smdistributed.modelparallel.torch.save_checkpoint` API with the partial checkpointing option set to true (`partial=True`). This saves each model partition individually. In addition to the model and the optimizer state, you can also save any additional custom data

through the `user_content` argument. The checkpointed model, optimizer, and user content are saved as separate files. The `save_checkpoint` API call creates checkpoint folders in the following structure.

```
- path
  - ${tag}_partial (folder for partial checkpoints)
    - model_rankinfo.pt
    - optimizer_rankinfo.pt
    - fp16_states_rankinfo.pt
    - user_content.pt
  - $tag (checkpoint file for full checkpoints)
  - user_content_$tag (user_content file for full checkpoints)
  - newest (a file that indicates the newest checkpoint)
```

To resume training from partial checkpoints, use the [smdistributed.modelparallel.torch.resume_from_checkpoint] API with `partial=True`, and specify the checkpoint directory and the tag used while saving the partial checkpoints. Note that the actual loading of model weights happens after model partitioning, during the first run of the `smdistributed.modelparallel.torch.step`-decorated training step function.

When saving a partial checkpoint, the library also saves the model partition decision as files with `.pt` file extension. Conversely, when resuming from the partial checkpoint, the library loads the partition decision files together. Once the partition decision is loaded, you can't change the partition.

The following code snippet shows how to set the checkpoint APIs in a PyTorch training script.

```
import smdistributed.modelparallel.torch as smp

model = ...
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...     # additional custom data
checkpoint_path = "/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag=f"total_steps{total_steps}",
```

```
    partial=True,
    model=model,
    optimizer=optimizer,
    user_content=user_content
    num_kept_partial_checkpoints=5
)

# Load a checkpoint.
# This automatically loads the most recently saved checkpoint.
smp_checkpoint = smp.resume_from_checkpoint(
    path=checkpoint_path,
    partial=True
)
```

Full checkpointing

To save the final model artifact for inference purposes, use the `smdistributed.modelparallel.torch.save_checkpoint` API with `partial=False`, which combines the model partitions to create a single model artifact. Note that this does not combine the optimizer states.

To initialize training with particular weights, given a full model checkpoint, you can use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=False`. Note that this does not load optimizer states.

> **Note**
>
> With tensor parallelism, in general, the `state_dict` must be translated between the original model implementation and the `DistributedModel` implementation. Optionally, you can provide the `state_dict` translation function as an argument to the `smdistributed.modelparallel.torch.resume_from_checkpoint`. However, for the section called "Supported Models Out of the Box", the library takes care of this translation automatically.

The following code shows an example of how to use the checkpoint APIs for fully checkpointing a PyTorch model trained with model parallelism.

```
import smdistributed.modelparallel.torch as smp
```

```
model = ...
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...     # additional custom data
checkpoint_path = "/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag=f"total_steps{total_steps}",
    partial=False,
    model=model,
    optimizer=optimizer,
    user_content=user_content
    num_kept_partial_checkpoints=5
)

# Load a checkpoint.
# This automatically loads the most recently saved checkpoint.
smp_checkpoint = smp.resume_from_checkpoint(
    path=checkpoint_path,
    partial=False
)
```

Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0)

The SageMaker model parallelism library provides Python functions for saving partial or full checkpoints for training jobs with tensor parallelism. The following procedure shows how to use `smp.save()` and `smp.load()` to save and load a checkpoint when you use tensor parallelism.

> **Note**
>
> This checkpointing method is recommended if you use PyTorch, the section called "Tensor Parallelism", and the SageMaker model parallelism library between v1.6.0 and v1.9.0.

1. Prepare a model object and wrap it with the library's wrapper function `smp.DistributedModel()`.

```
model = MyModel(...)
```

```
model = smp.DistributedModel(model)
```

2. Prepare an optimizer for the model. A set of model parameters is an iterable argument required by optimizer functions. To prepare a set of model parameters, you must process `model.parameters()` to assign unique IDs to individual model parameters.

   If there are parameters with duplicated IDs in the model parameter iterable, loading the checkpointed optimizer state fails. To create an iterable of model parameters with unique IDs for your optimizer, see the following:

```
unique_params = []
unique_params_set = set()
for p in model.parameters():
  if p not in unique_params_set:
    unique_params.append(p)
    unique_params_set.add(p)
del unique_params_set

optimizer = MyOpt(unique_params, ...)
```

3. Wrap the optimizer using the library's wrapper function `smp.DistributedOptimizer()`.

```
optimizer = smp.DistributedOptimizer(optimizer)
```

4. Save the model and the optimizer state using [`smp.save()`]. Depending on how you want to save checkpoints, choose one of the following two options:

   - **Option 1:** Save a partial model on each `mp_rank` for a single `MP_GROUP`.

```
model_dict = model.local_state_dict() # save a partial model
opt_dict = optimizer.local_state_dict() # save a partial optimizer state
# Save the dictionaries at rdp_rank 0 as a checkpoint
if smp.rdp_rank() == 0:
    smp.save(
        {"model_state_dict": model_dict, "optimizer_state_dict": opt_dict},
        f"/checkpoint.pt",
        partial=True,
    )
```

     With tensor parallelism, the library saves checkpointed files named in the following format: `checkpoint.pt_{pp_rank}_{tp_rank}`.

> **Note**
>
> With tensor parallelism, make sure you set the if statement as `if smp.rdp_rank() == 0` instead of `if smp.dp_rank() == 0`. When the optimizer state is sharded with tensor parallelism, all reduced-data parallel ranks must save their own partition of the optimizer state. Using a wrong *if* statement for checkpointing might result in a stalling training job. For more information about using `if smp.dp_rank() == 0` without tensor parallelism, see General Instruction for Saving and Loading in the *SageMaker Python SDK documentation*.

- **Option 2:** Save the full model.

```
if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True) # save the full model
    if smp.rank() == 0:
        smp.save(
            {"model_state_dict": model_dict},
            "/checkpoint.pt",
            partial=False,
        )
```

> **Note**
>
> Consider the following for full checkpointing:
>
> - If you set `gather_to_rank0=True`, all ranks other than `0` return empty dictionaries.
> - For full checkpointing, you can only checkpoint the model. Full checkpointing of optimizer states is currently not supported.
> - The full model only needs to be saved at `smp.rank() == 0`.

5. Load the checkpoints using `smp.load()`. Depending on how you checkpointed in the previous step, choose one of the following two options:

- **Option 1:** Load the partial checkpoints.

```
checkpoint = smp.load("/checkpoint.pt", partial=True)
model.load_state_dict(checkpoint["model_state_dict"], same_partition_load=False)
```

```
optimizer.load_state_dict(checkpoint["optimizer_state_dict"])
```

You can set `same_partition_load=True` in `model.load_state_dict()` for a faster load, if you know that the partition will not change.

- **Option 2:** Load the full checkpoints.

```
if smp.rdp_rank() == 0:
    checkpoint = smp.load("/checkpoint.pt", partial=False)
    model.load_state_dict(checkpoint["model_state_dict"])
```

The `if smp.rdp_rank() == 0` condition is not required, but it can help avoid redundant loading among different `MP_GROUPS`. Full checkpointing optimizer state dict is currently not supported with tensor parallelism.

Checkpointing a distributed TensorFlow model

To save a TensorFlow model while training with model parallelism, use the following functions provided by the SageMaker model parallelism library.

- `smdistributed.modelparallel.tensorflow.DistributedModel.save_model`
- `smdistributed.modelparallel.tensorflow.CheckpointManager`

Fine-tuning a distributed model

The fine-tuning needs to be configured in your training script. The following code snippet shows an example structure of a training script using the AutoModelForCausalLM class of Hugging Face Transformers with modifications for registering the `smdistributed.model.parallel.torch` modules and settings for fine-tuning.

> **Note**
>
> Fine-tuning a distributed transformer (a Transformer model wrapped by `smp.DistributedModel()`) with the smp.delayed_param_initialization function activated requires the fine-tuning job to be configured with an FSx for Lustre file system. In cases where you want to fine-tune a large-scale model with the delayed parameter initialization option, you should set up an FSx for Lustre file system.

```
import argparse
from transformers import AutoModelForCausalLM
import smdistributed.modelparallel
import smdistributed.modelparallel.torch as smp

def parse_args():

    parser = argparse.ArgumentParser()

    # set an arg group for model
    model_grp = parser.add_argument_group(
        title="model", description="arguments to describe model configuration"
    )

    ... # set up numerous args to parse from the configuration dictionary to the script
 for training

    # add arg for activating fine-tuning
    model_grp.add_argument(
        "--fine_tune",
        type=int,
        default=0,
        help="Fine-tune model from checkpoint or pretrained model",
    )

def main():
    """Main function to train GPT."""
    args = parse_args()

    ... # parse numerous args

    if args.fine_tune > 0 and args.delayed_param > 0 and smp.rank() == 0:
        pretrained_model = AutoModelForCausalLM.from_pretrained(
            args.model_name or args.model_dir
        )
        model_state_dict = pretrained_model.state_dict()
        path = os.path.join(args.model_dir, "fullmodel.pt")
        torch.save(model_state_dict, path)

    # create a Transformer model and wrap by smp.model_creation()
    # with options to configure model parallelism parameters offered by SageMaker
    with smp.model_creation(
        tensor_parallelism=smp.tp_size() > 1 or args.use_distributed_transformer > 0,
```

```
        zero_init=args.use_distributed_transformer == 0,
        dtype=dtype,
        distribute_embedding=args.sharded_data_parallel_degree > 1 and smp.tp_size() >
1,
        use_alibi=args.alibi > 0,
        attention_in_fp32=args.attention_in_fp32 > 0,
        fp32_residual_addition=args.residual_addition_in_fp32 > 0,
        query_key_layer_scaling=args.query_key_layer_scaling > 0 and args.bf16 < 1,
        fused_softmax=args.fused_softmax > 0,
        fused_dropout=args.fused_dropout > 0,
        fused_bias_gelu=args.fused_bias_gelu > 0,
        flash_attention=args.flash_attention > 0,
    ):
        if args.fine_tune > 0 and args.delayed_param == 0:
            model = AutoModelForCausalLM.from_pretrained(
                args.model_name or args.model_dir
            )
        else:
            model = AutoModelForCausalLM.from_config(model_config)

    # wrap the model by smp.DistributedModel() to apply SageMaker model parallelism
    model = smp.DistributedModel(
        model, trace_device="gpu", backward_passes_per_step=args.gradient_accumulation
    )

    # wrap the optimizer by smp.DistributedOptimizer() to apply SageMaker model
parallelism
    optimizer= ... # define an optimizer
    optimizer = smp.DistributedOptimizer(
        optimizer,
        static_loss_scale=None,
        dynamic_loss_scale=True,
        dynamic_loss_args={"scale_window": 1000, "min_scale": 1, "delayed_shift": 2},
    )

    # for fine-tuning, use smp.resume_from_checkpoint() to load a pre-trained model
    if args.fine_tune > 0 and args.delayed_param > 0:
        smp.resume_from_checkpoint(args.model_dir, tag="fullmodel.pt", partial=False)
```

For a complete example of training scripts and Jupyter notebooks, see the GPT-2 examples for PyTorch in the *SageMaker Examples GitHub repository*.

Amazon SageMaker model parallelism library v1 examples

This page provides a list of blogs and Jupyter notebooks that present practical examples of implementing the SageMaker model parallelism (SMP) library v1 to run distributed training jobs on SageMaker.

Blogs and Case Studies

The following blogs discuss case studies about using SMP v1.

- New performance improvements in the Amazon SageMaker model parallelism library, *AWS Machine Learning Blog* (December 16, 2022)
- Train gigantic models with near-linear scaling using sharded data parallelism on Amazon SageMaker, *AWS Machine Learning Blog* (October 31, 2022)

Example notebooks

Example notebooks are provided in the SageMaker examples GitHub repository. To download the examples, run the following command to clone the repository and go to `training/distributed_training/pytorch/model_parallel`.

> **Note**
>
> Clone and run the example notebooks in the following SageMaker ML IDEs.
>
> - SageMaker JupyterLab (available in Studio created after December 2023)
> - SageMaker Code Editor (available in Studio created after December 2023)
> - Studio Classic (available as an application in Studio created after December 2023)
> - SageMaker Notebook Instances

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
cd amazon-sagemaker-examples/training/distributed_training/pytorch/model_parallel
```

SMP v1 example notebooks for PyTorch

- Train GPT-2 with near-linear scaling using the sharded data parallelism technique in the SageMaker model parallelism library

- Fine-tune GPT-2 with near-linear scaling using sharded data parallelism technique in the SageMaker model parallelism library
- Train GPT-NeoX-20B with near-linear scaling using the sharded data parallelism technique in the SageMaker model parallelism library
- Train GPT-J 6B using the sharded data parallelism and tensor parallelism techniques in the SageMaker model parallelism library
- Train FLAN-T5 with near-linear scaling using sharded data parallelism technique in the SageMaker model parallelism library
- Train Falcon with near-linear scaling using sharded data parallelism technique in the SageMaker model parallelism library

SMP v1 example notebooks for TensorFlow

- CNN with TensorFlow 2.3.1 and the SageMaker model parallelism library
- HuggingFace with TensorFlow Distributed model parallelism library Training on SageMaker

SageMaker Distributed Model Parallelism Best Practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library.

Setting Up the Right Configuration for a Given Model

When scaling up a model, we recommend you to go over the following list in order. Each list item discusses the advantage of using the library's techniques along with the tradeoffs that might arise.

> **Tip**
>
> If a model can fit well using a subset of the library's features, adding more model parallelism or memory saving features does not usually improve performance.

Using large GPU instance types

- In the realm of model parallelism, it is best to use powerful instances with large GPU memories to handle overhead from model parallelism operations such as partitioning models across multiple GPUs. We recommend using `ml.p4d` or `ml.p3dn` instances for training large DL

models. These instances are also equipped with Elastic Fabric Adapter (EFA), which provides higher network bandwidth and enables large-scale training with model parallelism.

Sharding optimizer state

- The impact of sharding optimizer state depends on the number of data parallel ranks. Typically, a higher degree of data parallelism (proportional to the size of compute node) can improve the efficiency of memory usage.

  When you want to downsize a cluster, make sure you check the optimizer state sharding configuration. For example, a large DL model with optimizer state sharding that fits on a compute cluster with 16 GPUs (for example, two P4d or P4de instances) might not always fit on a node with 8 GPUs (for example, a single P4d or P4de instance). This is because the combined memory of 8 GPUs is lower than the combined memory of 16 GPUs, and the required memory per GPU for sharding over 8 GPUs is also higher than the memory per GPU for sharding over the 16-GPU scenario. As a result, the increased memory requirement might not fit into the smaller cluster.

  For more information, see Optimizer State Sharding.

Activation checkpointing

- Memory efficiency can be improved by using activation checkpointing for a group of modules. The more you group the modules, the more efficient the memory usage. When checkpointing sequential modules for layers, the `strategy` argument of the `smp.set_activation_checkpointing` function groups the layers together for checkpointing. For example, grouping two or more layers together for checkpointing is more memory efficient than checkpointing one layer at a time, and this trades extra computation time for reduced memory usage.

  For more information, see Activation Checkpointing.

Tensor parallelism

- The degree of tensor parallelism should be a power of two (2, 4, 8, ..., 2^n), where the maximum degree must be equal to the number of GPUs per node. For example, if you use a node with 8 GPUs, possible numbers for the degree of tensor parallelism are 2, 4, and 8. We don't

recommend arbitrary numbers (such as 3, 5, 6, and 7) for the degree of tensor parallelism. When you use multiple nodes, misconfiguring the degree of tensor parallelism might result in running tensor parallelism across the nodes; this adds significant overhead from communication of activations across the nodes and can become computationally expensive.

For more information, see Tensor Parallelism.

Pipeline parallelism across nodes

- You can run pipeline parallelism both within a single node and across multiple nodes. When you use pipeline parallelism in combination with tensor parallelism, we recommend running pipeline parallelism across multiple nodes and keeping tensor parallelism within individual nodes.
- Pipeline parallelism comes with the following three knobs: `microbatches`, `active_microbatches`, and `prescaled_batch`.
  - When you use tensor parallelism with pipeline parallelism, we recommend activating `prescaled_batch` so that the batch size per model parallel group can be increased for efficient pipelining. With `prescaled_batch` activated, the batch size set in the training script becomes `tp_size` times the batch size set for each rank without `prescaled_batch`.
  - Increasing the number of `microbatches` helps achieve efficient pipelining and better performance. Note that the effective microbatch size is the batch size divided by number of microbatches. If you increase the number of microbatches while keeping batch size constant, each microbatch processes fewer samples.
  - The number of `active_microbatches` is the maximum number of microbatches that are simultaneously in process during pipelining. For each active microbatch in process, its activations and gradients take up GPU memory. Therefore, increasing `active_microbatches` takes up more GPU memory.
- If both GPU and GPU memory are underutilized, increase `active_microbatches` for better parallelization during pipelining.
- For more information about how to use tensor parallelism with pipeline parallelism, see Tensor parallelism combined with pipeline parallelism.
- To find descriptions of the aforementioned parameters, see Parameters for `smdistributed` in the *SageMaker Python SDK documentation*.

Offloading activations to CPU

- Make sure that this is used in combination with activation checkpointing and pipeline parallelism. To ensure that the offloading and preloading happen in the background, specify a value greater than 1 to the microbatches parameter.
- When offloading activations, you might be able to increase `active_microbatches` and sometimes match with the total number of microbatches. This depends on which modules are checkpointed and how the model is partitioned.

  For more information, see Activation Offloading.

Reference configurations

The SageMaker model parallelism training team provides the following reference points based on experiments with the GPT-2 model, the sequence length of 512, and the vocabulary size of 50,000.

The number of model parameters	Instance type	Pipeline parallelism	Tensor parallelism	Optimizer state sharding	Activation checkpointing	Prescaled batch	Batch size
10 billion	16 ml.p4d.24xlarge	1	4	True	Each transformer layer	True	batch_size=40
30 billion	16 ml.p4d.24xlarge	1	8	True	Each transformer layer	True	batch_size=32
60 billion	32 ml.p4d.24xlarge	2	8	True	Each transformer layer	True	batch_size=56 , microbatches=4 , active_microbatches=2

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn't fit, try increasing the degree of tensor parallelism.

Modifying Your Training Script

- Before you use the SageMaker model parallel library's features in your training script, review The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls.
- To launch a training job faster, use the SageMaker local mode. This helps you quickly run a training job locally on a SageMaker notebook instance. Depending on the scale of the ML instance on which your SageMaker notebook instance is running, you might need to adjust the size of your model by changing the model configurations, such as the hidden width, number of transformer layers, and attention heads. Validate if the reduced model runs well on the notebook instance before using a large cluster for training the full model.

Monitoring and Logging a Training Job Using the SageMaker Console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker console.

1. In the left navigation pane, choose **Training**.
2. Choose **Training jobs**.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the **Monitor** section to see the automated visualization.
5. To see training job logs, choose **View logs** in the **Monitor** section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of **algo-n-1234567890**. The **algo-1** log stream tracks training logs from the main (0th) node.

For more information, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics.

Permissions

To run a SageMaker training job with model parallelism or the SageMaker distributed training example notebooks, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add `AmazonFSxFullAccess`.
- To use Amazon S3 as a data channel, add `AmazonS3FullAccess`.
- To use Docker, build your own container, and push it to Amazon ECR, add `AmazonEC2ContainerRegistryFullAccess`.
- To have a full access to use the entire suite of SageMaker features, add `AmazonSageMakerFullAccess`.

The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker's model parallelism library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow training script and Modify a PyTorch Training Script, respectively.

Batch Size and Number of Microbatches

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
- Choosing a number of microbatches that is too small or too large can lower performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.
- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set `drop_remainder=True` in the `tf.Dataset.batch()` call (in TensorFlow), or set `drop_last=True` in `DataLoader` (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

Manual Partitioning

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

Data Preparation

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with `smp.dp_rank()`. If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by `smp.dp_rank()`. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

Returning Tensors from `smp.DistributedModel`

- Any tensor that is returned from the `smp.DistributedModel.call` (for TensorFlow) or `smp.DistributedModel.forward` (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

The `@smp.step` Decorator

- If an `smp.step`-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the `non_split_inputs` list when calling `smp.step`. This prevents the library from attempting to split the tensor into microbatches. For more information see `smp.step` in the API documentation.

Delaying Parameter Initialization

For very large models over 100 billion parameters, weight initialization through the CPU memory might result in an out-of-memory error. To get around this, the library offers `smp.delay_param_initialization` context manager. This delays the physical allocation of parameters until they move to GPU during the first execution of a `smp.step`-decorated function. This avoids unnecessary memory usage of the CPU during the initialization of training. Use the context manager when you create a model object as shown in the following code.

```
with smp.delay_param_initialization(enabled=True):
    model = MyModel()
```

Tensor Parallelism for PyTorch

- If you are using a seed for deterministic results, set the seed based on `smp.dp_rank()` (for example, `torch.manual_seed(42 + smp.dp_rank())`). If you do not do this, different partitions of an `nn.Parameter` are initialized in the same way, impacting convergence.
- SageMaker's model parallelism library uses NCCL to implement collectives needed for the distribution of the modules. Especially for smaller models, if too many NCCL calls are scheduled on the GPU at the same time, memory usage might increase because of additional space used by NCCL. To counteract this, `smp` throttles the NCCL calls so that the number of ongoing NCCL operations at any given time is less than or equal to a given limit. The default limit is 8, but this can be adjusted using the environment variable `SMP_NCCL_THROTTLE_LIMIT`. If you observe more memory usage than you expect while using tensor parallelism, you can try reducing this limit. However, choosing a limit that is too small might cause throughput loss. To disable throttling altogether, you can set `SMP_NCCL_THROTTLE_LIMIT=-1`.
