What is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. Amazon EC2 enables you to scale up or down to handle changes in requirements or spikes in popularity, reducing your need to forecast traffic.

For more information about cloud computing, see What is cloud computing?

Features of Amazon EC2

Amazon EC2 provides the following features:

- Virtual computing environments, known as instances
- Preconfigured templates for your instances, known as Amazon Machine Images (AMIs), that package the bits you need for your server (including the operating system and additional software)
- Various configurations of CPU, memory, storage, and networking capacity for your instances, known as instance types
- Secure login information for your instances using key pairs (AWS stores the public key, and you store the private key in a secure place)
- Storage volumes for temporary data that’s deleted when you stop, hibernate, or terminate your instance, known as instance store volumes
- Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS), known as Amazon EBS volumes
- Multiple physical locations for your resources, such as instances and Amazon EBS volumes, known as Regions and Availability Zones
- A firewall that enables you to specify the protocols, ports, and source IP ranges that can reach your instances using security groups
- Static IPv4 addresses for dynamic cloud computing, known as Elastic IP addresses
- Metadata, known as tags, that you can create and assign to your Amazon EC2 resources
- Virtual networks you can create that are logically isolated from the rest of the AWS Cloud, and that you can optionally connect to your own network, known as virtual private clouds (VPCs)

For more information about the features of Amazon EC2, see the Amazon EC2 product page.

For more information about running your website on AWS, see Web Hosting.

How to get started with Amazon EC2

First, you need to get set up to use Amazon EC2. After you are set up, you are ready to complete the Get Started tutorial for Amazon EC2. Whenever you need more information about an Amazon EC2 feature, you can read the technical documentation.
Get up and running

- Set up to use Amazon EC2 (p. 5)
- Tutorial: Get started with Amazon EC2 Linux instances (p. 9)

Basics

- Instances and AMIs (p. 190)
- Regions and Zones (p. 867)
- Instance types (p. 193)
- Tags (p. 1462)

Networking and security

- Key pairs (p. 1137)
- Security groups (p. 1152)
- Elastic IP addresses (p. 914)
- Virtual private clouds (p. 1033)

Storage

- Amazon EBS (p. 1175)
- Instance store (p. 1408)

Working with Linux instances

- AWS Systems Manager Run Command in the AWS Systems Manager User Guide
- Tutorial: Install a LAMP web server on Amazon Linux 2 (p. 15)
- Tutorial: Configure SSL/TLS on Amazon Linux 2 (p. 25)

If you have questions about whether AWS is right for you, contact AWS Sales. If you have technical questions about Amazon EC2, use the Amazon EC2 forum.

Related services

You can provision Amazon EC2 resources, such as instances and volumes, directly using Amazon EC2. You can also provision Amazon EC2 resources using other services in AWS. For more information, see the following documentation:

- Amazon EC2 Auto Scaling User Guide
- AWS CloudFormation User Guide
- AWS Elastic Beanstalk Developer Guide
- AWS OpsWorks User Guide

To automatically distribute incoming application traffic across multiple instances, use Elastic Load Balancing. For more information, see the Elastic Load Balancing User Guide.

To get a managed relational database in the cloud, use Amazon Relational Database Service (Amazon RDS) to launch a database instance. Although you can set up a database on an EC2 instance, Amazon

Related services
RDS offers the advantage of handling your database management tasks, such as patching the software, backing up, and storing the backups. For more information, see the Amazon Relational Database Service Developer Guide.

To make it easier to manage Docker containers on a cluster of EC2 instances, use Amazon Elastic Container Service (Amazon ECS). For more information, see the Amazon Elastic Container Service Developer Guide or the Amazon Elastic Container Service User Guide for AWS Fargate.

To monitor basic statistics for your instances and Amazon EBS volumes, use Amazon CloudWatch. For more information, see the Amazon CloudWatch User Guide.

To detect potentially unauthorized or malicious use of your EC2 instances, use Amazon GuardDuty. For more information see the Amazon GuardDuty User Guide.

Access Amazon EC2

Amazon EC2 provides a web-based user interface, the Amazon EC2 console. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting EC2 from the console home page.

If you prefer to use a command line interface, you have the following options:

**AWS Command Line Interface (CLI)**
Provides commands for a broad set of AWS products, and is supported on Windows, Mac, and Linux. To get started, see AWS Command Line Interface User Guide. For more information about the commands for Amazon EC2, see ec2 in the AWS CLI Command Reference.

**AWS Tools for Windows PowerShell**
Provides commands for a broad set of AWS products for those who script in the PowerShell environment. To get started, see the AWS Tools for Windows PowerShell User Guide. For more information about the cmdlets for Amazon EC2, see the AWS Tools for PowerShell Cmdlet Reference.

Amazon EC2 supports creating resources using AWS CloudFormation. You create a template, in JSON or YAML, that describes your AWS resources, and AWS CloudFormation provisions and configures those resources for you. You can reuse your CloudFormation templates to provision the same resources multiple times, whether in the same Region and account or in multiple Regions and accounts. For more information about the resource types and properties for Amazon EC2, see EC2 resource type reference in the AWS CloudFormation User Guide.

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named Action. For more information about the API actions for Amazon EC2, see Actions in the Amazon EC2 API Reference.

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automate tasks such as cryptographically signing your requests, retrying requests, and handling error responses, making it is easier for you to get started. For more information, see Tools to Build on AWS.

Pricing for Amazon EC2

When you sign up for AWS, you can get started with Amazon EC2 for free using the AWS Free Tier.
Amazon Elastic Compute Cloud
User Guide for Linux Instances

PCI DSS compliance

Amazon EC2 provides the following purchasing options for instances:

**On-Demand Instances**

Pay for the instances that you use by the second, with no long-term commitments or upfront payments.

**Savings Plans**

You can reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.

**Reserved Instances**

You can reduce your Amazon EC2 costs by making a commitment to a specific instance configuration, including instance type and Region, for a term of 1 or 3 years.

**Spot Instances**

Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.

For a complete list of charges and prices for Amazon EC2, see Amazon EC2 pricing.

To calculate the cost of a sample provisioned environment, see Cloud Economics Center.

To see your bill, go to the Billing and Cost Management Dashboard in the AWS Billing and Cost Management console. Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see AWS Billing and Cost Management User Guide.

If you have questions concerning AWS billing, accounts, and events, contact AWS Support.

For an overview of Trusted Advisor, a service that helps you optimize the costs, security, and performance of your AWS environment, see AWS Trusted Advisor.

**PCI DSS compliance**

Amazon EC2 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see PCI DSS Level 1.
Set up to use Amazon EC2

Complete the tasks in this section to get set up for launching an Amazon EC2 instance for the first time:

1. Sign up for AWS (p. 5)
2. Create a key pair (p. 5)
3. Create a security group (p. 6)

When you are finished, you will be ready for the Amazon EC2 Getting started (p. 9) tutorial.

Sign up for AWS

When you sign up for Amazon Web Services, your AWS account is automatically signed up for all services in AWS, including Amazon EC2. You are charged only for the services that you use.

With Amazon EC2, you pay only for what you use. If you are a new AWS customer, you can get started with Amazon EC2 for free. For more information, see AWS Free Tier.

If you have an AWS account already, skip to the next task. If you don't have an AWS account, use the following procedure to create one.

To create an AWS account

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Create a key pair

AWS uses public-key cryptography to secure the login information for your instance. A Linux instance has no password; you use a key pair to log in to your instance securely. You specify the name of the key pair when you launch your instance, then provide the private key when you log in using SSH.

If you haven't created a key pair already, you can create one by using the Amazon EC2 console. Note that if you plan to launch instances in multiple Regions, you'll need to create a key pair in each Region. For more information about Regions, see Regions and Zones (p. 867).

To create your key pair

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Key Pairs.
3. Choose Create key pair.
4. For **Name**, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can't include leading or trailing spaces.

5. For **Key pair type**, choose either **RSA** or **ED25519**. Note that **ED25519** keys are not supported for Windows instances, EC2 Instance Connect, or EC2 Serial Console.

6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.

   If you chose **ED25519** in the previous step, the **Private key file format** options do not appear, and the private key format defaults to **pem**.

7. Choose **Create key pair**.

8. The private key file is automatically downloaded by your browser. The base file name is the name you specified as the name of your key pair, and the file name extension is determined by the file format you chose. Save the private key file in a safe place.

   **Important**

   This is the only chance for you to save the private key file.

9. If you will use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

   ```bash
   chmod 400 my-key-pair.pem
   ```

   If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see **Error: Unprotected private key file** (p. 1487).

For more information, see Amazon EC2 key pairs and Linux instances (p. 1137).

### Create a security group

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your instance from your IP address using SSH. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere.

Note that if you plan to launch instances in multiple Regions, you'll need to create a security group in each Region. For more information about Regions, see Regions and Zones (p. 867).

### Prerequisites

You'll need the public IPv4 address of your local computer. The security group editor in the Amazon EC2 console can automatically detect the public IPv4 address for you. Alternatively, you can use the search phrase "what is my IP address" in an Internet browser, or use the following service: Check IP. If you are connecting through an Internet service provider (ISP) or from behind a firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

You can create a custom security group using one of the following methods.

**New console**

#### To create a security group with least privilege

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. From the navigation bar, select a Region for the security group. Security groups are specific to a Region, so you should select the same Region in which you created your key pair.
3. In the navigation pane, choose **Security Groups**.
4. Choose **Create security group**.
5. For **Basic details**, do the following:
   a. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by \_SG\_, plus the Region name. For example, me\_SG\_uswest2.
   b. In the **VPC** list, select your default VPC for the Region.
6. For **Inbound rules**, create rules that allow specific traffic to reach your instance. For example, use the following rules for a web server that accepts HTTP and HTTPS traffic. For more examples, see **Security group rules for different use cases** (p. 1167).
   a. Choose **Add rule**. For **Type**, choose HTTP. For **Source**, choose Anywhere.
   b. Choose **Add rule**. For **Type**, choose HTTPS. For **Source**, choose Anywhere.
   c. Choose **Add rule**. For **Type**, choose SSH. For **Source**, do one of the following:
      - Choose **My IP** to automatically add the public IPv4 address of your local computer.
      - Choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix /32, for example, 203.0.113.25/32. If your company or your router allocates addresses from a range, specify the entire range, such as 203.0.113.0/24.

   **Warning**
   For security reasons, do not choose Anywhere for **Source** with a rule for SSH. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.
7. For **Outbound rules**, keep the default rule, which allows all outbound traffic.
8. Choose **Create security group**.

**Old console**

**To create a security group with least privilege**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create Security Group**.
4. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by \_SG\_, plus the Region name. For example, me\_SG\_uswest2.
5. In the **VPC** list, select your default VPC for the Region.
6. On the **Inbound** tab, create the following rules (choose **Add rule** for each new rule):
   - Choose **HTTP** from the **Type** list, and make sure that **Source** is set to Anywhere (0.0.0.0/0).
   - Choose **HTTPS** from the **Type** list, and make sure that **Source** is set to Anywhere (0.0.0.0/0).
   - Choose **SSH** from the **Type** list. In the **Source** box, choose **My IP** to automatically populate the field with the public IPv4 address of your local computer. Alternatively, choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix /32, for example, 203.0.113.25/32. If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24.
Warning
For security reasons, do not allow SSH access from all IP addresses to your instance.
This is acceptable for a short time in a test environment, but it is unsafe for production environments.

7. On the **Outbound** tab, keep the default rule, which allows all outbound traffic.
8. Choose **Create**.

Command line

**To create a security group with least privilege**

Use one of the following commands:

- `create-security-group` *(AWS CLI)*

For more information, see *Amazon EC2 security groups for Linux instances (p. 1152).*
Tutorial: Get started with Amazon EC2 Linux instances

Use this tutorial to get started with Amazon Elastic Compute Cloud (Amazon EC2). You’ll learn how to launch, connect to, and use a Linux instance. An instance is a virtual server in the AWS Cloud. With Amazon EC2, you can set up and configure the operating system and applications that run on your instance.

When you sign up for AWS, you can get started with Amazon EC2 using the AWS Free Tier. If you created your AWS account less than 12 months ago, and have not already exceeded the free tier benefits for Amazon EC2, it will not cost you anything to complete this tutorial, because we help you select options that are within the free tier benefits. Otherwise, you’ll incur the standard Amazon EC2 usage fees from the time that you launch the instance until you terminate the instance (which is the final task of this tutorial), even if it remains idle.

Contents

• Overview (p. 9)
• Prerequisites (p. 10)
• Step 1: Launch an instance (p. 10)
• Step 2: Connect to your instance (p. 11)
• Step 3: Clean up your instance (p. 11)
• Next steps (p. 12)

Related tutorials

• If you’d prefer to launch a Windows instance, see this tutorial in the Amazon EC2 User Guide for Windows Instances: Get started with Amazon EC2 Windows instances.

• If you’d prefer to use the command line, see this tutorial in the AWS Command Line Interface User Guide: Using Amazon EC2 through the AWS CLI.

Overview

The instance is an Amazon EBS-backed instance (meaning that the root volume is an EBS volume). You can either specify the Availability Zone in which your instance runs, or let Amazon EC2 select an Availability Zone for you. When you launch your instance, you secure it by specifying a key pair and security group. When you connect to your instance, you must specify the private key of the key pair that you specified when launching your instance.
Prerequisites

Before you begin, be sure that you've completed the steps in Set up to use Amazon EC2 (p. 5).

Step 1: Launch an instance

You can launch a Linux instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you launch your first instance quickly, so it doesn't cover all possible options. For more information about the advanced options, see Launch an instance using the Launch Instance Wizard (p. 477). For information about other ways to launch your instance, see Launch your instance (p. 475).

To launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console dashboard, choose Launch Instance.
3. The Choose an Amazon Machine Image (AMI) page displays a list of basic configurations, called Amazon Machine Images (AMIs), that serve as templates for your instance. Select an HVM version of Amazon Linux 2. Notice that these AMIs are marked "Free tier eligible."
4. On the Choose an Instance Type page, you can select the hardware configuration of your instance. Select the t2.micro instance type, which is selected by default. The t2.micro instance type is eligible for the free tier. In Regions where t2.micro is unavailable, you can use a t3.micro instance under the free tier. For more information, see AWS Free Tier.
5. On the Choose an Instance Type page, choose Review and Launch to let the wizard complete the other configuration settings for you.
6. On the Review Instance Launch page, under Security Groups, you'll see that the wizard created and selected a security group for you. You can use this security group, or alternatively you can select the security group that you created when getting set up using the following steps:
   a. Choose Edit security groups.
   b. On the Configure Security Group page, ensure that Select an existing security group is selected.
c. Select your security group from the list of existing security groups, and then choose **Review and Launch**.

7. On the **Review Instance Launch** page, choose **Launch**.

8. When prompted for a key pair, select **Choose an existing key pair**, then select the key pair that you created when getting set up.

   **Warning**
   Don't select **Proceed without a key pair**. If you launch your instance without a key pair, then you can't connect to it.

When you are ready, select the acknowledgement check box, and then choose **Launch Instances**.

9. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.

10. On the **Instances** screen, you can view the status of the launch. It takes a short time for an instance to launch. When you launch an instance, its initial state is **pending**. After the instance starts, its state changes to **running** and it receives a public DNS name. (If the **Public IPv4 DNS** column is hidden, choose the settings icon (```)) in the top-right corner, toggle on **Public IPv4 DNS**, and choose **Confirm**.

11. It can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks; you can view this information in the **Status check** column.

---

**Step 2: Connect to your instance**

There are several ways to connect to your Linux instance. For more information, see **Connect to your Linux instance** (p. 499).

**Important**
You can't connect to your instance unless you launched it with a key pair for which you have the .pem file and you launched it with a security group that allows SSH access from your computer.

If you can't connect to your instance, see **Troubleshoot connecting to your instance** (p. 1480) for assistance.

**Step 3: Clean up your instance**

After you've finished with the instance that you created for this tutorial, you should clean up by terminating the instance. If you want to do more with this instance before you clean up, see **Next steps** (p. 12).

**Important**
Terminating an instance effectively deletes it; you can't reconnect to an instance after you've terminated it.

If you launched an instance that is not within the **AWS Free Tier**, you'll stop incurring charges for that instance as soon as the instance status changes to **shutting down** or **terminated**. To keep your instance for later, but not incur charges, you can stop the instance now and then start it again later. For more information, see **Stop and start your instance** (p. 524).

**To terminate your instance**

1. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
2. Choose **Instance state**, **Terminate instance**.
3. Choose **Terminate** when prompted for confirmation.
After you start your instance, you might want to try some of the following exercises:

- Learn how to remotely manage your EC2 instance using Run Command. For more information, see AWS Systems Manager Run Command in the AWS Systems Manager User Guide.
- Configure a CloudWatch alarm to notify you if your usage exceeds the Free Tier. For more information, see Tracking your AWS Free Tier usage in the AWS Billing and Cost Management User Guide.
- Add an EBS volume. For more information, see Create an Amazon EBS volume (p. 1199) and Attach an Amazon EBS volume to an instance (p. 1202).
- Install the LAMP stack. For more information, see Tutorial: Install a LAMP web server on Amazon Linux 2 (p. 15).
Best practices for Amazon EC2

This list of practices will help you get the maximum benefit from Amazon EC2.

Security

- Manage access to AWS resources and APIs using identity federation, IAM users, and IAM roles. Establish credential management policies and procedures for creating, distributing, rotating, and revoking AWS access credentials. For more information, see IAM Best Practices in the IAM User Guide.
- Implement the least permissive rules for your security group. For more information, see Security group rules (p. 1153).
- Regularly patch, update, and secure the operating system and applications on your instance. For more information about updating Amazon Linux 2 or the Amazon Linux AMI, see Manage software on your Linux instance in the Amazon EC2 User Guide for Linux Instances.

Storage

- Understand the implications of the root device type for data persistence, backup, and recovery. For more information, see Storage for the root device (p. 73).
- Use separate Amazon EBS volumes for the operating system versus your data. Ensure that the volume with your data persists after instance termination. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).
- Use the instance store available for your instance to store temporary data. Remember that the data stored in instance store is deleted when you stop, hibernate, or terminate your instance. If you use instance store for database storage, ensure that you have a cluster with a replication factor that ensures fault tolerance.
- Encrypt EBS volumes and snapshots. For more information, see Amazon EBS encryption (p. 1335).

Resource management

- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see Instance metadata and user data (p. 606) and Tag your Amazon EC2 resources (p. 1462).
- View your current limits for Amazon EC2. Plan to request any limit increases in advance of the time that you’ll need them. For more information, see Amazon EC2 service quotas (p. 1475).

Backup and recovery

- Regularly back up your EBS volumes using Amazon EBS snapshots (p. 1227), and create an Amazon Machine Image (AMI) (p. 70) from your instance to save the configuration as a template for launching future instances.
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see Amazon EC2 instance IP addressing (p. 880).
- Monitor and respond to events. For more information, see Monitor Amazon EC2 (p. 785).
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see Elastic network interfaces (p. 922). For an automated solution, you can use Amazon EC2 Auto Scaling. For more information, see the Amazon EC2 Auto Scaling User Guide.
• Regularly test the process of recovering your instances and Amazon EBS volumes if they fail.

Networking

• Set the time-to-live (TTL) value for your applications to 255, for IPv4 and IPv6. If you use a smaller value, there is a risk that the TTL will expire while application traffic is in transit, causing reachability issues for your instances.
Tutorials for Amazon EC2 Instances Running Linux

The following tutorials show you how to perform common tasks using EC2 instances running Linux. AWS provides Amazon Linux 2 and the Amazon Linux AMI. For more information, see Amazon Linux 2 and Amazon Linux AMI. For video tutorials, see AWS Instructional Videos and Labs.

Tutorials
- Tutorial: Install a LAMP web server on Amazon Linux 2 (p. 15)
- Tutorial: Configure SSL/TLS on Amazon Linux 2 (p. 25)
- Tutorial: Host a WordPress blog on Amazon Linux 2 (p. 39)
- Tutorial: Install a LAMP web server on the Amazon Linux AMI (p. 48)
- Tutorial: Configure SSL/TLS with the Amazon Linux AMI (p. 59)

Tutorial: Install a LAMP web server on Amazon Linux 2

The following procedures help you install an Apache web server with PHP and MariaDB (a community-developed fork of MySQL) support on your Amazon Linux 2 instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Important
If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux AMI, see Tutorial: Install a LAMP web server on the Amazon Linux AMI (p. 48). For Ubuntu, see the following Ubuntu community documentation: ApacheMySQLPHP. For other distributions, see their specific documentation.

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the AWSDocs-InstallALAMPServer-AL2 Automation document.

Tasks
- Step 1: Prepare the LAMP server (p. 15)
- Step 2: Test your LAMP server (p. 19)
- Step 3: Secure the database server (p. 20)
- Step 4: (Optional) Install phpMyAdmin (p. 21)
- Troubleshoot (p. 24)
- Related topics (p. 24)

Step 1: Prepare the LAMP server

Prerequisites
- This tutorial assumes that you have already launched a new instance using Amazon Linux 2, with a public DNS name that is reachable from the internet. For more information, see Step 1: Launch an
instance (p. 10). You must also have configured your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see Authorize inbound traffic for your Linux instances (p. 1134).

- The following procedure installs the latest PHP version available on Amazon Linux 2, currently PHP 7.2. If you plan to use PHP applications other than those described in this tutorial, you should check their compatibility with PHP 7.2.

To prepare the LAMP server

1. Connect to your instance (p. 11).
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

   The –y option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

   `[ec2-user ~]$ sudo yum update -y`

3. Install the `lamp-mariadb10.2-php7.2` and `php7.2` Amazon Linux Extras repositories to get the latest versions of the LAMP MariaDB and PHP packages for Amazon Linux 2.

   `[ec2-user ~]$ sudo amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2`

   If you receive an error stating `sudo: amazon-linux-extras: command not found`, then your instance was not launched with an Amazon Linux 2 AMI (perhaps you are using the Amazon Linux AMI instead). You can view your version of Amazon Linux using the following command.

   `cat /etc/system-release`

   To set up a LAMP web server on Amazon Linux AMI, see Tutorial: Install a LAMP web server on the Amazon Linux AMI (p. 48).

4. Now that your instance is current, you can install the Apache web server, MariaDB, and PHP software packages.

   Use the `yum install` command to install multiple software packages and all related dependencies at the same time.

   `[ec2-user ~]$ sudo yum install -y httpd mariadb-server`

   You can view the current versions of these packages using the following command:

   `yum info package_name`

5. Start the Apache web server.

   `[ec2-user ~]$ sudo systemctl start httpd`

6. Use the `systemctl` command to configure the Apache web server to start at each system boot.

   `[ec2-user ~]$ sudo systemctl enable httpd`

   You can verify that `httpd` is on by running the following command:
7. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a launch-wizard-N security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose Instances and select your instance.
   c. On the Security tab, view the inbound rules. You should see the following rule:

<table>
<thead>
<tr>
<th>Port range</th>
<th>Protocol</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>tcp</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

   Warning
   Using 0.0.0.0/0 allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

d. Choose the link for the security group. Using the procedures in Add rules to a security group (p. 1160), add a new inbound security rule with the following values:

   - **Type**: HTTP
   - **Protocol**: TCP
   - **Port Range**: 80
   - **Source**: Custom

8. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. If there is no content in /var/www/html, you should see the Apache test page. You can get the public DNS for your instance using the Amazon EC2 console (check the Public DNS column; if this column is hidden, choose Show/Hide Columns (the gear-shaped icon) and choose Public DNS).

   Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see Add rules to a security group (p. 1160).

   **Important**
   If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.
Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is `/var/www/html`, which by default is owned by root.

To allow the `ec2-user` account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

**To set file permissions**

1. Add your user (in this case, `ec2-user`) to the `apache` group.

   ```bash
   [ec2-user ~]$ sudo usermod -a -G apache ec2-user
   ```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
   a. Log out (use the `exit` command or close the terminal window):

   ```bash
   [ec2-user ~]$ exit
   ```

   b. To verify your membership in the `apache` group, reconnect to your instance, and then run the following command:

   ```bash
   [ec2-user ~]$ groups
   ec2-user adm wheel apache systemd-journal
   ```

3. Change the group ownership of `/var/www` and its contents to the `apache` group.

   ```bash
   [ec2-user ~]$ sudo chown -R ec2-user:apache /var/www
   ```
4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of /var/www and its subdirectories.

   [ec2-user ~]$ sudo chmod 2775 /var/www && find /var/www -type d -exec sudo chmod 2775 {} \;

5. To add group write permissions, recursively change the file permissions of /var/www and its subdirectories:

   [ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

**To secure your web server (Optional)**

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see Tutorial: Configure SSL/TLS on Amazon Linux 2 (p. 25).

**Step 2: Test your LAMP server**

If your server is installed and running, and your file permissions are set correctly, your ec2-user account should be able to create a PHP file in the /var/www/html directory that is available from the internet.

**To test your LAMP server**

1. Create a PHP file in the Apache document root.

   If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in To set file permissions (p. 18).

2. In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

   http://my.public.dns.amazonaws.com/phpinfo.php

   You should see the PHP information page:
If you do not see this page, verify that the /var/www/html/phpinfo.php file was created properly in the previous step. You can also verify that all of the required packages were installed with the following command.

```
[ec2-user ~]$ sudo yum list installed httpd mariadb-server php-mysqlnd
```

If any of the required packages are not listed in your output, install them with the `sudo yum install package` command. Also verify that the php7.2 and lamp-mariadb10.2-php7.2 extras are enabled in the output of the `amazon-linux-extras` command.

3. Delete the phpinfo.php file. Although this can be useful information, it should not be broadcast to the internet for security reasons.

```
[ec2-user ~]$ rm /var/www/html/phpinfo.php
```

You should now have a fully functional LAMP web server. If you add content to the Apache document root at /var/www/html, you should be able to view that content at the public DNS address for your instance.

### Step 3: Secure the database server

The default installation of the MariaDB server has several features that are great for testing and development, but they should be disabled or removed for production servers. The `mysql_secure_installation` command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MariaDB server, we recommend performing this procedure.
To secure the MariaDB server

1. Start the MariaDB server.

   [ec2-user ~]# sudo systemctl start mariadb

2. Run `mysql_secure_installation`.

   [ec2-user ~]# sudo mysql_secure_installation

   a. When prompted, type a password for the root account.
      i. Type the current root password. By default, the root account does not have a password set. Press Enter.
      ii. Type `Y` to set a password, and type a secure password twice. For more information about creating a secure password, see https://identitysafe.norton.com/password-generator/. Make sure to store this password in a safe place.

         Setting a root password for MariaDB is only the most basic measure for securing your database. When you build or install a database-driven application, you typically create a database service user for that application and avoid using the root account for anything but database administration.

   b. Type `Y` to remove the anonymous user accounts.
   c. Type `Y` to disable the remote root login.
   d. Type `Y` to remove the test database.
   e. Type `Y` to reload the privilege tables and save your changes.

3. (Optional) If you do not plan to use the MariaDB server right away, stop it. You can restart it when you need it again.

   [ec2-user ~]# sudo systemctl stop mariadb

4. (Optional) If you want the MariaDB server to start at every boot, type the following command.

   [ec2-user ~]# sudo systemctl enable mariadb

---

Step 4: (Optional) Install phpMyAdmin

phpMyAdmin is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

**Important**
We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see Securing your phpMyAdmin installation. For general information about securing a web server on an EC2 instance, see Tutorial: Configure SSL/TLS on Amazon Linux 2 (p. 25).

To install phpMyAdmin

1. Install the required dependencies.

   [ec2-user ~]# sudo yum install php-mbstring php-xml -y
2. Restart Apache.

```
[ec2-user ~]# sudo systemctl restart httpd
```

```
[ec2-user ~]# sudo systemctl restart php-fpm
```

```
[ec2-user ~]# cd /var/www/html
```

5. Select a source package for the latest phpMyAdmin release from https://www.phpmyadmin.net/downloads. To download the file directly to your instance, copy the link and paste it into a `wget` command, as in this example:

```
[ec2-user html]# wget https://www.phpmyadmin.net/downloads/phpMyAdmin-latest-all-languages.tar.gz
```

6. Create a phpMyAdmin folder and extract the package into it with the following command.

```
[ec2-user html]# mkdir phpMyAdmin && tar -xvzf phpMyAdmin-latest-all-languages.tar.gz --strip-components 1
```

7. Delete the `phpMyAdmin-latest-all-languages.tar.gz` tarball.

```
[ec2-user html]# rm phpMyAdmin-latest-all-languages.tar.gz
```

8. (Optional) If the MySQL server is not running, start it now.

```
[ec2-user ~]# sudo systemctl start mariadb
```

9. In a web browser, type the URL of your phpMyAdmin installation. This URL is the public DNS address (or the public IP address) of your instance followed by a forward slash and the name of your installation directory. For example:

```
http://my.public.dns.amazonaws.com/phpMyAdmin
```

You should see the phpMyAdmin login page:
10. Log in to your phpMyAdmin installation with the root user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. We suggest that you begin by manually creating the configuration file, as follows:

a. To start with a minimal configuration file, use your favorite text editor to create a new file, and then copy the contents of config.sample.inc.php into it.
b. Save the file as `config.inc.php` in the `phpMyAdmin` directory that contains `index.php`.

c. Refer to post-file creation instructions in the `Using the Setup script` section of the `phpMyAdmin` installation instructions for any additional setup.

For information about using `phpMyAdmin`, see the `phpMyAdmin User Guide`.

**Troubleshoot**

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

**I can't connect to my server using a web browser**

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

  You can verify that `httpd` is on by running the following command:

  ```
  [ec2-user ~]$ sudo systemctl is-enabled httpd
  ```

  If the `httpd` process is not running, repeat the steps described in To prepare the LAMP server (p. 16).

- **Is the firewall correctly configured?**

  Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see Add rules to a security group (p. 1160).

**I can't connect to my server using HTTPS**

Perform the following checks to see if your Apache web server is configured to support HTTPS.

- **Is the web server correctly configured?**

  After you install Apache, the server is configured for HTTP traffic. To support HTTPS, enable TLS on the server and install an SSL certificate. For information, see Tutorial: Configure SSL/TLS on Amazon Linux 2 (p. 25).

- **Is the firewall correctly configured?**

  Verify that the security group for the instance contains a rule to allow HTTPS traffic on port 443. For more information, see Add rules to a security group (p. 1160).

- The chown command: https://en.wikipedia.org/wiki/Chown

For more information about registering a domain name for your web server, or transferring an existing domain name to this host, see Creating and Migrating Domains and Subdomains to Amazon Route 53 in the Amazon Route 53 Developer Guide.

Tutorial: Configure SSL/TLS on Amazon Linux 2

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with Amazon Linux 2 and Apache web server. This tutorial assumes that you are not using a load balancer. If you are using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from AWS Certificate Manager instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. Amazon Linux 2 disables server-side support for all versions of SSL by default. Security standards bodies consider TLS 1.0 to be unsafe, and both TLS 1.0 and TLS 1.1 are on track to be formally deprecated by the IETF. This tutorial contains guidance based exclusively on enabling TLS 1.2. (A newer TLS 1.3 protocol exists, but it is not installed by default on Amazon Linux 2.) For more information about the updated encryption standards, see RFC 7568 and RFC 8446.

This tutorial refers to modern web encryption simply as TLS.

**Important**

These procedures are intended for use with Amazon Linux 2. We also assume that you are starting with a new Amazon EC2 instance. If you are trying to set up an EC2 instance running a different distribution, or an instance running an old version of Amazon Linux 2, some procedures in this tutorial might not work. For the Amazon Linux AMI, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI (p. 59). For Ubuntu, see the following Ubuntu community documentation: ApacheMySQLPHP. For Red Hat Enterprise Linux, see the following: Setting up the Apache HTTP Web Server. For other distributions, see their specific documentation.

Contents

- Prerequisites (p. 25)
- Step 1: Enable TLS on the server (p. 26)
- Step 2: Obtain a CA-signed certificate (p. 28)
- Step 3: Test and harden the security configuration (p. 33)
- Troubleshoot (p. 35)
- Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 (p. 36)

Prerequisites

Before you begin this tutorial, complete the following steps:
Launch an EBS-backed Amazon Linux 2 instance. For more information, see Step 1: Launch an instance (p. 10).

Configure your security groups to allow your instance to accept connections on the following TCP ports:
- SSH (port 22)
- HTTP (port 80)
- HTTPS (port 443)

For more information, see Authorize inbound traffic for your Linux instances (p. 1134).

Install the Apache web server. For step-by-step instructions, see Tutorial: Install a LAMP Web Server on Amazon Linux 2 (p. 15). Only the httpd package and its dependencies are needed, so you can ignore the instructions involving PHP and MariaDB.

To identify and authenticate websites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public website, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use Amazon Route 53.

Step 1: Enable TLS on the server

This procedure takes you through the process of setting up TLS on Amazon Linux 2 with a self-signed digital certificate.

Note
A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site are greeted by security warnings.

To enable TLS on a server

1. Connect to your instance (p. 11) and confirm that Apache is running.

```
[ec2-user ~]# sudo systemctl is-enabled httpd
```

If the returned value is not "enabled," start Apache and set it to start each time the system boots.

```
[ec2-user ~]# sudo systemctl start httpd && sudo systemctl enable httpd
```

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

   Note
   The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]# sudo yum update -y
```

3. Now that your instance is current, add TLS support by installing the Apache module `mod_ssl`.

```
[ec2-user ~]# sudo yum install -y mod_ssl
```

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:
- `/etc/httpd/conf.d/ssl.conf`
The configuration file for mod_ssl. It contains directives telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept.

- /etc/pki/tls/certs/make-dummy-cert

A script to generate a self-signed X.509 certificate and private key for your server host. This certificate is useful for testing that Apache is properly set up to use TLS. Because it offers no proof of identity, it should not be used in production. If used in production, it triggers warnings in Web browsers.

4. Run the script to generate a self-signed dummy certificate and key for testing.

```
[ec2-user ~]# cd /etc/pki/tls/certs
sudo ./make-dummy-cert localhost.crt
```

This generates a new file localhost.crt in the /etc/pki/tls/certs/ directory. The specified file name matches the default that is assigned in the SSLCertificateFile directive in /etc/httpd/conf.d/ssl.conf.

This file contains both a self-signed certificate and the certificate's private key. Apache requires the certificate and key to be in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as follows in the abbreviated example.

```
-----BEGIN PRIVATE KEY-----
MIIEvgIBADANBgkqhkiG9w0BAQEFAASCRAv5wgSwAnAAoIBAQD2KKx/8Zk94m1q3gOMZf92N6Lei9+3tAg2Q5p0b9KDHzLlOOC18u1PTcMrAh5k5EiC0wzmNeoBCl0wYR6GOrGAKKtK9dn7CUiyvubUsyVyoQMVQw97IeakHWeM1iEJFXg6kZ0vGwnwKMoK144D9dX7IDuaF1Yx5+eroA+1Lqf3ZZSaaO00b1MIYTH1gwMBZoT...
56tET7THv7vOEf4/iUosIrEzaMaJ0mqkmY1A70qQQQKBgBF3HlqNRNHuuywCp0DFEs27hDpDinrquEvoZiggkDm1h2rti1ipj/GhrvTpoQ1v0fK/YXw8vSgeaBuw3VS/LXU99HvqG604FqD3nAyB9h10BE13r1HjUVbj7moH+RhnNz6eqdsccS09VtRao4QQVAo8uHeYeOXLwCwHaLP
-----END PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
MIIEaCICA0gAwIBAgICWxQwDQYJKoZIhvcNAQELBQAwgbExCzAJBgNVBAYTAiIwMRwwEAYDVQQIDAlTb21lU3RhdGUxETAPBgNVBAcMCFNvbWVDaXR5MRkwFwYDVQQKDBBTb21lT3JnYW5pemF0aW9uMR8wHQYDVQQDDBBpcC0xNzItMzEtMjAtMjM2MSQwIgYJKoZIhvcNAQkBFhVy...
25rUR/tZxLB30w2pNWTX37q3uFYH6s/swWtHpKKZH2V8DedRejNKAov4ws6F0Cu1jvubUsyVyoQMVQw97IeakHWeM1iEJFXg6kZ0vGwnwKMoK144D9d1U3WanWxheT6F1S2vU84sTEXXJZejw8g+sHgn282sCmclknYHcrCVD2vB1LZJKS2v9a32akhBtsQ8kFMomWPP2aODMMF5GVUH0d0BQE8sBJxg=
-----END CERTIFICATE-----
```

The file names and extensions are a convenience and have no effect on function. For example, you can call a certificate cert.crt, cert.pem, or any other file name, so long as the related directive in the ssl.conf file uses the same name.

Note
When you replace the default TLS files with your own customized files, be sure that they are in PEM format.

5. Open the /etc/httpd/conf.d/ssl.conf file using your favorite text editor (such as vim or nano) and comment out the following line, because the self-signed dummy certificate also contains the key. If you do not comment out this line before you complete the next step, the Apache service fails to start.
Step 2: Obtain a CA-signed certificate

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical. A CA promises, at a minimum, to validate a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically tied to the public key. When a browser connects to a web server over HTTPS, the server presents a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a chain of trust consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the Let's Encrypt project, which also supports the automation of the certificate creation and renewal process. For more information about using Let's Encrypt as your CA, see Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 (p. 36).

If you plan to offer commercial-grade services, AWS Certificate Manager is a good option.

Underlying the host certificate is the key. As of 2019, government and industry groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents, through 2030. The default modulus size generated by OpenSSL in Amazon Linux 2 is 2048 bits, which is suitable for use.
in a CA-signed certificate. In the following procedure, an optional step provided for those who want a customized key, for example, one with a larger modulus or using a different encryption algorithm.

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.

**To obtain a CA-signed certificate**

1. [Connect to your instance](#) and navigate to `/etc/pki/tls/private/`. This is the directory where you store the server’s private key for TLS. If you prefer to use an existing host key to generate the CSR, skip to Step 3.

2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys works with your web server, but they vary in the degree and type of security that they implement.

   - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.
     
     ```
     [ec2-user ~]$ sudo openssl genrsa -out custom.key
     ```

   - **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, `custom.key`, is a 4096-bit RSA private key.
     
     ```
     [ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
     ```

   - **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, `custom.key`, is a 4096-bit RSA private key encrypted with the AES-128 cipher.
     
     **Important**
     Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

     ```
     [ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out custom.key 4096
     ```

   - **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.

     ```
     [ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
     ```

     The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, according to NIST.

     **Note**
     Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

     Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as shown in the following example.

     ```
     [ec2-user ~]$ sudo chown root:root custom.key
     ```
Step 2: Obtain a CA-signed certificate

The preceding commands yield the following result.

```
-rw------- root root custom.key
```

After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key. The following example uses `custom.key`.

```
[ec2-user ~]$ sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country Name</td>
<td>The two-letter ISO abbreviation for your country.</td>
<td>US (=United States)</td>
</tr>
<tr>
<td>State or Province Name</td>
<td>The name of the state or province where your organization is located.</td>
<td>Washington</td>
</tr>
<tr>
<td>Locality Name</td>
<td>The location of your organization, such as a city.</td>
<td>Seattle</td>
</tr>
<tr>
<td>Organization Name</td>
<td>The full legal name of your organization. Do not abbreviate your organization name.</td>
<td>Example Corporation</td>
</tr>
<tr>
<td>Organizational Unit Name</td>
<td>Additional organizational information, if any.</td>
<td>Example Dept</td>
</tr>
<tr>
<td>Common Name</td>
<td>This value must exactly match the web address that you expect users to enter into a browser. Usually, this means a domain name with a prefixed hostname or alias in the form <code>www.example.com</code>. In testing with a self-signed certificate and no DNS resolution, the common name may consist of the hostname alone. CAs also offer more expensive certificates that accept wild-card names such as <code>*.example.com</code>.</td>
<td><a href="http://www.example.com">www.example.com</a></td>
</tr>
<tr>
<td>Email Address</td>
<td>The server administrator's email address.</td>
<td><a href="mailto:someone@example.com">someone@example.com</a></td>
</tr>
</tbody>
</table>

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA's recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file `csr.pem` contains your public key, your digital signature of your public key, and the metadata that you entered.

4. Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If `www.example.com` is the common name,
then example.com would be a good SAN, and vice versa. A visitor to your site entering either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an intermediate certificate file that contains additional certificates needed to complete the CA's chain of trust.

Note
Your CA might send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a .pem or .crt file extension. If you are uncertain which file to use, open the files with a text editor and find the one containing one or more blocks beginning with the following line.

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following line.

```
- - - - -END CERTIFICATE - - - - -
```

You can also test the file at the command line as shown in the following.

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with .p7b, .p7c, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the /etc/pki/tls/certs directory.

Note
There are several ways to upload your new certificate to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/certs directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2 defaults (owner=root, group=root, read/write for owner only). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root custom.crt
[ec2-user certs]$ sudo chmod 600 custom.crt
[ec2-user certs]$ ls -al custom.crt
```

These commands should yield the following result.

```
-rw------- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The following example shows the commands to use.
Step 2: Obtain a CA-signed certificate

These commands should yield the following result.

```
-rw-r--r-- root root intermediate.crt
```

6. Place the private key that you used to create the CSR in the /etc/pki/tls/private/ directory.

   Note
   There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/private directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2 defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user private]$ sudo chown root:root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ ls -al custom.key
```

These commands should yield the following result.

```
-rw------- root root custom.key
```

7. Edit /etc/httpd/conf.d/ssl.conf to reflect your new certificate and key files.

   a. Provide the path and file name of the CA-signed host certificate in Apache's SSLCertificateFile directive:

   ```
   SSLCertificateFile /etc/pki/tls/certs/custom.crt
   ```

   b. If you received an intermediate certificate file (intermediate.crt in this example), provide its path and file name using Apache's SSLCACertificateFile directive:

   ```
   SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
   ```

   Note
   Some CAs combine the host certificate and the intermediate certificates in a single file, making the SSLCACertificateFile directive unnecessary. Consult the instructions provided by your CA.

   c. Provide the path and file name of the private key (custom.key in this example) in Apache's SSLCertificateKeyFile directive:

   ```
   SSLCertificateKeyFile /etc/pki/tls/private/custom.key
   ```

8. Save /etc/httpd/conf.d/ssl.conf and restart Apache.
Step 3: Test and harden the security configuration

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as Qualys SSL Labs, which performs a free and thorough analysis of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see how Qualys formulates its scores.

Important
Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the Qualys SSL Labs site, enter the fully qualified domain name of your server, in the form www.example.com. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. The following table summarizes the report for a domain with settings identical to the default Apache configuration on Amazon Linux 2, and with a default Certbot certificate.

<table>
<thead>
<tr>
<th>Overall rating</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate</td>
<td>100%</td>
</tr>
<tr>
<td>Protocol support</td>
<td>95%</td>
</tr>
<tr>
<td>Key exchange</td>
<td>70%</td>
</tr>
<tr>
<td>Cipher strength</td>
<td>90%</td>
</tr>
</tbody>
</table>

Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems, listed here in order of severity:

✗ The RC4 cipher is supported for use by certain older browsers. A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several serious weaknesses. Unless you have very good reasons to support legacy browsers, you should disable this.

✗ Old TLS versions are supported. The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.

✗ Forward secrecy is not fully supported. Forward secrecy is a feature of algorithms that encrypt using temporary (ephemeral) session keys derived from the private key. This means in practice that attackers cannot decrypt HTTPS data even if they possess a web server’s long-term private key.

To correct and future-proof the TLS configuration

1. Open the configuration file /etc/httpd/conf.d/ssl.conf in a text editor and comment out the following line by entering "#" at the beginning of the line.

```bash
#SSLProtocol all -SSLv3
```
2. Add the following directive:

```bash
#SSLProtocol all -SSLv3
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

This directive explicitly disables SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive conveys more clearly, to a human reader, what the server is configured to do.

**Note**
Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

**To modify the list of allowed ciphers**

1. In the configuration file `/etc/httpd/conf.d/ssl.conf`, find the section with the `SSLCipherSuite` directive and comment out the existing line by entering "#" at the beginning of the line.

```bash
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```

2. Specify explicit cipher suites and a cipher order that prioritizes forward secrecy and avoids insecure ciphers. The `SSLCipherSuite` directive used here is based on output from the Mozilla SSL Configuration Generator, which tailors a TLS configuration to the specific software running on your server. (For more information, see Mozilla's useful resource Security/Server Side TLS.) First determine your Apache and OpenSSL versions by using the output from the following commands.

```
[ec2-user ~]$ yum list installed | grep httpd
[ec2-user ~]$ yum list installed | grep openssl
```

For example, if the returned information is Apache 2.4.34 and OpenSSL 1.0.2, we enter this into the generator. If you choose the "modern" compatibility model, this creates an `SSLCipherSuite` directive that aggressively enforces security but still works for most browsers. If your software doesn't support the modern configuration, you can update your software or choose the "intermediate" configuration instead.

```text
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-CHACHA20-POLY1305:
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:
```

The selected ciphers have **ECDHE** in their names, an abbreviation for Elliptic Curve Diffie-Hellman Ephemeral. The term *ephemeral* indicates forward secrecy. As a by-product, these ciphers do not support RC4.

We recommend that you use an explicit list of ciphers instead of relying on defaults or terse directives whose content isn't visible.

Copy the generated directive into `/etc/httpd/conf.d/ssl.conf`.

**Note**
Though shown here on several lines for readability, the directive must be on a single line when copied to `/etc/httpd/conf.d/ssl.conf`, with only a colon (no spaces) between cipher names.
3. Finally, uncomment the following line by removing the "#" at the beginning of the line.

```bash
#SSLHonorCipherOrder on
```

This directive forces the server to prefer high-ranking ciphers, including (in this case) those that support forward secrecy. With this directive turned on, the server tries to establish a strong secure connection before falling back to allowed ciphers with lesser security.

After completing both of these procedures, save the changes to `/etc/httpd/conf.d/ssl.conf` and restart Apache.

If you test the domain again on Qualys SSL Labs, you should see that the RC4 vulnerability and other warnings are gone and the summary looks something like the following.

<table>
<thead>
<tr>
<th>Overall rating</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate</td>
<td>100%</td>
</tr>
<tr>
<td>Protocol support</td>
<td>100%</td>
</tr>
<tr>
<td>Key exchange</td>
<td>90%</td>
</tr>
<tr>
<td>Cipher strength</td>
<td>90%</td>
</tr>
</tbody>
</table>

Each update to OpenSSL introduces new ciphers and removes support for old ones. Keep your EC2 Amazon Linux 2 instance up-to-date, watch for security announcements from OpenSSL, and be alert to reports of new security exploits in the technical press.

**Troubleshoot**

- **My Apache webserver doesn't start unless I enter a password**

  This is expected behavior if you installed an encrypted, password-protected, private server key.

  You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

  ```bash
  [ec2-user ~]$ cd /etc/pki/tls/private/
  [ec2-user private]$ sudo cp custom.key custom.key.bak
  [ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out custom.key.nocrypt
  [ec2-user private]$ sudo mv custom.key.nocrypt custom.key
  [ec2-user private]$ sudo chown root:root custom.key
  [ec2-user private]$ sudo chmod 600 custom.key
  [ec2-user private]$ sudo systemctl restart httpd
  ``

  Apache should now start without prompting you for a password.

- **I get errors when I run sudo yum install -y mod_ssl.**

  When you are installing the required packages for SSL, you may see errors similar to the following.

  ```bash
  Error: httpd24-tools conflicts with httpd-tools-2.2.34-1.16.amzn1.x86_64
  Error: httpd24 conflicts with httpd-2.2.34-1.16.amzn1.x86_64
  ```
Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2

The Let's Encrypt certificate authority is the centerpiece of an effort by the Electronic Frontier Foundation (EFF) to encrypt the entire internet. In line with that goal, Let's Encrypt host certificates are designed to be created, validated, installed, and maintained with minimal human intervention. The automated aspects of certificate management are carried out by a software agent running on your web server. After you install and configure the agent, it communicates securely with Let's Encrypt and performs administrative tasks on Apache and the key management system. This tutorial uses the free Certbot agent because it allows you either to supply a customized encryption key as the basis for your certificates, or to allow the agent itself to create a key based on its defaults. You can also configure Certbot to renew your certificates on a regular basis without human interaction, as described in To automate Certbot (p. 39). For more information, consult the Certbot User Guide and man page.

Certbot is not officially supported on Amazon Linux 2, but is available for download and functions correctly when installed. We recommend that you make the following backups to protect your data and avoid inconvenience:

- Before you begin, take a snapshot of your Amazon EBS root volume. This allows you to restore the original state of your EC2 instance. For information about creating EBS snapshots, see Create Amazon EBS snapshots (p. 1231).
- The procedure below requires you to edit your httpd.conf file, which controls Apache's operation. Certbot makes its own automated changes to this and other configuration files. Make a backup copy of your entire /etc/httpd directory in case you need to restore it.

Prepare to install

Complete the following procedures before you install Certbot.

1. Download the Extra Packages for Enterprise Linux (EPEL) 7 repository packages. These are required to supply dependencies needed by Certbot.
   a. Navigate to your home directory (/home/ec2-user). Download EPEL using the following command.

   ```
   [ec2-user ~]$ sudo wget --no-parent -A 'epel-release-*.rpm' https://dl.fedoraproject.org/pub/epel/7/x86_64/Packages/e/
   ```

   b. Install the repository packages as shown in the following command.

   ```
   [ec2-user ~]$ sudo rpm -Uvh dl.fedoraproject.org/pub/epel/7/x86_64/Packages/e/epel-release-*.rpm
   ```

   c. Enable EPEL as shown in the following command.

   ```
   [ec2-user ~]$ sudo yum-config-manager ----enable epel
   ```

   You can confirm that EPEL is enabled with the following command.
[ec2-user ~]# sudo yum repolist all

It should return information similar to the following.

[ec2-user ~]#
... epel/x86_64 Extra Packages for Enterprise Linux 7 - x86_64 enabled: 12949+175 epel-debuginfo/x86_64 Extra Packages for Enterprise Linux 7 - x86_64 enabled: 2890 epel-source/x86_64 Extra Packages for Enterprise Linux 7 - Source enabled: 0 epel-testing/x86_64 Extra Packages for Enterprise Linux 7 - Testing - x86_64 enabled: 778+12 epel-testing-debuginfo/x86_64 Extra Packages for Enterprise Linux 7 - Testing - x86_64 - Debug enabled: 107 epel-testing-source/x86_64 Extra Packages for Enterprise Linux 7 - Testing - x86_64 - Source enabled: 0...

2. Edit the main Apache configuration file, /etc/httpd/conf/httpd.conf. Locate the "Listen 80" directive and add the following lines after it, replacing the example domain names with the actual Common Name and Subject Alternative Name (SAN).

<VirtualHost *:80>
    DocumentRoot "/var/www/html"
    ServerName "example.com"
    ServerAlias "www.example.com"
</VirtualHost>

Save the file and restart Apache.

[ec2-user ~]# sudo systemctl restart httpd

Install and run Certbot

This procedure is based on the EFF documentation for installing Certbot on Fedora and on RHEL 7. It describes the default use of Certbot, resulting in a certificate based on a 2048-bit RSA key.

1. Install Certbot packages and dependencies using the following command.

[ec2-user ~]# sudo yum install -y certbot python2-certbot-apache

2. Run Certbot.

[ec2-user ~]# sudo certbot

3. At the prompt "Enter email address (used for urgent renewal and security notices)," enter a contact address and press Enter.

4. Agree to the Let's Encrypt Terms of Service at the prompt. Enter "A" and press Enter to proceed.

---

Please read the Terms of Service at https://letsencrypt.org/documents/LE-SA-v1.2-November-15-2017.pdf. You must agree in order to register with the ACME server at

37
5. At the authorization for EFF to put you on their mailing list, enter "Y" or "N" and press Enter.

6. Certbot displays the Common Name and Subject Alternative Name (SAN) that you provided in the VirtualHost block.

   Which names would you like to activate HTTPS for?
   1: example.com
   2: www.example.com

   Select the appropriate numbers separated by commas and/or spaces, or leave input blank to select all options shown (Enter 'c' to cancel):

   Leave the input blank and press Enter.

7. Certbot displays the following output as it creates certificates and configures Apache. It then prompts you about redirecting HTTP queries to HTTPS.

   Obtaining a new certificate
   Performing the following challenges:
   http-01 challenge for example.com
   http-01 challenge for www.example.com
   Waiting for verification...
   Cleaning up challenges
   Created an SSL vhost at /etc/httpd/conf/httpd-le-ssl.conf
   Deploying Certificate for example.com to VirtualHost /etc/httpd/conf/httpd-le-ssl.conf
   Enabling site /etc/httpd/conf/httpd-le-ssl.conf by adding Include to root configuration
   Deploying Certificate for www.example.com to VirtualHost /etc/httpd/conf/httpd-le-ssl.conf

   Please choose whether or not to redirect HTTP traffic to HTTPS, removing HTTP access.
   1: No redirect - Make no further changes to the webserver configuration.
   2: Redirect - Make all requests redirect to secure HTTPS access. Choose this for new sites, or if you're confident your site works on HTTPS. You can undo this change by editing your web server's configuration.

   Select the appropriate number [1-2] then [enter] (press 'c' to cancel):

   To allow visitors to connect to your server via unencrypted HTTP, enter "1". If you want to accept only encrypted connections via HTTPS, enter "2". Press Enter to submit your choice.

8. Certbot completes the configuration of Apache and reports success and other information.

   Congratulations! You have successfully enabled https://example.com and https://www.example.com

   You should test your configuration at:
   https://www.ssllabs.com/ssltest/analyze.html?d=example.com

   IMPORTANT NOTES:
   - Congratulations! Your certificate and chain have been saved at:
     /etc/letsencrypt/live/certbot.oneeyedman.net/fullchain.pem
   - Your key file has been saved at:
     /etc/letsencrypt/live/certbot.oneeyedman.net/privkey.pem
   - Your cert will expire on 2019-08-01. To obtain a new or tweaked version of this certificate in the future, simply run certbot again with the "certonly" option. To non-interactively renew *all* of
your certificates, run "certbot renew"
- Your account credentials have been saved in your Certbot
  configuration directory at /etc/letsencrypt. You should make a
  secure backup of this folder now. This configuration directory will
  also contain certificates and private keys obtained by Certbot so
  making regular backups of this folder is ideal.

9. After you complete the installation, test and optimize the security of your server as described in
   Step 3: Test and harden the security configuration (p. 33).

Configure automated certificate renewal

Certbot is designed to become an invisible, error-resistant part of your server system. By default, it
generates host certificates with a short, 90-day expiration time. If you have not configured your system
to call the command automatically, you must re-run the certbot command manually before expiration.
This procedure shows how to automate Certbot by setting up a cron job.

To automate Certbot

1. Open the /etc/crontab file in a text editor, such as vim or nano, using sudo. Alternatively, use
   sudo crontab -e.
2. Add a line similar to the following and save the file.

   39 1,13 * * * root certbot renew --no-self-upgrade

Here is an explanation of each component:

39 1,13 * * *

Schedules a command to be run at 01:39 and 13:39 every day. The selected values are arbitrary,
but the Certbot developers suggest running the command at least twice daily. This guarantees
that any certificate found to be compromised is promptly revoked and replaced.

root

The command runs with root permissions.

certbot renew --no-self-upgrade

The command to be run. The renew subcommand causes Certbot to check any previously
obtained certificates and to renew those that are approaching expiration. The --no-self-
upgrade flag prevents Certbot from upgrading itself without your intervention.

3. Restart the cron daemon.

   [ec2-user ~]# sudo systemctl restart crond

Tutorial: Host a WordPress blog on Amazon Linux 2

The following procedures will help you install, configure, and secure a WordPress blog on your Amazon
Linux instance. This tutorial is a good introduction to using Amazon EC2 in that you have full control over
a web server that hosts your WordPress blog, which is not typical with a traditional hosting service.

You are responsible for updating the software packages and maintaining security patches for your server.
For a more automated WordPress installation that does not require direct interaction with the web
server configuration, the AWS CloudFormation service provides a WordPress template that can also get you started quickly. For more information, see Get started in the AWS CloudFormation User Guide. If you'd prefer to host your WordPress blog on a Windows instance, see Deploy a WordPress blog on your Amazon EC2 Windows instance in the Amazon EC2 User Guide for Windows Instances. If you need a high-availability solution with a decoupled database, see Deploying a high-availability WordPress website in the AWS Elastic Beanstalk Developer Guide.

Important
These procedures are intended for use with Amazon Linux. For more information about other distributions, see their specific documentation. Many steps in this tutorial do not work on Ubuntu instances. For help installing WordPress on an Ubuntu instance, see WordPress in the Ubuntu documentation.

Option: Complete this tutorial using automation
To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run one of the following Automation documents: AWSDocs-HostingAWordPressBlog-AL (Amazon Linux) or AWSDocs-HostingAWordPressBlog-AL2 (Amazon Linux 2).

Topics
• Prerequisites (p. 40)
• Install WordPress (p. 40)
• Next steps (p. 47)
• Help! My public DNS name changed and now my blog is broken (p. 48)

Prerequisites
This tutorial assumes that you have launched an Amazon Linux instance with a functional web server with PHP and database (either MySQL or MariaDB) support by following all of the steps in Tutorial: Install a LAMP web server on the Amazon Linux AMI (p. 48) for Amazon Linux AMI or Tutorial: Install a LAMP web server on Amazon Linux 2 (p. 15) for Amazon Linux 2. This tutorial also has steps for configuring a security group to allow HTTP and HTTPS traffic, as well as several steps to ensure that file permissions are set properly for your web server. For information about adding rules to your security group, see Add rules to a security group (p. 1160).

We strongly recommend that you associate an Elastic IP address (EIP) to the instance you are using to host a WordPress blog. This prevents the public DNS address for your instance from changing and breaking your installation. If you own a domain name and you want to use it for your blog, you can update the DNS record for the domain name to point to your EIP address (for help with this, contact your domain name registrar). You can have one EIP address associated with a running instance at no charge. For more information, see Elastic IP addresses (p. 914).

If you don't already have a domain name for your blog, you can register a domain name with Route 53 and associate your instance's EIP address with your domain name. For more information, see Registering domain names using Amazon Route 53 in the Amazon Route 53 Developer Guide.

Install WordPress
Connect to your instance, and download the WordPress installation package.

To download and unzip the WordPress installation package
1. Download the latest WordPress installation package with the wget command. The following command should always download the latest release.

```bash
[ec2-user ~]# wget https://wordpress.org/latest.tar.gz
```
2. Unzip and unarchive the installation package. The installation folder is unzipped to a folder called `wordpress`.

```
[ec2-user ~]$ tar -xzf latest.tar.gz
```

**To create a database user and database for your WordPress installation**

Your WordPress installation needs to store information, such as blog posts and user comments, in a database. This procedure helps you create your blog’s database and a user that is authorized to read and save information to it.

1. Start the database server.
   - Amazon Linux 2
     ```
     [ec2-user ~]$ sudo systemctl start mariadb
     ```
   - Amazon Linux AMI
     ```
     [ec2-user ~]$ sudo service mysqld start
     ```

2. Log in to the database server as the `root` user. Enter your database `root` password when prompted; this may be different than your `root` system password, or it might even be empty if you have not secured your database server.

   If you have not secured your database server yet, it is important that you do so. For more information, see To secure the MariaDB server (p. 21) (Amazon Linux 2) or To secure the database server (p. 54) (Amazon Linux AMI).

   ```
   [ec2-user ~]$ mysql -u root -p
   ```

3. Create a user and password for your MySQL database. Your WordPress installation uses these values to communicate with your MySQL database. Enter the following command, substituting a unique user name and password.

   CREATE USER 'wordpress-user'@'localhost' IDENTIFIED BY 'your_strong_password';

   Make sure that you create a strong password for your user. Do not use the single quote character (`) in your password, because this will break the preceding command. For more information about creating a secure password, go to http://www.pctools.com/guides/password/. Do not reuse an existing password, and make sure to store this password in a safe place.

4. Create your database. Give your database a descriptive, meaningful name, such as `wordpress-db`.

   Note
   The punctuation marks surrounding the database name in the command below are called backticks. The backtick (`) key is usually located above the Tab key on a standard keyboard. Backticks are not always required, but they allow you to use otherwise illegal characters, such as hyphens, in database names.

   ```
   CREATE DATABASE `wordpress-db`;
   ```

5. Grant full privileges for your database to the WordPress user that you created earlier.

   ```
   GRANT ALL PRIVILEGES ON `wordpress-db`.* TO "wordpress-user"@"localhost";
   ```

6. Flush the database privileges to pick up all of your changes.
FLUSH PRIVILEGES;

7. Exit the `mysql` client.

```
exit
```

To create and edit the `wp-config.php` file

The WordPress installation folder contains a sample configuration file called `wp-config-sample.php`. In this procedure, you copy this file and edit it to fit your specific configuration.

1. Copy the `wp-config-sample.php` file to a file called `wp-config.php`. This creates a new configuration file and keeps the original sample file intact as a backup.

```
```

2. Edit the `wp-config.php` file with your favorite text editor (such as `nano` or `vim`) and enter values for your installation. If you do not have a favorite text editor, `nano` is suitable for beginners.

```
[ec2-user ~]$ nano wordpress/wp-config.php
```

a. Find the line that defines `DB_NAME` and change `database_name_here` to the database name that you created in Step 4 (p. 41) of To create a database user and database for your WordPress installation (p. 41).

```
define('DB_NAME', 'wordpress-db');
```

b. Find the line that defines `DB_USER` and change `username_here` to the database user that you created in Step 3 (p. 41) of To create a database user and database for your WordPress installation (p. 41).

```
define('DB_USER', 'wordpress-user');
```

c. Find the line that defines `DB_PASSWORD` and change `password_here` to the strong password that you created in Step 3 (p. 41) of To create a database user and database for your WordPress installation (p. 41).

```
define('DB_PASSWORD', 'your_strong_password');
```

d. Find the section called Authentication Unique Keys and Salts. These KEY and SALT values provide a layer of encryption to the browser cookies that WordPress users store on their local machines. Basically, adding long, random values here makes your site more secure. Visit [https://api.wordpress.org/secret-key/1.1/salt/](https://api.wordpress.org/secret-key/1.1/salt/) to randomly generate a set of key values that you can copy and paste into your `wp-config.php` file. To paste text into a PuTTY terminal, place the cursor where you want to paste the text and right-click your mouse inside the PuTTY terminal.

For more information about security keys, go to [https://wordpress.org/support/article/editing-wp-config-php/#security-keys](https://wordpress.org/support/article/editing-wp-config-php/#security-keys).

**Note**
The values below are for example purposes only; do not use these values for your installation.
Install WordPress

e. Save the file and exit your text editor.

To install your WordPress files under the Apache document root

- Now that you’ve unzipped the installation folder, created a MySQL database and user, and customized the WordPress configuration file, you are ready to copy your installation files to your web server document root so you can run the installation script that completes your installation. The location of these files depends on whether you want your WordPress blog to be available at the actual root of your web server (for example, my.public.dns.amazonaws.com) or in a subdirectory or folder under the root (for example, my.public.dns.amazonaws.com/blog).

- If you want WordPress to run at your document root, copy the contents of the wordpress installation directory (but not the directory itself) as follows:

```
[ec2-user ~]$ cp -r wordpress/* /var/www/html/
```

- If you want WordPress to run in an alternative directory under the document root, first create that directory, and then copy the files to it. In this example, WordPress will run from the directory blog:

```
[ec2-user ~]$ mkdir /var/www/html/blog
[ec2-user ~]$ cp -r wordpress/* /var/www/html/blog/
```

Important

For security purposes, if you are not moving on to the next procedure immediately, stop the Apache web server (httpd) now. After you move your installation under the Apache document root, the WordPress installation script is unprotected and an attacker could gain access to your blog if the Apache web server were running. To stop the Apache web server, enter the command `sudo service httpd stop`. If you are moving on to the next procedure, you do not need to stop the Apache web server.

To allow WordPress to use permalinks

Wordpress permalinks need to use Apache .htaccess files to work properly, but this is not enabled by default on Amazon Linux. Use this procedure to allow all overrides in the Apache document root.

1. Open the httpd.conf file with your favorite text editor (such as nano or vim). If you do not have a favorite text editor, nano is suitable for beginners.
2. Find the section that starts with `<Directory "/var/www/html">`.

```html
<Directory "/var/www/html">
    # Possible values for the Options directive are "None", "All",
    # or any combination of:
    #  Indexes Includes FollowSymLinks SymLinksifOwnerMatch ExecCGI MultiViews
    #
    # Note that "MultiViews" must be named *explicitly* --- "Options All"
    # doesn't give it to you.
    #
    # The Options directive is both complicated and important. Please see
    # http://httpd.apache.org/docs/2.4/mod/core.html#options
    # for more information.
    #
    Options Indexes FollowSymLinks
    #
    # AllowOverride controls what directives may be placed in .htaccess files.
    # It can be "All", "None", or any combination of the keywords:
    #  Options FileInfo AuthConfig Limit
    #
    AllowOverride None
    #
    # Controls who can get stuff from this server.
    #
    Require all granted
</Directory>
```

3. Change the `AllowOverride None` line in the above section to read `AllowOverride All`.

   **Note**
   There are multiple `AllowOverride` lines in this file; be sure you change the line in the `<Directory "/var/www/html">` section.

4. Save the file and exit your text editor.

**To install the PHP graphics drawing library on Amazon Linux 2**

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

Use the following command to install the PHP graphics drawing library on Amazon Linux 2. For example, if you installed php7.2 from amazon-linux-extras as part of installing the LAMP stack, this command installs version 7.2 of the PHP graphics drawing library.

```
[ec2-user ~]# sudo yum install php-gd
```

To verify the installed version, use the following command:

```
[ec2-user ~]# sudo yum list installed | grep php-gd
```

The following is example output:
To install the PHP graphics drawing library on the Amazon Linux AMI

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

To verify which versions are available, use the following command:

```
[ec2-user ~]$ yum list | grep php-gd
```

The following is an example line from the output for the PHP graphics drawing library (version 7.2):

| php72-gd.x86_64 | 7.2.30-1.22.amzn1 | amzn-updates |

Use the following command to install a specific version of the PHP graphics drawing library (for example, version 7.2) on the Amazon Linux AMI:

```
[ec2-user ~]# sudo yum install php72-gd
```

To fix file permissions for the Apache web server

Some of the available features in WordPress require write access to the Apache document root (such as uploading media through the Administration screens). If you have not already done so, apply the following group memberships and permissions (as described in greater detail in the LAMP web server tutorial (p. 48)).

1. Grant file ownership of `/var/www` and its contents to the `apache` user.

   ```
   [ec2-user ~]# sudo chown -R apache /var/www
   ```

2. Grant group ownership of `/var/www` and its contents to the `apache` group.

   ```
   [ec2-user ~]# sudo chgrp -R apache /var/www
   ```

3. Change the directory permissions of `/var/www` and its subdirectories to add group write permissions and to set the group ID on future subdirectories.

   ```
   [ec2-user ~]# sudo chmod 2775 /var/www
   [ec2-user ~]# find /var/www -type d -exec sudo chmod 2775 {} \;
   ```

4. Recursively change the file permissions of `/var/www` and its subdirectories to add group write permissions.

   ```
   [ec2-user ~]# find /var/www -type f -exec sudo chmod 0664 {} \;
   ```

5. Restart the Apache web server to pick up the new group and permissions.

   - Amazon Linux 2
     ```
     [ec2-user ~]# sudo systemctl restart httpd
     ```
   - Amazon Linux AMI
     ```
     [ec2-user ~]# sudo service httpd restart
     ```
To run the WordPress installation script with Amazon Linux 2

You are ready to install WordPress. The commands that you use depend on the operating system. The commands in this procedure are for use with Amazon Linux 2. Use the procedure that follows this one with Amazon Linux AMI.

1. Use the `systemctl` command to ensure that the `httpd` and database services start at every system boot.

   ```bash
   [ec2-user ~]$ sudo systemctl enable httpd && sudo systemctl enable mariadb
   ```

2. Verify that the database server is running.

   ```bash
   [ec2-user ~]$ sudo systemctl status mariadb
   ```

   If the database service is not running, start it.

   ```bash
   [ec2-user ~]$ sudo systemctl start mariadb
   ```

3. Verify that your Apache web server (`httpd`) is running.

   ```bash
   [ec2-user ~]$ sudo systemctl status httpd
   ```

   If the `httpd` service is not running, start it.

   ```bash
   [ec2-user ~]$ sudo systemctl start httpd
   ```

4. In a web browser, type the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the `blog` folder). You should see the WordPress installation script. Provide the information required by the WordPress installation. Choose Install WordPress to complete the installation. For more information, see Step 5: Run the Install Script on the WordPress website.

To run the WordPress installation script with Amazon Linux AMI

1. Use the `chkconfig` command to ensure that the `httpd` and database services start at every system boot.

   ```bash
   [ec2-user ~]$ sudo chkconfig httpd on && sudo chkconfig mysqld on
   ```

2. Verify that the database server is running.

   ```bash
   [ec2-user ~]$ sudo service mysqld status
   ```

   If the database service is not running, start it.

   ```bash
   [ec2-user ~]$ sudo service mysqld start
   ```

3. Verify that your Apache web server (`httpd`) is running.

   ```bash
   [ec2-user ~]$ sudo service httpd status
   ```

   If the `httpd` service is not running, start it.
4. In a web browser, type the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the blog folder). You should see the WordPress installation script. Provide the information required by the WordPress installation. Choose **Install WordPress** to complete the installation. For more information, see Step 5: Run the Install Script on the WordPress website.

**Next steps**

After you have tested your WordPress blog, consider updating its configuration.

**Use a custom domain name**

If you have a domain name associated with your EC2 instance's EIP address, you can configure your blog to use that name instead of the EC2 public DNS address. For more information, see Changing The Site URL on the WordPress website.

**Configure your blog**

You can configure your blog to use different themes and plugins to offer a more personalized experience for your readers. However, sometimes the installation process can backfire, causing you to lose your entire blog. We strongly recommend that you create a backup Amazon Machine Image (AMI) of your instance before attempting to install any themes or plugins so you can restore your blog if anything goes wrong during installation. For more information, see Create your own AMI (p. 71).

**Increase capacity**

If your WordPress blog becomes popular and you need more compute power or storage, consider the following steps:

- Expand the storage space on your instance. For more information, see Amazon EBS Elastic Volumes (p. 1323).
- Move your MySQL database to Amazon RDS to take advantage of the service's ability to scale easily.

**Improve network performance of your internet traffic**

If you expect your blog to drive traffic from users located around the world, consider AWS Global Accelerator. Global Accelerator helps you achieve lower latency by improving internet traffic performance between your users' client devices and your WordPress application running on AWS. Global Accelerator uses the AWS global network to direct traffic to a healthy application endpoint in the AWS Region that is closest to the client.

**Learn more about WordPress**

Help! My public DNS name changed and now my blog is broken

Your WordPress installation is automatically configured using the public DNS address for your EC2 instance. If you stop and restart the instance, the public DNS address changes (unless it is associated with an Elastic IP address) and your blog will not work anymore because it references resources at an address that no longer exists (or is assigned to another EC2 instance). A more detailed description of the problem and several possible solutions are outlined in https://wordpress.org/support/article/changing-the-site-url/.

If this has happened to your WordPress installation, you may be able to recover your blog with the procedure below, which uses the wp-cli command line interface for WordPress.

**To change your WordPress site URL with the wp-cli**

1. Connect to your EC2 instance with SSH.
2. Note the old site URL and the new site URL for your instance. The old site URL is likely the public DNS name for your EC2 instance when you installed WordPress. The new site URL is the current public DNS name for your EC2 instance. If you are not sure of your old site URL, you can use curl to find it with the following command.

```
[ec2-user ~]$ curl localhost | grep wp-content
```

You should see references to your old public DNS name in the output, which will look like this (old site URL in red):

```
<script type='text/javascript' src='http://ec2-52-8-139-223.us-west-1.compute.amazonaws.com/wp-content/themes/twentyfifteen/js/functions.js?ver=20150330'></script>
```

3. Download the wp-cli with the following command.

```
```

4. Search and replace the old site URL in your WordPress installation with the following command.

```
[ec2-user ~]$ php wp-cli.phar search-replace 'old_site_url' 'new_site_url' --path=path/to/wordpress/installation --skip-columns=guid
```

5. In a web browser, enter the new site URL of your WordPress blog to verify that the site is working properly again. If it is not, see https://wordpress.org/support/article/changing-the-site-url/ and https://wordpress.org/support/article/how-to-install-wordpress/#common-installation-problems for more information.

---

**Tutorial: Install a LAMP web server on the Amazon Linux AMI**

The following procedures help you install an Apache web server with PHP and MySQL support on your Amazon Linux instance (sometimes called a LAMP web server or LAMP stack). You can use this server
to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

**Important**
If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux 2, see Tutorial: Install a LAMP web server on Amazon Linux 2 (p. 15). For Ubuntu, see the following Ubuntu community documentation: ApacheMySQLPHP. For other distributions, see their specific documentation.

**Option: Complete this tutorial using automation**
To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the AWSDocs-InstallALAMPServer-AL Automation document.

**Tasks**
- Step 1: Prepare the LAMP server (p. 49)
- Step 2: Test your Lamp server (p. 52)
- Step 3: Secure the database server (p. 54)
- Step 4: (Optional) Install phpMyAdmin (p. 55)
- Troubleshoot (p. 58)
- Related topics (p. 59)

**Step 1: Prepare the LAMP server**

**Prerequisites**
This tutorial assumes that you have already launched a new instance using the Amazon Linux AMI, with a public DNS name that is reachable from the internet. For more information, see Step 1: Launch an instance (p. 10). You must also have configured your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see Authorize inbound traffic for your Linux instances (p. 1134).

**To install and start the LAMP web server with the Amazon Linux AMI**

1. **Connect to your instance (p. 11).**
2. **To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.**

   The `–y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

   ```bash
   [ec2-user ~]$ sudo yum update -y
   ```

3. **Now that your instance is current, you can install the Apache web server, MySQL, and PHP software packages.**

   **Important**
   Some applications may not be compatible with the following recommended software environment. Before installing these packages, check whether your LAMP applications are compatible with them. If there is a problem, you may need to install an alternative environment. For more information, see The application software I want to run on my server is incompatible with the installed PHP version or other software (p. 58)

   Use the `yum install` command to install multiple software packages and all related dependencies at the same time.
Step 1: Prepare the LAMP server

[ec2-user ~]$
```bash
sudo yum install -y httpd24 php72 mysql57-server php72-mysqlnd
```

If you receive the error `No package package-name available`, then your instance was not launched with the Amazon Linux AMI (perhaps you are using Amazon Linux 2 instead). You can view your version of Amazon Linux with the following command.

```shell

cat /etc/system-release
```

4. Start the Apache web server.

[ec2-user ~]$
```bash
sudo service httpd start
Starting httpd: [ OK ]
```

5. Use the `chkconfig` command to configure the Apache web server to start at each system boot.

[ec2-user ~]$
```bash
sudo chkconfig httpd on
```

The `chkconfig` command does not provide any confirmation message when you successfully use it to enable a service.

You can verify that `httpd` is on by running the following command:

[ec2-user ~]$
```bash
chkconfig --list httpd
```

```
httpd           0:off   1:off   2:on    3:on    4:on    5:on    6:off
```

Here, `httpd` is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

6. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a `launch-wizard-N` security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.

a. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.

b. Choose `Instances` and select your instance.

c. On the `Security` tab, view the inbound rules. You should see the following rule:

<table>
<thead>
<tr>
<th>Port range</th>
<th>Protocol</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>tcp</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

**Warning**

Using `0.0.0.0/0` allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it’s unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

d. Choose the link for the security group. Using the procedures in `Add rules to a security group (p. 1160)`, add a new inbound security rule with the following values:

- **Type**: HTTP
- **Protocol**: TCP
- **Port Range**: 80
- **Source**: Custom

7. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. You can get the public DNS address for your instance using the Amazon EC2 console. If there is no content in `/var/www/html`, you should see the Apache test page. When you add
content to the document root, your content appears at the public DNS address of your instance instead of this test page.

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see Add rules to a security group (p. 1160).

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is `/var/www/html`, which by default is owned by root.
To allow the ec2-user account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add ec2-user to the apache group, to give the apache group ownership of the /var/www directory and assign write permissions to the group.

**To set file permissions**

1. Add your user (in this case, ec2-user) to the apache group.

   ```bash
   [ec2-user ~]# sudo usermod -a -G apache ec2-user
   ```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
   a. Log out (use the exit command or close the terminal window):

   ```bash
   [ec2-user ~]# exit
   ```

   b. To verify your membership in the apache group, reconnect to your instance, and then run the following command:

   ```bash
   [ec2-user ~]# groups
   ec2-user wheel apache
   ```

3. Change the group ownership of /var/www and its contents to the apache group.

   ```bash
   [ec2-user ~]# sudo chown -R ec2-user:apache /var/www
   ```

4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of /var/www and its subdirectories.

   ```bash
   [ec2-user ~]# sudo chmod 2775 /var/www
   [ec2-user ~]# find /var/www -type d -exec sudo chmod 2775 {} 
   ```

5. To add group write permissions, recursively change the file permissions of /var/www and its subdirectories:

   ```bash
   [ec2-user ~]# find /var/www -type f -exec sudo chmod 0664 {} 
   ```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

**(Optional) Secure your web server**

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI (p. 59).

**Step 2: Test your Lamp server**

If your server is installed and running, and your file permissions are set correctly, your ec2-user account should be able to create a PHP file in the /var/www/html directory that is available from the internet.
To test your LAMP web server

1. Create a PHP file in the Apache document root.
   
   ```
   ```

   If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in Step 1: Prepare the LAMP server (p. 49).

2. In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

   `http://my.public.dns.amazonaws.com/phpinfo.php`

You should see the PHP information page:

![PHP Version 7.2.0](image)

If you do not see this page, verify that the `/var/www/html/phpinfo.php` file was created properly in the previous step. You can also verify that all of the required packages were installed with the following command. The package versions in the second column do not need to match this example output.

```
[ec2-user ~]# sudo yum list installed httpd24 php72 mysql57-server php72-mysqlnd
Loaded plugins: priorities, update-motd, upgrade-helper
Installed Packages
httpd24.x86_64                      2.4.25-1.68.amzn1              @amzn-updates
updates                           5.6.35-1.23.amzn1              @amzn-updates
mysql56-server.x86_64              7.0.14-1.20.amzn1              @amzn-updates
updates                           2.0.170718                  
php70.x86_64                       20170718                      
Zend Extension Build               API20170718.NTS              
Zend Extension                     20170718                      
PHP Extension Build                API20170718.NTS              
PHP Extension                      20170718                      
```
Step 3: Secure the database server

The default installation of the MySQL server has several features that are great for testing and development, but they should be disabled or removed for production servers. The `mysql_secure_installation` command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MySQL server, we recommend performing this procedure.

To secure the database server

1. Start the MySQL server.

   ```bash
   [ec2-user ~]# sudo service mysqld start
   Initializing MySQL database:
   ... 
   PLEASE REMEMBER TO SET A PASSWORD FOR THE MySQL root USER !
   ... 
   Starting mysqld: [ OK ]
   ```

2. Run `mysql_secure_installation`.

   ```bash
   [ec2-user ~]# sudo mysql_secure_installation
   ```

   a. When prompted, type a password for the root account.
      
      i. Type the current root password. By default, the root account does not have a password set. Press Enter.
      
      ii. Type `Y` to set a password, and type a secure password twice. For more information about creating a secure password, see https://identitysafe.norton.com/password-generator/. Make sure to store this password in a safe place.

      Setting a root password for MySQL is only the most basic measure for securing your database. When you build or install a database-driven application, you typically create a database service user for that application and avoid using the root account for anything but database administration.

   b. Type `Y` to remove the anonymous user accounts.
   c. Type `Y` to disable the remote root login.
   d. Type `Y` to remove the test database.
   e. Type `Y` to reload the privilege tables and save your changes.

3. (Optional) If you do not plan to use the MySQL server right away, stop it. You can restart it when you need it again.
Step 4: (Optional) Install phpMyAdmin

**To install phpMyAdmin**

phpMyAdmin is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

**Important**
We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see Securing your phpMyAdmin installation.

**Note**
The Amazon Linux package management system does not currently support the automatic installation of phpMyAdmin in a PHP 7 environment. This tutorial describes how to install phpMyAdmin manually.

1. Log in to your EC2 instance using SSH.
2. Install the required dependencies.

   ```
   [ec2-user ~]$ sudo yum install php72-mbstring.x86_64 -y
   ```

3. Restart Apache.

   ```
   [ec2-user ~]$ sudo service httpd restart
   Stopping httpd: [ OK ]
   Starting httpd: [ OK ]
   ```

   ```
   [ec2-user ~]$ cd /var/www/html
   [ec2-user html]$ 
   ```

5. Select a source package for the latest phpMyAdmin release from https://www.phpmyadmin.net/downloads. To download the file directly to your instance, copy the link and paste it into a `wget` command, as in this example:

   ```
   ```

6. Create a phpMyAdmin folder and extract the package into it using the following command.
7. Delete the `phpMyAdmin-latest-all-languages.tar.gz` tarball.

```
[ec2-user html]$ rm phpMyAdmin-latest-all-languages.tar.gz
```

8. (Optional) If the MySQL server is not running, start it now.

```
[ec2-user ~]$ sudo service mysqld start
Starting mysqld:                                          [  OK  ]
```

9. In a web browser, type the URL of your phpMyAdmin installation. This URL is the public DNS address (or the public IP address) of your instance followed by a forward slash and the name of your installation directory. For example:

```
http://my.public.dns.amazonaws.com/phpMyAdmin
```

You should see the phpMyAdmin login page:
10. Log in to your phpMyAdmin installation with the root user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. To configure phpMyAdmin, you can manually create a configuration file, use the setup console, or combine both approaches.

For information about using phpMyAdmin, see the phpMyAdmin User Guide.
Troubleshoot

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

I can't connect to my server using a web browser.

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

  You can verify that `httpd` is on by running the following command:

  ```bash
  [ec2-user ~]$ chkconfig --list httpd
  httpd           0:off   1:off   2:on   3:on   4:on   5:on   6:off
  ```

  Here, `httpd` is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

  If the `httpd` process is not running, repeat the steps described in Step 1: Prepare the LAMP server (p. 49).

- **Is the firewall correctly configured?**

  Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see Add rules to a security group (p. 1160).

The application software I want to run on my server is incompatible with the installed PHP version or other software

This tutorial recommends installing the most up-to-date versions of Apache HTTP Server, PHP, and MySQL. Before installing an additional LAMP application, check its requirements to confirm that it is compatible with your installed environment. If the latest version of PHP is not supported, it is possible (and entirely safe) to downgrade to an earlier supported configuration. You can also install more than one version of PHP in parallel, which solves certain compatibility problems with a minimum of effort. For information about configuring a preference among multiple installed PHP versions, see Amazon Linux AMI 2016.09 Release Notes.

**How to downgrade**

The well-tested previous version of this tutorial called for the following core LAMP packages:

- `httpd24`
- `php56`
- `mysql55-server`
- `php56-mysqlnd`

If you have already installed the latest packages as recommended at the start of this tutorial, you must first uninstall these packages and other dependencies as follows:

  ```bash
  [ec2-user ~]$ sudo yum remove -y httpd24 php72 mysql57-server php72-mysqlnd perl-DBD-MySQL
  ```

  Next, install the replacement environment:

Tutorial: Configure SSL/TLS with the Amazon Linux AMI

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with the Amazon Linux AMI and Apache web server. This tutorial assumes that you are not using a load balancer. If you are using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from AWS Certificate Manager instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. The Amazon Linux AMI disables server-side support all versions of SSL by default. Security standards bodies consider TLS 1.0 to be unsafe, and both TLS 1.0 and TLS 1.1 are on track to be formally deprecated by the IETF. This tutorial contains guidance based exclusively on enabling TLS 1.2. (A newer TLS 1.3 protocol exists in draft form, but is not supported on Amazon Linux.) For more information about the updated encryption standards, see RFC 7568 and RFC 8446.

This tutorial refers to modern web encryption simply as TLS.
Prerequisites

Before you begin this tutorial, complete the following steps:

- Launch an EBS-backed instance using the Amazon Linux AMI. For more information, see Step 1: Launch an instance (p. 10).
- Configure your security group to allow your instance to accept connections on the following TCP ports:
  - SSH (port 22)
  - HTTP (port 80)
  - HTTPS (port 443)
  For more information, see Authorize inbound traffic for your Linux instances (p. 1134).
- Install Apache web server. For step-by-step instructions, see Tutorial: Installing a LAMP Web Server on Amazon Linux (p. 48). Only the http24 package and its dependencies are needed; you can ignore the instructions involving PHP and MySQL.
- To identify and authenticate web sites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public web site, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use Amazon Route 53.

Step 1: Enable TLS on the server

This procedure takes you through the process of setting up TLS on Amazon Linux with a self-signed digital certificate.

Note

A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site receive security warnings.

To enable TLS on a server

1. Connect to your instance (p. 11) and confirm that Apache is running.

```bash
[ec2-user ~]# sudo service httpd status
```

If necessary, start Apache.
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure you have the latest security updates and bug fixes.

**Note**
The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Now that your instance is current, add TLS support by installing the Apache module `mod_ssl`:

```
[ec2-user ~]$ sudo yum install -y mod24_ssl
```

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:

```
/etc/httpd/conf.d/ssl.conf
```

The configuration file for `mod_ssl`. It contains "directives" telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept.

```
/etc/pki/tls/private/localhost.key
```

An automatically generated, 2048-bit RSA private key for your Amazon EC2 host. During installation, OpenSSL used this key to generate a self-signed host certificate, and you can also use this key to generate a certificate signing request (CSR) to submit to a certificate authority (CA).

```
/etc/pki/tls/certs/localhost.crt
```

An automatically generated, self-signed X.509 certificate for your server host. This certificate is useful for testing that Apache is properly set up to use TLS.

The `.key` and `.crt` files are both in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as in this abbreviated example of a certificate:

```
-----BEGIN CERTIFICATE-----
MIIEazCCA10gAwIBAgICWxQwDQYJKoZIhvcNAQELBQAwgbExCzAJBgNVBAYTAi0t
MRgWBAYDVQQIDA1Tb21lU3RhdGUxETAPBgNVBAcMCFNvbWVDaXR5MRkwFwYDVQQK
DBBTb21lT3JnYW5pemF0aW9uMR0wGgYDVQQLDBZTb21lT3JnYW5pemF0aW9u
bml0MRkwFwYDVQQDDBBpcC0xNzItMzEtMjAtMjM2MTIwIgYJKoZIhvcNAQkBFhVy...

z5rRUE/XzxrLb2Owz2pWWTjXkQ3uYHH6s/sBwthHppKZm/LVdDEFjNKAVk4w4s6F0
WanXweh76/S5vZ4xF5Eb8Hw+7hGnZZ89wOsc1knYhrCVD2vn8lZJfKS2vak
32azhBx9TSukFmOnWPP2a0DMFMFGYUHo/0BQEB8sBJxg==
-----END CERTIFICATE-----
```

The file names and extensions are a convenience and have no effect on function; you can call a certificate `cert.crt`, `cert.pem`, or any other file name, so long as the related directive in the `ssl.conf` file uses the same name.

**Note**
When you replace the default TLS files with your own customized files, be sure that they are in PEM format.
4. Restart Apache.

```
[ec2-user ~]# sudo service httpd restart
```

5. Your Apache web server should now support HTTPS (secure HTTP) over port 443. Test it by typing the IP address or fully qualified domain name of your EC2 instance into a browser URL bar with the prefix `https://`. Because you are connecting to a site with a self-signed, untrusted host certificate, your browser may display a series of security warnings.

Override the warnings and proceed to the site. If the default Apache test page opens, it means that you have successfully configured TLS on your server. All data passing between the browser and server is now safely encrypted.

To prevent site visitors from encountering warning screens, you need to obtain a certificate that not only encrypts, but also publicly authenticates you as the owner of the site.

**Step 2: Obtain a CA-signed certificate**

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical; a CA promises to validate, at a minimum, a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically tied to the public key. When a browser connects to a web server over HTTPS, the server presents a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a chain of trust consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the Let's Encrypt project, which also supports the automation of the certificate creation and renewal process. For more information about using Let's Encrypt as your CA, see Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 (p. 36).

If you plan to offer commercial-grade services, AWS Certificate Manager is a good option.

Underlying the host certificate is the key. As of 2017, government and industry groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents through 2030. The default modulus size generated by OpenSSL in Amazon Linux is 2048 bits, which means that the existing auto-generated key is suitable for use in a CA-signed certificate. An alternative procedure is described below for those who desire a customized key, for instance, one with a larger modulus or using a different encryption algorithm.

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.
To obtain a CA-signed certificate

1. **Connect to your instance (p. 11)** and navigate to /etc/pki/tls/private/. This is the directory where the server's private key for TLS is stored. If you prefer to use your existing host key to generate the CSR, skip to Step 3.

2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys work with your web server, but they vary in how (and how much) security they implement.
   
   - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.
     
     ```
     [ec2-user ~]$ sudo openssl genrsa -out custom.key
     ```
   
   - **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, `custom.key`, is a 4096-bit RSA private key.
     
     ```
     [ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
     ```
   
   - **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, `custom.key`, is a 4096-bit RSA private key encrypted with the AES-128 cipher.
     
     ```
     [ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out custom.key 4096
     ```
   
     **Important**

     Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

   ```
   [ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out custom.key 4096
   ```
   
   - **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.
     
     ```
     [ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
     ```
     
     The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, according to NIST.

     **Note**

     Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

   Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as follows:

   ```
   [ec2-user ~]$ sudo chown root.root custom.key
   [ec2-user ~]$ sudo chmod 600 custom.key
   [ec2-user ~]$ ls -al custom.key
   ```

   The commands above should yield the following result:

   ```
   -rw------- root root custom.key
   ```

63
After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key; the example below uses custom.key:

```
[ec2-user ~]# sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country Name</td>
<td>The two-letter ISO abbreviation for your country.</td>
<td>US (=United States)</td>
</tr>
<tr>
<td>State or Province Name</td>
<td>The name of the state or province where your organization is located. This name cannot be abbreviated.</td>
<td>Washington</td>
</tr>
<tr>
<td>Locality Name</td>
<td>The location of your organization, such as a city.</td>
<td>Seattle</td>
</tr>
<tr>
<td>Organization Name</td>
<td>The full legal name of your organization. Do not abbreviate your organization name.</td>
<td>Example Corporation</td>
</tr>
<tr>
<td>Organizational Unit Name</td>
<td>Additional organizational information, if any.</td>
<td>Example Dept</td>
</tr>
<tr>
<td>Common Name</td>
<td>This value must exactly match the web address that you expect users to type into a browser. Usually, this means a domain name with a prefixed host name or alias in the form <strong><a href="http://www.example.com">www.example.com</a></strong>. In testing with a self-signed certificate and no DNS resolution, the common name may consist of the host name alone. CAs also offer more expensive certificates that accept wild-card names such as *<strong>.example.com</strong>.</td>
<td><a href="http://www.example.com">www.example.com</a></td>
</tr>
<tr>
<td>Email Address</td>
<td>The server administrator's email address.</td>
<td><a href="mailto:someone@example.com">someone@example.com</a></td>
</tr>
</tbody>
</table>

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA’s recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file `csr.pem` contains your public key, your digital signature of your public key, and the metadata that you entered.

4. Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If `www.example.com` is the common name, then `example.com` would be a good SAN, and vice versa. A visitor to your site typing in either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an *intermediate certificate* file that contains additional certificates needed to complete the CA’s chain of trust.
Note
Your CA may send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a .pem or .crt extension. If you are uncertain which file to use, open the files with a text editor and find the one containing one or more blocks beginning with the following:

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following:

```
- - - - -END CERTIFICATE - - - - -
```

You can also test a file at the command line as follows:

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with .p7b, .p7c, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the /etc/pki/tls/certs directory.

Note
There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/certs directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user certs]$ sudo chown root.root custom.crt
[ec2-user certs]$ sudo chmod 600 custom.crt
[ec2-user certs]$ ls -al custom.crt
```

The commands above should yield the following result:

```
-rw------- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The commands would be:

```
[ec2-user certs]$ sudo chown root.root intermediate.crt
[ec2-user certs]$ sudo chmod 644 intermediate.crt
[ec2-user certs]$ ls -al intermediate.crt
```

The commands above should yield the following result:

```
-rw-r--r-- root root intermediate.crt
```
6. If you used a custom key to create your CSR and the resulting host certificate, remove or rename the old key from the `/etc/pki/tls/private/` directory, and then install the new key there.

   **Note**
   There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (vi, nano, notepad, etc.) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] privileges when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

   From inside the `/etc/pki/tls/private` directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux defaults (owner=root, group=root, read/write for owner only). The commands would be as follows:

   ```
   [ec2-user private]# sudo chown root.root custom.key
   [ec2-user private]# sudo chmod 600 custom.key
   [ec2-user private]# ls -al custom.key
   ```

   The commands above should yield the following result:

   ```
   -rw------- root root custom.key
   ```

7. Edit `/etc/httpd/conf.d/ssl.conf` to reflect your new certificate and key files.

   a. Provide the path and file name of the CA-signed host certificate in Apache's `SSLCertificateFile` directive:

   ```
   SSLCertificateFile /etc/pki/tls/certs/custom.crt
   ```

   b. If you received an intermediate certificate file (`intermediate.crt` in this example), provide its path and file name using Apache's `SSLCACertificateFile` directive:

   ```
   SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
   ```

   **Note**
   Some CAs combine the host certificate and the intermediate certificates in a single file, making this directive unnecessary. Consult the instructions provided by your CA.

   c. Provide the path and file name of the private key in Apache's `SSLCertificateKeyFile` directive:

   ```
   SSLCertificateKeyFile /etc/pki/tls/private/custom.key
   ```

8. Save `/etc/httpd/conf.d/ssl.conf` and restart Apache.

   ```
   [ec2-user ~]# sudo service httpd restart
   ```

9. Test your server by entering your domain name into a browser URL bar with the prefix `https://`. Your browser should load the test page over HTTPS without generating errors.

**Step 3: Test and harden the security configuration**

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as Qualys SSL Labs, which performs a free and thorough analysis.
Step 3: Test and harden the security configuration

of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see how Qualys formulates its scores.

Important
Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the Qualys SSL Labs site, type the fully qualified domain name of your server, in the form www.example.com. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems. For example:

✗ The RC4 cipher is supported for use by certain older browsers. A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several serious weaknesses. Unless you have very good reasons to support legacy browsers, you should disable this.

✗ Old TLS versions are supported. The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.

To correct the TLS configuration

1. Open the configuration file /etc/httpd/conf.d/ssl.conf in a text editor and comment out the following lines by typing "#" at the beginning of each:

```bash
#SSLProtocol all -SSLv3
#SSLProxyProtocol all -SSLv3
```

2. Add the following directives:

```bash
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
SSLProxyProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

These directives explicitly disable SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive communicates more clearly, to a human reader, what the server is configured to do.

Note
Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

To modify the list of allowed ciphers

1. Open the configuration file /etc/httpd/conf.d/ssl.conf and find the section with commented-out examples for configuring SSLCipherSuite and SSLProxyCipherSuite.

```bash
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5
#SSLProxyCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```

Leave these as they are, and below them add the following directives:

```bash
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
SSLProxyProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

Though shown here on several lines for readability, each of these two directives must be on a single line without spaces between the cipher names.
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-
CHACHA20-POLY1305:
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-
SHA256:ECDHE-ECDSA-AES256-SHA384:
ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256:AES:!aNULL:!
eNULL:!EXPORT:!DES:
!RC4:!MD5:!PSK:!aECDH!:EDH-DES-DES-CBC3-SHA!:EDH-DES-DES-CBC3-SHA!:KRB5-DES-CBC3-SHA

SSLProxyCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-
ECDSA-CHACHA20-POLY1305:
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-
SHA256:ECDHE-ECDSA-AES256-SHA384:
ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256:AES:!aNULL:!
eNULL:!EXPORT:!DES:
!RC4:!MD5:!PSK:!aECDH!:EDH-DES-DES-CBC3-SHA!:EDH-DES-DES-CBC3-SHA!:KRB5-DES-CBC3-SHA

These ciphers are a subset of the much longer list of supported ciphers in OpenSSL. They were
selected and ordered according to the following criteria:

- Support for forward secrecy
- Strength
- Speed
- Specific ciphers before cipher families
- Allowed ciphers before denied ciphers

The high-ranking ciphers have ECDHE in their names, for Elliptic Curve Diffie-Hellman Ephemeral; the
ephemeral indicates forward secrecy. Also, RC4 is now among the forbidden ciphers near the end.

We recommend that you use an explicit list of ciphers instead relying on defaults or terse directives
whose content isn't visible. The cipher list shown here is just one of many possible lists; for instance,
you might want to optimize a list for speed rather than forward secrecy.

If you anticipate a need to support older clients, you can allow the DES-CBC3-SHA cipher suite.

Each update to OpenSSL introduces new ciphers and deprecates old ones. Keep your EC2 Amazon
Linux instance up to date, watch for security announcements from OpenSSL, and be alert to reports
of new security exploits in the technical press.

2. Uncomment the following line by removing the "#":

```plaintext
#SSLHonorCipherOrder on
```

This command forces the server to prefer high-ranking ciphers, including (in this case) those that
support forward secrecy. With this directive turned on, the server tries to establish a strongly secure
connection before falling back to allowed ciphers with lesser security.

3. Restart Apache. If you test the domain again on Qualys SSL Labs, you should see that the RC4
vulnerability is gone.

Troubleshoot

- **My Apache webserver won't start unless I enter a password**

  This is expected behavior if you installed an encrypted, password-protected, private server key.
You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

```
[ec2-user ~]$ cd /etc/pki/tls/private/
[ec2-user private]$ sudo cp custom.key custom.key.bak
[ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out custom.key.nocrypt
[ec2-user private]$ sudo mv custom.key.nocrypt custom.key
[ec2-user private]$ sudo chown root.root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ sudo service httpd restart
```

Apache should now start without prompting you for a password.
Amazon Machine Images (AMI)

An Amazon Machine Image (AMI) provides the information required to launch an instance. You must specify an AMI when you launch an instance. You can launch multiple instances from a single AMI when you need multiple instances with the same configuration. You can use different AMIs to launch instances when you need instances with different configurations.

An AMI includes the following:

- One or more Amazon Elastic Block Store (Amazon EBS) snapshots, or, for instance-store-backed AMIs, a template for the root volume of the instance (for example, an operating system, an application server, and applications).
- Launch permissions that control which AWS accounts can use the AMI to launch instances.
- A block device mapping that specifies the volumes to attach to the instance when it's launched.

Contents

- Use an AMI (p. 70)
- Create your own AMI (p. 71)
- Buy, share, and sell AMIs (p. 71)
- Deregister your AMI (p. 72)
- Amazon Linux 2 and Amazon Linux AMI (p. 72)
- AMI types (p. 72)
- Linux AMI virtualization types (p. 75)
- Boot modes (p. 77)
- Find a Linux AMI (p. 84)
- Shared AMIs (p. 88)
- Paid AMIs (p. 98)
- AMI lifecycle (p. 102)
- Use encryption with EBS-backed AMIs (p. 156)
- Understand AMI billing information (p. 161)
- Amazon Linux (p. 164)
- User provided kernels (p. 182)
- Configure the Amazon Linux 2 MATE desktop connection (p. 187)

Use an AMI

The following diagram summarizes the AMI lifecycle. After you create and register an AMI, you can use it to launch new instances. (You can also launch instances from an AMI if the AMI owner grants you launch permissions.) You can copy an AMI within the same AWS Region or to different AWS Regions. When you no longer require an AMI, you can deregister it.
Create your own AMI

You can launch an instance from an existing AMI, customize the instance (for example, install software (p. 560) on the instance), and then save this updated configuration as a custom AMI. Instances launched from this new custom AMI include the customizations that you made when you created the AMI.

The root storage device of the instance determines the process you follow to create an AMI. The root volume of an instance is either an Amazon Elastic Block Store (Amazon EBS) volume or an instance store volume. For more information about the root device volume, see Amazon EC2 instance root device volume (p. 1432).

- To create an Amazon EBS-backed AMI, see Create an Amazon EBS-backed Linux AMI (p. 102).
- To create an instance store-backed AMI, see Create an instance store-backed Linux AMI (p. 107).

To help categorize and manage your AMIs, you can assign custom tags to them. For more information, see Tag your Amazon EC2 resources (p. 1462).

Buy, share, and sell AMIs

After you create an AMI, you can keep it private so that only you can use it, or you can share it with a specified list of AWS accounts. You can also make your custom AMI public so that the community can use it. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see Shared AMIs (p. 88).

You can purchase AMIs from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it to other Amazon EC2 users. For more information about buying or selling AMIs, see Paid AMIs (p. 98).
Deregister your AMI

You can deregister an AMI when you have finished with it. After you deregister an AMI, it can't be used to launch new instances. Existing instances launched from the AMI are not affected. For more information, see Deregister your Linux AMI (p. 151).

Amazon Linux 2 and Amazon Linux AMI

Amazon Linux 2 and the Amazon Linux AMI are supported and maintained Linux images provided by AWS. The following are some of the features of Amazon Linux 2 and Amazon Linux AMI:

- A stable, secure, and high-performance execution environment for applications running on Amazon EC2.
- Provided at no additional charge to Amazon EC2 users.
- Repository access to multiple versions of MySQL, PostgreSQL, Python, Ruby, Tomcat, and many more common packages.
- Updated on a regular basis to include the latest components, and these updates are also made available in the yum repositories for installation on running instances.
- Includes packages that enable easy integration with AWS services, such as the AWS CLI, Amazon EC2 API and AMI tools, the Boto library for Python, and the Elastic Load Balancing tools.

For more information, see Amazon Linux (p. 164).

AMI types

You can select an AMI to use based on the following characteristics:

- Region (see Regions and Zones (p. 867))
- Operating system
- Architecture (32-bit or 64-bit)
- Launch permissions (p. 72)
- Storage for the root device (p. 73)

Launch permissions

The owner of an AMI determines its availability by specifying launch permissions. Launch permissions fall into the following categories.

<table>
<thead>
<tr>
<th>Launch permission</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>The owner grants launch permissions to all AWS accounts.</td>
</tr>
<tr>
<td>explicit</td>
<td>The owner grants launch permissions to specific AWS accounts.</td>
</tr>
<tr>
<td>implicit</td>
<td>The owner has implicit launch permissions for an AMI.</td>
</tr>
</tbody>
</table>
Amazon and the Amazon EC2 community provide a large selection of public AMIs. For more information, see Shared AMIs (p. 88). Developers can charge for their AMIs. For more information, see Paid AMIs (p. 98).

**Storage for the root device**

All AMIs are categorized as either *backed by Amazon EBS* or *backed by instance store*. The former means that the root device for an instance launched from the AMI is an Amazon Elastic Block Store (Amazon EBS) volume created from an Amazon EBS snapshot. The latter means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3. For more information, see Amazon EC2 instance root device volume (p. 1432).

The following table summarizes the important differences when using the two types of AMIs.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Amazon EBS-backed AMI</th>
<th>Amazon instance store-backed AMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boot time for an instance</td>
<td>Usually less than 1 minute</td>
<td>Usually less than 5 minutes</td>
</tr>
<tr>
<td>Size limit for a root device</td>
<td>64 TiB**</td>
<td>10 GiB</td>
</tr>
<tr>
<td>Root device volume</td>
<td>EBS volume</td>
<td>Instance store volume</td>
</tr>
<tr>
<td>Data persistence</td>
<td>By default, the root volume is deleted when the instance terminates.* Data on any other EBS volumes persists after instance termination by default.</td>
<td>Data on any instance store volumes persists only during the life of the instance.</td>
</tr>
<tr>
<td>Modifications</td>
<td>The instance type, kernel, RAM disk, and user data can be changed while the instance is stopped.</td>
<td>Instance attributes are fixed for the life of an instance.</td>
</tr>
<tr>
<td>Charges</td>
<td>You're charged for instance usage, EBS volume usage, and storing your AMI as an EBS snapshot.</td>
<td>You're charged for instance usage and storing your AMI in Amazon S3.</td>
</tr>
<tr>
<td>AMI creation/bundling</td>
<td>Uses a single command/call</td>
<td>Requires installation and use of AMI tools</td>
</tr>
<tr>
<td>Stopped state</td>
<td>Can be in a stopped state. Even when the instance is stopped and not running, the root volume is persisted in Amazon EBS</td>
<td>Cannot be in stopped state; instances are running or terminated</td>
</tr>
</tbody>
</table>

\* By default, EBS root volumes have the `DeleteOnTermination` flag set to `true`. For information about how to change this flag so that the volume persists after termination, see Change the root volume to persist (p. 1436).

** Supported with io2 EBS Block Express only. For more information, see io2 Block Express volumes (p. 1188).

**Determine the root device type of your AMI**

**To determine the root device type of an AMI using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, click **AMIs**, and select the AMI.
3. Check the value of **Root Device Type** in the **Details** tab as follows:
   - If the value is **ebs**, this is an Amazon EBS-backed AMI.
   - If the value is **instance store**, this is an instance store-backed AMI.

**To determine the root device type of an AMI using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 3).

- **describe-images** (AWS CLI)
- **Get-EC2Image** (AWS Tools for Windows PowerShell)

**Stopped state**

You can stop an Amazon EBS-backed instance, but not an Amazon EC2 instance store-backed instance. Stopping causes the instance to stop running (its status goes from **running** to **stopping** to **stopped**). A stopped instance persists in Amazon EBS, which allows it to be restarted. Stopping is different from terminating; you can't restart a terminated instance. Because Amazon EC2 instance store-backed instances can't be stopped, they're either running or terminated. For more information about what happens and what you can do while an instance is stopped, see [Stop and start your instance](p. 524).

**Default data storage and persistence**

Instances that use an instance store volume for the root device automatically have instance store available (the root volume contains the root partition and you can store additional data). You can add persistent storage to your instance by attaching one or more EBS volumes. Any data on an instance store volume is deleted when the instance fails or terminates. For more information, see [Instance store lifetime](p. 1409).

Instances that use Amazon EBS for the root device automatically have an EBS volume attached. The volume appears in your list of volumes like any other. With most instance types, Amazon EBS-backed instances don't have instance store volumes by default. You can add instance store volumes or additional EBS volumes using a block device mapping. For more information, see [Block device mappings](p. 1441).

**Boot times**

Instances launched from an Amazon EBS-backed AMI launch faster than instances launched from an instance store-backed AMI. When you launch an instance from an instance store-backed AMI, all the parts have to be retrieved from Amazon S3 before the instance is available. With an Amazon EBS-backed AMI, only the parts required to boot the instance need to be retrieved from the snapshot before the instance is available. However, the performance of an instance that uses an EBS volume for its root device is slower for a short time while the remaining parts are retrieved from the snapshot and loaded into the volume. When you stop and restart the instance, it launches quickly, because the state is stored in an EBS volume.

**AMI creation**

To create Linux AMIs backed by instance store, you must create an AMI from your instance on the instance itself using the Amazon EC2 AMI tools.

AMI creation is much easier for AMIs backed by Amazon EBS. The **CreateImage** API action creates your Amazon EBS-backed AMI and registers it. There's also a button in the AWS Management Console that lets you create an AMI from a running instance. For more information, see [Create an Amazon EBS-backed Linux AMI](p. 102).
**How you're charged**

With AMIs backed by instance store, you're charged for instance usage and storing your AMI in Amazon S3. With AMIs backed by Amazon EBS, you're charged for instance usage, EBS volume storage and usage, and storing your AMI as an EBS snapshot.

With Amazon EC2 instance store-backed AMIs, each time you customize an AMI and create a new one, all of the parts are stored in Amazon S3 for each AMI. So, the storage footprint for each customized AMI is the full size of the AMI. For Amazon EBS-backed AMIs, each time you customize an AMI and create a new one, only the changes are stored. So the storage footprint for subsequent AMIs you customize after the first is much smaller, resulting in lower AMI storage charges.

When an Amazon EBS-backed instance is stopped, you're not charged for instance usage; however, you're still charged for volume storage. As soon as you start your instance, we charge a minimum of one minute for usage. After one minute, we charge only for the seconds used. For example, if you run an instance for 20 seconds and then stop it, we charge for a full one minute. If you run an instance for 3 minutes and 40 seconds, we charge for exactly 3 minutes and 40 seconds of usage. We charge you for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

**Linux AMI virtualization types**

Linux Amazon Machine Images use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions (CPU, network, and storage) for better performance.

For the best performance, we recommend that you use current generation instance types and HVM AMIs when you launch your instances. For more information about current generation instance types, see Amazon EC2 Instance Types. If you are using previous generation instance types and would like to upgrade, see Upgrade Paths.

The following table compares HVM and PV AMIs.

<table>
<thead>
<tr>
<th></th>
<th>HVM</th>
<th>PV</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>HVM AMIs are presented with a fully virtualized set of hardware and boot by executing the master boot record of the root block device of your image. This virtualization type provides the ability to run an operating system directly on top of a virtual machine without any modification, as if it were run on the bare-metal hardware. The Amazon EC2 host system emulates some or all of the underlying hardware that is presented to the guest.</td>
<td>PV AMIs boot with a special boot loader called PV-GRUB, which starts the boot cycle and then chain loads the kernel specified in the menu.lst file on your image. Paravirtual guests can run on host hardware that does not have explicit support for virtualization. Historically, PV guests had better performance than HVM guests in many cases, but because of enhancements in HVM virtualization and the availability of PV drivers for HVM AMIs, this is no longer true. For more information about PV-GRUB and its use in Amazon EC2, see Enabling Your Own Linux Kernels (p. 182).</td>
</tr>
</tbody>
</table>
Virtualization types

<table>
<thead>
<tr>
<th>HVM</th>
<th>PV</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Support for hardware extensions</strong></td>
<td>Yes. Unlike PV guests, HVM guests can take advantage of hardware extensions that provide fast access to the underlying hardware on the host system. For more information on CPU virtualization extensions available in Amazon EC2, see Intel Virtualization Technology on the Intel website. HVM AMIs are required to take advantage of enhanced networking and GPU processing. In order to pass through instructions to specialized network and GPU devices, the OS needs to be able to have access to the native hardware platform; HVM virtualization provides this access. For more information, see Enhanced networking on Linux (p. 952) and Linux accelerated computing instances (p. 289).</td>
</tr>
<tr>
<td><strong>Supported instance types</strong></td>
<td>All current generation instance types support HVM AMIs.</td>
</tr>
<tr>
<td><strong>Supported Regions</strong></td>

**PV on HVM**

Paravirtual guests traditionally performed better with storage and network operations than HVM guests because they could leverage special drivers for I/O that avoided the overhead of emulating network and disk hardware, whereas HVM guests had to translate these instructions to emulated hardware. Now PV drivers are available for HVM guests, so operating systems that cannot be ported to run in a paravirtualized environment can still see performance advantages in storage and network I/O by using them. With these PV on HVM drivers, HVM guests can get the same, or better, performance than paravirtual guests.
Boot modes

When a computer boots, the first software that it runs is responsible for initializing the platform and providing an interface for the operating system to perform platform-specific operations.

Default boot modes

In EC2, two variants of the boot mode software are supported: Legacy BIOS and Unified Extensible Firmware Interface (UEFI). By default, Intel and AMD instance types run on Legacy BIOS, and Graviton instance types run on UEFI.

Running Intel and AMD instances types on UEFI

Most Intel and AMD instance types can run on both UEFI and Legacy BIOS. To use UEFI, you must select an AMI with the boot mode parameter set to `uefi`, and the operating system contained in the AMI must be configured to support UEFI.

Purpose of the AMI boot mode parameter

The AMI boot mode parameter signals to EC2 which boot mode to use when launching an instance. When the boot mode parameter is set to `uefi`, EC2 attempts to launch the instance on UEFI. If the operating system is not configured to support UEFI, the instance launch might be unsuccessful.

Warning
Setting the boot mode parameter does not automatically configure the operating system for the specified boot mode. The configuration is specific to the operating system. For the configuration instructions, see the manual for your operating system.

Possible boot mode parameter on an AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: `uefi` or `legacy-bios`. Some AMIs do not have a boot mode parameter. For AMIs with no boot mode parameter, the instances launched from these AMIs use the default value of the instance type—`uefi` on Graviton, and `legacy-bios` on all Intel and AMD instance types.

Topics

- Considerations (p. 77)
- Requirements for launching an instance with UEFI (p. 78)
- Determine the boot mode parameter of an AMI (p. 78)
- Determine the supported boot modes of an instance type (p. 79)
- Determine the boot mode of an instance (p. 79)
- Determine the boot mode of the OS (p. 80)
- Set the boot mode of an AMI (p. 81)

Considerations

- Default boot modes:
  - Intel and AMD instance types: Legacy BIOS
  - Graviton instance types: UEFI
  - Intel and AMD instance types that support UEFI, in addition to Legacy BIOS:
    - Virtualized: C5, C5a, C5ad, C5d, C5n, D3, D3en, G4, I3en, M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, R5, R5a, R5ad, R5b, R5d, R5dn, R5n, T3, T3a, and z1d
• UEFI Secure Boot is currently not supported.

Requirements for launching an instance with UEFI

To launch an instance in UEFI mode, you must select an instance type that supports UEFI, and configure
the AMI and the OS for UEFI, as follows:

• **Instance type** – When launching an instance, you must select an instance type that supports UEFI. For
more information, see Determine the supported boot modes of an instance type (p. 79).

• **AMI** – When launching an instance, you must select an AMI that is configured for UEFI. The AMI must
be configured as follows:
  • **OS** – The operating system contained in the AMI must be configured to use UEFI; otherwise, the
instance launch will fail. For more information, see Determine the boot mode of the OS (p. 80).
  • **AMI boot mode parameter** – The boot mode parameter of the AMI must be set to **uefi**. For more
information, see Determine the boot mode parameter of an AMI (p. 78).

AWS does not provide AMIs that are already configured to support UEFI. You must configure the
AMI (p. 81), import the AMI through VM Import/Export, or import the AMI through CloudEndure.

Determine the boot mode parameter of an AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter
values: **uefi** and **legacy-bios**.

Some AMIs do not have a boot mode parameter. When an AMI has no boot mode parameter, the
instances launched from the AMI use the default value of the instance type, which is **uefi** on Graviton,
and **legacy-bios** on Intel and AMD instance types.

To determine the boot mode parameter of an AMI (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**, and then select the AMI.
3. On the **Details** tab, inspect the **Boot mode** field.

To determine the boot mode parameter of an AMI when launching an instance (console)

When launching an instance using the launch instance wizard, at the step to select an AMI, inspect the
**Boot mode** field. For more information, see Step 1: Choose an Amazon Machine Image (AMI) (p. 477).

To determine the boot mode parameter of an AMI (AWS CLI version 1.19.34 and later and version
2.1.32 and later)

Use the **describe-images** command to determine the boot mode of an AMI.

```bash
aws ec2 --region us-east-1 describe-images --image-id ami-0abcdef1234567890
```

Expected output

```json
{
  "Images": [
    {
      "BootMode": "uefi"
    }
  ]
}
```
Determine the supported boot modes of an instance type

To determine the supported boot modes of an instance type (AWS CLI version 1.19.34 and later and version 2.1.32 and later)

Use the `describe-instance-types` command to determine the supported boot modes of an instance type. By including the `--query` parameter, you can filter the output. In this example, the output is filtered to return only the supported boot modes.

The following example shows that `m5.2xlarge` supports both UEFI and Legacy BIOS boot modes.

```bash
aws ec2 --region us-east-1 describe-instance-types --instance-types m5.2xlarge --query "InstanceTypes[*].SupportedBootModes"
```

Expected output

```json
[
  [
    "legacy-bios",
    "uefi"
  ]
]
```

The following example shows that `t2.xlarge` supports only Legacy BIOS.

```bash
aws ec2 --region us-east-1 describe-instance-types --instance-types t2.xlarge --query "InstanceTypes[*].SupportedBootModes"
```

Expected output

```json
[
  [
    "legacy-bios"
  ]
]
```

Determine the boot mode of an instance

When an instance is launched, the value for its boot mode parameter is determined by the value of the boot mode parameter of the AMI used to launch it, as follows:
• An AMI with a boot mode parameter of `uefi` creates an instance with a boot mode parameter of `uefi`.
• An AMI with a boot mode parameter of `legacy-bios` creates an instance with no boot mode parameter. An instance with no boot mode parameter uses its default value, which is `legacy-bios` in this case.
• An AMI with no boot mode parameter value creates an instance with no boot mode parameter value.

The value of the instance's boot mode parameter determines the mode in which it boots. If there is no value, the default boot mode is used, which is `uefi` on Graviton, and `legacy-bios` on Intel and AMD instance types.

**To determine the boot mode of an instance (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Details** tab, inspect the **Boot mode** field.

**To determine the boot mode of an instance (AWS CLI version 1.19.34 and later and version 2.1.32 and later)**

Use the `describe-instances` command to determine the boot mode of an instance.

```bash
aws ec2 --region us-east-1 describe-instances --instance-ids i-1234567890abcdef0
```

Expected output

```json
{
    "Reservations": [
        {
            "Groups": [],
            "Instances": [
                {
                    "AmiLaunchIndex": 0,
                    "ImageId": "ami-0e2063e7f6dc3bee8",
                    "InstanceId": "i-1234567890abcdef0",
                    "InstanceType": "m5.2xlarge",
                    ...
                },
                {
                    "BootMode": "uefi"
                }
            ],
            "OwnerId": "1234567890",
            "ReservationId": "r-1234567890abcdef0"
        }
    ]
}
```

**Determine the boot mode of the OS**

The boot mode of the OS guides EC2 on which boot mode to use to boot an instance. To view whether the operating system of your instance is configured for UEFI, you need to connect to your instance via SSH.

**To determine the boot mode of the instance's OS**

1. Connect to your Linux instance using SSH (p. 502).
2. To view the boot mode of the OS, try one of the following:
Set the boot mode of an AMI

When you create an AMI using the register-image command, you can set the boot mode of the AMI to either uefi or legacy-bios.

To convert an existing Legacy BIOS-based instance to UEFI, or an existing UEFI-based instance to Legacy BIOS, you need to perform a number of steps: First, modify the instance's volume and OS to support the selected boot mode. Then, create a snapshot of the volume. Finally, use register-image to create the AMI using the snapshot.

You can't set the boot mode of an AMI using the create-image command. With create-image, the AMI inherits the boot mode of the EC2 instance used for creating the AMI. For example, if you create an AMI from an EC2 instance running on Legacy BIOS, the AMI boot mode will be configured as legacy-bios.

Warning
Before proceeding with these steps, you must first make suitable modifications to the instance's volume and OS to support booting via the selected boot mode; otherwise, the resulting AMI...
will not be usable. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

**To set the boot mode of an AMI (AWS CLI version 1.19.34 and later and version 2.1.32 and later)**

1. Make suitable modifications to the instance's volume and OS to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

   **Note**
   If you don't perform this step, the AMI will not be usable.

2. To find the volume ID of the instance, use the `describe-instances` command. You'll create a snapshot of this volume in the next step.

   ```bash
   aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
   ``

   **Expected output**

   ```json
   ...
   "BlockDeviceMappings": [
   {
   "DeviceName": "/dev/sda1",
   "Ebs": {
   "AttachTime": 
   "DeleteOnTermination": true,
   "Status": "attached",
   "VolumeId": "vol-1234567890abcdef0"
   }
   }
   ...
   ```

3. To create a snapshot of the volume, use the `create-snapshot` command. Use the volume ID from the previous step.

   ```bash
   aws ec2 create-snapshot --region us-east-1 --volume-id vol-1234567890abcdef0 --description "add text"
   ``

   **Expected output**

   ```json
   {  
   "Description": "add text",
   "Encrypted": false,
   "OwnerId": "123",
   "Progress": ",",
   "SnapshotId": "snap-01234567890abcdef0",
   "StartTime": ",",
   "State": "pending",
   "VolumeId": "vol-1234567890abcdef0",
   "VolumeSize": 30,
   "Tags": []
   }
   ```

4. Note the snapshot ID in the output from the previous step.

5. Wait until the snapshot creation is completed before going to the next step. To query the state of the snapshot, use the `describe-snapshots` command.

   ```bash
   aws ec2 describe-snapshots --region us-east-1 --snapshot-ids snap-01234567890abcdef0
   ```
Example output

```json
{
    "Snapshots": [
        {
            "Description": "This is my snapshot",
            "Encrypted": false,
            "VolumeId": "vol-049df61146c4d7901",
            "State": "completed",
            "VolumeSize": 8,
            "StartTime": "2019-02-28T21:28:32.000Z",
            "Progress": "100%",
            "OwnerId": "012345678910",
            "SnapshotId": "snap-0123456789abcdef",
            ...
        }
    ]
}
```

6. To create a new AMI, use the `register-image` command. Use the snapshot ID that you noted in the earlier step. To set the boot mode to UEFI, add the `--boot-mode uefi` parameter to the command.

```bash
aws ec2 register-image \
    --region us-east-1 \
    --description "add description" \
    --name "add name" \
    --block-device-mappings "DeviceName=/dev/sda1,Ebs={SnapshotId=snap-0123456789abcdef,DeleteOnTermination=true}" \
    --architecture x86_64 \
    --root-device-name /dev/sda1 \
    --virtualization-type hvm \
    --ena-support \
    --boot-mode uefi
```

Expected output

```json
{
    "ImageId": "ami-new_ami_123"
}
```

7. To verify that the newly-created AMI has the boot mode that you specified in the previous step, use the `describe-images` command.

```bash
aws ec2 describe-images --region us-east-1 --image-id ami-new_ami_123
```

Expected output

```json
{
    "Images": [
        {
            "Architecture": "x86_64",
            "CreationDate": "2021-01-06T14:31:04.000Z",
            "ImageId": "ami-new_ami_123",
            "ImageLocation": "",
            ...
            "BootMode": "uefi"
        }
    ]
}
```
8. Launch a new instance using the newly-created AMI. All new instances created from this AMI will inherit the same boot mode.
9. To verify that the new instance has the expected boot mode, use the `describe-instances` command.

Find a Linux AMI

Before you can launch an instance, you must select an AMI to use. As you select an AMI, consider the following requirements you might have for the instances that you’ll launch:

- The Region
- The operating system
- The architecture: 32-bit (`i386`), 64-bit (`x86_64`), or 64-bit ARM (`arm64`)
- The root device type: Amazon EBS or instance store
- The provider (for example, Amazon Web Services)
- Additional software (for example, SQL server)

If you need to find a Windows AMI, see Find a Windows AMI in the Amazon EC2 User Guide for Windows Instances.

Contents

- Find a Linux AMI using the Amazon EC2 console (p. 84)
- Find an AMI using the AWS CLI (p. 85)
- Find the latest Amazon Linux AMI using Systems Manager (p. 85)
- Use a Systems Manager parameter to find an AMI (p. 86)

Find a Linux AMI using the Amazon EC2 console

You can find Linux AMIs using the Amazon EC2 console. You can select from the list of AMIs when you use the launch wizard to launch an instance, or you can search through all available AMIs using the Images page. AMI IDs are unique to each AWS Region.

To find a Linux AMI using the launch wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose Launch instance.
4. On the Quick Start tab, select from one of the commonly used AMIs in the list. If you don't see the AMI that you need, select the My AMIs, AWS Marketplace, or Community AMIs tab to find additional AMIs. For more information, see Step 1: Choose an Amazon Machine Image (AMI) (p. 477).

To find a Linux AMI using the Images page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose AMIs.
4. (Optional) Use the Filter options to scope the list of displayed AMIs to see only the AMIs that interest you. For example, to list all Linux AMIs provided by AWS, select Public images. Choose the Search bar and select Owner from the menu, then select Amazon images. Choose the Search bar again to select Platform and then the operating system from the list provided.

5. (Optional) Choose the Show/Hide Columns icon to select which image attributes to display, such as the root device type. Alternatively, you can select an AMI from the list and view its properties in the Details tab.

6. Before you select an AMI, it's important that you check whether it's backed by instance store or by Amazon EBS and that you are aware of the effects of this difference. For more information, see Storage for the root device (p. 73).

7. To launch an instance from this AMI, select it and then choose Launch. For more information about launching an instance using the console, see Launching your instance from an AMI (p. 478). If you're not ready to launch the instance now, make note of the AMI ID for later.

Find an AMI using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to list only the Linux AMIs that meet your needs. After locating an AMI that meets your needs, make note of its ID so that you can use it to launch instances. For more information, see Launching an Instance Using the AWS CLI in the AWS Command Line Interface User Guide.

The describe-images command supports filtering parameters. For example, use the --owners parameter to display public AMIs owned by Amazon.

```
aws ec2 describe-images --owners self amazon
```

You can add the following filter to the previous command to display only AMIs backed by Amazon EBS.

```
--filters "Name=root-device-type,Values=ebs"
```

**Important**

Omitting the --owners flag from the describe-images command will return all images for which you have launch permissions, regardless of ownership.

Find the latest Amazon Linux AMI using Systems Manager

Amazon EC2 provides AWS Systems Manager public parameters for AWS-maintained public AMIs that you can use when launching instances. For example, the EC2-provided parameter /aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2 is available in all Regions and always points to the latest version of the Amazon Linux 2 AMI in a given Region.

The Amazon EC2 AMI public parameters are available from the following path:

```
/aws/service/ami-amazon-linux-latest
```

You can view a list of all Linux AMIs in the current AWS Region by using the following command in the AWS CLI.

```
aws ssm get-parameters-by-path --path /aws/service/ami-amazon-linux-latest --query "Parameters[].Name"
```

To launch an instance using a public parameter
Use a Systems Manager parameter to find an AMI

When you launch an instance using the EC2 launch wizard in the console, you can either select an AMI from the list, or you can select an AWS Systems Manager parameter that points to an AMI ID. If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID.

A Systems Manager parameter is a customer-defined key-value pair that you can create in Systems Manager Parameter Store. The Parameter Store provides a central store to externalize your application configuration values. For more information, see AWS Systems Manager Parameter Store in the AWS Systems Manager User Guide.

When you create a parameter that points to an AMI ID, make sure that you specify the data type as awsc2:image. This data type ensures that when the parameter is created or modified, the parameter value is validated as an AMI ID. For more information, see Native parameter support for Amazon Machine Image IDs in the AWS Systems Manager User Guide.

Contents
- Use cases (p. 86)
- Launch an instance using a Systems Manager parameter (p. 87)
  - Permissions (p. 88)
  - Limitations (p. 88)

Use cases

By using Systems Manager parameters to point to AMI IDs, you can make it easier for your users to select the correct AMI when launching instances, and you can simplify the maintenance of automation code.

Easier for users

If you require instances to be launched using a specific AMI, and if that AMI is updated regularly, we recommend that you require your users to select a Systems Manager parameter to find the AMI. By requiring your users to select a Systems Manager parameter, you can ensure that the latest AMI is used to launch instances.

For example, every month in your organization you might create a new version of your AMI that has the latest operating system and application patches. You also require your users to launch instances...
using the latest version of your AMI. To ensure that your users use the latest version, you can create a Systems Manager parameter (for example, golden-ami) that points to the correct AMI ID. Each time a new version of the AMI is created, you update the AMI ID value in the parameter so that it always points to the latest AMI. Your users don't need to know about the periodic updates to the AMI, because they continue to select the same Systems Manager parameter every time. By having users select a Systems Manager parameter, you make it easier for them to select the correct AMI for an instance launch.

**Simplify automation code maintenance**

If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID. If a new version of the AMI is created, you change the AMI ID value in the parameter so that it points to the latest AMI. The automation code that references the parameter doesn't need to be modified every time a new version of the AMI is created. This greatly simplifies maintenance of automation and helps drive down deployment costs.

**Note**

Running instances are not affected when you change the AMI ID to which the Systems Manager parameter points.

**Launch an instance using a Systems Manager parameter**

You can launch an instance using the console or the AWS CLI. Instead of specifying an AMI ID, you can specify an AWS Systems Manager parameter that points to an AMI ID.

**To find a Linux AMI using a Systems Manager parameter (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. Choose **Search by Systems Manager parameter** (at top right).
5. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
6. Choose **Search**. The AMIs that match the AMI ID appear in the list.
7. Select the AMI from the list, and choose **Select**.

For more information about launching an instance from an AMI using the launch wizard, see Step 1: Choose an Amazon Machine Image (AMI) (p. 477).

**To launch an instance using an AWS Systems Manager parameter instead of an AMI ID (AWS CLI)**

The following example uses the Systems Manager parameter golden-ami to launch an m5.xlarge instance. The parameter points to an AMI ID.

To specify the parameter in the command, use the following syntax: `resolve:ssm:/parameter-name`, where `resolve:ssm` is the standard prefix and `parameter-name` is the unique parameter name. Note that the parameter name is case-sensitive. Backslashes for the parameter name are only necessary when the parameter is part of a hierarchy, for example, `/amis/production/golden-ami`. You can omit the backslash if the parameter is not part of a hierarchy.

In this example, the --count and --security-group parameters are not included. For --count, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami
  --instance-type m5.xlarge
```

87
To launch an instance using a specific version of an AWS Systems Manager parameter (AWS CLI)

Systems Manager parameters have version support. Each iteration of a parameter is assigned a unique version number. You can reference the version of the parameter as follows: `resolve:ssm:parameter-name:version`, where `version` is the unique version number. By default, the latest version of the parameter is used when no version is specified.

The following example uses version 2 of the parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```bash
aws ec2 run-instances
  --image-id resolve:ssm:golden-ami:2
  --instance-type m5.xlarge
  ...
```

To launch an instance using a public parameter provided by AWS

Amazon EC2 provides Systems Manager public parameters for public AMIs provided by AWS. For example, the public parameter `/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2` is available in all Regions and always points to the latest version of the Amazon Linux 2 AMI in the Region.

```bash
aws ec2 run-instances
  --image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2
  --instance-type m5.xlarge
  ...
```

Permissions

If you use Systems Manager parameters that point to AMI IDs in the launch instance wizard, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your IAM policy. `ssm:DescribeParameters` grants your IAM users the permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your IAM users the permission to get the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see [Use the EC2 launch wizard](p. 1117).

Limitations

AMIs and Systems Manager parameters are Region specific. To use the same Systems Manager parameter name across Regions, create a Systems Manager parameter in each Region with the same name (for example, `golden-ami`). In each Region, point the Systems Manager parameter to an AMI in that Region.

Shared AMIs

A *shared AMI* is an AMI that a developer created and made available for others to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content. You can also create your own AMIs and share them with others.

You use a shared AMI at your own risk. Amazon can’t vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center and perform the appropriate due diligence. We recommend that you get an AMI from a trusted source.
Amazon's public images have an aliased owner, which appears as `amazon` in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

For information about creating an AMI, see Create an instance store-backed Linux AMI or Create an Amazon EBS-backed Linux AMI. For information about building, delivering, and maintaining your applications on the AWS Marketplace, see the AWS Marketplace Documentation.

## Contents

- Find shared AMIs (p. 89)
- Make an AMI public (p. 91)
- Share an AMI with specific AWS accounts (p. 92)
- Use bookmarks (p. 94)
- Guidelines for shared Linux AMIs (p. 94)

## Find shared AMIs

You can use the Amazon EC2 console or the command line to find shared AMIs.

AMIs are a regional resource. Therefore, when searching for a shared AMI (public or private), you must search for it from within the Region from which it is being shared. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an AMI (p. 138).

### Topics

- Find a shared AMI (console) (p. 89)
- Find a shared AMI (AWS CLI) (p. 89)
- Use shared AMIs (p. 90)

## Find a shared AMI (console)

### To find a shared private AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Private images**. All AMIs that have been shared with you are listed. To granulate your search, choose the Search bar and use the filter options provided in the menu.

### To find a shared public AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**. To granulate your search, choose the Search bar and use the filter options provided in the menu.
4. Use filters to list only the types of AMIs that interest you. For example, choose **Owner** : and then choose **Amazon images** to display only Amazon's public images.

## Find a shared AMI (AWS CLI)

Use the `describe-images` command (AWS CLI) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

### Example: List all public AMIs
Find shared AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

Example: List AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

Example: List AMIs owned by Amazon

The following command lists the AMIs owned by Amazon. Amazon's public AMIs have an aliased owner, which appears as `amazon` in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

```
aws ec2 describe-images --owners amazon
```

Example: List AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

Example: Scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
--filters "Name=root-device-type,Values=ebs"
```

Use shared AMIs

Before you use a shared AMI, take the following steps to confirm that there are no pre-installed credentials that would allow unwanted access to your instance by a third party and no pre-configured remote logging that could transmit sensitive data to a third party. Check the documentation for the Linux distribution used by the AMI for information about improving the security of the system.

To ensure that you don't accidentally lose access to your instance, we recommend that you initiate two SSH sessions and keep the second session open until you've removed credentials that you don't recognize and confirmed that you can still log into your instance using SSH.

1. Identify and disable any unauthorized public SSH keys. The only key in the file should be the key you used to launch the AMI. The following command locates `authorized_keys` files:

   ```
   [ec2-user ~]$ sudo find / -name "authorized_keys" -print -exec cat {} \;
   ```

2. Disable password-based authentication for the root user. Open the `sshd_config` file and edit the `PermitRootLogin` line as follows:

   ```
   PermitRootLogin without-password
   ```

   Alternatively, you can disable the ability to log into the instance as the root user:
Make an AMI public

Amazon EC2 enables you to share your AMIs with other AWS accounts. You can allow all AWS accounts to use the AMI to launch instances (by making the AMI public), or only allow a few specific accounts to use the AMI to launch instances (see Share an AMI with specific AWS accounts (p. 92)). You are not billed when your AMI is used by other AWS accounts to launch instances; only the accounts launching instances using the AMI are billed for the instances they launch.

AMIs with encrypted volumes cannot be made public.

AMIs are a regional resource. Therefore, sharing an AMI makes it available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an AMI (p. 138).

To avoid exposing sensitive data when you share an AMI, read the security considerations in Guidelines for shared Linux AMIs (p. 94) and follow the recommended actions.

If an AMI has a product code, or contains a snapshot of an encrypted volume, you can’t make it public; you can share the AMI only with specific AWS accounts.

Topics

- Share an AMI with all AWS accounts (console) (p. 91)
- Share an AMI with all AWS accounts (AWS CLI) (p. 92)

Share an AMI with all AWS accounts (console)

After you make an AMI public, it is available in Community AMIs when you launch an instance in the same Region using the console. Note that it can take a short while for an AMI to appear in Community AMIs after you make it public. It can also take a short while for an AMI to be removed from Community AMIs after you make it private again.

To share a public AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions, Modify Image Permissions**.
4. Choose **Public** and choose **Save**.

### Share an AMI with all AWS accounts (AWS CLI)

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner’s, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts) or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

**To make an AMI public**

1. Use the `modify-image-attribute` command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

   ```bash
   aws ec2 modify-image-attribute \
   --image-id ami-0abcdef1234567890 \
   --launch-permission "Add=[{Group=all}]"
   ```

2. To verify the launch permissions of the AMI, use the `describe-image-attribute` command.

   ```bash
   aws ec2 describe-image-attribute \
   --image-id ami-0abcdef1234567890 \
   --attribute launchPermission
   ```

3. (Optional) To make the AMI private again, remove the `all` group from its launch permissions.

   Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

   ```bash
   aws ec2 modify-image-attribute \
   --image-id ami-0abcdef1234567890 \
   --launch-permission "Remove=[{Group=all}]
   ```

### Share an AMI with specific AWS accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need is the AWS account IDs. You can only share AMIs that have unencrypted volumes and volumes that are encrypted with a customer managed key. If you share an AMI with encrypted volumes, you must also share any customer managed keys used to encrypt them. For more information, see Share an Amazon EBS snapshot (p. 1242). You cannot share an AMI that has volumes that are encrypted with an AWS managed key.

AMIs are a regional resource. Therefore, sharing an AMI makes it available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an AMI (p. 138).

There is no limit to the number of AWS accounts with which an AMI can be shared. User-defined tags that you attach to a shared AMI are available only to your AWS account and not to the other accounts that the AMI is shared with.
Share an AMI (console)

To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs.
3. Select your AMI in the list, and then choose Actions, Modify Image Permissions.
4. Specify the AWS account number of the user with whom you want to share the AMI in the AWS Account Number field, then choose Add Permission.

   To share this AMI with multiple users, repeat this step until you have added all the required users.

   **Note**
   You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see Share an Amazon EBS snapshot (p. 1242).

5. Choose Save when you are done.
6. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the Permissions tab. To find AMIs that are shared with you, see Find shared AMIs (p. 89).

Share an AMI (AWS CLI)

Use the modify-image-attribute command (AWS CLI) to share an AMI as shown in the following examples.

**To grant explicit launch permissions**

The following command grants launch permissions for the specified AMI to the specified AWS account.

```
aws ec2 modify-image-attribute \\
    --image-id ami-0abcdef1234567890 \\
    --launch-permission "Add=[{UserId=123456789012}]"
```

**Note**
You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see Share an Amazon EBS snapshot (p. 1242).

**To remove launch permissions for an account**

The following command removes launch permissions for the specified AMI from the specified AWS account:

```
aws ec2 modify-image-attribute \\
    --image-id ami-0abcdef1234567890 \\
    --launch-permission "Remove=[{UserId=123456789012}]"
```

**To remove all launch permissions**

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.
Use bookmarks

If you have created a public AMI, or shared an AMI with another AWS user, you can create a bookmark that allows a user to access your AMI and launch an instance in their own account immediately. This is an easy way to share AMI references, so users don’t have to spend time finding your AMI in order to use it.

Note that your AMI must be public, or you must have shared it with the user to whom you want to send the bookmark.

To create a bookmark for your AMI

1. Type a URL with the following information, where region is the Region in which your AMI resides:

   ```
   https://console.aws.amazon.com/ec2/v2/home?
   region=region#LaunchInstanceWizard:ami=ami_id
   ```
   
   For example, this URL launches an instance from the ami-0abcdef1234567890 AMI in the us-east-1 Region:

   ```
   https://console.aws.amazon.com/ec2/v2/home?region=us-east-1#LaunchInstanceWizard:ami=ami-0abcdef1234567890
   ```

2. Distribute the link to users who want to use your AMI.
3. To use a bookmark, choose the link or copy and paste it into your browser. The launch wizard opens, with the AMI already selected.

Guidelines for shared Linux AMIs

Use the following guidelines to reduce the attack surface and improve the reliability of the AMIs you create.

**Important**

No list of security guidelines can be exhaustive. Build your shared AMIs carefully and take time to consider where you might expose sensitive data.

Contents

- Update the AMI tools before using them (p. 95)
- Disable password-based remote logins for root (p. 95)
- Disable local root access (p. 95)
- Remove SSH host key pairs (p. 96)
- Install public key credentials (p. 96)
- Disabling sshd DNS checks (optional) (p. 97)
- Identify yourself (p. 98)
- Protect yourself (p. 98)

If you are building AMIs for AWS Marketplace, see Best practices for building AMIs in the AWS Marketplace Seller Guide for guidelines, policies, and best practices.
For additional information about sharing AMIs safely, see the following articles:

- How To Share and Use Public AMIs in A Secure Manner
- Public AMI Publishing: Hardening and Clean-up Requirements

**Update the AMI tools before using them**

For AMIs backed by instance store, we recommend that your AMIs download and upgrade the Amazon EC2 AMI creation tools before you use them. This ensures that new AMIs based on your shared AMIs have the latest AMI tools.

For Amazon Linux 2, install the `aws-amitools-ec2` package and add the AMI tools to your PATH with the following command. For the Amazon Linux AMI, `aws-amitools-ec2` package is already installed by default.

```
[ec2-user ~]$ sudo yum install -y aws-amitools-ec2 && export PATH=$PATH:/opt/aws/bin > /etc/profile.d/aws-amitools-ec2.sh && . /etc/profile.d/aws-amitools-ec2.sh
```

Upgrade the AMI tools with the following command:

```
[ec2-user ~]$ sudo yum upgrade -y aws-amitools-ec2
```

For other distributions, make sure you have the latest AMI tools.

**Disable password-based remote logins for root**

Using a fixed root password for a public AMI is a security risk that can quickly become known. Even relying on users to change the password after the first login opens a small window of opportunity for potential abuse.

To solve this problem, disable password-based remote logins for the root user.

**To disable password-based remote logins for root**

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

   ```
   #PermitRootLogin yes
   ```

2. Change the line to:

   ```
   PermitRootLogin without-password
   ```

The location of this configuration file might differ for your distribution, or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

**Disable local root access**

When you work with shared AMIs, a best practice is to disable direct root logins. To do this, log into your running instance and issue the following command:

```
[ec2-user ~]$ sudo passwd -l root
```
Note
This command does not impact the use of `sudo`.

Remove SSH host key pairs

If you plan to share an AMI derived from a public AMI, remove the existing SSH host key pairs located in `/etc/ssh`. This forces SSH to generate new unique SSH key pairs when someone launches an instance using your AMI, improving security and reducing the likelihood of "man-in-the-middle" attacks.

Remove all of the following key files that are present on your system.

- `ssh_host_dsa_key`
- `ssh_host_dsa_key.pub`
- `ssh_host_key`
- `ssh_host_key.pub`
- `ssh_host_rsa_key`
- `ssh_host_rsa_key.pub`
- `ssh_host_ecdsa_key`
- `ssh_host_ecdsa_key.pub`
- `ssh_host_ed25519_key`
- `ssh_host_ed25519_key.pub`

You can securely remove all of these files with the following command.

```
[ec2-user ~]$ sudo shred -u /etc/ssh/*_key /etc/ssh/*_key.pub
```

Warning
Secure deletion utilities such as `shred` may not remove all copies of a file from your storage media. Hidden copies of files may be created by journalling file systems (including Amazon Linux default ext4), snapshots, backups, RAID, and temporary caching. For more information see the `shred` documentation.

Important
If you forget to remove the existing SSH host key pairs from your public AMI, our routine auditing process notifies you and all customers running instances of your AMI of the potential security risk. After a short grace period, we mark the AMI private.

Install public key credentials

After configuring the AMI to prevent logging in using a password, you must make sure users can log in using another mechanism.

Amazon EC2 allows users to specify a public-private key pair name when launching an instance. When a valid key pair name is provided to the `RunInstances` API call (or through the command line API tools), the public key (the portion of the key pair that Amazon EC2 retains on the server after a call to `CreateKeyPair` or `ImportKeyPair`) is made available to the instance through an HTTP query against the instance metadata.

To log in through SSH, your AMI must retrieve the key value at boot and append it to `/root/.ssh/authorized_keys` (or the equivalent for any other user account on the AMI). Users can launch instances of your AMI with a key pair and log in without requiring a root password.

Many distributions, including Amazon Linux and Ubuntu, use the `cloud-init` package to inject public key credentials for a configured user. If your distribution does not support `cloud-init`, you can add
the following code to a system start-up script (such as /etc/rc.local) to pull in the public key you specified at launch for the root user.

**Note**
In the following example, the IP address http://169.254.169.254/ is a link-local address and is valid only from the instance.

**IMDSv2**

```bash
if [ ! -d /root/.ssh ]; then
  mkdir -p /root/.ssh
  chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
if [ $? -eq 0 ]; then
  cat /tmp/my-key >> /root/.ssh/authorized_keys
  chmod 700 /root/.ssh/authorized_keys
  rm /tmp/my-key
fi
```

**IMDSv1**

```bash
if [ ! -d /root/.ssh ]; then
  mkdir -p /root/.ssh
  chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
if [ $? -eq 0 ]; then
  cat /tmp/my-key >> /root/.ssh/authorized_keys
  chmod 700 /root/.ssh/authorized_keys
  rm /tmp/my-key
fi
```

This can be applied to any user account; you do not need to restrict it to root.

**Note**
Rebundling an instance based on this AMI includes the key with which it was launched. To prevent the key's inclusion, you must clear out (or delete) the `authorized_keys` file or exclude this file from rebundling.

**Disabling sshd DNS checks (optional)**

Disabling sshd DNS checks slightly weakens your sshd security. However, if DNS resolution fails, SSH logins still work. If you do not disable sshd checks, DNS resolution failures prevent all logins.

**To disable sshd DNS checks**

1. Open the `/etc/sshd/sshd_config` file with a text editor and locate the following line:

   ```
   #UseDNS yes
   ```

2. Change the line to:

   ```
   UseDNS no
   ```
Note
The location of this configuration file can differ for your distribution or if you are not running
OpenSSH. If this is the case, consult the relevant documentation.

Identify yourself

Currently, there is no easy way to know who provided a shared AMI, because each AMI is represented by
an account ID.

We recommend that you post a description of your AMI, and the AMI ID, in the Amazon EC2 forum. This
provides a convenient central location for users who are interested in trying new shared AMIs.

Protect yourself

We recommend against storing sensitive data or software on any AMI that you share. Users who launch a
shared AMI might be able to rebundle it and register it as their own. Follow these guidelines to help you
to avoid some easily overlooked security risks:

- We recommend using the --exclude directory option on ec2-bundle-vol to skip any
directories and subdirectories that contain secret information that you would not like to include
in your bundle. In particular, exclude all user-owned SSH public/private key pairs and SSH
authorized_keys files when bundling the image. The Amazon public AMIs store these in /
root/.ssh for the root account, and /home/username/.ssh/ for regular user accounts. For more
information, see ec2-bundle-vol (p. 124).

- Always delete the shell history before bundling. If you attempt more than one bundle upload in the
same AMI, the shell history contains your secret access key. The following example should be the last
command you run before bundling from within the instance.

[ec2-user ~]$ shred -u ~/.history

Warning
The limitations of shred described in the warning above apply here as well.
Be aware that bash writes the history of the current session to the disk on exit. If you log out
of your instance after deleting ~/.bash_history, and then log back in, you will find that
~/.bash_history has been re-created and contains all of the commands you ran during
your previous session.
Other programs besides bash also write histories to disk, Use caution and remove or exclude
unnecessary dot-files and dot-directories.

- Bundling a running instance requires your private key and X.509 certificate. Put these and other
credentials in a location that is not bundled (such as the instance store).

Paid AMIs

A paid AMI is an AMI that you can purchase from a developer.

Amazon EC2 integrates with AWS Marketplace, enabling developers to charge other Amazon EC2 users
for the use of their AMIs or to provide support for instances.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs
that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories,
such as Developer Tools, to enable you to find products to suit your requirements. For more information
about AWS Marketplace, see the AWS Marketplace site.

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No
additional parameters are required. The instance is charged according to the rates set by the owner of
the AMI, as well as the standard usage fees for the related web services, for example, the hourly rate for running an m1.small instance type in Amazon EC2. Additional taxes might also apply. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

**Important**
Amazon DevPay is no longer accepting new sellers or products. AWS Marketplace is now the single, unified e-commerce platform for selling software and services through AWS. For information about how to deploy and sell software from AWS Marketplace, see Selling in AWS Marketplace. AWS Marketplace supports AMIs backed by Amazon EBS.

**Contents**
- Sell your AMI (p. 99)
- Find a paid AMI (p. 99)
- Purchase a paid AMI (p. 100)
- Get the product code for your instance (p. 100)
- Use paid support (p. 101)
- Bills for paid and supported AMIs (p. 101)
- Manage your AWS Marketplace subscriptions (p. 101)

**Sell your AMI**

You can sell your AMI using AWS Marketplace. AWS Marketplace offers an organized shopping experience. Additionally, AWS Marketplace also supports AWS features such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on the AWS Marketplace, see Selling in AWS Marketplace.

**Find a paid AMI**

There are several ways that you can find AMIs that are available for you to purchase. For example, you can use AWS Marketplace, the Amazon EC2 console, or the command line. Alternatively, a developer might let you know about a paid AMI themselves.

**Find a paid AMI using the console**

**To find a paid AMI using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose AMIs.
3. Choose Public images for the first filter.
4. In the Search bar, choose Owner, then AWS Marketplace.
5. If you know the product code, choose Product Code, then type the product code.

**Find a paid AMI using AWS Marketplace**

**To find a paid AMI using AWS Marketplace**

1. Open AWS Marketplace.
2. Enter the name of the operating system in the search box, and click Go.
3. To scope the results further, use one of the categories or filters.
4. Each product is labeled with its product type: either AMI or Software as a Service.
Find a paid AMI using the AWS CLI

You can find a paid AMI using the following `describe-images` command (AWS CLI).

```bash
aws ec2 describe-images
  --owners aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The output from `describe-images` includes an entry for the product code like the following:

```json
"ProductCodes": [ 
  {
    "ProductCodeId": "product_code",
    "ProductCodeType": "marketplace"
  }
],
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```bash
aws ec2 describe-images
  --owners aws-marketplace \
  --filters "Name=product-code,Values=product_code" \
  --query "sort_by(Images, &CreationDate)[-1].[ImageId]"
```

Purchase a paid AMI

You must sign up for (purchase) a paid AMI before you can launch an instance using the AMI.

Typically a seller of a paid AMI presents you with information about the AMI, including its price and a link where you can buy it. When you click the link, you're first asked to log into AWS, and then you can purchase the AMI.

Purchase a paid AMI using the console

You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see Launch an AWS Marketplace instance (p. 497).

Subscribe to a product using AWS Marketplace

To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be subscribed to the product from which to launch the instance. There are two ways to subscribe to products in the AWS Marketplace:

- **AWS Marketplace website**: You can launch preconfigured software quickly with the 1-Click deployment feature.
- **Amazon EC2 launch wizard**: You can search for an AMI and launch an instance directly from the wizard. For more information, see Launch an AWS Marketplace instance (p. 497).

Get the product code for your instance

You can retrieve the AWS Marketplace product code for your instance using its instance metadata. For more information about retrieving metadata, see Instance metadata and user data (p. 606).
To retrieve a product code, use the following command:

**IMDSv2**

```
```

**IMDSv1**

```
```

If the instance has a product code, Amazon EC2 returns it.

**Use paid support**

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

**Important**

You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.

To associate a product code with your AMI, use one of the following commands, where **ami_id** is the ID of the AMI and **product_code** is the product code:

- **modify-image-attribute** (AWS CLI)
  
  ```
  aws ec2 modify-image-attribute --image-id ami_id --product-codes "product_code"
  ```

- **Edit-EC2ImageAttribute** (AWS Tools for Windows PowerShell)
  
  ```
  PS C:\> Edit-EC2ImageAttribute -ImageId ami_id -ProductCode product_code
  ```

After you set the product code attribute, it cannot be changed or removed.

**Bills for paid and supported AMIs**

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see Paying for products in the AWS Marketplace Buyer Guide.

**Manage your AWS Marketplace subscriptions**

On the AWS Marketplace website, you can check your subscription details, view the vendor's usage instructions, manage your subscriptions, and more.

**To check your subscription details**

1. Log in to the AWS Marketplace.
2. Choose **Your Marketplace Account**.
3. Choose **Manage your software subscriptions**.
4. All your current subscriptions are listed. Choose **Usage Instructions** to view specific instructions for using the product, for example, a user name for connecting to your running instance.

**To cancel an AWS Marketplace subscription**

1. Ensure that you have terminated any instances running from the subscription.
   a. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
   b. In the navigation pane, choose **Instances**.
   c. Select the instance, and choose **Actions, Instance State, Terminate**.
   d. Choose **Yes, Terminate** when prompted for confirmation.
2. Log in to the **AWS Marketplace**, and choose **Your Marketplace Account**, then **Manage your software subscriptions**.
3. Choose **Cancel subscription**. You are prompted to confirm your cancellation.

**Note**
After you've canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.

---

**AMI lifecycle**

**Topics**
- Create an AMI (p. 102)
- Copy an AMI (p. 138)
- Store and restore an AMI using S3 (p. 143)
- Deprecate an AMI (p. 148)
- Deregister your Linux AMI (p. 151)
- Automate the EBS-backed AMI lifecycle (p. 156)

**Create an AMI**

You can create Amazon EBS-back Linux AMIs and instance store-backed AMIs.

**Topics**
- Create an Amazon EBS-backed Linux AMI (p. 102)
- Create an instance store-backed Linux AMI (p. 107)

For information about how to create a Windows AMI, see [Create a custom Windows AMI](#).

**Create an Amazon EBS-backed Linux AMI**

To create an Amazon EBS-backed Linux AMI, start from an instance that you've launched from an existing Amazon EBS-backed Linux AMI. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the [AWS Server Migration Service](https://aws.amazon.com/migration/) or [VM Import/Export](https://aws.amazon.com/migration/), or any other AMI
you can access. After you customize the instance to suit your needs, create and register a new AMI, which you can use to launch new instances with these customizations.

The procedures described below work for Amazon EC2 instances backed by encrypted Amazon Elastic Block Store (Amazon EBS) volumes (including the root volume) as well as for unencrypted volumes.

The AMI creation process is different for instance store-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see Storage for the root device (p. 73). For more information about creating an instance store-backed Linux AMI, see Create an instance store-backed Linux AMI (p. 107).

For more information about creating an Amazon EBS-backed Windows AMI, see Create an Amazon EBS-backed Windows AMI in the Amazon EC2 User Guide for Windows Instances.

**Overview of creating Amazon EBS-backed AMIs**

First, launch an instance from an AMI that’s similar to the AMI that you’d like to create. You can connect to your instance and customize it. When the instance is configured correctly, ensure data integrity by stopping the instance before you create an AMI, then create the image. When you create an Amazon EBS-backed AMI, we automatically register it for you.

Amazon EC2 powers down the instance before creating the AMI to ensure that everything on the instance is stopped and in a consistent state during the creation process. If you’re confident that your instance is in a consistent state appropriate for AMI creation, you can tell Amazon EC2 not to power down and reboot the instance. Some file systems, such as XFS, can freeze and unfreeze activity, making it safe to create the image without rebooting the instance.

During the AMI-creation process, Amazon EC2 creates snapshots of your instance's root volume and any other EBS volumes attached to your instance. You’re charged for the snapshots until you deregister the AMI and delete the snapshots. For more information, see Deregister your Linux AMI (p. 151). If any volumes attached to the instance are encrypted, the new AMI only launches successfully on instances that support Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 1335).

Depending on the size of the volumes, it can take several minutes for the AMI-creation process to complete (sometimes up to 24 hours). You may find it more efficient to create snapshots of your volumes before creating your AMI. This way, only small, incremental snapshots need to be created when the AMI is created, and the process completes more quickly (the total time for snapshot creation remains the same). For more information, see Create Amazon EBS snapshots (p. 1231).

After the process completes, you have a new AMI and snapshot created from the root volume of the instance. When you launch an instance using the new AMI, we create a new EBS volume for its root volume using the snapshot.

If you add instance-store volumes or EBS volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. The instance-store volumes specified in the block device mapping for the new instance are new and don’t contain any data from the instance store volumes of the instance you used to create the AMI. The data on EBS volumes persists. For more information, see Block device mappings (p. 1441).

When you create a new instance from an EBS-backed AMI, you should initialize both its root volume and any additional EBS storage before putting it into production. For more information, see Initialize Amazon EBS volumes (p. 1381).

**Create a Linux AMI from an instance**

You can create an AMI using the AWS Management Console or the command line. The following diagram summarizes the process for creating an Amazon EBS-backed AMI from a running EC2 instance. Start with
an existing AMI, launch an instance, customize it, create a new AMI from it, and finally launch an instance of your new AMI. The steps in the following diagram match the steps in the procedure below.

**New console**

**To create an AMI from an instance using the console**

1. Select an appropriate EBS-backed AMI to serve as a starting point for your new AMI, and configure it as needed before launch. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

2. Choose Launch to launch an instance of the EBS-backed AMI that you've selected. Accept the default values as you step through the wizard. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

3. While the instance is running, connect to it. You can perform any of the following actions on your instance to customize it for your needs:
   - Install software and applications
   - Copy data
   - Reduce start time by deleting temporary files, defragmenting your hard drive, and zeroing out free space
   - Attach additional EBS volumes

4. (Optional) Create snapshots of all the volumes attached to your instance. For more information about creating snapshots, see Create Amazon EBS snapshots (p. 1231).

5. In the navigation pane, choose Instances, select your instance, and then choose Actions, Image and templates, Create image.

   **Tip**
   If this option is disabled, your instance isn't an Amazon EBS-backed instance.

6. On the Create image page, specify the following information, and then choose Create image.

   - **Image name** – A unique name for the image.
   - **Image description** – An optional description of the image, up to 255 characters.
   - **No reboot** – This option is not selected by default. Amazon EC2 shuts down the instance, takes snapshots of any attached volumes, creates and registers the AMI, and then reboots the instance. Select No reboot to avoid having your instance shut down.

   **Warning**
   If you select No reboot, the AMI will be crash consistent (all the volumes are snapshotted at the same time), but not application consistent (all the operating system buffers are not flushed to disk before the snapshots are created).

   - **Instance volumes** – The fields in this section enable you to modify the root volume, and add additional Amazon EBS and instance store volumes.
     - The root volume is defined in the first row. To change the size of the root volume, for **Size**, enter the required value.
Create an AMI

- If you select Delete on termination, when you terminate the instance created from this AMI, the EBS volume is deleted. If you clear Delete on termination, when you terminate the instance, the EBS volume is not deleted. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).
- To add an EBS volume, choose Add volume (which adds a new row). For Volume type, choose EBS, and fill in the fields in the row. When you launch an instance from your new AMI, additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.
- To add an instance store volume, see Add instance store volumes to an AMI (p. 1418). When you launch an instance from your new AMI, additional volumes are automatically initialized and mounted. These volumes do not contain data from the instance store volumes of the running instance on which you based your AMI.
- Tags – You can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.
  - To tag the AMI and the snapshots with the same tags, choose Tag image and snapshots together. The same tags are applied to the AMI and every snapshot that is created.
  - To tag the AMI and the snapshots with different tags, choose Tag image and snapshots separately. Different tags are applied to the AMI and the snapshots that are created. However, all the snapshots get the same tags; you can't tag each snapshot with a different tag.

To add a tag, choose Add tag, and enter the key and value for the tag. Repeat for each tag.

7. To view the status of your AMI while it is being created, in the navigation pane, choose AMIs. Initially, the status is pending but should change to available after a few minutes.

(Optional) To view the snapshot that was created for the new AMI, choose Snapshots. When you launch an instance from this AMI, we use this snapshot to create its root device volume.

8. Launch an instance from your new AMI. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

9. The new running instance contains all of the customizations that you applied in previous steps.

Old console

To create an AMI from an instance using the console

1. Select an appropriate EBS-backed AMI to serve as a starting point for your new AMI, and configure it as needed before launch. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

2. Choose Launch to launch an instance of the EBS-backed AMI that you've selected. Accept the default values as you step through the wizard. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

3. While the instance is running, connect to it. You can perform any of the following actions on your instance to customize it for your needs:
   - Install software and applications
   - Copy data
   - Reduce start time by deleting temporary files, defragmenting your hard drive, and zeroing out free space
   - Attach additional EBS volumes

4. (Optional) Create snapshots of all the volumes attached to your instance. For more information about creating snapshots, see Create Amazon EBS snapshots (p. 1231).

5. In the navigation pane, choose Instances, select your instance, and then choose Actions, Image, Create Image.
Tip
If this option is disabled, your instance isn’t an Amazon EBS-backed instance.

6. In the Create Image dialog box, specify the following information, and then choose Create Image.

- **Image name** – A unique name for the image.
- **Image description** – An optional description of the image, up to 255 characters.
- **No reboot** – This option is not selected by default. Amazon EC2 shuts down the instance, takes snapshots of any attached volumes, creates and registers the AMI, and then reboots the instance. Select No reboot to avoid having your instance shut down.

**Warning**
If you select No reboot, we can’t guarantee the file system integrity of the created image.

- **Instance Volumes** – The fields in this section enable you to modify the root volume, and add additional Amazon EBS and instance store volumes. For information about each field, pause on the icon next to each field to display field tooltips. Some important points are listed below.
  - To change the size of the root volume, locate Root in the Volume Type column, and for Size (GiB), type the required value.
  - If you select Delete on Termination, when you terminate the instance created from this AMI, the EBS volume is deleted. If you clear Delete on Termination, when you terminate the instance, the EBS volume is not deleted. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).
  - To add an EBS volume, choose Add New Volume (which adds a new row). For Volume Type, choose EBS, and fill in the fields in the row. When you launch an instance from your new AMI, additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.
  - To add an instance store volume, see Add instance store volumes to an AMI (p. 1418). When you launch an instance from your new AMI, additional volumes are automatically initialized and mounted. These volumes do not contain data from the instance store volumes of the running instance on which you based your AMI.

7. To view the status of your AMI while it is being created, in the navigation pane, choose AMIs. Initially, the status is pending but should change to available after a few minutes.

(Optional) To view the snapshot that was created for the new AMI, choose Snapshots. When you launch an instance from this AMI, we use this snapshot to create its root device volume.

8. Launch an instance from your new AMI. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

9. The new running instance contains all of the customizations that you applied in previous steps.

**To create an AMI from an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `create-image` (AWS CLI)
- `New-EC2Image` (AWS Tools for Windows PowerShell)

**Create a Linux AMI from a snapshot**

If you have a snapshot of the root device volume of an instance, you can create an AMI from this snapshot using the AWS Management Console or the command line.
To create an AMI from a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under Elastic Block Store, choose Snapshots.
3. Choose the snapshot and choose Actions, Create Image.
4. In the Create Image from EBS Snapshot dialog box, complete the fields to create your AMI, then choose Create. If you’re re-creating a parent instance, then choose the same options as the parent instance.
   - **Architecture**: Choose i386 for 32-bit or x86_64 for 64-bit.
   - **Root device name**: Enter the appropriate name for the root volume. For more information, see Device names on Linux instances (p. 1439).
   - **Virtualization type**: Choose whether instances launched from this AMI use paravirtual (PV) or hardware virtual machine (HVM) virtualization. For more information, see Linux AMI virtualization types (p. 75).
   - (PV virtualization type only) **Kernel ID** and **RAM disk ID**: Choose the AKI and ARI from the lists. If you choose the default AKI or don't choose an AKI, you must specify an AKI every time you launch an instance using this AMI. In addition, your instance may fail the health checks if the default AKI is incompatible with the instance.
   - (Optional) **Block Device Mappings**: Add volumes or expand the default size of the root volume for the AMI. For more information about resizing the file system on your instance for a larger volume, see Extend a Linux file system after resizing a volume (p. 1331).

To create an AMI from a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- register-image (AWS CLI)
- Register-EC2Image (AWS Tools for Windows PowerShell)

Launch an instance from an AMI you created

You can launch an instance from an AMI that you created from an instance or snapshot.

To launch an instance from your AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under Images, choose AMIs.
3. Set the filter to Owned by me and select your AMI.
5. Follow the wizard to launch your instance. For more information about each step in the wizard, see Launch an instance using the Launch Instance Wizard (p. 477).

Create an instance store-backed Linux AMI

The AMI that you specify when you launch your instance determines the type of root device volume.

To create an instance store-backed Linux AMI, start from an instance that you’ve launched from an existing instance store-backed Linux AMI. After you’ve customized the instance to suit your needs, bundle the volume and register a new AMI, which you can use to launch new instances with these customizations.
**Important**

Only the following instance types support an instance store volume as the root device: C3, D2, G2, I2, M3, and R3.

The AMI creation process is different for Amazon EBS-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see Storage for the root device (p. 73). If you need to create an Amazon EBS-backed Linux AMI, see Create an Amazon EBS-backed Linux AMI (p. 102).

**Overview of the creation process for instance store-backed AMIs**

The following diagram summarizes the process of creating an AMI from an instance store-backed instance.

![Diagram of the AMI creation process](image)

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, you can bundle it. It takes several minutes for the bundling process to complete. After the process completes, you have a bundle, which consists of an image manifest (`image.manifest.xml`) and files (`image.part.xx`) that contain a template for the root volume. Next you upload the bundle to your Amazon S3 bucket and then register your AMI.

When you launch an instance using the new AMI, we create the root volume for the instance using the bundle that you uploaded to Amazon S3. The storage space used by the bundle in Amazon S3 incurs charges to your account until you delete it. For more information, see Deregister your Linux AMI (p. 151).

If you add instance store volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. For more information, see Block device mappings (p. 1441).

**Prerequisites**

Before you can create an AMI, you must complete the following tasks:

- Install the AMI tools. For more information, see Set up the AMI tools (p. 109).
- Install the AWS CLI. For more information, see Getting Set Up with the AWS Command Line Interface.
- Ensure that you have an Amazon S3 bucket for the bundle. To create an Amazon S3 bucket, open the Amazon S3 console and click **Create Bucket**. Alternatively, you can use the AWS CLI `mb` command.
- Ensure that you have your AWS account ID. For more information, see AWS Account Identifiers in the AWS General Reference.
- Ensure that you have your access key ID and secret access key. For more information, see Access Keys in the AWS General Reference.
• Ensure that you have an X.509 certificate and corresponding private key.
  • If you need to create an X.509 certificate, see Manage signing certificates (p. 111). The X.509 certificate and private key are used to encrypt and decrypt your AMI.
  • [China (Beijing)] Use the $EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-cn-north-1.pem certificate.
  • [AWS GovCloud (US-West)] Use the $EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-gov.pem certificate.
• Connect to your instance and customize it. For example, you can install software and applications, copy data, delete temporary files, and modify the Linux configuration.

Tasks
• Set up the AMI tools (p. 109)
• Create an AMI from an instance store-backed Amazon Linux instance (p. 112)
• Create an AMI from an instance store-backed Ubuntu instance (p. 114)
• Convert your instance store-backed AMI to an Amazon EBS-backed AMI (p. 118)

Set up the AMI tools
You can use the AMI tools to create and manage instance store-backed Linux AMIs. To use the tools, you must install them on your Linux instance. The AMI tools are available as both an RPM and as a .zip file for Linux distributions that don’t support RPM.

To set up the AMI tools using the RPM
1. Install Ruby using the package manager for your Linux distribution, such as yum. For example:

   [ec2-user ~]$ sudo yum install -y ruby

2. Download the RPM file using a tool such as wget or curl. For example:

3. Verify the RPM file's signature using the following command:

   [ec2-user ~]$ rpm -K ec2-ami-tools.noarch.rpm

   The command above should indicate that the file's SHA1 and MD5 hashes are OK. If the command indicates that the hashes are NOT OK, use the following command to view the file's Header SHA1 and MD5 hashes:

   [ec2-user ~]$ rpm -Kv ec2-ami-tools.noarch.rpm

   Then, compare your file's Header SHA1 and MD5 hashes with the following verified AMI tools hashes to confirm the file's authenticity:

   • Header SHA1: a1f662d6f25f69871104e6a62187fa4df508f880
   • MD5: 9faff05258064e2f7909b66142de6782

   If your file's Header SHA1 and MD5 hashes match the verified AMI tools hashes, continue to the next step.
4. Install the RPM using the following command:
5. Verify your AMI tools installation using the `ec2-ami-tools-version (p. 122)` command.

5. Verify your AMI tools installation using the `ec2-ami-tools-version (p. 122)` command.

| [ec2-user ~]# sudo yum install ec2-ami-tools.noarch.rpm |

Note
If you receive a load error such as "cannot load such file -- ec2/amitools/version (LoadError)" complete the next step to add the location of your AMI tools installation to your RUBYLIB path.

6. (Optional) If you received an error in the previous step, add the location of your AMI tools installation to your RUBYLIB path.

   a. Run the following command to determine the paths to add.

   | [ec2-user ~]# rpm -qil ec2-ami-tools | grep ec2/amitools/version |
   | /usr/lib/ruby/site_ruby/ec2/amitools/version.rb |
   | /usr/lib64/ruby/site_ruby/ec2/amitools/version.rb |

   In the above example, the missing file from the previous load error is located at /usr/lib/ruby/site_ruby and /usr/lib64/ruby/site_ruby.

   b. Add the locations from the previous step to your RUBYLIB path.

   | [ec2-user ~]# export RUBYLIB=$RUBYLIB:/usr/lib/ruby/site_ruby:/usr/lib64/ruby/site_ruby |

   c. Verify your AMI tools installation using the `ec2-ami-tools-version (p. 122)` command.

   | [ec2-user ~]# ec2-ami-tools-version |

To set up the AMI tools using the .zip file

1. Install Ruby and unzipping using the package manager for your Linux distribution, such as `apt-get`. For example:

   | [ec2-user ~]# sudo apt-get update -y && sudo apt-get install -y ruby unzip |

2. Download the .zip file using a tool such as wget or curl. For example:

   | [ec2-user ~]# wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.zip |

3. Unzip the files into a suitable installation directory, such as /usr/local/ec2.

   | [ec2-user ~]# sudo mkdir -p /usr/local/ec2 |
   | $ sudo unzip ec2-ami-tools.zip -d /usr/local/ec2 |

   Notice that the .zip file contains a folder `ec2-ami-tools-x.x.x`, where `x.x.x` is the version number of the tools (for example, `ec2-ami-tools-1.5.7`).

4. Set the `EC2_AMITOOL_HOME` environment variable to the installation directory for the tools. For example:

   | [ec2-user ~]# export EC2_AMITOOL_HOME=/usr/local/ec2/ec2-ami-tools-x.x.x |
5. Add the tools to your `PATH` environment variable. For example:

```
[ec2-user ~]$ export PATH=$EC2_AMITOOL_HOME/bin:$PATH
```

6. You can verify your AMI tools installation using the `ec2-ami-tools-version` command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

**Manage signing certificates**

Certain commands in the AMI tools require a signing certificate (also known as X.509 certificate). You must create the certificate and then upload it to AWS. For example, you can use a third-party tool such as OpenSSL to create the certificate.

**To create a signing certificate**

1. Install and configure OpenSSL.
2. Create a private key using the `openssl genrsa` command and save the output to a `.pem` file. We recommend that you create a 2048- or 4096-bit RSA key.

```
openssl genrsa 2048 > private-key.pem
```

3. Generate a certificate using the `openssl req` command.

```
openssl req -new -x509 -nodes -sha256 -days 365 -key private-key.pem -outform PEM -out certificate.pem
```

To upload the certificate to AWS, use the `upload-signing-certificate` command.

```
aws iam upload-signing-certificate --user-name user-name --certificate-body file://path/to/certificate.pem
```

To list the certificates for a user, use the `list-signing-certificates` command:

```
aws iam list-signing-certificates --user-name user-name
```

To disable or re-enable a signing certificate for a user, use the `update-signing-certificate` command. The following command disables the certificate:

```
aws iam update-signing-certificate --certificate-id OFHPLP4ZULTHYPMSYEX7O4BEXAMPLE --status Inactive --user-name user-name
```

To delete a certificate, use the `delete-signing-certificate` command:

```
aws iam delete-signing-certificate --user-name user-name --certificate-id OFHPLP4ZULTHYPMSYEX7O4BEXAMPLE
```

**Create an AMI from an instance store-backed instance**

The following procedures are for creating an instance store-backed AMI from an instance store-backed instance. Before you begin, ensure that you've read the Prerequisites (p. 108).

**Topics**

- Create an AMI from an instance store-backed Amazon Linux instance (p. 112)
Create an AMI from an instance store-backed Ubuntu instance (p. 114)

Create an AMI from an instance store-backed Amazon Linux instance

This section describes the creation of an AMI from an Amazon Linux instance. The following procedures may not work for instances running other Linux distributions. For Ubuntu-specific procedures, see Create an AMI from an instance store-backed Ubuntu instance (p. 114).

To prepare to use the AMI tools (HVM instances only)

1. The AMI tools require GRUB Legacy to boot properly. Use the following command to install GRUB:

   [ec2-user ~]$
   sudo yum install -y grub

2. Install the partition management packages with the following command:

   [ec2-user ~]$
   sudo yum install -y gdisk kpartx parted

To create an AMI from an instance store-backed Amazon Linux instance

This procedure assumes that you have satisfied the prerequisites in Prerequisites (p. 108).

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.
   a. Create a temporary directory on your instance for your credentials as follows:

      [ec2-user ~]$
      mkdir /tmp/cert

   This enables you to exclude your credentials from the created image.
   b. Copy your X.509 certificate and corresponding private key from your computer to the /tmp/cert directory on your instance using a secure copy tool such as scp (p. 503). The \(-i \text{my-private-key}.pem\) option in the following \(scp\) command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

      you@your_computer:~ $ scp -i my-private-key.pem /
      path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /
      path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
      user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
      pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100%  717     0.7KB/s   00:00
      cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100%  685     0.7KB/s   00:00

   Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

   2. Prepare the bundle to upload to Amazon S3 by running the \(ec2-bundle-vol\) (p. 124) command from inside your instance. Be sure to specify the \(-e\) option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include *,.sw, *.swo, *.swp, *.pem, *.priv, *.id_rsa*, *.id_dsa* *.gpg, */.jks, */.ssh/authorized_keys, and */.bash_history. To include all of these files, use the \(--no-filter\) option. To include some of these files, use the \(--include\) option.

   \textbf{Important}
   
   By default, the AMI bundling process creates a compressed, encrypted collection of files in the /tmp directory that represents your root volume. If you do not have enough free
disk space in /tmp to store the bundle, you need to specify a different location for the bundle to be stored with the -d /path/to/bundle/storage option. Some instances have ephemeral storage mounted at /mnt or /media/ephemeral0 that you can use, or you can also create (p. 1199), attach (p. 1202), and mount (p. 1208) a new Amazon Elastic Block Store (Amazon EBS) volume to store the bundle.

a. You must run the **ec2-bundle-vol** command as root. For most commands, you can use **sudo** to gain elevated permissions, but in this case, you should run **sudo -E su** to keep your environment variables.

```
[ec2-user ~]$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
[root ec2-user]#
```

b. To create the AMI bundle, run the **ec2-bundle-vol** (p. 124) command as follows:

```
[root ec2-user]# ec2-bundle-vol -k /tmp/cert/ HKZYKTAI2ECKXYTBH3HXYV42BEXAMPLE.pem -c /tmp/cert/ HKZYKTAI2ECKXYTBH3HXYV42BEXAMPLE.pem -u 123456789012 -r x86_64 -e /tmp/cert --partition gpt
```

**Note**
For the China (Beijing) and AWS GovCloud (US-West) Regions, use the --ec2cert parameter and specify the certificates as per the prerequisites (p. 108).

It can take a few minutes to create the image. When this command completes, your /tmp (or non-default) directory contains the bundle (image.manifest.xml, plus multiple image.part.xx files).

c. Exit from the root shell.

```
[root ec2-user]# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the image.manifest.xml file for your AMI. For more information, see Block device mappings (p. 1441).

a. Create a backup of your image.manifest.xml file.

```
[ec2-user ~]$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

b. Reformat the image.manifest.xml file so that it is easier to read and edit.

```
[ec2-user ~]$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/ image.manifest.xml
```

c. Edit the block device mappings in image.manifest.xml with a text editor. The example below shows a new entry for the ephemeral0 instance store volume.

**Note**
For a list of excluded files, see **ec2-bundle-vol** (p. 124).

```xml
<block_device_mapping>
  <mapping>
    <virtual>ami</virtual>
```

```
d. Save the `image.manifest.xml` file and exit your text editor.

4. To upload your bundle to Amazon S3, run the `ec2-upload-bundle` (p. 135) command as follows.

    ```
    [ec2-user ~]$ ec2-upload-bundle -b my-s3-bucket/bundle_folder/bundle_name -m /tmp/image.manifest.xml -a your_access_key_id -s your_secret_access_key
    ```

    **Important**
    To register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

    ```
    [ec2-user ~]$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
    ```

    **Important**
    If you specified a path with the `--bundle-storage` option in Step 2 (p. 112), use that path instead of `/tmp`.

6. To register your AMI, run the `register-image` command as follows.

    ```
    [ec2-user ~]$ aws ec2 register-image --image-location my-s3-bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-type hvm
    ```

    **Important**
    If you previously specified a Region for the `ec2-upload-bundle` (p. 135) command, specify that Region again for this command.

**Create an AMI from an instance store-backed Ubuntu instance**

This section describes the creation of an AMI from an Ubuntu Linux instance with an instance store volume as the root volume. The following procedures may not work for instances running other Linux distributions. For procedures specific to Amazon Linux, see Create an AMI from an instance store-backed Amazon Linux instance (p. 112).

**To prepare to use the AMI tools (HVM instances only)**

The AMI tools require GRUB Legacy to boot properly. However, Ubuntu is configured to use GRUB 2. You must check to see that your instance uses GRUB Legacy, and if not, you need to install and configure it.

HVM instances also require partitioning tools to be installed for the AMI tools to work properly.
1. GRUB Legacy (version 0.9x or less) must be installed on your instance. Check to see if GRUB Legacy is present and install it if necessary.

   a. Check the version of your GRUB installation.

   ```
   ubuntu:~$ grub-install --version
   grub-install (GRUB) 1.99-21ubuntu3.10
   ```

   In this example, the GRUB version is greater than 0.9x, so you must install GRUB Legacy. Proceed to Step 1.b (p. 115). If GRUB Legacy is already present, you can skip to Step 2 (p. 115).

   b. Install the `grub` package using the following command.

   ```
   ubuntu:~$ sudo apt-get install -y grub
   ```

2. Install the following partition management packages using the package manager for your distribution.

   • `gdisk` (some distributions may call this package `gptfdisk` instead)
   • `kpartx`
   • `parted`

   Use the following command.

   ```
   ubuntu:~$ sudo apt-get install -y gdisk kpartx parted
   ```

3. Check the kernel parameters for your instance.

   ```
   ubuntu:~$ cat /proc/cmdline
   Boot_IMAGE=/boot/vmlinuz-3.2.0-54-virtual root=UUID=4f392932-ed93-4f8f-aee7-72bc5bb6ca9d ro console=ttyS0 xen_emul_unplug=unnecessary
   ```

   Note the options following the kernel and root device parameters: `ro`, `console=ttyS0`, and `xen_emul_unplug=unnecessary`. Your options may differ.

4. Check the kernel entries in `/boot/grub/menu.lst`.

   ```
   ubuntu:~$ grep ^kernel /boot/grub/menu.lst
   kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=hvc0
   kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
   kernel /boot/memtest86+.bin
   ```

   Note that the `console` parameter is pointing to `hvc0` instead of `ttyS0` and that the `xen_emul_unplug=unnecessary` parameter is missing. Again, your options may differ.

5. Edit the `/boot/grub/menu.lst` file with your favorite text editor (such as `vim` or `nano`) to change the console and add the parameters you identified earlier to the boot entries.

   ```
   title Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual
   root (hd0)
   kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=ttyS0 xen_emul_unplug=unnecessary
   initrd /boot/initrd.img-3.2.0-54-virtual
   ```
Create an AMI

6. Verify that your kernel entries now contain the correct parameters.

```
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro
console=ttyS0 xen_emul_unplug=unnecessary
initrd /boot/initrd.img-3.2.0-54-virtual
```

7. [For Ubuntu 14.04 and later only] Starting with Ubuntu 14.04, instance store backed Ubuntu AMIs use a GPT partition table and a separate EFI partition mounted at /boot/efi. The `ec2-bundle-vol` command will not bundle this boot partition, so you need to comment out the `/etc/fstab` entry for the EFI partition as shown in the following example.

```
LABEL=cloudimg-rootfs / ext4 defaults 0 0
LABEL=UEFI /boot/efi vfat defaults 0 0
/dev/xvdb /mnt auto defaults,nobootwait,comment=cloudconfig 0 2
```

To create an AMI from an instance store-backed Ubuntu instance

This procedure assumes that you have satisfied the prerequisites in Prerequisites (p. 108).

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.

   a. Create a temporary directory on your instance for your credentials as follows:

   ```
   ubuntu:~$ mkdir /tmp/cert
   ```

   This enables you to exclude your credentials from the created image.

   b. Copy your X.509 certificate and private key from your computer to the `/tmp/cert` directory on your instance, using a secure copy tool such as `scp` (p. 503). The `-i my-private-key.pem` option in the following `scp` command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

   ```
   you@your_computer:~ $ scp -i my-private-key.pem /path/to/pk-HKZYKTAIG2ECMXYIHB3HXV42BEXAMPLE.pem /path/to/cert-HKZYKTAIG2ECMXYIHB3HXV42BEXAMPLE.pem ec2-user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
   ```

   Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in `/tmp/cert`.

2. Prepare the bundle to upload to Amazon S3 by running the `ec2-bundle-vol` command from your instance. Be sure to specify the `-e` option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*`, `*.gpg`, `*.jks`,...
important
by default, the AMI bundling process creates a compressed, encrypted collection of files in the /tmp directory that represents your root volume. If you do not have enough free disk space in /tmp to store the bundle, you need to specify a different location for the bundle to be stored with the --d /path/to/bundle/storage option. Some instances have ephemeral storage mounted at /mnt or /media/ephemeral0 that you can use, or you can also create (p. 1199), attach (p. 1202), and mount (p. 1208) a new Amazon Elastic Block Store (Amazon EBS) volume to store the bundle.

a. you must run the ec2-bundle-vol command needs as root. For most commands, you can use sudo to gain elevated permissions, but in this case, you should run sudo -E su to keep your environment variables.

ubuntu:~$ sudo -E su

note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

root@ubuntu:#

b. to create the AMI bundle, run the ec2-bundle-vol (p. 124) command as follows.

root@ubuntu:~# ec2-bundle-vol -k /tmp/cert/ pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u your_aws_account_id -r x86_64 -e /tmp/cert --partition gpt

important
for Ubuntu 14.04 and later HVM instances, add the --partition mbr flag to bundle the boot instructions properly; otherwise, your newly-created AMI will not boot.

It can take a few minutes to create the image. When this command completes, your tmp directory contains the bundle (image.manifest.xml, plus multiple image.part.xx files).

c. exit from the root shell.

root@ubuntu:~# exit

3. (optional) to add more instance store volumes, edit the block device mappings in the image.manifest.xml file for your AMI. For more information, see Block device mappings (p. 1441).

a. create a backup of your image.manifest.xml file.

ubuntu:~$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak

b. reformat the image.manifest.xml file so that it is easier to read and edit.

ubuntu:~$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/image.manifest.xml

c. edit the block device mappings in image.manifest.xml with a text editor. The example below shows a new entry for the ephemeral01 instance store volume.

<block_device_mapping>
  <mapping>
  </mapping>
</block_device_mapping>
Create an AMI

```xml
<block_device_mapping>
    <mapping>
        <virtual>ami</virtual>
        <device>sda</device>
    </mapping>
    <mapping>
        <virtual>ephemeral0</virtual>
        <device>sdb</device>
    </mapping>
    <mapping>
        <virtual>ephemeral1</virtual>
        <device>sdc</device>
    </mapping>
    <mapping>
        <virtual>root</virtual>
        <device>/dev/sda1</device>
    </mapping>
</block_device_mapping>
```

d. Save the `image.manifest.xml` file and exit your text editor.

4. To upload your bundle to Amazon S3, run the `ec2-upload-bundle` (p. 135) command as follows.

```bash
ubuntu:~$ ec2-upload-bundle -b my-s3-bucket/bundle_folder/bundle_name -m /tmp/image.manifest.xml -a your_access_key_id -s your_secret_access_key
```

**Important**
If you intend to register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

```bash
ubuntu:~$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

**Important**
If you specified a path with the `-d /path/to/bundle/storage` option in Step 2 (p. 116), use that same path below, instead of `/tmp`.

6. To register your AMI, run the `register-image` AWS CLI command as follows.

```bash
ubuntu:~$ aws ec2 register-image --image-location my-s3-bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-type hvm
```

**Important**
If you previously specified a Region for the `ec2-upload-bundle` (p. 135) command, specify that Region again for this command.

7. [Ubuntu 14.04 and later] Uncomment the EFI entry in `/etc/fstab`; otherwise, your running instance will not be able to reboot.

Convert your instance store-backed AMI to an Amazon EBS-backed AMI

You can convert an instance store-backed Linux AMI that you own to an Amazon EBS-backed Linux AMI.

**Important**
You cannot convert an instance store-backed Windows AMI to an Amazon EBS-backed Windows AMI and you cannot convert an AMI that you do not own.
To convert an instance store-backed AMI to an Amazon EBS-backed AMI

1. Launch an Amazon Linux instance from an Amazon EBS-backed AMI. For more information, see Launch an instance using the Launch Instance Wizard (p. 477). Amazon Linux instances have the AWS CLI and AMI tools pre-installed.

2. Upload the X.509 private key that you used to bundle your instance store-backed AMI to your instance. We use this key to ensure that only you and Amazon EC2 can access your AMI.
   a. Create a temporary directory on your instance for your X.509 private key as follows:

   ```bash
   [ec2-user ~]$ mkdir /tmp/cert
   ```
   
   b. Copy your X.509 private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as `scp` (p. 503). The `my-private-key` parameter in the following command is the private key you use to connect to your instance with SSH. For example:

   ```bash
   you@your_computer:$ scp -i /path/to/pk-HKZYKTAIG2ECMXYIB3HXV4ZBEXAMPLE.pem ec2-user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/pk-HKZYKTAIG2ECMXYIB3HXV4ZBEXAMPLE.pem
   ```

3. Set environment variables for your AWS access key and secret key.

   ```bash
   [ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id
   [ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key
   ```

4. Prepare an Amazon Elastic Block Store (Amazon EBS) volume for your new AMI.
   a. Create an empty EBS volume in the same Availability Zone as your instance using the `create-volume` command. Note the volume ID in the command output.

   ```bash
   [ec2-user ~]$ aws ec2 create-volume --size 10 --region us-west-2 --availability-zone us-west-2b
   ```

   b. Attach the volume to your Amazon EBS-backed instance using the `attach-volume` command.

   ```bash
   [ec2-user ~]$ aws ec2 attach-volume --volume-id volume_id --instance-id instance_id --device /dev/sdb --region us-west-2
   ```

5. Create a folder for your bundle.

   ```bash
   [ec2-user ~]$ mkdir /tmp/bundle
   ```

6. Download the bundle for your instance store-based AMI to /tmp/bundle using the `ec2-download-bundle` (p. 130) command.

   ```bash
   [ec2-user ~]$ ec2-download-bundle -b my-s3-bucket/bundle_folder/bundle_name -m image.manifest.xml -a $AWS_ACCESS_KEY_ID -s $AWS_SECRET_ACCESS_KEY --privatekey /path/to/pk-HKZYKTAIG2ECMXYIB3HXV4ZBEXAMPLE.pem -d /tmp/bundle
   ```

7. Reconstitute the image file from the bundle using the `ec2-unbundle` (p. 134) command.
   a. Change directories to the bundle folder.
b. Run the `ec2-unbundle` (p. 134) command.

```bash
[ec2-user bundle]$ ec2-unbundle -m image.manifest.xml --privatekey /path/to/pk-HKZYKTA1G2ECMXYTBN3HXXY4ZBEXAMPLE.pem
```

8. Copy the files from the unbundled image to the new EBS volume.

```bash
[ec2-user bundle]$ sudo dd if=/tmp/bundle/image of=/dev/sdb bs=1M
```

9. Probe the volume for any new partitions that were unbundled.

```bash
[ec2-user bundle]$ sudo partprobe /dev/sdb1
```

10. List the block devices to find the device name to mount.

```bash
[ec2-user bundle]$ lsblk
NAME          MAJ:MIN   RK  SIZE  NW   TYPE MOUNTPOINT
/dev/sda      202:0    0  8G    0 disk
  /dev/sda1    202:1    0  8G    0 part /
/dev/sdb      202:80   0 10G    0 disk
  /dev/sdb1    202:81   0 10G    0 part
```

In this example, the partition to mount is `/dev/sdb1`, but your device name will likely be different. If your volume is not partitioned, then the device to mount will be similar to `/dev/sdb` (without a device partition trailing digit).

11. Create a mount point for the new EBS volume and mount the volume.

```bash
[ec2-user bundle]$ sudo mkdir /mnt/ebs
[ec2-user bundle]$ sudo mount /dev/sdb1 /mnt/ebs
```

12. Open the `/etc/fstab` file on the EBS volume with your favorite text editor (such as `vim` or `nano`) and remove any entries for instance store (ephemeral) volumes. Because the EBS volume is mounted on `/mnt/ebs`, the `fstab` file is located at `/mnt/ebs/etc/fstab`.

```bash
[ec2-user bundle]$ sudo nano /mnt/ebs/etc/fstab
# LABEL=/     /           ext4    defaults,noatime  1   1
tmpfs        /dev/shm    tmpfs    defaults  0   0
devpts       /dev/pts    devpts  gid=5,mode=620  0   0
sysfs        /sys        sysfs   defaults  0   0
proc         /proc       proc    defaults  0   0
/dev/sdb2    /media/ephemeral0 auto    defaults,comment=cloudconfig 0 2
```

In this example, the last line should be removed.

13. Unmount the volume and detach it from the instance.

```bash
[ec2-user bundle]$ sudo umount /mnt/ebs
[ec2-user bundle]$ aws ec2 detach-volume --volume-id volume_id --region us-west-2
```

14. Create an AMI from the new EBS volume as follows.

a. Create a snapshot of the new EBS volume.

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --volume-id volume_id --region us-west-2
```
Create an AMI

b. Check to see that your snapshot is complete.

```bash
[ec2-user bundle]$ aws ec2 describe-snapshots --region us-west-2 --snapshot-id snapshot_id
```

c. Identify the processor architecture, virtualization type, and the kernel image (aki) used on the original AMI with the `describe-images` command. You need the AMI ID of the original instance store-backed AMI for this step.

```bash
[ec2-user bundle]$ aws ec2 describe-images --region us-west-2 --image-id ami-id --output text
```

| IMAGES | x86_64 amazon/amzn-ami-pv-2013.09.2.x86_64-s3 ami-8ef297be amazon available public machine aki-fc8f11cc instance-store paravirtual xen |

In this example, the architecture is x86_64 and the kernel image ID is aki-fc8f11cc. Use these values in the following step. If the output of the above command also lists an ari ID, take note of that as well.

d. Register your new AMI with the snapshot ID of your new EBS volume and the values from the previous step. If the previous command output listed an ari ID, include that in the following command with `--ramdisk-id ari_id`.

```bash
[ec2-user bundle]$ aws ec2 register-image --region us-west-2 --name your_new_ami_name --block-device-mappings DeviceName=device-name,Ebs={SnapshotId=snapshot_id} --virtualization-type paravirtual --architecture x86_64 --kernel-id aki-fc8f11cc --root-device-name device-name
```

15. (Optional) After you have tested that you can launch an instance from your new AMI, you can delete the EBS volume that you created for this procedure.

```bash
aws ec2 delete-volume --volume-id volume_id
```

AMI tools reference

You can use the AMI tools commands to create and manage instance store-backed Linux AMIs. To set up the tools, see Set up the AMI tools (p. 109).

For information about your access keys, see Best Practices for Managing AWS Access Keys.

Commands

- ec2-ami-tools-version (p. 122)
- ec2-bundle-image (p. 122)
- ec2-bundle-vol (p. 124)
- ec2-delete-bundle (p. 128)
- ec2-download-bundle (p. 130)
- ec2-migrate-manifest (p. 132)
- ec2-unbundle (p. 134)
- ec2-upload-bundle (p. 135)
- Common options for AMI tools (p. 137)
ec2-ami-tools-version

Description
Describes the version of the AMI tools.

Syntax
ec2-ami-tools-version

Output
The version information.

Example
This example command displays the version information for the AMI tools that you're using.

[ec2-user ~]# ec2-ami-tools-version
1.5.2 20071010

ec2-bundle-image

Description
Creates an instance store-backed Linux AMI from an operating system image created in a loopback file.

Syntax
ec2-bundle-image -c path -k path -u account -i path [-d path] [--ec2cert path] [--productcodes code1,code2,...] [-B mapping] [-p prefix]

Options
-c, --cert path
The user's PEM encoded RSA public key certificate file.
Required: Yes
-k, --privatekey path
The path to a PEM-encoded RSA key file. You'll need to specify this key to unbundle this bundle, so keep it in a safe place. Note that the key doesn't have to be registered to your AWS account.
Required: Yes
-u, --user account
The user's AWS account ID, without dashes.
Required: Yes
-i, --image path
The path to the image to bundle.
Required: Yes
-d, --destination path
The directory in which to create the bundle.
Default: /tmp
Required: No

--ec2cert path

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the
path to that certificate must be specified with this option. The path to the certificate varies based
on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/
aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file
in Set up the AMI tools (p. 109), the certificates are located at $EC2_AMITOOL_HOME/etc/ec2/
amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch architecture

Image architecture. If you don’t provide the architecture on the command line, you’ll be prompted
for it when bundling starts.

Valid values: i386 | x86_64
Required: No

--productcodes code1,code2,...

Product codes to attach to the image at registration time, separated by commas.
Required: No

-B, --block-device-mapping mapping

Defines how block devices are exposed to an instance of this AMI if its instance type supports the
specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is
the corresponding device name. Virtual names include the following:
• ami—The root file system device, as seen by the instance
• root—The root file system device, as seen by the kernel
• swap—The swap device, as seen by the instance
• ephemeralN—The Nth instance store volume

Required: No

-p, --prefix prefix

The filename prefix for bundled AMI files.

Default: The name of the image file. For example, if the image path is /var/spool/my-image/
version-2/debian.img, then the default prefix is debian.img.

Required: No

--kernel kernel_id

Deprecated. Use register-image to set the kernel.

Required: No

--ramdisk ramdisk_id

Deprecated. Use register-image to set the RAM disk if required.
Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example creates a bundled AMI from an operating system image that was created in a loopback file.

```
[ec2-user ~]$ ec2-bundle-image -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -i image.img -d bundled/ -r x86_64
Please specify a value for arch [i386]:
Bundling image file...
Splitting bundled/image.gz.crypt...
Created image.part.00
Created image.part.01
Created image.part.02
Created image.part.03
Created image.part.04
Created image.part.05
Created image.part.06
Created image.part.07
Created image.part.08
Created image.part.09
Created image.part.10
Created image.part.11
Created image.part.12
Created image.part.13
Created image.part.14
Generating digests for each part...
Digests generated.
Creating bundle manifest...
ec2-bundle-image complete.
```

e2-bundle-vol

Description

Creates an instance store-backed Linux AMI by compressing, encrypting, and signing a copy of the root device volume for the instance.

Amazon EC2 attempts to inherit product codes, kernel settings, RAM disk settings, and block device mappings from the instance.

By default, the bundle process excludes files that might contain sensitive information. These files include *,sw,* .sw,.sw,.swo,*.swp,*..pem,*.priv,*id_rsa,*id_dsa* *.gpg,*.jks, */.ssh/authorized_keys, and */.bash_history. To include all of these files, use the --no-filter option. To include some of these files, use the --include option.

For more information, see Create an instance store-backed Linux AMI (p. 107).

Syntax

```
```
Options

-c, --cert path

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey path

The path to the user's PEM-encoded RSA key file.

Required: Yes

-u, --user account

The user's AWS account ID, without dashes.

Required: Yes

-d, --destination destination

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert path

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in Set up the AMI tools (p. 109), the certificates are located at $EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch architecture

The image architecture. If you don't provide this on the command line, you'll be prompted to provide it when the bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes code1,code2,...

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping mapping

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:
• ami—The root file system device, as seen by the instance
• root—The root file system device, as seen by the kernel
Create an AMI

- swap—The swap device, as seen by the instance
- ephemeralN—The Nth instance store volume

Required: No
-a, --all

Bundle all directories, including those on remotely mounted file systems.

Required: No
-e, --exclude directory1,directory2,...

A list of absolute directory paths and files to exclude from the bundle operation. This parameter overrides the --all option. When exclude is specified, the directories and subdirectories listed with the parameter will not be bundled with the volume.

Required: No
-i, --include file1,file2,...

A list of files to include in the bundle operation. The specified files would otherwise be excluded from the AMI because they might contain sensitive information.

Required: No
--no-filter

If specified, we won't exclude files from the AMI because they might contain sensitive information.

Required: No
-p, --prefix prefix

The file name prefix for bundled AMI files.

Default: image
Required: No
-s, --size size

The size, in MB (1024 * 1024 bytes), of the image file to create. The maximum size is 10240 MB.

Default: 10240
Required: No
--[no-]inherit

Indicates whether the image should inherit the instance's metadata (the default is to inherit). Bundling fails if you enable --inherit but the instance metadata is not accessible.

Required: No
-v, --volume volume

The absolute path to the mounted volume from which to create the bundle.

Default: The root directory (/)
Required: No
-P, --partition type

Indicates whether the disk image should use a partition table. If you don't specify a partition table type, the default is the type used on the parent block device of the volume, if applicable, otherwise the default is gpt.
Valid values: mbr | gpt | none

Required: No

--script script

A customization script to be run right before bundling. The script must expect a single argument, the
mount point of the volume.

Required: No

--fstab path

The path to the fstab to bundle into the image. If this is not specified, Amazon EC2 bundles /etc/
fstab.

Required: No

--generate-fstab

Bundles the volume using an Amazon EC2-provided fstab.

Required: No

--grub-config

The path to an alternate grub configuration file to bundle into the image. By default, ec2-bundle-
vol expects either /boot/grub/menu.lst or /boot/grub/grub.conf to exist on the cloned
image. This option allows you to specify a path to an alternative grub configuration file, which will
then be copied over the defaults (if present).

Required: No

--kernel kernel_id

Deprecated. Use register-image to set the kernel.

Required: No

--ramdisk ramdisk_id

Deprecated. Use register-image to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling.

Example

This example creates a bundled AMI by compressing, encrypting and signing a snapshot of the local
machine’s root file system.

```
[ec2-user ~]$ ec2-bundle-vol -d /mnt -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -r x86_64

```

**ec2-delete-bundle**

**Description**

Deletes the specified bundle from Amazon S3 storage. After you delete a bundle, you can't launch instances from the corresponding AMI.

**Syntax**

```
```

**Options**

- **-b, --bucket** `bucket`
  
  The name of the Amazon S3 bucket containing the bundled AMI, followed by an optional ‘/’-delimited path prefix
  
  Required: Yes

- **-a, --access-key** `access_key_id`
  
  The AWS access key ID.
  
  Required: Yes

- **-s, --secret-key** `secret_access_key`
  
  The AWS secret access key.
  
  Required: Yes

- **-t, --delegation-token** `token`
  
  The delegation token to pass along to the AWS request. For more information, see the [Using Temporary Security Credentials](#).
  
  Required: Only when you are using temporary security credentials.
Default: The value of the `AWS_DELEGATION_TOKEN` environment variable (if set).

`--region region`

The Region to use in the request signature.

Default: us-east-1

Required: Required if using signature version 4

`--sigversion version`

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

`-m, --manifest path`

The path to the manifest file.

Required: You must specify `--prefix` or `--manifest`.

`-p, --prefix prefix`

The bundled AMI filename prefix. Provide the entire prefix. For example, if the prefix is image.img, use `-p image.img` and not `-p image`.

Required: You must specify `--prefix` or `--manifest`.

`--clear`

Deletes the Amazon S3 bucket if it's empty after deleting the specified bundle.

Required: No

`--retry`

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

`-y, --yes`

Automatically assumes the answer to all prompts is yes.

Required: No

Output

Amazon EC2 displays status messages indicating the stages and status of the delete process.

Example

This example deletes a bundle from Amazon S3.

```
[ec2-user ~]$ ec2-delete-bundle -b DOC-EXAMPLE-BUCKET1 -a your_access_key_id -s your_secret_access_key
Deleting files: 
DOC-EXAMPLE-BUCKET1/
image.manifest.xml
```
ec2-download-bundle

Description

Downloads the specified instance store-backed Linux AMIs from Amazon S3 storage.

Syntax

```
ec2-download-bundle -b bucket -a access_key_id -s secret_access_key -k path
```

Options

- **-b, --bucket** *bucket*

  The name of the Amazon S3 bucket where the bundle is located, followed by an optional ‘/’-delimited path prefix.

  Required: Yes

- **-a, --access-key** *access_key_id*

  The AWS access key ID.

  Required: Yes

- **-s, --secret-key** *secret_access_key*

  The AWS secret access key.

  Required: Yes

- **-k, --privatekey** *path*

  The private key used to decrypt the manifest.

  Required: Yes
--url url
    The Amazon S3 service URL.
    Default: https://s3.amazonaws.com/
    Required: No
--region region
    The Region to use in the request signature.
    Default: us-east-1
    Required: Required if using signature version 4
--sigv version
    The signature version to use when signing the request.
    Valid values: 2 | 4
    Default: 4
    Required: No
-m, --manifest file
    The name of the manifest file (without the path). We recommend that you specify either the
    manifest (-m) or a prefix (-p).
    Required: No
-p, --prefix prefix
    The filename prefix for the bundled AMI files.
    Default: image
    Required: No
-d, --directory directory
    The directory where the downloaded bundle is saved. The directory must exist.
    Default: The current working directory.
    Required: No
--retry
    Automatically retries on all Amazon S3 errors, up to five times per operation.
    Required: No

**Output**

Status messages indicating the various stages of the download process are displayed.

**Example**

This example creates the bundled directory (using the Linux `mkdir` command) and downloads the
bundle from the `DOC-EXAMPLE-BUCKET1` Amazon S3 bucket.

```
[ec2-user ~]$ mkdir bundled
```
Create an AMI

```
[ec2-user ~]$ ec2-download-bundle -b DOC-EXAMPLE-BUCKET1/bundles/bundle_name -m image.manifest.xml -a your_access_key_id -s your_secret_access_key -k HKZKTAIG2ECMYIIBH3HXV4ZBEXAMPLE.pem -d mybundle
```

Downloading manifest image.manifest.xml from DOC-EXAMPLE-BUCKET1 to mybundle/image.manifest.xml ...  
Downloading part image.part.00 from DOC-EXAMPLE-BUCKET1/bundles/bundle_name to mybundle/image.part.00 ... 
Downloaded image.part.00 from DOC-EXAMPLE-BUCKET1 
Downloading part image.part.01 from DOC-EXAMPLE-BUCKET1/bundles/bundle_name to mybundle/image.part.01 ... 
Downloaded image.part.01 from DOC-EXAMPLE-BUCKET1 
Downloading part image.part.02 from DOC-EXAMPLE-BUCKET1/bundles/bundle_name to mybundle/image.part.02 ... 
Downloaded image.part.02 from DOC-EXAMPLE-BUCKET1 
Downloading part image.part.03 from DOC-EXAMPLE-BUCKET1/bundles/bundle_name to mybundle/image.part.03 ...

Downloading part image.part.05 from DOC-EXAMPLE-BUCKET1/bundles/bundle_name to mybundle/image.part.05 ... 
Downloaded image.part.05 from DOC-EXAMPLE-BUCKET1 
Downloading part image.part.06 from DOC-EXAMPLE-BUCKET1/bundles/bundle_name to mybundle/image.part.06 ... 
Downloaded image.part.06 from DOC-EXAMPLE-BUCKET1
```

e2-migrate-manifest

Description

Modifies an instance store-backed Linux AMI (for example, its certificate, kernel, and RAM disk) so that it supports a different Region.

Syntax

```
e2-migrate-manifest -c path -k path -m path {(-a access_key_id -s secret_access_key --region region) | (--no-mapping)} [--ec2cert ec2_cert_path] [--kernel kernel-id] [--ramdisk ramdisk_id]
```

Options

- `-c`, `--cert path`
  
The user's PEM encoded RSA public key certificate file.
  
  Required: Yes

- `-k`, `--privatekey path`
  
The path to the user's PEM-encoded RSA key file.
  
  Required: Yes

- `--manifest path`
  
The path to the manifest file.
  
  Required: Yes

- `-a`, `--access-key access_key_id`
  
The AWS access key ID.
  
  Required: Required if using automatic mapping.
-s, --secret-key  _secret_access_key_

    The AWS secret access key.

    Required: Required if using automatic mapping.

--region  _region_

    The Region to look up in the mapping file.

    Required: Required if using automatic mapping.

--no-mapping

    Disables automatic mapping of kernels and RAM disks.

    During migration, Amazon EC2 replaces the kernel and RAM disk in the manifest file with a kernel
    and RAM disk designed for the destination region. Unless the --no-mapping parameter is given,
    ec2-migrate-bundle might use the DescribeRegions and DescribeImages operations to
    perform automated mappings.

    Required: Required if you're not providing the -a, -s, and --region options used for automatic
    mapping.

--ec2cert  _path_

    The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

    The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the
    path to that certificate must be specified with this option. The path to the certificate varies based
    on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the ZIP file
    in Set up the AMI tools (p. 109), the certificates are located at $EC2_AMITOOL_HOME/etc/ec2/
    amitools/.

    Required: Only for the us-gov-west-1 and cn-north-1 Regions.

--kernel  _kernel_id_

    The ID of the kernel to select.

    **Important**
    We recommend that you use PV-GRUB instead of kernels and RAM disks. For more
    information, see Enabling Your Own Linux Kernels (p. 182).

    Required: No

--ramdisk  _ramdisk_id_

    The ID of the RAM disk to select.

    **Important**
    We recommend that you use PV-GRUB instead of kernels and RAM disks. For more
    information, see Enabling Your Own Linux Kernels (p. 182).

    Required: No

**Output**

Status messages describing the stages and status of the bundling process.

**Example**

This example copies the AMI specified in the my-ami.manifest.xml manifest from the US to the EU.
Create an AMI

[ec2-user ~]$ ec2-migrate-manifest --manifest my-ami.manifest.xml --cert cert-HKZYKTAIG2ECMXYIBH3HXV4ZBQ5CL0.pem --privatekey pk-HKZYKTAIG2ECMXYIBH3HXV4ZBQ5CL0.pem --region eu-west-1

Backing up manifest...
Successfully migrated my-ami.manifest.xml It is now suitable for use in eu-west-1.

ec2-unbundle

Description

Re-creates the bundle from an instance store-backed Linux AMI.

Syntax

ec2-unbundle -k path -m path [-s source_directory] [-d destination_directory]

Options

-k, --privatekey path
  The path to your PEM-encoded RSA key file.
  Required: Yes
-m, --manifest path
  The path to the manifest file.
  Required: Yes
-s, --source source_directory
  The directory containing the bundle.
  Default: The current directory.
  Required: No
-d, --destination destination_directory
  The directory in which to unbundle the AMI. The destination directory must exist.
  Default: The current directory.
  Required: No

Example

This Linux and UNIX example unbundles the AMI specified in the image.manifest.xml file.

[ec2-user ~]$ mkdir unbundled
[ec2-user ~]$ ec2-unbundle -m mybundle/image.manifest.xml -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -s mybundle -d unbundled
[ec2-user ~]$ ls -l unbundled
  total 1025008
  -rw-r--r-- 1 root root 1048578048 Aug 25 23:46 image.img

Output

Status messages indicating the various stages of the unbundling process are displayed.
ec2-upload-bundle

Description

Uploads the bundle for an instance store-backed Linux AMI to Amazon S3 and sets the appropriate ACLs on the uploaded objects. For more information, see Create an instance store-backed Linux AMI (p. 107).

Syntax

```
```

Options

```
-b, --bucket bucket
  The name of the Amazon S3 bucket in which to store the bundle, followed by an optional ‘/’-delimited path prefix. If the bucket doesn't exist, it's created if the bucket name is available.
  Required: Yes
-a, --access-key access_key_id
  Your AWS access key ID.
  Required: Yes
-s, --secret-key secret_access_key
  Your AWS secret access key.
  Required: Yes
-t, --delegation-token token
  The delegation token to pass along to the AWS request. For more information, see the Using Temporary Security Credentials.
  Required: Only when you are using temporary security credentials.
  Default: The value of the AWS_DELEGATION_TOKEN environment variable (if set).
-m, --manifest path
  The path to the manifest file. The manifest file is created during the bundling process and can be found in the directory containing the bundle.
  Required: Yes
--url url
  Deprecated. Use the --region option instead unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.
  The Amazon S3 endpoint service URL.
  Default: https://s3.amazonaws.com/
  Required: No
--region region
  The Region to use in the request signature for the destination S3 bucket.
  • If the bucket doesn't exist and you don't specify a Region, the tool creates the bucket without a location constraint (in us-east-1).
• If the bucket doesn’t exist and you specify a Region, the tool creates the bucket in the specified Region.
• If the bucket exists and you don’t specify a Region, the tool uses the bucket's location.
• If the bucket exists and you specify us-east-1 as the Region, the tool uses the bucket's actual location without any error message, any existing matching files are over-written.
• If the bucket exists and you specify a Region (other than us-east-1) that doesn’t match the bucket's actual location, the tool exits with an error.

If your bucket is constrained to the EU location (and not eu-west-1), use the --location flag instead. The --location flag is the only way to target that specific location restraint.

Default: us-east-1

Required: Required if using signature version 4

--sigv version

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

--acl acl

The access control list policy of the bundled image.

Valid values: public-read | aws-exec-read

Default: aws-exec-read

Required: No

-d, --directory directory

The directory containing the bundled AMI parts.

Default: The directory containing the manifest file (see the -m option).

Required: No

--part part

Starts uploading the specified part and all subsequent parts. For example, --part 04.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

--skipmanifest

Does not upload the manifest.

Required: No

--location location

Deprecated. Use the --region option instead, unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.
The location constraint of the destination Amazon S3 bucket. If the bucket exists and you specify a location that doesn't match the bucket's actual location, the tool exits with an error. If the bucket exists and you don't specify a location, the tool uses the bucket's location. If the bucket doesn't exist and you specify a location, the tool creates the bucket in the specified location. If the bucket doesn't exist and you don't specify a location, the tool creates the bucket without a location constraint (in us-east-1).

Default: If --region is specified, the location is set to that specified Region. If --region is not specified, the location defaults to us-east-1.

Required: No

Output

Amazon EC2 displays status messages that indicate the stages and status of the upload process.

Example

This example uploads the bundle specified by the image.manifest.xml manifest.

```
[ec2-user ~]$ ec2-upload-bundle -b DOC-EXAMPLE-BUCKET1/bundles/bundle_name -m image.manifest.xml -a your_access_key_id -s your_secret_access_key
Creating bucket...
Uploading bundled image parts to the S3 bucket DOC-EXAMPLE-BUCKET1 ...
Uploaded image.part.00
Uploaded image.part.01
Uploaded image.part.02
Uploaded image.part.03
Uploaded image.part.04
Uploaded image.part.05
Uploaded image.part.06
Uploaded image.part.07
Uploaded image.part.08
Uploaded image.part.09
Uploaded image.part.10
Uploaded image.part.11
Uploaded image.part.12
Uploaded image.part.13
Uploaded image.part.14
Uploading manifest ...
Uploaded manifest.
Bundle upload completed.
```

Common options for AMI tools

Most of the AMI tools accept the following optional parameters.

--help, -h

Displays the help message.

--version

Displays the version and copyright notice.

--manual

Displays the manual entry.

--batch

Runs in batch mode, suppressing interactive prompts.
--debug

Displays information that can be useful when troubleshooting problems.

Copy an AMI

You can copy an Amazon Machine Image (AMI) within or across AWS Regions. You can copy both Amazon EBS-backed AMIs and instance-store-backed AMIs. You can copy AMIs with encrypted snapshots and also change encryption status during the copy process. You can copy AMIs that are shared with you.

Copying a source AMI results in an identical but distinct target AMI with its own unique identifier. You can change or deregister the source AMI with no effect on the target AMI. The reverse is also true.

With an Amazon EBS-backed AMI, each of its backing snapshots is copied to an identical but distinct target snapshot. If you copy an AMI to a new Region, the snapshots are complete (non-incremental) copies. If you encrypt unencrypted backing snapshots or encrypt them to a new KMS key, the snapshots are complete (non-incremental) copies. Subsequent copy operations of an AMI result in incremental copies of the backing snapshots.

There are no charges for copying an AMI. However, standard storage and data transfer rates apply. If you copy an EBS-backed AMI, you will incur charges for the storage of any additional EBS snapshots.

Considerations

- You can use IAM policies to grant or deny users permissions to copy AMIs. Resource-level permissions specified for the CopyImage action apply only to the new AMI. You cannot specify resource-level permissions for the source AMI.
- AWS does not copy launch permissions, user-defined tags, or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions, user-defined tags, and Amazon S3 bucket permissions to the new AMI.
- If you are using an AWS Marketplace AMI, or an AMI that was directly or indirectly derived from an AWS Marketplace AMI, you cannot copy it across accounts. Instead, launch an EC2 instance using the AWS Marketplace AMI and then create an AMI from the instance. For more information, see Create an Amazon EBS-backed Linux AMI (p. 102).

Contents

- Permissions for copying an instance store-backed AMI (p. 138)
- Copy an AMI (p. 139)
- Stop a pending AMI copy operation (p. 140)
- Cross-Region copying (p. 141)
- Cross-account copying (p. 142)
- Encryption and copying (p. 142)

Permissions for copying an instance store-backed AMI

If you use an IAM user to copy an instance store-backed AMI, the user must have the following Amazon S3 permissions: s3:CreateBucket, s3:GetBucketAcl, s3:ListAllMyBuckets, s3:GetObject, s3:PutObject, and s3:PutObjectAcl.

The following example policy allows the user to copy the AMI source in the specified bucket to the specified Region.

```json
{

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": "s3:ListAllMyBuckets",
    "Resource": ["arn:aws:s3:::*"]
  },
  {
    "Effect": "Allow",
    "Action": "s3:GetObject",
    "Resource": ["arn:aws:s3:::ami-source-bucket/*"]
  },
  {
    "Effect": "Allow",
    "Action": ["s3:CreateBucket", "s3:GetBucketAcl", "s3:PutObjectAcl", "s3:PutObject"],
    "Resource": ["arn:aws:s3:::amis-for-123456789012-in-us-east-1/*"]
  }
]

To find the Amazon Resource Name (ARN) of the AMI source bucket, open the Amazon EC2 console at https://console.aws.amazon.com/ec2/, in the navigation pane choose AMIs, and locate the bucket name in the Source column.

**Note**

The s3:CreateBucket permission is only needed the first time that the IAM user copies an instance store-backed AMI to an individual Region. After that, the Amazon S3 bucket that is already created in the Region is used to store all future AMIs that you copy to that Region.

**Copy an AMI**

You can copy an AMI using the AWS Management Console, the AWS Command Line Interface or SDKs, or the Amazon EC2 API, all of which support the CopyImage action.

**Prerequisite**

Create or obtain an AMI backed by an Amazon EBS snapshot. Note that you can use the Amazon EC2 console to search a wide variety of AMIs provided by AWS. For more information, see Create an Amazon EBS-backed Linux AMI (p. 102) and Finding an AMI.

**To copy an AMI using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console navigation bar, select the Region that contains the AMI. In the navigation pane, choose Images, AMIs to display the list of AMIs available to you in the Region.
3. Select the AMI to copy and choose Actions, Copy AMI.
4. In the Copy AMI dialog box, specify the following information and then choose Copy AMI:
   - **Destination region**: The Region in which to copy the AMI. For more information, see Cross-Region copying (p. 141).
Copy an AMI

- **Name**: A name for the new AMI. You can include operating system information in the name, as we do not provide this information when displaying details about the AMI.

- **Description**: By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.

- **Encryption**: Select this field to encrypt the target snapshots, or to re-encrypt them using a different key. If you have enabled encryption by default (p. 1338), the Encryption option is set and cannot be unset. For more information, see Encryption and copying (p. 142).

- **KMS Key**: The KMS key to use to encrypt the target snapshots.

5. We display a confirmation page to let you know that the copy operation has been initiated and to provide you with the ID of the new AMI.

To check on the progress of the copy operation immediately, follow the provided link. To check on the progress later, choose **Done**, and then when you are ready, use the navigation bar to switch to the target Region (if applicable) and locate your AMI in the list of AMIs.

The initial status of the target AMI is **pending** and the operation is complete when the status is **available**.

**To copy an AMI using the AWS CLI**

You can copy an AMI using the `copy-image` command. You must specify both the source and destination Regions. You specify the source Region using the `--source-region` parameter. You can specify the destination Region using either the `--region` parameter or an environment variable. For more information, see Configuring the AWS Command Line Interface.

When you encrypt a target snapshot during copying, you must specify these additional parameters: `--encrypted` and `--kms-key-id`.

**To copy an AMI using the Tools for Windows PowerShell**

You can copy an AMI using the `Copy-EC2Image` command. You must specify both the source and destination Regions. You specify the source Region using the `-SourceRegion` parameter. You can specify the destination Region using either the `-Region` parameter or the `Set-AWSDefaultRegion` command. For more information, see Specifying AWS Regions.

When you encrypt a target snapshot during copying, you must specify these additional parameters: `-Encrypted` and `-KmsKeyId`.

**Stop a pending AMI copy operation**

You can stop a pending AMI copy as follows.

**To stop an AMI copy operation using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose AMIs.
4. Select the AMI to stop copying and choose Actions, Deregister.
5. When asked for confirmation, choose Continue.

**To stop an AMI copy operation using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `deregister-image` (AWS CLI)
Cross-Region copying

Copying an AMI across geographically diverse Regions provides the following benefits:

- Consistent global deployment: Copying an AMI from one Region to another enables you to launch consistent instances in different Regions based on the same AMI.
- Scalability: You can more easily design and build global applications that meet the needs of your users, regardless of their location.
- Performance: You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of Region-specific features, such as instance types or other AWS services.
- High availability: You can design and deploy applications across AWS Regions, to increase availability.

The following diagram shows the relations among a source AMI and two copied AMIs in different Regions, as well as the EC2 instances launched from each. When you launch an instance from an AMI, it resides in the same Region where the AMI resides. If you make changes to the source AMI and want those changes to be reflected in the AMIs in the target Regions, you must recopy the source AMI to the target Regions.

When you first copy an instance store-backed AMI to a Region, we create an Amazon S3 bucket for the AMIs copied to that Region. All instance store-backed AMIs that you copy to that Region are stored in this bucket. The bucket names have the following format: amis-for-account-in-region-hash. For example: amis-for-123456789012-in-us-east-2-yhjmxvp6.

Prerequisite

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different Region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination Region may still use the resources from the source Region, which can impact performance and cost.

Limits

- Destination Regions are limited to 100 concurrent AMI copies.
• You cannot copy a paravirtual (PV) AMI to a Region that does not support PV AMIs. For more information, see Linux AMI virtualization types (p. 75).

Cross-account copying

You can share an AMI with another AWS account. Sharing an AMI does not affect the ownership of the AMI. The owning account is charged for the storage in the Region. For more information, see Share an AMI with specific AWS accounts (p. 92).

If you copy an AMI that has been shared with your account, you are the owner of the target AMI in your account. The owner of the source AMI is charged standard Amazon EBS or Amazon S3 transfer fees, and you are charged for the storage of the target AMI in the destination Region.

Resource Permissions

To copy an AMI that was shared with you from another account, the owner of the source AMI must grant you read permissions for the storage that backs the AMI, either the associated EBS snapshot (for an Amazon EBS-backed AMI) or an associated S3 bucket (for an instance store-backed AMI). If the shared AMI has encrypted snapshots, the owner must share the key or keys with you as well.

Encryption and copying

The following table shows encryption support for various AMI-copying scenarios. While it is possible to copy an unencrypted snapshot to yield an encrypted snapshot, you cannot copy an encrypted snapshot to yield an unencrypted one.

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Description</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Unencrypted-to-unencrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Encrypted-to-encrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>3</td>
<td>Unencrypted-to-encrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>4</td>
<td>Encrypted-to-unencrypted</td>
<td>No</td>
</tr>
</tbody>
</table>

Note

Encrypting during the CopyImage action applies only to Amazon EBS-backed AMIs. Because an instance store-backed AMI does not rely on snapshots, you cannot use copying to change its encryption status.

By default (i.e., without specifying encryption parameters), the backing snapshot of an AMI is copied with its original encryption status. Copying an AMI backed by an unencrypted snapshot results in an identical target snapshot that is also unencrypted. If the source AMI is backed by an encrypted snapshot, copying it results in an identical target snapshot that is encrypted by the same AWS KMS key. Copying an AMI backed by multiple snapshots preserves, by default, the source encryption status in each target snapshot.

If you specify encryption parameters while copying an AMI, you can encrypt or re-encrypt its backing snapshots. The following example shows a non-default case that supplies encryption parameters to the CopyImage action in order to change the target AMI’s encryption state.

Copy an unencrypted source AMI to an encrypted target AMI

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The CopyImage action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is...
backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

**Note**
Enabling encryption by default (p. 1338) has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.

Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

For more information about copying AMIs with encrypted snapshots, see Use encryption with EBS-backed AMIs (p. 156).

**Store and restore an AMI using S3**

You can store an Amazon Machine Image (AMI) in an Amazon S3 bucket, copy the AMI to another S3 bucket, and then restore it from the S3 bucket. By storing and restoring an AMI using S3 buckets, you can copy AMIs from one AWS partition to another, for example, from the main commercial partition to the AWS GovCloud (US) partition. You can also make archival copies of AMIs by storing them in an S3 bucket.

The supported APIs for storing and restoring an AMI using S3 are `CreateStoreImageTask`, `DescribeStoreImageTasks`, and `CreateRestoreImageTask`.

`CopyImage` is the recommended API to use for copying AMIs **within** an AWS partition. However, `CopyImage` can’t copy an AMI to **another** partition.

**Warning**
Ensure that you comply with all applicable laws and business requirements when moving data between AWS partitions or AWS Regions, including, but not limited to, any applicable government regulations and data residency requirements.

**Topics**
- Use cases (p. 143)
- How the AMI store and restore APIs work (p. 144)
- Limitations (p. 146)
- Costs (p. 146)
- Securing your AMIs (p. 146)
- Permissions for storing and restoring AMIs using S3 (p. 146)
- Work with the AMI store and restore APIs (p. 147)

**Use cases**

**Use the store and restore APIs to do the following:**
- Copy an AMI from one AWS partition to another AWS partition (p. 143)
- Make archival copies of AMIs (p. 144)

**Copy an AMI from one AWS partition to another AWS partition**

By storing and restoring an AMI using S3 buckets, you can copy an AMI from one AWS partition to another, or from one AWS Region to another. In the following example, you copy an AMI from the main commercial partition to the AWS GovCloud (US) partition, specifically from the `us-east-2` Region to the `us-gov-east-1` Region.
To copy an AMI from one partition to another, follow these steps:

- Store the AMI in an S3 bucket in the current Region by using `CreateStoreImageTask`. In this example, the S3 bucket is located in `us-east-2`. For an example command, see `Store an AMI in an S3 bucket` (p. 147).
- Monitor the progress of the store task by using `DescribeStoreImageTasks`. The object becomes visible in the S3 bucket when the task is completed. For an example command, see `Describe the progress of an AMI store task` (p. 147).
- Copy the stored AMI object to an S3 bucket in the target partition using a procedure of your choice. In this example, the S3 bucket is located in `us-gov-east-1`.

  **Note**
  Because you need different AWS credentials for each partition, you can't copy an S3 object directly from one partition to another. The process for copying an S3 object across partitions is outside the scope of this documentation. We provide the following copy processes as examples, but you must use the copy process that meets your security requirements.

  - To copy one AMI across partitions, the copy process could be as straightforward as the following: Download the object from the source bucket to an intermediate host (for example, an EC2 instance or a laptop), and then upload the object from the intermediate host to the source bucket. For each stage of the process, use the AWS credentials for the partition.
  - For more sustained usage, consider developing an application that manages the copies, potentially using S3 multipart downloads and uploads.
- Restore the AMI from the S3 bucket in the target partition by using `CreateRestoreImageTask`. In this example, the S3 bucket is located in `us-gov-east-1`. For an example command, see `Restore an AMI from an S3 bucket` (p. 148).
- Monitor the progress of the restore task by describing the AMI to check when its state becomes available. You can also monitor the progress percentages of the snapshots that make up the restored AMI by describing the snapshots.

**Make archival copies of AMIs**

You can make archival copies of AMIs by storing them in an S3 bucket. For an example command, see `Store an AMI in an S3 bucket` (p. 147).

The AMI is packed into a single object in S3, and all of the AMI metadata (excluding sharing information) is preserved as part of the stored AMI. The AMI data is compressed as part of the storage process. AMIs that contain data that can easily be compressed will result in smaller objects in S3. To reduce costs, you can use less expensive S3 storage tiers. For more information, see `Amazon S3 Storage Classes` and `Amazon S3 pricing`.

**How the AMI store and restore APIs work**

To store and restore an AMI using S3, you use the following APIs:

- `CreateStoreImageTask` – Stores the AMI in an S3 bucket
- `DescribeStoreImageTasks` – Provides the progress of the AMI store task
- `CreateRestoreImageTask` – Restores the AMI from an S3 bucket

**How the APIs work**

- `CreateStoreImageTask` (p. 145)
- `DescribeStoreImageTasks` (p. 145)
- `CreateRestoreImageTask` (p. 145)
CreateStoreImageTask

The CreateStoreImageTask (p. 147) API stores an AMI as a single object in an S3 bucket.

The API creates a task that reads all of the data from the AMI and its snapshots, and then uses an S3 multipart upload to store the data in an S3 object. The API takes all of the components of the AMI, including most of the non-Region-specific AMI metadata, and all the EBS snapshots contained in the AMI, and packs them into a single object in S3. The data is compressed as part of the upload process to reduce the amount of space used in S3, so the object in S3 might be smaller than the sum of the sizes of the snapshots in the AMI.

If there are AMI and snapshot tags visible to the account calling this API, they are preserved.

The object in S3 has the same ID as the AMI, but with a .bin extension. The following data is also stored as S3 metadata tags on the S3 object: AMI name, AMI description, AMI registration date, AMI owner account, and a timestamp for the store operation.

The sum of the sizes of all the AMIs in progress is limited to 600 GB of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit. For example, if an AMI with 100 GB of snapshot data and another AMI with 200 GB of snapshot data are currently being stored, another request will be accepted, because the total in progress is 300 GB, which is less than the limit. But if a single AMI with 800 GB of snapshot data is currently being stored, further tasks are rejected until the task is completed.

DescribeStoreImageTasks

The DescribeStoreImageTasks (p. 147) API describes the progress of the AMI store tasks. You can describe tasks for specified AMIs. If you don't specify AMIs, you get a paginated list of all of the store image tasks that have been processed in the last 31 days.

For each AMI task, the response indicates if the task is InProgress, Completed, or Failed. For tasks InProgress, the response shows an estimated progress as a percentage.

Tasks are listed in reverse chronological order.

Currently, only tasks from the previous month can be viewed.

CreateRestoreImageTask

The CreateRestoreImageTask (p. 148) API starts a task that restores an AMI from an S3 object that was previously created by using a CreateStoreImageTask (p. 147) request.

The restore task can be performed in the same or a different Region in which the store task was performed.

The S3 bucket from which the AMI object will be restored must be in the same Region in which the restore task is requested. The AMI will be restored in this Region.

The AMI is restored with its metadata, such as the name, description, and block device mappings corresponding to the values of the stored AMI. The name must be unique for AMIs in the Region for this account. If you do not provide a name, the new AMI gets the same name as the original AMI. The AMI gets a new AMI ID that is generated at the time of the restore process.

The time it takes to complete the AMI restoration task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can view the progress of the task by describing the AMI (describe-images) or its EBS snapshots (describe-snapshots). If the task fails, the AMI and snapshots are moved to a failed state.
The sum of the sizes of all of the AMIs in progress is limited to 300 GB (based on the size after restoration) of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit.

**Limitations**

- Only EBS-backed AMIs can be stored using these APIs.
- Paravirtual (PV) AMIs are not supported.
- The size of an AMI (before compression) that can be stored is limited to the size limit of a single S3 object, which is 1 TB.
- Quota on store image (p. 147) requests: 600 GB of storage work (snapshot data) in progress.
- Quota on restore image (p. 148) requests: 300 GB of restore work (snapshot data) in progress.
- For the duration of the store task, the snapshots must not be deleted and the IAM principal doing the store must have access to the snapshots, otherwise the store process will fail.
- You can't create multiple copies of an AMI in the same S3 bucket.
- An AMI that is stored in an S3 bucket can't be restored with its original AMI ID. You can mitigate this by using AMI aliasing.
- Currently the store and restore APIs are only supported by using the AWS Command Line Interface, AWS SDKs, and Amazon EC2 API. You can't store and restore an AMI using the Amazon EC2 console.

**Costs**

When you store and restore AMIs using S3, you are charged for the services that are used by the store and restore APIs, and for data transfer. The APIs use S3 and the EBS Direct API (used internally by these APIs to access the snapshot data). For more information, see Amazon S3 pricing and Amazon EBS pricing.

**Securing your AMIs**

To use the store and restore APIs, the S3 bucket and the AMI must be in the same Region. It is important to ensure that the S3 bucket is configured with sufficient security to secure the content of the AMI and that the security is maintained for as long as the AMI objects remain in the bucket. If this can't be done, use of these APIs is not recommended. Ensure that public access to the S3 bucket is not allowed. We recommend enabling Server Side Encryption for the S3 buckets in which you store the AMIs, although it's not required.

For information about how to set the appropriate security settings for your S3 buckets, review the following security topics:

- Blocking public access to your Amazon S3 storage
- Setting default server-side encryption behavior for Amazon S3 buckets
- What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only?
- Enabling Amazon S3 server access logging

When the AMI snapshots are copied to the S3 object, the data is then copied over TLS connections. You can store AMIs with encrypted snapshots, but the snapshots are decrypted as part of the store process.

**Permissions for storing and restoring AMIs using S3**

If your IAM principals will store or restore AMIs using S3, you need to grant them the required permissions.

The following example policy includes all of the actions that are required to allow an IAM principal to carry out the store and restore tasks.
You can also craft policies so that IAM principals can only access named resources. For more example policies, see Access management for AWS resources in the IAM User Guide.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:DeleteObject",
            "s3:GetObject",
            "s3:ListBucket",
            "s3:PutObject",
            "s3:AbortMultipartUpload",
            "ebs:CompleteSnapshot",

            "ec2:DescribeTags"
         ],
         "Resource": "*"
      }
   ]
}
```

Work with the AMI store and restore APIs

Topics

- Store an AMI in an S3 bucket (p. 147)
- Describe the progress of an AMI store task (p. 147)
- Restore an AMI from an S3 bucket (p. 148)

Store an AMI in an S3 bucket

To store an AMI (AWS CLI)

Use the `create-store-image-task` command. Specify the ID of the AMI and the name of the S3 bucket in which to store the AMI.

```
aws ec2 create-store-image-task \  
   --image-id ami-1234567890abcdef0 \  
   --bucket myamibucket
```

Expected output

```
{
   "ObjectKey": "ami-1234567890abcdef0.bin"
}
```

Describe the progress of an AMI store task

To describe the progress of an AMI store task (AWS CLI)
Use the `describe-store-image-tasks` command.

```
aws ec2 describe-store-image-tasks
```

Expected output

```
{
  "AmiId": "ami-1234567890abcdef0",
  "Bucket": "myamibucket",
  "ProgressPercentage": 17,
  "S3ObjectKey": "ami-1234567890abcdef0.bin",
  "StoreTaskState": "InProgress",
  "StoreTaskFailureReason": null,
  "TaskStartTime": "2021-01-01T01:01:01.001Z"
}
```

**Restore an AMI from an S3 bucket**

**To restore an AMI (AWS CLI)**

Use the `create-restore-image-task` command. Using the values for `S3ObjectKey` and `Bucket` from the `describe-store-image-tasks` output, specify the object key of the AMI and the name of the S3 bucket to which the AMI was copied. Also specify a name for the restored AMI. The name must be unique for AMIs in the Region for this account.

**Note**
The restored AMI gets a new AMI ID.

```
aws ec2 create-restore-image-task \
  --object-key ami-1234567890abcdef0.bin \
  --bucket myamibucket \
  --name "New AMI Name"
```

Expected output

```
{
  "ImageId": "ami-0eab20fe36f83e1a8"
}
```

**Deprecate an AMI**

You can deprecate an AMI to indicate that it is out of date and should not be used. You can also specify a future deprecation date for an AMI, indicating when the AMI will be out of date. For example, you might deprecate an AMI that is no longer actively maintained, or you might deprecate an AMI that has been superseded by a newer version. By default, deprecated AMIs do not appear in AMI listings, preventing new users from using out-of-date AMIs. However, existing users and launch services, such as launch templates and Auto Scaling groups, can continue to use a deprecated AMI by specifying its ID. To delete the AMI so that users and services cannot use it, you must `deregister (p. 151)` it.

After an AMI is deprecated:

- For AMI users, the deprecated AMI does not appear in `DescribeImages` API calls unless you specify its ID or specify that deprecated AMIs must appear. AMI owners continue to see deprecated AMIs in `DescribeImages` API calls.
- For AMI users, the deprecated AMI is not available to select via the EC2 console. For example, a deprecated AMI does not appear in the AMI catalog in the launch instance wizard. AMI owners continue to see deprecated AMIs in the EC2 console.
For AMI users, if you know the ID of a deprecated AMI, you can continue to launch instances using the deprecated AMI by using the API, CLI, or the SDKs.

Launch services, such as launch templates and Auto Scaling groups, can continue to reference deprecated AMIs.

EC2 instances that were launched using an AMI that is subsequently deprecated are not affected, and can be stopped, started, and rebooted.

You can deprecate both private and public AMIs.

You can also create Amazon Data Lifecycle Manager EBS-backed AMI policies to automate the deprecation of EBS-backed AMIs. For more information, see Automate AMI lifecycles (p. 1292).

**Topics**

- Costs (p. 149)
- Limitations (p. 146)
- Deprecate an AMI (p. 149)
- Describe deprecated AMIs (p. 150)
- Cancel the deprecation of an AMI (p. 151)

**Costs**

When you deprecate an AMI, the AMI is not deleted. The AMI owner continues to pay for the AMI's snapshots. To stop paying for the snapshots, the AMI owner must delete the AMI by deregistering (p. 151) it.

**Limitations**

- To deprecate an AMI, you must be the owner of the AMI.
- You can't use the EC2 console to deprecate an AMI or to cancel the deprecation of an AMI.

**Deprecate an AMI**

You can deprecate an AMI on a specific date and time. You must be the AMI owner to perform this procedure.

**To deprecate an AMI on a specific date (AWS CLI)**

Use the `enable-image-deprecation` command. Specify the ID of the AMI and the date and time on which to deprecate the AMI. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.

```
aws ec2 enable-image-deprecation \
  --image-id ami-1234567890abcdef0 \
  --deprecate-at "2021-10-15T17:12:00Z"
```

Expected output

```
{
  "RequestID": "59dbff89-35bd-4eac-99ed-be587EXAMPLE",
  "Return": "true"
}
```
Describe deprecated AMIs

When you describe all AMIs using the describe-images command, the results are different depending on whether you are an AMI user or the AMI owner.

- If you are an AMI user:

  By default, when you describe all AMIs using the describe-images command, deprecated AMIs that are not owned by you, but which are shared with you, do not appear in the results. To include deprecated AMIs in the results, you must specify the --include-deprecated true parameter. The default value for --include-deprecated is false. If you omit this parameter, deprecated AMIs do not appear in the results.

- If you are the AMI owner:

  When you describe all AMIs using the describe-images command, all the AMIs that you own, including deprecated AMIs, appear in the results. You do not need to specify the --include-deprecated true parameter. Furthermore, you cannot exclude deprecated AMIs that you own from the results by using --include-deprecated false.

If an AMI is deprecated, the DeprecationTime field appears in the results.

**Note**
A deprecated AMI is an AMI whose deprecation date is in the past. If you have set the deprecation date to a date in the future, the AMI is not yet deprecated.

**To include all deprecated AMIs when describing all AMIs (AWS CLI)**

Use the describe-images command and specify the --include-deprecated parameter with a value of true to include all deprecated AMIs that are not owned by you in the results.

```bash
aws ec2 describe-images \
  --region us-east-1 \
  --owners 123456example \
  --include-deprecated true
```

**To describe the deprecation date of an AMI (AWS CLI)**

Use the describe-images command and specify the ID of the AMI.

Note that if you specify --include-deprecated false together with the AMI ID, the deprecated AMI will be returned in the results.

```bash
aws ec2 describe-images \
  --region us-east-1 \
  --image-ids ami-1234567890EXAMPLE
```

**Expected output**

The DeprecationTime field displays the date on which the AMI is set to be deprecated. If the AMI is not set to be deprecated, the DeprecationTime field does not appear in the output.

```json
{
  "Images": [
    {
      "VirtualizationType": "hvm",
      "Description": "Provided by Red Hat, Inc.",
      "PlatformDetails": "Red Hat Enterprise Linux",
      "EnaSupport": true,
      "Hypervisor": "xen",
```

150
Cancel the deprecation of an AMI

You can cancel the deprecation of an AMI, which removes the **DeprecationTime** field from the `describe-images` output. You must be the AMI owner to perform this procedure.

**To cancel the deprecation of an AMI (AWS CLI)**

Use the `disable-image-deprecation` command and specify the ID of the AMI.

```bash
aws ec2 disable-image-deprecation \
  --image-id ami-1234567890abcdef0
```

**Expected output**

```json
{
  "RequestID": "11aabb229-4eac-35bd-99ed-be587EXAMPLE",
  "Return": "true"
}
```

Deregister your Linux AMI

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances.

When you deregister an AMI, it doesn't affect any instances that you've already launched from the AMI. You'll continue to incur usage costs for these instances. Therefore, if you are finished with these instances, you should terminate them.

The procedure that you'll use to clean up your AMI depends on whether it is backed by Amazon EBS or instance store. For more information, see Determine the root device type of your AMI (p. 73).
Note
An AMI must be owned by your account in order to deregister it.

Contents
- Clean up your Amazon EBS-backed AMI (p. 152)
- Clean up your instance store-backed AMI (p. 155)

Clean up your Amazon EBS-backed AMI

When you deregister an Amazon EBS-backed AMI, it doesn't affect the snapshot(s) that were created for the volume(s) of the instance during the AMI creation process. You'll continue to incur storage costs for the snapshots. Therefore, if you are finished with the snapshots, you should delete them.

The following diagram illustrates the process for cleaning up your Amazon EBS-backed AMI.
You can use one of the following methods to clean up your Amazon EBS-backed AMI.

New console

**To clean up your Amazon EBS-backed AMI using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. **Deregister the AMI**

   a. In the navigation pane, choose AMIs.
   
   b. Select the AMI to deregister, and take note of its ID — this can help you find the snapshots to delete in the next step.
   
   c. Choose Actions, and then Deregister. When prompted for confirmation, choose Continue.

   **Note**
   It might take a few minutes before the console removes the AMI from the list. Choose Refresh to refresh the status.

3. **Delete snapshots that are no longer needed**

   a. In the navigation pane, choose Snapshots.
   
   b. Select a snapshot to delete (look for the AMI ID from the prior step in the Description column).
   
   c. Choose Actions, and then Delete. When prompted for confirmation, choose Yes, Delete.

4. **Terminate instances (Optional)**

   If you are finished with an instance that you launched from the AMI, you can terminate it.

   a. In the navigation pane, choose Instances then select the instance to terminate.
   
   b. Choose Actions, then Instance state, and then Terminate instance. When prompted for confirmation, choose Terminate.

   **Note**
   You may need to scroll down for some of the Actions menu items.

Old console

**To clean up your Amazon EBS-backed AMI using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. **Deregister the AMI**

   a. In the navigation pane, choose AMIs.
   
   b. Select the AMI to deregister, and take note of its ID — this can help you find the snapshots to delete in the next step.
   
   c. Choose Actions, and then Deregister. When prompted for confirmation, choose Continue.

   **Note**
   It may take a few minutes before the console removes the AMI from the list. Choose Refresh to refresh the status.

3. **Delete snapshots that are no longer needed**

   a. In the navigation pane, choose Snapshots.
   
   b. Select a snapshot to delete (look for the AMI ID from the prior step in the Description column).
c. Choose **Actions**, and then choose **Delete**. When prompted for confirmation, choose **Yes, Delete**.

4. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it.

a. In the navigation pane, choose **Instances** then select the instance to terminate.

b. Choose **Actions**, then **Instance State**, and then **Terminate**. When prompted for confirmation, choose **Yes, Terminate**.

**AWS CLI**

Follow these steps to clean up your Amazon EBS-backed AMI using the AWS CLI

1. **Deregister the AMI**

Deregister the AMI using the `deregister-image` command:

```
aws ec2 deregister-image --image-id ami-12345678
```

2. **Delete snapshots that are no longer needed**

Delete snapshots that are no longer needed by using the `delete-snapshot` command:

```
aws ec2 delete-snapshot --snapshot-id snap-1234567890abcdef0
```

3. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it by using the `terminate-instances` command:

```
aws ec2 terminate-instances --instance-ids i-12345678
```

**PowerShell**

Follow these steps to clean up your Amazon EBS-backed AMI using the AWS Tools for Windows PowerShell

1. **Deregister the AMI**

Deregister the AMI using the `Unregister-EC2Image` cmdlet:

```
Unregister-EC2Image -ImageId ami-12345678
```

2. **Delete snapshots that are no longer needed**

Delete snapshots that are no longer needed by using the `Remove-EC2Snapshot` cmdlet:

```
Remove-EC2Snapshot -SnapshotId snap-12345678
```

3. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it by using the `Remove-EC2Instance` cmdlet:

```
Remove-EC2Instance -InstanceId i-12345678
```
Clean up your instance store-backed AMI

When you deregister an instance store-backed AMI, it doesn't affect the files that you uploaded to Amazon S3 when you created the AMI. You'll continue to incur usage costs for these files in Amazon S3. Therefore, if you are finished with these files, you should delete them.

The following diagram illustrates the process for cleaning up your instance store-backed AMI.

To clean up your instance store-backed AMI

1. Deregister the AMI using the `deregister-image` command as follows.

   ```bash
   aws ec2 deregister-image --image-id ami_id
   ```

2. Delete the bundle in Amazon S3 using the `ec2-delete-bundle (p. 128)` (AMI tools) command as follows.
Automate the EBS-backed AMI lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, copy, deprecation, and deregistration of Amazon EBS-backed AMIs and their backing snapshots. For more information, see Amazon Data Lifecycle Manager (p. 1280).

Use encryption with EBS-backed AMIs

AMIs that are backed by Amazon EBS snapshots can take advantage of Amazon EBS encryption. Snapshots of both data and root volumes can be encrypted and attached to an AMI. You can launch instances and copy images with full EBS encryption support included. Encryption parameters for these operations are supported in all Regions where AWS KMS is available.

EC2 instances with encrypted EBS volumes are launched from AMIs in the same way as other instances. In addition, when you launch an instance from an AMI backed by unencrypted EBS snapshots, you can encrypt some or all of the volumes during launch.

Like EBS volumes, snapshots in AMIs can be encrypted by either your default AWS KMS key, or to a customer managed key that you specify. You must in all cases have permission to use the selected KMS key.

AMIs with encrypted snapshots can be shared across AWS accounts. For more information, see Shared AMIs (p. 88).

Encryption with EBS-backed AMIs topics

- Instance-launching scenarios (p. 156)
- Image-copying scenarios (p. 159)

Instance-launching scenarios

Amazon EC2 instances are launched from AMIs using the RunInstances action with parameters supplied through block device mapping, either by means of the AWS Management Console or directly using the Amazon EC2 API or CLI. For more information about block device mapping, see Block device mapping. For examples of controlling block device mapping from the AWS CLI, see Launch, List, and Terminate EC2 Instances.

By default, without explicit encryption parameters, a RunInstances action maintains the existing encryption state of an AMI’s source snapshots while restoring EBS volumes from them. If Encryption by default (p. 1338) is enabled, all volumes created from the AMI (whether from encrypted or unencrypted
snapshots) will be encrypted. If encryption by default is not enabled, then the instance maintains the encryption state of the AMI.

You can also launch an instance and simultaneously apply a new encryption state to the resulting volumes by supplying encryption parameters. Consequently, the following behaviors are observed:

**Launch with no encryption parameters**

- An unencrypted snapshot is restored to an unencrypted volume, unless encryption by default is enabled, in which case all the newly created volumes will be encrypted.
- An encrypted snapshot that you own is restored to a volume that is encrypted to the same KMS key.
- An encrypted snapshot that you do not own (for example, the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key.

The default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

**Instance launch behaviors with `Encrypted` set, but no `KmsKeyId` specified**

- An unencrypted snapshot is restored to an EBS volume that is encrypted by your AWS account's default KMS key.
- An encrypted snapshot that you own is restored to an EBS volume encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a non-default KMS key for an encryption operation. The following behaviors result:

**Instance with both `Encrypted` and `KmsKeyId` set**

- An unencrypted snapshot is restored to an EBS volume encrypted by the specified KMS key.
- An encrypted snapshot is restored to an EBS volume encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

The following sections provide examples of launching instances from AMIs using non-default encryption parameters. In each of these scenarios, parameters supplied to the `RunInstances` action result in a change of encryption state during restoration of a volume from a snapshot.

For information about using the console to launch an instance from an AMI, see [Launch your instance](p. 475).

**Encrypt a volume during launch**

In this example, an AMI backed by an unencrypted snapshot is used to launch an EC2 instance with an encrypted EBS volume.
The `Encrypted` parameter alone results in the volume for this instance being encrypted. Providing a `KmsKeyId` parameter is optional. If no KMS key ID is specified, the AWS account's default KMS key is used to encrypt the volume. To encrypt the volume to a different KMS key that you own, supply the `KmsKeyId` parameter.

**Re-encrypt a volume during launch**

In this example, an AMI backed by an encrypted snapshot is used to launch an EC2 instance with an EBS volume encrypted by a new KMS key.

If you own the AMI and supply no encryption parameters, the resulting instance has a volume encrypted by the same KMS key as the snapshot. If the AMI is shared rather than owned by you, and you supply no
encryption parameters, the volume is encrypted by your default KMS key. With encryption parameters supplied as shown, the volume is encrypted by the specified KMS key.

**Change encryption state of multiple volumes during launch**

In this more complex example, an AMI backed by multiple snapshots (each with its own encryption state) is used to launch an EC2 instance with a newly encrypted volume and a re-encrypted volume.

![Diagram](image)

In this scenario, the `RunInstances` action is supplied with encryption parameters for each of the source snapshots. When all possible encryption parameters are specified, the resulting instance is the same regardless of whether you own the AMI.

**Image-copying scenarios**

Amazon EC2 AMIs are copied using the `CopyImage` action, either through the AWS Management Console or directly using the Amazon EC2 API or CLI.

By default, without explicit encryption parameters, a `CopyImage` action maintains the existing encryption state of an AMI's source snapshots during copy. You can also copy an AMI and simultaneously apply a new encryption state to its associated EBS snapshots by supplying encryption parameters. Consequently, the following behaviors are observed:

**Copy with no encryption parameters**

- An unencrypted snapshot is copied to another unencrypted snapshot, unless encryption by default is enabled, in which case all the newly created snapshots will be encrypted.
• An encrypted snapshot that you own is copied to a snapshot encrypted with the same KMS key.
• An encrypted snapshot that you do not own (that is, the AMI is shared with you) is copied to a snapshot that is encrypted by your AWS account's default KMS key.

All of these default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

**Copy-image behaviors with `Encrypted` set, but no `KmsKeyId` specified**

• An unencrypted snapshot is copied to a snapshot encrypted by the AWS account's default KMS key.
• An encrypted snapshot is copied to a snapshot encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
• An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is copied to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a customer managed KMS key for an encryption operation. The following behaviors result:

**Copy-image behaviors with both `Encrypted` and `KmsKeyId` set**

• An unencrypted snapshot is copied to a snapshot encrypted by the specified KMS key.
• An encrypted snapshot is copied to a snapshot encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

The following section provides an example of copying an AMI using non-default encryption parameters, resulting in a change of encryption state.

For detailed instructions using the console, see [Copy an AMI](p. 138).

### Encrypt an unencrypted image during copy

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

**Note**

Enabling [encryption by default](p. 1338) has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.

Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

**Note**

You can also copy an image with multiple snapshots and configure the encryption state of each individually.
Understand AMI billing information

There are many Amazon Machine Images (AMIs) to choose from when launching your instances, and they support a variety of operating system platforms and features. To understand how the AMI you choose when launching your instance affects the bottom line on your AWS bill, you can research the associated operating system platform and billing information. Do this before you launch any On-Demand or Spot Instances, or purchase a Reserved Instance.

Here are two examples of how researching your AMI in advance can help you choose the AMI that best suits your needs:

- For Spot Instances, you can use the AMI **Platform details** to confirm that the AMI is supported for Spot Instances.
- When purchasing a Reserved Instance, you can make sure that you select the operating system platform (**Platform**) that maps to the AMI **Platform details**.

For more information about instance pricing, see Amazon EC2 pricing.

Contents
- AMI billing information fields (p. 161)
- Finding AMI billing and usage details (p. 162)
- Verify AMI charges on your bill (p. 164)

AMI billing information fields

The following fields provide billing information associated with an AMI:

**Platform details**
- The platform details associated with the billing code of the AMI. For example, Red Hat Enterprise Linux.

**Usage operation**
- The operation of the Amazon EC2 instance and the billing code that is associated with the AMI. For example, RunInstances:0010. Usage operation corresponds to the lineitem/Operation column on your AWS Cost and Usage Report (CUR) and in the AWS Price List API.

You can view these fields on the Instances or AMIs page in the Amazon EC2 console, or in the response that is returned by the describe-images command.

Sample data: usage operation by platform

The following table lists some of the platform details and usage operation values that can be displayed on the Instances or AMIs pages in the Amazon EC2 console, or in the response that is returned by the describe-images command.

<table>
<thead>
<tr>
<th>Platform details</th>
<th>Usage operation **</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux/UNIX</td>
<td>RunInstances</td>
</tr>
<tr>
<td>Red Hat BYOL Linux</td>
<td>RunInstances:00g0</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux</td>
<td>RunInstances:0010</td>
</tr>
</tbody>
</table>
## Platform details

<table>
<thead>
<tr>
<th>Platform details</th>
<th>Usage operation **</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Hat Enterprise Linux with HA</td>
<td>RunInstances:1010</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Standard and HA</td>
<td>RunInstances:1014</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Enterprise and HA</td>
<td>RunInstances:1110</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Standard</td>
<td>RunInstances:0014</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Web</td>
<td>RunInstances:0210</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Enterprise</td>
<td>RunInstances:0110</td>
</tr>
<tr>
<td>SQL Server Enterprise</td>
<td>RunInstances:0100</td>
</tr>
<tr>
<td>SQL Server Standard</td>
<td>RunInstances:0004</td>
</tr>
<tr>
<td>SQL Server Web</td>
<td>RunInstances:0200</td>
</tr>
<tr>
<td>SUSE Linux</td>
<td>RunInstances:000g</td>
</tr>
<tr>
<td>Windows</td>
<td>RunInstances:0002</td>
</tr>
<tr>
<td>Windows BYOL</td>
<td>RunInstances:0800</td>
</tr>
<tr>
<td>Windows with SQL Server Enterprise *</td>
<td>RunInstances:0102</td>
</tr>
<tr>
<td>Windows with SQL Server Standard *</td>
<td>RunInstances:0006</td>
</tr>
<tr>
<td>Windows with SQL Server Web *</td>
<td>RunInstances:0202</td>
</tr>
</tbody>
</table>

* If two software licenses are associated with an AMI, the **Platform details** field shows both.

** If you are running Spot Instances, the **Platform details** field might be different from the **Usage operation** value that is listed here. For example, if lineitem/Operation displays RunInstances:0010:SV006, it means that Amazon EC2 is running Red Hat Enterprise Linux Spot Instance-hour in US East (Virginia) in VPC Zone #6.

### Finding AMI billing and usage details

In the Amazon EC2 console, you can view the AMI billing information from the **AMIs** page or from the **Instances** page. You can also find billing information using the AWS CLI or the instance metadata service.

The following fields can help you verify AMI charges on your bill:

- **Platform details**
- **Usage operation**
- **AMI ID**

### Find AMI billing information (console)

Follow these steps to view AMI billing information in the Amazon EC2 console:
Look up AMI billing information from the AMIs page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs, and then select an AMI.
3. On the Details tab, check the values for Platform details and Usage operation.

Look up AMI billing information from the Instances page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select an instance.
3. On the Details tab (or the Description tab if you are using the prior version of the console), check the values for Platform details and Usage operation.

Find AMI billing information (AWS CLI)

To find the AMI billing information using the AWS CLI, you need to know the AMI ID. If you don't know the AMI ID, you can get it from the instance using the describe-instances command.

To find the AMI ID

If you know the instance ID, you can get the AMI ID for the instance by using the describe-instances command.

```
aws ec2 describe-instances --instance-ids i-123456789abcdef123
```

In the output, the AMI ID is specified in the ImageId field.

```
..."Instances": [ 
  
   "AmiLaunchIndex": 0,
   "ImageId": "ami-0123456789EXAMPLE",
   "InstanceId": "i-123456789abcdef123",
   ...
  ]
...
```

To find the AMI billing information

If you know the AMI ID, you can use the describe-images command to get the AMI platform and usage operation details.

```
$ aws ec2 describe-images --image-ids ami-0123456789EXAMPLE
```

The following example output shows the PlatformDetails and UsageOperation fields. In this example, the ami-0123456789EXAMPLE platform is Red Hat Enterprise Linux and the usage operation and billing code is RunInstances:0010.

```
{
   "Images": [
   
   { 
   "VirtualizationType": "hvm",
   "Description": "Provided by Red Hat, Inc.",
   "Hypervisor": "xen",
   "EnaSupport": true,
   "SriovNetSupport": "simple",
   "ImageId": "ami-0123456789EXAMPLE",
   "State": "available",
   ...}]
...}
Verify AMI charges on your bill

To ensure that you're not incurring unplanned costs, you can verify that the billing information for an instance in your AWS Cost and Usage Report (CUR) matches the billing information that's associated with the AMI that you used to launch the instance.

To verify the billing information, find the instance ID in your CUR and check the corresponding value in the `lineitem/Operation` column. That value should match the value for Usage operation that's associated with the AMI.

For example, the AMI `ami-0123456789EXAMPLE` has the following billing information:

- **Platform details** = Red Hat Enterprise Linux
- **Usage operation** = RunInstances:0010

If you launched an instance using this AMI, you can find the instance ID in your CUR, and check the corresponding value in the `lineitem/Operation` column. In this example, the value should be RunInstances:0010.

Amazon Linux

Amazon Linux is provided by Amazon Web Services (AWS). It is designed to provide a stable, secure, and high-performance execution environment for applications running on Amazon EC2. It also includes packages that enable easy integration with AWS, including launch configuration tools and many popular AWS libraries and tools. AWS provides ongoing security and maintenance updates for all instances running Amazon Linux. Many applications developed on CentOS (and similar distributions) run on Amazon Linux.

Amazon Linux availability

AWS provides Amazon Linux 2 and the Amazon Linux AMI. If you are migrating from another Linux
distribution to Amazon Linux, we recommend that you migrate to Amazon Linux 2.

The last version of the Amazon Linux AMI, 2018.03, reaches the end of standard support on December
31, 2020. For more information, see the following blog post: Amazon Linux AMI end of life. If you are
currently using the Amazon Linux AMI, we recommend that you migrate to Amazon Linux 2. To migrate
to Amazon Linux 2, launch an instance or create a virtual machine using the current Amazon Linux 2
image. Install your applications, plus any required packages. Test your application, and make any changes
required for it to run on Amazon Linux 2.

For more information, see Amazon Linux 2 and Amazon Linux AMI. For Amazon Linux Docker container
images, see amazonlinux on Docker Hub.

Connect to an Amazon Linux instance

Amazon Linux does not allow remote root SSH by default. Also, password authentication is disabled
to prevent brute-force password attacks. To enable SSH logins to an Amazon Linux instance, you must
provide your key pair to the instance at launch. You must also set the security group used to launch your
instance to allow SSH access. By default, the only account that can log in remotely using SSH is ec2-user;
this account also has sudo privileges. If you enable remote root login, be aware that it is less secure than
relying on key pairs and a secondary user.

Identify Amazon Linux images

Each image contains a unique /etc/image-id file that identifies it. This file contains the following
information about the image:

- image_name, image_version, image_arch — Values from the build recipe that Amazon used to
  construct the image.
- image_stamp — A unique, random hex value generated during image creation.
- image_date — The UTC time of image creation, in YYYYMMDDhhmms format
- recipe_name, recipe_id — The name and ID of the build recipe Amazon used to construct the
  image.

Amazon Linux contains an /etc/system-release file that specifies the current release that is
installed. This file is updated using yum and is part of the system-release RPM.

Amazon Linux also contains a machine-readable version of /etc/system-release that follows the
CPE specification; see /etc/system-release-cpe.
Amazon Linux 2

The following is an example of /etc/image-id for the current version of Amazon Linux 2:

```
[ec2-user ~]$ cat /etc/image-id
image_name="amzn2-ami-hvm"
image_version="2"
image_arch="x86_64"
image_file="amzn2-ami-hvm-2.0.20180810-x86_64.xfs.gpt"
image_stamp="8008-2abd"
image_date="20180811020321"
recipe_name="amzn2 ami"
recipe_id="c652686a-2415-9819-65fb-4dee-9792-289d-1e2846bd"
```

The following is an example of /etc/system-release for the current version of Amazon Linux 2:

```
[ec2-user ~]$ cat /etc/system-release
Amazon Linux 2
```

The following is an example of /etc/os-release for Amazon Linux 2:

```
[ec2-user ~]$ cat /etc/os-release
NAME="Amazon Linux"
VERSION="2"
ID="amzn"
ID_LIKE="centos rhel fedora"
VERSION_ID="2"
PRETTY_NAME="Amazon Linux 2"
ANSI_COLOR="0;33"
CPE_NAME="cpe:2.3:o:amazon:amazon_linux:2"
HOME_URL="https://amazonlinux.com/
```

Amazon Linux AMI

The following is an example of /etc/image-id for the current Amazon Linux AMI:

```
[ec2-user ~]$ cat /etc/image-id
image_name="amzn-ami-hvm"
image_version="2018.03"
image_arch="x86_64"
image_file="amzn-ami-hvm-2018.03.0.20180811-x86_64.ext4.gpt"
image_stamp="cc81-f2f3"
image_date="20180811012746"
recipe_name="amzn ami"
recipe_id="5b283820-dc60-a7ea-d436-39fa-439f-02ea-5c802dbd"
```

The following is an example of /etc/system-release for the current Amazon Linux AMI:

```
[ec2-user ~]$ cat /etc/system-release
Amazon Linux AMI release 2018.03
```

AWS command line tools

The following command line tools for AWS integration and usage are included in the Amazon Linux AMI, or in the default repositories for Amazon Linux 2. For the complete list of packages in the Amazon Linux AMI, see Amazon Linux AMI 2017.09 Packages.

- aws-amitools-ec2
• aws-apitools-as
• aws-apitools-cfn
• aws-apitools-elb
• aws-apitools-mon
• aws-cfn-bootstrap
• aws-cli

Amazon Linux 2 and the minimal versions of Amazon Linux (amzn-ami-minimal-* and amzn2-ami-minimal-*) do not always contain all of these packages; however, you can install them from the default repositories using the following command:

```
[ec2-user ~]$ sudo yum install -y package_name
```

For instances launched using IAM roles, a simple script has been included to prepare AWS_CREDENTIAL_FILE, JAVA_HOME, AWS_PATH, PATH, and product-specific environment variables after a credential file has been installed to simplify the configuration of these tools.

Also, to allow the installation of multiple versions of the API and AMI tools, we have placed symbolic links to the desired versions of these tools in /opt/aws, as described here:

```
/opit/aws/bin
```

Symbolic links to /bin directories in each of the installed tools directories.

```
/opit/aws/{apitools|amitools}
```

Products are installed in directories of the form name-version and a symbolic link name that is attached to the most recently installed version.

```
/opit/aws/{apitools|amitools}/name/environment.sh
```

Used by /etc/profile.d/aws-apitools-common.sh to set product-specific environment variables, such as EC2_HOME.

## Package repository

Amazon Linux 2 and the Amazon Linux AMI are designed to be used with online package repositories hosted in each Amazon EC2 AWS Region. These repositories provide ongoing updates to packages in Amazon Linux 2 and the Amazon Linux AMI, as well as access to hundreds of additional common open-source server applications. The repositories are available in all Regions and are accessed using yum update tools. Hosting repositories in each Region enables us to deploy updates quickly and without any data transfer charges.

Amazon Linux 2 and the Amazon Linux AMI are updated regularly with security and feature enhancements. If you do not need to preserve data or customizations for your instances, you can simply launch new instances using the current AMI. If you need to preserve data or customizations for your instances, you can maintain those instances through the Amazon Linux package repositories. These repositories contain all the updated packages. You can choose to apply these updates to your running instances. Older versions of the AMI and update packages continue to be available for use, even as new versions are released.

**Important**

Your instance must have access to the internet in order to access the repository.

To install packages, use the following command:

```
[ec2-user ~]$ sudo yum install package
```
For the Amazon Linux AMI, access to the Extra Packages for Enterprise Linux (EPEL) repository is configured, but it is not enabled by default. Amazon Linux 2 is not configured to use the EPEL repository. EPEL provides third-party packages in addition to those that are in the repositories. The third-party packages are not supported by AWS. You can enable the EPEL repository with the following commands:

- For Amazon Linux 2:

  ```bash
  ```

- For the Amazon Linux AMI:

  ```bash
  [ec2-user ~]$ sudo yum-config-manager --enable epel
  ```

If you find that Amazon Linux does not contain an application you need, you can simply install the application directly on your Amazon Linux instance. Amazon Linux uses RPMs and yum for package management, and that is likely the simplest way to install new applications. You should always check to see if an application is available in our central Amazon Linux repository first, because many applications are available there. These applications can easily be added to your Amazon Linux instance.

To upload your applications onto a running Amazon Linux instance, use scp or sftp and then configure the application by logging on to your instance. Your applications can also be uploaded during the instance launch by using the PACKAGE_SETUP action from the built-in cloud-init package. For more information, see cloud-init (p. 170).

### Security updates

Security updates are provided using the package repositories as well as updated AMI security alerts are published in the Amazon Linux Security Center. For more information about AWS security policies or to report a security problem, go to the AWS Security Center.

Amazon Linux is configured to download and install critical or important security updates at launch time. We recommend that you make the necessary updates for your use case after launch. For example, you may want to apply all updates (not just security updates) at launch, or evaluate each update and apply only the ones applicable to your system. This is controlled using the following cloud-init setting: repo_upgrade. The following snippet of cloud-init configuration shows how you can change the settings in the user data text you pass to your instance initialization:

```bash
#cloud-config
repo_upgrade: security
```

The possible values for repo_upgrade are as follows:

- **critical**
  - Apply outstanding critical security updates.
- **important**
  - Apply outstanding critical and important security updates.
- **medium**
  - Apply outstanding critical, important, and medium security updates.
- **low**
  - Apply all outstanding security updates, including low-severity security updates.
security
Apply outstanding critical or important updates that Amazon marks as security updates.

bugfix
Apply updates that Amazon marks as bug fixes. Bug fixes are a larger set of updates, which include security updates and fixes for various other minor bugs.

all
Apply all applicable available updates, regardless of their classification.

none
Do not apply any updates to the instance on startup.

The default setting for `repo_upgrade` is security. That is, if you don't specify a different value in your user data, by default, Amazon Linux performs the security upgrades at launch for any packages installed at that time. Amazon Linux also notifies you of any updates to the installed packages by listing the number of available updates upon login using the `/etc/motd` file. To install these updates, you need to run `sudo yum upgrade` on the instance.

Repository configuration

With Amazon Linux, AMIs are treated as snapshots in time, with a repository and update structure that always gives you the latest packages when you run `yum update -y`.

The repository structure is configured to deliver a continuous flow of updates that enable you to roll from one version of Amazon Linux to the next. For example, if you launch an instance from an older version of the Amazon Linux AMI (such as 2017.09 or earlier) and run `yum update -y`, you end up with the latest packages.

You can disable rolling updates by enabling the `lock-on-launch` feature. The lock-on-launch feature locks your instance to receive updates only from the specified release of the AMI. For example, you can launch a 2017.09 AMI and have it receive only the updates that were released prior to the 2018.03 AMI, until you are ready to migrate to the 2018.03 AMI.

**Important**
If you lock to a version of the repositories that is not the latest, you do not receive further updates. To receive a continuous flow of updates, you must use the latest AMI, or consistently update your AMI with the repositories pointed to latest.

To enable lock-on-launch in new instances, launch it with the following user data passed to cloud-init:

```
#cloud-config
repo_releasever: 2017.09
```

To lock existing instances to their current AMI version

1. Edit `/etc/yum.conf`.
2. Comment out `releasever=latest`.
3. To clear the cache, run `yum clean all`.

Extras library (Amazon Linux 2)

With Amazon Linux 2, you can use the Extras Library to install application and software updates on your instances. These software updates are known as topics. You can install a specific version of a topic or omit the version information to use the most recent version.
To list the available topics, use the following command:

```
[ec2-user ~]$ amazon-linux-extras list
```

To enable a topic and install the latest version of its package to ensure freshness, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras install topic
```

To enable topics and install specific versions of their packages to ensure stability, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras install topic=version
```

To remove a package installed from a topic, use the following command:

```
[ec2-user ~]$ sudo yum remove $(yum list installed | grep amzn2extra-topic | awk '{ print $1 }')
```

**Note**
This command does not remove packages that were installed as dependencies of the extra.

To disable a topic and make the packages inaccessible to the yum package manager, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras disable topic
```

**Important**
This command is intended for advanced users. Improper usage of this command could cause package compatibility conflicts.

### Access source packages for reference

You can view the source of packages you have installed on your instance for reference purposes by using tools provided in Amazon Linux. Source packages are available for all of the packages included in Amazon Linux and the online package repository. Simply determine the package name for the source package you want to install and use the `yumdownloader --source` command to view source within your running instance. For example:

```
[ec2-user ~]$ yumdownloader --source bash
```

The source RPM can be unpacked, and, for reference, you can view the source tree using standard RPM tools. After you finish debugging, the package is available for use.

### cloud-init

The cloud-init package is an open-source application built by Canonical that is used to bootstrap Linux images in a cloud computing environment, such as Amazon EC2. Amazon Linux contains a customized version of cloud-init. It enables you to specify actions that should happen to your instance at boot time. You can pass desired actions to cloud-init through the user data fields when launching an instance. This means you can use common AMIs for many use cases and configure them dynamically at startup. Amazon Linux also uses cloud-init to perform initial configuration of the ec2-user account.

For more information, see the cloud-init documentation.
Amazon Linux uses the cloud-init actions found in /etc/cloud/cloud.cfg.d and /etc/cloud/cloud.cfg. You can create your own cloud-init action files in /etc/cloud/cloud.cfg.d. All files in this directory are read by cloud-init. They are read in lexical order, and later files overwrite values in earlier files.

The cloud-init package performs these (and other) common configuration tasks for instances at boot:

- Set the default locale.
- Set the hostname.
- Parse and handle user data.
- Generate host private SSH keys.
- Add a user's public SSH keys to .ssh/authorized_keys for easy login and administration.
- Prepare the repositories for package management.
- Handle package actions defined in user data.
- Execute user scripts found in user data.
- Mount instance store volumes, if applicable.
  - By default, the ephemeral0 instance store volume is mounted at /media/ephemeral0 if it is present and contains a valid file system; otherwise, it is not mounted.
  - By default, any swap volumes associated with the instance are mounted (only for m1.small and c1.medium instance types).
- You can override the default instance store volume mount with the following cloud-init directive:

```
#cloud-config
mounts:
  - [ ephemeral0 ]
```

For more control over mounts, see Mounts in the cloud-init documentation.

- Instance store volumes that support TRIM are not formatted when an instance launches, so you must partition and format them before you can mount them. For more information, see Instance store volume TRIM support (p. 1422). You can use the disk_setup module to partition and format your instance store volumes at boot. For more information, see Disk Setup in the cloud-init documentation.

## Supported user-data formats

The cloud-init package supports user-data handling of a variety of formats:

- Gzip
  - If user-data is gzip compressed, cloud-init decompresses the data and handles it appropriately.
- MIME multipart
  - Using a MIME multipart file, you can specify more than one type of data. For example, you could specify both a user-data script and a cloud-config type. Each part of the multipart file can be handled by cloud-init if it is one of the supported formats.
- Base64 decoding
  - If user-data is base64-encoded, cloud-init determines if it can understand the decoded data as one of the supported types. If it understands the decoded data, it decodes the data and handles it appropriately. If not, it returns the base64 data intact.
- User-Data script
  - Begins with #! or Content-Type: text/x-shellscript.
  - The script is run by /etc/init.d/cloud-init-user-scripts during the first boot cycle. This occurs late in the boot process (after the initial configuration actions are performed).
- Include file
  - Begins with `#include` or `Content-Type: text/x-include-url`.
  - This content is an include file. The file contains a list of URLs, one per line. Each of the URLs is read, and their content passed through this same set of rules. The content read from the URL can be gzipped, MIME-multi-part, or plaintext.

- Cloud Config Data
  - Begins with `#cloud-config` or `Content-Type: text/cloud-config`.
  - This content is cloud-config data. For a commented example of supported configuration formats, see the examples.

- Upstart job (not supported on Amazon Linux 2)
  - Begins with `#upstart-job` or `Content-Type: text/upstart-job`.
  - This content is stored in a file in `/etc/init`, and upstart consumes the content as per other upstart jobs.

- Cloud Boothook
  - Begins with `#cloud-boothook` or `Content-Type: text/cloud-boothook`.
  - This content is boothook data. It is stored in a file under `/var/lib/cloud` and then runs immediately.
  - This is the earliest "hook" available. There is no mechanism provided for running it only one time. The boothook must take care of this itself. It is provided with the instance ID in the environment variable `INSTANCE_ID`. Use this variable to provide a once-per-instance set of boothook data.

---

**Subscribe to Amazon Linux notifications**

To be notified when new AMIs are released, you can subscribe using Amazon SNS.

**To subscribe to Amazon Linux notifications**

2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select the Region in which the SNS notification that you are subscribing to was created.
3. In the navigation pane, choose **Subscriptions**, **Create subscription**.
4. For the **Create subscription** dialog box, do the following:
   a. [Amazon Linux 2] For **Topic ARN**, copy and paste the following Amazon Resource Name (ARN):
   b. [Amazon Linux] For **Topic ARN**, copy and paste the following Amazon Resource Name (ARN):
   c. For **Protocol**, choose **Email**.
   d. For **Endpoint**, enter an email address that you can use to receive the notifications.
   e. Choose **Create subscription**.
5. You receive a confirmation email with the subject line "AWS Notification - Subscription Confirmation". Open the email and choose **Confirm subscription** to complete your subscription.

Whenever AMIs are released, we send notifications to the subscribers of the corresponding topic. To stop receiving these notifications, use the following procedure to unsubscribe.

**To unsubscribe from Amazon Linux notifications**

2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use the Region in which the SNS notification was created.
3. In the navigation pane, choose Subscriptions, select the subscription, and choose Actions, Delete subscriptions.

4. When prompted for confirmation, choose Delete.

Amazon Linux AMI SNS message format

The schema for the SNS message is as follows.

```json
{
    "description": "Validates output from AMI Release SNS message",
    "type": "object",
    "properties": {
        "v1": {
            "type": "object",
            "properties": {
                "ReleaseVersion": {
                    "description": "Major release (ex. 2018.03)",
                    "type": "string"
                },
                "ImageVersion": {
                    "description": "Full release (ex. 2018.03.0.20180412)",
                    "type": "string"
                },
                "ReleaseNotes": {
                    "description": "Human-readable string with extra information",
                    "type": "string"
                },
                "Regions": {
                    "type": "object",
                    "description": "Each key will be a region name (ex. us-east-1)",
                    "additionalProperties": {
                        "type": "array",
                        "items": {
                            "type": "object",
                            "properties": {
                                "Name": {
                                    "description": "AMI Name (ex. amzn-ami-hvm-2018.03.0.20180412-x86_64-gp2)"
                                },
                                "ImageId": {
                                    "description": "AMI Name (ex. ami-467ca739)
                                }
                            }
                        }[
                            "Name",
                            "ImageId"
                        ]
                    }
                }
            }[
            "ReleaseVersion",
            "ImageVersion",
            "ReleaseNotes",
            "Regions"
        ]
    },
    "required": [
        "v1"
    ]
}
```
Run Amazon Linux 2 as a virtual machine on premises

Use the Amazon Linux 2 virtual machine (VM) images for on-premises development and testing. These images are available for use on the following virtualization platforms:

- VMWare
- KVM
- VirtualBox (Oracle VM)
- Microsoft Hyper-V

To use the Amazon Linux 2 virtual machine images with one of the supported virtualization platforms, do the following:

- Step 1: Prepare the seed.iso boot image (p. 174)
- Step 2: Download the Amazon Linux 2 VM image (p. 176)
- Step 3: Boot and connect to your new VM (p. 176)

Step 1: Prepare the seed.iso boot image

The seed.iso boot image includes the initial configuration information that is needed to boot your new VM, such as the network configuration, host name, and user data.

**Note**
The seed.iso boot image includes only the configuration information required to boot the VM. It does not include the Amazon Linux 2 operating system files.

To generate the seed.iso boot image, you need two configuration files:

- meta-data—This file includes the hostname and static network settings for the VM.
- user-data—This file configures user accounts, and specifies their passwords, key pairs, and access mechanisms. By default, the Amazon Linux 2 VM image creates a ec2-user user account. You use the user-data configuration file to set the password for the default user account.

To create the seed.iso boot disc

1. Create a new folder named seedconfig and navigate into it.
2. Create the meta-data configuration file.
   a. Create a new file named meta-data.
   b. Open the meta-data file using your preferred editor and add the following.

```
local-hostname: vm_hostname
# eth0 is the default network interface enabled in the image. You can configure static network settings with an entry like the following.
network-interfaces: |
  auto eth0
  iface eth0 inet static
  address 192.168.1.10
  network 192.168.1.0
  netmask 255.255.255.0
  broadcast 192.168.1.255
```

174
Replace `vm_hostname` with a VM host name of your choice, and configure the network settings as required.

c. Save and close the `meta-data` configuration file.

For an example `meta-data` configuration file that specifies a VM hostname (amazonlinux.onprem), configures the default network interface (eth0), and specifies static IP addresses for the necessary network devices, see the sample Seed.iso file.

3. Create the `user-data` configuration file.

a. Create a new file named `user-data`.

b. Open the `user-data` file using your preferred editor and add the following.

```yaml
#cloud-config
#vim:syntax=yaml
users:
  # A user by the name `ec2-user` is created in the image by default.
  - default
chpasswd:
  list: |
    ec2-user:plain_text_password
  # In the above line, do not add any spaces after `ec2-user:'.
```

Replace `plain_text_password` with a password of your choice for the default `ec2-user` user account.

c. (Optional) By default, cloud-init applies network settings each time the VM boots. Add the following to prevent cloud-init from applying network settings at each boot, and to retain the network settings applied during the first boot.

```yaml
# NOTE: Cloud-init applies network settings on every boot by default. To retain network settings from first boot, add following `write_files` section:
write_files:
  - path: /etc/cloud/cloud.cfg.d/80_disable_network_after_firstboot.cfg
    content: |
      # Disable network configuration after first boot
      network:
        config: disabled
```

d. Save and close the `user-data` configuration file.

You can also create additional user accounts and specify their access mechanisms, passwords, and key pairs. For more information about the supported directives, see Modules. For an example `user-data` file that creates three additional users and specifies a custom password for the default `ec2-user` user account, see the sample Seed.iso file.

4. Create the `seed.iso` boot image using the `meta-data` and `user-data` configuration files.

For Linux, use a tool such as `genisoimage`. Navigate into the seedconfig folder, and run the following command.

```
$ genisoimage -output seed.iso -volid cidata -joliet -rock user-data meta-data
```

For macOS, use a tool such as `hdiutil`. Navigate one level up from the seedconfig folder, and run the following command.
Step 2: Download the Amazon Linux 2 VM image

We offer a different Amazon Linux 2 VM image for each of the supported virtualization platforms. Download the correct VM image for your chosen platform:

- VMWare
- KVM
- Oracle VirtualBox
- Microsoft Hyper-V

Step 3: Boot and connect to your new VM

To boot and connect to your new VM, you must have the seed.iso boot image (created in Step 1) and an Amazon Linux 2 VM image (downloaded in Step 2). The steps vary depending on your chosen VM platform.

VMWare vSphere

The VM image for VMware is made available in the OVF format.

To boot the VM using VMWare vSphere

1. Create a new datastore for the seed.iso file, or add it to an existing datastore.
2. Deploy the OVF template, but do not start the VM yet.
3. In the Navigator panel, right-click the new virtual machine and choose Edit Settings.
4. On the Virtual Hardware tab, for New device, choose CD/DVD Drive, and then choose Add.
5. For New CD/DVD Drive, choose Datastore ISO File. Select the datastore to which you added the seed.iso file, browse to and select the seed.iso file, and then choose OK.
6. For New CD/DVD Drive, select Connect, and then choose OK.

After you have associated the datastore with the VM, you should be able to boot it.

KVM

To boot the VM using KVM

1. Open the Create new VM wizard.
2. For Step 1, choose Import existing disk image.
3. For Step 2, browse to and select the VM image. For OS type and Version, choose Linux and Red Hat Enterprise Linux 7.0 respectively.
4. For Step 3, specify the amount of RAM and the number of CPUs to use.
5. For Step 4, enter a name for the new VM and select Customize configuration before install, and choose Finish.
6. In the Configuration window for the VM, choose Add Hardware.
7. In the Add New Virtual Hardware window, choose Storage.
8. In the Storage configuration, choose Select or create custom storage. For Device type, choose CDROM device. Choose Manage, Browse Local, and then navigate to and select the seed.iso file. Choose Finish.
9. Choose **Begin Installation**.

**Oracle VirtualBox**

**To boot the VM using Oracle VirtualBox**

1. Open Oracle VirtualBox and choose **New**.
2. For **Name**, enter a descriptive name for the virtual machine, and for **Type** and **Version**, select **Linux** and **Red Hat (64-bit)** respectively. Choose **Continue**.
3. For **Memory size**, specify the amount of memory to allocate to the virtual machine, and then choose **Continue**.
4. For **Hard disk**, choose **Use an existing virtual hard disk file**, browse to and open the VM image, and then choose **Create**.
5. Before you start the VM, you must load the **seed.iso** file in the virtual machine's virtual optical drive:
   a. Select the new VM, choose **Settings**, and then choose **Storage**.
   b. In the **Storage Devices** list, under **Controller: IDE**, choose the **Empty** optical drive.
   c. In the **Attributes** section for the optical drive, choose the browse button, select **Choose Virtual Optical Disk File**, and then select the **seed.iso** file. Choose **OK** to apply the changes and close the Settings.

After you have added the **seed.iso** file to the virtual optical drive, you should be able to start the VM.

**Microsoft Hyper-V**

The VM image for Microsoft Hyper-V is compressed into a zip file. You must extract the contents of the zip file.

**To boot the VM using Microsoft Hyper-V**

1. Open the **New Virtual Machine Wizard**.
2. When prompted to select a generation, select **Generation 1**.
3. When prompted to configure the network adapter, for **Connection** choose **External**.
4. When prompted to connect a virtual hard disk, choose **Use an existing virtual hard disk**, choose **Browse**, and then navigate to and select the VM image. Choose **Finish** to create the VM.
5. Right-click the new VM and choose **Settings**. In the **Settings** window, under **IDE Controller 1**, choose **DVD Drive**.
6. For the DVD drive, choose **Image file** and then browse to and select the **seed.iso** file.
7. Apply the changes and start the VM.

After the VM has booted, log in using one of the user accounts that is defined in the **user-data** configuration file. After you have logged in for the first time, you can then disconnect the seed.iso boot image from the VM.

**Kernel Live Patching on Amazon Linux 2**

Kernel Live Patching for Amazon Linux 2 enables you to apply security vulnerability and critical bug patches to a running Linux kernel, without reboots or disruptions to running applications. This allows you to benefit from improved service and application availability, while keeping your infrastructure secure and up to date.

AWS releases two types of kernel live patches for Amazon Linux 2:
- **Security updates**—Include updates for Linux common vulnerabilities and exposures (CVE). These updates are typically rated as *important* or *critical* using the Amazon Linux Security Advisory ratings. They generally map to a Common Vulnerability Scoring System (CVSS) score of 7 and higher. In some cases, AWS might provide updates before a CVE is assigned. In these cases, the patches might appear as bug fixes.

- **Bug fixes**—Include fixes for critical bugs and stability issues that are not associated with CVEs.

AWS provides kernel live patches for an Amazon Linux 2 kernel version for up to 3 months after its release. After the 3-month period, you must update to a later kernel version to continue to receive kernel live patches.

Amazon Linux 2 kernel live patches are made available as signed RPM packages in the existing Amazon Linux 2 repositories. The patches can be installed on individual instances using existing `yum` workflows, or they can be installed on a group of managed instances using AWS Systems Manager.

Kernel Live Patching on Amazon Linux 2 is provided at no additional cost.

**Topics**
- Supported configurations and prerequisites (p. 178)
- Work with Kernel Live Patching (p. 178)
- Limitations (p. 182)
- Frequently asked questions (p. 182)

**Supported configurations and prerequisites**

Kernel Live Patching is supported on Amazon EC2 instances and on-premises virtual machines (p. 174) running Amazon Linux 2.

To use Kernel Live Patching on Amazon Linux 2, you must use:

- A 64-bit (x86_64) architecture that is supported by Amazon Linux 2
- Amazon Linux 2 with kernel version `4.14.165-131.185` or later

**Note**
The 64-bit ARM (arm64) architecture is not supported.

**Work with Kernel Live Patching**

You can enable and use Kernel Live Patching on individual instances using the command line on the instance itself, or you can enable and use Kernel Live Patching on a group of managed instances using AWS Systems Manager.

The following sections explain how to enable and use Kernel Live Patching on individual instances using the command line.

For more information about enabling and using Kernel Live Patching on a group of managed instances, see Use Kernel Live Patching on Amazon Linux 2 instances in the *AWS Systems Manager User Guide*.

**Topics**
- Enable Kernel Live Patching (p. 179)
- View the available kernel live patches (p. 180)
- Apply kernel live patches (p. 180)
- View the applied kernel live patches (p. 181)
- Disable Kernel Live Patching (p. 182)
Enable Kernel Live Patching

Kernel Live Patching is disabled by default on Amazon Linux 2. To use live patching, you must install the `yum` plugin for Kernel Live Patching and enable the live patching functionality.

Prerequisites

Kernel Live Patching requires `binutils`. If you do not have `binutils` installed, install it using the following command:

```
$ sudo yum install binutils
```

To enable Kernel Live Patching

1. Kernel live patches are available for Amazon Linux 2 with kernel version 4.14.165-131.185 or later. To check your kernel version, run the following command.

```
$ sudo yum list kernel
```

2. If you already have a supported kernel version, skip this step. If you do not have a supported kernel version, run the following commands to update the kernel to the latest version and to reboot the instance.

```
$ sudo yum install -y kernel
$ sudo reboot
```

3. Install the `yum` plugin for Kernel Live Patching.

```
$ sudo yum install -y yum-plugin-kernel-livepatch
```

4. Enable the `yum` plugin for Kernel Live Patching.

```
$ sudo yum kernel-livepatch enable -y
```

This command also installs the latest version of the kernel live patch RPM from the configured repositories.

5. To confirm that the `yum` plugin for kernel live patching has installed successfully, run the following command.

```
$ rpm -qa | grep kernel-livepatch
```

When you enable Kernel Live Patching, an empty kernel live patch RPM is automatically applied. If Kernel Live Patching was successfully enabled, this command returns a list that includes the initial empty kernel live patch RPM.

6. Install the `kpatch` package.

```
$ sudo yum install -y kpatch-runtime
```

7. Update the `kpatch` service if it was previously installed.

```
$ sudo yum update kpatch-runtime
```

8. Start the `kpatch` service. This service loads all of the kernel live patches upon initialization or at boot.
# sudo systemctl enable kpatch.service

9. Configure the Amazon Linux 2 Kernel Live Patching repository, which contains the kernel live patches.

    # sudo amazon-linux-extras enable livepatch

---

**View the available kernel live patches**

Amazon Linux security alerts are published to the Amazon Linux Security Center. For more information about the Amazon Linux 2 security alerts, which include alerts for kernel live patches, see the Amazon Linux Security Center. Kernel live patches are prefixed with `ALASLIVEPATCH`. The Amazon Linux Security Center might not list kernel live patches that address bugs.

You can also discover the available kernel live patches for advisories and CVEs using the command line.

**To list all available kernel live patches for advisories**

Use the following command.

    $ yum updateinfo list

The following shows example output.

```
Loaded plugins: extras_suggestions, kernel-livepatch, langpacks, priorities, update-motd
ALASLIVEPATCH-2020-002 important/Sec. kernel-livepatch-4.14.165-133.209-1.0-3.amzn2.x86_64
ALASLIVEPATCH-2020-005 medium/Sec. kernel-livepatch-4.14.165-133.209-1.0-4.amzn2.x86_64
updateinfo list done
```

**To list all available kernel live patches for CVEs**

Use the following command.

    $ yum updateinfo list cves

The following shows example output.

```
Loaded plugins: extras_suggestions, kernel-livepatch, langpacks, priorities, update-motd
CVE-2019-15918 important/Sec. kernel-livepatch-4.14.165-133.209-1.0-3.amzn2.x86_64
CVE-2019-20096 important/Sec. kernel-livepatch-4.14.165-133.209-1.0-3.amzn2.x86_64
CVE-2020-8648 medium/Sec. kernel-livepatch-4.14.165-133.209-1.0-4.amzn2.x86_64
updateinfo list done
```

**Apply kernel live patches**

You apply kernel live patches using the `yum` package manager in the same way that you would apply regular updates. The `yum` plugin for Kernel Live Patching manages the kernel live patches that are to be applied and eliminates the need to reboot.

**Tip**

We recommend that you update your kernel regularly using Kernel Live Patching to ensure that it remains secure and up to date.
You can choose to apply a specific kernel live patch, or to apply any available kernel live patches along with your regular security updates.

**To apply a specific kernel live patch**

1. Get the kernel live patch version using one of the commands described in View the available kernel live patches (p. 180).
2. Apply the kernel live patch for your Amazon Linux 2 kernel.

   ```
   $ sudo yum install kernel-livepatch-\*kernel_version*.x86_64
   ```

   For example, the following command applies a kernel live patch for Amazon Linux 2 kernel version 4.14.165-133.209.

   ```
   $ sudo yum install kernel-livepatch-4.14.165-133.209-1.0-4.amzn2.x86_64
   ```

**To apply any available kernel live patches along with your regular security updates**

Use the following command.

```
$ sudo yum update --security
```

Omit the `--security` option to include bug fixes.

**Important**

- The kernel version is not updated after applying kernel live patches. The version is only updated to the new version after the instance is rebooted.
- An Amazon Linux 2 kernel receives kernel live patches for a period of three months. After the three month period has lapsed, no new kernel live patches are released for that kernel version. To continue to receive kernel live patches after the three-month period, you must reboot the instance to move to the new kernel version, which will then continue receiving kernel live patches for the next three months. To check the support window for your kernel version, run `yum kernel-livepatch supported`.

**View the applied kernel live patches**

**To view the applied kernel live patches**

Use the following command.

```
$ kpatch list
```

The command returns a list of the loaded and installed security update kernel live patches. The following is example output.

```
Loaded patch modules:
 livepatch_cifs_lease_buffer_len [enabled]
 livepatch_CVE_2019_20096 [enabled]
 livepatch_CVE_2020_8648 [enabled]

Installed patch modules:
 livepatch_cifs_lease_buffer_len (4.14.165-133.209.amzn2.x86_64)
 livepatch_CVE_2019_20096 (4.14.165-133.209.amzn2.x86_64)
 livepatch_CVE_2020_8648 (4.14.165-133.209.amzn2.x86_64)
```
Note
A single kernel live patch can include and install multiple live patches.

Disable Kernel Live Patching

If you no longer need to use Kernel Live Patching, you can disable it at any time.

To disable Kernel Live Patching

1. Remove the RPM packages for the applied kernel live patches.

```bash
$ sudo yum kernel-livepatch disable
```

2. Uninstall the `yum` plugin for Kernel Live Patching.

```bash
$ sudo yum remove yum-plugin-kernel-livepatch
```

3. Reboot the instance.

```bash
$ sudo reboot
```

Limitations

Kernel Live Patching has the following limitations:

- While applying a kernel live patch, you can't perform hibernation, use advanced debugging tools (such as SystemTap, kprobes, and eBPF-based tools), or access ftrace output files used by the Kernel Live Patching infrastructure.
- Amazon Linux 2 instances with 64-bit ARM (arm64) architecture are not supported.

Frequently asked questions

For frequently asked questions about Kernel Live Patching for Amazon Linux 2, see the Amazon Linux 2 Kernel Live Patching FAQ.

User provided kernels

If you need a custom kernel on your Amazon EC2 instances, you can start with an AMI that is close to what you want, compile the custom kernel on your instance, and update the bootloader to point to the new kernel. This process varies depending on the virtualization type that your AMI uses. For more information, see Linux AMI virtualization types (p. 75).

Contents

- HVM AMIs (GRUB) (p. 182)
- Paravirtual AMIs (PV-GRUB) (p. 183)

HVM AMIs (GRUB)

HVM instance volumes are treated like actual physical disks. The boot process is similar to that of a bare metal operating system with a partitioned disk and bootloader, which enables it to work with all currently supported Linux distributions. The most common bootloader is GRUB or GRUB2.
By default, GRUB does not send its output to the instance console because it creates an extra boot delay. For more information, see Instance console output (p. 1515). If you are installing a custom kernel, you should consider enabling GRUB output.

You don't need to specify a fallback kernel, but we recommend that you have a fallback when you test a new kernel. GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel enables the instance to boot even if the new kernel isn't found.

The legacy GRUB for Amazon Linux uses /boot/grub/menu.lst. GRUB2 for Amazon Linux 2 uses /etc/default/grub. For more information about updating the default kernel in the bootloader, see the documentation for your Linux distribution.

Paravirtual AMIs (PV-GRUB)

Amazon Machine Images that use paravirtual (PV) virtualization use a system called PV-GRUB during the boot process. PV-GRUB is a paravirtual bootloader that runs a patched version of GNU GRUB 0.97. When you start an instance, PV-GRUB starts the boot process and then chain loads the kernel specified by your image's menu.lst file.

PV-GRUB understands standard grub.conf or menu.lst commands, which allows it to work with all currently supported Linux distributions. Older distributions such as Ubuntu 10.04 LTS, Oracle Enterprise Linux, or CentOS 5.x require a special "ec2" or "xen" kernel package, while newer distributions include the required drivers in the default kernel package.

Most modern paravirtual AMIs use a PV-GRUB AKI by default (including all of the paravirtual Linux AMIs available in the Amazon EC2 Launch Wizard Quick Start menu), so there are no additional steps that you need to take to use a different kernel on your instance, provided that the kernel you want to use is compatible with your distribution. The best way to run a custom kernel on your instance is to start with an AMI that is close to what you want and then to compile the custom kernel on your instance and modify the menu.lst file to boot with that kernel.

You can verify that the kernel image for an AMI is a PV-GRUB AKI. Run the following describe-images command (substituting your kernel image ID) and check whether the Name field starts with pv-grub:

```bash
aws ec2 describe-images --filters Name=image-id,Values=aki-880531cd
```

Contents

- Limitations of PV-GRUB (p. 183)
- Configure GRUB for paravirtual AMIs (p. 184)
- Amazon PV-GRUB Kernel Image IDs (p. 184)
- Update PV-GRUB (p. 186)

Limitations of PV-GRUB

PV-GRUB has the following limitations:

- You can't use the 64-bit version of PV-GRUB to start a 32-bit kernel or vice versa.
- You can't specify an Amazon ramdisk image (ARI) when using a PV-GRUB AKI.
- AWS has tested and verified that PV-GRUB works with these file system formats: EXT2, EXT3, EXT4, JFS, XFS, and ReiserFS. Other file system formats might not work.
- PV-GRUB can boot kernels compressed using the gzip, bzip2, lzo, and xz compression formats.
- Cluster AMIs don't support or need PV-GRUB, because they use full hardware virtualization (HVM). While paravirtual instances use PV-GRUB to boot, HVM instance volumes are treated like actual disks, and the boot process is similar to the boot process of a bare metal operating system with a partitioned disk and bootloader.
• PV-GRUB versions 1.03 and earlier don't support GPT partitioning; they support MBR partitioning only.
• If you plan to use a logical volume manager (LVM) with Amazon Elastic Block Store (Amazon EBS) volumes, you need a separate boot partition outside of the LVM. Then you can create logical volumes with the LVM.

**Configure GRUB for paravirtual AMIs**

To boot PV-GRUB, a GRUB `menu.lst` file must exist in the image; the most common location for this file is `/boot/grub/menu.lst`.

The following is an example of a `menu.lst` configuration file for booting an AMI with a PV-GRUB AKI. In this example, there are two kernel entries to choose from: Amazon Linux 2018.03 (the original kernel for this AMI), and Vanilla Linux 4.16.4 (a newer version of the Vanilla Linux kernel from [https://www.kernel.org/](https://www.kernel.org/)). The Vanilla entry was copied from the original entry for this AMI, and the `kernel` and `initrd` paths were updated to the new locations. The `default 0` parameter points the bootloader to the first entry it sees (in this case, the Vanilla entry), and the `fallback 1` parameter points the bootloader to the next entry if there is a problem booting the first.

```
default 0
fallback 1
timeout 0
hiddenmenu
title Vanilla Linux 4.16.4
root (hd0)
kernel /boot/vmlinuz-4.16.4 root=LABEL=/ console=hvc0
initrd /boot/initrd.img-4.16.4

title Amazon Linux 2018.03 (4.14.26-46.32.amzn1.x86_64)
root (hd0)
kernel /boot/vmlinuz-4.14.26-46.32.amzn1.x86_64 root=LABEL=/ console=hvc0
initrd /boot/initramfs-4.14.26-46.32.amzn1.x86_64.img
```

You don't need to specify a fallback kernel in your `menu.lst` file, but we recommend that you have a fallback when you test a new kernel. PV-GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel allows the instance to boot even if the new kernel isn't found.

PV-GRUB checks the following locations for `menu.lst`, using the first one it finds:

• `(hd0)/boot/grub`
• `(hd0,0)/boot/grub`
• `(hd0,0)/grub`
• `(hd0,1)/boot/grub`
• `(hd0,1)/grub`
• `(hd0,2)/boot/grub`
• `(hd0,2)/grub`
• `(hd0,3)/boot/grub`
• `(hd0,3)/grub`

Note that PV-GRUB 1.03 and earlier only check one of the first two locations in this list.

**Amazon PV-GRUB Kernel Image IDs**

PV-GRUB AKIs are available in all Amazon EC2 regions, excluding Asia Pacific (Osaka). There are AKIs for both 32-bit and 64-bit architecture types. Most modern AMIs use a PV-GRUB AKI by default.
We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Use the following `describe-images` command to get a list of the PV-GRUB AKIs for the current region:

```
aws ec2 describe-images --owners amazon --filters Name=name,Values=pv-grub-*.gz
```

PV-GRUB is the only AKI available in the `ap-southeast-2` Region. You should verify that any AMI you want to copy to this Region is using a version of PV-GRUB that is available in this Region.

The following are the current AKI IDs for each Region. Register new AMIs using an hd0 AKI.

**Note**
We continue to provide hd00 AKIs for backward compatibility in Regions where they were previously available.

**ap-northeast-1, Asia Pacific (Tokyo)**

Update PV-GRUB

We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Also, older versions of PV-GRUB are not available in all regions, so if you copy an AMI that uses an older version to a Region that does not support that version, you will be unable to boot instances launched from that AMI until you update the kernel image. Use the following procedures to check your instance's version of PV-GRUB and update it if necessary.

**To check your PV-GRUB version**

1. Find the kernel ID for your instance.

   ```bash
   aws ec2 describe-instance-attribute --instance-id instance_id --attribute kernel --region region
   ```
The kernel ID for this instance is aki-70cb0e10.

2. View the version information of that kernel ID.

```bash
aws ec2 describe-images --image-ids aki-70cb0e10 --region region
```

This kernel image is PV-GRUB 1.05. If your PV-GRUB version is not the newest version (as shown in Amazon PV-GRUB Kernel Image IDs (p. 184)), you should update it using the following procedure.

**To update your PV-GRUB version**

If your instance is using an older version of PV-GRUB, you should update it to the latest version.

1. Identify the latest PV-GRUB AKI for your Region and processor architecture from Amazon PV-GRUB Kernel Image IDs (p. 184).
2. Stop your instance. Your instance must be stopped to modify the kernel image used.

```bash
aws ec2 stop-instances --instance-ids instance_id --region region
```

3. Modify the kernel image used for your instance.

```bash
aws ec2 modify-instance-attribute --instance-id instance_id --kernel kernel_id --region region
```

4. Restart your instance.

```bash
aws ec2 start-instances --instance-ids instance_id --region region
```

**Configure the Amazon Linux 2 MATE desktop connection**

The MATE desktop environment is pre-installed and pre-configured in the AMI with the following description: Amazon Linux 2 with .Net Core, Mono, and MATE Desktop Environment. The environment provides an intuitive graphical user interface for administering Amazon Linux 2 instances with minimal use of the command line. The interface uses graphical representations, such as icons, windows, toolbars, folders, wallpapers, and desktop widgets. Built-in, GUI-based tools are available to perform common tasks. For example, there are tools for adding and removing software, applying updates, organizing files, launching programs, and monitoring system health.
Important

`xrdp` is the remote desktop software bundled in the AMI. By default, `xrdp` uses a self-signed TLS certificate to encrypt remote desktop sessions. Neither AWS nor the `xrdp` maintainers recommend using self-signed certificates in production. Instead, obtain a certificate from an appropriate certificate authority (CA) and install it on your instances. For more information about TLS configuration, see TLS security layer on the `xrdp` wiki.

Prerequisite

To run the commands shown in this topic, you must install the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, and configure your AWS profile.

Options

1. Install the AWS CLI – For more information, see Installing the AWS CLI and Configuration basics in the AWS Command Line Interface User Guide.

Configure the RDP connection

Follow these steps to set up a Remote Desktop Protocol (RDP) connection from your local machine to an Amazon Linux 2 instance running the MATE desktop environment.

1. To get the ID of the AMI for Amazon Linux 2 that includes MATE in the AMI name, use the `describe-images` command from your local command line tool.

   ```bash
   aws ec2 describe-images --filters "Name=name,Values=amzn2*MATE*" --query "Images[*].[ImageId,Name,Description]"
   [  
      "ami-0123example0abc12",
      "amzn2-x86_64-MATEDE_DOTNET-2020.12.04",
      ".NET Core 5.0, Mono 6.12, PowerShell 7.1, and MATE DE pre-installed to run your .NET applications on Amazon Linux 2 with Long Term Support (LTS)."
   ],
   [  
      "ami-0456example0def34",
      "amzn2-x86_64-MATEDE_DOTNET-2020.04.14",
      "Amazon Linux 2 with .Net Core, PowerShell, Mono, and MATE Desktop Environment"
   ]
   ]
   ``

   Choose the AMI that is appropriate for your use.

2. Launch an EC2 instance with the AMI that you located in the previous step. Configure the security group to allow for inbound TCP traffic to port 3389. For more information about configuring security groups, see Security groups for your VPC. This configuration enables you to use an RDP client to connect to the instance.

3. Connect to the instance using SSH. Run the following command on your Linux instance to set the password for `ec2-user`.

   ```bash
   [ec2-user ~]$ sudo passwd ec2-user
   ```

4. Install the certificate and key.

   If you already have a certificate and key, copy them to the `/etc/xrdp/` directory as follows:
Configure the RDP connection

- Certificate — /etc/xrdp/cert.pem
- Key — /etc/xrdp/key.pem

If you do not have a certificate and key, use the following command to generate them in the /etc/xrdp directory.

```
$ sudo openssl req -x509 -sha384 -newkey rsa:3072 -nodes -keyout /etc/xrdp/key.pem -out /etc/xrdp/cert.pem -days 365
```

**Note**
This command generates a certificate that is valid for 365 days.

5. Open an RDP client on the computer from which you will connect to the instance (for example, Remote Desktop Connection on a computer running Microsoft Windows). Enter ec2-user as the user name and enter the password that you set in the previous step.

To disable the MATE Desktop Environment on your Amazon EC2 instance

You can turn off the GUI environment at any time by running one of the following commands on your Linux instance.

```
[ec2-user ~]$ sudo systemctl disable xrdp
```

```
[ec2-user ~]$ sudo systemctl stop xrdp
```

To enable the MATE Desktop Environment on your Amazon EC2 instance

To turn the GUI back on, you can run one of the following commands on your Linux instance.

```
[ec2-user ~]$ sudo systemctl enable xrdp
```

```
[ec2-user ~]$ sudo systemctl start xrdp
```
Amazon EC2 instances

If you're new to Amazon EC2, see the following topics to get started:

- What is Amazon EC2? (p. 1)
- Set up to use Amazon EC2 (p. 5)
- Tutorial: Get started with Amazon EC2 Linux instances (p. 9)
- Instance lifecycle (p. 471)

Before you launch a production environment, you need to answer the following questions.

Q. What instance type best meets my needs?

Amazon EC2 provides different instance types to enable you to choose the CPU, memory, storage, and networking capacity that you need to run your applications. For more information, see Instance types (p. 193).

Q. What purchasing option best meets my needs?

Amazon EC2 supports On-Demand Instances (the default), Spot Instances, and Reserved Instances. For more information, see Instance purchasing options (p. 320).

Q. Which type of root volume meets my needs?

Each instance is backed by Amazon EBS or backed by instance store. Select an AMI based on which type of root volume you need. For more information, see Storage for the root device (p. 73).

Q. Can I remotely manage a fleet of EC2 instances and machines in my hybrid environment?

AWS Systems Manager enables you to remotely and securely manage the configuration of your Amazon EC2 instances, and your on-premises instances and virtual machines (VMs) in hybrid environments, including VMs from other cloud providers. For more information, see the AWS Systems Manager User Guide.

Instances and AMIs

An Amazon Machine Image (AMI) is a template that contains a software configuration (for example, an operating system, an application server, and applications). From an AMI, you launch an instance, which is a copy of the AMI running as a virtual server in the cloud. You can launch multiple instances of an AMI, as shown in the following figure.
Your instances keep running until you stop, hibernate, or terminate them, or until they fail. If an instance fails, you can launch a new one from the AMI.

**Instances**

An instance is a virtual server in the cloud. Its configuration at launch is a copy of the AMI that you specified when you launched the instance.

You can launch different types of instances from a single AMI. An *instance type* essentially determines the hardware of the host computer used for your instance. Each instance type offers different compute and memory capabilities. Select an instance type based on the amount of memory and computing power that you need for the application or software that you plan to run on the instance. For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

After you launch an instance, it looks like a traditional host, and you can interact with it as you would any computer. You have complete control of your instances; you can use `sudo` to run commands that require root privileges.

Your AWS account has a limit on the number of instances that you can have running. For more information about this limit, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.

**Storage for your instance**

The root device for your instance contains the image used to boot the instance. The root device is either an Amazon Elastic Block Store (Amazon EBS) volume or an instance store volume. For more information, see Amazon EC2 instance root device volume (p. 1432).

Your instance may include local storage volumes, known as instance store volumes, which you can configure at launch time with block device mapping. For more information, see Block device mappings (p. 1441). After these volumes have been added to and mapped on your instance, they are available for you to mount and use. If your instance fails, or if your instance is stopped or terminated, the data on these volumes is lost; therefore, these volumes are best used for temporary data. To keep important data safe, you should use a replication strategy across multiple instances, or store your persistent data in Amazon S3 or Amazon EBS volumes. For more information, see Storage (p. 1174).
Security best practices

- Use AWS Identity and Access Management (IAM) to control access to your AWS resources, including your instances. You can create IAM users and groups under your AWS account, assign security credentials to each, and control the access that each has to resources and services in AWS. For more information, see Identity and access management for Amazon EC2 (p. 1068).

- Restrict access by only allowing trusted hosts or networks to access ports on your instance. For example, you can restrict SSH access by restricting incoming traffic on port 22. For more information, see Amazon EC2 security groups for Linux instances (p. 1152).

- Review the rules in your security groups regularly, and ensure that you apply the principle of least privilege—only open up permissions that you require. You can also create different security groups to deal with instances that have different security requirements. Consider creating a bastion security group that allows external logins, and keep the remainder of your instances in a group that does not allow external logins.

- Disable password-based logins for instances launched from your AMI. Passwords can be found or cracked, and are a security risk. For more information, see Disable password-based remote logins for root (p. 95). For more information about sharing AMIs safely, see Shared AMIs (p. 88).

Stop and terminate instances

You can stop or terminate a running instance at any time.

Stop an instance

When an instance is stopped, the instance performs a normal shutdown, and then transitions to a stopped state. All of its Amazon EBS volumes remain attached, and you can start the instance again at a later time.

You are not charged for additional instance usage while the instance is in a stopped state. A minimum of one minute is charged for every transition from a stopped state to a running state. If the instance type was changed while the instance was stopped, you will be charged the rate for the new instance type after the instance is started. All of the associated Amazon EBS usage of your instance, including root device usage, is billed using typical Amazon EBS prices.

When an instance is in a stopped state, you can attach or detach Amazon EBS volumes. You can also create an AMI from the instance, and you can change the kernel, RAM disk, and instance type.

Terminate an instance

When an instance is terminated, the instance performs a normal shutdown. The root device volume is deleted by default, but any attached Amazon EBS volumes are preserved by default, determined by each volume's deleteOnTermination attribute setting. The instance itself is also deleted, and you can't start the instance again at a later time.

To prevent accidental termination, you can disable instance termination. If you do so, ensure that the disableApiTermination attribute is set to true for the instance. To control the behavior of an instance shutdown, such as shutdown -h in Linux or shutdown in Windows, set the instanceInitiatedShutdownBehavior instance attribute to stop or terminate as desired. Instances with Amazon EBS volumes for the root device default to stop, and instances with instance-store root devices are always terminated as the result of an instance shutdown.

For more information, see Instance lifecycle (p. 471).

Note

Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see Avoiding Unexpected Charges in the AWS Billing and Cost Management User Guide. For more information about Amazon EBS costs, see Amazon EBS pricing.
AMIs

Amazon Web Services (AWS) publishes many Amazon Machine Images (AMIs) that contain common software configurations for public use. In addition, members of the AWS developer community have published their own custom AMIs. You can also create your own custom AMI or AMIs; doing so enables you to quickly and easily start new instances that have everything you need. For example, if your application is a website or a web service, your AMI could include a web server, the associated static content, and the code for the dynamic pages. As a result, after you launch an instance from this AMI, your web server starts, and your application is ready to accept requests.

All AMIs are categorized as either backed by Amazon EBS, which means that the root device for an instance launched from the AMI is an Amazon EBS volume, or backed by instance store, which means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

The description of an AMI indicates the type of root device (either ebs or instance store). This is important because there are significant differences in what you can do with each type of AMI. For more information about these differences, see Storage for the root device (p. 73).

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances. Existing instances launched from the AMI are not affected. Therefore, if you are also finished with the instances launched from these AMIs, you should terminate them.

Instance types

When you launch an instance, the instance type that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities, and is grouped in an instance family based on these capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance.

Amazon EC2 provides each instance with a consistent and predictable amount of CPU capacity, regardless of its underlying hardware.

Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is underused, an instance can consume a higher share of that resource while it's available.

Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

Contents

- Hardware specifications (p. 197)
- AMI virtualization types (p. 198)
- Instances built on the Nitro System (p. 199)
- Networking and storage features (p. 200)
- Instance limits (p. 203)
- General purpose instances (p. 203)
- Compute optimized instances (p. 258)
Available instance types

Amazon EC2 provides a wide selection of instance types optimized for different use cases. To determine which instance types meet your requirements, such as supported Regions, compute resources, or storage resources, see Find an Amazon EC2 instance type (p. 309).

Current generation instances

For the best performance, we recommend that you use the following instance types when you launch new instances. For more information, see Amazon EC2 Instance Types.

Previous generation instances

Amazon Web Services offers previous generation instance types for users who have optimized their applications around them and have yet to upgrade. We encourage you to use current generation instance types to get the best performance, but we continue to support the following previous generation instance types. For more information about which current generation instance type would be a suitable upgrade, see Previous Generation Instances.

Hardware specifications

For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance second, it's convenient and inexpensive to test multiple instance types before making a decision.
If your needs change, even after you make a decision, you can resize your instance later. For more information, see Change the instance type (p. 310).

Note
Amazon EC2 instances typically run on 64-bit virtual Intel processors as specified in the instance type product pages. For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types. However, confusion may result from industry naming conventions for 64-bit CPUs. Chip manufacturer Advanced Micro Devices (AMD) introduced the first commercially successful 64-bit architecture based on the Intel x86 instruction set. Consequently, the architecture is widely referred to as AMD64 regardless of the chip manufacturer. Windows and several Linux distributions follow this practice. This explains why the internal system information on an Ubuntu or Windows EC2 instance displays the CPU architecture as AMD64 even though the instances are running on Intel hardware.

Processor features

Intel processor features

Amazon EC2 instances that run on Intel processors may include the following features. Not all of the following processor features are supported by all instance types. For detailed information about which features are available for each instance type, see Amazon EC2 Instance Types.

• **Intel AES New Instructions (AES-NI)** — Intel AES-NI encryption instruction set improves upon the original Advanced Encryption Standard (AES) algorithm to provide faster data protection and greater security. All current generation EC2 instances support this processor feature.

• **Intel Advanced Vector Extensions (Intel AVX, Intel AVX2, and Intel AVX-512)** — Intel AVX and Intel AVX2 are 256-bit, and Intel AVX-512 is a 512-bit instruction set extension designed for applications that are Floating Point (FP) intensive. Intel AVX instructions improve performance for applications like image and audio/video processing, scientific simulations, financial analytics, and 3D modeling and analysis. These features are only available on instances launched with HVM AMIs.

• **Intel Turbo Boost Technology** — Intel Turbo Boost Technology processors automatically run cores faster than the base operating frequency.

• **Intel Deep Learning Boost (Intel DL Boost)** — Accelerates AI deep learning use cases. The 2nd Gen Intel Xeon Scalable processors extend Intel AVX-512 with a new Vector Neural Network Instruction (VNNI/INT8) that significantly increases deep learning inference performance over previous generation Intel Xeon Scalable processors (with FP32) for image recognition/segmentation, object detection, speech recognition, language translation, recommendation systems, reinforcement learning, and more. VNNI may not be compatible with all Linux distributions.

The following instances support VNNI: M5n, R5n, M5dn, M5zn, R5b, R5dn, D3, and D3en. C5 and C5d instances support VNNI for only 12xlarge, 24xlarge, and metal instances.

AMI virtualization types

The virtualization type of your instance is determined by the AMI that you use to launch it. Current generation instance types support hardware virtual machine (HVM) only. Some previous generation instance types support para virtual (PV) and some AWS Regions support PV instances. For more information, see Linux AMI virtualization types (p. 75).

For best performance, we recommend that you use an HVM AMI. In addition, HVM AMIs are required to take advantage of enhanced networking. HVM virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses PV network and storage drivers for improved performance.
Instances built on the Nitro System

The Nitro System is a collection of AWS-built hardware and software components that enable high performance, high availability, and high security. For more information, see AWS Nitro System.

The Nitro System provides bare metal capabilities that eliminate virtualization overhead and support workloads that require full access to host hardware. Bare metal instances are well suited for the following:

- Workloads that require access to low-level hardware features (for example, Intel VT) that are not available or fully supported in virtualized environments
- Applications that require a non-virtualized environment for licensing or support

Nitro components

The following components are part of the Nitro System:

- Nitro card
  - Local NVMe storage volumes
  - Networking hardware support
  - Management
  - Monitoring
  - Security
- Nitro security chip, integrated into the motherboard
- Nitro hypervisor - A lightweight hypervisor that manages memory and CPU allocation and delivers performance that is indistinguishable from bare metal for most workloads.

Instance types

The following instances are built on the Nitro System:

- **Virtualized**: A1, C5, C5a, C5ad, C5d, C5n, C6g, C6gd, C6gn, D3, D3en, G4, I3en, Inf1, M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6g, M6gd, M6i, p3dn.24xlarge, P4, R5, R5a, R5ad, R5b, R5d, R5dn, R5n, R6g, R6gd, T3, T3a, T4g, high memory (u-*), X2gd, and z1d
- **Bare metal**: a1.metal, c5.metal, c5d.metal, c5n.metal, c6g.metal, c6gd.metal, i3.metal, i3en.metal, m5.metal, m5d.metal, m5dn.metal, m5n.metal, m5zn.metal, m6g.metal, m6gd.metal, mac1.metal, r5.metal, r5b.metal, r5d.metal, r5dn.metal, r5n.metal, r6g.metal, r6gd.metal, u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, u-24tb1.metal, x2gd.metal, and z1d.metal

Networking and storage features

When you select an instance type, this determines the networking and storage features that are available. To describe an instance type, use the `describe-instance-types` command.

Networking features

- IPv6 is supported on all current generation instance types and the C3, R3, and I2 previous generation instance types.
- To maximize the networking and bandwidth performance of your instance type, you can do the following:
  - Launch supported instance types into a cluster placement group to optimize your instances for high performance computing (HPC) applications. Instances in a common cluster placement group can benefit from high-bandwidth, low-latency networking. For more information, see Placement groups (p. 1018).
  - Enable enhanced networking for supported current generation instance types to get significantly higher packet per second (PPS) performance, lower network jitter, and lower latencies. For more information, see Enhanced networking on Linux (p. 952).
- Current generation instance types that are enabled for enhanced networking have the following networking performance attributes:
  - Traffic within the same Region over private IPv4 or IPv6 can support 5 Gbps for single-flow traffic and up to 25 Gbps for multi-flow traffic (depending on the instance type).
  - Traffic to and from Amazon S3 buckets within the same Region over the public IP address space or through a VPC endpoint can use all available instance aggregate bandwidth.
  - The maximum transmission unit (MTU) supported varies across instance types. All Amazon EC2 instance types support standard Ethernet V2 1500 MTU frames. All current generation instances support 9001 MTU, or jumbo frames, and some previous generation instances support them as well. For more information, see Network maximum transmission unit (MTU) for your EC2 instance (p. 1030).

Storage features

- Some instance types support EBS volumes and instance store volumes, while other instance types support only EBS volumes. Some instance types that support instance store volumes use solid state drives (SSD) to deliver very high random I/O performance. Some instance types support NVMe instance store volumes. Some instance types support NVMe EBS volumes. For more information, see Amazon EBS and NVMe on Linux instances (p. 1350) and NVMe SSD volumes (p. 1421).
- To obtain additional, dedicated capacity for Amazon EBS I/O, you can launch some instance types as EBS–optimized instances. Some instance types are EBS–optimized by default. For more information, see Amazon EBS–optimized instances (p. 1354).

Summary of networking and storage features

The following table summarizes the networking and storage features supported by current generation instance types.

202
Instance limits

There is a limit on the total number of instances that you can launch in a region, and there are additional limits on some instance types.

For more information about the default limits, see How many instances can I run in Amazon EC2?

For more information about viewing your current limits or requesting an increase in your current limits, see Amazon EC2 service quotas (p. 1475).

General purpose instances

General purpose instances provide a balance of compute, memory, and networking resources, and can be used for a wide range of workloads.

M5 and M5a instances

These instances provide an ideal cloud infrastructure, offering a balance of compute, memory, and networking resources for a broad range of applications that are deployed in the cloud. They are well-suited for the following:

- Small and midsize databases
- Data processing tasks that require additional memory
- Caching fleets
- Backend servers for SAP, Microsoft SharePoint, cluster computing, and other enterprise applications

For more information, see Amazon EC2 M5 Instances.

Bare metal instances, such as m5.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

M5zn

These instances are ideal for applications that benefit from extremely high single-thread performance, high throughput, and low latency networking. They are well-suited for the following:

- Gaming
- High performance computing
- Simulation modeling

For more information, see Amazon EC2 M5 Instances.

Bare metal instances, such as m5zn.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

M6g and M6gd instances

These instances are powered by AWS Graviton2 processors and deliver balanced compute, memory, and networking for a broad range of general purpose workloads. They are well suited for the following:

- Application servers
- Microservices
- Gaming servers
- Midsize data stores
- Caching fleets

Bare metal instances, such as m6g.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 M6g Instances.

M6i instances

These instances are well suited for general-purpose workloads such as the following:

- Application servers and web servers
- Microservices
- High performance computing
- App development
- Small and midsize databases
- Caching fleets

For more information, see Amazon EC2 M6i Instances.

Mac1 instances

These instances are powered by Apple Mac mini computers. They provide up to 10 Gbps of network bandwidth and 8 Gbps EBS bandwidth through high-speed Thunderbolt 3 connections. They are well suited to develop, build, test, and sign applications for Apple devices, such as iPhone, iPad, iPod, Mac, Apple Watch, and Apple TV.

For more information, see Amazon EC2 Mac instances (p. 250).

T2, T3, T3a, and T4g instances

These instances provide a baseline level of CPU performance with the ability to burst to a higher level when required by your workload. An Unlimited instance can sustain high CPU performance for any period of time whenever required. For more information, see Burstable performance instances (p. 216). They are well-suited for the following:

- Websites and web applications
- Code repositories
- Development, build, test, and staging environments
- Microservices

For more information, see Amazon EC2 T2 Instances, Amazon EC2 T3 Instances, and Amazon EC2 T4g Instances.

For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

For more information about specifying CPU options, see Optimize CPU options (p. 575).

**Instance performance**

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some general purpose instances are EBS-optimized by default at no additional cost. For more information, see Amazon EBS–optimized instances (p. 1354).

Some general purpose instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see Processor state control for your EC2 instance (p. 564).

**Network performance**

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see Enhanced networking on Linux (p. 952).

The following is a summary of network performance for general purpose instances that support enhanced networking.

### SSD I/O performance

If you use a Linux AMI with kernel version 4.4 or later and use all the SSD-based instance store volumes available to your instance, you get the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

<table>
<thead>

</tbody>
</table>

* For these instances, you can get up to the specified performance.

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write
operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called over-provisioning. The SSD-based instance store volumes provided to an instance don’t have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you’ve written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see Instance store volume TRIM support (p. 1422).

### Instance features

* The root device volume must be an Amazon EBS volume.

For more information, see the following:
Amazon Elastic Compute Cloud
User Guide for Linux Instances
General purpose

- Amazon EBS and NVMe on Linux instances (p. 1350)
- Amazon EC2 instance store (p. 1408)
- Placement groups (p. 1018)

Release notes

- M5, M5d, and T3 instances feature a 3.1 GHz Intel Xeon Platinum 8000 series processor from either the first generation (Skylake-SP) or second generation (Cascade Lake).
- M5a, M5ad, and T3a instances feature a 2.5 GHz AMD EPYC 7000 series processor.
- M5zn instances are powered by Intel Cascade Lake CPUs that deliver all-core turbo frequency of up to 4.5 GHz and up to 100 Gbps network bandwidth.
- M6g and M6gd instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- M6i instances feature third generation Intel Xeon Scalable processors (Ice Lake) and support the Intel Advanced Vector Extensions 512 (Intel AVX-512) instruction set.
- Mac1 instances feature a 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processor.
- T4g instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- Instances built on the Nitro System (p. 199), M4, t2.large and larger, t3.large and larger, and t3a.large and larger instance types require 64-bit HVM AMIs. They have high-memory, and require a 64-bit operating system to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. In addition, you must use an HVM AMI to take advantage of enhanced networking.
- Instances built on the Nitro System (p. 199) have the following requirements:
  - NVMe drivers (p. 1350) must be installed
  - Elastic Network Adapter (ENA) drivers (p. 953) must be installed

The following Linux AMIs meet these requirements:
- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with linux-aws kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

Instances with an AWS Graviton Processor have the following requirements:
- Use an AMI for the 64-bit Arm architecture.
- Support booting through UEFI with ACPI tables and support ACPI hot-plug of PCI devices.

The following Linux AMIs meet these requirements:
- Amazon Linux 2 (64-bit Arm)
- Ubuntu 16.04 or later (64-bit Arm)
- Red Hat Enterprise Linux 8.0 or later (64-bit Arm)
- SUSE Linux Enterprise Server 15 or later (64-bit Arm)
- Debian 10 or later (64-bit Arm)

To get the best performance from your M6i instances, ensure that they have ENA driver version 2.2.9 or later. Using an ENA driver earlier than version 1.2 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
- Amazon Linux 2 with kernel 4.14.186

215
• Ubuntu 20.04 with kernel 5.4.0-1025-aws
• Red Hat Enterprise Linux 8.3 with kernel 4.18.0-240.1.1.el8_3.Arch
• SUSE Linux Enterprise Server 15 SP2 with kernel 5.3.18-24.15.1
• Amazon EC2 Mac instances support macOS Mojave (version 10.14), macOS Catalina (version 10.15), and macOS Big Sur (version 11).
• Instances built on the Nitro System support a maximum of 28 attachments, including network interfaces, EBS volumes, and NVMe instance store volumes. For more information, see Nitro System volume limits (p. 1432).
• Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
• To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y
CONFIG_PCIEASPM=y
```
• Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
• Instances built on the Nitro System should have system-logind or acpid installed to support clean shutdown through API requests.
• There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see How many instances can I run in Amazon EC2? in the Amazon EC2 FAQ.

Burstable performance instances

Many general purpose workloads are on average not busy, and do not require a high level of sustained CPU performance. The following graph illustrates the CPU utilization for many common workloads that customers run in the AWS Cloud today.
These low-to-moderate CPU utilization workloads lead to wastage of CPU cycles and, as a result, you pay for more than you use. To overcome this, you can leverage the low-cost burstable general purpose instances, which are the T instances.

The T instance family provides a baseline CPU performance with the ability to burst above the baseline at any time for as long as required. The baseline CPU is defined to meet the needs of the majority of general purpose workloads, including large-scale micro-services, web servers, small and medium databases, data logging, code repositories, virtual desktops, development and test environments, and business-critical applications. The T instances offer a balance of compute, memory, and network resources, and provide you with the most cost-effective way to run a broad spectrum of general purpose applications that have a low-to-moderate CPU usage. They can save you up to 15% in costs when compared to M instances, and can lead to even more cost savings with smaller, more economical instance sizes, offering as low as 2 vCPUs and 0.5 GiB of memory. The smaller T instance sizes, such as nano, micro, small, and medium, are well suited for workloads that need a small amount of memory and do not expect high CPU usage.

**EC2 burstable instance types**

The EC2 burstable instances consist of T4g, T3a and T3 instance types, and the previous generation T2 instance types.

The T4g instance types are the latest generation of burstable instances. They provide the best price for performance, and provide you with the lowest cost of all the EC2 instance types. The T4g instance types are powered by Arm-based **AWS Graviton2** processors with extensive ecosystem support from operating systems vendors, independent software vendors, and popular AWS services and applications.

The following table summarizes the key differences between the burstable instance types.

<table>

**Previous generation**

| T2   | Previous generation burstable instances | Intel Xeon processors |

For more information about instance pricing and additional specifications, see Amazon EC2 Pricing and Amazon EC2 Instance Types.

If your account is less than 12 months old, you can use a t2.micro instance for free (or a t3.micro instance in Regions where t2.micro is unavailable) within certain usage limits. For more information, see AWS Free Tier.

### Supported purchasing options for T instances

- On-Demand Instances
- Reserved Instances
- Dedicated Instances (T3 only)
- Spot Instances

T instances are not supported on a Dedicated Host. For more information, see Instance purchasing options (p. 320).

### Contents

- Best practices (p. 218)
- Key concepts and definitions for burstable performance instances (p. 219)
- Unlimited mode for burstable performance instances (p. 225)
- Standard mode for burstable performance instances (p. 232)
- Work with burstable performance instances (p. 241)
- Monitor your CPU credits (p. 246)

### Best practices

Follow these best practices to get the maximum benefit from burstable performance instances.

- Ensure that the instance size you choose passes the minimum memory requirements of your operating system and applications. Operating systems with graphical user interfaces that consume significant memory and CPU resources (for example, Windows) might require a t3.micro or larger instance size for many use cases. As the memory and CPU requirements of your workload grow over time, you have the flexibility with the T instances to scale to larger instance sizes of the same instance type, or to select another instance type.
• Enable AWS Compute Optimizer for your account and review the Compute Optimizer recommendations for your workload. Compute Optimizer can help assess whether instances should be up sized to improve performance or downsized for cost savings.
• For additional requirements, see Release notes (p. 215).

Key concepts and definitions for burstable performance instances

Traditional Amazon EC2 instance types provide fixed CPU resources, while burstable performance instances provide a baseline level of CPU utilization with the ability to burst CPU utilization above the baseline level. This ensures that you pay only for baseline CPU plus any additional burst CPU usage resulting in lower compute costs. The baseline utilization and ability to burst are governed by CPU credits. Burstable performance instances are the only instance types that use credits for CPU usage.

Each burstable performance instance continuously earns credit when it stays below the CPU baseline, and continuously spends credits when it bursts above the baseline. The amount of credits earned or spent depends on the CPU utilization of the instance:

• If the CPU utilization is below baseline, then credits earned are greater than credits spent.
• If the CPU utilization is equal to baseline, then credits earned are equal to credits spent.
• If the CPU utilization is higher than baseline, then credits spent are higher than credits earned.

When the credits earned are greater than credits spent, then the difference is called accrued credits, which can be used later to burst above baseline CPU utilization. Similarly, when the credits spent are more than credits earned, the instance behavior depends on the credit configuration mode—Standard mode or Unlimited mode.

In Standard mode, when credits spent are more than credits earned, the instance uses the accrued credits to burst above baseline CPU utilization. If there are no accrued credits remaining, then the instance gradually comes down to baseline CPU utilization and cannot burst above baseline until it accrues more credits.

In Unlimited mode, if the instance bursts above baseline CPU utilization, then the instance first uses the accrued credits to burst. If there are no accrued credits remaining, then the instance spends surplus credits to burst. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a flat additional rate per vCPU-hour.

• Baseline utilization (p. 224)

Key concepts and definitions

The following key concepts and definitions are applicable to burstable performance instances.

CPU utilization

CPU utilization is the percentage of allocated EC2 compute units that are currently in use on the instance. This metric measures the percentage of allocated CPU cycles that are being utilized on an
instance. The CPU Utilization CloudWatch metric shows CPU usage per instance and not CPU usage per core. The baseline CPU specification of an instance is also based on the CPU usage per instance. To measure CPU utilization using the AWS Management Console or the AWS CLI, see Get statistics for a specific instance (p. 833).

CPU credit

A unit of vCPU-time.

Examples:

1 CPU credit = 1 vCPU * 100% utilization * 1 minute.
1 CPU credit = 1 vCPU * 50% utilization * 2 minutes
1 CPU credit = 2 vCPU * 25% utilization * 2 minutes

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline. Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows: Baseline utilization % = (number of credits earned/number of vCPUs)/60 minutes

Earned credits

Credits earned continuously by an instance when it is running.

Number of credits earned per hour = % baseline utilization * number of vCPUs * 60 minutes

Example:

A t3.nano with 2 vCPUs and a baseline utilization of 5% earns 6 credits per hour, calculated as follows:

2 vCPUs * 5% baseline * 60 minutes = 6 credits per hour

Spent or used credits

Credits used continuously by an instance when it is running.

CPU credits spent per minute = Number of vCPUs * CPU utilization * 1 minute

Accrued credits

Unspent CPU credits when an instance uses fewer credits than is required for baseline utilization. In other words, accrued credits = (Earned credits – Used credits) below baseline.

Example:

If a t3.nano is running at 2% CPU utilization, which is below its baseline of 5% for an hour, the accrued credits is calculated as follows:

Accrued CPU credits = (Earned credits per hour – Used credits per hour) = 6 – 2 vCPUs * 2% CPU utilization * 60 minutes = 6 – 2.4 = 3.6 accrued credits per hour

Credit accrual limit

Depends on the instance size but in general is equal to the number of maximum credits earned in 24 hours.
Example:

For t3.nano, the credit accrual limit = 24 * 6 = 144 credits

Launch credits

Only applicable for T2 instances configured for Standard mode. Launch credits are a limited number of CPU credits that are allocated to a new T2 instance so that, when launched in Standard mode, it can burst above the baseline.

Surplus credits

Credits that are spent by an instance after it depletes its accrued credit balance. The surplus credits are designed for burstable instances to sustain high performance for an extended period of time, and are only used in Unlimited mode. The surplus credits balance is used to determine how many credits were used by the instance for bursting in Unlimited mode.

Standard mode

Credit configuration mode, which allows an instance to burst above the baseline by spending credits it has accrued in its credit balance.

Unlimited mode

Credit configuration mode, which allows an instance to burst above the baseline by sustaining high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour.

The following table summarizes the key credit differences between the burstable instance types.

<table>
<thead>

</tbody>
</table>
Earn CPU credits

Each burstable performance instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. The accounting process for whether credits are accrued or spent also happens at a millisecond-level resolution, so you don’t have to worry about overspending CPU credits; a short burst of CPU uses a small fraction of a CPU credit.

If a burstable performance instance uses fewer CPU resources than is required for baseline utilization (such as when it is idle), the unspent CPU credits are accrued in the CPU credit balance. If a burstable performance instance needs to burst above the baseline utilization level, it spends the accrued credits. The more credits that a burstable performance instance has accrued, the more time it can burst beyond its baseline when more CPU utilization is needed.

The following table lists the burstable performance instance types, the rate at which CPU credits are earned per hour, the maximum number of earned CPU credits that an instance can accrue, the number of vCPUs per instance, and the baseline utilization as a percentage of a full core (using a single vCPU).

<table>

</tbody>
</table>

* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.

** The percentage baseline utilization in the table is per vCPU. In CloudWatch, CPU utilization is shown per vCPU. For example, the CPU utilization for a t3.large instance operating at the baseline level is shown as 30% in CloudWatch CPU metrics. For information about how to calculate the baseline utilization, see Baseline utilization (p. 224).

*** Each vCPU is a thread of either an Intel Xeon core or an AMD EPYC core, except for T2 and T4g instances.

CPU credit earn rate

The number of CPU credits earned per hour is determined by the instance size. For example, a t3.nano earns six credits per hour, while a t3.small earns 24 credits per hour. The preceding table lists the credit earn rate for all instances.

CPU credit accrual limit

While earned credits never expire on a running instance, there is a limit to the number of earned credits that an instance can accrue. The limit is determined by the CPU credit balance limit. After the limit is reached, any new credits that are earned are discarded, as indicated by the following image. The full
bucket indicates the CPU credit balance limit, and the spillover indicates the newly earned credits that exceed the limit.

The CPU credit balance limit differs for each instance size. For example, a t3.micro instance can accrue a maximum of 288 earned CPU credits in the CPU credit balance. The preceding table lists the maximum number of earned credits that each instance can accrue.

T2 Standard instances also earn launch credits. Launch credits do not count towards the CPU credit balance limit. If a T2 instance has not spent its launch credits, and remains idle over a 24-hour period while accruing earned credits, its CPU credit balance appears as over the limit. For more information, see Launch credits (p. 233).

T4g, T3a and T3 instances do not earn launch credits. These instances launch as unlimited by default, and therefore can burst immediately upon start without any launch credits.

Accrued CPU credits life span

CPU credits on a running instance do not expire.

For T2, the CPU credit balance does not persist between instance stops and starts. If you stop a T2 instance, the instance loses all its accrued credits.

For T4g, T3a and T3, the CPU credit balance persists for seven days after an instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

For more information, see CPUCreditBalance in the CloudWatch metrics table (p. 247).

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline.

Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows:

\[
\frac{\text{number of credits earned}/\text{number of vCPUs}}{60 \text{ minutes}} = \% \text{ baseline utilization}
\]

For example, a t3.nano instance, with 2 vCPUs, earns 6 credits per hour, resulting in a baseline utilization of 5%, which is calculated as follows:

\[
\frac{6 \text{ credits earned}/2 \text{ vCPUs}}{60 \text{ minutes}} = 5\% \text{ baseline utilization}
\]
A t3.xlarge instance, with 4 vCPUs, earns 96 credits per hour, resulting in a baseline utilization of 40% \((96/4)/60\).

The following graph provides an example of a t3.large with an average CPU utilization below the baseline.

![Example of t3.large](image)

**Unlimited mode for burstable performance instances**

A burstable performance instance configured as unlimited can sustain high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter.

For the vast majority of general-purpose workloads, instances configured as unlimited provide ample performance without any additional charges. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour. For information about pricing, see Amazon EC2 pricing and T2/T3/T4 Unlimited Mode Pricing.

If you use a t2.micro or t3.micro instance under the AWS Free Tier offer and use it in unlimited mode, charges might apply if your average utilization over a rolling 24-hour period exceeds the baseline utilization (p. 224) of the instance.

T4g, T3a and T3 instances launch as unlimited by default. If the average CPU usage over a 24-hour period exceeds the baseline, you incur charges for surplus credits. If you launch Spot Instances as unlimited and plan to use them immediately and for a short duration, with no idle time for accruing CPU credits, you incur charges for surplus credits. We recommend that you launch your Spot Instances in standard (p. 232) mode to avoid paying higher costs. For more information, see Surplus credits can incur charges (p. 228) and Burstable performance instances (p. 414).

**Contents**

- Unlimited mode concepts (p. 226)
  - How Unlimited burstable performance instances work (p. 226)
  - When to use unlimited mode versus fixed CPU (p. 226)
  - Surplus credits can incur charges (p. 228)
  - No launch credits for T2 Unlimited instances (p. 228)
**Unlimited mode concepts**

The **unlimited** mode is a credit configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set unlimited as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

**How Unlimited burstable performance instances work**

If a burstable performance instance configured as unlimited depletes its CPU credit balance, it can spend surplus credits to burst beyond the baseline (p. 224). When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a **flat additional rate** per vCPU-hour.

The following graph shows the CPU usage of a **t3.large**. The baseline CPU utilization for a **t3.large** is 30%. If the instance runs at 30% CPU utilization or less on average over a 24-hour period, there is no additional charge because the cost is already covered by the instance hourly price. However, if the instance runs at 40% CPU utilization on average over a 24-hour period, as shown in the graph, the instance is billed for the additional 10% CPU usage at a **flat additional rate** per vCPU-hour.

For more information about the baseline utilization per vCPU for each instance type and how many credits each instance type earns, see the **credit table** (p. 222).

**When to use unlimited mode versus fixed CPU**

When determining whether you should use a burstable performance instance in unlimited mode, such as T3, or a fixed performance instance, such as M5, you need to determine the breakeven CPU usage. The breakeven CPU usage for a burstable performance instance is the point at which a burstable performance instance costs the same as a fixed performance instance. The breakeven CPU usage helps you determine the following:
• If the average CPU usage over a 24-hour period is at or below the breakeven CPU usage, use a
  burstable performance instance in unlimited mode so that you can benefit from the lower price of a
  burstable performance instance while getting the same performance as a fixed performance instance.
• If the average CPU usage over a 24-hour period is above the breakeven CPU usage, the burstable
  performance instance will cost more than the equivalently-sized fixed performance instance. If a T3
  instance continuously bursts at 100% CPU, you end up paying approximately 1.5 times the price of an
  equivalently-sized M5 instance.

The following graph shows the breakeven CPU usage point where a t3.large costs the same as an
m5.large. The breakeven CPU usage point for a t3.large is 42.5%. If the average CPU usage is at
42.5%, the cost of running the t3.large is the same as an m5.large, and is more expensive if the
average CPU usage is above 42.5%. If the workload needs less than 42.5% average CPU usage, you can
benefit from the lower price of the t3.large while getting the same performance as an m5.large.

The following table shows how to calculate the breakeven CPU usage threshold so that you can
determine when it’s less expensive to use a burstable performance instance in unlimited mode or a
fixed performance instance. The columns in the table are labeled A through K.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>vCPUs</th>
<th>T3 price*/hour</th>
<th>M5 price*/hour</th>
<th>Price difference</th>
<th>T3 price per vCPU utilization</th>
<th>Charge per minute for surplus credits</th>
<th>Additional burst minutes available per vCPU</th>
<th>Additional CPU % available</th>
<th>Breakeven CPU %</th>
</tr>
</thead>
<tbody>
<tr>
<td>t3.large</td>
<td>2</td>

<td>30%</td>
<td>$0.05</td>
<td>15</td>
<td>12.5%</td>
<td>42.5%</td>
</tr>
</tbody>
</table>

* Price is based on us-east-1 and Linux OS.

The table provides the following information:
• Column A shows the instance type, t3.large.
• Column B shows the number of vCPUs for the t3.large.
• Column C shows the price of a t3.large per hour.
• Column D shows the price of an m5.large per hour.
• Column E shows the price difference between the t3.large and the m5.large.
Column F shows the baseline utilization per vCPU of the **t3.large**, which is 30%. At the baseline, the hourly cost of the instance covers the cost of the CPU usage.

Column G shows the flat additional rate per vCPU-hour that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.

Column H shows the flat additional rate per vCPU-minute that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.

Column I shows the number of additional minutes that the **t3.large** can burst per hour at 100% CPU while paying the same price per hour as an **m5.large**.

Column J shows the additional CPU usage (in %) over baseline that the instance can burst while paying the same price per hour as an **m5.large**.

Column K shows the breakeven CPU usage (in %) that the **t3.large** can burst without paying more than the **m5.large**. Anything above this, and the **t3.large** costs more than the **m5.large**.

The following table shows the breakeven CPU usage (in %) for T3 instance types compared to the similarly-sized M5 instance types.

<table>
<thead>

**Surplus credits can incur charges**

If the average CPU utilization of an instance is at or below the baseline, the instance incurs no additional charges. Because an instance earns a maximum number of credits (p. 222) in a 24-hour period (for example, a **t3.micro** instance can earn a maximum of 288 credits in a 24-hour period), it can spend surplus credits up to that maximum without being charged.

However, if CPU utilization stays above the baseline, the instance cannot earn enough credits to pay down the surplus credits that it has spent. The surplus credits that are not paid down are charged at a flat additional rate per vCPU-hour. For information about the rate, see  T2/T3/T4g Unlimited Mode Pricing.

Surplus credits that were spent earlier are charged when any of the following occurs:

- The spent surplus credits exceed the maximum number of credits (p. 222) the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.
- The instance is stopped or terminated.
- The instance is switched from unlimited to standard.

Spent surplus credits are tracked by the CloudWatch metric **CPUSurplusCreditBalance**. Surplus credits that are charged are tracked by the CloudWatch metric **CPUSurplusCreditsCharged**. For more information, see Additional CloudWatch metrics for burstable performance instances (p. 247).

**No launch credits for T2 Unlimited instances**

T2 Standard instances receive launch credits (p. 233), but T2 Unlimited instances do not. A T2 Unlimited instance can burst beyond the baseline at any time with no additional charge, as long as its average CPU utilization is at or below the baseline over a rolling 24-hour window or its lifetime, whichever is shorter. As such, T2 Unlimited instances do not require launch credits to achieve high performance immediately after launch.
If a T2 instance is switched from standard to unlimited, any accrued launch credits are removed from the CPUCreditBalance before the remaining CPUCreditBalance is carried over.

T4g, T3a and T3 instances never receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

**Enable unlimited mode**

You can switch from unlimited to standard, and from standard to unlimited, at any time on a running or stopped instance. For more information, see Launch a burstable performance instance as Unlimited or Standard (p. 242) and Modify the credit specification of a burstable performance instance (p. 245).

You can set unlimited as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option. For more information, see Set the default credit specification for the account (p. 246).

You can check whether your burstable performance instance is configured as unlimited or standard using the Amazon EC2 console or the AWS CLI. For more information, see View the credit specification of a burstable performance instance (p. 244) and View the default credit specification (p. 246).

**What happens to credits when switching between Unlimited and Standard**

CPUCreditBalance is a CloudWatch metric that tracks the number of credits accrued by an instance. CPUSurplusCreditBalance is a CloudWatch metric that tracks the number of surplus credits spent by an instance.

When you change an instance configured as unlimited to standard, the following occurs:

- The CPUCreditBalance value remains unchanged and is carried over.
- The CPUSurplusCreditBalance value is immediately charged.

When a standard instance is switched to unlimited, the following occurs:

- The CPUCreditBalance value containing accrued earned credits is carried over.
- For T2 Standard instances, any launch credits are removed from the CPUCreditBalance value, and the remaining CPUCreditBalance value containing accrued earned credits is carried over.

**Monitor credit usage**

To see if your instance is spending more credits than the baseline provides, you can use CloudWatch metrics to track usage, and you can set up hourly alarms to be notified of credit usage. For more information, see Monitor your CPU credits (p. 246).

**Unlimited mode examples**

The following examples explain credit use for instances that are configured as unlimited.

**Examples**

- Example 1: Explain credit use with T3 Unlimited (p. 229)
- Example 2: Explain credit use with T2 Unlimited (p. 231)

**Example 1: Explain credit use with T3 Unlimited**

In this example, you see the CPU utilization of a t3.nano instance launched as unlimited, and how it spends earned and surplus credits to sustain CPU utilization.
A **t3.nano** instance earns 144 CPU credits over a rolling 24-hour period, which it can redeem for 144 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend surplus CPU credits—that it has **not yet earned**—to burst for as long as it needs. Because a **t3.nano** instance earns a maximum of 144 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 144 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. The following workflow references the numbered points on the graph:

**P1** – At 0 hours on the graph, the instance is launched as unlimited and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

**P2** – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits.

**P3** – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

**P4** – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

**P5** – For the next 5 hours, the instance bursts at 100% CPU utilization, and spends a total of 570 credits to sustain the burst. About an hour into this period, the instance depletes its entire CPUCreditBalance of 122 credits, and starts to spend surplus credits to sustain the high CPU utilization, totaling 448 surplus credits in this period (570-122=448). When the CPUSurplusCreditBalance value reaches 144 CPU credits (the maximum a **t3.nano** instance can earn in a 24-hour period), any surplus credits spent thereafter cannot be offset by earned credits. The surplus credits spent thereafter amounts to 304 credits (448-144=304), which results in a small additional charge at the end of the hour for 304 credits.

**P6** – For the next 13 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends, with no excess to pay down the CPUSurplusCreditBalance. The CPUSurplusCreditBalance value remains at 144 credits.

**P7** – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it uses to pay down the CPUSurplusCreditBalance.
Example 2: Explain credit use with T2 Unlimited

In this example, you see the CPU utilization of a t2.nano instance launched as unlimited, and how it spends earned and surplus credits to sustain CPU utilization.

A t2.nano instance earns 72 CPU credits over a rolling 24-hour period, which it can redeem for 72 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend surplus CPU credits—that it has not yet earned—to burst for as long as it needs. Because a t2.nano instance earns a maximum of 72 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 72 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. You can assume that, at the start of the time line in the graph, the instance has an accrued credit balance equal to the maximum number of credits it can earn in 24 hours. The following workflow references the numbered points on the graph:

1 – In the first 10 minutes, CPUCreditUsage is at 0, and the CPUCreditBalance value remains at its maximum of 72.

2 – At 23:40, as CPU utilization increases, the instance spends CPU credits and the CPUCreditBalance value decreases.

3 – At around 00:47, the instance depletes its entire CPUCreditBalance, and starts to spend surplus credits to sustain high CPU utilization.

4 – Surplus credits are spent until 01:55, when the CPUSurplusCreditBalance value reaches 72 CPU credits. This is equal to the maximum a t2.nano instance can earn in a 24-hour period. Any surplus credits spent thereafter cannot be offset by earned credits within the 24-hour period, which results in a small additional charge at the end of the hour.

5 – The instance continues to spend surplus credits until around 02:20. At this time, CPU utilization falls below the baseline, and the instance starts to earn credits at 3 credits per hour (or 0.25 credits every 5 minutes), which it uses to pay down the CPUSurplusCreditBalance. After the CPUSurplusCreditBalance value reduces to 0, the instance starts to accrue earned credits in its CPUCreditBalance at 0.25 credits every 5 minutes.

Calculating the bill
Surplus credits cost $0.05 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours.

Additional charges for this instance are 0.42 vCPU-hours x $0.05/vCPU-hour = $0.021, rounded to $0.02.

Here is the month-end bill for this T2 Unlimited instance:

<table>
<thead>
<tr>
<th>Service</th>
<th>Hours</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Elastic Compute Cloud</td>
<td>720.000</td>
<td>$4.18</td>
</tr>
<tr>
<td>Amazon Elastic Compute Cloud T2</td>
<td>0.420</td>
<td>$0.02</td>
</tr>
</tbody>
</table>

You can set billing alerts to be notified every hour of any accruing charges, and take action if required.

**Standard mode for burstable performance instances**

A burstable performance instance configured as standard is suited to workloads with an average CPU utilization that is consistently below the baseline CPU utilization of the instance. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. If the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level, so that the instance does not experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see Key concepts and definitions for burstable performance instances (p. 219).

    - Period 6: 76 – 90 hours (p. 240)
    - Period 7: 91 – 96 hours (p. 241)

**Standard mode concepts**

The standard mode is a configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set standard as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

**How standard burstable performance instances work**

When a burstable performance instance configured as standard is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. For T2 Standard, when
the instance is stopped, it loses all its accrued credits, and its credit balance is reset to zero. When it is
restarted, it receives a new set of launch credits, and begins to accrue earned credits. For T4g, T3a and
T3 Standard instances, the CPU credit balance persists for seven days after the instance stops and the
credits are lost thereafter. If you start the instance within seven days, no credits are lost.

T2 Standard instances receive two types of CPU credits: earned credits and launch credits. When a T2
Standard instance is in a running state, it continuously earns (at a millisecond-level resolution) a set rate
of earned credits per hour. At start, it has not yet earned credits for a good startup experience; therefore,
to provide a good startup experience, it receives launch credits at start, which it spends first while it
accrues earned credits.

T4g, T3a and T3 instances do not receive launch credits because they support Unlimited mode. The
Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to
burst beyond baseline and for as long as needed.

Launch credits

T2 Standard instances get 30 launch credits per vCPU at launch or start. For example, a t2.micro
instance has one vCPU and gets 30 launch credits, while a t2.xlarge instance has four vCPUs and gets
120 launch credits. Launch credits are designed to provide a good startup experience to allow instances
to burst immediately after launch before they have accrued earned credits.

Launch credits are spent first, before earned credits. Unspent launch credits are accrued in the CPU
credit balance, but do not count towards the CPU credit balance limit. For example, a t2.micro instance
has a CPU credit balance limit of 144 earned credits. If it is launched and remains idle for 24 hours,
its CPU credit balance reaches 174 (30 launch credits + 144 earned credits), which is over the limit.
However, after the instance spends the 30 launch credits, the credit balance cannot exceed 144. For more
information about the CPU credit balance limit for each instance size, see the credit table (p. 222).

The following table lists the initial CPU credit allocation received at launch or start, and the number of
vCPUs.

<table>

Launch credit limits

There is a limit to the number of times T2 Standard instances can receive launch credits. The default limit
is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-
hour period. For example, the limit is reached when one instance is stopped and started 100 times within
a 24-hour period, or when 100 instances are launched within a 24-hour period, or other combinations
that equate to 100 starts. New accounts may have a lower limit, which increases over time based on your
usage.
Tip
To ensure that your workloads always get the performance they need, switch to Unlimited mode for burstable performance instances (p. 225) or consider using a larger instance size.

Differences between launch credits and earned credits

The following table lists the differences between launch credits and earned credits.

<table>
<thead>
<tr>
<th>Credit earn rate</th>
<th>Launch credits</th>
<th>Earned credits</th>
</tr>
</thead>
<tbody>
<tr>
<td>T2 Standard instances get 30 launch credits per vCPU at launch or start. If a T2 instance is switched from unlimited to standard, it does not get launch credits at the time of switching.</td>
<td>Each T2 instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. For more information about the number of CPU credits earned per instance size, see the credit table (p. 222).</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Credit earn limit</th>
<th>Credit use</th>
<th>Credit expiration</th>
</tr>
</thead>
<tbody>
<tr>
<td>The limit for receiving launch credits is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. New accounts may have a lower limit, which increases over time based on your usage.</td>
<td>Launch credits are spent first, before earned credits.</td>
<td>When a T2 Standard instance is running, launch credits do not expire. When a T2 Standard instance stops or is switched to T2 Unlimited, all launch credits are lost.</td>
</tr>
<tr>
<td>A T2 instance cannot accrue more credits than the CPU credit balance limit. If the CPU credit balance has reached its limit, any credits that are earned after the limit is reached are discarded. Launch credits do not count towards the limit. For more information about the CPU credit balance limit for each T2 instance size, see the credit table (p. 222).</td>
<td>Earned credits are spent only after all launch credits are spent.</td>
<td>When a T2 instance is running, earned credits that have accrued do not expire. When the T2 instance stops, all accrued earned credits are lost.</td>
</tr>
</tbody>
</table>

The number of accrued launch credits and accrued earned credits is tracked by the CloudWatch metric CPUCreditBalance. For more information, see CPUCreditBalance in the CloudWatch metrics table (p. 247).

Standard mode examples

The following examples explain credit use when instances are configured as standard.

Examples

- Example 1: Explain credit use with T3 Standard (p. 234)
- Example 2: Explain credit use with T2 Standard (p. 236)

Example 1: Explain credit use with T3 Standard

In this example, you see how a t3.nano instance launched as standard earns, accrues, and spends earned credits. You see how the credit balance reflects the accrued earned credits.

A running t3.nano instance earns 144 credits every 24 hours. Its credit balance limit is 144 earned credits. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the credit table (p. 222).
You might launch a T3 Standard instance and use it immediately. Or, you might launch a T3 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance reaches its limit, which is the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

The following workflow references the numbered points on the graph:

**P1** – At 0 hours on the graph, the instance is launched as standard and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

**P2** – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits. Any credits that are earned in excess of the limit are discarded.

**P3** – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

**P4** – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

**P5** – For the next two hours, the instance bursts at 100% CPU utilization, and depletes its entire CPUCreditBalance value of 122 credits. At the end of this period, with the CPUCreditBalance at zero, CPU utilization is forced to drop to the baseline utilization level of 5%. At the baseline, the instance earns as many credits as it spends.

**P6** – For the next 14 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends. The CPUCreditBalance value remains at 0.

**P7** – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it accrues in its CPUCreditBalance.
Example 2: Explain credit use with T2 Standard

In this example, you see how a `t2.nano` instance launched as standard earns, accrues, and spends launch and earned credits. You see how the credit balance reflects not only accrued earned credits, but also accrued launch credits.

A `t2.nano` instance gets 30 launch credits when it is launched, and earns 72 credits every 24 hours. Its credit balance limit is 72 earned credits; launch credits do not count towards the limit. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the credit table (p. 222). For more information about limits, see Launch credit limits (p. 233).

You might launch a T2 Standard instance and use it immediately. Or, you might launch a T2 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance appears to exceed its limit because the balance reflects both accrued earned credits and accrued launch credits. However, after CPU is used, the launch credits are spent first. Thereafter, the limit always reflects the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

Period 1: 1 – 24 hours

At 0 hours on the graph, the T2 instance is launched as standard and immediately gets 30 launch credits. It earns credits while in the running state. The instance remains idle from the time it is launched —CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. At approximately 14 hours after launch, the credit balance is 72 (30 launch credits + 42 earned credits), which is equivalent to what the instance can earn in 24 hours. At 24 hours after launch, the credit balance exceeds 72 credits because the unspent launch credits are accrued in the credit balance—the credit balance is 102 credits: 30 launch credits + 72 earned credits.

<table>
<thead>
<tr>
<th>Credit Spend Rate</th>
<th>0 credits per 24 hours (0% CPU utilization)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Earn Rate</td>
<td>72 credits per 24 hours</td>
</tr>
<tr>
<td>Credit Discard Rate</td>
<td>0 credits per 24 hours</td>
</tr>
<tr>
<td>Credit Balance</td>
<td>102 credits (30 launch credits + 72 earned credits)</td>
</tr>
</tbody>
</table>
Conclusion

If there is no CPU utilization after launch, the instance accrues more credits than what it can earn in 24 hours (30 launch credits + 72 earned credits = 102 credits).

In a real-world scenario, an EC2 instance consumes a small number of credits while launching and running, which prevents the balance from reaching the maximum theoretical value in this example.

Period 2: 25 – 36 hours

For the next 12 hours, the instance continues to remain idle and earn credits, but the credit balance does not increase. It plateaus at 102 credits (30 launch credits + 72 earned credits). The credit balance has reached its limit of 72 accrued earned credits, so newly earned credits are discarded.

<table>
<thead>
<tr>
<th>Credit Spend Rate</th>
<th>0 credits per 24 hours (0% CPU utilization)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Earn Rate</td>
<td>72 credits per 24 hours (3 credits per hour)</td>
</tr>
<tr>
<td>Credit Discard Rate</td>
<td>72 credits per 24 hours (100% of credit earn rate)</td>
</tr>
<tr>
<td>Credit Balance</td>
<td>102 credits (30 launch credits + 72 earned credits) —balance is unchanged</td>
</tr>
</tbody>
</table>

Conclusion

An instance constantly earns credits, but it cannot accrue more earned credits if the credit balance has reached its limit. After the limit is reached, newly earned credits are discarded. Launch credits do not count towards the credit balance limit. If the balance includes accrued launch credits, the balance appears to be over the limit.

Period 3: 37 – 61 hours

For the next 25 hours, the instance uses 2% CPU, which requires 30 credits. In the same period, it earns 75 credits, but the credit balance decreases. The balance decreases because the accrued launch credits are spent first, while newly earned credits are discarded because the credit balance is already at its limit of 72 earned credits.
Credit Spend Rate: 28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—30 credits over 25 hours

Credit Earn Rate: 72 credits per 24 hours

Credit Discard Rate: 72 credits per 24 hours (100% of credit earn rate)

Credit Balance: 72 credits (30 launch credits were spent; 72 earned credits remain unspent)

Conclusion

An instance spends launch credits first, before spending earned credits. Launch credits do not count towards the credit limit. After the launch credits are spent, the balance can never go higher than what can be earned in 24 hours. Furthermore, while an instance is running, it cannot get more launch credits.

Period 4: 62 – 72 hours

For the next 11 hours, the instance uses 2% CPU, which requires 13.2 credits. This is the same CPU utilization as in the previous period, but the balance does not decrease. It stays at 72 credits.

The balance does not decrease because the credit earn rate is higher than the credit spend rate. In the time that the instance spends 13.2 credits, it also earns 33 credits. However, the balance limit is 72 credits, so any earned credits that exceed the limit are discarded. The balance plateaus at 72 credits, which is different from the plateau of 102 credits during Period 2, because there are no accrued launch credits.
Credit Spend Rate

28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—13.2 credits over 11 hours

Credit Earn Rate

72 credits per 24 hours

Credit Discard Rate

43.2 credits per 24 hours (60% of credit earn rate)

Credit Balance

72 credits (0 launch credits, 72 earned credits)—balance is at its limit

Conclusion

After launch credits are spent, the credit balance limit is determined by the number of credits that an instance can earn in 24 hours. If the instance earns more credits than it spends, newly earned credits over the limit are discarded.

Period 5: 73 – 75 hours

For the next three hours, the instance bursts at 20% CPU utilization, which requires 36 credits. The instance earns nine credits in the same three hours, which results in a net balance decrease of 27 credits. At the end of three hours, the credit balance is 45 accrued earned credits.
Credit Spend Rate | 288 credits per 24 hours (12 credits per hour, 20% CPU utilization, 400% of credit earn rate)—36 credits over 3 hours
Credit Earn Rate | 72 credits per 24 hours (9 credits over 3 hours)
Credit Discard Rate | 0 credits per 24 hours
Credit Balance | 45 credits (previous balance (72) - spent credits (36) + earned credits (9))—balance decreases at a rate of 216 credits per 24 hours (spend rate 288/24 + earn rate 72/24 = balance decrease rate 216/24)

Conclusion

If an instance spends more credits than it earns, its credit balance decreases.

**Period 6: 76 – 90 hours**

For the next 15 hours, the instance uses 2% CPU, which requires 18 credits. This is the same CPU utilization as in Periods 3 and 4. However, the balance increases in this period, whereas it decreased in Period 3 and plateaued in Period 4.

In Period 3, the accrued launch credits were spent, and any earned credits that exceeded the credit limit were discarded, resulting in a decrease in the credit balance. In Period 4, the instance spent fewer credits than it earned. Any earned credits that exceeded the limit were discarded, so the balance plateaued at its maximum of 72 credits.

In this period, there are no accrued launch credits, and the number of accrued earned credits in the balance is below the limit. No earned credits are discarded. Furthermore, the instance earns more credits than it spends, resulting in an increase in the credit balance.

Credit Spend Rate | 28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—18 credits over 15 hours
Credit Earn Rate | 72 credits per 24 hours (45 credits over 15 hours)
Credit Discard Rate | 0 credits per 24 hours
Credit Balance

72 credits (balance increases at a rate of 43.2 credits per 24 hours—change rate = spend rate 28.8/24 + earn rate 72/24)

Conclusion

If an instance spends fewer credits than it earns, its credit balance increases.

Period 7: 91 – 96 hours

For the next six hours, the instance remains idle—CPU utilization is 0%—and no credits are spent. This is the same CPU utilization as in Period 2, but the balance does not plateau at 102 credits—it plateaus at 72 credits, which is the credit balance limit for the instance.

In Period 2, the credit balance included 30 accrued launch credits. The launch credits were spent in Period 3. A running instance cannot get more launch credits. After its credit balance limit is reached, any earned credits that exceed the limit are discarded.

Credit Spend Rate

0 credits per 24 hours (0% CPU utilization)

Credit Earn Rate

72 credits per 24 hours

Credit Discard Rate

72 credits per 24 hours (100% of credit earn rate)

Credit Balance

72 credits (0 launch credits, 72 earned credits)

Conclusion

An instance constantly earns credits, but cannot accrue more earned credits if the credit balance limit has been reached. After the limit is reached, newly earned credits are discarded. The credit balance limit is determined by the number of credits that an instance can earn in 24 hours. For more information about credit balance limits, see the credit table (p. 222).

Work with burstable performance instances

The steps for launching, monitoring, and modifying these instances are similar. The key difference is the default credit specification when they launch. If you do not change the default credit specification, the default is that:

- T4g, T3a and T3 instances launch as unlimited
- T2 instances launch as standard

4 Credit Spend Rate

0 credits per 24 hours (0% CPU utilization)

Credit Earn Rate

72 credits per 24 hours

Credit Discard Rate

72 credits per 24 hours (100% of credit earn rate)

Credit Balance

72 credits (0 launch credits, 72 earned credits)
Launch a burstable performance instance as Unlimited or Standard

You can launch your instances as unlimited or standard using the Amazon EC2 console, an AWS SDK, a command line tool, or with an Auto Scaling group. For more information, see Use an Auto Scaling group to launch a burstable performance instance as Unlimited.

Requirements

- You must launch your instances using an Amazon EBS volume as the root device. For more information, see Amazon EC2 instance root device volume.
- For more information about AMI and driver requirements for these instances, see Release notes.

To launch a burstable performance instance as Unlimited or Standard (console)

1. Follow the Launch an instance using the Launch Instance Wizard procedure.
2. On the Choose an Instance Type page, select an instance type, and choose Next: Configure Instance Details.
3. Choose a credit specification.
   - To launch a T4g, T3a and T3 instance as standard, clear Unlimited.
   - To launch a T2 instance as unlimited, select Unlimited.
4. Continue as prompted by the wizard. When you've finished reviewing your options on the Review Instance Launch page, choose Launch. For more information, see Launch an instance using the Launch Instance Wizard.

To launch a burstable performance instance as Unlimited or Standard (AWS CLI)

Use the run-instances command to launch your instances. Specify the credit specification using the --credit-specification CpuCredits= parameter. Valid credit specifications are unlimited and standard.

- For T4g, T3a and T3, if you do not include the --credit-specification parameter, the instance launches as unlimited by default.
- For T2, if you do not include the --credit-specification parameter, the instance launches as standard by default.

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t3.micro --key-name MyKeyPair --credit-specification "CpuCredits=unlimited"
```

Use an Auto Scaling group to launch a burstable performance instance as Unlimited

When burstable performance instances are launched or started, they require CPU credits for a good bootstrapping experience. If you use an Auto Scaling group to launch your instances, we recommend...
that you configure your instances as unlimited. If you do, the instances use surplus credits when they are automatically launched or restarted by the Auto Scaling group. Using surplus credits prevents performance restrictions.

Create a launch template

You must use a launch template for launching instances as unlimited in an Auto Scaling group. A launch configuration does not support launching instances as unlimited.

To create a launch template that launches instances as Unlimited (console)

1. Follow the Creating a Launch Template for an Auto Scaling Group procedure.
2. In Launch template contents, for Instance type, choose an instance size.
3. To launch instances as unlimited in an Auto Scaling group, under Advanced details, for Credit specification, choose Unlimited.
4. When you've finished defining the launch template parameters, choose Create launch template.

   For more information, see Creating a Launch Template for an Auto Scaling Group in the Amazon EC2 Auto Scaling User Guide.

To create a launch template that launches instances as Unlimited (AWS CLI)

Use the create-launch-template command and specify unlimited as the credit specification.

- For T4g, T3a and T3, if you do not include the CreditSpecification={CpuCredits=unlimited} value, the instance launches as unlimited by default.
- For T2, if you do not include the CreditSpecification={CpuCredits=unlimited} value, the instance launches as standard by default.

```bash
aws ec2 create-launch-template --launch-template-name MyLaunchTemplate --version-description FirstVersion --launch-template-data ImageId=ami-8c1be5f6,InstanceType=t3.medium,CreditSpecification={CpuCredits=unlimited}
```

Associate an Auto Scaling group with a launch template

To associate the launch template with an Auto Scaling group, create the Auto Scaling group using the launch template, or add the launch template to an existing Auto Scaling group.

To create an Auto Scaling group using a launch template (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose Auto Scaling Groups, Create Auto Scaling group.
4. Choose Launch Template, select your launch template, and then choose Next Step.
5. Complete the fields for the Auto Scaling group. When you've finished reviewing your configuration settings on the Review page, choose Create Auto Scaling group. For more information, see Creating an Auto Scaling Group Using a Launch Template in the Amazon EC2 Auto Scaling User Guide.

To create an Auto Scaling group using a launch template (AWS CLI)

Use the create-auto-scaling-group AWS CLI command and specify the --launch-template parameter.

To add a launch template to an existing Auto Scaling group (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose Auto Scaling Groups.
4. From the Auto Scaling group list, select an Auto Scaling group, and choose Actions, Edit.
5. On the Details tab, for Launch Template, choose a launch template, and then choose Save.

To add a launch template to an existing Auto Scaling group (AWS CLI)
Use the update-auto-scaling-group AWS CLI command and specify the --launch-template parameter.

View the credit specification of a burstable performance instance
You can view the credit specification (unlimited or standard) of a running or stopped instance.

New console

To view the credit specification of a burstable instance
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance.
4. Choose Details and view the Credit specification field. The value is either unlimited or standard.

Old console

To view the credit specification of a burstable instance
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance.
4. Choose Description and view the T2/T3 Unlimited field.
   • If the value is Enabled, then your instance is configured as unlimited.
   • If the value is Disabled, then your instance is configured as standard.

To describe the credit specification of a burstable performance instance (AWS CLI)
Use the describe-instance-credit-specifications command. If you do not specify one or more instance IDs, all instances with the credit specification of unlimited are returned, as well as instances that were previously configured with the unlimited credit specification. For example, if you resize a T3 instance to an M4 instance, while it is configured as unlimited, Amazon EC2 returns the M4 instance.

Example

```
aws ec2 describe-instance-credit-specifications --instance-id i-1234567890abcdef0
```

The following is example output:

```
{
   "InstanceCreditSpecifications": [
   {
      "InstanceId": "i-1234567890abcdef0",
      "CpuCredits": "unlimited"
   }
```
Modify the credit specification of a burstable performance instance

You can switch the credit specification of a running or stopped instance at any time between unlimited and standard.

New console

To modify the credit specification of a burstable performance instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose Actions, Instance settings, Change credit specification. This option is enabled only if you selected a burstable performance instance.
5. To change the credit specification to unlimited, select the check box next to the instance ID. To change the credit specification to standard, clear the check box next to the instance ID.

Old console

To modify the credit specification of a burstable performance instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose Actions, Instance Settings, Change T2/T3 Unlimited. This option is enabled only if you selected a burstable performance instance.
5. The current credit specification appears in parentheses after the instance ID. To change the credit specification to unlimited, choose Enable. To change the credit specification to standard, choose Disable.

To modify the credit specification of a burstable performance instance (AWS CLI)

Use the modify-instance-credit-specification command. Specify the instance and its credit specification using the --instance-credit-specification parameter. Valid credit specifications are unlimited and standard.

Example

```
aws ec2 modify-instance-credit-specification --region us-east-1 --instance-credit-specification "InstanceId=i-1234567890abcdef0,CpuCredits=unlimited"
```

The following is example output:

```
{
    "SuccessfulInstanceCreditSpecifications": [
        {
            "InstanceId": "i- 1234567890abcdef0"
        }
    ],
    "UnsuccessfulInstanceCreditSpecifications": []
}
```
Set the default credit specification for the account

You can set the default credit specification for each burstable performance instance family at the account level per AWS Region.

If you use the Launch Instance Wizard in the EC2 console to launch instances, the value you select for the credit specification overrides the account-level default credit specification. If you use the AWS CLI to launch instances, all new burstable performance instances in the account launch using the default credit specification. The credit specification for existing running or stopped instances is not affected.

Consideration

The default credit specification for an instance family can be modified only once in a rolling 5-minute period, and up to four times in a rolling 24-hour period.

To set the default credit specification at the account level (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose EC2 Dashboard.
3. From Account attributes, choose Default credit specification.
4. Choose Manage.
5. For each instance family, choose Unlimited or Standard, and then choose Update.

To set the default credit specification at the account level (AWS CLI)

Use the modify-default-credit-specification command. Specify the AWS Region, instance family, and the default credit specification using the --cpu-credits parameter. Valid default credit specifications are unlimited and standard.

```
aws ec2 modify-default-credit-specification --region us-east-1 --instance-family t2 --cpu-credits unlimited
```

View the default credit specification

You can view the default credit specification of a burstable performance instance family at the account level per AWS Region.

To view the default credit specification at the account level (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose EC2 Dashboard.
3. From Account attributes, choose Default credit specification.

To view the default credit specification at the account level (AWS CLI)

Use the get-default-credit-specification command. Specify the AWS Region and instance family.

```
aws ec2 get-default-credit-specification --region us-east-1 --instance-family t2
```

Monitor your CPU credits

You can see the credit balance for each instance in the Amazon EC2 per-instance metrics of the CloudWatch console.
Additional CloudWatch metrics for burstable performance instances

Burstable performance instances have these additional CloudWatch metrics, which are updated every five minutes:

- **CPUCreditUsage** – The number of CPU credits spent during the measurement period.
- **CPUCreditBalance** – The number of CPU credits that an instance has accrued. This balance is depleted when the CPU bursts and CPU credits are spent more quickly than they are earned.
- **CPUSurplusCreditBalance** – The number of surplus CPU credits spent to sustain CPU utilization when the CPUCreditBalance value is zero.
- **CPUSurplusCreditsCharged** – The number of surplus CPU credits exceeding the [maximum number of CPU credits](p. 222) that can be earned in a 24-hour period, and thus attracting an additional charge.

The last two metrics apply only to instances configured as unlimited.

The following table describes the CloudWatch metrics for burstable performance instances. For more information, see List the available CloudWatch metrics for your instances (p. 821).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUCreditUsage</td>
<td>The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).&lt;br&gt;<strong>Units</strong>: Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>CPUCreditBalance</td>
<td>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.&lt;br&gt;Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.&lt;br&gt;The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.&lt;br&gt;<strong>Units</strong>: Credits (vCPU-minutes)</td>
</tr>
</tbody>
</table>

When an instance is running, credits in the CPUCreditBalance do not expire. When a T4g, T3a or T3 instance stops, the credits expire.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CPUCreditBalance</strong></td>
<td>The CPUCreditBalance value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the CPUCreditBalance value does not persist, and all accrued credits are lost.</td>
</tr>
<tr>
<td></td>
<td>CPU credit metrics are available at a five-minute frequency only. <strong>Units:</strong> Credits (vCPU-minutes)</td>
</tr>
<tr>
<td><strong>CPUSurplusCreditBalance</strong></td>
<td>The number of surplus credits that have been spent by an unlimited instance when its CPUCreditBalance value is zero.</td>
</tr>
<tr>
<td></td>
<td>The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge.</td>
</tr>
<tr>
<td><strong>CPUSurplusCreditsCharged</strong></td>
<td>The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge.</td>
</tr>
<tr>
<td></td>
<td>Spent surplus credits are charged when any of the following occurs:</td>
</tr>
<tr>
<td></td>
<td>• The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.</td>
</tr>
<tr>
<td></td>
<td>• The instance is stopped or terminated.</td>
</tr>
<tr>
<td></td>
<td>• The instance is switched from unlimited to standard.</td>
</tr>
</tbody>
</table>

**Calculate CPU credit usage**

The CPU credit usage of instances is calculated using the instance CloudWatch metrics described in the preceding table.

Amazon EC2 sends the metrics to CloudWatch every five minutes. A reference to the prior value of a metric at any point in time implies the previous value of the metric, sent five minutes ago.

**Calculate CPU credit usage for Standard instances**

- The CPU credit balance increases if CPU utilization is below the baseline, when the credits spent are less than the credits earned in the prior five-minute interval.
- The CPU credit balance decreases if CPU utilization is above the baseline, when the credits spent are more than the credits earned in the prior five-minute interval.

Mathematically, this is captured by the following equation:

**Example**

\[
\text{CPUCreditBalance} = \text{prior CPUCreditBalance} + \left[\text{Credits earned per hour} \times \frac{5}{60} - \text{CPUCreditUsage}\right]
\]
The size of the instance determines the number of credits that the instance can earn per hour and the number of earned credits that it can accrue in the credit balance. For information about the number of credits earned per hour, and the credit balance limit for each instance size, see the credit table (p. 222).

Example

This example uses a t3.nano instance. To calculate the CPUCreditBalance value of the instance, use the preceding equation as follows:

- **CPUCreditBalance** – The current credit balance to calculate.
- **prior CPUCreditBalance** – The credit balance five minutes ago. In this example, the instance had accrued two credits.
- **Credits earned per hour** – A t3.nano instance earns six credits per hour.
- **5/60** – Represents the five-minute interval between CloudWatch metric publication. Multiply the credits earned per hour by 5/60 (five minutes) to get the number of credits that the instance earned in the past five minutes. A t3.nano instance earns 0.5 credits every five minutes.
- **CPUCreditUsage** – How many credits the instance spent in the past five minutes. In this example, the instance spent one credit in the past five minutes.

Using these values, you can calculate the CPUCreditBalance value:

**Example**

\[
\text{CPUCreditBalance} = 2 + [0.5 - 1] = 1.5
\]

Calculate CPU credit usage for Unlimited instances

When a burstable performance instance needs to burst above the baseline, it always spends accrued credits before spending surplus credits. When it depletes its accrued CPU credit balance, it can spend surplus credits to burst CPU for as long as it needs. When CPU utilization falls below the baseline, surplus credits are always paid down before the instance accrues earned credits.

We use the term Adjusted balance in the following equations to reflect the activity that occurs in this five-minute interval. We use this value to arrive at the values for the CPUCreditBalance and CPUSurplusCreditBalance CloudWatch metrics.

**Example**

\[
\text{Adjusted balance} = [\text{prior CPUCreditBalance} - \text{prior CPUSurplusCreditBalance}] + [\text{Credits earned per hour} \times (5/60) - \text{CPUCreditUsage}]
\]

A value of 0 for Adjusted balance indicates that the instance spent all its earned credits for bursting, and no surplus credits were spent. As a result, both CPUCreditBalance and CPUSurplusCreditBalance are set to 0.

A positive Adjusted balance value indicates that the instance accrued earned credits, and previous surplus credits, if any, were paid down. As a result, the Adjusted balance value is assigned to CPUCreditBalance, and the CPUSurplusCreditBalance is set to 0. The instance size determines the maximum number of credits (p. 222) that it can accrue.

**Example**

\[
\text{CPUCreditBalance} = \min [\text{max earned credit balance}, \text{Adjusted balance}]
\]

\[
\text{CPUSurplusCreditBalance} = 0
\]
A negative Adjusted balance value indicates that the instance spent all its earned credits that it accrued and, in addition, also spent surplus credits for bursting. As a result, the Adjusted balance value is assigned to CPUSurplusCreditBalance and CPUCreditBalance is set to 0. Again, the instance size determines the maximum number of credits (p. 222) that it can accrue.

**Example**

\[
\text{CPUSurplusCreditBalance} = \min \left[ \max \text{ earned credit balance}, -\text{Adjusted balance} \right]
\]
\[
\text{CPUCreditBalance} = 0
\]

If the surplus credits spent exceed the maximum credits that the instance can accrue, the surplus credit balance is set to the maximum, as shown in the preceding equation. The remaining surplus credits are charged as represented by the CPUSurplusCreditsCharged metric.

**Example**

\[
\text{CPUSurplusCreditsCharged} = \max \left[ -\text{Adjusted balance} - \max \text{ earned credit balance}, 0 \right]
\]

Finally, when the instance terminates, any surplus credits tracked by the CPUSurplusCreditBalance are charged. If the instance is switched from unlimited to standard, any remaining CPUSurplusCreditBalance is also charged.

**Amazon EC2 Mac instances**

Mac1 instances natively support the macOS operating system. They are built on Mac mini hardware and powered by 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processors. These instances are ideal for developing, building, testing, and signing applications for Apple devices, such as iPhone, iPad, iPod, Mac, Apple Watch, and Apple TV. You can connect to your Mac instance using SSH or Apple Remote Desktop (ARD).

For more information, see Amazon EC2 Mac Instances and Pricing.

**Contents**

- Considerations (p. 250)
- Launch a Mac instance using the console (p. 251)
- Launch a Mac instance using the AWS CLI (p. 252)
- Connect to your instance using SSH (p. 253)
- Connect to your instance using Apple Remote Desktop (p. 253)
- Modify macOS screen resolution on Mac instances (p. 254)
- EC2 macOS AMIs (p. 254)
- Update the operating system and software (p. 255)
- EC2 macOS Init (p. 256)
- EC2 System Monitoring for macOS (p. 256)
- Increase the size of an EBS volume on your Mac instance (p. 256)
- Stop and terminate your Mac instance (p. 256)
- Subscribe to macOS AMI notifications (p. 257)
- Release the Dedicated Host for your Mac instance (p. 258)

**Considerations**

The following considerations apply to Mac instances:
• Mac instances are available only as bare metal instances on Dedicated Hosts (p. 415), with a minimum allocation period of 24 hours before you can release the Dedicated Host. You can launch one Mac instance per Dedicated Host. You can share the Dedicated Host with the AWS accounts or organizational units within your AWS organization, or the entire AWS organization.

• Mac instances are available only as On-Demand Instances. They are not available as Spot Instances or Reserved Instances. You can save money on Mac instances by purchasing a Savings Plan.

• Mac instances can run one of the following operating systems:
  • macOS Catalina (version 10.15)
  • macOS Mojave (version 10.14)
  • macOS Big Sur (version 11)

• If you attach an EBS volume to a running Mac instance, you must reboot the instance to make the volume available.

• If you resized an existing EBS volume on a running Mac instance, you must reboot the instance to make the new size available.

• If you attach a network interface to a running Mac instance, you must reboot the instance to make the network interface available.

• AWS does not manage or support the internal SSD on the Apple hardware. We strongly recommend that you use Amazon EBS volumes instead. EBS volumes provide the same elasticity, availability, and durability benefits on Mac instances as they do on any other EC2 instance.

• We recommend using General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2) with Mac instances for optimal EBS performance.

• You cannot use Mac instances with Amazon EC2 Auto Scaling.

• Automatic software updates are disabled. We recommend that you apply updates and test them on your instance before you put the instance into production. For more information, see Update the operating system and software (p. 255).

• When you stop or terminate a Mac instance, a scrubbing workflow is performed on the Dedicated Host. For more information, see Stop and terminate your Mac instance (p. 256).

• **Warning**
  Do not use FileVault. If data-at-rest and data-in-transit is required, use EBS encryption to avoid boot issues and performance impact. Enabling FileVault will result in the host failing to boot due to the partitions being locked.

### Launch a Mac instance using the console

You can launch a Mac instance using the AWS Management Console as described in the following procedure. Mac instances require a Dedicated Host (p. 415).

#### To launch a Mac instance onto a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Choose Allocate Dedicated Host and then do the following:
   a. For **Instance family**, choose mac1. If mac1 doesn't appear in the list, it's not supported in the currently selected Region.
   b. For **Instance type**, select mac1.metal.
   c. For **Availability Zone**, choose the Availability Zone for the Dedicated Host.
   d. For **Quantity**, keep 1.
   e. Choose Allocate.
4. Select the Dedicated Host that you created and then do the following:
   a. Choose **Actions**, Launch instances onto host.
b. Select a macOS AMI.

c. Select the `mac1.metal` instance type.

d. On the **Configure Instance Details** page, verify that **Tenancy** and **Host** are preconfigured based on the Dedicated Host you created. Update **Affinity** as needed.

e. Complete the wizard, specifying EBS volumes, security groups, and key pairs as needed.

5. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console. The initial state of an instance is **pending**. The instance is ready when its state changes to **running** and it passes status checks.

### Launch a Mac instance using the AWS CLI

Use the following `allocate-hosts` command to allocate a Dedicated Host for your Mac instance.

```bash
aws ec2 allocate-hosts --region us-east-1 --instance-type mac1.metal --availability-zone us-east-1b --auto-placement "on" --quantity 1
```

Use the following `run-instances` command to launch a Mac instance.

```bash
aws ec2 run-instances --region us-east-1 --instance-type mac1.metal --placement Tenancy=host --image-id ami_id --key-name my-key-pair
```

The initial state of an instance is **pending**. The instance is ready when its state changes to **running** and it passes status checks. Use the following `describe-instance-status` command to display status information for your instance:

```bash
aws ec2 describe-instance-status --instance-ids i-017f8354e2dc69c4f
```

The following is example output for an instance that is running and has passed status checks.

```json
{
   "InstanceStatuses": [
      {
         "AvailabilityZone": "us-east-1b",
         "InstanceId": "i-017f8354e2dc69c4f",
         "InstanceState": {
            "Code": 16,
            "Name": "running"
         },
         "InstanceStatus": {
            "Details": [
               {
                  "Name": "reachability",
                  "Status": "passed"
               }
            ],
            "Status": "ok"
         },
         "SystemStatus": {
            "Details": [
               {
                  "Name": "reachability",
                  "Status": "passed"
               }
            ],
            "Status": "ok"
         }
      }
   ]
}
```
Connect to your instance using SSH

Amazon EC2 Mac instances do not allow remote root SSH by default. Password authentication is disabled to prevent brute-force password attacks. The ec2-user account is configured to log in remotely using SSH. The ec2-user account also has `sudo` privileges. After you connect to your instance, you can add other users.

To support connecting to your instance using SSH, launch the instance using a key pair and a security group that allows SSH access, and ensure that the instance has internet connectivity. You provide the `.pem` file for the key pair when you connect to the instance.

Use the following procedure to connect to your Mac instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).

**To connect to your instance using SSH**

1. Verify that your local computer has an SSH client installed by entering `ssh` at the command line. If your computer doesn't recognize the command, search for an SSH client for your operating system and install it.
2. Get the public DNS name of your instance. Using the Amazon EC2 console, you can find the public DNS name on both the **Details** and the **Networking** tabs. Using the AWS CLI, you can find the public DNS name using the `describe-instances` command.
3. Locate the `.pem` file for the key pair that you specified when you launched the instance.
4. Connect to your instance using the following `ssh` command, specifying the public DNS name of the instance and the `.pem` file.

   ```bash
   ssh -i /path/my-key-pair.pem ec2-user@my-instance-public-dns-name
   ```

Connect to your instance using Apple Remote Desktop

Use the following procedure to connect to your instance using Apple Remote Desktop (ARD).

**To connect to your instance using ARD**

1. Verify that your local computer has an ARD client or a VNC client that supports ARD installed. On macOS, you can leverage the built-in Screen Sharing application. Otherwise, search for ARD for your operating system and install it.
2. From your local computer, connect to your instance using SSH (p. 253).
3. Set up a password for the ec2-user account using the `passwd` command as follows.

   ```bash
   [ec2-user ~]# sudo passwd ec2-user
   ```

4. Start the Apple Remote Desktop agent and enable remote desktop access as follows.

   ```bash
   [ec2-user ~]# sudo /System/Library/CoreServices/RemoteManagement/ARDAgent.app/Contents/Resources/kickstart/activate -configure -access -on -restart -agent -privil -all
   ```

5. From your computer, connect to your instance using the following `ssh` command. In addition to the options shown in the previous section, use the `-L` option to enable port forwarding and forward all traffic on local port 5900 to the ARD server on the instance.
ssh -L 5900:localhost:5900 -i /path/my-key-pair.pem ec2-user@my-instance-public-dns-name

6. From your local computer, use the ARD client or VNC client that supports ARD to connect to localhost on port 5900. For example, use the Screen Sharing application on macOS as follows:
   a. Open Finder and launch the Screen Sharing application.
   b. For Connect to, enter localhost.
   c. Log in as prompted, using ec2-user as the user name and the password that you created for the ec2-user account.

Modify macOS screen resolution on Mac instances

Once you connect to your EC2 Mac instance using ARD or a VNC client that supports ARD installed, you can modify the screen resolution of your macOS environment using any of the publicly available macOS tools or utilities, such as displayplacer

Modifying screen resolution using displayplacer

1. Install displayplacer.

brew tap jakehilborn/jakehilborn && brew install displayplacer

2. Show current screen info and possible screen resolutions.

displayplacer list

3. Apply desired screen resolution.

displayplacer "id:<screenID> res:<width>x<height> origin:(0,0) degree:0"

For example:

RES="2560x1600"
displayplacer "id:69784AF1-CD7D-B79B-E5D4-60D937407F68 res:${RES} scaling:off origin:(0,0) degree:0"

EC2 macOS AMIs

Amazon EC2 macOS is designed to provide a stable, secure, and high-performance environment for developer workloads running on Amazon EC2 Mac instances. EC2 macOS AMIs includes packages that enable easy integration with AWS, such as launch configuration tools and popular AWS libraries and tools. EC2 macOS AMIs include the following by default:

- ENA drivers
- EC2 macOS Init
- EC2 System Monitoring for macOS
- SSM Agent for macOS
- AWS Command Line Interface (AWS CLI) version 2
- Command Line Tools for Xcode
- Homebrew
AWS provides updated EC2 macOS AMIs on a regular basis that include updates to AWS-owned packages and the latest fully-tested macOS version. Additionally, AWS provides updated AMIs with the latest minor version updates or major version updates as soon as they can be fully tested and vetted. If you do not need to preserve data or customizations to your Mac instances, you can get the latest updates by launching a new instance using the current AMI and then terminating the previous instance. Otherwise, you can choose which updates to apply to your Mac instances.

**Update the operating system and software**

You can install operating system updates from Apple using the `softwareupdate` command.

**To install operating system updates from Apple**

1. List the packages with available updates using the following command.

   ```bash
   [ec2-user ~]$ softwareupdate --list
   ```

2. Install all updates or only specific updates. To install specific updates, use the following command.

   ```bash
   [ec2-user ~]$ sudo softwareupdate --install label
   ```

   To install all updates instead, use the following command.

   ```bash
   [ec2-user ~]$ sudo softwareupdate --install --all
   ```

System administrators can use AWS Systems Manager to roll out pre-approved operating system updates. For more information, see the AWS Systems Manager User Guide.

You can use Homebrew to install updates to packages in the EC2 macOS AMIs, so that you have the latest version of these packages on your instances. You can also use Homebrew to install and run common macOS applications on Amazon EC2 macOS. For more information, see the Homebrew Documentation.

**To install updates using Homebrew**

1. Update Homebrew using the following command.

   ```bash
   [ec2-user ~]$ brew update
   ```

2. List the packages with available updates using the following command.

   ```bash
   [ec2-user ~]$ brew outdated
   ```

3. Install all updates or only specific updates. To install specific updates, use the following command.

   ```bash
   [ec2-user ~]$ brew upgrade formula
   ```

   To install all updates instead, use the following command.

   ```bash
   [ec2-user ~]$ brew upgrade
   ```

**Warning**

Do not install beta or prerelease macOS versions on your EC2 Mac instances, as this configuration is currently not supported. Installing beta or prerelease macOS versions will lead
to degradation of your EC2 Mac Dedicated Host when you stop or terminate your instance, and will prevent you from starting or launching a new instance on that host.

**EC2 macOS Init**

EC2 macOS Init is used to initialize EC2 Mac instances at launch. It uses priority groups to run logical groups of tasks at the same time.

The launchd plist file is /Library/LaunchDaemons/com.amazon.ec2.macos-init.plist. The files for EC2 macOS Init are located in /usr/local/aws/ec2-macos-init.

For more information, see https://github.com/aws/ec2-macos-init.

**EC2 System Monitoring for macOS**

EC2 System Monitoring for macOS provides CPU utilization metrics to Amazon CloudWatch. It sends these metrics to CloudWatch over a custom serial device in 1-minute periods. You can enable or disable this agent as follows. It is enabled by default.

```bash
sudo setup-ec2monitoring [enable | disable]
```

**Increase the size of an EBS volume on your Mac instance**

You can increase the size of your Amazon EBS volumes on your Mac instance. For more information, see Amazon EBS Elastic Volumes (p. 1323).

After you increase the size of the volume, you must increase the size of your APFS container as follows.

**Make increased disk space available for use**

1. Determine if a restart is needed. If you resized an existing EBS volume on a running Mac instance, you must reboot the instance to make the new size available. If disk space modification was done during launch time, a reboot will not be needed.

   View current status of disk sizes:
   
   ```bash
   [ec2-user ~]# diskutil list external physical
   /dev/disk0 (external, physical):
   #:                       TYPE NAME                    SIZE       IDENTIFIER
   0:      GUID_partition_scheme                        *322.1 GB   disk0
   1:                        EFI #EFI#                     209.7 MB   disk0s1
   2:                 Apple_APFS #Container disk2#         321.9 GB   disk0s2
   ```

2. Copy and paste the following command.

   ```bash
   PDISK=$(diskutil list physical external | head -n1 | cut -d" " -f1)
   APFSCONT=$(diskutil list physical external | grep "Apple_APFS" | tr -s " " | cut -d" " -f8)
   yes | sudo diskutil repairDisk $PDISK
   ```

3. Copy and paste the following command.

   ```bash
   sudo diskutil apfs resizeContainer $APFSCONT 0
   ```

**Stop and terminate your Mac instance**

When you stop a Mac instance, the instance remains in the stopping state for about 15 minutes before it enters the stopped state.
When you stop or terminate a Mac instance, Amazon EC2 performs a scrubbing workflow on the underlying Dedicated Host to erase the internal SSD, to clear the persistent NVRAM variables, and if needed, to update the bridgeOS software on the underlying Mac mini. This ensures that Mac instances provide the same security and data privacy as other EC2 Nitro instances. It also enables you to run the latest macOS AMIs without manually updating the bridgeOS software. During the scrubbing workflow, the Dedicated Host temporarily enters the pending state. If the bridgeOS software does not need to be updated, the scrubbing workflow takes up to 50 minutes to complete. If the bridgeOS software needs to be updated, the scrubbing workflow can take up to 3 hours to complete.

You can't start the stopped Mac instance or launch a new Mac instance until after the scrubbing workflow completes, at which point the Dedicated Host enters the available state.

Metering and billing is paused when the Dedicated Host enters the pending state. You are not charged for the duration of the scrubbing workflow.

Subscribe to macOS AMI notifications

To be notified when new AMIs are released or when bridgeOS has been updated, subscribe for notifications using Amazon SNS.

To subscribe to macOS AMI notifications

2. In the navigation bar, change the Region to US East (N. Virginia), if necessary. You must use this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose Subscriptions.
4. Choose Create subscription.
5. For the Create subscription dialog box, do the following:
   a. For Topic ARN, copy and paste one of the following Amazon Resource Names (ARNs):
      • arn:aws:sns:us-east-1:898855652048:amazon-ec2-macos-ami-updates
      • arn:aws:sns:us-east-1:898855652048:amazon-ec2-bridgeos-updates
   b. Email:
      For Endpoint, type an email address that you can use to receive the notifications. After you create your subscription you'll receive a confirmation message with the subject line AWS Notification – Subscription Confirmation. Open the email and choose Confirm subscription to complete your subscription
   c. SMS:
      For Endpoint, type a phone number that you can use to receive the notifications.
   d. AWS Lambda, Amazon SQS, Amazon Kinesis Data Firehose (Notifications come in JSON format):
      For Endpoint, enter the ARN for the Lambda function, SQS queue, or Firehose stream you can use to receive the notifications.
   e. Choose Create subscription.

Whenever macOS AMIs are released, we send notifications to the subscribers of the amazon-ec2-macos-ami-updates topic. Whenever bridgeOS is updated, we send notifications to the subscribers of the amazon-ec2-bridgeos-updates topic. If you no longer want to receive these notifications, use the following procedure to unsubscribe.
To unsubscribe from macOS AMI notifications

2. In the navigation bar, change the Region to US East (N. Virginia), if necessary. You must use this Region because the SNS notifications were created in this Region.
3. In the navigation pane, choose Subscriptions.
4. Select the subscriptions and then choose Actions, Delete subscriptions When prompted for confirmation, choose Delete.

Release the Dedicated Host for your Mac instance

When you are finished with your Mac instance, you can release the Dedicated Host. Before you can release the Dedicated Host, you must stop or terminate the Mac instance. You cannot release the host until the allocation period exceeds the 24-hour minimum.

To release the Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Instance state, then choose either Stop instance or Terminate instance.
4. In the navigation pane, choose Dedicated Hosts.
5. Select the Dedicated Host and choose Actions, Release host.
6. When prompted for confirmation, choose Release.

Compute optimized instances

Compute optimized instances are ideal for compute-bound applications that benefit from high-performance processors.

C5 and C5n instances

These instances are well suited for the following:

- Batch processing workloads
- Media transcoding
- High-performance web servers
- High-performance computing (HPC)
- Scientific modeling
- Dedicated gaming servers and ad serving engines
- Machine learning inference and other compute-intensive applications

Bare metal instances, such as c5.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 C5 Instances.

C6g, C6gd, and C6gn instances

These instances are powered by AWS Graviton2 processors and are ideal for running advanced, compute-intensive workloads, such as the following:
- High-performance computing (HPC)
- Batch processing
- Ad serving
- Video encoding
- Gaming servers
- Scientific modeling
- Distributed analytics
- CPU-based machine learning inference

Bare metal instances, such as c6g.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 C6g Instances.

Contents

</tbody>
</table>

For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

For more information about specifying CPU options, see Optimize CPU options (p. 575).
Instance performance

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some compute optimized instances are EBS-optimized by default at no additional cost. For more information, see Amazon EBS–optimized instances (p. 1354).

Some compute optimized instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see Processor state control for your EC2 instance (p. 564).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see Enhanced networking on Linux (p. 952).

The following is a summary of network performance for compute optimized instances that support enhanced networking.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Network performance</th>
<th>Enhanced networking</th>
</tr>
</thead>

### SSD I/O performance

If you use a Linux AMI with kernel version 4.4 or later and use all the SSD-based instance store volumes available to your instance, you get the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

<table>
<thead>
<tr>
<th>Instance Size</th>

</table>

* For these instances, you can get up to the specified performance.

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called over-provisioning. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see Instance store volume TRIM support (p. 1422).

### Instance features

The following is a summary of features for compute optimized instances:

<table>
<thead>
<tr>
<th></th>
<th>EBS only</th>
<th>NVMe EBS</th>
<th>Instance store</th>
<th>Placement group</th>
</tr>
</thead>
<tbody>
<tr>
<td>C4</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>
## EBS only | NVMe EBS | Instance store | Placement group
---|---|---|---
C5 | Yes | Yes | No | Yes
C5a | Yes | Yes | No | Yes
C5ad | No | Yes | NVMe * | Yes
C5d | No | Yes | NVMe * | Yes
C5n | Yes | Yes | No | Yes
C6g | Yes | Yes | No | Yes
C6gd | No | Yes | NVMe * | Yes
C6gn | Yes | Yes | No | Yes

* The root device volume must be an Amazon EBS volume.

For more information, see the following:
- Amazon EBS and NVMe on Linux instances (p. 1350)
- Amazon EC2 instance store (p. 1408)
- Placement groups (p. 1018)

### Release notes

- C5 and C5d instances feature a 3.1 GHz Intel Xeon Platinum 8000 series processor from either the first generation (Skylake-SP) or second generation (Cascade Lake).
- C5a and C5ad instances feature a second-generation AMD EPYC processor (Rome) running at frequencies as high as 3.3 GHz.
- C6g, C6gd, and C6gn instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- C4 instances and instances built on the Nitro System (p. 199) require 64-bit EBS-backed HVM AMIs. They have high-memory and require a 64-bit operating system to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. In addition, you must use an HVM AMI to take advantage of enhanced networking.
- Instances built on the Nitro System have the following requirements:
  - NVMe drivers (p. 1350) must be installed
  - Elastic Network Adapter (ENA) drivers (p. 953) must be installed

The following Linux AMIs meet these requirements:
- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with linux-aws kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Instances with an AWS Graviton processors have the following requirements:
  - Use an AMI for the 64-bit Arm architecture.
Memory optimized instances

Memory optimized instances are designed to deliver fast performance for workloads that process large data sets in memory.

R5, R5a, R5b, and R5n instances

These instances are well suited for the following:

- High-performance, relational (MySQL) and NoSQL (MongoDB, Cassandra) databases.
• Distributed web scale cache stores that provide in-memory caching of key-value type data (Memcached and Redis).
• In-memory databases using optimized data storage formats and analytics for business intelligence (for example, SAP HANA).
• Applications performing real-time processing of big unstructured data (financial services, Hadoop/Spark clusters).
• High-performance computing (HPC) and Electronic Design Automation (EDA) applications.

R5b instances support io2 Block Express volumes. All io2 volumes attached to an R5b instance during or after launch automatically run on EBS Block Express. For more information, see io2 Block Express volumes.

Bare metal instances, such as r5.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 R5 Instances.

R6g and R6gd instances
These instances are powered by AWS Graviton2 processors and are ideal for running memory-intensive workloads, such as the following:
• Open-source databases (for example, MySQL, MariaDB, and PostgreSQL)
• In-memory caches (for example, Memcached, Redis, and KeyDB)

Bare metal instances, such as r6g.metal, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 R6g Instances.

High memory (u-*) instances
These instances offer 6 TiB, 9 TiB, 12 TiB, 18 TiB, and 24 TiB of memory per instance. They are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database.

For more information, see Amazon EC2 High Memory Instances and Storage Configuration for SAP HANA. For information about supported operating systems, see Migrating SAP HANA on AWS to an EC2 High Memory Instance.

X1 instances
These instances are well suited for the following:
• In-memory databases such as SAP HANA, including SAP-certified support for Business Suite S/4HANA, Business Suite on HANA (SoH), Business Warehouse on HANA (BW), and Data Mart Solutions on HANA. For more information, see SAP HANA on the AWS Cloud.
• Big-data processing engines such as Apache Spark or Presto.
• High-performance computing (HPC) applications.

For more information, see Amazon EC2 X1 Instances.

X1e instances
These instances are well suited for the following:
• High-performance databases.
• In-memory databases such as SAP HANA. For more information, see SAP HANA on the AWS Cloud.
• Memory-intensive enterprise applications.

For more information, see Amazon EC2 X1e Instances.

X2gd instances
These instances are well suited for the following:
  • In-memory databases, such as Redis and Memcached.
  • Relational databases, such as MySQL and PostGreSQL.
  • Electronic design automation (EDA) workloads, such as physical verification and layout tools.
  • Memory-intensive workloads, such as real-time analytics and real-time caching servers.

For more information, see Amazon EC2 X2gd Instances.

z1d instances
These instances deliver both high compute and high memory and are well-suited for the following:
  • Electronic Design Automation (EDA)
  • Relational database workloads

z1d.metal instances provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 z1d Instances.

* Each logical processor is a hyperthread on 224 cores.

For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

For more information about specifying CPU options, see Optimize CPU options (p. 575).

Memory performance

X1 instances include Intel Scalable Memory Buffers, providing 300 GiB/s of sustainable memory-read bandwidth and 140 GiB/s of sustainable memory-write bandwidth.

For more information about how much RAM can be enabled for memory optimized instances, see Hardware specifications (p. 269).

Memory optimized instances have high memory and require 64-bit HVM AMIs to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on memory optimized instances. For more information, see Linux AMI virtualization types (p. 75).

Instance performance

Memory optimized instances enable increased cryptographic performance through the latest Intel AES-NI feature, support Intel Transactional Synchronization Extensions (TSX) to boost the performance of in-
memory transactional data processing, and support Advanced Vector Extensions 2 (Intel AVX2) processor instructions to expand most integer commands to 256 bits.

Some memory optimized instances provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (measured by CPU frequency) from a core. For more information, see Processor state control for your EC2 instance (p. 564).

## Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see Enhanced networking on Linux (p. 952).

The following is a summary of network performance for memory optimized instances that support enhanced networking.

## SSD I/O Performance

If you use a Linux AMI with kernel version 4.4 or later and use all the SSD-based instance store volumes available to your instance, you get the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

<table>
<thead>

</tbody>
</table>

* For these instances, you can get up to the specified performance.

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.
SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called over-provisioning. The SSD-based instance store volumes provided to an instance don’t have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you’ve written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see Instance store volume TRIM support (p. 1422).

**Instance features**

The following is a summary of features for memory optimized instances.

### EBS only | NVMe EBS | Instance store | Placement group
---|---|---|---
R4 | Yes | No | No | Yes
R5 | Yes | Yes | No | Yes
R5a | Yes | Yes | No | Yes
R5ad | Yes | Yes | NVME * | Yes
R5b | Yes ** | Yes | No | Yes
R5d | Yes | Yes | NVME * | Yes
R5dn | Yes | Yes | NVME * | Yes
R5n | Yes | Yes | No | Yes
R6g | Yes | Yes | No | Yes
R6gd | Yes | Yes | NVMe * | Yes
High memory | Yes | Yes | No | Virtualized: Yes
| | | | Bare metal: No
X1 | No | No | SSD | Yes
X2gd | No | Yes | NVME * | Yes
X1e | No | No | SSD | Yes
z1d | No | Yes | NVME * | Yes

---

**All io2 volumes attached to an R5b instance during or after launch automatically run on EBS Block Express. For more information, see io2 Block Express volumes.**

** The root device volume must be an Amazon EBS volume.

For more information, see the following:

- [Amazon EBS and NVMe on Linux instances (p. 1350)]
Support for vCPUs

Memory optimized instances provide a high number of vCPUs, which can cause launch issues with operating systems that have a lower vCPU limit. We strongly recommend that you use the latest AMIs when you launch memory optimized instances.

The following AMIs support launching memory optimized instances:

- Amazon Linux 2 (HVM)
- Amazon Linux AMI 2016.03 (HVM) or later
- Ubuntu Server 14.04 LTS (HVM)
- Red Hat Enterprise Linux 7.1 (HVM)
- SUSE Linux Enterprise Server 12 SP1 (HVM)
- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2
- Windows Server 2012
- Windows Server 2008 R2 64-bit
- Windows Server 2008 SP2 64-bit

Release notes

- R4 instances feature up to 64 vCPUs and are powered by two AWS-customized Intel XEON processors based on E5-2686v4 that feature high-memory bandwidth and larger L3 caches to boost the performance of in-memory applications.
- R5, R5b, and R5d instances feature a 3.1 GHz Intel Xeon Platinum 8000 series processor from either the first generation (Skylake-SP) or second generation (Cascade Lake).
- R5a and R5ad instances feature a 2.5 GHz AMD EPYC 7000 series processor.
- R6g and R6gd instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- High memory instances (u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal) are the first instances to be powered by an eight-socket platform with the latest generation Intel Xeon Platinum 8176M (Skylake) processors that are optimized for mission-critical enterprise workloads. High Memory instances with 18 TB and 24 TB of memory (u-18tb1.metal and u-24tb1.metal) are the first instances powered by an 8-socket platform with 2nd Generation Intel Xeon Scalable 8280L (Cascade Lake) processors.
- X1e and X1 instances feature up to 128 vCPUs and are powered by four Intel Xeon E7-8880 v3 processors that feature high-memory bandwidth and larger L3 caches to boost the performance of in-memory applications.
- Instances built on the Nitro System have the following requirements:
  - **NVMe drivers (p. 1350)** must be installed
  - **Elastic Network Adapter (ENA) drivers (p. 953)** must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
Storage optimized instances

Storage optimized instances are designed for workloads that require high, sequential read and write access to very large data sets on local storage. They are optimized to deliver tens of thousands of low-latency, random I/O operations per second (IOPS) to applications.
D2 instances

These instances are well suited for the following:

- Massive parallel processing (MPP) data warehouse
- MapReduce and Hadoop distributed computing
- Log or data processing applications

D3 and D3en instances

These instances offer scale out of instance storage and are well suited for the following:

- Distributed file systems for Hadoop workloads
- File storage workloads such as GPFC and BeeFS
- Large data lakes for HPC workloads

H1 instances

These instances are well suited for the following:

- Data-intensive workloads such as MapReduce and distributed file systems
- Applications requiring sequential access to large amounts of data on direct-attached instance storage
- Applications that require high-throughput access to large quantities of data

I3 and I3en instances

These instances are well suited for the following:

- High frequency online transaction processing (OLTP) systems
- Relational databases
- NoSQL databases
- Cache for in-memory databases (for example, Redis)
- Data warehousing applications
- Distributed file systems

Bare metal instances provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see Amazon EC2 I3 Instances.

Contents

- Hardware specifications (p. 283)
- Instance performance (p. 284)
- Network performance (p. 284)
- SSD I/O performance (p. 286)
- Instance features (p. 287)

Hardware specifications

The primary data storage for D2, D3, and D3en instances is HDD instance store volumes. The primary data storage for I3 and I3en instances is non-volatile memory express (NVMe) SSD instance store volumes.

Instance store volumes persist only for the life of the instance. When you stop, hibernate, or terminate an instance, the applications and data in its instance store volumes are erased. We recommend that you regularly back up or replicate important data in your instance store volumes. For more information, see Amazon EC2 instance store (p. 1408) and SSD instance store volumes (p. 1421).

The following is a summary of the hardware specifications for storage optimized instances.

For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

For more information about specifying CPU options, see Optimize CPU options (p. 575).

### Instance performance

To ensure the best disk throughput performance from your instance on Linux, we recommend that you use the most recent version of Amazon Linux 2 or the Amazon Linux AMI.

For instances with NVMe instance store volumes, you must use a Linux AMI with kernel version 4.4 or later. Otherwise, your instance will not achieve the maximum IOPS performance available.

D2 instances provide the best disk performance when you use a Linux kernel that supports persistent grants, an extension to the Xen block ring protocol that significantly improves disk throughput and scalability. For more information about persistent grants, see this article in the Xen Project Blog.

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some storage optimized instances are EBS-optimized by default at no additional cost. For more information, see Amazon EBS–optimized instances (p. 1354).

Some storage optimized instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see Processor state control for your EC2 instance (p. 564).

### Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see Enhanced networking on Linux (p. 952).

The following is a summary of network performance for storage optimized instances that support enhanced networking.
<table>
<thead>
<tr>
<th>Instance type</th>
<th>Network performance</th>
<th>Enhanced networking</th>
</tr>
</thead>
<tbody>
<tr>
<td>d2.xlarge</td>

SSD I/O performance

If you use a Linux AMI with kernel version 4.4 or later and use all the SSD-based instance store volumes available to your instance, you get the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

<table>
<thead>
<tr>
<th>Instance Size</th>
<th>100% Random Read IOPS</th>

</tbody>
</table>

* For these instances, you can get up to the specified performance.

As you fill your SSD-based instance store volumes, the I/O performance that you get decreases. This is due to the extra work that the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called over-provisioning. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more
free space, which can reduce write amplification and increase performance. For more information, see Instance store volume TRIM support (p. 1422).

Instance features

The following is a summary of features for storage optimized instances:

<table>
<thead>

* The root device volume must be an Amazon EBS volume.

For more information, see the following:

- Amazon EBS and NVMe on Linux instances (p. 1350)
- Amazon EC2 instance store (p. 1408)
- Placement groups (p. 1018)

Support for vCPUs

The d2.8xlarge instance type provides 36 vCPUs, which might cause launch issues in some Linux operating systems that have a vCPU limit of 32. We strongly recommend that you use the latest AMIs when you launch d2.8xlarge instances.

The following Linux AMIs support launching d2.8xlarge instances with 36 vCPUs:

- Amazon Linux 2 (HVM)
- Amazon Linux AMI 2018.03 (HVM)
- Ubuntu Server 14.04 LTS (HVM) or later
- Red Hat Enterprise Linux 7.1 (HVM)
- SUSE Linux Enterprise Server 12 (HVM)

If you must use a different AMI for your application, and your d2.8xlarge instance launch does not complete successfully (for example, if your instance status changes to stopped during launch with a Client.InstanceInitiatedShutdown state transition reason), modify your instance as described in the following procedure to support more than 32 vCPUs so that you can use the d2.8xlarge instance type.

To update an instance to support more than 32 vCPUs

1. Launch a D2 instance using your AMI, choosing any D2 instance type other than d2.8xlarge.
2. Update the kernel to the latest version by following your operating system-specific instructions. For example, for RHEL 6, use the following command:

```
sudo yum update -y kernel
```

3. Stop the instance.

4. (Optional) Create an AMI from the instance that you can use to launch any additional d2.8xlarge instances that you need in the future.

5. Change the instance type of your stopped instance to d2.8xlarge (choose Actions, Instance settings, Change instance type, and then follow the directions).

6. Start the instance. If the instance launches properly, you are done. If the instance still does not boot properly, proceed to the next step.

7. (Optional) If the instance still does not boot properly, the kernel on your instance may not support more than 32 vCPUs. However, you may be able to boot the instance if you limit the vCPUs.

   a. Change the instance type of your stopped instance to any D2 instance type other than d2.8xlarge (choose Actions, Instance settings, Change instance type, and then follow the directions).

   b. Add the `maxcpus=32` option to your boot kernel parameters by following your operating system-specific instructions. For example, for RHEL 6, edit the `/boot/grub/menu.lst` file and add the following option to the most recent and active kernel entry:

   ```
   default=0
timeout=1
splashimage=(hd0,0)/boot/grub/splash.xpm.gz
hiddenmenu
title Red Hat Enterprise Linux Server (2.6.32-504.3.3.el6.x86_64)
root (hd0,0)
kernel /boot/vmlinux-2.6.32-504.3.3.el6.x86_64 maxcpus=32 console=ttyS0 ro
root=UUID=9996863e-b964-47d3-a33b-3920974f7bd9 rd_NO_LUKS KEYBOARDTYPE=pc
KEYTABLE=en_US.UTF-8 xen_blkfront.sda_is_xvda=1 console=ttyS0,115200n8
console=tty0 rd_NO_MD SYSFONT=latarcyrheb-sun16 crashkernel=auto rd_NO_LVM
rd_NO_DM
initrd /boot/initramfs-2.6.32-504.3.3.el6.x86_64.img
   ```

   c. Stop the instance.

   d. (Optional) Create an AMI from the instance that you can use to launch any additional d2.8xlarge instances that you need in the future.

   e. Change the instance type of your stopped instance to d2.8xlarge (choose Actions, Instance Settings, Change Instance Type, and then follow the directions).

   f. Start the instance.

**Release notes**

- You must launch storage optimized instances using an HVM AMI. For more information, see Linux AMI virtualization types (p. 75).

- Instances built on the Nitro System (p. 199) have the following requirements:
  - NVMe drivers (p. 1350) must be installed
  - Elastic Network Adapter (ENA) drivers (p. 953) must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
Accelerated computing

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.

To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```bash
CONFIG_HOTPLUG_PCI_PCIE=y
CONFIG_PCIEASPM=y
```

Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.

With FreeBSD AMIs, bare metal instances take nearly an hour to boot and I/O to the local NVMe storage does not complete. As a workaround, add the following line to `/boot/loader.conf` and reboot:

```bash
hw.nvme.per_cpu_io_queues="0"
```

- The `d2.8xlarge` instance type has 36 vCPUs, which might cause launch issues in some Linux operating systems that have a vCPU limit of 32. For more information, see Support for vCPUs (p. 287).
- The `d3.8xlarge` and `d3en.12xlarge` instances support a maximum of three attachments, including the root volume. If you exceed the attachment limit when you add a network interface or EBS volume, this causes attachment issues on your instance.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see How many instances can I run in Amazon EC2? in the Amazon EC2 FAQ.

## Linux accelerated computing instances

Accelerated computing instances use hardware accelerators, or co-processors, to perform some functions, such as floating point number calculations, graphics processing, or data pattern matching, more efficiently than is possible in software running on CPUs. These instances enable more parallelism for higher throughput on compute-intensive workloads.

If you require high processing capability, you'll benefit from using accelerated computing instances, which provide access to hardware-based compute accelerators such as Graphics Processing Units (GPUs), Field Programmable Gate Arrays (FPGAs), or AWS Inferentia.

## Contents

- GPU instances (p. 290)
- Instances with AWS Inferentia (p. 291)

• Install AMD drivers on Linux instances (p. 303)
• Activate NVIDIA GRID Virtual Applications (p. 308)
• Optimize GPU settings (p. 308)

GPU instances

GPU-based instances provide access to NVIDIA GPUs with thousands of compute cores. You can use these instances to accelerate scientific, engineering, and rendering applications by leveraging the CUDA or Open Computing Language (OpenCL) parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

G4ad and G4dn instances

G4ad instances use AMD Radeon Pro V520 GPUs and 2nd generation AMD EPYC processors, and are well-suited for graphics applications such as remote graphics workstations, game streaming, and rendering that leverage industry-standard APIs such as OpenGL, DirectX, and Vulkan. They provide up to 4 AMD Radeon Pro V520 GPUs, 64 vCPUs, 25 Gbps networking, and 2.4 TB local NVMe-based SSD storage.

G4dn instances use NVIDIA Tesla GPUs and provide a cost-effective, high-performance platform for general purpose GPU computing using the CUDA or machine learning frameworks along with graphics applications using DirectX or OpenGL. These instances provide high-bandwidth networking, powerful half and single-precision floating-point capabilities, along with INT8 and INT4 precisions. Each GPU has 16 GiB of GDDR6 memory, making G4dn instances well-suited for machine learning inference, video transcoding, and graphics applications like remote graphics workstations and game streaming in the cloud.

For more information, see Amazon EC2 G4 Instances.

G4dn instances support NVIDIA GRID Virtual Workstation. For more information, see NVIDIA Marketplace offerings.

G3 instances

These instances use NVIDIA Tesla M60 GPUs and provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. G3 instances also provide NVIDIA GRID Virtual Workstation features, such as support for four monitors with resolutions up to 4096x2160, and NVIDIA GRID Virtual Applications. G3 instances are well-suited for applications such as 3D visualizations, graphics-intensive remote workstations, 3D rendering, video encoding, virtual reality, and other server-side graphics workloads requiring massively parallel processing power.

For more information, see Amazon EC2 G3 Instances.

G3 instances support NVIDIA GRID Virtual Workstation and NVIDIA GRID Virtual Applications. To activate either of these features, see Activate NVIDIA GRID Virtual Applications (p. 308).

G2 instances

These instances use NVIDIA GRID K520 GPUs and provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. NVIDIA GRID GPUs also support NVIDIA’s fast capture...
and encode API operations. Example applications include video creation services, 3D visualizations, streaming graphics-intensive applications, and other server-side graphics workloads.

**P4d instances**

These instances use NVIDIA A100 GPUs and provide a high-performance platform for machine learning and HPC workloads. P4d instances offer 400 Gbps of aggregate network bandwidth throughput and support, Elastic Fabric Adapter (EFA). They are the first EC2 instances to provide multiple network cards.

For more information, see Amazon EC2 P4d Instances.

P4d instances support NVIDIA NVSwitch GPU interconnect and NVIDIA GPUDirect RDMA.

**P3 instances**

These instances use NVIDIA Tesla V100 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models or through a machine learning framework. P3 instances provide high-bandwidth networking, powerful half, single, and double-precision floating-point capabilities, and up to 32 GiB of memory per GPU, which makes them ideal for deep learning, computational fluid dynamics, computational finance, seismic analysis, molecular modeling, genomics, rendering, and other server-side GPU compute workloads. Tesla V100 GPUs do not support graphics mode.

For more information, see Amazon EC2 P3 Instances.

P3 instances support NVIDIA NVLink peer to peer transfers. For more information, see NVIDIA NVLink.

**P2 instances**

P2 instances use NVIDIA Tesla K80 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models. P2 instances provide high-bandwidth networking, powerful single and double precision floating-point capabilities, and 12 GiB of memory per GPU, which makes them ideal for deep learning, graph databases, high-performance databases, computational fluid dynamics, computational finance, seismic analysis, molecular modeling, genomics, rendering, and other server-side GPU compute workloads.

P2 instances support NVIDIA GPUDirect peer to peer transfers. For more information, see NVIDIA GPUDirect.

**Instances with AWS Inferentia**

These instances are designed to accelerate machine learning using AWS Inferentia, a custom AI/ML chip from Amazon that provides high performance and low latency machine learning inference. These instances are optimized for deploying deep learning (DL) models for applications, such as natural language processing, object detection and classification, content personalization and filtering, and speech recognition.

There are a variety of ways that you can get started:

- Use SageMaker, a fully-managed service that is the easiest way to get started with machine learning models. For more information, see Compile and deploy a TensorFlow model on Inf1 using Sagemaker Neo.
- Launch an Inf1 instance using the Deep Learning AMI. For more information, see AWS Inferentia with DLAMI in the AWS Deep Learning AMI Developer Guide.
- Launch an Inf1 instance using your own AMI and install the AWS Neuron SDK, which enables you to compile, run, and profile deep learning models for AWS Inferentia.
- Launch a container instance using an Inf1 instance and an Amazon ECS-optimized AMI. For more information, see Amazon Linux 2 (Inferentia) AMIs in the Amazon Elastic Container Service Developer Guide.
- Create an Amazon EKS cluster with nodes running Inf1 instances. For more information, see Inferentia support in the Amazon EKS User Guide.

For more information, see Machine Learning on AWS.

Inf1 instances

Inf1 instances use AWS Inferentia machine learning inference chips. Inferentia was developed to enable highly cost-effective low latency inference performance at any scale.

For more information, see Amazon EC2 Inf1 Instances.

FPGA instances

FPGA-based instances provide access to large FPGAs with millions of parallel system logic cells. You can use FPGA-based accelerated computing instances to accelerate workloads such as genomics, financial analysis, real-time video processing, big data analysis, and security workloads by leveraging custom hardware accelerations. You can develop these accelerations using hardware description languages such as Verilog or VHDL, or by using higher-level languages such as OpenCL parallel computing frameworks. You can either develop your own hardware acceleration code or purchase hardware accelerations through the AWS Marketplace.

The FPGA Developer AMI provides the tools for developing, testing, and building AFIs. You can use the FPGA Developer AMI on any EC2 instance with at least 32 GB of system memory (for example, C5, M4, and R4 instances).

For more information, see the documentation for the AWS FPGA Hardware Development Kit.

F1 instances

F1 instances use Xilinx UltraScale+ VU9P FPGAs and are designed to accelerate computationally intensive algorithms, such as data-flow or highly parallel operations not suited to general purpose CPUs. Each FPGA in an F1 instance contains approximately 2.5 million logic elements and approximately 6,800 Digital Signal Processing (DSP) engines, along with 64 GiB of local DDR ECC protected memory, connected to the instance by a dedicated PCIe Gen3 x16 connection. F1 instances provide local NVMe SSD volumes.

Developers can use the FPGA Developer AMI and AWS Hardware Developer Kit to create custom hardware accelerations for use on F1 instances. The FPGA Developer AMI includes development tools for full-cycle FPGA development in the cloud. Using these tools, developers can create and share Amazon FPGA Images (AFIs) that can be loaded onto the FPGA of an F1 instance.

For more information, see Amazon EC2 F1 Instances.

Hardware specifications

For more information about the hardware specifications for each Amazon EC2 instance type, see Amazon EC2 Instance Types.

For more information about specifying CPU options, see Optimize CPU options (p. 575).
Instance performance

There are several GPU setting optimizations that you can perform to achieve the best performance on your instances. For more information, see Optimize GPU settings (p. 308).

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some accelerated computing instances are EBS-optimized by default at no additional cost. For more information, see Amazon EBS–optimized instances (p. 1354).

Some accelerated computing instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see Processor state control for your EC2 instance (p. 564).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see Enhanced networking on Linux (p. 952).

The following is a summary of network performance for accelerated computing instances that support enhanced networking.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Network performance</th>
<th>Enhanced networking</th>

* The root device volume must be an Amazon EBS volume.

For more information, see the following:

- Amazon EBS and NVMe on Linux instances (p. 1350)
- Amazon EC2 instance store (p. 1408)
- Placement groups (p. 1018)

### Release notes

- You must launch the instance using an HVM AMI.
- Instances built on the Nitro System (p. 199) have the following requirements:
  - NVMe drivers (p. 1350) must be installed
  - Elastic Network Adapter (ENA) drivers (p. 953) must be installed
The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

- GPU-based instances can't access the GPU unless the NVIDIA drivers are installed. For more information, see Install NVIDIA drivers on Linux instances (p. 296).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y
CONFIG_PCIEASPM=y
```

- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- There is a limit of 100 AFIs per Region.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see How many instances can I run in Amazon EC2? in the Amazon EC2 FAQ.

## Install NVIDIA drivers on Linux instances

An instance with an attached NVIDIA GPU, such as a P3 or G4dn instance, must have the appropriate NVIDIA driver installed. Depending on the instance type, you can either download a public NVIDIA driver, download a driver from Amazon S3 that is available only to AWS customers, or use an AMI with the driver pre-installed.

To install AMD drivers on an instance with an attached AMD GPU, such as a G4ad instance, see Install AMD drivers on Linux instances (p. 303) instead.

Contents

- Types of NVIDIA drivers (p. 297)
- Available drivers by instance type (p. 297)
- Installation options (p. 297)
  - Option 1: AMIs with the NVIDIA drivers installed (p. 298)
  - Option 2: Public NVIDIA drivers (p. 298)
  - Option 3: GRID drivers (G3 and G4dn instances) (p. 299)
  - Option 4: NVIDIA gaming drivers (G4dn instances) (p. 301)
- Install an additional version of CUDA (p. 303)
Types of NVIDIA drivers

The following are the main types of NVIDIA drivers that can be used with GPU-based instances.

Tesla drivers

These drivers are intended primarily for compute workloads, which use GPUs for computational tasks such as parallelized floating-point calculations for machine learning and fast Fourier transforms for high performance computing applications.

GRID drivers

These drivers are certified to provide optimal performance for professional visualization applications that render content such as 3D models or high-resolution videos. You can configure GRID drivers to support two modes. Quadro Virtual Workstations provide access to four 4K displays per GPU. GRID vApps provide RDSH App hosting capabilities.

Gaming drivers

These drivers contain optimizations for gaming and are updated frequently to provide performance enhancements. They support a single 4K display per GPU.

NVIDIA control panel

The NVIDIA control panel is supported with GRID and Gaming drivers. It is not supported with Tesla drivers.

Supported APIs for Tesla, GRID, and gaming drivers

- OpenCL, OpenGL, and Vulkan
- NVIDIA CUDA and related libraries (for example, cuDNN, TensorRT, nvJPEG, and cuBLAS)
- NVENC for video encoding and NVDEC for video decoding

Available drivers by instance type

The following table summarizes the supported NVIDIA drivers for each GPU instance type.

<table>
<thead>
<tr>
<th>Instance type</th>

† Using Marketplace AMIs only

Installation options

Use one of the following options to get the NVIDIA drivers required for your GPU instance.

Options
Accelerated computing

- Option 1: AMIs with the NVIDIA drivers installed (p. 298)
- Option 2: Public NVIDIA drivers (p. 298)
- Option 3: GRID drivers (G3 and G4dn instances) (p. 299)
- Option 4: NVIDIA gaming drivers (G4dn instances) (p. 301)

**Option 1: AMIs with the NVIDIA drivers installed**

AWS and NVIDIA offer different Amazon Machine Images (AMI) that come with the NVIDIA drivers installed.

- Marketplace offerings with the Tesla driver
- Marketplace offerings with the GRID driver
- Marketplace offerings with the Gaming driver

To update the driver version installed using one of these AMIs, you must uninstall the NVIDIA packages from your instance to avoid version conflicts. Use this command to uninstall the NVIDIA packages:

```
[ec2-user ~]# sudo yum erase nvidia cuda
```

The CUDA toolkit package has dependencies on the NVIDIA drivers. Uninstalling the NVIDIA packages erases the CUDA toolkit. You must reinstall the CUDA toolkit after installing the NVIDIA driver.

**Option 2: Public NVIDIA drivers**

The options offered by AWS come with the necessary license for the driver. Alternatively, you can install the public drivers and bring your own license. To install a public driver, download it from the NVIDIA site as described here.

Alternatively, you can use the options offered by AWS instead of the public drivers. To use a GRID driver on a P3 instance, use the AWS Marketplace AMIs as described in Option 1 (p. 298). To use a GRID driver on a G3 or G4dn instance, use the AWS Marketplace AMIs, as described in Option 1 or install the NVIDIA drivers provided by AWS as described in Option 3 (p. 299).

**To download a public NVIDIA driver**

Log on to your Linux instance and download the 64-bit NVIDIA driver appropriate for the instance type from [http://www.nvidia.com/Download/Find.aspx](http://www.nvidia.com/Download/Find.aspx). For **Product Type**, **Product Series**, and **Product**, use the options in the following table.

<table>
<thead>
<tr>
<th>Instance</th>
<th>Product Type</th>
<th>Product Series</th>
<th>Product</th>
</tr>
</thead>
<tbody>
<tr>
<td>G2</td>
<td>GRID</td>
<td>GRID Series</td>
<td>GRID K520</td>
</tr>
<tr>
<td>G3</td>
<td>Tesla</td>
<td>M-Class</td>
<td>M60</td>
</tr>
<tr>
<td>G4dn †</td>
<td>Tesla</td>
<td>T-Series</td>
<td>T4</td>
</tr>
<tr>
<td>P2</td>
<td>Tesla</td>
<td>K-Series</td>
<td>K80</td>
</tr>
<tr>
<td>P3</td>
<td>Tesla</td>
<td>V-Series</td>
<td>V100</td>
</tr>
<tr>
<td>P4d</td>
<td>Tesla</td>
<td>A-Series</td>
<td>A100</td>
</tr>
</tbody>
</table>

† G4dn instances require driver version 418.87 or later.

**To install the NVIDIA driver on Linux**
For more information about installing and configuring the driver, see the NVIDIA Driver Installation Quickstart Guide.

**Option 3: GRID drivers (G3 and G4dn instances)**

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA Tesla T4 or NVIDIA Tesla M60 hardware. Upon installation of the software, you are bound by the terms of the NVIDIA GRID Cloud End User License Agreement.

**Prerequisites**

- Install the AWS CLI on your Linux instance and configure default credentials. For more information, see Installing the AWS CLI in the AWS Command Line Interface User Guide.
- IAM users must have the permissions granted by the AmazonS3ReadOnlyAccess policy.

**To install the NVIDIA GRID driver on your Linux instance**

1. Connect to your Linux instance. Install gcc and make, if they are not already installed.
2. Update your package cache and get the package updates for your instance.
   - For Amazon Linux, CentOS, and Red Hat Enterprise Linux:
     ```bash
     [ec2-user ~]$ sudo yum update -y
     ```
   - For Ubuntu and Debian:
     ```bash
     $ sudo apt-get update -y
     ```
3. (Ubuntu 16.04 and later, with the linux-aws package) Upgrade the linux-aws package to receive the latest version.
   ```bash
   $ sudo apt-get upgrade -y linux-aws
   ```
4. Reboot your instance to load the latest kernel version.
   ```bash
   [ec2-user ~]$ sudo reboot
   ```
5. Reconnect to your instance after it has rebooted.
6. Install the gcc compiler and the kernel headers package for the version of the kernel you are currently running.
   - For Amazon Linux, CentOS, and Red Hat Enterprise Linux:
     ```bash
     [ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
     ```
   - For Ubuntu and Debian:
     ```bash
     $ sudo apt-get install -y gcc make linux-headers-$(uname -r)
     ```
7. [CentOS, Red Hat Enterprise Linux, Ubuntu, Debian] Disable the nouveau open source driver for NVIDIA graphics cards.
   a. Add nouveau to the /etc/modprobe.d/blacklist.conf blacklist file. Copy the following code block and paste it into a terminal.
     ```bash
     [ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
     EOF
     ```
b. Edit the `/etc/default/grub` file and add the following line:

```
GRUB_CMDLINE_LINUX="rd.blacklist=nouveau"
```

c. Rebuild the Grub configuration.

- For CentOS and Red Hat Enterprise Linux:
  
  ```bash
  [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
  ```

- For Ubuntu and Debian:

  ```bash
  $ sudo update-grub
  ```

8. Download the GRID driver installation utility using the following command:

```
```

Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

Starting with GRID version 11.0, you can use the driver packages under `latest` for both G3 and G4dn instances. We will not add versions later than 11.0 to `g4/latest`, but will keep version 11.0 and the earlier versions specific to G4dn under `g4/latest`.

9. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

10. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

12. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

13. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.
a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol NICE DCV.

b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications (p. 308).

Option 4: NVIDIA gaming drivers (G4dn instances)

These drivers are available to AWS customers only. By downloading them, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA Tesla T4 hardware. Upon installation of the software, you are bound by the terms of the NVIDIA GRID Cloud End User License Agreement.

Prerequisites

- Install the AWS CLI on your Linux instance and configure default credentials. For more information, see Installing the AWS CLI in the AWS Command Line Interface User Guide.
- IAM users must have the permissions granted by the AmazonS3ReadOnlyAccess policy.

To install the NVIDIA gaming driver on your Linux instance

1. Connect to your Linux instance. Install gcc and make, if they are not already installed.
2. Update your package cache and get the package updates for your instance.
   - For Amazon Linux, CentOS, and Red Hat Enterprise Linux:
     
     ```bash
     [ec2-user ~]$ sudo yum update -y
     ```
   - For Ubuntu and Debian:
     
     ```bash
     # sudo apt-get update -y
     ```
3. (Ubuntu 16.04 and later, with the linux-aws package) Upgrade the linux-aws package to receive the latest version.

   ```bash
   # sudo apt-get upgrade -y linux-aws
   ```
4. Reboot your instance to load the latest kernel version.

   ```bash
   [ec2-user ~]$ sudo reboot
   ```
5. Reconnect to your instance after it has rebooted.
6. Install the gcc compiler and the kernel headers package for the version of the kernel you are currently running.
   - For Amazon Linux, CentOS, and Red Hat Enterprise Linux:
     
     ```bash
     [ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
     ```
   - For Ubuntu and Debian:
     
     ```bash
     $ sudo apt-get install -y gcc make linux-headers-$(uname -r)
     ```
7. [CentOS, Red Hat Enterprise Linux, Ubuntu, Debian] Disable the nouveau open source driver for NVIDIA graphics cards.
a. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` blacklist file. Copy the following code block and paste it into a terminal.

```
[ec2-user ~]# cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist riva
EOF
```

b. Edit the `/etc/default/grub` file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

c. Rebuild the Grub configuration.

- For CentOS and Red Hat Enterprise Linux:

```
[ec2-user ~]# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

- For Ubuntu and Debian:

```
$ sudo update-grub
```

8. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]# aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]# aws s3 ls --recursive s3://nvidia-gaming/linux/
```

9. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]# chmod +x NVIDIA-Linux-x86_64*.run
```

10. Run the installer using the following command:

```
[ec2-user ~]# sudo ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Use the following command to create the required configuration file.

```
[ec2-user ~]# cat << EOF | sudo tee /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

12. Use the following command to download and rename the certification file.

- For version 460.39 or later:

```
[ec2-user ~]# sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2021_10_2.cert"
```
• For version 440.68 to 445.48:

```bash
```

• For earlier versions:

```bash
```

13. Reboot the instance.

```bash
[ec2-user ~]$ sudo reboot
```

14. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol NICE DCV. If you do not require this functionality, do not complete this step.

### Install an additional version of CUDA

After you install an NVIDIA graphics driver on your instance, you can install a version of CUDA other than the version that is bundled with the graphics driver. The following procedure demonstrates how to configure multiple versions of CUDA on the instance.

**To install the CUDA toolkit**

1. Connect to your Linux instance.
2. Open the NVIDIA website and select the version of CUDA that you need.
3. Select the architecture, distribution, and version for the operating system on your instance. For **Installer Type**, select **runfile (local)**.
4. Follow the instructions to download the install script.
5. Add run permissions to the install script that you downloaded using the following command.

```bash
[ec2-user ~]$ chmod +x downloaded_installer_file
```

6. Run the install script as follows to install the CUDA toolkit and add the CUDA version number to the toolkit path.

```bash
```

7. (Optional) Set the default CUDA version as follows.

```bash
[ec2-user ~]$ ln -s /usr/local/cuda-version /usr/local/cuda
```

### Install AMD drivers on Linux instances

An instance with an attached AMD GPU, such as a G4ad instance, must have the appropriate AMD driver installed. Depending on your requirements, you can either use an AMI with the driver preinstalled or download a driver from Amazon S3.

To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a G4dn instance, see [Install NVIDIA drivers on Linux instances](p. 296) instead.
Contents
- AMD Radeon Pro Software for Enterprise Driver (p. 304)
- AMIs with the AMD driver installed (p. 304)
- AMD driver download (p. 304)
- Set up an interactive desktop (p. 306)

AMD Radeon Pro Software for Enterprise Driver

The AMD Radeon Pro Software for Enterprise Driver is built to deliver support for professional-grade graphics use cases. Using the driver, you can configure your instances with two 4K displays per GPU.

Supported APIs
- OpenGL, OpenCL
- Vulkan
- AMD Advanced Media Framework
- Video Acceleration API

AMIs with the AMD driver installed

AWS offers different Amazon Machine Images (AMI) that come with the AMD drivers installed. Open Marketplace offerings with the AMD driver.

AMD driver download

If you aren't using an AMI with the AMD driver installed, you can download the AMD driver and install it on your instance.

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the AMD Radeon Pro V520 hardware. Upon installation of the software, you are bound by the terms of the AMD Software End User License Agreement.

Prerequisites
- Install the AWS CLI on your Linux instance and configure default credentials. For more information, see Installing the AWS CLI in the AWS Command Line Interface User Guide.
- IAM users must have the permissions granted by the AmazonS3ReadOnlyAccess policy.

To install the AMD driver on your Linux instance

1. Connect to your Linux instance. Install gcc and make, if they are not already installed.
2. Update your package cache and get the package updates for your instance.
   - For Amazon Linux 2:
     
     ```
     $ sudo amazon-linux-extras install epel -y
     $ sudo yum update -y
     ```
   - For Ubuntu:
     
     ```
     $ sudo dpkg --add-architecture i386
     ```
$ sudo apt-get update -y && sudo apt upgrade -y

- For CentOS:

$ sudo yum install epel-release -y
$ sudo yum update -y

3. Reboot the instance.

$ sudo reboot

4. Reconnect to the instance after it reboots.

5. Download the latest AMD driver.

$ aws s3 cp --recursive s3://ec2-amd-linux-drivers/latest/ .

- For Amazon Linux 2 and CentOS:

$ tar -xf amdgpu-pro-*rhel*.tar.xz

- For Ubuntu:

$ tar -xf amdgpu-pro*ubuntu*.xz

7. Change to the folder for the extracted driver.

8. Add the GPG keys for the driver installation.

- For Amazon Linux 2 and CentOS:

$ sudo rpm --import RPM-GPG-KEY-amdgpu

- For Ubuntu:

$ sudo apt install linux-modules-extra-$(uname -r) -y
$ cat RPM-GPG-KEY-amdgpu | sudo apt-key add -

9. Run the self install script to install the full graphics stack.

$ ./amdgpu-pro-install -y --opencl=pal,legacy

10. Reboot the instance.

$ sudo reboot

11. Confirm that the driver is functional.

$ dmesg | grep amdgpu

The response should look like the following:

Initialized amdgpu
Set up an interactive desktop

After you confirm that your instance has the AMD GPU driver installed and amdgpu is in use, you can install an interactive desktop manager. We recommend the MATE desktop environment for the best compatibility and performance.

Prerequisite

Open a text editor and save the following as a file named `xorg.conf`. You'll need this file on your instance.

```plaintext
Section "ServerLayout"
    Identifier     "Layout0"
    Screen          0 "Screen0"
    InputDevice     "Keyboard0" "CoreKeyboard"
    InputDevice     "Mouse0" "CorePointer"
EndSection
Section "Files"
    ModulePath "/opt/amdgpu/lib64/xorg/modules/drivers"
    ModulePath "/opt/amdgpu/lib/xorg/modules"
    ModulePath "/opt/amdgpu-pro/lib/xorg/modules/extensions"
    ModulePath "/opt/amdgpu-pro/lib64/xorg/modules/extensions"
    ModulePath "/usr/lib64/xorg/modules"
    ModulePath "/usr/lib/xorg/modules"
EndSection
Section "InputDevice"
    # generated from default
    Identifier     "Mouse0"
    Driver         "mouse"
    Option         "Protocol" "auto"
    Option         "Device" "/dev/psaux"
    Option         "Emulate3Buttons" "no"
    Option         "ZAxisMapping" "4 5"
EndSection
Section "InputDevice"
    # generated from default
    Identifier     "Keyboard0"
    Driver         "kbd"

    Option         "AllowEmptyInitialConfiguration" "True"
    SubSection "Display"
        Virtual    3840 2160
        Depth      32
EndSubSection
```
To set up an interactive desktop on Amazon Linux 2

1. Install the EPEL repository.

   ```bash
   $ sudo amazon-linux-extras install epel -y
   ```

2. Install the MATE desktop.

   ```bash
   $ sudo amazon-linux-extras install mate-desktop1.x -y
   $ sudo yum groupinstall "MATE Desktop" -y
   $ sudo systemctl disable firewalld
   ```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.

4. Reboot the instance.

   ```bash
   $ sudo reboot
   ```

5. (Optional) Install the NICE DCV server to use NICE DCV as a high-performance display protocol, and then connect to a NICE DCV session using your preferred client.

To set up an interactive desktop on Ubuntu

1. Install the MATE desktop.

   ```bash
   $ sudo apt install xorg-dev ubuntu-mate-desktop -y
   $ sudo apt purge ifupdown -y
   ```

2. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.

3. Reboot the instance.

   ```bash
   $ sudo reboot
   ```

4. Install the AMF encoder for the appropriate version of Ubuntu.

   ```bash
   $ sudo apt install ./amdgpu-pro-20.20-*/amf-amdgpu-pro_20.20-*/amd64.deb
   ```

5. (Optional) Install the NICE DCV server to use NICE DCV as a high-performance display protocol, and then connect to a NICE DCV session using your preferred client.

6. After the DCV installation give the DCV User video permissions:

   ```bash
   $ sudo usermod -aG video dcv
   ```

To set up an interactive desktop on CentOS

1. Install the EPEL repository.

   ```bash
   $ sudo yum update -y
   $ sudo yum install epel-release -y
   ```

2. Install the MATE desktop.

   ```bash
   $ sudo yum groupinstall "MATE Desktop" -y
   ```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`

4. Reboot the instance.

```bash
$ sudo systemctl disable firewalld
```

5. (Optional) Install the NICE DCV server to use NICE DCV as a high-performance display protocol, and then connect to a NICE DCV session using your preferred client.

### Activate NVIDIA GRID Virtual Applications

To activate the GRID Virtual Applications on G3 and G4dn instances (NVIDIA GRID Virtual Workstation is enabled by default), you must define the product type for the driver in the `/etc/nvidia/gridd.conf` file.

#### To activate GRID Virtual Applications on Linux instances

1. Create the `/etc/nvidia/gridd.conf` file from the provided template file.

   ```bash
   [ec2-user ~]$ sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
   ```

2. Open the `/etc/nvidia/gridd.conf` file in your favorite text editor.

3. Find the `FeatureType` line, and set it equal to 0. Then add a line with `IgnoreSP=TRUE`.

   ```plaintext
   FeatureType=0
   IgnoreSP=TRUE
   ```

4. Save the file and exit.

5. Reboot the instance to pick up the new configuration.

   ```bash
   [ec2-user ~]$ sudo reboot
   ```

### Optimize GPU settings

There are several GPU setting optimizations that you can perform to achieve the best performance on G3, G4dn, P2, P3, P3dn, and P4d instances. With some of these instance types, the NVIDIA driver uses an autoboost feature, which varies the GPU clock speeds. By disabling autoboost and setting the GPU clock speeds to their maximum frequency, you can consistently achieve the maximum performance with your GPU instances. The following procedure helps you to configure the GPU settings to be persistent, disable the autoboost feature if needed, and set the GPU clock speeds to their maximum frequency.

#### To optimize GPU settings

1. Configure the GPU settings to be persistent. This command can take several minutes to run.

   ```bash
   [ec2-user ~]$ sudo nvidia-persistenced
   ```

2. G2, G3, and P2 instances: Disable the autoboost feature for all GPUs on the instance.

   ```bash
   [ec2-user ~]$ sudo nvidia-smi --auto-boost-default=0
   ```

   **Note**

   GPUs on G4dn, P3, P3dn, and P4d instances do not support autoboost.
3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error "Setting applications clocks is not supported for GPU...", which you can ignore.

- G3 instances:
  
  ```
  [ec2-user ~]$ sudo nvidia-smi -ac 2505,1177
  ```

- G4dn instances:
  
  ```
  [ec2-user ~]$ sudo nvidia-smi -ac 5001,1590
  ```

- P2 instances:
  
  ```
  [ec2-user ~]$ sudo nvidia-smi -ac 2505,875
  ```

- P3 and P3dn instances:
  
  ```
  [ec2-user ~]$ sudo nvidia-smi -ac 877,1530
  ```

- P4d instances:
  
  ```
  [ec2-user ~]$ sudo nvidia-smi -ac 1215,1410
  ```

### Find an Amazon EC2 instance type

Before you can launch an instance, you must select an instance type to use. The instance type that you choose might depend on your requirements for the instances that you'll launch. For example, you might choose an instance type based on the following requirements:

- Availability Zone or Region
- Compute
- Memory
- Networking
- Pricing
- Storage

### Find an instance type using the console

You can find an instance type that meets your needs using the Amazon EC2 console.

**To find an instance type using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **Instance Types**.
4. (Optional) Choose the preferences (gear) icon to select which instance type attributes to display, such as **On-Demand Linux pricing**, and then choose **Confirm**. Alternatively, select an instance type and view all attributes using the **Details** pane.
5. Use the instance type attributes to filter the list of displayed instance types to only the instance types that meet your needs. For example, you can list all instance types that have more than eight vCPUs and also support hibernation.

6. (Optional) Select multiple instance types to see a side-by-side comparison across all attributes in the Details pane.

7. (Optional) To save the list of instance types to a comma-separated values (.csv) file for further review, choose Download list CSV. The file includes all instance types that match the filters you set.

8. After locating instance types that meet your needs, you can use them to launch instances. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

Find an instance type using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to find an instance type that meet your needs.

To find an instance type using the AWS CLI

1. If you have not done so already, install the AWS CLI For more information, see the AWS Command Line Interface User Guide.

2. Use the describe-instance-types command to filter instance types based on instance attributes. For example, you can use the following command to display only instance types with 48 vCPUs.

   ```bash
   aws ec2 describe-instance-types --filters "Name=vcpu-info.default-vcpus,Values=48"
   ```

3. Use the describe-instance-type-offerings command to filter instance types offered by location (Region or Availability Zone). For example, you can use the following command to display the instance types offered in the specified Availability Zone.

   ```bash
   aws ec2 describe-instance-type-offerings --location-type "availability-zone" --filters Name=location,Values=us-east-2a --region us-east-2
   ```

4. After locating instance types that meet your needs, make note of them so that you can use these instance types when you launch instances. For more information, see Launching your instance in the AWS Command Line Interface User Guide.

Change the instance type

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can resize your instance by changing its instance type. For example, if your t2.micro instance is too small for its workload, you can change it to another instance type that is appropriate for the workload.

You might also want to migrate from a previous generation instance type to a current generation instance type to take advantage of some features; for example, support for IPv6.

If you want a recommendation for an instance type that is best able to handle your existing workload, you can use AWS Compute Optimizer. For more information, see Get recommendations for an instance type (p. 316).

Contents

- Requirements for changing the instance type (p. 311)
- Compatibility for changing the instance type (p. 311)
- Change the instance type of an Amazon EBS–backed instance (p. 312)
- Migrate an instance store-backed instance (p. 314)
- Migrate to a new instance configuration (p. 315)
Requirements for changing the instance type

To resize your Amazon EC2 instance by changing its instance type, consider the following requirements:

- The steps for changing the instance type are different depending on whether the root device volume (p. 1432) for your instance is an EBS volume or an instance store volume.
  - If the root device is an EBS volume, you can change the instance type of the original instance. For the instructions, see Change the instance type of an Amazon EBS–backed instance (p. 312).
  - If the root device is an instance store volume, you must migrate your application to a new instance that is configured with the instance type that you need. For the instructions, see Migrate an instance store-backed instance (p. 314).
- You must select an instance type that is compatible with the configuration of the instance. If the instance type that you want is not compatible with the instance configuration you have, then you must migrate your application to a new instance with the instance type that you need.
- To change the instance type, the instance must be in the stopped state.
- You cannot resize an instance if hibernation is enabled.

Compatibility for changing the instance type

You can resize an instance only if its current instance type and the new instance type that you want are compatible in the following ways:

- **Virtualization type**: Linux AMIs use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). You can't resize an instance that was launched from a PV AMI to an instance type that is HVM only. For more information, see Linux AMI virtualization types (p. 75). To check the virtualization type of your instance, see the Virtualization field on the details pane of the Instances screen in the Amazon EC2 console.
- **Architecture**: AMIs are specific to the architecture of the processor, so you must select an instance type with the same processor architecture as the current instance type. For example:
  - If you are resizing an instance type with a processor based on the Arm architecture, you are limited to the instance types that support a processor based on the Arm architecture, such as C6g and M6g.
  - The following instance types are the only instance types that support 32-bit AMIs: t2.nano, t2.micro, t2.small, t2.medium, c3.large, t1.micro, m1.small, m1.medium, and c1.medium. If you are resizing a 32-bit instance, you are limited to these instance types.
- **Network**: Newer instance types must be launched in a VPC. Therefore, you can't resize an instance in the EC2-Classic platform to a instance type that is available only in a VPC unless you have a nondefault VPC. To check whether your instance is in a VPC, check the VPC ID value on the details pane of the Instances screen in the Amazon EC2 console. For more information, see Migrate from EC2-Classic to a VPC (p. 1053).
- **Enhanced networking**: Instance types that support enhanced networking (p. 952) require the necessary drivers installed. For example, instances based on the Nitro System (p. 199) require EBS-backed AMIs with the Elastic Network Adapter (ENA) drivers installed. To resize an instance from a type that does not support enhanced networking to a type that supports enhanced networking, you must install the ENA drivers (p. 953) or ixgbevf drivers (p. 963) on the instance, as appropriate.
- **Network cards**: Some instance types support multiple network cards (p. 924). You must select an instance type that supports the same number of network cards as the current instance type.
- **NVMe**: EBS volumes are exposed as NVMe block devices on instances built on the Nitro System (p. 199). If you resize an instance from an instance type that does not support NVMe to an instance type that supports NVMe, you must first install the NVMe drivers (p. 1350) on your instance. Also, the device names for devices that you specify in the block device mapping are renamed using NVMe device names (/dev/nvme[0–26]+n1). Therefore, to mount file systems at boot time using /etc/fstab, you must use UUID/Label instead of device names.
Change the instance type of an Amazon EBS–backed instance

Considerations

You must stop your Amazon EBS–backed instance before you can change its instance type. When you stop and start an instance, be aware of the following:

- We move the instance to new hardware; however, the instance ID does not change.
- If your instance has a public IPv4 address, we release the address and give it a new public IPv4 address. The instance retains its private IPv4 addresses, any Elastic IP addresses, and any IPv6 addresses.
- When you resize an instance, the resized instance usually has the same number of instance store volumes that you specified when you launched the original instance. With instance types that support NVMe instance store volumes (which are available by default), the resized instance might have additional instance store volumes, depending on the AMI. Otherwise, you can migrate your application to an instance with a new instance type manually, specifying the number of instance store volumes that you need when you launch the new instance.
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. To prevent this, you can suspend the scaling processes for the group while you’re resizing your instance. For more information, see Suspending and Resuming Scaling Processes in the Amazon EC2 Auto Scaling User Guide.
- If your instance is in a cluster placement group (p. 1019) and, after changing the instance type, the instance start fails, try the following: stop all the instances in the cluster placement group, change the instance type for the affected instance, and then restart all the instances in the cluster placement group.
- Ensure that you plan for downtime while your instance is stopped. Stopping and resizing an instance may take a few minutes, and restarting your instance may take a variable amount of time depending on your application’s startup scripts.

For more information, see Stop and start your instance (p. 524).

Change the instance type

Use the following procedure to change the instance type of an Amazon EBS–backed instance using the AWS Management Console.

New console

To change the instance type of an Amazon EBS–backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see Compatibility for changing the instance type (p. 311).
2. Open the Amazon EC2 console.
3. In the navigation pane, choose Instances.
4. Select the instance and choose **Actions, Instance state, Stop instance**.
5. In the confirmation dialog box, choose **Stop**. It can take a few minutes for the instance to stop.
6. With the instance still selected, choose **Actions, Instance settings, Change instance type**. This action is grayed out if the instance state is not stopped.
7. In the **Change instance type** dialog box, do the following:
   a. From **Instance type**, select the instance type that you want. If the instance type that you want does not appear in the list, then it is not compatible with the configuration of your instance (for example, because of virtualization type). For more information, see Compatibility for changing the instance type (p. 311).
   b. (Optional) If the instance type that you selected supports EBS–optimization, select **EBS-optimized** to enable EBS–optimization or deselect **EBS-optimized** to disable EBS–optimization. If the instance type that you selected is EBS–optimized by default, **EBS-optimized** is selected and you can't deselect it.
   c. Choose **Apply** to accept the new settings.
8. To restart the stopped instance, select the instance and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the running state.
9. (Troubleshooting) If your instance won't boot, it is possible that one of the requirements for the new instance type was not met. For more information, see Why is my Linux instance not booting after I changed its type?

**Old console**

**To change the instance type of an Amazon EBS–backed instance**

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see Compatibility for changing the instance type (p. 311).
2. Open the Amazon EC2 console.
3. In the navigation pane, choose **Instances**.
4. Select the instance and choose **Actions, Instance State, Stop**.
5. In the confirmation dialog box, choose **Yes, Stop**. It can take a few minutes for the instance to stop.
6. With the instance still selected, choose **Actions, Instance Settings, Change Instance Type**. This action is grayed out if the instance state is not stopped.
7. In the **Change Instance Type** dialog box, do the following:
   a. From **Instance Type**, select the instance type that you want. If the instance type that you want does not appear in the list, then it is not compatible with the configuration of your instance (for example, because of virtualization type). For more information, see Compatibility for changing the instance type (p. 311).
   b. (Optional) If the instance type that you selected supports EBS–optimization, select **EBS-optimized** to enable EBS–optimization or deselect **EBS-optimized** to disable EBS–optimization. If the instance type that you selected is EBS–optimized by default, **EBS-optimized** is selected and you can't deselect it.
   c. Choose **Apply** to accept the new settings.
8. To restart the stopped instance, select the instance and choose **Actions, Instance State, Start**.
9. In the confirmation dialog box, choose **Yes, Start**. It can take a few minutes for the instance to enter the running state.
10. (Troubleshooting) If your instance won't boot, it is possible that one of the requirements for the new instance type was not met. For more information, see Why is my Linux instance not booting after I changed its type?
Migrate an instance store-backed instance

You can't change the instance type of an instance store-back instance. Instead, you must migrate your application to a new instance that is configured with the instance type that you need. To migrate your application to a new instance, you must create an image from your original instance, and then launch a new instance from this image with the instance type that you need. To ensure that your users can continue to use the applications that you're hosting on your instance uninterrupted, you must take any Elastic IP address that you've associated with your original instance and associate it with the new instance. Then you can terminate the original instance.

**New console**

**To migrate an instance store-backed instance**

1. Back up any data on your instance store volumes that you need to keep to persistent storage. To migrate data on your EBS volumes that you need to keep, take a snapshot of the volumes (see Create Amazon EBS snapshots (p. 1231)) or detach the volume from the instance so that you can attach it to the new instance later (see Detach an Amazon EBS volume from a Linux instance (p. 1224)).

2. Create an AMI from your instance store-backed instance by satisfying the prerequisites and following the procedures in Create an instance store-backed Linux AMI (p. 107). When you are finished creating an AMI from your instance, return to this procedure.

3. Open the Amazon EC2 console and in the navigation pane, choose AMIs. From the filter lists, choose Owned by me, and select the image that you created in the previous step. Notice that AMI Name is the name that you specified when you registered the image and Source is your Amazon S3 bucket.

   **Note**
   
   If you do not see the AMI that you created in the previous step, make sure that you have selected the Region in which you created your AMI.

4. Choose Launch. When you specify options for the instance, be sure to select the new instance type that you want. If the instance type that you want can't be selected, then it is not compatible with configuration of the AMI that you created (for example, because of virtualization type). You can also specify any EBS volumes that you detached from the original instance.

   It can take a few minutes for the instance to enter the running state.

5. (Optional) You can terminate the instance that you started with, if it's no longer needed. Select the instance and verify that you are about to terminate the original instance, not the new instance (for example, check the name or launch time). Choose Instance state, Terminate instance.

**Old console**

**To migrate an instance store-backed instance**

1. Back up any data on your instance store volumes that you need to keep to persistent storage. To migrate data on your EBS volumes that you need to keep, take a snapshot of the volumes (see Create Amazon EBS snapshots (p. 1231)) or detach the volume from the instance so that you can attach it to the new instance later (see Detach an Amazon EBS volume from a Linux instance (p. 1224)).

2. Create an AMI from your instance store-backed instance by satisfying the prerequisites and following the procedures in Create an instance store-backed Linux AMI (p. 107). When you are finished creating an AMI from your instance, return to this procedure.

3. Open the Amazon EC2 console and in the navigation pane, choose AMIs. From the filter lists, choose Owned by me, and choose the image that you created in the previous step. Notice that
AMI Name is the name that you specified when you registered the image and Source is your Amazon S3 bucket.

Note
If you do not see the AMI that you created in the previous step, make sure that you have selected the Region in which you created your AMI.

4. Choose Launch. When you specify options for the instance, be sure to select the new instance type that you want. If the instance type that you want can't be selected, then it is not compatible with configuration of the AMI that you created (for example, because of virtualization type). You can also specify any EBS volumes that you detached from the original instance.

It can take a few minutes for the instance to enter the running state.

5. (Optional) You can terminate the instance that you started with, if it's no longer needed. Select the instance and verify that you are about to terminate the original instance, not the new instance (for example, check the name or launch time). Choose Actions, Instance State, Terminate.

Migrate to a new instance configuration

If the current configuration of your instance is incompatible with the new instance type that you want, then you can't resize the instance to that instance type. Instead, you can migrate your application to a new instance with a configuration that is compatible with the new instance type that you want.

If you want to move from an instance launched from a PV AMI to an instance type that is HVM only, the general process is as follows:

New console

To migrate your application to a compatible instance

1. Back up any data on your instance store volumes that you need to keep to persistent storage. To migrate data on your EBS volumes that you need to keep, create a snapshot of the volumes (see Create Amazon EBS snapshots (p. 1231)) or detach the volume from the instance so that you can attach it to the new instance later (see Detach an Amazon EBS volume from a Linux instance (p. 1224)).

2. Launch a new instance, selecting the following:
   - An HVM AMI.
   - The HVM only instance type.
   - If you are using an Elastic IP address, select the VPC that the original instance is currently running in.
   - Any EBS volumes that you detached from the original instance and want to attach to the new instance, or new EBS volumes based on the snapshots that you created.
   - If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.

3. Install your application and any required software on the instance.

4. Restore any data that you backed up from the instance store volumes of the original instance.

5. If you are using an Elastic IP address, assign it to the newly launched instance as follows:
   a. In the navigation pane, choose Elastic IP.
   b. Select the Elastic IP address that is associated with the original instance and choose Actions, Disassociate Elastic IP address. When prompted for confirmation, choose Disassociate.
   c. With the Elastic IP address still selected, choose Actions, Associate Elastic IP address.
d. For **Resource type**, choose **Instance**.
e. For **Instance**, choose the instance with which to associate the Elastic IP address. You can also enter text to search for a specific instance.
f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
g. Choose **Associate**.

6. (Optional) You can terminate the original instance if it's no longer needed. Select the instance and verify that you are about to terminate the original instance, not the new instance (for example, check the name or launch time). Choose **Instance state, Terminate instance**.

**Old console**

To migrate your application to a compatible instance

1. Back up any data on your instance store volumes that you need to keep to persistent storage. To migrate data on your EBS volumes that you need to keep, create a snapshot of the volumes (see [Create Amazon EBS snapshots](p. 1231)) or detach the volume from the instance so that you can attach it to the new instance later (see [Detach an Amazon EBS volume from a Linux instance](p. 1224)).

2. Launch a new instance, selecting the following:
   - An HVM AMI.
   - The HVM only instance type.
   - If you are using an Elastic IP address, select the VPC that the original instance is currently running in.
   - Any EBS volumes that you detached from the original instance and want to attach to the new instance, or new EBS volumes based on the snapshots that you created.
   - If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.

3. Install your application and any required software on the instance.

4. Restore any data that you backed up from the instance store volumes of the original instance.

5. If you are using an Elastic IP address, assign it to the newly launched instance as follows:
   a. In the navigation pane, choose **Elastic IPs**.
   b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate address**. When prompted for confirmation, choose **Disassociate address**.
   c. With the Elastic IP address still selected, choose **Actions, Associate address**.
   d. From **Instance**, select the new instance, and then choose **Associate**.

6. (Optional) You can terminate the original instance if it's no longer needed. Select the instance and verify that you are about to terminate the original instance, not the new instance (for example, check the name or launch time). Choose **Actions, Instance State, Terminate**.

**Get recommendations for an instance type**

AWS Compute Optimizer provides Amazon EC2 instance recommendations to help you improve performance, save money, or both. You can use these recommendations to decide whether to move to a new instance type.

To make recommendations, Compute Optimizer analyzes your existing instance specifications and utilization metrics. The compiled data is then used to recommend which Amazon EC2 instance types are
best able to handle the existing workload. Recommendations are returned along with per-hour instance pricing.

This topic outlines how to view recommendations through the Amazon EC2 console. For more information, see the AWS Compute Optimizer User Guide.

**Note**
To get recommendations from Compute Optimizer, you must first opt in to Compute Optimizer. For more information, see Getting Started with AWS Compute Optimizer in the AWS Compute Optimizer User Guide.

**Contents**
- Limitations (p. 317)
- Findings (p. 317)
- View recommendations (p. 317)
- Considerations for evaluating recommendations (p. 319)
- Additional resources (p. 319)

**Limitations**

Compute Optimizer currently generates recommendations for M, C, R, T, and X instance types. Other instance types are not considered by Compute Optimizer. If you're using other instance types, they will not be listed in the Compute Optimizer recommendations view. For information about these and other instance types, see Instance types (p. 193).

**Findings**

Compute Optimizer classifies its findings for EC2 instances as follows:

- **Under-provisioned** – An EC2 instance is considered under-provisioned when at least one specification of your instance, such as CPU, memory, or network, does not meet the performance requirements of your workload. Under-provisioned EC2 instances might lead to poor application performance.

- **Over-provisioned** – An EC2 instance is considered over-provisioned when at least one specification of your instance, such as CPU, memory, or network, can be sized down while still meeting the performance requirements of your workload, and when no specification is under-provisioned. Over-provisioned EC2 instances might lead to unnecessary infrastructure cost.

- **Optimized** – An EC2 instance is considered optimized when all specifications of your instance, such as CPU, memory, and network, meet the performance requirements of your workload, and the instance is not over-provisioned. An optimized EC2 instance runs your workloads with optimal performance and infrastructure cost. For optimized instances, Compute Optimizer might sometimes recommend a new generation instance type.

- **None** – There are no recommendations for this instance. This might occur if you've been opted in to Compute Optimizer for less than 12 hours, or when the instance has been running for less than 30 hours, or when the instance type is not supported by Compute Optimizer. For more information, see Limitations (p. 317) in the previous section.

**View recommendations**

After you opt in to Compute Optimizer, you can view the findings that Compute Optimizer generates for your EC2 instances in the EC2 console. You can then access the Compute Optimizer console to view the recommendations. If you recently opted in, findings might not be reflected in the EC2 console for up to 12 hours.
New console

**To view a recommendation for an EC2 instance through the EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, and then choose the instance ID.
3. On the instance summary page, in the **AWS Compute Optimizer** banner near the bottom of the page, choose **View detail**.

   The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose the settings (⚙️) icon to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.

   **Note**
   If you’ve purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Old console

**To view a recommendation for an EC2 instance through the EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select an instance, and on the **Description** tab, inspect the **Finding** field. Choose **View detail**.

   The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose the settings (⚙️) icon to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.

   **Note**
   If you’ve purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Determine whether you want to use one of the recommendations. Decide whether to optimize for performance improvement, for cost reduction, or for a combination of the two. For more information, see **Viewing Resource Recommendations** in the **AWS Compute Optimizer User Guide**.

**To view recommendations for all EC2 instances across all Regions through the Compute Optimizer console**

2. Choose **View recommendations for all EC2 instances**.
3. You can perform the following actions on the recommendations page:
Considerations for evaluating recommendations

Before changing an instance type, consider the following:

- The recommendations don’t forecast your usage. Recommendations are based on your historical usage over the most recent 14-day time period. Be sure to choose an instance type that is expected to meet your future resource needs.

- Focus on the graphed metrics to determine whether actual usage is lower than instance capacity. You can also view metric data (average, peak, percentile) in CloudWatch to further evaluate your EC2 instance recommendations. For example, notice how CPU percentage metrics change during the day and whether there are peaks that need to be accommodated. For more information, see Viewing Available Metrics in the Amazon CloudWatch User Guide.

- Compute Optimizer might supply recommendations for burstable performance instances, which are T3, T3a, and T2 instances. If you periodically burst above the baseline, make sure that you can continue to do so based on the vCPUs of the new instance type. For more information, see Key concepts and definitions for burstable performance instances (p. 219).

- If you’ve purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

- Consider conversions to newer generation instances, where possible.

- When migrating to a different instance family, make sure the current instance type and the new instance type are compatible, for example, in terms of virtualization, architecture, or network type. For more information, see Compatibility for changing the instance type (p. 311).

- Finally, consider the performance risk rating that’s provided for each recommendation. Performance risk indicates the amount of effort you might need to spend in order to validate whether the recommended instance type meets the performance requirements of your workload. We also recommend rigorous load and performance testing before and after making any changes.

There are other considerations when resizing an EC2 instance. For more information, see Change the instance type (p. 310).

Additional resources

For more information:
Instance purchasing options

Amazon EC2 provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand Instances** – Pay, by the second, for the instances that you launch.
- **Savings Plans** – Reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.
- **Reserved Instances** – Reduce your Amazon EC2 costs by making a commitment to a consistent instance configuration, including instance type and Region, for a term of 1 or 3 years.
- **Spot Instances** – Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.
- **Dedicated Hosts** – Pay for a physical host that is fully dedicated to running your instances, and bring your existing per-socket, per-core, or per-VM software licenses to reduce costs.
- **Dedicated Instances** – Pay, by the hour, for instances that run on single-tenant hardware.
- **Capacity Reservations** – Reserve capacity for your EC2 instances in a specific Availability Zone for any duration.

If you require a capacity reservation, purchase Reserved Instances or Capacity Reservations for a specific Availability Zone. Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if they can be interrupted. Dedicated Hosts or Dedicated Instances can help you address compliance requirements and reduce costs by using your existing server-bound software licenses. For more information, see Amazon EC2 Pricing.

For more information about Savings Plans, see the Savings Plans User Guide.

Contents

- Determine the instance lifecycle (p. 320)
- On-Demand Instances (p. 322)
- Reserved Instances (p. 325)
- Scheduled Reserved Instances (p. 366)
- Spot Instances (p. 367)
- Dedicated Hosts (p. 415)
- Dedicated Instances (p. 446)
- On-Demand Capacity Reservations (p. 451)

Determine the instance lifecycle

The lifecycle of an instance starts when it is launched and ends when it is terminated. The purchasing option that you choose affects the lifecycle of the instance. For example, an On-Demand Instance runs when you launch it and ends when you terminate it. A Spot Instance runs as long as capacity is available and your maximum price is higher than the Spot price.

Use the following procedure to determine the lifecycle of an instance.
To determine the instance lifecycle using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
4. On the Details tab, under Instance details, find Lifecycle. If the value is spot, the instance is a Spot Instance. If the value is normal, the instance is either an On-Demand Instance or a Reserved Instance.
5. On the Details tab, under Host and placement group, find Tenancy. If the value is host, the instance is running on a Dedicated Host. If the value is dedicated, the instance is a Dedicated Instance.
6. (Optional) If you have purchased a Reserved Instance and want to verify that it is being applied, you can check the usage reports for Amazon EC2. For more information, see Amazon EC2 usage reports (p. 1476).

To determine the instance lifecycle using the AWS CLI

Use the following describe-instances command:

```
aws ec2 describe-instances --instance-ids i-1234567890abcdef0
```

If the instance is running on a Dedicated Host, the output contains the following information:

"Tenancy": "host"

If the instance is a Dedicated Instance, the output contains the following information:

"Tenancy": "dedicated"

If the instance is a Spot Instance, the output contains the following information:

"InstanceLifecycle": "spot"

Otherwise, the output does not contain InstanceLifecycle.
On-Demand Instances

With On-Demand Instances, you pay for compute capacity by the second with no long-term commitments. You have full control over its lifecycle—you decide when to launch, stop, hibernate, start, reboot, or terminate it.

There is no long-term commitment required when you purchase On-Demand Instances. You pay only for the seconds that your On-Demand Instances are in the running state. The price per second for a running On-Demand Instance is fixed, and is listed on the Amazon EC2 Pricing, On-Demand Pricing page.

We recommend that you use On-Demand Instances for applications with short-term, irregular workloads that cannot be interrupted.

For significant savings over On-Demand Instances, use AWS Savings Plans, Spot Instances (p. 367), or Reserved Instances (p. 325).

Contents

- Work with On-Demand Instances (p. 322)
- On-Demand Instance limits (p. 322)
  - Calculate how many vCPUs you need (p. 323)
  - Request a limit increase (p. 324)
  - Monitor On-Demand Instance limits and usage (p. 324)
- Query the prices of On-Demand Instances (p. 325)

Work with On-Demand Instances

You can work with On-Demand Instances in the following ways:

- Launch your instance (p. 475)
- Connect to your Linux instance (p. 499)
- Stop and start your instance (p. 524)
- Hibernate your On-Demand or Reserved Linux instance (p. 528)
- Reboot your instance (p. 544)
- Instance retirement (p. 544)
- Terminate your instance (p. 547)
- Recover your instance (p. 554)
- Configure your Amazon Linux instance (p. 555)
- Identify EC2 Linux instances (p. 654)

If you're new to Amazon EC2, see How to get started with Amazon EC2 (p. 1).

On-Demand Instance limits

There is a limit on the number of running On-Demand Instances per AWS account per Region. On-Demand Instance limits are managed in terms of the number of virtual central processing units (vCPUs) that your running On-Demand Instances are using, regardless of the instance type.

The following table lists the On-Demand Instance limits. Each limit specifies the default vCPUs for one or more instance families. For information about the different instance families, generations, and sizes, see Amazon EC2 Instance Types.
Note
New AWS accounts might start with limits that are lower than these defaults. Amazon EC2 monitors your usage and raises your limits automatically based on your usage.

<table>
<thead>
<tr>
<th>Limit</th>
<th>Default vCPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running On-Demand All Standard (A, C, D, H, I, M, R, T, Z) instances</td>
<td>1,152</td>
</tr>
<tr>
<td>Running On-Demand All F instances</td>
<td>128</td>
</tr>
<tr>
<td>Running On-Demand All G instances</td>
<td>128</td>
</tr>
<tr>
<td>Running On-Demand High Memory (u-*) instances</td>
<td>448</td>
</tr>
<tr>
<td>Running On-Demand All Inf instances</td>
<td>128</td>
</tr>
<tr>
<td>Running On-Demand All P instances</td>
<td>128</td>
</tr>
<tr>
<td>Running On-Demand All X instances</td>
<td>128</td>
</tr>
</tbody>
</table>

You can launch any combination of instance types that meet your changing application needs, as long as the number of vCPUs does not exceed your account limit. For example, with a Standard instance limit of 256 vCPUs, you could launch 32 m5.2xlarge instances (32 x 8 vCPUs) or 16 c5.4xlarge instances (16 x 16 vCPUs). For more information, see EC2 On-Demand Instance limits.

Calculate how many vCPUs you need

You can use the vCPU limits calculator to determine the number of vCPUs that you require for your application needs.

When using the calculator, keep the following in mind: The calculator assumes that you have reached your current limit. The value that you enter for **Instance count** is the number of instances that you need to launch in addition to what is permitted by your current limit. The calculator adds your current limit to the **Instance count** to arrive at a new limit.

The following screenshot shows the vCPU limits calculator.
You can view and use the following controls and information:

- **Instance type** – The instance types that you add to the vCPU limits calculator.
- **Instance count** – The number of instances that you require for the selected instance type.
- **vCPU count** – The number of CPUs that corresponds to the **Instance count**.
- **Current limit** – Your current limit for the limit type to which the instance type belongs. The limit applies to all instance types of the same limit type. For example, in the preceding screenshot, the current limit for m5.2xlarge and c5.4xlarge is 1,920 CPUs, which is the limit for all the instance types that belong to the All Standard instances limit.
- **New limit** – The new limit, in number of CPUs, which is calculated by adding **vCPU count** and **Current limit**.
- **X** – Choose the **X** to remove the row.
- **Add instance type** – Choose **Add instance type** to add another instance type to the calculator.
- **Limits calculation** – Displays the current limit, vCPUs needed, and new limit for the limit types.
  - **Instance limit name** – The limit type for the instance types that you selected.
  - **Current limit** – The current limit for the limit type.
  - **vCPUs needed** – The number of CPUs that corresponds to the number of instances that you specified in **Instance count**. For the All Standard instances limit type, the vCPUs needed is calculated by adding the values for **vCPU count** for all the instance types of this limit type.
  - **New limit** – The new limit is calculated by adding **Current limit** and **vCPUs needed**.
- **Options** – Choose **Request limit increase** to request a limit increase for the corresponding limit type.

**To calculate the number of required CPUs**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select a Region.
3. From the left navigator, choose **Limits**.
4. Choose **Calculate vCPU limit**.
5. Choose **Add instance type**, choose the required instance type, and specify the required number of instances. To add more instance types, choose **Add instance type** again.
6. View **Limits calculation** for the required new limit.
7. When you've finished using the calculator, choose **Close**.

**Request a limit increase**

You can request a limit increase for each On-Demand Instance limit type from the Limits page or the vCPU limits calculator in the Amazon EC2 console. Complete the required fields on the AWS Support Center limit increase form with your use case. For **Primary Instance Type**, select the limit type that corresponds to the **Instance limit name** in the vCPU limits calculator. For the new limit value, use the value that appears in the **New limit** column in the vCPU limits calculator. For more information about requesting a limit increase, see [Amazon EC2 service quotas](p. 1475).

**Monitor On-Demand Instance limits and usage**

You can view and manage your On-Demand Instance limits using the following:

- The **Limits page** in the Amazon EC2 console
- The Amazon EC2 Services quotas page in the Service Quotas console
- The get-service-quota AWS CLI
- The Service Limits page in the AWS Trusted Advisor console
For more information, see Amazon EC2 service quotas (p. 1475) in the Amazon EC2 User Guide for Linux Instances, Viewing a Service Quota in the Service Quotas User Guide, and AWS Trusted Advisor.

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against limits. You can also configure alarms to warn about approaching limits. For more information, see Using Amazon CloudWatch Alarms in the Service Quotas User Guide.

Query the prices of On-Demand Instances

You can use the Price List Service API or the AWS Price List API to query the prices of On-Demand Instances. For more information, see Using the AWS Price List API in the AWS Billing and Cost Management User Guide.

Reserved Instances

Reserved Instances provide you with significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. Reserved Instances are not physical instances, but rather a billing discount applied to the use of On-Demand Instances in your account. These On-Demand Instances must match certain attributes, such as instance type and Region, in order to benefit from the billing discount.

Savings Plans also offer significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. With Savings Plans, you make a commitment to a consistent usage amount, measured in USD per hour. This provides you with the flexibility to use the instance configurations that best meet your needs and continue to save money, instead of making a commitment to a specific instance configuration. For more information, see the AWS Savings Plans User Guide.

Reserved Instances topics

- Reserved Instance overview (p. 325)
- Key variables that determine Reserved Instance pricing (p. 326)
- Reserved Instance limits (p. 327)
- Regional and zonal Reserved Instances (scope) (p. 328)
- Types of Reserved Instances (offering classes) (p. 329)
- How Reserved Instances are applied (p. 329)
- Use your Reserved Instances (p. 334)
- How you are billed (p. 335)
- Buying Reserved Instances (p. 339)
- Sell in the Reserved Instance Marketplace (p. 348)
- Modify Reserved Instances (p. 354)
- Exchange Convertible Reserved Instances (p. 361)

Reserved Instance overview

The following diagram shows a basic overview of purchasing and using Reserved Instances.
In this scenario, you have a running On-Demand Instance (T2) in your account, for which you're currently paying On-Demand rates. You purchase a Reserved Instance that matches the attributes of your running instance, and the billing benefit is immediately applied. Next, you purchase a Reserved Instance for a C4 instance. You do not have any running instances in your account that match the attributes of this Reserved Instance. In the final step, you launch an instance that matches the attributes of the C4 Reserved Instance, and the billing benefit is immediately applied.

**Key variables that determine Reserved Instance pricing**

The Reserved Instance pricing is determined by the following key variables.

**Instance attributes**

A Reserved Instance has four instance attributes that determine its price.

- **Instance type:** For example, m4. large. This is composed of the instance family (for example, m4) and the instance size (for example, large).
- **Region:** The Region in which the Reserved Instance is purchased.
- **Tenancy:** Whether your instance runs on shared (default) or single-tenant (dedicated) hardware. For more information, see Dedicated Instances (p. 446).
- **Platform:** The operating system; for example, Windows or Linux/Unix. For more information, see Choosing a platform (p. 340).

**Term commitment**

You can purchase a Reserved Instance for a one-year or three-year commitment, with the three-year commitment offering a bigger discount.

- **One-year:** A year is defined as 31536000 seconds (365 days).
- **Three-year:** Three years is defined as 94608000 seconds (1095 days).

Reserved Instances do not renew automatically; when they expire, you can continue using the EC2 instance without interruption, but you are charged On-Demand rates. In the above example, when the Reserved Instances that cover the T2 and C4 instances expire, you go back to paying the On-Demand rates until you terminate the instances or purchase new Reserved Instances that match the instance attributes.
Payment options

The following payment options are available for Reserved Instances:

- **All Upfront**: Full payment is made at the start of the term, with no other costs or additional hourly charges incurred for the remainder of the term, regardless of hours used.
- **Partial Upfront**: A portion of the cost must be paid upfront and the remaining hours in the term are billed at a discounted hourly rate, regardless of whether the Reserved Instance is being used.
- **No Upfront**: You are billed a discounted hourly rate for every hour within the term, regardless of whether the Reserved Instance is being used. No upfront payment is required.

**Note**

No Upfront Reserved Instances are based on a contractual obligation to pay monthly for the entire term of the reservation. For this reason, a successful billing history is required before you can purchase No Upfront Reserved Instances.

Generally speaking, you can save more money making a higher upfront payment for Reserved Instances. You can also find Reserved Instances offered by third-party sellers at lower prices and shorter term lengths on the Reserved Instance Marketplace. For more information, see Sell in the Reserved Instance Marketplace (p. 348).

Offering class

If your computing needs change, you might be able to modify or exchange your Reserved Instance, depending on the offering class.

- **Standard**: These provide the most significant discount, but can only be modified. Standard Reserved Instances can’t be exchanged.
- **Convertible**: These provide a lower discount than Standard Reserved Instances, but can be exchanged for another Convertible Reserved Instance with different instance attributes. Convertible Reserved Instances can also be modified.

For more information, see Types of Reserved Instances (offering classes) (p. 329).

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to modify (p. 354), exchange (p. 361), or sell (p. 348) your Reserved Instance if your needs change.

For more information, see the Amazon EC2 Reserved Instances Pricing page.

Reserved Instance limits

There is a limit to the number of Reserved Instances that you can purchase per month. For each Region you can purchase 20 regional (p. 330) Reserved Instances per month plus an additional 20 zonal (p. 329) Reserved Instances per month for each Availability Zone.

For example, in a Region with three Availability Zones, the limit is 80 Reserved Instances per month: 20 regional Reserved Instances for the Region plus 20 zonal Reserved Instances for each of the three Availability Zones (20x3=60).

A regional Reserved Instance applies a discount to a running On-Demand Instance. The default On-Demand Instance limit is 20. You cannot exceed your running On-Demand Instance limit by purchasing regional Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 regional Reserved Instances, the 20 regional Reserved Instances are used to apply a discount to the 20 running On-Demand Instances. If you purchase more regional Reserved Instances, you will not be able to launch more instances because you have reached your On-Demand Instance limit.
Before purchasing regional Reserved Instances, make sure your On-Demand Instance limit matches or exceeds the number of regional Reserved Instances you intend to own. If required, make sure you request an increase to your On-Demand Instance limit before purchasing more regional Reserved Instances.

A zonal Reserved Instance—a Reserved Instance that is purchased for a specific Availability Zone—provides capacity reservation as well as a discount. You can exceed your running On-Demand Instance limit by purchasing zonal Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 zonal Reserved Instances, you can launch a further 20 On-Demand Instances that match the specifications of your zonal Reserved Instances, giving you a total of 40 running instances.

The Amazon EC2 console provides limit information. For more information, see View your current limits (p. 1475).

**Regional and zonal Reserved Instances (scope)**

When you purchase a Reserved Instance, you determine the scope of the Reserved Instance. The scope is either regional or zonal.

- **Regional**: When you purchase a Reserved Instance for a Region, it's referred to as a *regional* Reserved Instance.
- **Zonal**: When you purchase a Reserved Instance for a specific Availability Zone, it's referred to as a *zonal* Reserved Instance.

The scope does not affect the price. You pay the same price for a regional or zonal Reserved Instance. For more information about Reserved Instance pricing, see Key variables that determine Reserved Instance pricing (p. 326) and Amazon EC2 Reserved Instances Pricing.

**Differences between regional and zonal Reserved Instances**

The following table highlights some key differences between regional Reserved Instances and zonal Reserved Instances:

<table>
<thead>
<tr>
<th></th>
<th>Regional Reserved Instances</th>
<th>Zonal Reserved Instances</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ability to reserve capacity</td>
<td>A regional Reserved Instance does not reserve capacity.</td>
<td>A zonal Reserved Instance reserves capacity in the specified Availability Zone.</td>
</tr>
<tr>
<td>Availability Zone flexibility</td>
<td>The Reserved Instance discount applies to instance usage in any Availability Zone in the specified Region.</td>
<td>No Availability Zone flexibility—the Reserved Instance discount applies to instance usage in the specified Availability Zone only.</td>
</tr>
<tr>
<td>Instance size flexibility</td>
<td>The Reserved Instance discount applies to instance usage within the instance family, regardless of size. Only supported on Amazon Linux/Unix Reserved Instances with default tenancy. For more information, see Instance size flexibility determined by normalization factor (p. 330).</td>
<td>No instance size flexibility—the Reserved Instance discount applies to instance usage for the specified instance type and size only.</td>
</tr>
<tr>
<td>Queuing a purchase</td>
<td>You can queue purchases for regional Reserved Instances.</td>
<td>You can’t queue purchases for zonal Reserved Instances.</td>
</tr>
</tbody>
</table>
Types of Reserved Instances (offering classes)

The offering class of a Reserved Instance is either Standard or Convertible. A Standard Reserved Instance provides a more significant discount than a Convertible Reserved Instance, but you can't exchange a Standard Reserved Instance. You can exchange Convertible Reserved Instances. You can modify Standard and Convertible Reserved Instances.

The configuration of a Reserved Instance comprises a single instance type, platform, scope, and tenancy over a term. If your computing needs change, you might be able to modify or exchange your Reserved Instance.

Differences between Standard and Convertible Reserved Instances

The following are the differences between Standard and Convertible Reserved Instances.

<table>
<thead>
<tr>
<th></th>
<th>Standard Reserved Instance</th>
<th>Convertible Reserved Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modifying Reserved Instances</td>
<td>Some attributes can be modified. For more information, see Modify Reserved Instances (p. 354).</td>
<td>Some attributes can be modified. For more information, see Modify Reserved Instances (p. 354).</td>
</tr>
<tr>
<td>Exchanging Reserved Instances</td>
<td>Can't be exchanged.</td>
<td>Can be exchanged during the term for another Convertible Reserved Instance with new attributes, including instance family, instance type, platform, scope, or tenancy. For more information, see Exchange Convertible Reserved Instances (p. 361).</td>
</tr>
</tbody>
</table>

How Reserved Instances are applied

If you purchase a Reserved Instance and you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have an eligible running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see Use your Reserved Instances (p. 334).

Reserved Instances apply to usage in the same manner, irrespective of the offering type (Standard or Convertible), and are automatically applied to running On-Demand Instances with matching attributes.

How zonal Reserved Instances are applied

Reserved Instances assigned to a specific Availability Zone provide the Reserved Instance discount to matching instance usage in that Availability Zone. For example, if you purchase two c4.xlarge default tenancy Linux/Unix Standard Reserved Instances in Availability Zone us-east-1a, then up to two
c4.xlarge default tenancy Linux/Unix instances running in the Availability Zone us-east-1a can benefit from the Reserved Instance discount. The attributes (tenancy, platform, Availability Zone, instance type, and instance size) of the running instances must match that of the Reserved Instances.

**How regional Reserved Instances are applied**

Regional Reserved Instances are purchased for a Region and provide Availability Zone flexibility. The Reserved Instance discount applies to instance usage in any Availability Zone in that Region.

Regional Reserved Instances also provide instance size flexibility where the Reserved Instance discount applies to instance usage within the instance family, regardless of size.

**Limitations for instance size flexibility**

Instance size flexibility does not apply to the following Reserved Instances:

- Reserved Instances that are purchased for a specific Availability Zone (zonal Reserved Instances)
- Reserved Instances with dedicated tenancy
- Reserved Instances for G4dn instances

**Instance size flexibility determined by normalization factor**

Instance size flexibility is determined by the normalization factor of the instance size. The discount applies either fully or partially to running instances of the same instance family, depending on the instance size of the reservation, in any Availability Zone in the Region. The only attributes that must be matched are the instance family, tenancy, and platform.

Instance size flexibility is applied from the smallest to the largest instance size within the instance family based on the normalization factor.

The following table lists the different sizes within an instance family, and the corresponding normalization factor per hour. This scale is used to apply the discounted rate of Reserved Instances to the normalized usage of the instance family.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

For example, a `t2.medium` instance has a normalization factor of 2. If you purchase a `t2.medium` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia) and you have two running `t2.small` instances in your account in that Region, the billing benefit is applied in full to both instances.

Or, if you have one `t2.large` instance running in your account in the US East (N. Virginia) Region, the billing benefit is applied to 50% of the usage of the instance.

The normalization factor is also applied when modifying Reserved Instances. For more information, see Modify Reserved Instances (p. 354).
Normalization factor for bare metal instances

Instance size flexibility also applies to bare metal instances within the instance family. If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on bare metal instances, you can benefit from the Reserved Instance savings within the same instance family. The opposite is also true: if you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on instances in the same family as a bare metal instance, you can benefit from the Reserved Instance savings on the bare metal instance.

The metal instance size does not have a single normalization factor. A bare metal instance has the same normalization factor as the equivalent virtualized instance size within the same instance family. For example, an i3.metal instance has the same normalization factor as an i3.16xlarge instance.

<table>
<thead>
<tr>
<th>Instance size</th>

<td>144</td>
</tr>
<tr>
<td>c5.metal</td>
<td>c5d.metal</td>
</tr>
<tr>
<td>u-*.metal</td>
<td>896</td>
</tr>
</tbody>
</table>

For example, an i3.metal instance has a normalization factor of 128. If you purchase an i3.metal default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia), the billing benefit can apply as follows:

- If you have one running i3.16xlarge in your account in that Region, the billing benefit is applied in full to the i3.16xlarge instance (i3.16xlarge normalization factor = 128).
- Or, if you have two running i3.8xlarge instances in your account in that Region, the billing benefit is applied in full to both i3.8xlarge instances (i3.8xlarge normalization factor = 64).
- Or, if you have four running i3.4xlarge instances in your account in that Region, the billing benefit is applied in full to all four i3.4xlarge instances (i3.4xlarge normalization factor = 32).

The opposite is also true. For example, if you purchase two i3.8xlarge default tenancy Amazon Linux/Unix Reserved Instances in the US East (N. Virginia), and you have one running i3.metal instance in that Region, the billing benefit is applied in full to the i3.metal instance.

Examples of applying Reserved Instances

The following scenarios cover the ways in which Reserved Instances are applied.

Example Scenario 1: Reserved Instances in a single account

You are running the following On-Demand Instances in account A:

- 4 x m3.large Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1b
- 1 x c4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1c
You purchase the following Reserved Instances in account A:

- 4 x m3.large Linux, default tenancy Reserved Instances in Availability Zone us-east-1a (capacity is reserved)
- 4 x m4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1
- 1 x c4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The discount and capacity reservation of the four m3.large zonal Reserved Instances is used by the four m3.large instances because the attributes (instance size, Region, platform, tenancy) between them match.
- The m4.large regional Reserved Instances provide Availability Zone and instance size flexibility, because they are regional Amazon Linux Reserved Instances with default tenancy.

An m4.large is equivalent to 4 normalized units/hour.

You've purchased four m4.large regional Reserved Instances, and in total, they are equal to 16 normalized units/hour (4x4). Account A has two m4.xlarge instances running, which is equivalent to 16 normalized units/hour (2x8). In this case, the four m4.large regional Reserved Instances provide the billing benefit to an entire hour of usage of the two m4.xlarge instances.

- The c4.large regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy, and applies to the c4.xlarge instance. A c4.large instance is equivalent to 4 normalized units/hour and a c4.xlarge is equivalent to 8 normalized units/hour.

In this case, the c4.large regional Reserved Instance provides partial benefit to c4.xlarge usage. This is because the c4.large Reserved Instance is equivalent to 4 normalized units/hour of usage, but the c4.xlarge instance requires 8 normalized units/hour. Therefore, the c4.large Reserved Instance billing discount applies to 50% of c4.xlarge usage. The remaining c4.xlarge usage is charged at the On-Demand rate.

Example Scenario 2: Regional Reserved Instances in linked accounts

Reserved Instances are first applied to usage within the purchasing account, followed by qualifying usage in any other account in the organization. For more information, see Reserved Instances and consolidated billing (p. 337). For regional Reserved Instances that offer instance size flexibility, the benefit is applied from the smallest to the largest instance size within the instance family.

You're running the following On-Demand Instances in account A (the purchasing account):

- 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x m4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b
- 2 x c4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x c4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b

Another customer is running the following On-Demand Instances in account B—a linked account:

- 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a

You purchase the following regional Reserved Instances in account A:

- 4 x m4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1
- 2 x c4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1

333
The regional Reserved Instance benefits are applied in the following way:

- The discount of the four `m4.xlarge` Reserved Instances is used by the two `m4.xlarge` instances and the single `m4.2xlarge` instance in account A (purchasing account). All three instances match the attributes (instance family, Region, platform, tenancy). The discount is applied to instances in the purchasing account (account A) first, even though account B (linked account) has two `m4.xlarge` that also match the Reserved Instances. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.
- The discount of the two `c4.xlarge` Reserved Instances applies to the two `c4.xlarge` instances, because they are a smaller instance size than the `c4.2xlarge` instance. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.

**Example Scenario 3: Zonal Reserved Instances in a linked account**

In general, Reserved Instances that are owned by an account are applied first to usage in that account. However, if there are qualifying, unused Reserved Instances for a specific Availability Zone (zonal Reserved Instances) in other accounts in the organization, they are applied to the account before regional Reserved Instances owned by the account. This is done to ensure maximum Reserved Instance utilization and a lower bill. For billing purposes, all the accounts in the organization are treated as one account. The following example might help explain this.

You're running the following On-Demand Instance in account A (the purchasing account):

- 1 x `m4.xlarge` Linux, default tenancy instance in Availability Zone us-east-1a

A customer is running the following On-Demand Instance in linked account B:

- 1 x `m4.xlarge` Linux, default tenancy instance in Availability Zone us-east-1b

You purchase the following regional Reserved Instances in account A:

- 1 x `m4.xlarge` Linux, default tenancy Reserved Instance in Region us-east-1

A customer also purchases the following zonal Reserved Instances in linked account C:

- 1 x `m4.xlarge` Linux, default tenancy Reserved Instances in Availability Zone us-east-1a

The Reserved Instance benefits are applied in the following way:

- The discount of the `m4.xlarge` zonal Reserved Instance owned by account C is applied to the `m4.xlarge` usage in account A.
- The discount of the `m4.xlarge` regional Reserved Instance owned by account A is applied to the `m4.xlarge` usage in account B.
- If the regional Reserved Instance owned by account A was first applied to the usage in account A, the zonal Reserved Instance owned by account C remains unused and usage in account B is charged at On-Demand rates.

For more information, see Reserved Instances in the Billing and Cost Management Report.

**Use your Reserved Instances**

Reserved Instances are automatically applied to running On-Demand Instances provided that the specifications match. If you have no running On-Demand Instances that match the specifications of
your Reserved Instance, the Reserved Instance is unused until you launch an instance with the required specifications.

If you're launching an instance to take advantage of the billing benefit of a Reserved Instance, ensure that you specify the following information during launch:

- **Platform**: You must choose an Amazon Machine Image (AMI) that matches the platform (product description) of your Reserved Instance. For example, if you specified Linux/UNIX, you can launch an instance from an Amazon Linux AMI or an Ubuntu AMI.

- **Instance type**: Specify the same instance type as your Reserved Instance; for example, `t2.large`.

- **Availability Zone**: If you purchased a zonal Reserved Instance for a specific Availability Zone, you must launch the instance into the same Availability Zone. If you purchased a regional Reserved Instance, you can launch your instance into any Availability Zone.

- **Tenancy**: The tenancy of your instance must match the tenancy of the Reserved Instance; for example, dedicated or shared. For more information, see Dedicated Instances (p. 446).

For more information, see Launch an instance using the Launch Instance Wizard (p. 477). For examples of how Reserved Instances are applied to your running instances, see How Reserved Instances are applied (p. 329).

You can use Amazon EC2 Auto Scaling or other AWS services to launch the On-Demand Instances that use your Reserved Instance benefits. For more information, see the Amazon EC2 Auto Scaling User Guide.

### How you are billed

All Reserved Instances provide you with a discount compared to On-Demand pricing. With Reserved Instances, you pay for the entire term regardless of actual use. You can choose to pay for your Reserved Instance upfront, partially upfront, or monthly, depending on the payment option (p. 327) specified for the Reserved Instance.

When Reserved Instances expire, you are charged On-Demand rates for EC2 instance usage. You can queue a Reserved Instance for purchase up to three years in advance. This can help you ensure that you have uninterrupted coverage. For more information, see Queue your purchase (p. 340).

The AWS Free Tier is available for new AWS accounts. If you are using the AWS Free Tier to run Amazon EC2 instances, and you purchase a Reserved Instance, you are charged under standard pricing guidelines. For information, see AWS Free Tier.

### Contents

- Usage billing (p. 335)
- Viewing your bill (p. 337)
- Reserved Instances and consolidated billing (p. 337)
- Reserved Instance discount pricing tiers (p. 337)

### Usage billing

Reserved Instances are billed for every clock-hour during the term that you select, regardless of whether an instance is running. Each clock-hour starts on the hour (zero minutes and zero seconds past the hour) of a standard 24-hour clock. For example, 1:00:00 to 1:59:59 is one clock-hour. For more information about instance states, see Instance lifecycle (p. 471).

A Reserved Instance billing benefit can be applied to a running instance on a per-second basis. Per-second billing is available for instances using an open-source Linux distribution, such as Amazon Linux
and Ubuntu. Per-hour billing is used for commercial Linux distributions, such as Red Hat Enterprise Linux and SUSE Linux Enterprise Server.

A Reserved Instance billing benefit can apply to a maximum of 3600 seconds (one hour) of instance usage per clock-hour. You can run multiple instances concurrently, but can only receive the benefit of the Reserved Instance discount for a total of 3600 seconds per clock-hour; instance usage that exceeds 3600 seconds in a clock-hour is billed at the On-Demand rate.

For example, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances concurrently for one hour, one instance is charged at one hour of Reserved Instance usage and the other three instances are charged at three hours of On-Demand usage.

However, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances for 15 minutes (900 seconds) each within the same hour, the total running time for the instances is one hour, which results in one hour of Reserved Instance usage and 0 hours of On-Demand usage.

If multiple eligible instances are running concurrently, the Reserved Instance billing benefit is applied to all the instances at the same time up to a maximum of 3600 seconds in a clock-hour; thereafter, On-Demand rates apply.

**Cost Explorer** on the Billing and Cost Management console enables you to analyze the savings against running On-Demand Instances. The Reserved Instances FAQ includes an example of a list value calculation.

If you close your AWS account, On-Demand billing for your resources stops. However, if you have any Reserved Instances in your account, you continue to receive a bill for these until they expire.
Viewing your bill

You can find out about the charges and fees to your account by viewing the AWS Billing and Cost Management console.

- The Dashboard displays a spend summary for your account.
- On the Bills page, under Details expand the Elastic Compute Cloud section and the Region to get billing information about your Reserved Instances.

You can view the charges online, or you can download a CSV file.

You can also track your Reserved Instance utilization using the AWS Cost and Usage Report. For more information, see Reserved Instances under Cost and Usage Report in the AWS Billing and Cost Management User Guide.

Reserved Instances and consolidated billing

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing payer account. The instance usage across all member accounts is aggregated in the payer account every month. This is typically useful for companies in which there are different functional teams or groups; then, the normal Reserved Instance logic is applied to calculate the bill. For more information, see Consolidated billing for AWS Organizations.

If you close the account that purchased the Reserved Instance, the payer account is charged for the Reserved instance until the Reserved Instance expires. After the closed account is permanently deleted in 90 days, the member accounts no longer benefit from the Reserved Instance billing discount.

Reserved Instance discount pricing tiers

If your account qualifies for a discount pricing tier, it automatically receives discounts on upfront and instance usage fees for Reserved Instance purchases that you make within that tier level from that point on. To qualify for a discount, the list value of your Reserved Instances in the Region must be $500,000 USD or more.

The following rules apply:

- Pricing tiers and related discounts apply only to purchases of Amazon EC2 Standard Reserved Instances.
- Pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tiers do not apply to Reserved Instances for Linux with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tier discounts only apply to purchases made from AWS. They do not apply to purchases of third-party Reserved Instances.
- Discount pricing tiers are currently not applicable to Convertible Reserved Instance purchases.

Topics

- Calculate Reserved Instance pricing discounts (p. 338)
- Buy with a discount tier (p. 338)
- Crossing pricing tiers (p. 339)
- Consolidated billing for pricing tiers (p. 339)
Calculate Reserved Instance pricing discounts

You can determine the pricing tier for your account by calculating the list value for all of your Reserved Instances in a Region. Multiply the hourly recurring price for each reservation by the total number of hours for the term and add the undiscounted upfront price (also known as the fixed price) at the time of purchase. Because the list value is based on undiscounted (public) pricing, it is not affected if you qualify for a volume discount or if the price drops after you buy your Reserved Instances.

\[
\text{List value} = \text{fixed price} + (\text{undiscounted recurring hourly price} \times \text{hours in term})
\]

For example, for a 1-year Partial Upfront t2.small Reserved Instance, assume the upfront price is $60.00 and the hourly rate is $0.007. This provides a list value of $121.32.

\[
121.32 = 60.00 + (0.007 \times 8760)
\]

New console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. To display the Upfront price column, choose the settings icon (○) in the top-right corner, toggle on Upfront price, and choose Confirm.

Old console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. To display the Upfront Price column, choose the settings icon (○) in the top-right corner, select Upfront Price, and choose Close.

To view the fixed price values for Reserved Instances using the command line

- describe-reserved-instances (AWS CLI)
- Get-EC2ReservedInstance (AWS Tools for Windows PowerShell)
- DescribeReservedInstances (Amazon EC2 API)

Buy with a discount tier

When you buy Reserved Instances, Amazon EC2 automatically applies any discounts to the part of your purchase that falls within a discount pricing tier. You don't need to do anything differently, and you can buy Reserved Instances using any of the Amazon EC2 tools. For more information, see Buying Reserved Instances (p. 339).

After the list value of your active Reserved Instances in a Region crosses into a discount pricing tier, any future purchase of Reserved Instances in that Region are charged at a discounted rate. If a single purchase of Reserved Instances in a Region takes you over the threshold of a discount tier, then the portion of the purchase that is above the price threshold is charged at the discounted rate. For more
information about the temporary Reserved Instance IDs that are created during the purchase process, see Crossing pricing tiers (p. 339).

If your list value falls below the price point for that discount pricing tier—for example, if some of your Reserved Instances expire—future purchases of Reserved Instances in the Region are not discounted. However, you continue to get the discount applied against any Reserved Instances that were originally purchased within the discount pricing tier.

When you buy Reserved Instances, one of four possible scenarios occurs:

- **No discount**—Your purchase within a Region is still below the discount threshold.
- **Partial discount**—Your purchase within a Region crosses the threshold of the first discount tier. No discount is applied to one or more reservations and the discounted rate is applied to the remaining reservations.
- **Full discount**—Your entire purchase within a Region falls within one discount tier and is discounted appropriately.
- **Two discount rates**—Your purchase within a Region crosses from a lower discount tier to a higher discount tier. You are charged two different rates: one or more reservations at the lower discounted rate, and the remaining reservations at the higher discounted rate.

**Crossing pricing tiers**

If your purchase crosses into a discounted pricing tier, you see multiple entries for that purchase: one for that part of the purchase charged at the regular price, and another for that part of the purchase charged at the applicable discounted rate.

The Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier, or from one discounted tier to another. There is an ID for each set of reservations in a tier. Consequently, the ID returned by your purchase CLI command or API action is different from the actual ID of the new Reserved Instances.

**Consolidated billing for pricing tiers**

A consolidated billing account aggregates the list value of member accounts within a Region. When the list value of all active Reserved Instances for the consolidated billing account reaches a discount pricing tier, any Reserved Instances purchased after this point by any member of the consolidated billing account are charged at the discounted rate (as long as the list value for that consolidated account stays above the discount pricing tier threshold). For more information, see Reserved Instances and consolidated billing (p. 337).

**Buying Reserved Instances**

To purchase a Reserved Instance, search for Reserved Instance offerings from AWS and third-party sellers, adjusting your search parameters until you find the exact match that you're looking for.

When you search for Reserved Instances to buy, you receive a quote on the cost of the returned offerings. When you proceed with the purchase, AWS automatically places a limit price on the purchase price. The total cost of your Reserved Instances won't exceed the amount that you were quoted.

If the price rises or changes for any reason, the purchase is not completed. If, at the time of purchase, there are offerings similar to your choice but at a lower price, AWS sells you the offerings at the lower price.

Before you confirm your purchase, review the details of the Reserved Instance that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase.
Note
To purchase and modify Reserved Instances, ensure that your IAM user account has the appropriate permissions, such as the ability to describe Availability Zones. For information, see Example Policies for Working With the AWS CLI or an AWS SDK and Example Policies for Working in the Amazon EC2 Console.

Topics
- Choosing a platform (p. 340)
- Queue your purchase (p. 340)
- Buy Standard Reserved Instances (p. 341)
- Buy Convertible Reserved Instances (p. 343)
- Buy from the Reserved Instance Marketplace (p. 346)
- View your Reserved Instances (p. 346)
- Cancel a queued purchase (p. 346)
- Renew a Reserved Instance (p. 347)

Choosing a platform

Amazon EC2 supports the following Linux platforms for Reserved Instances:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- Red Hat Enterprise Linux with HA

When you purchase a Reserved Instance, you must choose an offering for a platform that represents the operating system for your instance.

- For SUSE Linux and RHEL distributions, you must choose offerings for those specific platforms, i.e., for the SUSE Linux or Red Hat Enterprise Linux platforms.
- For all other Linux distributions (including Ubuntu), choose an offering for the Linux/UNIX platform.
- If you bring your existing RHEL subscription, you must choose an offering for the Linux/UNIX platform, not an offering for the Red Hat Enterprise Linux platform.

Important
If you plan to purchase a Reserved Instance to apply to an On-Demand Instance that was launched from an AWS Marketplace AMI, first check the PlatformDetails field of the AMI. The PlatformDetails field indicates which Reserved Instance to purchase. The platform details of the AMI must match the platform of the Reserved Instance, otherwise the Reserved Instance will not be applied to the On-Demand Instance. For information about how to view the platform details of the AMI, see Understand AMI billing information (p. 161).

For information about the supported platforms for Windows, see Choosing a platform in the Amazon EC2 User Guide for Windows Instances.

Queue your purchase

By default, when you purchase a Reserved Instance, the purchase is made immediately. Alternatively, you can queue your purchases for a future date and time. For example, you can queue a purchase for
around the time that an existing Reserved Instance expires. This can help you ensure that you have uninterrupted coverage.

You can queue purchases for regional Reserved Instances, but not zonal Reserved Instances or Reserved Instances from other sellers. You can queue a purchase up to three years in advance. On the scheduled date and time, the purchase is made using the default payment method. After the payment is successful, the billing benefit is applied.

You can view your queued purchases in the Amazon EC2 console. The status of a queued purchase is queued. You can cancel a queued purchase any time before its scheduled time. For details, see Cancel a queued purchase (p. 346).

**Buy Standard Reserved Instances**

You can buy Standard Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Standard Reserved Instance.

**New console**

**To buy Standard Reserved Instances using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

   To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.
5. Select other configurations as needed, and then choose **Search**.
6. For each Reserved Instance that you want to purchase, enter the desired quantity, and choose **Add to cart**.

   To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd party** in the **Seller** column in the search results. The **Term** column displays non-standard terms. For more information, see Buy from the Reserved Instance Marketplace (p. 346).
7. To see a summary of the Reserved Instances that you selected, choose **View cart**.
8. If **Order on is Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order all**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.
10. Choose **Close**.

    The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

    **Note**

    If the status goes to **Retired**, AWS might not have received your payment.
Old console

**To buy Standard Reserved Instances using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose **Search**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd Party** in the **Seller** column in the search results. The **Term** column displays non-standard terms.

6. For each Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of the Reserved Instances that you selected, choose **View Cart**.
8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **payment-pending** to **active**. When the Reserved Instance is **active**, it is ready to use.

**Note**

If the status goes to **retired**, AWS might not have received your payment.

**To buy a Standard Reserved Instance using the AWS CLI**

1. Find available Reserved Instances using the `describe-reserved-instances-offerings` command. Specify `standard` for the `--offering-class` parameter to return only Standard Reserved Instances.

You can apply additional parameters to narrow your results. For example, if you want to purchase a regional t2.large Reserved Instance with a default tenancy for Linux/UNIX for a 1-year term only:

```bash
aws ec2 describe-reserved-instances-offerings \
  --instance-type t2.large \
  --offering-class standard \
  --product-description "Linux/UNIX" \
  --instance-tenancy default \
  --filters Name=duration,Values=31536000 Name=scope,Values=Region
```

To find Reserved Instances on the Reserved Instance Marketplace only, use the `marketplace` filter and do not specify a duration in the request, as the term might be shorter than a 1- or 3-year term.

```bash
aws ec2 describe-reserved-instances-offerings \
  --instance-type t2.large \
```
When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"

2. Use the `purchase-reserved-instances-offering` command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```bash
aws ec2 purchase-reserved-instances-offering
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

`--purchase-time "2020-12-01T00:00:00Z"`

3. Use the `describe-reserved-instances` command to get the status of your Reserved Instance.

```bash
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- Get-EC2ReservedInstancesOffering
- New-EC2ReservedInstance
- Get-EC2ReservedInstance

After the purchase is complete, if you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see Use your Reserved Instances (p. 334).

For examples of how Reserved Instances are applied to your running instances, see How Reserved Instances are applied (p. 329).

**Buy Convertible Reserved Instances**

You can buy Convertible Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Convertible Reserved Instance.

**New console**

**To buy Convertible Reserved Instances using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.

5. Select other configurations as needed and choose **Search**.

6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to cart**.

7. To see a summary of your selection, choose **View cart**.

8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.

9. To complete the order, choose **Order all**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

    The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

    **Note**
    If the status goes to **Retired**, AWS might not have received your payment.

**Old console**

**To buy Convertible Reserved Instances using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.

3. For **Offering Class**, choose **Convertible** to display Convertible Reserved Instances.

4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.

5. Select other configurations as needed and choose **Search**.

6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.

7. To see a summary of your selection, choose **View Cart**.

8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.

9. To complete the order, choose **Order**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

    The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.
Note
If the status goes to retired, AWS might not have received your payment.

To buy a Convertible Reserved Instance using the AWS CLI

1. Find available Reserved Instances using the describe-reserved-instances-offerings command. Specify convertible for the --offering-class parameter to return only Convertible Reserved Instances. You can apply additional parameters to narrow your results; for example, if you want to purchase a regional t2.large Reserved Instance with a default tenancy for Linux/UNIX:

   ```bash
   aws ec2 describe-reserved-instances-offerings \
   --instance-type t2.large \
   --offering-class convertible \
   --product-description "Linux/UNIX" \
   --instance-tenancy default \
   --filters Name=scope,Values=Region
   ```

   When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

   ```json
   "ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
   ```

2. Use the purchase-reserved-instances-offering command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

   ```bash
   aws ec2 purchase-reserved-instances-offering \
   --reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
   --instance-count 1
   ```

   By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

   ```bash
   --purchase-time "2020-12-01T00:00:00Z"
   ```

3. Use the describe-reserved-instances command to get the status of your Reserved Instance.

   ```bash
   aws ec2 describe-reserved-instances
   ```

   Alternatively, use the following AWS Tools for Windows PowerShell commands:

   - Get-EC2ReservedInstancesOffering
   - New-EC2ReservedInstance
   - Get-EC2ReservedInstance

If you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see Use your Reserved Instances (p. 334).

For examples of how Reserved Instances are applied to your running instances, see How Reserved Instances are applied (p. 329).
Buy from the Reserved Instance Marketplace

You can purchase Reserved Instances from third-party sellers who own Reserved Instances that they no longer need from the Reserved Instance Marketplace. You can do this using the Amazon EC2 console or a command line tool. The process is similar to purchasing Reserved Instances from AWS. For more information, see Buy Standard Reserved Instances (p. 341).

There are a few differences between Reserved Instances purchased in the Reserved Instance Marketplace and Reserved Instances purchased directly from AWS:

- **Term** – Reserved Instances that you purchase from third-party sellers have less than a full standard term remaining. Full standard terms from AWS run for one year or three years.
- **Upfront price** – Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees remain the same as the fees set when the Reserved Instances were originally purchased from AWS.
- **Types of Reserved Instances** – Only Amazon EC2 Standard Reserved Instances can be purchased from the Reserved Instance Marketplace. Convertible Reserved Instances, Amazon RDS, and Amazon ElastiCache Reserved Instances are not available for purchase on the Reserved Instance Marketplace.

Basic information about you is shared with the seller, for example, your ZIP code and country information.

This information enables sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax) and is provided as a disbursement report. In rare circumstances, AWS might have to provide the seller with your email address, so that they can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS shares the legal entity name of the seller on the buyer’s purchase invoice. If you need additional information about the seller for tax or related reasons, contact AWS Support.

View your Reserved Instances

You can view the Reserved Instances you’ve purchased using the Amazon EC2 console, or a command line tool.

**To view your Reserved Instances in the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. Your queued, active, and retired Reserved Instances are listed. The **State** column displays the state.
4. If you are a seller in the Reserved Instance Marketplace, the **My Listings** tab displays the status of a reservation that’s listed in the Reserved Instance Marketplace (p. 348). For more information, see Reserved Instance listing states (p. 352).

**To view your Reserved Instances using the command line**

- `describe-reserved-instances` (AWS CLI)
- `Get-EC2ReservedInstance` (Tools for Windows PowerShell)

Cancel a queued purchase

You can queue a purchase up to three years in advance. You can cancel a queued purchase any time before its scheduled time.
To cancel a queued purchase

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. Select one or more Reserved Instances.
4. Choose Actions, Delete queued Reserved Instances.
5. When prompted for confirmation, choose Delete, and then Close.

To cancel a queued purchase using the command line

- delete-queued-reserved-instances (AWS CLI)
- Remove-EC2QueuedReservedInstance (Tools for Windows PowerShell)

Renew a Reserved Instance

You can renew a Reserved Instance before it is scheduled to expire. Renewing a Reserved Instance queues the purchase of a Reserved Instance with the same configuration until the current Reserved Instance expires.

To renew an Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. Select one or more Reserved Instances.
5. To complete the order, choose Order all, and then Close.
Sell in the Reserved Instance Marketplace

The Reserved Instance Marketplace is a platform that supports the sale of third-party and AWS customers' unused Standard Reserved Instances, which vary in term lengths and pricing options. For example, you might want to sell Reserved Instances after moving instances to a new AWS Region, changing to a new instance type, ending projects before the term expiration, when your business needs change, or if you have unneeded capacity.

As soon as you list your Reserved Instances in the Reserved Instance Marketplace, they are available for potential buyers to find. All Reserved Instances are grouped according to the duration of the term remaining and the hourly price.

To fulfill a buyer's request, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping. Then, AWS sells the Reserved Instance with the next lowest price, until the buyer's entire order is fulfilled. AWS then processes the transactions and transfers ownership of the Reserved Instances to the buyer.

You own your Reserved Instance until it's sold. After the sale, you've given up the capacity reservation and the discounted recurring fees. If you continue to use your instance, AWS charges you the On-Demand price starting from the time that your Reserved Instance was sold.

If you want to sell your unused Reserved Instances on the Reserved Instance Marketplace, you must meet certain eligibility criteria.

For information about buying Reserved Instances on the Reserved Instance Marketplace, see Buy from the Reserved Instance Marketplace (p. 346).

Contents

- Restrictions and limitations (p. 348)

- Tax information (p. 350)
- Price your Reserved Instances (p. 350)
- List your Reserved Instances (p. 351)
- Reserved Instance listing states (p. 352)
- Lifecycle of a listing (p. 352)
- After your Reserved Instance is sold (p. 353)
- Getting paid (p. 353)
- Information shared with the buyer (p. 353)

Restrictions and limitations

Before you can sell your unused reservations, you must register as a seller in the Reserved Instance Marketplace. For information, see Register as a seller (p. 349).

The following limitations and restrictions apply when selling Reserved Instances:

- Only Amazon EC2 Standard Reserved Instances can be sold in the Reserved Instance Marketplace. Amazon EC2 Convertible Reserved Instances cannot be sold. Reserved Instances for other AWS services, such as Amazon RDS and Amazon ElastiCache, cannot be sold.
- There must be at least one month remaining in the term of the Standard Reserved Instance.
- You cannot sell a Standard Reserved Instance in a Region that is disabled by default.
• The minimum price allowed in the Reserved Instance Marketplace is $0.00.
• You can sell No Upfront, Partial Upfront, or All Upfront Reserved Instances in the Reserved Instance Marketplace. If there is an upfront payment on a Reserved Instance, it can be sold only after AWS has received the upfront payment and the reservation has been active (you’ve owned it) for at least 30 days.
• You cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see Price your Reserved Instances (p. 350). You can also modify your Reserved Instances before listing them. For information, see Modify Reserved Instances (p. 354).
• In order to list a regional Reserved Instance in the marketplace, you must modify the scope to zonal as it is not possible to sell regional Reserved Instances via the console.
• AWS charges a service fee of 12 percent of the total upfront price of each Standard Reserved Instance you sell in the Reserved Instance Marketplace. The upfront price is the price the seller is charging for the Standard Reserved Instance.
• When you register as a seller, the bank you specify must have a US address. For more information, see Additional seller requirements for paid products in the AWS Marketplace Seller Guide.
• Amazon Internet Services Private Limited (AISPL) customers can't sell Reserved Instances in the Reserved Instance Marketplace even if they have a US bank account. For more information, see What are the differences between AWS accounts and AISPL accounts?

Register as a seller

Note
Only the AWS account root user can register an account as a seller.

To sell in the Reserved Instance Marketplace, you must first register as a seller. During registration, you provide the following information:

• Bank information—AWS must have your bank information in order to disburse funds collected when you sell your reservations. The bank you specify must have a US address. For more information, see Bank account for disbursement (p. 349).
• Tax information—All sellers are required to complete a tax information interview to determine any necessary tax reporting obligations. For more information, see Tax information (p. 350).

After AWS receives your completed seller registration, you receive an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

Bank account for disbursement

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see Additional seller requirements for paid products in the AWS Marketplace Seller Guide.

To register a default bank account for disbursements

1. Open the Reserved Instance Marketplace Seller Registration page and sign in using your AWS credentials.
2. On the Manage Bank Account page, provide the following information about the bank through to receive payment:
   • Bank account holder name
   • Routing number
   • Account number
   • Bank account type
Note
If you are using a corporate bank account, you are prompted to send the information about the bank account via fax (1-206-765-3424).

After registration, the bank account provided is set as the default, pending verification with the bank. It can take up to two weeks to verify a new bank account, during which time you can't receive disbursements. For an established account, it usually takes about two days for disbursements to complete.

To change the default bank account for disbursement

1. On the Reserved Instance Marketplace Seller Registration page, sign in with the account that you used when you registered.
2. On the Manage Bank Account page, add a new bank account or modify the default bank account as needed.

Tax information

Your sale of Reserved Instances might be subject to a transaction-based tax, such as sales tax or value-added tax. You should check with your business's tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you must complete a tax interview in the Seller Registration Portal. The interview collects your tax information and populates an IRS form W-9, W-8BEN, or W-8BEN-E, which is used to determine any necessary tax reporting obligations.

The tax information you enter as part of the tax interview might differ depending on whether you operate as an individual or business, and whether you or your business are a US or non-US person or entity. As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, contact your tax, legal, or other professional advisor.
- To fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

Based on your tax interview responses and IRS reporting thresholds, Amazon might file Form 1099-K. Amazon mails a copy of your Form 1099-K on or before January 31 in the year following the year that your tax account reaches the threshold levels. For example, if your account reaches the threshold in 2018, your Form 1099-K is mailed on or before January 31, 2019.

For more information about IRS requirements and Form 1099-K, see the IRS website.

Price your Reserved Instances

The upfront fee is the only fee that you can specify for the Reserved Instance that you’re selling. The upfront fee is the one-time fee that the buyer pays when they purchase a Reserved Instance.

The following are important limits to note:

- You can sell up to $50,000 in Reserved Instances. To increase this limit, complete the EC2 Reserved Instance Sales form.
• You can sell up to 5,000 Reserved Instances. To increase this limit, complete the EC2 Reserved Instance Sales form.

• The minimum price is $0. The minimum allowed price in the Reserved Instance Marketplace is $0.00.

You cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.

You can cancel your listing at any time, as long as it’s in the active state. You cannot cancel the listing if it’s already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances are removed from the listing.

Because the value of Reserved Instances decreases over time, by default, AWS can set prices to decrease in equal increments month over month. However, you can set different upfront prices based on when your reservation sells.

For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount that you would accept if a customer were to purchase that Reserved Instance with nine months remaining. You could set another price with five months remaining, and yet another price with one month remaining.

List your Reserved Instances

As a registered seller, you can choose to sell one or more of your Reserved Instances. You can choose to sell all of them in one listing or in portions. In addition, you can list Reserved Instances with any configuration of instance type, platform, and scope.

The console determines a suggested price. It checks for offerings that match your Reserved Instance and matches the one with the lowest price. Otherwise, it calculates a suggested price based on the cost of the Reserved Instance for its remaining time. If the calculated value is less than $1.01, the suggested price is $1.01.

If you cancel your listing and a portion of that listing has already been sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

To list a Reserved Instance in the Reserved Instance Marketplace using the AWS Management Console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. Select the Reserved Instances to list, and choose Actions, Sell Reserved Instances.
4. On the Configure Your Reserved Instance Listing page, set the number of instances to sell and the upfront price for the remaining term in the relevant columns. See how the value of your reservation changes over the remainder of the term by selecting the arrow next to the Months Remaining column.
5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, choose Reset.
6. Choose Continue when you are finished configuring your listing.
7. Confirm the details of your listing, on the Confirm Your Reserved Instance Listing page and if you’re satisfied, choose List Reserved Instance.

To view your listings in the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. Select the Reserved Instance that you've listed and choose the My Listings tab near the bottom of the page.

To manage Reserved Instances in the Reserved Instance Marketplace using the AWS CLI

1. Get a list of your Reserved Instances by using the describe-reserved-instances command.
2. Note the ID of the Reserved Instance you want to list and call create-reserved-instances-listing. You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the describe-reserved-instances-listings command.
4. To cancel your listing, use the cancel-reserved-instances-listings command.

Reserved Instance listing states

Listing State on the My Listings tab of the Reserved Instances page displays the current status of your listings:

The information displayed by Listing State is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the State column in the Reserved Instances page. This State information is about your reservation.

- active—The listing is available for purchase.
- canceled—The listing is canceled and isn't available for purchase in the Reserved Instance Marketplace.
- closed—The Reserved Instance is not listed. A Reserved Instance might be closed because the sale of the listing was completed.

Lifecycle of a listing

When all the instances in your listing are matched and sold, the My Listings tab shows that the Total instance count matches the count listed under Sold. Also, there are no Available instances left for your listing, and its Status is closed.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the listing ID and the listing that it represents, which now has fewer reservations for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as closed.

For example, you create a listing Reserved Instances listing ID Sec28771-05ff-4b9b-aa31-9e57dexample with a listing count of 5.

The My Listings tab in the Reserved Instance console page displays the listing this way:

Reserved Instance listing ID Sec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 0
- Available = 5
- Status = active

A buyer purchases two of the reservations, which leaves a count of three reservations still available for sale. Because of this partial sale, AWS creates a new reservation with a count of three to represent the remaining reservations that are still for sale.
This is how your listing looks in the **My Listings** tab:

*Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample*

- Total reservation count = 5
- Sold = 2
- Available = 3
- Status = active

If you cancel your listing and a portion of that listing has already sold, the cancelation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

**After your Reserved Instance is sold**

When your Reserved Instance is sold, AWS sends you an email notification. Each day that there is any kind of activity, you receive one email notification capturing all the activities of the day. Activities can include when you create or sell a listing, or when AWS sends funds to your account.

**To track the status of a Reserved Instance listing in the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation page, choose **Reserved Instances**.
3. Choose the **My Listings** tab.

   The **My Listings** tab contains the **Listing State** value. It also contains information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and canceled.

You can also use the `describe-reserved-instances-listings` command with the appropriate filter to obtain information about your listings.

**Getting paid**

As soon as AWS receives funds from the buyer, a message is sent to the registered owner account email for the sold Reserved Instance.

AWS sends an Automated Clearing House (ACH) wire transfer to your specified bank account. Typically, this transfer occurs between one to three days after your Reserved Instance has been sold. Disbursements take place once a day. You will receive an email with a disbursement report after the funds are released. Keep in mind that you can't receive disbursements until AWS receives verification from your bank. This can take up to two weeks.

The Reserved Instance that you sold continues to appear when you describe your Reserved Instances.

You receive a cash disbursement for your Reserved Instances through a wire transfer directly into your bank account. AWS charges a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the Reserved Instance Marketplace.

**Information shared with the buyer**

When you sell in the Reserved Instance Marketplace, AWS shares your company's legal name on the buyer's statement in accordance with US regulations. In addition, if the buyer calls AWS Support because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS might need to provide the buyer with your email address so that the buyer can contact you directly.
For similar reasons, the buyer’s ZIP code and country information are provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, contact AWS Support.

Modify Reserved Instances

When your needs change, you can modify your Standard or Convertible Reserved Instances and continue to benefit from the billing benefit. You can modify attributes such as the Availability Zone, instance size (within the same instance family), and scope of your Reserved Instance.

Note

You can also exchange a Convertible Reserved Instance for another Convertible Reserved Instance with a different configuration. For more information, see Exchange Convertible Reserved Instances (p. 361).

You can modify all or a subset of your Reserved Instances. You can separate your original Reserved Instances into two or more new Reserved Instances. For example, if you have a reservation for 10 instances in us-east-1a and decide to move 5 instances to us-east-1b, the modification request results in two new reservations: one for 5 instances in us-east-1a and the other for 5 instances in us-east-1b.

You can also merge two or more Reserved Instances into a single Reserved Instance. For example, if you have four t2.small Reserved Instances of one instance each, you can merge them to create one t2.large Reserved Instance. For more information, see Support for modifying instance sizes (p. 356).

After modification, the benefit of the Reserved Instances is applied only to instances that match the new parameters. For example, if you change the Availability Zone of a reservation, the capacity reservation and pricing benefits are automatically applied to instance usage in the new Availability Zone. Instances that no longer match the new parameters are charged at the On-Demand rate, unless your account has other applicable reservations.

If your modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your reservations at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. You can get the effective date of the modified Reserved Instances by using the describe-reserved-instances command.

- The original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Reserved Instance. If you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.

- The modified reservation lists a $0 fixed price and not the fixed price of the original reservation.

- The fixed price of the modified reservation does not affect the discount pricing tier calculations applied to your account, which are based on the fixed price of the original reservation.

If your modification request fails, your Reserved Instances maintain their original configuration, and are immediately available for another modification request.

There is no fee for modification, and you do not receive any new bills or invoices.

You can modify your reservations as frequently as you like, but you cannot change or cancel a pending modification request after you submit it. After the modification has completed successfully, you can submit another modification request to roll back any changes you made, if needed.

Contents
Requirements and restrictions for modification

You can modify these attributes as follows.

<table>
<thead>
<tr>
<th>Modifiable attribute</th>
<th>Supported platforms</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change <strong>Availability Zones</strong> within the same Region</td>
<td>Linux and Windows</td>
<td>-</td>
</tr>
<tr>
<td>Change the <strong>scope</strong> from Availability Zone to Region and vice versa</td>
<td>Linux and Windows</td>
<td>If you change the scope from Availability Zone to Region, you lose the capacity reservation benefit. If you change the scope from Region to Availability Zone, you lose Availability Zone flexibility and instance size flexibility (if applicable). For more information, see How Reserved Instances are applied (p. 329).</td>
</tr>
<tr>
<td>Change the <strong>instance size</strong> within the same instance family</td>
<td>Linux/UNIX only</td>
<td>The reservation must use default tenancy. Some instance families are not supported, because there are no other sizes available. For more information, see Support for modifying instance sizes (p. 356).</td>
</tr>
<tr>
<td>Change the <strong>network</strong> from EC2-Classic to Amazon VPC and vice versa</td>
<td>Linux and Windows</td>
<td>The network platform must be available in your AWS account. If you created your AWS account after 2013-12-04, it does not support EC2-Classic.</td>
</tr>
</tbody>
</table>

Requirements

Amazon EC2 processes your modification request if there is sufficient capacity for your new configuration (if applicable), and if the following conditions are met:

- The Reserved Instance cannot be modified before or at the same time that you purchase it
- The Reserved Instance must be active
• There cannot be a pending modification request
• The Reserved Instance is not listed in the Reserved Instance Marketplace
• There must be a match between the instance size footprint of the original reservation and the new configuration. For more information, see Support for modifying instance sizes (p. 356).
• The original Reserved Instances are all Standard Reserved Instances or all Convertible Reserved Instances, not some of each type
• The original Reserved Instances must expire within the same hour, if they are Standard Reserved Instances
• The Reserved Instance is not a G4 instance.

Support for modifying instance sizes

You can modify the instance size of a Reserved Instance if the following requirements are met.

Requirements

• The platform is Linux/UNIX.
• You must select another instance size in the same instance family. For example, you cannot modify an Reserved Instance from t2 to t3, whether you use the same size or a different size.

You cannot modify the instance size of Reserved Instances for the following instances, because each of these instance families has only one size:
• cc2.8xlarge
• cr1.8xlarge
• hs1.8xlarge
• t1.micro
• The original and new Reserved Instance must have the same instance size footprint.

Contents

• Instance size footprint (p. 356)
• Normalization factors for bare metal instances (p. 358)

Instance size footprint

Each Reserved Instance has an instance size footprint, which is determined by the normalization factor of the instance size and the number of instances in the reservation. When you modify the instance sizes in an Reserved Instance, the footprint of the new configuration must match that of the original configuration, otherwise the modification request is not processed.

To calculate the instance size footprint of a Reserved Instance, multiply the number of instances by the normalization factor. In the Amazon EC2 console, the normalization factor is measured in units. The following table describes the normalization factor for the instance sizes in an instance family. For example, t2.medium has a normalization factor of 2, so a reservation for four t2.medium instances has a footprint of 8 units.

<table>

<td>small</td>
<td>1</td>
</tr>
</tbody>
</table>
You can allocate your reservations into different instance sizes across the same instance family as long as the instance size footprint of your reservation remains the same. For example, you can divide a reservation for one \texttt{t2.large} (1 @ 4 units) instance into four \texttt{t2.small} (4 @ 1 unit) instances. Similarly, you can combine a reservation for four \texttt{t2.small} instances into one \texttt{t2.large} instance. However, you cannot change your reservation for two \texttt{t2.small} instances into one \texttt{t2.large} instance because the footprint of the new reservation (4 units) is larger than the footprint of the original reservation (2 units).

In the following example, you have a reservation with two \texttt{t2.micro} instances (1 unit) and a reservation with one \texttt{t2.small} instance (1 unit). If you merge both of these reservations to a single reservation with one \texttt{t2.medium} instance (2 units), the footprint of the new reservation equals the footprint of the combined reservations.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>medium</td>
<td>2</td>
</tr>
<tr>
<td>large</td>
<td>4</td>
</tr>
<tr>
<td>xlarge</td>
<td>8</td>
</tr>
<tr>
<td>2xlarge</td>
<td>16</td>
</tr>
<tr>
<td>3xlarge</td>
<td>24</td>
</tr>
<tr>
<td>4xlarge</td>
<td>32</td>
</tr>
<tr>
<td>6xlarge</td>
<td>48</td>
</tr>
<tr>
<td>8xlarge</td>
<td>64</td>
</tr>
<tr>
<td>9xlarge</td>
<td>72</td>
</tr>
<tr>
<td>10xlarge</td>
<td>80</td>
</tr>
<tr>
<td>12xlarge</td>
<td>96</td>
</tr>
<tr>
<td>16xlarge</td>
<td>128</td>
</tr>
<tr>
<td>18xlarge</td>
<td>144</td>
</tr>
<tr>
<td>24xlarge</td>
<td>192</td>
</tr>
<tr>
<td>32xlarge</td>
<td>256</td>
</tr>
<tr>
<td>56xlarge</td>
<td>448</td>
</tr>
<tr>
<td>112xlarge</td>
<td>896</td>
</tr>
</tbody>
</table>
You can also modify a reservation to divide it into two or more reservations. In the following example, you have a reservation with a `t2.medium` instance (2 units). You can divide the reservation into two reservations, one with two `t2.nano` instances (.5 units) and the other with three `t2.micro` instances (1.5 units).

Normalization factors for bare metal instances

You can modify a reservation with `metal` instances using other sizes within the same instance family. Similarly, you can modify a reservation with instances other than bare metal instances using the `metal` size within the same instance family. Generally, a bare metal instance is the same size as the largest available instance size within the same instance family. For example, an `i3.metal` instance is the same size as an `i3.16xlarge` instance, so they have the same normalization factor.

The following table describes the normalization factor for the bare metal instance sizes in the instance families that have bare metal instances. The normalization factor for `metal` instances depends on the instance family, unlike the other instance sizes.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1.metal</td>
<td>32</td>
</tr>
<tr>
<td>m5zn.metal</td>
<td>z1d.metal</td>
</tr>
</tbody>
</table>
Reserved Instances

Instance size          Normalization factor
----------------------  -----------------------------
c6g.metal | c6gd.metal | i3.metal | m6g.metal | m6gd.metal | r6g.metal | r6gd.metal | x2gd.metal    | 128

For example, an \texttt{i3.metal} instance has a normalization factor of 128. If you purchase an \texttt{i3.metal} default tenancy Amazon Linux/Unix Reserved Instance, you can divide the reservation as follows:

- An \texttt{i3.16xlarge} is the same size as an \texttt{i3.metal} instance, so its normalization factor is 128 (128/1). The reservation for one \texttt{i3.metal} instance can be modified into one \texttt{i3.16xlarge} instance.
- An \texttt{i3.8xlarge} is half the size of an \texttt{i3.metal} instance, so its normalization factor is 64 (128/2). The reservation for one \texttt{i3.metal} instance can be divided into two \texttt{i3.8xlarge} instances.
- An \texttt{i3.4xlarge} is a quarter the size of an \texttt{i3.metal} instance, so its normalization factor is 32 (128/4). The reservation for one \texttt{i3.metal} instance can be divided into four \texttt{i3.4xlarge} instances.

Submit modification requests

Before you modify your Reserved Instances, ensure that you have read the applicable restrictions (p. 355). Before you modify the instance size, calculate the total instance size footprint (p. 356) of the original reservations that you want to modify and ensure that it matches the total instance size footprint of your new configurations.

New console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at \url{https://console.aws.amazon.com/ec2/}.
2. On the Reserved Instances page, select one or more Reserved Instances to modify, and choose Actions, Modify Reserved Instances.

   \textbf{Note}

   If your Reserved Instances are not in the active state or cannot be modified, Modify ReservedInstances is disabled.

3. The first entry in the modification table displays attributes of the selected Reserved Instances, and at least one target configuration beneath it. The Units column displays the total instance size footprint. Choose Add for each new configuration to add. Modify the attributes as needed for each configuration.

   - **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
   - **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
   - **Instance type**: Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
   - **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose Add, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can...
change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.

4. Choose Continue.

5. To confirm your modification choices when you finish specifying your target configurations, choose Submit modifications.

6. You can determine the status of your modification request by looking at the State column in the Reserved Instances screen. The following are the possible states.

- **active (pending modification)** — Transition state for original Reserved Instances
- **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created
- **retired** — Reserved Instances successfully modified and replaced
- **active** — One of the following:
  - New Reserved Instances created from a successful modification request
  - Original Reserved Instances after a failed modification request

Old console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. On the Reserved Instances page, select one or more Reserved Instances to modify, and choose Actions, Modify Reserved Instances.

   **Note**
   If your Reserved Instances are not in the active state or cannot be modified, Modify Reserved Instances is disabled.

3. The first entry in the modification table displays attributes of selected Reserved Instances, and at least one target configuration beneath it. The Units column displays the total instance size footprint. Choose Add for each new configuration to add. Modify the attributes as needed for each configuration, and then choose Continue:

   - **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
   - **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
   - **Instance Type**: Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
   - **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose Add, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.

4. To confirm your modification choices when you finish specifying your target configurations, choose Submit Modifications.

5. You can determine the status of your modification request by looking at the State column in the Reserved Instances screen. The following are the possible states.

   - **active (pending modification)** — Transition state for original Reserved Instances
   - **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created
   - **retired** — Reserved Instances successfully modified and replaced
   - **active** — One of the following:
To modify your Reserved Instances using the command line

1. To modify your Reserved Instances, you can use one of the following commands:
   - modify-reserved-instances (AWS CLI)
   - Edit-EC2ReservedInstance (AWS Tools for Windows PowerShell)

2. To get the status of your modification request (processing, fulfilled, or failed), use one of the following commands:
   - describe-reserved-instances-modifications (AWS CLI)
   - Get-EC2ReservedInstancesModification (AWS Tools for Windows PowerShell)

Troubleshoot modification requests

If the target configuration settings that you requested were unique, you receive a message that your request is being processed. At this point, Amazon EC2 has only determined that the parameters of your modification request are valid. Your modification request can still fail during processing due to unavailable capacity.

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for resubmitting another modification request. Ensure that you have read the applicable restrictions (p. 355) before submitting the request.

Not all selected Reserved Instances can be processed for modification

Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the Reserved Instances page in the Amazon EC2 console and check the information for the Reserved Instances.

Error in processing your modification request

You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of reservations you are modifying, you can get different versions of the message.

Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform—for one or more subsets of the Reserved Instances you are modifying. Try submitting the modification requests again, but ensure that the instance details of the reservations match, and that the target configurations for all subsets being modified are unique.

Exchange Convertible Reserved Instances

You can exchange one or more Convertible Reserved Instances for another Convertible Reserved Instance with a different configuration, including instance family, operating system, and tenancy. There are no limits to how many times you perform an exchange, as long as the new Convertible Reserved Instance is of an equal or higher value than the original Convertible Reserved Instances that you are exchanging.

When you exchange your Convertible Reserved Instance, the number of instances for your current reservation is exchanged for a number of instances that cover the equal or higher value of the configuration of the new Convertible Reserved Instance. Amazon EC2 calculates the number of Reserved Instances that you can receive as a result of the exchange.
You can't exchange Standard Reserved Instances, but you can modify them. For more information, see Modify Reserved Instances (p. 354).

Contents
- Requirements for exchanging Convertible Reserved Instances (p. 362)
- Calculate Convertible Reserved Instances exchanges (p. 363)
- Merge Convertible Reserved Instances (p. 363)
- Exchange a portion of a Convertible Reserved Instance (p. 364)
- Submit exchange requests (p. 365)

Requirements for exchanging Convertible Reserved Instances

If the following conditions are met, Amazon EC2 processes your exchange request. Your Convertible Reserved Instance must be:

- Active
- Not pending a previous exchange request

The following rules apply:

- Convertible Reserved Instances can only be exchanged for other Convertible Reserved Instances currently offered by AWS.
- Convertible Reserved Instances are associated with a specific Region, which is fixed for the duration of the reservation's term. You cannot exchange a Convertible Reserved Instance for a Convertible Reserved Instance in a different Region.
- You can exchange one or more Convertible Reserved Instances at a time for one Convertible Reserved Instance only.
- To exchange a portion of a Convertible Reserved Instance, you can modify it into two or more reservations, and then exchange one or more of the reservations for a new Convertible Reserved Instance. For more information, see Exchange a portion of a Convertible Reserved Instance (p. 364). For more information about modifying your Reserved Instances, see Modify Reserved Instances (p. 354).
- All Upfront Convertible Reserved Instances can be exchanged for Partial Upfront Convertible Reserved Instances, and vice versa.

**Note**
If the total upfront payment required for the exchange (true-up cost) is less than $0.00, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that true-up cost is $0.00 or more.

**Note**
If the total value (upfront price + hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- To benefit from better pricing, you can exchange a No Upfront Convertible Reserved Instance for an All Upfront or Partial Upfront Convertible Reserved Instance.
- You cannot exchange All Upfront and Partial Upfront Convertible Reserved Instances for No Upfront Convertible Reserved Instances.
- You can exchange a No Upfront Convertible Reserved Instance for another No Upfront Convertible Reserved Instance only if the new Convertible Reserved Instance's hourly price is the same or higher than the exchanged Convertible Reserved Instance's hourly price.
**Note**

If the total value (hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- If you exchange multiple Convertible Reserved Instances that have different expiration dates, the expiration date for the new Convertible Reserved Instance is the date that's furthest in the future.
- If you exchange a single Convertible Reserved Instance, it must have the same term (1-year or 3-years) as the new Convertible Reserved Instance. If you merge multiple Convertible Reserved Instances with different term lengths, the new Convertible Reserved Instance has a 3-year term. For more information, see Merge Convertible Reserved Instances (p. 363).
- After you exchange a Convertible Reserved Instance, the original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Convertible Reserved Instance. For example, if you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.

**Calculate Convertible Reserved Instances exchanges**

Exchanging Convertible Reserved Instances is free. However, you might be required to pay a true-up cost, which is a prorated upfront cost of the difference between the original Convertible Reserved Instances that you had and the new Convertible Reserved Instances that you receive from the exchange.

Each Convertible Reserved Instance has a list value. This list value is compared to the list value of the Convertible Reserved Instances that you want in order to determine how many instance reservations you can receive from the exchange.

For example: You have 1 x $35-list value Convertible Reserved Instance that you want to exchange for a new instance type with a list value of $10.

\[
\frac{35}{10} = 3.5
\]

You can exchange your Convertible Reserved Instance for three $10 Convertible Reserved Instances. It's not possible to purchase half reservations; therefore you must purchase an additional Convertible Reserved Instance to cover the remainder:

\[3.5 = 3 \text{ whole Convertible Reserved Instances} + 1 \text{ additional Convertible Reserved Instance}\]

The fourth Convertible Reserved Instance has the same end date as the other three. If you are exchanging Partial or All Upfront Convertible Reserved Instances, you pay the true-up cost for the fourth reservation. If the remaining upfront cost of your Convertible Reserved Instances is $500, and the new reservation would normally cost $600 on a prorated basis, you are charged $100.

\[
\text{\$600 prorated upfront cost of new reservations} - \text{\$500 remaining upfront cost of original reservations} = \text{\$100 difference}
\]

**Merge Convertible Reserved Instances**

If you merge two or more Convertible Reserved Instances, the term of the new Convertible Reserved Instance must be the same as the original Convertible Reserved Instances, or the highest of the original Convertible Reserved Instances. The expiration date for the new Convertible Reserved Instance is the expiration date that's furthest in the future.
For example, you have the following Convertible Reserved Instances in your account:

<table>
<thead>
<tr>
<th>Reserved Instance ID</th>
<th>Term</th>
<th>Expiration date</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaa1111</td>
<td>1-year</td>
<td>2018-12-31</td>
</tr>
<tr>
<td>bbbb2222</td>
<td>1-year</td>
<td>2018-07-31</td>
</tr>
<tr>
<td>cccc3333</td>
<td>3-year</td>
<td>2018-06-30</td>
</tr>
<tr>
<td>dddd4444</td>
<td>3-year</td>
<td>2019-12-31</td>
</tr>
</tbody>
</table>

- You can merge `aaaa1111` and `bbbb2222` and exchange them for a 1-year Convertible Reserved Instance. You cannot exchange them for a 3-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-12-31.
- You can merge `bbbb2222` and `cccc3333` and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-07-31.
- You can merge `cccc3333` and `dddd4444` and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2019-12-31.

**Exchange a portion of a Convertible Reserved Instance**

You can use the modification process to split your Convertible Reserved Instance into smaller reservations, and then exchange one or more of the new reservations for a new Convertible Reserved Instance. The following examples demonstrate how you can do this.

**Example Example: Convertible Reserved Instance with multiple instances**

In this example, you have a `t2.micro` Convertible Reserved Instance with four instances in the reservation. To exchange two `t2.micro` instances for an `m4.xlarge` instance:

1. Modify the `t2.micro` Convertible Reserved Instance by splitting it into two `t2.micro` Convertible Reserved Instances with two instances each.
2. Exchange one of the new `t2.micro` Convertible Reserved Instances for an `m4.xlarge` Convertible Reserved Instance.

**Example Example: Convertible Reserved Instance with a single instance**

In this example, you have a `t2.large` Convertible Reserved Instance. To change it to a smaller `t2.medium` instance and a `m3.medium` instance:
1. Modify the `t2.large` Convertible Reserved Instance by splitting it into two `t2.medium` Convertible Reserved Instances. A single `t2.large` instance has the same instance size footprint as two `t2.medium` instances.

2. Exchange one of the new `t2.medium` Convertible Reserved Instances for an `m3.medium` Convertible Reserved Instance.

For more information, see Support for modifying instance sizes (p. 356) and Submit exchange requests (p. 365).

Submit exchange requests

You can exchange your Convertible Reserved Instances using the Amazon EC2 console or a command line tool.

Exchange a Convertible Reserved Instance using the console

You can search for Convertible Reserved Instances offerings and select your new configuration from the choices provided.

New console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Reserved Instances, select the Convertible Reserved Instances to exchange, and choose Actions, Exchange Reserved Instance.
3. Select the attributes of the desired configuration, and choose Find offering.
4. Select a new Convertible Reserved Instance. At the bottom of the screen, you can view the number of Reserved Instances that you receive for the exchange, and any additional costs.
5. When you have selected a Convertible Reserved Instance that meets your needs, choose Review.
6. Choose Exchange, and then Close.

Old console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Reserved Instances, select the Convertible Reserved Instances to exchange, and choose Actions, Exchange Reserved Instance.
3. Select the attributes of the desired configuration, and choose Find Offering.
4. Select a new Convertible Reserved Instance. The **Instance Count** column displays the number of Reserved Instances that you receive for the exchange. When you have selected a Convertible Reserved Instance that meets your needs, choose **Exchange**.

The Reserved Instances that were exchanged are retired, and the new Reserved Instances are displayed in the Amazon EC2 console. This process can take a few minutes to propagate.

**Exchange a Convertible Reserved Instance using the command line interface**

To exchange a Convertible Reserved Instance, first find a new Convertible Reserved Instance that meets your needs:

- `describe-reserved-instances-offerings` (AWS CLI)
- `Get-EC2ReservedInstancesOffering` (Tools for Windows PowerShell)

Get a quote for the exchange, which includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:

- `get-reserved-instances-exchange-quote` (AWS CLI)
- `GetEC2-ReservedInstancesExchangeQuote` (Tools for Windows PowerShell)

Finally, perform the exchange:

- `accept-reserved-instances-exchange-quote` (AWS CLI)
- `Confirm-EC2ReservedInstancesExchangeQuote` (Tools for Windows PowerShell)

**Scheduled Reserved Instances**

With Scheduled Reserved Instances, you can reserve capacity that is scheduled to recur daily, weekly, or monthly, with a specified start time and duration, for a one-year term. After you complete your purchase, the instances are available to launch during the time windows that you specified.

**Important**

You cannot purchase Scheduled Reserved Instances at this time. AWS does not have any capacity available for Scheduled Reserved Instances or any plans to make it available in the future. To reserve capacity, use **On-Demand Capacity Reservations** (p. 451) instead. For discounted rates, use **Savings Plans**.
Spot Instances

A Spot Instance is an instance that uses spare EC2 capacity that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and is adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instance runs whenever capacity is available and the maximum price per hour for your request exceeds the Spot price.

Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if your applications can be interrupted. For example, Spot Instances are well-suited for data analysis, batch jobs, background processing, and optional tasks. For more information, see Amazon EC2 Spot Instances.

Topics

- Concepts (p. 367)
- How to get started (p. 368)
- Related services (p. 369)
- Pricing and savings (p. 369)

Concepts

Before you get started with Spot Instances, you should be familiar with the following concepts:

- **Spot capacity pool** – A set of unused EC2 instances with the same instance type (for example, m5.large) and Availability Zone.
- **Spot price** – The current price of a Spot Instance per hour.
- **Spot Instance request** – Requests a Spot Instance. The request provides the maximum price per hour that you are willing to pay for a Spot Instance. If you don’t specify a maximum price, the default maximum price is the On-Demand price. When the maximum price per hour for your request exceeds the Spot price, Amazon EC2 fulfills your request if capacity is available. A Spot Instance request is either one-time or persistent. Amazon EC2 automatically resubmits a persistent Spot Instance request after the Spot Instance associated with the request is terminated.
- **EC2 instance rebalance recommendation** - Amazon EC2 emits an instance rebalance recommendation signal to notify you that a Spot Instance is at an elevated risk of interruption. This signal gives you the opportunity to proactively rebalance your workloads across existing or new Spot Instances without having to wait for the two-minute Spot Instance interruption notice.
- **Spot Instance interruption** – Amazon EC2 terminates, stops, or hibernates your Spot Instance when Amazon EC2 needs the capacity back or the Spot price exceeds the maximum price for your request. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted.

Key differences between Spot Instances and On-Demand Instances

The following table lists the key differences between Spot Instances and On-Demand Instances.

<table>
<thead>
<tr>
<th></th>
<th>Spot Instances</th>
<th>On-Demand Instances</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch time</td>
<td>Can only be launched immediately if the Spot Instance request is active and capacity is available.</td>
<td>Can only be launched immediately if you make a manual launch request and capacity is available.</td>
</tr>
</tbody>
</table>
## Spot Instances vs. On-Demand Instances

<table>
<thead>
<tr>
<th>Available capacity</th>
<th>If capacity is not available, the Spot Instance request continues to automatically make the launch request until capacity becomes available.</th>
<th>If capacity is not available when you make a launch request, you get an insufficient capacity error (ICE).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hourly price</td>
<td>The hourly price for Spot Instances varies based on demand.</td>
<td>The hourly price for On-Demand Instances is static.</td>
</tr>
<tr>
<td>Rebalance recommendation</td>
<td>The signal that Amazon EC2 emits for a running Spot Instance when the instance is at an elevated risk of interruption.</td>
<td>You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).</td>
</tr>
<tr>
<td>Instance interruption</td>
<td>You can stop and start an Amazon EBS-backed Spot Instance. In addition, the Amazon EC2 Spot service can interrupt (p. 402) an individual Spot Instance if capacity is no longer available, the Spot price exceeds your maximum price, or demand for Spot Instances increases.</td>
<td>You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).</td>
</tr>
</tbody>
</table>

### Strategies for using Spot Instances

One strategy is to maintain a minimum level of guaranteed compute resources for your applications by launching a core group of On-Demand Instances, and supplementing them with Spot Instances when the opportunity arises.

### How to get started

The first thing you need to do is get set up to use Amazon EC2. It can also be helpful to have experience launching On-Demand Instances before launching Spot Instances.

#### Get up and running

- Set up to use Amazon EC2 (p. 5)
- Tutorial: Get started with Amazon EC2 Linux instances (p. 9)

#### Spot basics

- How Spot Instances work (p. 372)
Working with Spot Instances

- Prepare for interruptions (p. 406)
- Create a Spot Instance request (p. 380)
- Get request status information (p. 397)

Related services

You can provision Spot Instances directly using Amazon EC2. You can also provision Spot Instances using other services in AWS. For more information, see the following documentation.

Amazon EC2 Auto Scaling and Spot Instances

You can create launch templates or configurations with the maximum price that you are willing to pay, so that Amazon EC2 Auto Scaling can launch Spot Instances. For more information, see Requesting Spot Instances for fault-tolerant and flexible applications and Auto Scaling groups with multiple instance types and purchase options in the Amazon EC2 Auto Scaling User Guide.

Amazon EMR and Spot Instances

There are scenarios where it can be useful to run Spot Instances in an Amazon EMR cluster. For more information, see Spot Instances and When Should You Use Spot Instances in the Amazon EMR Management Guide.

AWS CloudFormation templates

AWS CloudFormation enables you to create and manage a collection of AWS resources using a template in JSON format. AWS CloudFormation templates can include the maximum price you are willing to pay. For more information, see EC2 Spot Instance Updates - Auto Scaling and CloudFormation Integration.

AWS SDK for Java

You can use the Java programming language to manage your Spot Instances. For more information, see Tutorial: Amazon EC2 Spot Instances and Tutorial: Advanced Amazon EC2 Spot Request Management.

AWS SDK for .NET

You can use the .NET programming environment to manage your Spot Instances. For more information, see Tutorial: Amazon EC2 Spot Instances.

Pricing and savings

You pay the Spot price for Spot Instances, which is set by Amazon EC2 and adjusted gradually based on the long-term supply of and demand for Spot Instances. If the maximum price for your request exceeds the current Spot price, Amazon EC2 fulfills your request if capacity is available. Your Spot Instances run until you terminate them, capacity is no longer available, the Spot price exceeds your maximum price, or your Amazon EC2 Auto Scaling group terminates them during scale in.

If you or Amazon EC2 interrupts a running Spot Instance, you are charged for the seconds used or the full hour, or you receive no charge, depending on the operating system used and who interrupted the Spot Instance. For more information, see Billing for interrupted Spot Instances (p. 410).

View prices

To view the current (updated every five minutes) lowest Spot price per AWS Region and instance type, see the Amazon EC2 Spot Instances Pricing page.
To view the Spot price history for the past three months, use the Amazon EC2 console or the describe-spot-price-history command (AWS CLI). For more information, see Spot Instance pricing history (p. 374).

We independently map Availability Zones to codes for each AWS account. Therefore, you can get different results for the same Availability Zone code (for example, us-west-2a) between different accounts.

View savings

You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. You can view the savings made in the last hour or the last three days, and you can view the average cost per vCPU hour and per memory (GiB) hour. Savings are estimated and may differ from actual savings because they do not include the billing adjustments for your usage. For more information about viewing savings information, see Savings from purchasing Spot Instances (p. 375).

View billing

Your bill provides details about your service usage. For more information, see Viewing your bill in the AWS Billing and Cost Management User Guide.

Best practices for EC2 Spot

Amazon EC2 Spot Instances are spare EC2 compute capacity in the AWS Cloud that are available to you at savings of up to 90% off compared to On-Demand prices. The only difference between On-Demand Instances and Spot Instances is that Spot Instances can be interrupted by Amazon EC2, with two minutes of notification, when Amazon EC2 needs the capacity back.

Spot Instances are recommended for stateless, fault-tolerant, flexible applications. For example, Spot Instances work well for big data, containerized workloads, CI/CD, stateless web servers, high performance computing (HPC), and rendering workloads.

While running, Spot Instances are exactly the same as On-Demand Instances. However, Spot does not guarantee that you can keep your running instances long enough to finish your workloads. Spot also does not guarantee that you can get immediate availability of the instances that you are looking for, or that you can always get the aggregate capacity that you requested. Moreover, Spot Instance interruptions and capacity can change over time because Spot Instance availability varies based on supply and demand, and past performance isn’t a guarantee of future results.

Spot Instances are not suitable for workloads that are inflexible, stateful, fault-intolerant, or tightly coupled between instance nodes. It’s also not recommended for workloads that are intolerant of occasional periods when the target capacity is not completely available. We strongly warn against using Spot Instances for these workloads or attempting to fail-over to On-Demand Instances to handle interruptions.

Regardless of whether you’re an experienced Spot user or new to Spot Instances, if you are currently experiencing issues with Spot Instance interruptions or availability, we recommend that you follow these best practices to have the best experience using the Spot service.

Spot best practices

- Prepare individual instances for interruptions (p. 371)
- Be flexible about instance types and Availability Zones (p. 371)
- Use EC2 Auto Scaling groups or Spot Fleet to manage your aggregate capacity (p. 371)
- Use the capacity optimized allocation strategy (p. 371)
- Use proactive capacity rebalancing (p. 372)
- Use integrated AWS services to manage your Spot Instances (p. 372)
Prepare individual instances for interruptions

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of EC2 instance rebalance recommendations and Spot Instance interruption notices.

An EC2 Instance rebalance recommendation is a new signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal gives you the opportunity to proactively manage the Spot Instance in advance of the two-minute Spot Instance interruption notice. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption. We've made it easy for you to use this new signal by using the Capacity Rebalancing feature in Auto Scaling groups and Spot Fleet. For more information, see Use proactive capacity rebalancing (p. 372).

A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 interrupts a Spot Instance. If your workload is "time-flexible," you can configure your Spot Instances to be stopped or hibernated, instead of being terminated, when they are interrupted. Amazon EC2 automatically stops or hibernates your Spot Instances on interruption, and automatically resumes the instances when we have available capacity.

We recommend that you create a rule in Amazon EventBridge that captures the rebalance recommendations and interruption notifications, and then triggers a checkpoint for the progress of your workload or gracefully handles the interruption. For more information, see Monitor rebalance recommendation signals (p. 400). For a detailed example that walks you through how to create and use event rules, see Taking Advantage of Amazon EC2 Spot Instance Interruption Notices.

For more information, see EC2 instance rebalance recommendations (p. 399) and Spot Instance interruptions (p. 402).

Be flexible about instance types and Availability Zones

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, m5.large) and Availability Zone (for example, us-east-1a). You should be flexible about which instance types you request and in which Availability Zones you can deploy your workload. This gives Spot a better chance to find and allocate your required amount of compute capacity. For example, don't just ask for c5.large if you'd be willing to use larges from the c4, m5, and m4 families.

Depending on your specific needs, you can evaluate which instance types you can be flexible across to fulfill your compute requirements. If a workload can be vertically scaled, you should include larger instance types (more vCPUs and memory) in your requests. If you can only scale horizontally, you should include older generation instance types because they are less in demand from On-Demand customers.

A good rule of thumb is to be flexible across at least 10 instance types for each workload. In addition, make sure that all Availability Zones are configured for use in your VPC and selected for your workload.

Use EC2 Auto Scaling groups or Spot Fleet to manage your aggregate capacity

Spot enables you to think in terms of aggregate capacity—in units that include vCPUs, memory, storage, or network throughput—rather than thinking in terms of individual instances. Auto Scaling groups and Spot Fleet enable you to launch and maintain a target capacity, and to automatically request resources to replace any that are disrupted or manually terminated. When you configure an Auto Scaling group or a Spot Fleet, you need only specify the instance types and target capacity based on your application needs. For more information, see Auto Scaling groups in the Amazon EC2 Auto Scaling User Guide and Create a Spot Fleet request (p. 717) in this user guide.

Use the capacity optimized allocation strategy

Allocation strategies in Auto Scaling groups help you to provision your target capacity without the need to manually look for the Spot capacity pools with spare capacity. We recommend using the capacity
optimized strategy because this strategy automatically provisions instances from the most-available Spot capacity pools. You can also take advantage of the capacity optimized allocation strategy in Spot Fleet. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances are reclaimed. For more information about allocation strategies, see Spot Instances in the Amazon EC2 Auto Scaling User Guide and Configure Spot Fleet for capacity optimization (p. 706) in this user guide.

Use proactive capacity rebalancing

Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running Spot Instance receives the two-minute Spot Instance interruption notice. When Capacity Rebalancing is enabled, Auto Scaling or Spot Fleet attempts to proactively replace Spot Instances that have received a rebalance recommendation, providing the opportunity to rebalance your workload to new Spot Instances that are not at elevated risk of interruption.

Capacity Rebalancing complements the capacity optimized allocation strategy (which is designed to help find the most optimal spare capacity) and the mixed instances policy (which is designed to enhance availability by deploying instances across multiple instance types running in multiple Availability Zones).

For more information, see Capacity Rebalancing (p. 707).

Use integrated AWS services to manage your Spot Instances

Other AWS services integrate with Spot to reduce overall compute costs without the need to manage the individual instances or fleets. We recommend that you consider the following solutions for your applicable workloads: Amazon EMR, Amazon ECS, AWS Batch, Amazon EKS, SageMaker, AWS Elastic Beanstalk, and Amazon GameLift. To learn more about Spot best practices with these services, see the Amazon EC2 Spot Instances Workshops Website.

How Spot Instances work

To launch a Spot Instance, either you create a Spot Instance request, or Amazon EC2 creates a Spot Instance request on your behalf. The Spot Instance launches when the Spot Instance request is fulfilled.

You can launch a Spot Instance using several different services. For more information, see Getting Started with Amazon EC2 Spot Instances. In this user guide, we describe the following ways to launch a Spot Instance using EC2:

- You can create a Spot Instance request. For more information, see Create a Spot Instance request (p. 380).
- You can create an EC2 Fleet, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the EC2 Fleet. For more information, see Create an EC2 Fleet (p. 693).
- You can create a Spot Fleet request, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the Spot Fleet request. For more information, see Create a Spot Fleet request (p. 717).

The Spot Instance request must include the maximum price that you're willing to pay per hour per instance. If you don't specify a price, the price defaults to the On-Demand price. The request can include other constraints such as the instance type and Availability Zone.

Your Spot Instance launches if the maximum price that you're willing to pay exceeds the Spot price, and if there is available capacity. If the maximum price you're willing to pay is lower than the Spot price, then your instance does not launch. However, because Amazon EC2 gradually adjusts the Spot price based on the long-term supply of and demand for Spot Instances, the maximum price you're willing to pay might eventually exceed the Spot price, in which case your instance will launch.
Your Spot Instance runs until you stop or terminate it, or until Amazon EC2 interrupts it (known as a Spot Instance interruption).

When you use Spot Instances, you must be prepared for interruptions. Amazon EC2 can interrupt your Spot Instance when the demand for Spot Instances rises, when the supply of Spot Instances decreases, or when the Spot price exceeds your maximum price. When Amazon EC2 interrupts a Spot Instance, it provides a Spot Instance interruption notice, which gives the instance a two-minute warning before Amazon EC2 interrupts it. You can't enable termination protection for Spot Instances. For more information, see Spot Instance interruptions (p. 402).

You can stop, start, reboot, or terminate an Amazon EBS-backed Spot Instance. The Spot service can stop, terminate, or hibernate a Spot Instance when it interrupts it.

Contents
- Launch Spot Instances in a launch group (p. 373)
- Launch Spot Instances in an Availability Zone group (p. 373)
- Launch Spot Instances in a VPC (p. 374)

Launch Spot Instances in a launch group

Specify a launch group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances only if it can launch them all. In addition, if the Spot service must terminate one of the instances in a launch group (for example, if the Spot price exceeds your maximum price), it must terminate them all. However, if you terminate one or more of the instances in a launch group, Amazon EC2 does not terminate the remaining instances in the launch group.

Although this option can be useful, adding this constraint can decrease the chances that your Spot Instance request is fulfilled and increase the chances that your Spot Instances are terminated. For example, your launch group includes instances in multiple Availability Zones. If capacity in one of these Availability Zones decreases and is no longer available, then Amazon EC2 terminates all instances for the launch group.

If you create another successful Spot Instance request that specifies the same (existing) launch group as an earlier successful request, then the new instances are added to the launch group. Subsequently, if an instance in this launch group is terminated, all instances in the launch group are terminated, which includes instances launched by the first and second requests.

Launch Spot Instances in an Availability Zone group

Specify an Availability Zone group in your Spot Instance request to tell the Spot service to launch a set of Spot Instances in the same Availability Zone. Amazon EC2 need not interrupt all instances in an Availability Zone group at the same time. If Amazon EC2 must interrupt one of the instances in an Availability Zone group, the others remain running.

Although this option can be useful, adding this constraint can lower the chances that your Spot Instance request is fulfilled.

If you specify an Availability Zone group but don't specify an Availability Zone in the Spot Instance request, the result depends on the network you specified.

Default VPC

Amazon EC2 uses the Availability Zone for the specified subnet. If you don't specify a subnet, it selects an Availability Zone and its default subnet, but not necessarily the lowest-priced zone. If you deleted the default subnet for an Availability Zone, then you must specify a different subnet.

Nondefault VPC

Amazon EC2 uses the Availability Zone for the specified subnet.
Launch Spot Instances in a VPC

You specify a subnet for your Spot Instances the same way that you specify a subnet for your On-Demand Instances.

- You should use the default maximum price (the On-Demand price), or base your maximum price on the Spot price history of Spot Instances in a VPC.
- [Default VPC] If you want your Spot instance launched in a specific low-priced Availability Zone, you must specify the corresponding subnet in your Spot instance request. If you do not specify a subnet, Amazon EC2 selects one for you, and the Availability Zone for this subnet might not have the lowest Spot price.
- [Nondefault VPC] You must specify the subnet for your Spot Instance.

Spot Instance pricing history

Spot Instance prices are set by Amazon EC2 and adjust gradually based on long-term trends in supply and demand for Spot Instance capacity.

When you request Spot Instances, we recommend that you use the default maximum price (the On-Demand price). When your request is fulfilled, your Spot Instances launch at the current Spot price, not exceeding the On-Demand price. If you want to specify a maximum price, we recommend that you first review the Spot price history. You can view the Spot price history for the last 90 days, filtering by instance type, operating system, and Availability Zone.

To view the current Spot prices

For the current Spot Instance prices, see Amazon EC2 Spot Instances Pricing.

To view the Spot price history (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Choose Pricing history.
4. For Graph, choose to compare the price history by Availability Zones or by Instance Types.

- If you choose Availability Zones, then choose the Instance type, operating system (Platform), and Date range for which to view the price history.
- If you choose Instance Types, then choose up to five Instance type(s), the Availability Zone, operating system (Platform), and Date range for which to view the price history.

The following screenshot shows a price comparison for different instance types.
5. Move your pointer over the graph to display the prices at specific times in the selected date range. The prices are displayed in the information blocks above the graph. The price displayed in the top row shows the price on a specific date. The price displayed in the second row shows the average price over the selected date range.

6. To display the price per vCPU, toggle on **Display normalized prices**. To display the price for the instance type, toggle off **Display normalized prices**.

**To view the Spot price history using the command line**

You can use one of the following commands. For more information, see Access Amazon EC2 (p. 3).

- `describe-spot-price-history` (AWS CLI)
- `Get-EC2SpotPriceHistory` (AWS Tools for Windows PowerShell)

**Savings from purchasing Spot Instances**

You can view the usage and savings information for Spot Instances at the per-fleet level, or for all running Spot Instances. At the per-fleet level, the usage and savings information includes all instances launched and terminated by the fleet. You can view this information from the last hour or the last three days.

The following screenshot from the **Savings** section shows the Spot usage and savings information for a Spot Fleet.

<table>
<thead>
<tr>
<th>Spot Instances</th>
<th>vCPU-hours</th>
<th>Mem(GiB)-hours</th>
<th>On-Demand total</th>
<th>Spot total</th>
<th>Savings</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>266</td>
<td>700</td>
<td>$9.55</td>
<td>$2.99</td>
<td>69%</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Details</th>
<th></th>
<th></th>
<th></th>
<th>$0.0112</th>
<th>$0.0043</th>
</tr>
</thead>
<tbody>
<tr>
<td>t3.medium (1)</td>
<td>2 vCPU hours</td>
<td>4 mem(GiB)-hours</td>
<td>$0.01 total</td>
<td>70% savings</td>
<td></td>
</tr>
<tr>
<td>m4.large (1)</td>
<td>144 vCPU hours</td>
<td>576 mem(GiB)-hours</td>
<td>$2.52 total</td>
<td>68% savings</td>
<td></td>
</tr>
<tr>
<td>t2.micro (2)</td>
<td>120 vCPU hours</td>
<td>120 mem(GiB)-hours</td>
<td>$0.46 total</td>
<td>70% savings</td>
<td></td>
</tr>
</tbody>
</table>

You can view the following usage and savings information:

- **Spot Instances** – The number of Spot Instances launched and terminated by the Spot Fleet. When viewing the savings summary, the number represents all your running Spot Instances.
- **vCPU-hours** – The number of vCPU hours used across all the Spot Instances for the selected time frame.
- **Mem(GiB)-hours** – The number of GiB hours used across all the Spot Instances for the selected time frame.
- **On-Demand total** – The total amount you would've paid for the selected time frame had you launched these instances as On-Demand Instances.
- **Spot total** – The total amount to pay for the selected time frame.
- **Savings** – The percentage that you are saving by not paying the On-Demand price.
- **Average cost per vCPU-hour** – The average hourly cost of using the vCPUs across all the Spot Instances for the selected time frame, calculated as follows: \( \text{Average cost per vCPU-hour} = \frac{\text{Spot total}}{\text{vCPU-hours}} \).
• **Average cost per mem(GiB)-hour** – The average hourly cost of using the GiBs across all the Spot Instances for the selected time frame, calculated as follows: \( \text{Average cost per mem(GiB)-hour} = \frac{\text{Spot total}}{\text{Mem(GiB)-hours}} \).

• **Details table** – The different instance types (the number of instances per instance type is in parentheses) that comprise the Spot Fleet. When viewing the savings summary, these comprise all your running Spot Instances.

Savings information can only be viewed using the Amazon EC2 console.

**To view the savings information for a Spot Fleet (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose **Spot Requests**.
3. Select the ID of a Spot Fleet request and scroll to the **Savings** section.
   
   Alternatively, select the check box next to the Spot Fleet request ID and choose the **Savings** tab.
4. By default, the page displays usage and savings information for the last three days. You can choose **last hour** or the **last three days**. For Spot Fleets that were launched less than an hour ago, the page shows the estimated savings for the hour.

**To view the savings information for all running Spot Instances (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose **Spot Requests**.
3. Choose **Savings summary**.

**Spot Instance requests**

To use Spot Instances, you create a Spot Instance request that includes the desired number of instances, the instance type, the Availability Zone, and the maximum price that you are willing to pay per instance hour. If your maximum price exceeds the current Spot price, Amazon EC2 fulfills your request immediately if capacity is available. Otherwise, Amazon EC2 waits until your request can be fulfilled or until you cancel the request.

The following illustration shows how Spot Instance requests work. Notice that the request type (one-time or persistent) determines whether the request is opened again when Amazon EC2 interrupts a Spot Instance or if you stop a Spot Instance. If the request is persistent, the request is opened again after your Spot Instance is interrupted. If the request is persistent and you stop your Spot Instance, the request only opens after you start your Spot Instance.
Spot Instance request states

A Spot Instance request can be in one of the following states:

- **open** – The request is waiting to be fulfilled.
- **active** – The request is fulfilled and has an associated Spot Instance.
- **failed** – The request has one or more bad parameters.
- **closed** – The Spot Instance was interrupted or terminated.
- **disabled** – You stopped the Spot Instance.
- **cancelled** – You canceled the request, or the request expired.
The following illustration represents the transitions between the request states. Notice that the transitions depend on the request type (one-time or persistent).

A one-time Spot Instance request remains active until Amazon EC2 launches the Spot Instance, the request expires, or you cancel the request. If the Spot price exceeds your maximum price or capacity is not available, your Spot Instance is terminated and the Spot Instance request is closed.

A persistent Spot Instance request remains active until it expires or you cancel it, even if the request is fulfilled. If the Spot price exceeds your maximum price or capacity is not available, your Spot Instance is interrupted. After your instance is interrupted, when your maximum price exceeds the Spot price or capacity becomes available again, the Spot Instance is started if stopped or resumed if hibernated. You can stop a Spot Instance and start it again if capacity is available and your maximum price exceeds the current Spot price. If the Spot Instance is terminated (irrespective of whether the Spot Instance is in a stopped or running state), the Spot Instance request is opened again and Amazon EC2 launches a new Spot Instance. For more information, see Stop a Spot Instance (p. 389), Start a Spot Instance (p. 390), and Terminate a Spot Instance (p. 391).

You can track the status of your Spot Instance requests, as well as the status of the Spot Instances launched, through the status. For more information, see Spot request status (p. 394).

**Define a duration for your Spot Instances**

Spot Instances with a defined duration (also known as Spot blocks) are no longer available to new customers from July 1, 2021. For customers who have previously used the feature, we will continue to support Spot Instances with a defined duration until December 31, 2022.

**Specify a tenancy for your Spot Instances**

You can run a Spot Instance on single-tenant hardware. Dedicated Spot Instances are physically isolated from instances that belong to other AWS accounts. For more information, see Dedicated Instances (p. 446) and the Amazon EC2 Dedicated Instances product page.

To run a Dedicated Spot Instance, do one of the following:

- Specify a tenancy of dedicated when you create the Spot Instance request. For more information, see Create a Spot Instance request (p. 380).
• Request a Spot Instance in a VPC with an instance tenancy of dedicated. For more information, see Create a VPC with an instance tenancy of dedicated (p. 448). You cannot request a Spot Instance with a tenancy of default if you request it in a VPC with an instance tenancy of dedicated.

All instance families support Dedicated Spot Instances except T instances. For each supported instance family, only the largest instance size or metal size supports Dedicated Spot Instances.

Service-linked role for Spot Instance requests

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see Using Service-Linked Roles in the IAM User Guide.

Amazon EC2 uses the service-linked role named AWSServiceRoleForEC2Spot to launch and manage Spot Instances on your behalf.

Permissions granted by AWSServiceRoleForEC2Spot

Amazon EC2 uses AWSServiceRoleForEC2Spot to complete the following actions:

• ec2:DescribeInstances – Describe Spot Instances
• ec2:StopInstances – Stop Spot Instances
• ec2:StartInstances – Start Spot Instances

Create the service-linked role

Under most circumstances, you don’t need to manually create a service-linked role. Amazon EC2 creates the AWSServiceRoleForEC2Spot service-linked role the first time you request a Spot Instance using the console.

If you had an active Spot Instance request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the AWSServiceRoleForEC2Spot role in your AWS account. For more information, see A New Role Appeared in My Account in the IAM User Guide.

If you use the AWS CLI or an API to request a Spot Instance, you must first ensure that this role exists.

To create AWSServiceRoleForEC2Spot using the console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. On the Select type of trusted entity page, choose EC2, EC2 - Spot Instances, Next: Permissions.
5. On the next page, choose Next: Review.

To create AWSServiceRoleForEC2Spot using the AWS CLI

Use the create-service-linked-role command as follows.

```
aws iam create-service-linked-role --aws-service-name spot.amazonaws.com
```
If you no longer need to use Spot Instances, we recommend that you delete the 
AWSServiceRoleForEC2Spot role. After this role is deleted from your account, Amazon EC2 will create 
the role again if you request Spot Instances.

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an encrypted AMI (p. 156) or an encrypted Amazon EBS snapshot (p. 1335) for 
your Spot Instances and you use a customer managed key for encryption, you must grant the 
AWSServiceRoleForEC2Spot role permission to use the customer managed key so that Amazon EC2 can 
launch Spot Instances on your behalf. To do this, you must add a grant to the customer managed key, as 
shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using 
Grants and Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide.

To grant the AWSServiceRoleForEC2Spot role permissions to use the customer managed key

- Use the create-grant command to add a grant to the customer managed key and to specify the 
principal (the AWSServiceRoleForEC2Spot service-linked role) that is given permission to perform 
the operations that the grant permits. The customer managed key is specified by the key-id 
parameter and the ARN of the customer managed key. The principal is specified by the grantee-principal 
parameter and the ARN of the AWSServiceRoleForEC2Spot service-linked role.

```
aws kms create-grant 
  --region us-east-1 
  --key-id arn:aws:kms:us-east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab 
  --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2Spot 
  --operations "Decrypt" "Encrypt" "GenerateDataKey" "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom" "ReEncryptTo"
```

Create a Spot Instance request

The procedure for requesting a Spot Instance is similar to the procedure for launching an On-Demand 
Instance. You can request a Spot Instance in the following ways:

- To request a Spot Instance using the console, use the launch instance wizard. For more information, 
see To create a Spot Instance request (console) (p. 381).
- To request a Spot Instance using the CLI, use the request-spot-instances command or the run-instances 
command. For more information, see To create a Spot Instance request using request-spot-instances 
(CLI) and To create a Spot Instance request using run-instances (CLI).

After you've submitted your Spot Instance request, you can't change the parameters of the request. This 
means that you can't make changes to the maximum price that you're willing to pay.

If you request multiple Spot Instances at one time, Amazon EC2 creates separate Spot Instance requests 
so that you can track the status of each request separately. For more information about tracking Spot 
Instance requests, see Spot request status (p. 394).

To launch a fleet that includes Spot Instances and On-Demand Instances, see Create a Spot Fleet 
request (p. 717).

Note
You can't launch a Spot Instance and an On-Demand Instance in the same call using the launch 
instance wizard or the run-instances command.

Prerequisites
Before you begin, decide on your maximum price, how many Spot Instances you'd like, and what instance type to use. To review Spot price trends, see Spot Instance pricing history (p. 374).

To create a Spot Instance request (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose Launch Instance.
4. On the Choose an Amazon Machine Image (AMI) page, choose an AMI. For more information, see Step 1: Choose an Amazon Machine Image (AMI) (p. 477).
5. On the Choose an Instance Type page, select the hardware configuration and size of the instance to launch, and then choose Next: Configure Instance Details. For more information, see Step 2: Choose an Instance Type (p. 478).
6. On the Configure Instance Details page, configure the Spot Instance request as follows:
   - **Number of instances**: Enter the number of instances to launch.
     - **Note**: Amazon EC2 creates a separate request for each Spot Instance.
   - (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose Launch into Auto Scaling Group to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the Amazon EC2 Auto Scaling User Guide.
   - **Purchasing option**: Choose Request Spot instances to launch a Spot Instance. When you choose this option, the following fields appear.
   - **Current price**: The current Spot price in each Availability Zone is displayed for the instance type that you selected.
   - (Optional) **Maximum price**: You can leave the field empty, or you can specify the maximum amount you're willing to pay.
     - If you leave the field empty, then the maximum price defaults to the current On-Demand price. Your Spot Instance launches at the current Spot price, not exceeding the On-Demand price.
     - If you specify a maximum price that is more than the current Spot Price, your Spot Instance launches and is charged at the current Spot price.
     - If you specify a maximum price that is lower than the Spot price, your Spot Instance is not launched.
   - **Persistent request**: Choose Persistent request to resubmit the Spot Instance request if your Spot Instance is interrupted.
   - **Interruption behavior**: By default, the Spot service terminates a Spot Instance when it is interrupted. If you choose Persistent request, you can then specify that the Spot service stops or hibernates your Spot Instance when it's interrupted. For more information, see Interruption behaviors (p. 403).
   - (Optional) **Request valid to**: Choose Edit to specify when the Spot Instance request expires.
   For more information about configuring your Spot Instance, see Step 3: Configure Instance Details (p. 479).
7. The AMI you selected includes one or more volumes of storage, including the root device volume. On the Add Storage page, you can specify additional volumes to attach to the instance by choosing Add New Volume. For more information, see Step 4: Add Storage (p. 481).
8. On the Add Tags page, specify tags (p. 1462) by providing key and value combinations. For more information, see Step 5: Add Tags (p. 482).
9. On the Configure Security Group page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other
traffic is ignored. (For more information about security groups, see Amazon EC2 security groups for Linux instances (p. 1152).) Select or create a security group, and then choose Review and Launch. For more information, see Step 6: Configure Security Group (p. 482).

10. On the Review Instance Launch page, check the details of your instance, and make any necessary changes by choosing the appropriate Edit link. When you are ready, choose Launch. For more information, see Step 7: Review Instance Launch and Select Key Pair (p. 482).

11. In the Select an existing key pair or create a new key pair dialog box, you can choose an existing key pair, or create a new one. For example, choose Choose an existing key pair, then select the key pair that you created when getting set up. For more information, see Amazon EC2 key pairs and Linux instances (p. 1137).

   Important
   If you choose the Proceed without key pair option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

12. To launch your instance, select the acknowledgment check box, then choose Launch Instances.

   If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot instance launch issues (p. 1477).

To create a Spot Instance request using request-spot-instances (AWS CLI)

Use the request-spot-instances command to create a one-time request.

```
aws ec2 request-spot-instances \
  --instance-count 5 \n  --type "one-time" \n  --launch-specification file:///specification.json
```

Use the request-spot-instances command to create a persistent request.

```
aws ec2 request-spot-instances \
  --instance-count 5 \n  --type "persistent" \n  --launch-specification file:///specification.json
```

For example launch specification files to use with these commands, see Spot Instance request example launch specifications (p. 392). If you download a launch specification file from the console, you must use the request-spot-fleet command instead (the console specifies a Spot Instance request using a Spot Fleet).

To create a Spot Instance request using run-instances (AWS CLI)

Use the run-instances command and specify the Spot Instance options in the --instance-market-options parameter.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \n  --instance-type t2.micro \n  --count 5 \n  --subnet-id subnet-08fc749671b2d077c \n  --key-name MyKeyPair \n  --security-group-ids sg-0b0384b66d7d692f9 \n  --instance-market-options file:///spot-options.json
```

The following is the data structure to specify in the JSON file for --instance-market-options. You can also specify ValidUntil and Instance Interruption Behavior. If you do not specify a field in the data structure, the default value is used. This example creates a one-time request and specifies 0.02 as the maximum price you're willing to pay for the Spot Instance.

\}

Find running Spot Instances

Amazon EC2 launches a Spot Instance when the maximum price exceeds the Spot price and capacity is available. A Spot Instance runs until it is interrupted or you terminate it yourself. If your maximum price is exactly equal to the Spot price, there is a chance that your Spot Instance remains running, depending on demand.

To find running Spot Instances (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests. You can see both Spot Instance requests and Spot Fleet requests. If a Spot Instance request has been fulfilled, Capacity is the ID of the Spot Instance. For a Spot Fleet, Capacity indicates how much of the requested capacity has been fulfilled. To view the IDs of the instances in a Spot Fleet, choose the expand arrow, or select the fleet and choose Instances.

   Note
   For Spot instance requests that are created by a Spot Fleet, the requests are not tagged instantly with the system tag that indicates the Spot Fleet to which they belong, and for a period of time may appear separate from Spot Fleet request.

Alternatively, in the navigation pane, choose Instances. In the top right corner, choose the settings icon (⚙️), and then under Attribute columns, select Instance lifecycle. For each instance, Instance lifecycle is either normal, spot, or scheduled.

To find running Spot Instances (AWS CLI)

To enumerate your Spot Instances, use the describe-spot-instance-requests command with the --query option.

\begin{verbatim}
aws ec2 describe-spot-instance-requests \
  --query "SpotInstanceRequests[*].{ID:InstanceId}"
\end{verbatim}

The following is example output:

\begin{verbatim}
[ 
  
  
  ],
  
  

}\]
\end{verbatim}

Alternatively, you can enumerate your Spot Instances using the describe-instances command with the --filters option.

\begin{verbatim}
aws ec2 describe-instances \
  --filters "Name=instance-lifecycle,Values=spot"
\end{verbatim}
To describe a single Spot Instance instance, use the `describe-spot-instance-requests` command with the `--spot-instance-request-ids` option.

```
aws ec2 describe-spot-instance-requests \
  --spot-instance-request-ids sir-08b93456
```

Tag Spot Instance requests

To help categorize and manage your Spot Instance requests, you can tag them with custom metadata. You can assign a tag to a Spot Instance request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Instance request, the instances and volumes that are launched by the Spot Instance request are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Instance request. You can assign a tag to a Spot Instance and volumes during launch, or afterward.

For more information about how tags work, see Tag your Amazon EC2 resources (p. 1462).

Contents

- Prerequisites (p. 384)
- Tag a new Spot Instance request (p. 386)
- Tag an existing Spot Instance request (p. 386)
- View Spot Instance request tags (p. 387)

Prerequisites

Grant the IAM user the permission to tag resources. For more information about IAM policies and example policies, see Example: Tag resources (p. 1108).

The IAM policy you create is determined by which method you use for creating a Spot Instance request.

- If you use the launch instance wizard or `run-instances` to request Spot Instances, see To grant an IAM user the permission to tag resources when using the launch instance wizard or `run-instances`.
- If you use the `request-spot-instances` command to request Spot Instances, see To grant an IAM user the permission to tag resources when using `request-spot-instances`.

To grant an IAM user the permission to tag resources when using the launch instance wizard or `run-instances`

Create a IAM policy that includes the following:

- The `ec2:RunInstances` action. This grants the IAM user permission to launch an instance.
- For `Resource`, specify `spot-instances-request`. This allows users to create Spot Instance requests, which request Spot Instances.
- The `ec2:CreateTags` action. This grants the IAM user permission to create tags.
- For `Resource`, specify `*`. This allows users to tag all resources that are created during instance launch.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLaunchInstances",
      "Effect": "Allow",
      "Action": ["ec2:RunInstances"]
    }
  ]
}
```
"ec2:RunInstances"
],
"Resource": [
  "arn:aws:ec2:us-east-1:image/*",
  "arn:aws:ec2:us-east-1:subnet/*",
  "arn:aws:ec2:us-east-1:network-interface/*",
  "arn:aws:ec2:us-east-1:security-group/*",
  "arn:aws:ec2:us-east-1:key-pair/*",
  "arn:aws:ec2:us-east-1:volume/*",
  "arn:aws:ec2:us-east-1:instance/*",
  "arn:aws:ec2:us-east-1:spot-instances-request/*"
]
}
{
  "Sid": "TagSpotInstanceRequests",
  "Effect": "Allow",
  "Action": "ec2:CreateTags",
  "Resource": "*"
}
}

**Note**

When you use the RunInstances action to create Spot Instance requests and tag the Spot Instance requests on create, you need to be aware of how Amazon EC2 evaluates the spot-instances-request resource in the RunInstances statement.

The spot-instances-request resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the spot-instances-request resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the spot-instances-request resource in the RunInstances statement.

Therefore, for the spot-instances-request resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the spot-instances-request resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the spot-instances-request resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the spot-instances-request resource or include a * wildcard in the CreateTags allow statement, otherwise the call will fail.

For example IAM policies, including policies that are not supported for Spot Instance requests, see [Work with Spot Instances](p. 1102).

**To grant an IAM user the permission to tag resources when using request-spot-instances**

Create a IAM policy that includes the following:

- The `ec2:RequestSpotInstances` action. This grants the IAM user permission to create a Spot Instance request.
- The `ec2:CreateTags` action. This grants the IAM user permission to create tags.
- For **Resource**, specify `spot-instances-request`. This allows users to tag only the Spot Instance request.
Tag a new Spot Instance request

To tag a new Spot Instance request using the console

1. Follow the Create a Spot Instance request (p. 380) procedure.
2. To add a tag, on the Add Tags page, choose Add Tag, and enter the key and value for the tag. Choose Add another tag for each additional tag.

   For each tag, you can tag the Spot Instance request, the Spot Instances, and the volumes with the same tag. To tag all three, ensure that Instances, Volumes, and Spot Instance Requests are selected. To tag only one or two, ensure that the resources you want to tag are selected, and the other resources are cleared.
3. Complete the required fields to create a Spot Instance request, and then choose Launch. For more information, see Create a Spot Instance request (p. 380).

To tag a new Spot Instance request using the AWS CLI

To tag a Spot Instance request when you create it, configure the Spot Instance request configuration as follows:

- Specify the tags for the Spot Instance request using the --tag-specification parameter.
- For ResourceType, specify spot-instances-request. If you specify another value, the Spot Instance request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the Spot Instance request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123.

```bash
aws ec2 request-spot-instances
--instance-count 5
--type "one-time"
--launch-specification file://specification.json
--tag-specification 'ResourceType=spot-instances-request,Tags=[{Key=Environment,Value=Production},{Key=Cost-Center,Value=123}]'
```

Tag an existing Spot Instance request

To tag an existing Spot Instance request using the console

After you have created a Spot Instance request, you can add tags to the Spot Instance request using the console.

2. Select your Spot Instance request.
3. Choose the **Tags** tab and choose **Create Tag**.

**To tag an existing Spot Instance using the console**

After your Spot Instance request has launched your Spot Instance, you can add tags to the instance using the console. For more information, see Add and delete tags on an individual resource (p. 1469).

**To tag an existing Spot Instance request or Spot Instance using the AWS CLI**

Use the **create-tags** command to tag existing resources. In the following example, the existing Spot Instance request and the Spot Instance are tagged with Key=purpose and Value=test.

```bash
aws ec2 create-tags \
--resources sir-08b93456 i-1234567890abcdef0 \
--tags Key=purpose,Value=test
```

**View Spot Instance request tags**

**To view Spot Instance request tags using the console**

2. Select your Spot Instance request and choose the **Tags** tab.

**To describe Spot Instance request tags**

Use the **describe-tags** command to view the tags for the specified resource. In the following example, you describe the tags for the specified request.

```bash
aws ec2 describe-tags \
--filters "Name=resource-id,Values=sir-11112222-3333-4444-5555-66666EXAMPLE"
```

```json
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-instances-request",
      "Value": "Production"
    },
    {
      "Key": "Another key",
      "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-instances-request",
      "Value": "Another value"
    }
  ]
}
```

You can also view the tags of a Spot Instance request by describing the Spot Instance request.

Use the **describe-spot-instance-requests** command to view the configuration of the specified Spot Instance request, which includes any tags that were specified for the request.

```bash
aws ec2 describe-spot-instance-requests \
```

387
Spot Instances

```
{

          "Value": "Another value"
        }
      ],
      "Type": "one-time",
      "InstanceInterruptionBehavior": "terminate"
    }
  ]
}
```
Cancel a Spot Instance request

If you no longer want your Spot Instance request, you can cancel it. You can only cancel Spot Instance requests that are open, active, or disabled.

- Your Spot Instance request is open when your request has not yet been fulfilled and no instances have been launched.
- Your Spot Instance request is active when your request has been fulfilled and Spot Instances have launched as a result.
- Your Spot Instance request is disabled when you stop your Spot Instance.

If your Spot Instance request is active and has an associated running Spot Instance, canceling the request does not terminate the instance. For more information about terminating a Spot Instance, see Terminate a Spot Instance (p. 391).

To cancel a Spot Instance request (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests and select the Spot Instance request.
3. Choose Actions, Cancel request.
4. (Optional) If you are finished with the associated Spot Instances, you can terminate them. In the Cancel Spot request dialog box, select Terminate instances, and then choose Confirm.

To cancel a Spot Instance request (AWS CLI)

- Use the cancel-spot-instance-requests command to cancel the specified Spot Instance request.

```
aws ec2 cancel-spot-instance-requests --spot-instance-request-ids sir-08b93456
```

Stop a Spot Instance

If you don’t need your Spot Instances now, but you want to restart them later without losing the data persisted in the Amazon EBS volume, you can stop them. The steps for stopping a Spot Instance are similar to the steps for stopping an On-Demand Instance.

**Note**

While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type.
We don't charge usage for a stopped Spot Instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes.

Limitations

- You can only stop a Spot Instance if the Spot Instance was launched from a persistent Spot Instance request.
- You can't stop a Spot Instance if the associated Spot Instance request is cancelled. When the Spot Instance request is cancelled, you can only terminate the Spot Instance.
- You can't stop a Spot Instance if it is part of a fleet or launch group, or Availability Zone group.
New console

**To stop a Spot Instance (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state**, **Stop instance**.
4. When prompted for confirmation, choose **Stop**.

Old console

**To stop a Spot Instance (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Actions**, **Instance State**, **Stop**.

AWS CLI

**To stop a Spot Instance (AWS CLI)**

- Use the `stop-instances` command to manually stop one or more Spot Instances.

```bash
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

**Start a Spot Instance**

You can start a Spot Instance that you previously stopped. The steps for starting a Spot Instance are similar to the steps for starting an On-Demand Instance.

**Prerequisites**

You can only start a Spot Instance if:

- You manually stopped the Spot Instance.
- The Spot Instance is an EBS-backed instance.
- Spot Instance capacity is available.
- The Spot price is lower than your maximum price.

**Limitations**

- You can't start a Spot Instance if it is part of fleet or launch group, or Availability Zone group.

New console

**To start a Spot Instance (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state**, **Start instance**.
Old console

**To start a Spot Instance (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Actions, Instance State, Start**.

AWS CLI

**To start a Spot Instance (AWS CLI)**

- Use the `start-instances` command to manually start one or more Spot Instances.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

**Terminate a Spot Instance**

If you terminate a running or stopped Spot Instance that was launched by a persistent Spot Instance request, the Spot Instance request transitions to the `open` state so that a new Spot Instance can be launched. To ensure that no new Spot Instance is launched, you must first cancel the Spot Instance request.

If you cancel an **active** Spot Instance request that has a running Spot Instance, the running Spot Instance is not automatically terminated; you must manually terminate the Spot Instance.

If you cancel a **disabled** Spot Instance request that has a stopped Spot Instance, the stopped Spot Instance is automatically terminated by the Amazon EC2 Spot service. There might be a short lag between when you cancel the Spot Instance request and when the Spot service terminates the Spot Instance.

For information about canceling a Spot Instance request, see [Cancel a Spot Instance request](p. 389).

New console

**To manually terminate a Spot Instance using the console**

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose **Instances**.
4. To confirm that the instance is a Spot Instance, check that **spot** appears in the **Instance lifecycle** column.
5. Select the instance, and choose **Actions, Instance state, Terminate instance**.
6. Choose **Terminate** when prompted for confirmation.

Old console

**To manually terminate a Spot Instance using the console**

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you
need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose **Instances**.
4. To confirm that the instance is a Spot Instance, check that **spot** appears in the **Lifecycle** column.
5. Select the instance, and choose **Actions, Instance State, Terminate**.
6. Choose **Yes, Terminate** when prompted for confirmation.

**AWS CLI**

**To manually terminate a Spot Instance using the AWS CLI**

- Use the `terminate-instances` command to manually terminate Spot Instances.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0 i-0598c7d356ebad8d7
```

**Spot Instance request example launch specifications**

The following examples show launch configurations that you can use with the `request-spot-instances` command to create a Spot Instance request. For more information, see Create a Spot Instance request (p. 380).

1. **Launch Spot Instances** (p. 392)
2. **Launch Spot Instances in the specified Availability Zone** (p. 392)
3. **Launch Spot Instances in the specified subnet** (p. 393)
4. **Launch a Dedicated Spot Instance** (p. 393)

**Example 1: Launch Spot Instances**

The following example does not include an Availability Zone or subnet. Amazon EC2 selects an Availability Zone for you. Amazon EC2 launches the instances in the default subnet of the selected Availability Zone.

```json
{
  "ImageId": "ami-1a2b3c4d",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d" ],
  "InstanceType": "m3.medium",
  "IamInstanceProfile": {
    "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

**Example 2: Launch Spot Instances in the specified Availability Zone**

The following example includes an Availability Zone. Amazon EC2 launches the instances in the default subnet of the specified Availability Zone.

```json
{
  "ImageId": "ami-1a2b3c4d",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d" ],
```
"InstanceType": "m3.medium",
"Placement": {
    "AvailabilityZone": "us-west-2a"
},
"IamInstanceProfile": {
    "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
}
}

Example 3: Launch Spot Instances in the specified subnet

The following example includes a subnet. Amazon EC2 launches the instances in the specified subnet. If the VPC is a nondefault VPC, the instance does not receive a public IPv4 address by default.

```json
{
    "ImageId": "ami-1a2b3c4d",
    "SecurityGroupIds": [ "sg-1a2b3c4d" ],
    "InstanceType": "m3.medium",
    "SubnetId": "subnet-1a2b3c4d",
    "IamInstanceProfile": {
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
    }
}
```

To assign a public IPv4 address to an instance in a nondefault VPC, specify the `AssociatePublicIpAddress` field as shown in the following example. When you specify a network interface, you must include the subnet ID and security group ID using the network interface, rather than using the `SubnetId` and `SecurityGroupIds` fields shown in example 3.

```json
{
    "ImageId": "ami-1a2b3c4d",
    "KeyName": "my-key-pair",
    "InstanceType": "m3.medium",
    "NetworkInterfaces": [
        {
            "DeviceIndex": 0,
            "SubnetId": "subnet-1a2b3c4d",
            "Groups": [ "sg-1a2b3c4d" ],
            "AssociatePublicIpAddress": true
        }
    ],
    "IamInstanceProfile": {
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
    }
}
```

Example 4: Launch a Dedicated Spot Instance

The following example requests Spot Instance with a tenancy of dedicated. A Dedicated Spot Instance must be launched in a VPC.

```json
{
    "ImageId": "ami-1a2b3c4d",
    "KeyName": "my-key-pair",
    "SecurityGroupIds": [ "sg-1a2b3c4d" ],
    "InstanceType": "c3.8xlarge",
    "SubnetId": "subnet-1a2b3c4d",
    "Placement": {
        "Tenancy": "dedicated"
    }
}
```
Spot request status

To help you track your Spot Instance requests and plan your use of Spot Instances, use the request status provided by Amazon EC2. For example, the request status can provide the reason why your Spot request isn’t fulfilled yet, or list the constraints that are preventing the fulfillment of your Spot request.

At each step of the process—also called the Spot request lifecycle—specific events determine successive request states.

Contents

- Lifecycle of a Spot request (p. 394)
- Get request status information (p. 397)
- Spot request status codes (p. 398)

Lifecycle of a Spot request

The following diagram shows you the paths that your Spot request can follow throughout its lifecycle, from submission to termination. Each step is depicted as a node, and the status code for each node describes the status of the Spot request and Spot Instance.

Pending evaluation

As soon as you create a Spot Instance request, it goes into the pending-evaluation state unless one or more request parameters are not valid (bad-parameters).
Status code | Request state | Instance state
--- | --- | ---
pending-evaluation | open | n/a
bad-parameters | closed | n/a

**Holding**

If one or more request constraints are valid but can't be met yet, or if there is not enough capacity, the request goes into a holding state waiting for the constraints to be met. The request options affect the likelihood of the request being fulfilled. For example, if you specify a maximum price below the current Spot price, your request stays in a holding state until the Spot price goes below your maximum price. If you specify an Availability Zone group, the request stays in a holding state until the Availability Zone constraint is met.

In the event of an outage of one of the Availability Zones, there is a chance that the spare EC2 capacity available for Spot Instance requests in other Availability Zones can be affected.

Status code | Request state | Instance state
--- | --- | ---
capacity-not-available | open | n/a
price-too-low | open | n/a
not-scheduled-yet | open | n/a
launch-group-constraint | open | n/a
az-group-constraint | open | n/a
placement-group-constraint | open | n/a
constraint-not-fulfillable | open | n/a

**Pending evaluation/fulfillment-terminal**

Your Spot Instance request can go to a terminal state if you create a request that is valid only during a specific time period and this time period expires before your request reaches the pending fulfillment phase. It might also happen if you cancel the request, or if a system error occurs.

Status code | Request state | Instance state
--- | --- | ---
schedule-expired | cancelled | n/a
canceled-before-fulfillment* | cancelled | n/a
bad-parameters | failed | n/a
system-error | closed | n/a

* If you cancel the request.

**Pending fulfillment**
When the constraints you specified (if any) are met and your maximum price is equal to or higher than the current Spot price, your Spot request goes into the pending-fulfillment state.

At this point, Amazon EC2 is getting ready to provision the instances that you requested. If the process stops at this point, it is likely to be because it was canceled by the user before a Spot Instance was launched. It might also be because an unexpected system error occurred.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending-fulfillment</td>
<td>open</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Fulfilled**

When all the specifications for your Spot Instances are met, your Spot request is fulfilled. Amazon EC2 launches the Spot Instances, which can take a few minutes. If a Spot Instance is hibernated or stopped when interrupted, it remains in this state until the request can be fulfilled again or the request is canceled.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>fulfilled</td>
<td>active</td>
<td>pending → running</td>
</tr>
<tr>
<td>fulfilled</td>
<td>active</td>
<td>stopped → running</td>
</tr>
</tbody>
</table>

If you stop a Spot Instance, your Spot request goes into the marked-for-stop or instance-stopped-by-user state until the Spot Instance can be started again or the request is cancelled.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>marked-for-stop</td>
<td>active</td>
<td>stopping</td>
</tr>
<tr>
<td>instance-stopped-by-user*</td>
<td>disabled or cancelled**</td>
<td>stopped</td>
</tr>
</tbody>
</table>

* A Spot Instance goes into the instance-stopped-by-user state if you stop the instance or run the shutdown command from the instance. After you've stopped the instance, you can start it again. On restart, the Spot Instance request returns to the pending-evaluation state and then Amazon EC2 launches a new Spot Instance when the constraints are met.

** The Spot request state is disabled if you stop the Spot Instance but do not cancel the request. The request state is cancelled if your Spot Instance is stopped and the request expires.

**Fulfilled-terminal**

Your Spot Instances continue to run as long as your maximum price is at or above the Spot price, there is available capacity for your instance type, and you don't terminate the instance. If a change in the Spot price or available capacity requires Amazon EC2 to terminate your Spot Instances, the Spot request goes into a terminal state. A request also goes into the terminal state if you cancel the Spot request or terminate the Spot Instances.

<td>terminated</td>
</tr>
<tr>
<td>instance-terminated-launch-group-constraint</td>
<td>closed (one-time), open (persistent)</td>
<td>terminated</td>
</tr>
</tbody>
</table>

* The request state is closed if you terminate the instance but do not cancel the request. The request state is cancelled if you terminate the instance and cancel the request. Even if you terminate a Spot Instance before you cancel its request, there might be a delay before Amazon EC2 detects that your Spot Instance was terminated. In this case, the request state can either be closed or cancelled.

### Persistent requests

When your Spot Instances are terminated (either by you or Amazon EC2), if the Spot request is a persistent request, it returns to the pending-evaluation state and then Amazon EC2 can launch a new Spot Instance when the constraints are met.

### Get request status information

You can get request status information using the AWS Management Console or a command line tool.

**To get request status information (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests and select the Spot request.
3. To check the status, on the Description tab, check the Status field.

**To get request status information using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- describe-spot-instance-requests (AWS CLI)
- Get-EC2SpotInstanceRequest (AWS Tools for Windows PowerShell)
Spot request status codes

Spot request status information is composed of a status code, the update time, and a status message. Together, these help you determine the disposition of your Spot request.

The following are the Spot request status codes:

**az-group-constraint**

Amazon EC2 cannot launch all the instances you requested in the same Availability Zone.

**bad-parameters**

One or more parameters for your Spot request are not valid (for example, the AMI you specified does not exist). The status message indicates which parameter is not valid.

**canceled-before-fulfillment**

The user canceled the Spot request before it was fulfilled.

**capacity-not-available**

There is not enough capacity available for the instances that you requested.

**constraint-not-fulfillable**

The Spot request can't be fulfilled because one or more constraints are not valid (for example, the Availability Zone does not exist). The status message indicates which constraint is not valid.

**fulfilled**

The Spot request is active, and Amazon EC2 is launching your Spot Instances.

**instance-stopped-by-price**

Your instance was stopped because the Spot price exceeded your maximum price.

**instance-stopped-by-user**

Your instance was stopped because a user stopped the instance or ran the shutdown command from the instance.

**instance-stopped-no-capacity**

Your instance was stopped due to EC2 capacity management needs.

**instance-terminated-by-price**

Your instance was terminated because the Spot price exceeded your maximum price. If your request is persistent, the process restarts, so your request is pending evaluation.

**instance-terminated-by-schedule**

Your Spot Instance was terminated at the end of its scheduled duration.

**instance-terminated-by-service**

Your instance was terminated from a stopped state.

**instance-terminated-by-user**

You terminated a Spot Instance that had been fulfilled, so the request state is closed (unless it's a persistent request) and the instance state is terminated.

**instance-terminated-launch-group-constraint**

One or more of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

**instance-terminated-no-capacity**

Your instance was terminated due to standard capacity management processes.
launch-group-constraint

Amazon EC2 cannot launch all the instances that you requested at the same time. All instances in a launch group are started and terminated together.

limit-exceeded

The limit on the number of EBS volumes or total volume storage was exceeded. For more information about these limits and how to request an increase, see Amazon EBS Limits in the Amazon Web Services General Reference.

marked-for-stop

The Spot Instance is marked for stopping.

marked-for-termination

The Spot Instance is marked for termination.

not-scheduled-yet

The Spot request is not evaluated until the scheduled date.

pending-evaluation

After you make a Spot Instance request, it goes into the pending-evaluation state while the system evaluates the parameters of your request.

pending-fulfillment

Amazon EC2 is trying to provision your Spot Instances.

placement-group-constraint

The Spot request can't be fulfilled yet because a Spot Instance can't be added to the placement group at this time.

price-too-low

The request can't be fulfilled yet because your maximum price is below the Spot price. In this case, no instance is launched and your request remains open.

request-canceled-and-instance-running

You canceled the Spot request while the Spot Instances are still running. The request is cancelled, but the instances remain running.

schedule-expired

The Spot request expired because it was not fulfilled before the specified date.

system-error

There was an unexpected system error. If this is a recurring issue, please contact AWS Support for assistance.

EC2 instance rebalance recommendations

An EC2 Instance rebalance recommendation is a new signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal can arrive sooner than the two-minute Spot Instance interruption notice (p. 407), giving you the opportunity to proactively manage the Spot Instance. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption.

It is not always possible for Amazon EC2 to send the rebalance recommendation signal before the two-minute Spot Instance interruption notice. Therefore, the rebalance recommendation signal can arrive along with the two-minute interruption notice.
Note
Rebalance recommendations are only supported for Spot Instances that are launched after November 5, 2020 00:00 UTC.

Topics
- Rebalance actions you can take (p. 400)
- Monitor rebalance recommendation signals (p. 400)
- Services that use the rebalance recommendation signal (p. 402)

Rebalance actions you can take
These are some of the possible rebalancing actions that you can take:

Graceful shutdown
When you receive the rebalance recommendation signal for a Spot Instance, you can start your instance shutdown procedures, which might include ensuring that processes are completed before stopping them. For example, you can upload system or application logs to Amazon Simple Storage Service (Amazon S3), you can shut down Amazon SQS workers, or you can complete deregistration from the Domain Name System (DNS). You can also save your work in external storage and resume it at a later time.

Prevent new work from being scheduled
When you receive the rebalance recommendation signal for a Spot Instance, you can prevent new work from being scheduled on the instance, while continuing to use the instance until the scheduled work is completed.

Proactively launch new replacement instances
You can configure Auto Scaling groups, EC2 Fleet, or Spot Fleet to automatically launch replacement Spot Instances when a rebalance recommendation signal is emitted. For more information, see Amazon EC2 Auto Scaling Capacity Rebalancing in the Amazon EC2 Auto Scaling User Guide, and Capacity Rebalancing (p. 680) for EC2 Fleet and Capacity Rebalancing (p. 707) for Spot Fleet in this user guide.

Monitor rebalance recommendation signals
You can monitor the rebalance recommendation signal so that, when it is emitted, you can take the actions that are specified in the preceding section. The rebalance recommendation signal is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events) and as instance metadata on the Spot Instance.

Monitor rebalance recommendation signals:
- Use Amazon EventBridge (p. 400)
- Use instance metadata (p. 402)

Use Amazon EventBridge
When the rebalance recommendation signal is emitted for a Spot Instance, the event for the signal is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

The following is an example event for the rebalance recommendation signal.

```
The following fields form the event pattern that is defined in the rule:

"detail-type": "EC2 Instance Rebalance Recommendation"

Identifies that the event is a rebalance recommendation event

"source": "aws.ec2"

Identifies that the event is from Amazon EC2

Create an EventBridge rule

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time Amazon EC2 emits a rebalance recommendation signal. The signal is emitted as an EC2 Instance Rebalance Recommendation event, which triggers the action defined by the rule.

To create an EventBridge rule for a rebalance recommendation event

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. Enter a Name for the rule, and, optionally, a description.

A rule can't have the same name as another rule in the same Region and on the same event bus.
4. For Define pattern, choose Event pattern.
5. Under Event matching pattern, choose Custom pattern.
6. In the Event pattern box, add the following pattern to match the EC2 Instance Rebalance Recommendation event, and then choose Save.

```json
{  
  "source": [  "aws.ec2" ],
  "detail-type": [  "EC2 Instance Rebalance Recommendation" ]
}
```

7. For Select event bus, choose AWS default event bus. When an AWS service in your account emits an event, it always goes to your account's default event bus.
8. Confirm that Enable the rule on the selected event bus is toggled on.
9. For Target, choose SNS topic to send an email, text message, or mobile push notification when the event occurs.
10. For Topic, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
11. For **Configure input**, choose the input for the email, text message, or mobile push notification.
12. Choose **Create**.

For more information, see **Creating a rule for an AWS service** and **Event Patterns** in the *Amazon EventBridge User Guide*.

**Use instance metadata**

The instance metadata category `events/recommendations/rebalance` provides the approximate time, in UTC, when the rebalance recommendation signal was emitted for a Spot Instance.

We recommend that you check for rebalance recommendation signals every 5 seconds so that you don't miss an opportunity to act on the rebalance recommendation.

If a Spot Instance receives a rebalance recommendation, the time that the signal was emitted is present in the instance metadata. You can retrieve the time that the signal was emitted as follows.

**IMDSv2**

```
```

**IMDSv1**

```
```

The following is example output, which indicates the time, in UTC, that the rebalance recommendation signal was emitted for the Spot Instance.

```
{"noticeTime": "2020-10-27T08:22:00Z"}
```

If the signal has not been emitted for the instance, `events/recommendations/rebalance` is not present and you receive an HTTP 404 error when you try to retrieve it.

**Services that use the rebalance recommendation signal**

Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet use the rebalance recommendation signal to make it easy for you to maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance receives the two-minute Spot Instance interruption notice. You can have these services monitor and respond proactively to changes affecting the availability of your Spot Instances. For more information, see the following:

- **Amazon EC2 Auto Scaling Capacity Rebalancing** in the *Amazon EC2 Auto Scaling User Guide*
- **Capacity Rebalancing (p. 680)** in the EC2 Fleet topic in this user guide
- **Capacity Rebalancing (p. 707)** in the Spot Fleet topic in this user guide

**Spot Instance interruptions**

You can launch Spot Instances on spare EC2 capacity for steep discounts in exchange for returning them when Amazon EC2 needs the capacity back. When Amazon EC2 reclaims a Spot Instance, we call this event a **Spot Instance interruption**.
Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. Therefore, you must ensure that your application is prepared for a Spot Instance interruption.

An On-Demand Instance specified in an EC2 Fleet or Spot Fleet cannot be interrupted.

Contents

- Reasons for interruption (p. 403)
- Interruption behaviors (p. 403)
- Specify the interruption behavior (p. 406)
- Prepare for interruptions (p. 406)
- Prepare for instance hibernation (p. 407)
- Spot Instance interruption notices (p. 407)
- Find interrupted Spot Instances (p. 409)
- Determine whether Amazon EC2 interrupted a Spot Instance (p. 410)
- Billing for interrupted Spot Instances (p. 410)

Reasons for interruption

The following are the possible reasons that Amazon EC2 might interrupt your Spot Instances:

- **Price** – The Spot price is greater than your maximum price.
- **Capacity** – Amazon EC2 can interrupt your Spot Instance when it needs it back. EC2 reclaims your instance mainly to repurpose capacity, but it can also occur for other reasons such as host maintenance or hardware decommission.
- **Constraints** – If your request includes a constraint such as a launch group or an Availability Zone group, these Spot Instances are terminated as a group when the constraint can no longer be met.

You can see the historical interruption rates for your instance type in the Spot Instance Advisor.

Interruption behaviors

You can specify that Amazon EC2 must do one of the following when it interrupts a Spot Instance:

- **Stop interrupted Spot Instances** (p. 403)
- **Hibernate interrupted Spot Instances** (p. 404)
- **Terminate interrupted Spot Instances** (this is the default behavior)

To change the interruption behavior, see Specify the interruption behavior (p. 406).

Stop interrupted Spot Instances

Prerequisites

You can specify the interruption behavior so that Amazon EC2 stops Spot Instances when they are interrupted if the following prerequisites are met.

- **Spot Instance request type** – must be persistent. You can't specify a launch group in the Spot Instance request.
EC2 Fleet or Spot Fleet request type – must be maintain

Root volume type – must be an EBS volume, not an instance store volume

After a Spot Instance is stopped by the Spot service, only the Spot service can restart the Spot Instance, and the same launch specification must be used.

For a Spot Instance launched by a persistent Spot Instance request, the Spot service restarts the stopped instance when capacity is available in the same Availability Zone and for the same instance type as the stopped instance.

If instances in an EC2 Fleet or Spot Fleet are stopped and the fleet is of type maintain, the Spot service launches replacement instances to maintain the target capacity. The Spot service finds the best Spot capacity pools based on the specified allocation strategy (lowestPrice, diversified, or InstancePoolsToUseCount); it does not prioritize the pool with the earlier stopped instances. Later, if the allocation strategy leads to a pool containing the earlier stopped instances, the Spot service restarts the stopped instances to meet the target capacity.

For example, consider a Spot Fleet with the lowestPrice allocation strategy. At initial launch, a c3.large pool meets the lowestPrice criteria for the launch specification. Later, when the c3.large instances are interrupted, the Spot service stops the instances and replenishes capacity from another pool that fits the lowestPrice strategy. This time, the pool happens to be a c4.large pool and the Spot service launches c4.large instances to meet the target capacity. Similarly, Spot Fleet could move to a c5.large pool the next time. In each of these transitions, the Spot service does not prioritize pools with earlier stopped instances, but rather prioritizes purely on the specified allocation strategy. The lowestPrice strategy can lead back to pools with earlier stopped instances. For example, if instances are interrupted in the c5.large pool and the lowestPrice strategy leads it back to the c3.large or c4.large pools, the earlier stopped instances are restarted to fulfill target capacity.

While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type. If you detach or delete an EBS volume, it is not attached when the Spot Instance is started. If you detach the root volume and the Spot service attempts to start the Spot Instance, instance start fails and the Spot service terminates the stopped instance.

You can terminate a Spot Instance while it is stopped. If you cancel a Spot Instance request, an EC2 Fleet, or a Spot Fleet, the Spot service terminates any associated Spot Instances that are stopped.

While a Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved. With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account.

Hibernate interrupted Spot Instances

Hibernate prerequisites

You can specify the interruption behavior so that Amazon EC2 hibernates Spot Instances when they are interrupted if the following prerequisites are met.

- Spot Instance request type – must be persistent. You can’t specify a launch group in the Spot Instance request.
- EC2 Fleet or Spot Fleet request type – must be maintain
- Supported instance families – C3, C4, C5, M4, M5, R3, R4
- Instance RAM size – must be less than 100 GB
- Supported operating systems (You must install the hibernation agent on a supported operating system. Alternatively, use a supported AMI, which already includes the agent.):
  - Amazon Linux 2
• Amazon Linux AMI
• Ubuntu with an AWS-tuned Ubuntu kernel (linux-aws) greater than 4.4.0-1041
• Windows Server 2008 R2 and later

**Supported AMIs** (the following supported AMIs include the hibernation agent):

- Amazon Linux 2
- Amazon Linux AMI 2017.09.1 or later
- Ubuntu Xenial 16.04 20171121 or later
- Windows Server 2008 R2 AMI 2017.11.19 or later
- Windows Server 2012 or Windows Server 2012 R2 AMI 2017.11.19 or later
- Windows Server 2016 AMI 2017.11.19 or later
- Windows Server 2019

**Root volume type** – must be an EBS volume, not an instance store volume, and it must be large enough to store the instance memory (RAM) during hibernation

**Start the hibernation agent** – We recommend that you use user data to start the agent on instance startup. Alternatively, you could start the agent manually.

**Recommendation**

- We strongly recommend that you use an encrypted Amazon EBS volume as the root volume, because instance memory is stored on the root volume during hibernation. This ensures that the contents of memory (RAM) are encrypted when the data is at rest on the volume and when data is moving between the instance and volume. Use one of the following three options to ensure that the root volume is an encrypted Amazon EBS volume:
  - EBS “single-step” encryption: In a single run-instances API call, you can launch encrypted EBS-backed EC2 instances from an unencrypted AMI. For more information, see [Use encryption with EBS-backed AMIs](p. 156).
  - EBS encryption by default: You can enable EBS encryption by default to ensure all new EBS volumes created in your AWS account are encrypted. For more information, see [Encryption by default](p. 1338).
  - Encrypted AMI: You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see [Encrypt an unencrypted image during copy](p. 160) and [Copy an AMI](p. 139).

When a Spot Instance is hibernated by the Spot service, the EBS volumes are preserved and instance memory (RAM) is preserved on the root volume. The private IP addresses of the instance are also preserved. Instance storage volumes and public IP addresses, other than Elastic IP addresses, are not preserved. While the instance is hibernating, you are charged only for the EBS volumes. With EC2 Fleet and Spot Fleet, if you have many hibernated instances, you can exceed the limit on the number of EBS volumes for your account.

The agent prompts the operating system to hibernate when the instance receives a signal from the Spot service. If the agent is not installed, the underlying operating system doesn't support hibernation, or there isn't enough volume space to save the instance memory, hibernation fails and the Spot service stops the instance instead.

When the Spot service hibernates a Spot Instance, you receive an interruption notice, but you do not have two minutes before the Spot Instance is interrupted. Hibernation begins immediately. While the instance is in the process of hibernating, instance health checks might fail. When the hibernation process completes, the state of the instance is stopped.

**Resuming a hibernated Spot Instance**
After a Spot Instance is hibernated by the Spot service, it can only be resumed by the Spot service. The Spot service resumes the instance when capacity becomes available with a Spot price that is less than your specified maximum price.

For more information, see Prepare for instance hibernation (p. 407).

For information about hibernating On-Demand Instances, see Hibernate your On-Demand or Reserved Linux instance (p. 528).

Specify the interruption behavior

If you do not specify an interruption behavior, the default is to terminate Spot Instances when they are interrupted. You can specify the interruption behavior when you create a Spot Instance request. The way in which you specify the interruption behavior is different depending on how you request Spot Instances.

If you request Spot Instances using the launch instance wizard (p. 477), you can specify the interruption behavior as follows: Select the Persistent request check box and then, from Interruption behavior, choose an interruption behavior.

If you request Spot Instances using the Spot console (p. 717), you can specify the interruption behavior as follows: Select the Maintain target capacity check box and then, from Interruption behavior, choose an interruption behavior.

If you configure Spot Instances in a launch template (p. 485), you can specify the interruption behavior as follows: In the launch template, expand Advanced details and select the Request Spot Instances check box. Choose Customize and then, from Interruption behavior, choose an interruption behavior.

If you configure Spot Instances in a launch configuration when using the request-spot-fleet CLI, you can specify the interruption behavior as follows: For InstanceInterruptionBehavior, specify an interruption behavior.

If you configure Spot Instances using the request-spot-instances CLI, you can specify the interruption behavior as follows: For --instance-interruption-behavior, specify an interruption behavior.

Prepare for interruptions

Here are some best practices to follow when you use Spot Instances:

- Use the default maximum price, which is the On-Demand price.
- Ensure that your instance is ready to go as soon as the request is fulfilled by using an Amazon Machine Image (AMI) that contains the required software configuration. You can also use user data to run commands at start-up.
- Store important data regularly in a place that isn't affected when the Spot Instance terminates. For example, you can use Amazon S3, Amazon EBS, or DynamoDB.
- Divide the work into small tasks (using a Grid, Hadoop, or queue-based architecture) or use checkpoints so that you can save your work frequently.
- Amazon EC2 emits a rebalance recommendation signal to the Spot Instance when the instance is at an elevated risk of interruption. You can rely on the rebalance recommendation to proactively manage Spot Instance interruptions without having to wait for the two-minute Spot Instance interruption notice. For more information, see EC2 instance rebalance recommendations (p. 399).
- Use the two-minute Spot Instance interruption notices to monitor the status of your Spot Instances. For more information, see Spot Instance interruption notices (p. 407).
- While we make every effort to provide these warnings as soon as possible, it is possible that your Spot Instance is interrupted before the warnings can be made available. Test your application to ensure that it handles an unexpected instance interruption gracefully, even if you are monitoring for rebalance.
recommendation signals and interruption notices. You can do so by running the application using an On-Demand Instance and then terminating the On-Demand Instance yourself.

Prepare for instance hibernation

You must install a hibernation agent on your instance, unless you used an AMI that already includes the agent. You must run the agent on instance startup, whether the agent was included in your AMI or you installed it yourself.

The following procedures help you prepare a Linux instance. For directions to prepare a Windows instance, see Prepare for instance hibernation in the Amazon EC2 User Guide for Windows Instances.

To prepare an Amazon Linux instance

1. Verify that your kernel supports hibernation and update the kernel if necessary.
2. If your AMI doesn't include the agent, install the agent using the following command.

```
sudo yum update; sudo yum install hibagent
```

3. Add the following to the user data:

```
#!/bin/bash
/usr/bin/enable-ec2-spot-hibernation
```

To prepare an Ubuntu instance

1. If your AMI doesn't include the agent, install the agent using the following command. The hibernation agent is only available on Ubuntu 16.04 or later.

```
sudo apt-get install hibagent
```

2. Add the following to the user data.

```
#!/bin/bash
/usr/bin/enable-ec2-spot-hibernation
```

Spot Instance interruption notices

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of Spot Instance interruption notices. A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 stops or terminates your Spot Instance. If you specify hibernation as the interruption behavior, you receive an interruption notice, but you do not receive a two-minute warning because the hibernation process begins immediately.

We recommend that you check for these interruption notices every 5 seconds.

The interruption notices are made available as a CloudWatch event and as items in the instance metadata (p. 606) on the Spot Instance. Events are emitted on a best effort basis.

EC2 Spot Instance interruption notice

When Amazon EC2 is going to interrupt your Spot Instance, it emits an event two minutes prior to the actual interruption (except for hibernation, which gets the interruption notice, but not two minutes in advance, because hibernation begins immediately). This event can be detected by Amazon CloudWatch
Events. For more information about CloudWatch events, see the Amazon CloudWatch Events User Guide. For a detailed example that walks you through how to create and use event rules, see Taking Advantage of Amazon EC2 Spot Instance Interruption Notices.

The following is an example of the event for Spot Instance interruption. The possible values for instance-action are hibernate, stop, and terminate.

```json
{
  "version": "0",
  "id": "12345678-1234-1234-1234-123456789012",
  "detail-type": "EC2 Spot Instance Interruption Warning",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-2",
  "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],
  "detail": {
    "instance-id": "i-1234567890abcdef0",
    "instance-action": "action"
  }
}
```

**instance-action**

If your Spot Instance is marked to be stopped or terminated by the Spot service, the instance-action item is present in your instance metadata (p. 606). Otherwise, it is not present. You can retrieve instance-action as follows.

**IMDSv2**

```
```

**IMDSv1**

```
```

The instance-action item specifies the action and the approximate time, in UTC, when the action will occur.

The following example indicates the time at which this instance will be stopped.

```json
{"action": "stop", "time": "2017-09-18T08:22:00Z"}
```

The following example indicates the time at which this instance will be terminated.

```json
{"action": "terminate", "time": "2017-09-18T08:22:00Z"}
```

If Amazon EC2 is not preparing to stop or terminate the instance, or if you terminated the instance yourself, instance-action is not present and you receive an HTTP 404 error when you try to retrieve it.

**termination-time**

This item is maintained for backward compatibility; you should use instance-action instead.
If your Spot Instance is marked for termination by the Spot service, the *termination-time* item is present in your instance metadata. Otherwise, it is not present. You can retrieve *termination-time* as follows.

**IMDSv2**

```bash

```

**IMDSv1**

```bash
[ec2-user ~]$ if curl -s http://169.254.169.254/latest/meta-data/spot/termination-time | grep -q .*T.*Z; then echo terminated; fi
```

The *termination-time* item specifies the approximate time in UTC when the instance receives the shutdown signal. For example:

```
2015-01-05T18:02:00Z
```

If Amazon EC2 is not preparing to terminate the instance, or if you terminated the Spot Instance yourself, the *termination-time* item is either not present (so you receive an HTTP 404 error) or contains a value that is not a time value.

If Amazon EC2 fails to terminate the instance, the request status is set to *fulfilled*. The *termination-time* value remains in the instance metadata with the original approximate time, which is now in the past.

### Find interrupted Spot Instances

In the console, the **Instances** pane displays all instances, including Spot Instances. You can identify a Spot Instance from the *spot* value in the **Instance lifecycle** column. The **Instance state** column indicates whether the instance is pending, running, stopping, stopped, shutting-down, or terminated. For a hibernated Spot Instance, the instance state is **stopped**.

#### To find an interrupted Spot Instance (console)

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**. In the top right corner, choose the settings icon (⚙️), and under **Attribute columns**, select **Instance lifecycle**. For Spot Instances, **Instance lifecycle** is **spot**.

   Alternatively, in the navigation pane, choose **Spot Requests**. You can see both Spot Instance requests and Spot Fleet requests. To view the IDs of the instances, select a Spot Instance request or a Spot Fleet request and choose the **Instances** tab. Choose an instance ID to display the instance in the **Instances** pane.

3. For each Spot Instance, you can view its state in the **Instance State** column.

#### To find interrupted Spot Instances (AWS CLI)

You can list your interrupted Spot Instances using the `describe-instances` command with the `--filters` parameter. To list only the instance IDs in the output, add the `--query` parameter.

```bash
aws ec2 describe-instances --filters
```

Determine whether Amazon EC2 interrupted a Spot Instance

If a Spot Instance is stopped, hibernated, or terminated, you can use CloudTrail to see whether Amazon EC2 interrupted the Spot Instance. In AWS CloudTrail, the event name `BidEvictedEvent` indicates that Amazon EC2 interrupted the Spot Instance.

To view `BidEvictedEvent` events in CloudTrail

1. Open the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. In the navigation pane, choose Event history.
3. In the filter drop-down, choose Event name, and then in the filter field to the right, enter `BidEvictedEvent`.
4. Choose `BidEvictedEvent` in the resulting list to view its details. Under Event record, you can find the instance ID.

For more information about using CloudTrail, see Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail (p. 863).

Billing for interrupted Spot Instances

When a Spot Instance is interrupted, you're charged as follows.

<table>
<thead>
<tr>
<th>Who interrupts the Spot Instance</th>
<th>Operating system</th>
<th>Interrupted in the first hour</th>
<th>Interrupted in any hour after the first hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>If <strong>you</strong> stop or terminate the Spot Instance</td>
<td>Windows and Linux (excluding RHEL and SUSE)</td>
<td>Charged for the seconds used</td>
<td>Charged for the seconds used</td>
</tr>
<tr>
<td></td>
<td>RHEL and SUSE</td>
<td>Charged for the full hour even if you used a partial hour</td>
<td>Charged for the full hours used, and charged a full hour for the interrupted partial hour</td>
</tr>
<tr>
<td>If the <strong>Amazon EC2 Spot service</strong> interrupts the Spot Instance</td>
<td>Windows and Linux (excluding RHEL and SUSE)</td>
<td>No charge</td>
<td>Charged for the seconds used</td>
</tr>
<tr>
<td></td>
<td>RHEL and SUSE</td>
<td>No charge</td>
<td>Charged for the full hours used, but no charge for the interrupted partial hour</td>
</tr>
</tbody>
</table>

Spot Instance data feed

To help you understand the charges for your Spot Instances, Amazon EC2 provides a data feed that describes your Spot Instance usage and pricing. This data feed is sent to an Amazon S3 bucket that you specify when you subscribe to the data feed.
Data feed files arrive in your bucket typically once an hour, and each hour of usage is typically covered in a single data file. These files are compressed (gzip) before they are delivered to your bucket. Amazon EC2 can write multiple files for a given hour of usage where files are large (for example, when file contents for the hour exceed 50 MB before compression).

**Note**
If you don’t have a Spot instance running during a certain hour, you don’t receive a data feed file for that hour.

**Contents**
- Data feed file name and format (p. 411)
- Amazon S3 bucket requirements (p. 412)
- Subscribe to your Spot Instance data feed (p. 412)
- Describe your Spot Instance data feed (p. 412)
- Delete your Spot Instance data feed (p. 413)

**Data feed file name and format**

The Spot Instance data feed file name uses the following format (with the date and hour in UTC):

`bucket-name.s3.amazonaws.com/optional-prefix/aws-account-id.YYYY-MM-DD-HH.n.unique-id.gz`

For example, if your bucket name is `my-bucket-name` and your prefix is `my-prefix`, your file names are similar to the following:

`my-bucket-name.s3.amazonaws.com/my-prefix/111122223333.2019-03-17-20.001.pwBdGTJG.gz`

For more information about bucket names, see Rules for bucket naming in the Amazon Simple Storage Service Developer Guide.

The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance hour and contains the fields listed in the following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timestamp</td>
<td>The timestamp used to determine the price charged for this instance usage.</td>
</tr>
<tr>
<td>UsageType</td>
<td>The type of usage and instance type being charged for. For m1.small Spot Instances, this field is set to SpotUsage. For all other instance types, this field is set to SpotUsage: {instance-type}. For example, SpotUsage: c1.medium.</td>
</tr>
<tr>
<td>Operation</td>
<td>The product being charged for. For Linux Spot Instances, this field is set to RunInstances. For Windows Spot Instances, this field is set to RunInstances:0002. Spot usage is grouped according to Availability Zone.</td>
</tr>
<tr>
<td>InstanceID</td>
<td>The ID of the Spot Instance that generated this instance usage.</td>
</tr>
<tr>
<td>MyBidID</td>
<td>The ID for the Spot Instance request that generated this instance usage.</td>
</tr>
<tr>
<td>MyMaxPrice</td>
<td>The maximum price specified for this Spot Instance request.</td>
</tr>
<tr>
<td>MarketPrice</td>
<td>The Spot price at the time specified in the Timestamp field.</td>
</tr>
<tr>
<td>Charge</td>
<td>The price charged for this instance usage.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>Version</td>
<td>The version included in the data feed file name for this record.</td>
</tr>
</tbody>
</table>

### Amazon S3 bucket requirements

When you subscribe to the data feed, you must specify an Amazon S3 bucket to store the data feed files. Before you choose an Amazon S3 bucket for the data feed, consider the following:

- You must have **FULL_CONTROL** permission to the bucket, which includes permission for the `s3:GetBucketAcl` and `s3:PutBucketAcl` actions.
  
  If you're the bucket owner, you have this permission by default. Otherwise, the bucket owner must grant your AWS account this permission.

- When you subscribe to a data feed, these permissions are used to update the bucket ACL to give the AWS data feed account **FULL_CONTROL** permission. The AWS data feed account writes data feed files to the bucket. If your account doesn't have the required permissions, the data feed files cannot be written to the bucket.

  **Note**
  If you update the ACL and remove the permissions for the AWS data feed account, the data feed files cannot be written to the bucket. You must resubscribe to the data feed to receive the data feed files.

- Each data feed file has its own ACL (separate from the ACL for the bucket). The bucket owner has **FULL_CONTROL** permission to the data files. The AWS data feed account has read and write permissions.

- If you delete your data feed subscription, Amazon EC2 doesn't remove the read and write permissions for the AWS data feed account on either the bucket or the data files. You must remove these permissions yourself.

### Subscribe to your Spot Instance data feed

To subscribe to your data feed, use the `create-spot-datafeed-subscription` command.

```bash
aws ec2 create-spot-datafeed-subscription \
   --bucket my-bucket-name \
   [--prefix my-prefix]
```

The following is example output:

```json
{
   "SpotDatafeedSubscription": {
      "OwnerId": "111122223333",
      "Bucket": "my-bucket-name",
      "Prefix": "my-prefix",
      "State": "Active"
   }
}
```

### Describe your Spot Instance data feed

To describe your data feed subscription, use the `describe-spot-datafeed-subscription` command.

```bash
aws ec2 describe-spot-datafeed-subscription
```
The following is example output:

```
{
    "SpotDatafeedSubscription": {
        "OwnerId": "123456789012",
        "Prefix": "spotdata",
        "Bucket": "my-s3-bucket",
        "State": "Active"
    }
}
```

**Delete your Spot Instance data feed**

To delete your data feed, use the `delete-spot-datafeed-subscription` command.

```
aws ec2 delete-spot-datafeed-subscription
```

**Spot Instance limits**

There is a limit on the number of running and requested Spot Instances per AWS account per Region. Spot Instance limits are managed in terms of the number of virtual central processing units (vCPUs) that your running Spot Instances are either using or will use pending the fulfillment of open Spot Instance requests. If you terminate your Spot Instances but do not cancel the Spot Instance requests, the requests count against your Spot Instance vCPU limit until Amazon EC2 detects the Spot Instance terminations and closes the requests.

There are six Spot Instance limits:

- All Standard (A, C, D, H, I, M, R, T, Z) Spot Instance Requests
- All F Spot Instance Requests
- All G Spot Instance Requests
- All Inf Spot Instance Requests
- All P Spot Instance Requests
- All X Spot Instance Requests

Each limit specifies the vCPU limit for one or more instance families. For information about the different instance families, generations, and sizes, see Amazon EC2 Instance Types.

With vCPU limits, you can use your limit in terms of the number of vCPUs that are required to launch any combination of instance types that meet your changing application needs. For example, say your All Standard Spot Instance Requests limit is 256 vCPUs, you could request 32 m5.2xlarge Spot Instances (32 x 8 vCPUs) or 16 c5.4xlarge Spot Instances (16 x 16 vCPUs), or a combination of any Standard Spot Instance types and sizes that total 256 vCPUs.

**Topics**

- Monitor Spot Instance limits and usage (p. 413)
- Request a Spot Instance limit increase (p. 414)

**Monitor Spot Instance limits and usage**

You can view and manage your Spot Instance limits using the following:

- The Limits page in the Amazon EC2 console
- The Amazon EC2 Services quotas page in the Service Quotas console
• The get-service-quota AWS CLI

For more information, see Amazon EC2 service quotas (p. 1475) in the Amazon EC2 User Guide for Linux Instances and Viewing a Service Quota in the Service Quotas User Guide.

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against limits. You can also configure alarms to warn about approaching limits. For more information, see Using Amazon CloudWatch Alarms in the Service Quotas User Guide.

Request a Spot Instance limit increase

Even though Amazon EC2 automatically increases your Spot Instance limits based on your usage, you can request a limit increase if necessary. For example, if you intend to launch more Spot Instances than your current limit allows, you can request a limit increase. You can also request a limit increase if you submit a Spot Instance request and you receive the error Max spot instance count exceeded.

To request a Spot Instance limit increase

2. For Limit type, choose EC2 Spot Instances.
3. For Region, select the required Region.
4. For Primary instance type, select the Spot Instance limit for which you want to request a limit increase.
5. For New limit value, enter the total number of vCPUs that you want to run concurrently. To determine the total number of vCPUs that you need, see Amazon EC2 Instance Types to find the number of vCPUs of each instance type.
6. (Conditional) You must create a separate limit request for each Spot Instance limit. To request an increase for another Spot Instance limit, choose Add another request and repeat steps 4 and 5 in this procedure.
7. For Use case description, enter your use case, and then choose Submit.

For more information about viewing limits and requesting a limit increase, see Amazon EC2 service quotas (p. 1475).

Burstable performance instances

If you launch your Spot Instances using a burstable performance instance type (p. 216), and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in Standard mode (p. 232) to avoid paying higher costs. If you launch burstable performance Spot Instances in Unlimited mode (p. 225) and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see When to use unlimited mode versus fixed CPU (p. 226).

Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use Unlimited mode (p. 225) for T2 Spot Instances, or use an instance type with dedicated CPU.
Dedicated Hosts

An Amazon EC2 Dedicated Host is a physical server with EC2 instance capacity fully dedicated to your use. Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses, including Windows Server, Microsoft SQL Server, SUSE, and Linux Enterprise Server.

For information about the configurations supported on Dedicated Hosts, see Dedicated Hosts Configuration.

Contents
- Differences between Dedicated Hosts and Dedicated Instances (p. 415)
- Bring your own license (p. 416)
- Dedicated Host instance capacity (p. 416)
- Dedicated Hosts restrictions (p. 417)
- Pricing and billing (p. 417)
- Work with Dedicated Hosts (p. 418)
- Work with shared Dedicated Hosts (p. 436)
- Host recovery (p. 440)
- Track configuration changes (p. 444)

Differences between Dedicated Hosts and Dedicated Instances

Dedicated Hosts and Dedicated Instances can both be used to launch Amazon EC2 instances onto physical servers that are dedicated for your use.

There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some differences between the two. The following table highlights some of the key differences between Dedicated Hosts and Dedicated Instances:

<table>
<thead>
<tr>
<th></th>
<th>Dedicated Host</th>
<th>Dedicated Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Billing</td>
<td>Per-host billing</td>
<td>Per-instance billing</td>
</tr>
<tr>
<td>Visibility of sockets, cores, and host ID</td>
<td>Provides visibility of the number of sockets and physical cores</td>
<td>No visibility</td>
</tr>
<tr>
<td>Host and instance affinity</td>
<td>Allows you to consistently deploy your instances to the same physical server over time</td>
<td>Not supported</td>
</tr>
<tr>
<td>Targeted instance placement</td>
<td>Provides additional visibility and control over how instances are placed on a physical server</td>
<td>Not supported</td>
</tr>
<tr>
<td>Automatic instance recovery</td>
<td>Supported. For more information, see Host recovery (p. 440).</td>
<td>Supported</td>
</tr>
<tr>
<td>Bring Your Own License (BYOL)</td>
<td>Supported</td>
<td>Not supported</td>
</tr>
</tbody>
</table>
Bring your own license

Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses. When you bring your own license, you are responsible for managing your own licenses. However, Amazon EC2 has features that help you maintain license compliance, such as instance affinity and targeted placement.

These are the general steps to follow in order to bring your own volume licensed machine image into Amazon EC2.

1. Verify that the license terms controlling the use of your machine images allow usage in a virtualized cloud environment.
2. After you have verified that your machine image can be used within Amazon EC2, import it using VM Import/Export. For information about how to import your machine image, see the VM Import/Export User Guide.
3. After you import your machine image, you can launch instances from it onto active Dedicated Hosts in your account.
4. When you run these instances, depending on the operating system, you might be required to activate these instances against your own KMS server.

**Note**

To track how your images are used in AWS, enable host recording in AWS Config. You can use AWS Config to record configuration changes to a Dedicated Host and use the output as a data source for license reporting. For more information, see Track configuration changes (p. 444).

Dedicated Host instance capacity

Support for multiple instance sizes on the same Dedicated Host is available for the following instance families: A1, C5, M5, R5, C5n, R5n, and M5n. Other instance families support only a single instance size on the same Dedicated Host.

For example, when you allocate an R5 Dedicated Host, it has 2 sockets and 48 physical cores on which you can run different instance sizes, such as r5.2xlarge and r5.4xlarge, up to the core capacity associated with the host. However, for each instance family, there is a limit on the number of instances that can be run for each instance size. For example, an R5 Dedicated Host supports up to 2 r5.8xlarge instances, which uses 32 of the physical cores. Additional R5 instances of another size can then be used to fill the host to core capacity. For the supported number of instance sizes for each instance family, see Dedicated Hosts Configuration.

The following table shows examples of different instance size combinations that you can run on a Dedicated Host.

<table>
<thead>
<tr>
<th>Instance family</th>
<th>Example instance size combinations</th>
</tr>
</thead>
</table>
| R5              | • Example 1: 4 x r5.4xlarge + 4 x r5.2xlarge  
• Example 2: 1 x r5.12xlarge + 1 x r5.4xlarge + 1 x r5.2xlarge + 5 x r5.xlarge + 2 x r5.large |
| C5              | • Example 1: 1 x c5.9xlarge + 2 x c5.4xlarge + 1 x c5.xlarge  
• Example 2: 4 x c5.4xlarge + 1 x c5.xlarge + 2 x c5.large |
| M5              | • Example 1: 4 x m5.4xlarge + 4 x m5.2xlarge  
• Example 2: 1 x m5.12xlarge + 1 x m5.4xlarge + 1 x m5.2xlarge + 5 x m5.xlarge + 2 x m5.large |
Dedicated Hosts restrictions

Before you allocate Dedicated Hosts, take note of the following limitations and restrictions:

- To run RHEL, SUSE Linux, and SQL Server on Dedicated Hosts, you must bring your own AMIs. RHEL, SUSE Linux, and SQL Server AMIs that are offered by AWS or that are available on AWS Marketplace can't be used with Dedicated Hosts. For more information on how to create your own AMI, see Bring your own license (p. 416).

  This restriction does not apply to hosts allocated for high memory instances (u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal). RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace can be used with these hosts.

- Up to two On-Demand Dedicated Hosts per instance family, per Region can be allocated. It is possible to request a limit increase: Request to Raise Allocation Limit on Amazon EC2 Dedicated Hosts.

- The instances that run on a Dedicated Host can only be launched in a VPC.

- Auto Scaling groups are supported when using a launch template that specifies a host resource group. For more information, see Creating a Launch Template for an Auto Scaling Group in the Amazon EC2 Auto Scaling User Guide.

- Amazon RDS instances are not supported.

- The AWS Free Usage tier is not available for Dedicated Hosts.

- Instance placement control refers to managing instance launches onto Dedicated Hosts. You cannot launch Dedicated Hosts into placement groups.

Pricing and billing

The price for a Dedicated Host varies by payment option.

Payment Options

- On-Demand Dedicated Hosts (p. 417)
- Dedicated Host Reservations (p. 417)
- Savings Plans (p. 418)
- Pricing for Windows Server on Dedicated Hosts (p. 418)

On-Demand Dedicated Hosts

On-Demand billing is automatically activated when you allocate a Dedicated Host to your account.

The On-Demand price for a Dedicated Host varies by instance family and Region. You pay per second (with a minimum of 60 seconds) for active Dedicated Host, regardless of the quantity or the size of instances that you choose to launch on it. For more information about On-Demand pricing, see Amazon EC2 Dedicated Hosts On-Demand Pricing.

You can release an On-Demand Dedicated Host at any time to stop accruing charges for it. For information about releasing a Dedicated Host, see Release Dedicated Hosts (p. 432).

Dedicated Host Reservations

Dedicated Host Reservations provide a billing discount compared to running On-Demand Dedicated Hosts. Reservations are available in three payment options:
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Dedicated Hosts

- **No Upfront**—No Upfront Reservations provide you with a discount on your Dedicated Host usage over a term and do not require an upfront payment. Available in one-year and three-year terms. Only some instance families support the three-year term for No Upfront Reservations.

- **Partial Upfront**—A portion of the reservation must be paid upfront and the remaining hours in the term are billed at a discounted rate. Available in one-year and three-year terms.

- **All Upfront**—Provides the lowest effective price. Available in one-year and three-year terms and covers the entire cost of the term upfront, with no additional future charges.

You must have active Dedicated Hosts in your account before you can purchase reservations. Each reservation can cover one or more hosts that support the same instance family in a single Availability Zone. Reservations are applied to the instance family on the host, not the instance size. If you have three Dedicated Hosts with different instances sizes (m4.xlarge, m4.medium, and m4.large) you can associate a single m4 reservation with all those Dedicated Hosts. The instance family and Availability Zone of the reservation must match that of the Dedicated Hosts you want to associate it with.

When a reservation is associated with a Dedicated Host, the Dedicated Host can't be released until the reservation's term is over.

For more information about reservation pricing, see Amazon EC2 Dedicated Hosts Pricing.

**Savings Plans**

Savings Plans are a flexible pricing model that offers significant savings over On-Demand Instances. With Savings Plans, you make a commitment to a consistent amount of usage, in USD per hour, for a term of one or three years. This provides you with the flexibility to use the Dedicated Hosts that best meet your needs and continue to save money, instead of making a commitment to a specific Dedicated Host. For more information, see the AWS Savings Plans User Guide.

**Pricing for Windows Server on Dedicated Hosts**

Subject to Microsoft licensing terms, you can bring your existing Windows Server and SQL Server licenses to Dedicated Hosts. There is no additional charge for software usage if you choose to bring your own licenses.

In addition, you can also use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts. This is common for scenarios where you have existing SQL Server licenses eligible to run on Dedicated Hosts, but need Windows Server to run the SQL Server workload. Windows Server AMIs provided by Amazon are supported on current generation instance types (p. 194) only. For more information, see Amazon EC2 Dedicated Hosts Pricing.

**Work with Dedicated Hosts**

To use a Dedicated Host, you first allocate hosts for use in your account. You then launch instances onto the hosts by specifying host tenancy for the instance. You must select a specific host for the instance to launch on to, or you can allow it to launch on to any host that has auto-placement enabled and matches its instance type. When an instance is stopped and restarted, the Host affinity setting determines whether it's restarted on the same, or a different, host.

If you no longer need an On-Demand host, you can stop the instances running on the host, direct them to launch on a different host, and then release the host.

Dedicated Hosts are also integrated with AWS License Manager. With License Manager, you can create a host resource group, which is a collection of Dedicated Hosts that are managed as a single entity. When creating a host resource group, you specify the host management preferences, such as auto-allocate and auto-release, for the Dedicated Hosts. This allows you to launch instances onto Dedicated Hosts without manually allocating and managing those hosts. For more information, see Host Resource Groups in the AWS License Manager User Guide.
Allocate Dedicated Hosts

To begin using Dedicated Hosts, you must allocate Dedicated Hosts in your account using the Amazon EC2 console or the command line tools. After you allocate the Dedicated Host, the Dedicated Host capacity is made available in your account immediately and you can start launching instances onto the Dedicated Host.

Support for multiple instance sizes of the same instance family on the same Dedicated Host is available for the following instance families: c5, m5, r5, c5n, r5n, and m5n. Other instance families support only one instance size on the same Dedicated Host.

Due to a hardware limitation with N-type Dedicated Hosts, such as C5n, M5n, and R5n, you cannot mix smaller instance sizes (large, xlarge, and 2xlarge) with larger instance sizes (4xlarge, 9xlarge, 18xlarge, and metal). If you require smaller and larger instance sizes on N-type hosts at the same time, you must allocate separate hosts for the smaller and larger instance sizes.

You can allocate a Dedicated Host using the following methods.

New console

**To allocate a Dedicated Host**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts and then choose Allocate Dedicated Host.
3. For Instance family, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.

   - To configure the Dedicated Host to support multiple instance types in the selected instance family, for **Support multiple instance types**, choose Enable. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the m5 instance family and choose this option, you can launch m5.large and m5.4xlarge instances onto the Dedicated Host.

   - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for Instance type, choose the
instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify m5.4xlarge as the supported instance type, you can launch only m5.4xlarge instances onto the Dedicated Host.

5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.

6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity](#).

7. To enable host recovery for the Dedicated Host, for **Host recovery**, choose **Enable**. For more information, see [Host recovery](#).

8. For **Quantity**, enter the number of Dedicated Hosts to allocate.

9. (Optional) Choose **Add tag** and enter a tag key and a tag value.

10. Choose **Allocate**.

---

Old console

**To allocate a Dedicated Host**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts, Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.

   - To configure the Dedicated Host to support multiple instance types in the selected instance family, select **Support multiple instance types**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the m5 instance family and choose this option, you can launch m5.xlarge and m5.4xlarge instances onto the Dedicated Host. The instance family must be powered by the Nitro System.

   - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify m5.4xlarge as the supported instance type, you can launch only m5.4xlarge instances onto the Dedicated Host.

5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.

6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity](#).

7. To enable host recovery for the Dedicated Host, for **Host recovery** choose **Enable**. For more information, see [Host recovery](#).

8. For **Quantity**, enter the number of Dedicated Hosts to allocate.

9. (Optional) Choose **Add Tag** and enter a tag key and a tag value.

10. Choose **Allocate host**.

---

**AWS CLI**

**To allocate a Dedicated Host**

Use the `allocate-hosts` AWS CLI command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.
aws ec2 allocate-hosts --instance-family "m5" --availability-zone "us-east-1a" --auto-placement "off" --host-recovery "on" --quantity 1

The following command allocates a Dedicated Host that supports untargeted m4.large instance launches in the eu-west-1a Availability Zone, enables host recovery, and applies a tag with a key of purpose and a value of production.

aws ec2 allocate-hosts --instance-type "m4.large" --availability-zone "eu-west-1a" --auto-placement "on" --host-recovery "on" --quantity 1 --tag-specifications 'ResourceType=dedicated-host,Tags=[[Key=purpose,Value=production]]'

PowerShell

### To allocate a Dedicated Host

Use the New-EC2Host AWS Tools for Windows PowerShell command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

PS C:\> New-EC2Host -InstanceFamily m5 -AvailabilityZone us-east-1a -AutoPlacement Off -HostRecovery On -Quantity 1

The following commands allocate a Dedicated Host that supports untargeted m4.large instance launches in the eu-west-1a Availability Zone, enable host recovery, and apply a tag with a key of purpose and a value of production.

The TagSpecification parameter used to tag a Dedicated Host on creation requires an object that specifies the type of resource to be tagged, the tag key, and the tag value. The following commands create the required object.

PS C:\> $tag = @{ Key="purpose"; Value="production" }
PS C:\> $tagspec = new-object Amazon.EC2.Model.TagSpecification
PS C:\> $tagspec.ResourceType = "dedicated-host"
PS C:\> $tagspec.Tags.Add($tag)

The following command allocates the Dedicated Host and applies the tag specified in the $tagspec object.

PS C:\> New-EC2Host -InstanceType m4.large -AvailabilityZone eu-west-1a -AutoPlacement On -HostRecovery On -Quantity 1 -TagSpecification $tagspec

### Launch instances onto a Dedicated Host

After you have allocated a Dedicated Host, you can launch instances onto it. You can't launch instances with host tenancy if you do not have active Dedicated Hosts with enough available capacity for the instance type that you are launching.

**Note**

The instances launched onto Dedicated Hosts can only be launched in a VPC. For more information, see [Introduction to VPC](#).

Before you launch your instances, take note of the limitations. For more information, see [Dedicated Hosts restrictions](#).

You can launch an instance onto a Dedicated Host using the following methods.
To launch an instance onto a specific Dedicated Host from the Dedicated Hosts page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Dedicated Hosts in the navigation pane.
3. On the Dedicated Hosts page, select a host and choose Actions, Launch Instance(s) onto Host.
4. Select an AMI from the list. SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.
5. On the Choose an Instance Type page, select the instance type to launch and then choose Next: Configure Instance Details.

If the Dedicated Host supports a single instance type only, the supported instance type is selected by default and can't be changed.

If the Dedicated Host supports multiple instance types, you must select an instance type within the supported instance family based on the available instance capacity of the Dedicated Host. We recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

6. On the Configure Instance Details page, configure the instance settings to suit your needs, and then for Affinity, choose one of the following options:

   - Off—The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
   - Host—If stopped, the instance always restarts on this specific host.

For more information about Affinity, see Understand auto-placement and affinity (p. 424).

The Tenancy and Host options are pre-configured based on the host that you selected.
9. When prompted, select an existing key pair or create a new one, and then choose Launch Instances.

To launch an instance onto a Dedicated Host using the Launch Instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, Launch Instance.
3. Select an AMI from the list. SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.
4. Select the type of instance to launch and choose Next: Configure Instance Details.
5. On the Configure Instance Details page, configure the instance settings to suit your needs, and then configure the following settings, which are specific to a Dedicated Host:

   - Tenancy—Choose Dedicated Host - Launch this instance on a Dedicated Host.
   - Host—Choose either Use auto-placement to launch the instance on any Dedicated Host that has auto-placement enabled, or select a specific Dedicated Host in the list. The list displays only Dedicated Hosts that support the selected instance type.
   - Affinity—Choose one of the following options:

     - Off—The instance launches onto the specified host, but it is not guaranteed to restart on it if stopped.
     - Host—If stopped, the instance always restarts on the specified host.
For more information, see Understand auto-placement and affinity (p. 424).

If you are unable to see these settings, check that you have selected a VPC in the Network menu.

8. When prompted, select an existing key pair or create a new one, and then choose Launch Instances.

AWS CLI

To launch an instance onto a Dedicated Host

Use the run-instances AWS CLI command and specify the instance affinity, tenancy, and host in the Placement request parameter.

PowerShell

To launch an instance onto a Dedicated Host

Use the New-EC2Instance AWS Tools for Windows PowerShell command and specify the instance affinity, tenancy, and host in the Placement request parameter.

Launch instances into a host resource group

When you launch an instance into a host resource group that has a Dedicated Host with available instance capacity, Amazon EC2 launches the instance onto that host. If the host resource group does not have a host with available instance capacity, Amazon EC2 automatically allocates a new host in the host resource group, and then launches the instance onto that host. For more information, see Host Resource Groups in the AWS License Manager User Guide.

Requirements and limits

- You must associate a core- or socket-based license configuration with the AMI.
- You can't use SQL Server, SUSE, or RHEL AMIs provided by Amazon EC2 with Dedicated Hosts.
- You can't target a specific host by choosing a host ID, and you can't enable instance affinity when launching an instance into a host resource group.

You can launch an instance into a host resource group using the following methods.

New console

To launch an instance into a host resource group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, Launch Instances.
3. Select an AMI.
4. Select the type of instance to launch and choose Next: Configure Instance Details.
5. On the Configure Instance Details page, configure the instance settings to suit your needs, and then do the following:
   a. For Tenancy, choose Dedicated Host.
   b. For Host resource group, choose Launch instance into a host resource group.
c. For **Host resource group name**, choose the host resource group in which to launch the instance.

6. Choose **Review and Launch**.

7. On the **Review Instance Launch** page, choose **Launch**.

8. When prompted, select an existing key pair or create a new one, and then choose **Launch Instances**.

**Old console**

**To launch an instance into a host resource group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, **Launch Instance**.
3. Select an AMI.
4. Select the type of instance to launch and choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, configure the instance settings to suit your needs, and then do the following:
   a. For **Tenancy**, choose **Dedicated Host**.
   b. For **Host resource group**, choose **Launch instance into a host resource group**.
   c. For **Host resource group name**, choose the host resource group in which to launch the instance.

6. Choose **Review and Launch**.

7. On the **Review Instance Launch** page, choose **Launch**.

8. When prompted, select an existing key pair or create a new one, and then choose **Launch Instances**.

**AWS CLI**

**To launch an instance into a host resource group**

Use the `run-instances` AWS CLI command, and in the `Placement` request parameter, omit the Tenancy option and specify the host resource group ARN.

**PowerShell**

**To launch an instance into a host resource group**

Use the `New-EC2Instance` AWS Tools for Windows PowerShell command, and in the `Placement` request parameter, omit the Tenancy option and specify the host resource group ARN.

**Understand auto-placement and affinity**

Placement control for Dedicated Hosts happens on both the instance level and host level.

**Auto-placement**

Auto-placement is configured at the host level. It allows you to manage whether instances that you launch are launched onto a specific host, or onto any available host that has matching configurations.

When the auto-placement of a Dedicated Host is *disabled*, it only accepts *Host* tenancy instance launches that specify its unique host ID. This is the default setting for new Dedicated Hosts.

When the auto-placement of a Dedicated Host is *enabled*, it accepts any untargeted instance launches that match its instance type configuration.
When launching an instance, you need to configure its tenancy. Launching an instance onto a Dedicated Host without providing a specific HostId enables it to launch on any Dedicated Host that has auto-placement enabled and that matches its instance type.

**Host affinity**

Host affinity is configured at the instance level. It establishes a launch relationship between an instance and a Dedicated Host.

When affinity is set to Host, an instance launched onto a specific host always restarts on the same host if stopped. This applies to both targeted and untargeted launches.

When affinity is set to Off, and you stop and restart the instance, it can be restarted on any available host. However, it tries to launch back onto the last Dedicated Host on which it ran (on a best-effort basis).

**Modify Dedicated Host auto-placement**

You can modify the auto-placement settings of a Dedicated Host after you have allocated it to your AWS account, using one of the following methods.

New console

**To modify the auto-placement of a Dedicated Host**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select a host and choose Actions, Modify host.
4. For Instance auto-placement, choose Enable to enable auto-placement, or clear Enable to disable auto-placement. For more information, see Understand auto-placement and affinity (p. 424).
5. Choose Save.

Old console

**To modify the auto-placement of a Dedicated Host**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Dedicated Hosts in the navigation pane.
3. On the Dedicated Hosts page, select a host and choose Actions, Modify Auto-Placement.
4. On the Modify Auto-placement window, for Allow instance auto-placement, choose Yes to enable auto-placement, or choose No to disable auto-placement. For more information, see Understand auto-placement and affinity (p. 424).
5. Choose Save.

AWS CLI

**To modify the auto-placement of a Dedicated Host**

Use the modify-hosts AWS CLI command. The following example enables auto-placement for the specified Dedicated Host.

```
aws ec2 modify-hosts --auto-placement on --host-ids h-012a3456b7890cdef
```
PowerShell

**To modify the auto-placement of a Dedicated Host**

Use the `Edit-EC2Host` AWS Tools for Windows PowerShell command. The following example enables auto-placement for the specified Dedicated Host.

```
PS C:\> Edit-EC2Host --AutoPlacement 1 --HostId h-012a3456b7890cdef
```

**Modify the supported instance types**

Support for multiple instance types on the same Dedicated Host is available for the following instance families: `c5`, `m5`, `r5`, `c5n`, `r5n`, and `m5n`. Other instance families support only a single instance type on the same Dedicated Host.

You can allocate a Dedicated Host using the following methods.

You can modify a Dedicated Host to change the instance types that it supports. If it currently supports a single instance type, you can modify it to support multiple instance types within that instance family. Similarly, if it currently supports multiple instance types, you can modify it to support a specific instance type only.

To modify a Dedicated Host to support multiple instance types, you must first stop all running instances on the host. The modification takes approximately 10 minutes to complete. The Dedicated Host transitions to the `pending` state while the modification is in progress. You can't start stopped instances or launch new instances on the Dedicated Host while it is in the `pending` state.

To modify a Dedicated Host that supports multiple instance types to support only a single instance type, the host must either have no running instances, or the running instances must be of the instance type that you want the host to support. For example, to modify a host that supports multiple instance types in the `m5` instance family to support only `m5.large` instances, the Dedicated Host must either have no running instances, or it must have only `m5.large` instances running on it.

You can modify the supported instance types using one of the following methods.

**New console**

**To modify the supported instance types for a Dedicated Host**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the Navigation pane, choose Dedicated Host.
3. Select the Dedicated Host to modify and choose Actions, Modify host.
4. Do one of the following, depending on the current configuration of the Dedicated Host:
   - If the Dedicated Host currently supports a specific instance type, **Support multiple instance types** is not enabled, and **Instance type** lists the supported instance type. To modify the host to support multiple types in the current instance family, for **Support multiple instance types**, choose Enable.
   - You must first stop all instances running on the host before modifying it to support multiple instance types.
   - If the Dedicated Host currently supports multiple instance types in an instance family, **Enabled** is selected for **Support multiple instance types**. To modify the host to support a specific instance type, for **Support multiple instance types**, clear **Enable**, and then for **Instance type**, select the specific instance type to support.
   - You can't change the instance family supported by the Dedicated Host.
5. Choose Save.

Old console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the Navigation pane, choose Dedicated Host.
3. Select the Dedicated Host to modify and choose Actions, Modify Supported Instance Types.
4. Do one of the following, depending on the current configuration of the Dedicated Host:

   • If the Dedicated Host currently supports a specific instance type, No is selected for Support multiple instance types. To modify the host to support multiple types in the current instance family, for Support multiple instance types, select Yes.

   You must first stop all instances running on the host before modifying it to support multiple instance types.

   • If the Dedicated Host currently supports multiple instance types in an instance family, Yes is selected for Support multiple instance types, and Instance family displays the supported instance family. To modify the host to support a specific instance type, for Support multiple instance types, select No, and then for Instance type, select the specific instance type to support.

   You can't change the instance family supported by the Dedicated Host.
5. Choose Save.

AWS CLI

To modify the supported instance types for a Dedicated Host

Use the modify-hosts AWS CLI command.

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```bash
aws ec2 modify-hosts --instance-family m5 --host-ids h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```bash
aws ec2 modify-hosts --instance-type m5.xlarge --instance-family --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the supported instance types for a Dedicated Host

Use the Edit-EC2Host AWS Tools for Windows PowerShell command.

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```powershell
PS C:\> Edit-EC2Host --InstanceFamily m5 --HostId h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```powershell
PS C:\> Edit-EC2Host --InstanceType m5.xlarge --HostId h-012a3456b7890cdef
```
Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
Dedicated Hosts

Modify instance tenancy and affinity

You can change the tenancy of an instance from dedicated to host, or from host to dedicated, after you have launched it. You can also modify the affinity between the instance and the host. To modify either instance tenancy or affinity, the instance must be in the stopped state.

You can modify an instance's tenancy and affinity using the following methods.

Console

To modify instance tenancy or affinity

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Instances, and select the instance to modify.
3. Choose Instance state, Stop.
4. Open the context (right-click) menu on the instance and choose Instance Settings, Modify Instance Placement.
5. On the Modify Instance Placement page, configure the following:
   - **Tenancy**—Choose one of the following:
     - Run a dedicated hardware instance—Launches the instance as a Dedicated Instance. For more information, see Dedicated Instances (p. 446).
     - Launch the instance on a Dedicated Host—Launches the instance onto a Dedicated Host with configurable affinity.
   - **Affinity**—Choose one of the following:
     - This instance can run on any one of my hosts—The instance launches onto any available Dedicated Host in your account that supports its instance type.
     - This instance can only run on the selected host—The instance is only able to run on the Dedicated Host selected for Target Host.
   - **Target Host**—Select the Dedicated Host that the instance must run on. If no target host is listed, you might not have available, compatible Dedicated Hosts in your account.

   For more information, see Understand auto-placement and affinity (p. 424).
6. Choose Save.

AWS CLI

To modify instance tenancy or affinity

Use the modify-instance-placement AWS CLI command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```bash
aws ec2 modify-instance-placement --instance-id i-1234567890abcdef0 --affinity host --host-id h-012a3456b7890cdef
```

PowerShell

To modify instance tenancy or affinity

Use the Edit-EC2InstancePlacement AWS Tools for Windows PowerShell command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.
View Dedicated Hosts

You can view details about a Dedicated Host and the individual instances on it using the following methods.

New console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. On the Dedicated Hosts page, select a host.
4. For information about the host, choose Details.

Available vCPUs indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose Running instances.

Old console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. On the Dedicated Hosts page, select a host.
4. For information about the host, choose Description. Available vCPUs indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose Instances.

AWS CLI

To view the capacity of a Dedicated Host

Use the describe-hosts AWS CLI command.

The following example uses the describe-hosts (AWS CLI) command to view the available instance capacity for a Dedicated Host that supports multiple instance types within the c5 instance family. The Dedicated Host already has two c5.4xlarge instances and four c5.2xlarge instances running on it.

```bash
$ aws ec2 describe-hosts --host-id h-012a3456b7890cdef

"AvailableInstanceCapacity": [...
```
PowerShell

To view the instance capacity of a Dedicated Host

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

Tag Dedicated Hosts

You can assign custom tags to your existing Dedicated Hosts to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host based on the custom tags that you assigned. Dedicated Host tags can also be used for cost allocation tracking.

You can also apply tags to Dedicated Hosts at the time of creation. For more information, see Allocate Dedicated Hosts (p. 419).

You can tag a Dedicated Host using the following methods.

New console

To tag a Dedicated Host

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host to tag, and then choose Actions, Manage tags.
4. In the Manage tags screen, choose Add tag, and then specify the key and value for the tag.
5. (Optional) Choose Add tag to add additional tags to the Dedicated Host.
6. Choose Save changes.

Old console

To tag a Dedicated Host

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host to tag, and then choose Tags.
4. Choose Add/Edit Tags.
5. In the Add/Edit Tags dialog box, choose Create Tag, and then specify the key and value for the tag.
6. (Optional) Choose Create Tag to add additional tags to the Dedicated Host.
7. Choose Save.
AWS CLI

To tag a Dedicated Host

Use the `create-tags` AWS CLI command.

The following command tags the specified Dedicated Host with `Owner=TeamA`.

```
aws ec2 create-tags --resources h-abc12345678909876 --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host

Use the `New-EC2Tag` AWS Tools for Windows PowerShell command.

The `New-EC2Tag` command needs a `Tag` object, which specifies the key and value pair to be used for the Dedicated Host tag. The following commands create a `Tag` object named `$tag`, with a key and value pair of `Owner` and `TeamA` respectively.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

The following command tags the specified Dedicated Host with the `$tag` object.

```
PS C:\> New-EC2Tag -Resource h-abc12345678909876 -Tag $tag
```

Monitor Dedicated Hosts

Amazon EC2 constantly monitors the state of your Dedicated Hosts. Updates are communicated on the Amazon EC2 console. You can view information about a Dedicated Host using the following methods.

Console

To view the state of a Dedicated Host

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Dedicated Hosts.
3. Locate the Dedicated Host in the list and review the value in the State column.

AWS CLI

To view the state of a Dedicated Host

Use the `describe-hosts` AWS CLI command and then review the state property in the `hostSet` response element.

```
aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

PowerShell

To view the state of a Dedicated Host

Use the `Get-EC2Host` AWS Tools for Windows PowerShell command and then review the state property in the `hostSet` response element.
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef

The following table explains the possible Dedicated Host states.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>available</td>
<td>AWS hasn't detected an issue with the Dedicated Host. No maintenance or repairs are scheduled. Instances can be launched onto this Dedicated Host.</td>
</tr>
<tr>
<td>released</td>
<td>The Dedicated Host has been released. The host ID is no longer in use. Released hosts can't be reused.</td>
</tr>
<tr>
<td>under-assessment</td>
<td>AWS is exploring a possible issue with the Dedicated Host. If action must be taken, you are notified via the AWS Management Console or email. Instances can't be launched onto a Dedicated Host in this state.</td>
</tr>
<tr>
<td>pending</td>
<td>The Dedicated Host cannot be used for new instance launches. It is either being modified to support multiple instance types (p. 426), or a host recovery (p. 440) is in progress.</td>
</tr>
<tr>
<td>permanent-failure</td>
<td>An unrecoverable failure has been detected. You receive an eviction notice through your instances and by email. Your instances might continue to run. If you stop or terminate all instances on a Dedicated Host with this state, AWS retires the host. AWS does not restart instances in this state. Instances can't be launched onto Dedicated Hosts in this state.</td>
</tr>
<tr>
<td>released-permanent-failure</td>
<td>AWS permanently releases Dedicated Hosts that have failed and no longer have running instances on them. The Dedicated Host ID is no longer available for use.</td>
</tr>
</tbody>
</table>

### Release Dedicated Hosts

Any running instances on the Dedicated Host must be stopped before you can release the host. These instances can be migrated to other Dedicated Hosts in your account so that you can continue to use them. These steps apply only to On-Demand Dedicated Hosts.

You can release a Dedicated Host using the following methods.

**New console**

**To release a Dedicated Host**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions**, **Release host**.
5. To confirm, choose **Release**.

**Old console**

**To release a Dedicated Host**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions**, **Release Hosts**.
5. Choose **Release** to confirm.

### AWS CLI

**To release a Dedicated Host**

Use the `release-hosts` AWS CLI command.

```
aws ec2 release-hosts --host-ids h-012a3456b7890cdef
```

### PowerShell

**To release a Dedicated Host**

```
PS C:\> Remove-EC2Hosts -HostId $HostId
```

After you release a Dedicated Host, you can't reuse the same host or host ID again, and you are no longer charged On-Demand billing rates for it. The state of the Dedicated Host is changed to `released`, and you are not able to launch any instances onto that host.

**Note**

If you have recently released Dedicated Hosts, it can take some time for them to stop counting towards your limit. During this time, you might experience `LimitExceeded` errors when trying to allocate new Dedicated Hosts. If this is the case, try allocating new hosts again after a few minutes.

The instances that were stopped are still available for use and are listed on the **Instances** page. They retain their host tenancy setting.

### Purchase Dedicated Host Reservations

You can purchase reservations using the following methods:

#### Console

**To purchase reservations**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Dedicated Hosts**, **Dedicated Host Reservations**, **Purchase Dedicated Host Reservation**.
3. On the **Purchase Dedicated Host Reservation** screen, you can search for available offerings using the default settings, or you can specify custom values for the following:
   - **Host instance family**—The options listed correspond with the Dedicated Hosts in your account that are not already assigned to a reservation.
   - **Availability Zone**—The Availability Zone of the Dedicated Hosts in your account that aren’t already assigned to a reservation.
   - **Payment option**—The payment option for the offering.
   - **Term**—The term of the reservation, which can be one or three years.
4. Choose **Find offering** and select an offering that matches your requirements.
5. Choose the Dedicated Hosts to associate with the reservation, and then choose Review.
6. Review your order and choose Order.

AWS CLI

To purchase reservations

1. Use the describe-host-reservation-offerings AWS CLI command to list the available offerings that match your needs. The following example lists the offerings that support instances in the m4 instance family and have a one-year term.

   ```bash
   aws ec2 describe-host-reservation-offerings --filter Name=instance-family,Values=m4 --max-duration 31536000
   ```

   The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

2. Use the purchase-host-reservation AWS CLI command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account, and it applies a tag with a key of purpose and a value of production.

   ```bash
   aws ec2 purchase-host-reservation --offering-id hro-03f707bf363b6b324 --host-id-set h-013abcd2000cbd123 --tag-specifications 'ResourceType=host-reservation,Tags={Key=purpose,Value=production}'
   ```

PowerShell

To purchase reservations

1. Use the Get-EC2HostReservationOffering AWS Tools for Windows PowerShell command to list the available offerings that match your needs. The following examples list the offerings that support instances in the m4 instance family and have a one-year term.

   ```powershell
   PS C:\> $filter = @{Name="instance-family"; Value="m4"}
   PS C:\> Get-EC2HostReservationOffering -filter $filter -MaxDuration 31536000
   ```

   The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

2. Use the New-EC2HostReservation AWS Tools for Windows PowerShell command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account.

   ```powershell
   PS C:\> New-EC2HostReservation -OfferingId hro-03f707bf363b6b324 -HostIdSet h-013abcd2000cbd123
   ```
View Dedicated Host reservations

You can view information about the Dedicated Hosts that are associated with your reservation, including:

- The term of the reservation
- The payment option
- The start and end dates

You can view details of your Dedicated Host reservations using the following methods.

Console

To view the details of a Dedicated Host reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Dedicated Hosts in the navigation pane.
3. On the Dedicated Hosts page, choose Dedicated Host Reservations, and then select the reservation from the list provided.
4. Choose Details for information about the reservation.
5. Choose Hosts for information about the Dedicated Hosts with which the reservation is associated.

AWS CLI

To view the details of a Dedicated Host reservation

Use the describe-host-reservations AWS CLI command.

```
aws ec2 describe-host-reservations
```

PowerShell

To view the details of a Dedicated Host reservation

Use the Get-EC2HostReservation AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2HostReservation
```

Tag Dedicated Host Reservations

You can assign custom tags to your Dedicated Host Reservations to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host Reservation based on the custom tags that you assigned.

You can tag a Dedicated Host Reservation using the command line tools only.

AWS CLI

To tag a Dedicated Host Reservation

Use the create-tags AWS CLI command.

```
aws ec2 create-tags --resources hr-1234563a4ff6c669ae --tags Key=Owner,Value=TeamA
```
PowerShell

To tag a Dedicated Host Reservation

Use the New-EC2Tag AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag parameter, which specifies the key and value pair to be used for the Dedicated Host Reservation tag. The following commands create the Tag parameter.

```powershell
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

```powershell
PS C:\> New-EC2Tag -Resource hr-123456789abcdef -Tag $tag
```

Work with shared Dedicated Hosts

Dedicated Host sharing enables Dedicated Host owners to share their Dedicated Hosts with other AWS accounts or within an AWS organization. This enables you to create and manage Dedicated Hosts centrally, and share the Dedicated Host across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Dedicated Host (owner) shares it with other AWS accounts (consumers). Consumers can launch instances onto Dedicated Hosts that are shared with them in the same way that they would launch instances onto Dedicated Hosts that they allocate in their own account. The owner is responsible for managing the Dedicated Host and the instances that they launch onto it. Owners can't modify instances that consumers launch onto shared Dedicated Hosts. Consumers are responsible for managing the instances that they launch onto Dedicated Hosts shared with them. Consumers can't view or modify instances owned by other consumers or by the Dedicated Host owner, and they can't modify Dedicated Hosts that are shared with them.

A Dedicated Host owner can share a Dedicated Host with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

- Billing and metering (p. 440)
- Dedicated Host limits (p. 440)
- Host recovery and Dedicated Host sharing (p. 440)
Prerequisites for sharing Dedicated Hosts

- To share a Dedicated Host, you must own it in your AWS account. You can’t share a Dedicated Host that has been shared with you.
- To share a Dedicated Host with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see Enable Sharing with AWS Organizations in the AWS RAM User Guide.

Limitations for sharing Dedicated Hosts

You can’t share Dedicated Hosts that have been allocated for the following instance types:
- u-6tb1.metal
- u-9tb1.metal
- u-12tb1.metal
- u-18tb1.metal
- u-24tb1.metal

Related services

AWS Resource Access Manager

Dedicated Host sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a resource share. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the AWS RAM User Guide.

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone us-east-1a for your AWS account might not have the same location as us-east-1a for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the Availability Zone ID (AZ ID). The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, use1-az1 is an Availability Zone ID for the us-east-1 Region and it is the same location in every AWS account.

To view the Availability Zone IDs for the Availability Zones in your account

2. The Availability Zone IDs for the current Region are displayed in the Your AZ ID panel on the right-hand side of the screen.

Share a Dedicated Host

When an owner shares a Dedicated Host, it enables consumers to launch instances on the host. Consumers can launch as many instances onto the shared host as its available capacity allows.

Important
Note that you are responsible for ensuring that you have appropriate license rights to share any BYOL licenses on your Dedicated Hosts.

If you share a Dedicated Host with auto-placement enabled, keep the following in mind as it could lead to unintended Dedicated Host usage:

- If consumers launch instances with Dedicated Host tenancy and they do not have capacity on a Dedicated Host that they own in their account, the instance is automatically launched onto the shared Dedicated Host.
To share a Dedicated Host, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. You can add the Dedicated Host to an existing resource, or you can add it to a new resource share.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Dedicated Host. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Dedicated Host after accepting the invitation.

**Note**
After you share a Dedicated Host, it could take a few minutes for consumers to have access to it.

You can share a Dedicated Host that you own by using one of the following methods.

**Amazon EC2 console**

**To share a Dedicated Host that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to share and choose **Actions, Share host**.
4. Select the resource share to which to add the Dedicated Host and choose **Share host**.
   
   It could take a few minutes for consumers to get access to the shared host.

**AWS RAM console**

**To share a Dedicated Host that you own using the AWS RAM console**

**AWS CLI**

**To share a Dedicated Host that you own using the AWS CLI**

Use the `create-resource-share` command.

**Unshare a shared Dedicated Host**

The Dedicated Host owner can unshare a shared Dedicated Host at any time. When you unshare a shared Dedicated Host, the following rules apply:

- Consumers with whom the Dedicated Host was shared can no longer launch new instances onto it.
- Instances owned by consumers that were running on the Dedicated Host at the time of unsharing continue to run but are scheduled for retirement. Consumers receive retirement notifications for the instances and they have two weeks to take action on the notifications. However, if the Dedicated Host is resharred with the consumer within the retirement notice period, the instance retirements are cancelled.

To unshare a shared Dedicated Host that you own, you must remove it from the resource share. You can do this by using one of the following methods.

**Amazon EC2 console**

**To unshare a shared Dedicated Host that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to unshare and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Dedicated Host has been added. Select the resource share from which to remove the Dedicated Host and choose **Remove host from resource share**.

**AWS RAM console**

**To unshare a shared Dedicated Host that you own using the AWS RAM console**

See **Updating a Resource Share** in the *AWS RAM User Guide*.

**Command line**

**To unshare a shared Dedicated Host that you own using the AWS CLI**

Use the `disassociate-resource-share` command.

### Identify a shared Dedicated Host

Owners and consumers can identify shared Dedicated Hosts using one of the following methods.

**Amazon EC2 console**

**To identify a shared Dedicated Host using the Amazon EC2 console**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Dedicated Hosts**. The screen lists Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The **Owner** column shows the AWS account ID of the Dedicated Host owner.

**Command line**

**To identify a shared Dedicated Host using the AWS CLI**

Use the `describe-hosts` command. The command returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you.

### View instances running on a shared Dedicated Host

Owners and consumers can view the instances running on a shared Dedicated Host at any time using one of the following methods.

**Amazon EC2 console**

**To view the instances running on a shared Dedicated Host using the Amazon EC2 console**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to view the instances and choose **Instances**. The tab lists the instances that are running on the host. Owners see all of the instances running on the host, including instances launched by consumers. Consumers only see running instances that they launched onto the host. The **Owner** column shows the AWS account ID of the account that launched the instance.
Command line

To view the instances running on a shared Dedicated Host using the AWS CLI

Use the `describe-hosts` command. The command returns the instances running on each Dedicated Host. Owners see all of the instances running on the host. Consumers only see running instances that they launched on the shared hosts. `InstanceOwnerId` shows the AWS account ID of the instance owner.

Shared Dedicated Host permissions

Permissions for owners

Owners are responsible for managing their shared Dedicated Hosts and the instances that they launch onto them. Owners can view all instances running on the shared Dedicated Host, including those launched by consumers. However, owners can’t take any action on running instances that were launched by consumers.

Permissions for consumers

Consumers are responsible for managing the instances that they launch onto a shared Dedicated Host. Consumers can’t modify the shared Dedicated Host in any way, and they can’t view or modify instances that were launched by other consumers or the Dedicated Host owner.

Billing and metering

There are no additional charges for sharing Dedicated Hosts.

Owners are billed for Dedicated Hosts that they share. Consumers are not billed for instances that they launch onto shared Dedicated Hosts.

Dedicated Host Reservations continue to provide billing discounts for shared Dedicated Hosts. Only Dedicated Host owners can purchase Dedicated Host Reservations for shared Dedicated Hosts that they own.

Dedicated Host limits

Shared Dedicated Hosts count towards the owner's Dedicated Hosts limits only. Consumer's Dedicated Hosts limits are not affected by Dedicated Hosts that have been shared with them. Similarly, instances that consumers launch onto shared Dedicated Hosts do not count towards their instance limits.

Host recovery and Dedicated Host sharing

Host recovery recovers instances launched by the Dedicated Host owner and the consumers with whom it has been shared. The replacement Dedicated Host is allocated to the owner's account. It is added to the same resource shares as the original Dedicated Host, and it is shared with the same consumers.

For more information, see Host recovery (p. 440).

Host recovery

Host recovery automatically restarts your instances on to a new replacement host if failures are detected on your Dedicated Host. Host recovery reduces the need for manual intervention and lowers the operational burden if there is an unexpected Dedicated Host failure.

Additionally, built-in integration with AWS License Manager automates the tracking and management of your licenses if a host recovery occurs.

Note

AWS License Manager integration is supported only in Regions in which AWS License Manager is available.
Host recovery basics

Host recovery uses host-level health checks to assess Dedicated Host availability and to detect underlying system failures. Examples of problems that can cause host-level health checks to fail include:

- Loss of network connectivity
- Loss of system power
- Hardware or software issues on the physical host

When a system failure is detected on your Dedicated Host, host recovery is initiated and Amazon EC2 automatically allocates a replacement Dedicated Host. The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Availability Zone
- Instance type
- Tags
- Auto placement settings

After the replacement Dedicated Host is allocated, the instances are recovered on to the replacement Dedicated Host. The recovered instances retain the same attributes as the original instances, including:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- EBS volume attachments
- All instance metadata

If instances have a host affinity relationship with the impaired Dedicated Host, the recovered instances establish host affinity with the replacement Dedicated Host.

When all of the instances have been recovered on to the replacement Dedicated Host, the impaired Dedicated Host is released, and the replacement Dedicated Host becomes available for use.

When host recovery is initiated, the AWS account owner is notified by email and by an AWS Personal Health Dashboard event. A second notification is sent after the host recovery has been successfully completed.

Stopped instances are not recovered on to the replacement Dedicated Host. If you attempt to start a stopped instance that targets the impaired Dedicated Host, the instance start fails. We recommend that you modify the stopped instance to either target a different Dedicated Host, or to launch on any available Dedicated Host with matching configurations and auto-placement enabled.
Instances with instance storage are not recovered on to the replacement Dedicated Host. As a remedial measure, the impaired Dedicated Host is marked for retirement and you receive a retirement notification after the host recovery is complete. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the remaining instances on the impaired Dedicated Host.

If you are using AWS License Manager to track your licenses, AWS License Manager allocates new licenses for the replacement Dedicated Host based on the license configuration limits. If the license configuration has hard limits that will be breached as a result of the host recovery, the recovery process is not allowed and you are notified of the host recovery failure through an Amazon SNS notification. If the license configuration has soft limits that will be breached as a result of the host recovery, the recovery is allowed to continue and you are notified of the limit breach through an Amazon SNS notification. For more information, see Using License Configurations in the AWS License Manager User Guide.

Supported instance types

Host recovery is supported for the following instance families: A1, C3, C4, C5, C5n, C6g, Inf1, M3, M4, M5, M5n, M6g, P3, R3, R4, R5, R5n, R6g, X1, X1e, X2gd, u-6tb1, u-9tb1, u-12tb1, u-18tb1, and u-24tb1.

To recover instances that are not supported, see Manually recover unsupported instances (p. 443).

Configure host recovery

You can configure host recovery at the time of Dedicated Host allocation, or after allocation using the Amazon EC2 console or AWS Command Line Interface (CLI).

Enable host recovery

You can enable host recovery at the time of Dedicated Host allocation or after allocation.

For more information about enabling host recovery at the time of Dedicated Host allocation, see Allocate Dedicated Hosts (p. 419).

To enable host recovery after allocation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host for which to enable host recovery, and then choose Actions, Modify Host Recovery.
4. For Host recovery, choose Enable, and then choose Save.

To enable host recovery after allocation using the AWS CLI

Use the modify-hosts command and specify the host-recovery parameter.

```
$ aws ec2 modify-hosts --host-recovery on --host-ids h-012a3456b7890cdef
```

Disable host recovery

You can disable host recovery at any time after the Dedicated Host has been allocated.
To disable host recovery after allocation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host for which to disable host recovery, and then choose Actions, Modify Host Recovery.
4. For Host recovery, choose Disable, and then choose Save.

To disable host recovery after allocation using the AWS CLI

Use the modify-hosts command and specify the host-recovery parameter.

```bash
$ aws ec2 modify-hosts --host-recovery off --host-ids h-012a3456b7890cdef
```

View the host recovery configuration

You can view the host recovery configuration for a Dedicated Host at any time.

To view the host recovery configuration for a Dedicated Host using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host, and in the Description tab, review the Host Recovery field.

To view the host recovery configuration for a Dedicated Host using the AWS CLI

Use the describe-hosts command.

```bash
$ aws ec2 describe-hosts --host-ids h-012a3456b7890cdef
```

The HostRecovery response element indicates whether host recovery is enabled or disabled.

Host recovery states

When a Dedicated Host failure is detected, the impaired Dedicated Host enters the under-assessment state, and all of the instances enter the impaired state. You can't launch instances on to the impaired Dedicated Host while it is in the under-assessment state.

After the replacement Dedicated Host is allocated, it enters the pending state. It remains in this state until the host recovery process is complete. You can't launch instances on to the replacement Dedicated Host while it is in the pending state. Recovered instances on the replacement Dedicated Host remain in the impaired state during the recovery process.

After the host recovery is complete, the replacement Dedicated Host enters the available state, and the recovered instances return to the running state. You can launch instances on to the replacement Dedicated Host after it enters the available state. The original impaired Dedicated Host is permanently released and it enters the released-permanent-failure state.

If the impaired Dedicated Host has instances that do not support host recovery, such as instances with instance store-backed volumes, the Dedicated Host is not released. Instead, it is marked for retirement and enters the permanent-failure state.

Manually recover unsupported instances

Host recovery does not support recovering instances that use instance store volumes. Follow the instructions below to manually recover any of your instances that could not be automatically recovered.
Warning
Data on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. To protect data from instance store volumes, back it up to persistent storage before the instance is stopped or terminated.

Manually recover EBS-backed instances
For EBS-backed instances that could not be automatically recovered, we recommend that you manually stop and start the instances to recover them onto a new Dedicated Host. For more information about stopping your instance, and about the changes that occur in your instance configuration when it's stopped, see Stop and start your instance (p. 524).

Manually recover instance store-backed instances
For instance store-backed instances that could not be automatically recovered, we recommend that you do the following:

1. Launch a replacement instance on a new Dedicated Host from your most recent AMI.
2. Migrate all of the necessary data to the replacement instance.
3. Terminate the original instance on the impaired Dedicated Host.

Related services
Dedicated Host integrates with the following services:

- **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the [AWS License Manager User Guide](#).

Pricing
There are no additional charges for using host recovery, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host recovery is initiated, you are no longer billed for the impaired Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the available state.

If the impaired Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the impaired Dedicated Host had an active Dedicated Host Reservation, it is transferred to the replacement Dedicated Host.

Track configuration changes
You can use AWS Config to record configuration changes for Dedicated Hosts, and for instances that are launched, stopped, or terminated on them. You can then use the information captured by AWS Config as a data source for license reporting.

AWS Config records configuration information for Dedicated Hosts and instances individually, and pairs this information through relationships. There are three reporting conditions:

- **AWS Config recording status**—When On, AWS Config is recording one or more AWS resource types, which can include Dedicated Hosts and Dedicated Instances. To capture the information required for license reporting, verify that hosts and instances are being recorded with the following fields.
- **Host recording status**—When Enabled, the configuration information for Dedicated Hosts is recorded.
• **Instance recording status**—When **Enabled**, the configuration information for Dedicated Instances is recorded.

If any of these three conditions are disabled, the icon in the **Edit Config Recording** button is red. To derive the full benefit of this tool, ensure that all three recording methods are enabled. When all three are enabled, the icon is green. To edit the settings, choose **Edit Config Recording**. You are directed to the **Set up AWS Config** page in the AWS Config console, where you can set up AWS Config and start recording for your hosts, instances, and other supported resource types. For more information, see **Setting up AWS Config using the Console** in the *AWS Config Developer Guide*.

**Note**
AWS Config records your resources after it discovers them, which might take several minutes.

After AWS Config starts recording configuration changes to your hosts and instances, you can get the configuration history of any host that you have allocated or released and any instance that you have launched, stopped, or terminated. For example, at any point in the configuration history of a Dedicated Host, you can look up how many instances are launched on that host, along with the number of sockets and cores on the host. For any of those instances, you can also look up the ID of its Amazon Machine Image (AMI). You can use this information to report on licensing for your own server-bound software that is licensed per-socket or per-core.

You can view configuration histories in any of the following ways:

- **By using the AWS Config console.** For each recorded resource, you can view a timeline page, which provides a history of configuration details. To view this page, choose the gray icon in the **Config Timeline** column of the **Dedicated Hosts** page. For more information, see **Viewing Configuration Details in the AWS Config Console** in the *AWS Config Developer Guide*.

- **By running AWS CLI commands.** First, you can use the `list-discovered-resources` command to get a list of all hosts and instances. Then, you can use the `get-resource-config-history` command to get the configuration details of a host or instance for a specific time interval. For more information, see **View Configuration Details Using the CLI** in the *AWS Config Developer Guide*.

- **By using the AWS Config API in your applications.** First, you can use the `ListDiscoveredResources` action to get a list of all hosts and instances. Then, you can use the `GetResourceConfigHistory` action to get the configuration details of a host or instance for a specific time interval.

For example, to get a list of all of your Dedicated Hosts from AWS Config, run a CLI command such as the following.

```bash
aws configservice list-discovered-resources --resource-type AWS::EC2::Host
```

To obtain the configuration history of a Dedicated Host from AWS Config, run a CLI command such as the following.

```bash
aws configservice get-resource-config-history --resource-type AWS::EC2::Instance --resource-id i-1234567890abcdef0
```

**To manage AWS Config settings using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the **Dedicated Hosts** page, choose **Edit Config Recording**.
3. In the AWS Config console, follow the steps provided to turn on recording. For more information, see **Setting up AWS Config using the Console**.

For more information, see **Viewing Configuration Details in the AWS Config Console**.
To activate AWS Config using the command line or API

- AWS CLI: Viewing Configuration Details (AWS CLI) in the AWS Config Developer Guide.
- Amazon EC2 API: GetResourceConfigHistory.

Dedicated Instances

Dedicated Instances are Amazon EC2 instances that run in a virtual private cloud (VPC) on hardware that's dedicated to a single customer. Dedicated Instances that belong to different AWS accounts are physically isolated at a hardware level, even if those accounts are linked to a single payer account. However, Dedicated Instances may share hardware with other instances from the same AWS account that are not Dedicated Instances.

Note

A Dedicated Host is also a physical server that's dedicated for your use. With a Dedicated Host, you have visibility and control over how instances are placed on the server. For more information, see Dedicated Hosts (p. 415).

Dedicated Instance basics

Each instance that you launch into a VPC has a tenancy attribute. This attribute has the following values.

- default
  - Your instance runs on shared hardware.
- dedicated
  - Your instance runs on single-tenant hardware.
- host
  - Your instance runs on a Dedicated Host, which is an isolated server with configurations that you can control.

After you launch an instance, there are some limitations to changing its tenancy.

- You cannot change the tenancy of an instance from default to dedicated or host after you've launched it.
- You cannot change the tenancy of an instance from dedicated or host to default after you've launched it.

You can change the tenancy of an instance from dedicated to host, or from host to dedicated after you've launched it. For more information, see Change the tenancy of an instance (p. 450).

Each VPC has a related instance tenancy attribute. This attribute has the following values.

- default
  - An instance launched into the VPC runs on shared hardware by default, unless you explicitly specify a different tenancy during instance launch.
- dedicated
  - An instance launched into the VPC is a Dedicated Instance by default, unless you explicitly specify a tenancy of host during instance launch. You cannot specify a tenancy of default during instance launch.
You can change the instance tenancy of a VPC from dedicated to default after you create it. You cannot change the instance tenancy of a VPC from default to dedicated after it is created.

To create Dedicated Instances, you can do the following:

- Create the VPC with the instance tenancy set to dedicated (all instances launched into this VPC are Dedicated Instances).
- Create the VPC with the instance tenancy set to default, and specify a tenancy of dedicated for any instances when you launch them.

**Dedicated Instances limitations**

Some AWS services or their features won't work with a VPC with the instance tenancy set to dedicated. Check the service's documentation to confirm if there are any limitations.

Some instance types cannot be launched into a VPC with the instance tenancy set to dedicated. For more information about supported instances types, see Amazon EC2 Dedicated Instances.

**Amazon EBS with Dedicated Instances**

When you launch an Amazon EBS-backed Dedicated Instance, the EBS volume doesn't run on single-tenant hardware.

**Reserved Instances with dedicated tenancy**

To guarantee that sufficient capacity is available to launch Dedicated Instances, you can purchase Dedicated Reserved Instances. For more information, see Reserved Instances (p. 325).

When you purchase a Dedicated Reserved Instance, you are purchasing the capacity to launch a Dedicated Instance into a VPC at a much reduced usage fee; the price break in the usage charge applies only if you launch an instance with dedicated tenancy. When you purchase a Reserved Instance with default tenancy, it applies only to a running instance with default tenancy; it would not apply to a running instance with dedicated tenancy.

You can't use the modification process to change the tenancy of a Reserved Instance after you've purchased it. However, you can exchange a Convertible Reserved Instance for a new Convertible Reserved Instance with a different tenancy.

**Automatic scaling of Dedicated Instances**

You can use Amazon EC2 Auto Scaling to launch Dedicated Instances. For more information, see Launching Auto Scaling Instances in a VPC in the Amazon EC2 Auto Scaling User Guide.

**Automatic recovery of Dedicated Instances**

You can configure automatic recovery for a Dedicated Instances if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. For more information, see Recover your instance (p. 554).

**Dedicated Spot Instances**

You can run a Dedicated Spot Instance by specifying a tenancy of dedicated when you create a Spot Instance request. For more information, see Specify a tenancy for your Spot Instances (p. 378).

**Pricing for Dedicated Instances**

Pricing for Dedicated Instances is different to pricing for On-Demand Instances. For more information, see the Amazon EC2 Dedicated Instances product page.
Burstable performance instances with Dedicated Instances

You can leverage the benefits of running on dedicated tenancy hardware with the section called “Burstable performance instances” (p. 216). T3 Dedicated Instances launch in unlimited mode by default, and they provide a baseline level of CPU performance with the ability to burst to a higher CPU level when required by your workload. The T3 baseline performance and ability to burst are governed by CPU credits. Because of the burstable nature of the T3 instance types, we recommend that you monitor how your T3 instances use the CPU resources of the dedicated hardware for the best performance. T3 Dedicated Instances are intended for customers with diverse workloads that display random CPU behavior, but that ideally have average CPU usage at or below the baseline usages. For more information, see the section called “Key concepts” (p. 219).

Amazon EC2 has systems in place to identify and correct variability in performance. However, it is still possible to experience short term variability if you launch multiple T3 Dedicated Instances that have correlated CPU usage patterns. For these more demanding or correlated workloads, we recommend using M5 or M5a Dedicated Instances rather than T3 Dedicated Instances.

Work with Dedicated Instances

You can create a VPC with an instance tenancy of dedicated to ensure that all instances launched into the VPC are Dedicated Instances. Alternatively, you can specify the tenancy of the instance during launch.

Topics
- Create a VPC with an instance tenancy of dedicated (p. 448)
- Launch Dedicated Instances into a VPC (p. 449)
- Display tenancy information (p. 449)
- Change the tenancy of an instance (p. 450)
- Change the tenancy of a VPC (p. 450)

Create a VPC with an instance tenancy of dedicated

When you create a VPC, you have the option of specifying its instance tenancy. If you're using the Amazon VPC console, you can create a VPC using the VPC wizard or the Your VPCs page.

To create a VPC with an instance tenancy of dedicated (VPC Wizard)

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. From the dashboard, choose Launch VPC Wizard.
3. Select a VPC configuration, and then choose Select.
4. For Hardware tenancy, choose Dedicated.
5. Choose Create VPC.

To create a VPC with an instance tenancy of dedicated (Create VPC dialog box)

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs, and then choose Create VPC.
3. For Tenancy, choose Dedicated. Specify the CIDR block, and choose Create VPC.

To set the tenancy option when you create a VPC using the command line

- create-vpc (AWS CLI)
- New-EC2Vpc (AWS Tools for Windows PowerSheel)
If you launch an instance into a VPC that has an instance tenancy of dedicated, your instance is automatically a Dedicated Instance, regardless of the tenancy of the instance.

**Launch Dedicated Instances into a VPC**

You can launch a Dedicated Instance using the Amazon EC2 launch instance wizard.

**To launch a Dedicated Instance into a default tenancy VPC using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an Amazon Machine Image (AMI) page, select an AMI and choose Select.
4. On the Choose an Instance Type page, select the instance type and choose Next: Configure Instance Details.
   
   **Note**
   
   Ensure that you choose an instance type that's supported as a Dedicated Instance. For more information, see Amazon EC2 Dedicated Instances.
5. On the Configure Instance Details page, select a VPC and subnet. For Tenancy, choose Dedicated - Run a dedicated instance, and then choose Next: Add Storage.
6. Continue as prompted by the wizard. When you've finished reviewing your options on the Review Instance Launch page, choose Launch to choose a key pair and launch the Dedicated Instance.

For more information about launching an instance with a tenancy of host, see Launch instances onto a Dedicated Host (p. 421).

**To set the tenancy option for an instance during launch using the command line**

- run-instances (AWS CLI)
- New-EC2Instance (AWS Tools for Windows PowerShell)

**Display tenancy information**

**To display tenancy information for your VPC using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Check the instance tenancy of your VPC in the Tenancy column.
4. If the Tenancy column is not displayed, choose the settings icon (⚙️) in the top-right corner, toggle on Tenancy, and choose Confirm.

**To display tenancy information for your instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Check the tenancy of your instance in the Tenancy column.
4. If the Tenancy column is not displayed, do one of the following:
   
   - Choose the settings icon (⚙️) in the top-right corner, toggle on Tenancy, and choose Confirm.
   - Select the instance. On the Details tab near the bottom of the page, under Host and placement group, check the value for Tenancy.
To describe the tenancy of your VPC using the command line

- `describe-vpcs` (AWS CLI)
- `Get-EC2Vpc` (AWS Tools for Windows PowerShell)

To describe the tenancy of your instance using the command line

- `describe-instances` (AWS CLI)
- `Get-EC2Instance` (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance using the command line

- `describe-reserved-instances` (AWS CLI)
- `Get-EC2ReservedInstance` (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance offering using the command line

- `describe-reserved-instances-offerings` (AWS CLI)
- `Get-EC2ReservedInstancesOffering` (AWS Tools for Windows PowerShell)

Change the tenancy of an instance

Depending on your instance type and platform, you can change the tenancy of a stopped Dedicated Instance to `host` after launching it. The next time the instance starts, it's started on a Dedicated Host that's allocated to your account. For more information about allocating and working with Dedicated Hosts, and the instance types that can be used with Dedicated Hosts, see Work with Dedicated Hosts (p. 418). Similarly, you can change the tenancy of a stopped Dedicated Host instance to `dedicated` after launching it. The next time the instance starts, it's started on single-tenant hardware that we control.

To change the tenancy of an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select your instance.
3. Choose **Instance state**, **Stop instance**, **Stop**.
4. Choose **Actions**, **Instance settings**, **Modify instance placement**.
5. For **Tenancy**, choose whether to run your instance on dedicated hardware or on a Dedicated Host. Choose **Save**.

To modify the tenancy value of an instance using the command line

- `modify-instance-placement` (AWS CLI)
- `Edit-EC2InstancePlacement` (AWS Tools for Windows PowerShell)

Change the tenancy of a VPC

You can change the instance tenancy attribute of a VPC from `dedicated` to `default`. Modifying the instance tenancy of the VPC does not affect the tenancy of any existing instances in the VPC. The next time you launch an instance in the VPC, it has a tenancy of `default`, unless you specify otherwise during launch.

You cannot change the tenancy attribute of a VPC from `default` to `dedicated` after it is created.
You can modify the instance tenancy attribute of a VPC using the AWS CLI, an AWS SDK, or the Amazon EC2 API only.

**To modify the instance tenancy attribute of a VPC using the AWS CLI**

- Use the `modify-vpc-tenancy` command to specify the ID of the VPC and instance tenancy value. The only supported value is `default`.

```
aws ec2 modify-vpc-tenancy --vpc-id vpc-1a2b3c4d --instance-tenancy default
```

---

**On-Demand Capacity Reservations**

On-Demand Capacity Reservations enable you to reserve compute capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This gives you the ability to create and manage Capacity Reservations independently from the billing discounts offered by Savings Plans or regional Reserved Instances.

By creating Capacity Reservations, you ensure that you always have access to EC2 capacity when you need it, for as long as you need it. You can create Capacity Reservations at any time, without entering into a one-year or three-year term commitment, and the capacity is available immediately. Billing starts as soon as the capacity is provisioned and the Capacity Reservation enters the active state. When you no longer need it, cancel the Capacity Reservation to stop incurring charges.

When you create a Capacity Reservation, you specify:

- The Availability Zone in which to reserve the capacity
- The number of instances for which to reserve capacity
- The instance attributes, including the instance type, tenancy, and platform/OS

Capacity Reservations can only be used by instances that match their attributes. By default, they are automatically used by running instances that match the attributes. If you don't have any running instances that match the attributes of the Capacity Reservation, it remains unused until you launch an instance with matching attributes.

In addition, you can use Savings Plans and regional Reserved Instances with your Capacity Reservations to benefit from billing discounts. AWS automatically applies your discount when the attributes of a Capacity Reservation match the attributes of a Savings Plan or regional Reserved Instance. For more information, see Billing discounts (p. 454).

Differences between Capacity Reservations, Reserved Instances, and Savings Plans

The following table highlights key differences between Capacity Reservations, Reserved Instances, and Savings Plans:

<table>
<thead>
<tr>
<th></th>
<th>Capacity Reservations</th>
<th>Zonal Reserved Instances</th>
<th>Regional Reserved Instances</th>
<th>Savings Plans</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Term</strong></td>
<td>No commitment required. Can be created and canceled as needed.</td>
<td>Requires a fixed one-year or three-year commitment</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Capacity benefit</strong></td>
<td>Capacity reserved in a specific Availability Zone.</td>
<td>No capacity reserved.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Billing discount</strong></td>
<td>No billing discount. †</td>
<td>Provides a billing discount.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Instance Limits</strong></td>
<td>Your On-Demand Instance limits per Region apply.</td>
<td>Default is 20 per Availability Zone. You can request a limit increase.</td>
<td>Default is 20 per Region. You can request a limit increase.</td>
<td>No limit.</td>
</tr>
</tbody>
</table>

† You can combine Capacity Reservations with Savings Plans or Regional Reserved Instances to receive a discount.

For more information, see the following:

- [Reserved Instances](p. 325)
- [Savings Plans User Guide]

Supported platforms

You must create the Capacity Reservation with the correct platform to ensure that it properly matches with your instances. Capacity Reservations support the following platforms:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- Red Hat Enterprise Linux
- SUSE Linux

When you purchase a Capacity Reservation, you must specify the platform that represents the operating system for your instance.

- For SUSE Linux and RHEL distributions, excluding BYOL, you must choose the specific platform. For example, the SUSE Linux or Red Hat Enterprise Linux platform.
- For all other Linux distributions (including Ubuntu), choose the Linux/UNIX platform.
- If you bring your existing RHEL subscription (BYOL), you must choose the Linux/UNIX platform.
For more information about the supported Windows platforms, see Supported platforms in the Amazon EC2 User Guide for Windows Instances.

**Capacity Reservation limits**

The number of instances for which you are allowed to reserve capacity is based on your account’s On-Demand Instance limit. You can reserve capacity for as many instances as that limit allows, minus the number of instances that are already running.

**Capacity Reservation limitations and restrictions**

Before you create Capacity Reservations, take note of the following limitations and restrictions.

- Active and unused Capacity Reservations count toward your On-Demand Instance limits.
- Capacity Reservations are not transferable from one AWS account to another. However, you can share Capacity Reservations with other AWS accounts. For more information, see Work with shared Capacity Reservations (p. 465).
- Zonal Reserved Instance billing discounts do not apply to Capacity Reservations.
- Capacity Reservations can’t be created in placement groups.
- Capacity Reservations can’t be used with Dedicated Hosts.
- Capacity Reservations do not ensure that a hibernated instance can resume after you try to start it.

**Capacity Reservation pricing and billing**

The price for a Capacity Reservation varies by payment option.

**Pricing**

When the Capacity Reservation enters the active state, you are charged the equivalent On-Demand rate whether you run instances in the reserved capacity or not. If you do not use the reservation, this shows up as unused reservation on your EC2 bill. When you run an instance that matches the attributes of a reservation, you just pay for the instance and nothing for the reservation. There are no upfront or additional charges.

For example, if you create a Capacity Reservation for 20 m4.large Linux instances and run 15 m4.large Linux instances in the same Availability Zone, you will be charged for 15 active instances and for 5 unused instances in the reservation.

Billing discounts for Savings Plans and regional Reserved Instances apply to Capacity Reservations. For more information, see Billing discounts (p. 454).

For more information, see Amazon EC2 Pricing.

**Billing**

Billing starts as soon as the capacity is provisioned and the Capacity Reservation enters the active state, and it continues while the Capacity Reservation remains in the active state.

Capacity Reservations are billed at per-second granularity. This means that you are charged for partial hours. For example, if a reservation remains active in your account for 24 hours and 15 minutes, you will be billed for 24.25 reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one m4.large Linux instance, which has an On-Demand rate of $0.10 per usage hour. In this example, the Capacity Reservation is active in the account for five hours. The Capacity Reservation is unused for the first hour, so it is billed for one unused hour at the m4.large instance type's standard On-Demand rate. In hours two through five, the Capacity Reservation is occupied by an m4.large
instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the \textit{m4.large} instance occupying it. In the sixth hour, the Capacity Reservation is canceled and the \textit{m4.large} instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the \textit{m4.large} instance type.

### Billing discounts

Billing discounts for Savings Plans and regional Reserved Instances apply to Capacity Reservations. AWS automatically applies these discounts to Capacity Reservations that have matching attributes. When a Capacity Reservation is used by an instance, the discount is applied to the instance. Discounts are preferentially applied to instance usage before covering unused Capacity Reservations.

Billing discounts for zonal Reserved Instances do not apply to Capacity Reservations.

For more information, see the following:

- Reserved Instances (p. 325)
- Savings Plans User Guide

### Viewing your bill

You can review the charges and fees to your account on the AWS Billing and Cost Management console.

- The \textbf{Dashboard} displays a spend summary for your account.
- On the \textbf{Bills} page, under Details, expand the \textbf{Elastic Compute Cloud} section and the Region to get billing information about your Capacity Reservations.

You can view the charges online, or you can download a CSV file. For more information, see Capacity Reservation Line Items in the \textit{AWS Billing and Cost Management User Guide}.

### Work with Capacity Reservations

To start using Capacity Reservations, you create the capacity reservation in the required Availability Zone. Then, you can launch instances into the reserved capacity, view its capacity utilization in real time, and increase or decrease its capacity as needed.

By default, Capacity Reservations automatically match new instances and running instances that have matching attributes (instance type, platform, and Availability Zone). This means that any instance with matching attributes automatically runs in the Capacity Reservation. However, you can also target a Capacity Reservation for specific workloads. This enables you to explicitly control which instances are allowed to run in that reserved capacity.

You can specify how the reservation ends. You can choose to cancel the Capacity Reservation or end it automatically at a specified time. If you specify an end time, the Capacity Reservation is canceled within an hour of the specified time. For example, if you specify 5/31/2019, 13:30:55, the Capacity Reservation...
is guaranteed to end between 13:30:55 and 14:30:55 on 5/31/2019. After a reservation ends, you can no longer target instances to the Capacity Reservation. Instances running in the reserved capacity continue to run uninterrupted. If instances targeting a Capacity Reservation are stopped, you cannot restart them until you remove their Capacity Reservation targeting preference or configure them to target a different Capacity Reservation.

Contents
- Create a Capacity Reservation (p. 455)
- Work with Capacity Reservation groups (p. 456)
- Launch instances into an existing Capacity Reservation (p. 459)
- Modify a Capacity Reservation (p. 460)
- Modify an instance’s Capacity Reservation settings (p. 461)
- View a Capacity Reservation (p. 462)
- Cancel a Capacity Reservation (p. 463)

Create a Capacity Reservation

After you create the Capacity Reservation, the capacity is available immediately. The capacity remains reserved for your use as long as the Capacity Reservation is active, and you can launch instances into it at any time. If the Capacity Reservation is open, new instances and existing instances that have matching attributes automatically run in the capacity of the Capacity Reservation. If the Capacity Reservation is targeted, instances must specifically target it to run in the reserved capacity.

Your request to create a Capacity Reservation could fail if one of the following is true:

- Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your application is flexible across instance types and sizes, try different instance attributes.
- The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see On-Demand Instance limits (p. 322).

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Capacity Reservations, and then choose Create Capacity Reservation.
3. On the Create a Capacity Reservation page, configure the following settings in the Instance details section. The instance type, platform, and Availability Zone of the instances that you launch must match the instance type, platform, and Availability Zone that you specify here or the Capacity Reservation is not applied. For example, if an open Capacity Reservation doesn't match, an instance launch that targets that Capacity Reservation explicitly will fail.
   a. Instance Type—The type of instance to launch into the reserved capacity.
   b. Launch EBS-optimized instances—Specify whether to reserve the capacity for EBS-optimized instances. This option is selected by default for some instance types. For more information about EBS-optimized instances, see Amazon Elastic Block Store (p. 1175).
   c. Attach instance store at launch—Specify whether instances launched into the Capacity Reservation use temporary block-level storage. The data on an instance store volume persists only during the life of the associated instance.
   d. Platform—The operating system for your instances. For more information, see Supported platforms (p. 452). For more information about the supported Windows platforms, see Supported platforms in the Amazon EC2 User Guide for Windows Instances.
   e. Availability Zone—The Availability Zone in which to reserve the capacity.
f. **Tenancy**—Specify whether to run on shared hardware (default) or a dedicated instance.

g. **Quantity**—The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the request is denied.

4. Configure the following settings in the **Reservation details** section:

a. **Reservation Ends**—Choose one of the following options:

   - **Manually**—Reserve the capacity until you explicitly cancel it.
   - **Specific time**—Cancel the capacity reservation automatically at the specified date and time.

b. **Instance eligibility**—Choose one of the following options:

   - **open**—(Default) The Capacity Reservation matches any instance that has matching attributes (instance type, platform, and Availability Zone). If you launch an instance with matching attributes, it is placed into the reserved capacity automatically.
   - **targeted**—The Capacity Reservation only accepts instances that have matching attributes (instance type, platform, and Availability Zone), and that explicitly target the reservation.

5. Choose **Request reservation**.

---

**To create a Capacity Reservation using the AWS CLI**

Use the `create-capacity-reservation` command. For more information, see Supported platforms (p. 452). For more information about the supported Windows platforms, see Supported platforms in the *Amazon EC2 User Guide for Windows Instances*.

For example, the following command creates a Capacity Reservation that reserves capacity for three `m5.2xlarge` instances running Red Hat Enterprise Linux AMIs in the `us-east-1a` Availability Zone.

```bash
aws ec2 create-capacity-reservation --instance-type m5.2xlarge --instance-platform Red Hat Enterprise Linux --availability-zone us-east-1a --instance-count 3
```

---

**Work with Capacity Reservation groups**

You can use AWS Resource Groups to create logical collections of Capacity Reservations, called **resource groups**. A resource group is a logical grouping of AWS resources that are all in the same AWS Region. You can include multiple Capacity Reservations that have different attributes (instance type, platform, and Availability Zone) in a single resource group.

When you create resource groups for your Capacity Reservations, you can target instances to a group of Capacity Reservations instead of an individual Capacity Reservation. Instances that target a group of Capacity Reservations match with any Capacity Reservation in the group that has matching attributes (instance type, platform, and Availability Zone) and available capacity. If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically matched with and moved into its reserved capacity.

To prevent unintended use of Capacity Reservations in a group, configure the Capacity Reservations in the group to accept only instances that explicitly target the capacity reservation. To do this, set **Instance eligibility** to `targeted` (old console) or **Only instances that specify this reservation** (new console) when creating the Capacity Reservation using the Amazon EC2 console. When using the AWS CLI, specify `--instance-match-criteria targeted` when creating the Capacity Reservation. Doing this ensures that only instances that explicitly target the group, or a Capacity Reservation in the group, can run in the group.

If a Capacity Reservation in a group is canceled or expires while it has running instances, the instances are automatically moved to another Capacity Reservation in the group that has matching attributes.
and available capacity. If there are no remaining Capacity Reservations in the group that have matching attributes and available capacity, the instances run in On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically moved into its reserved capacity.

**To create a group for your Capacity Reservations**

Use the `create-group` AWS CLI command. For `name`, provide a descriptive name for the group, and for `configuration`, specify two `Type` request parameters:

- `AWS::EC2::CapacityReservationPool` to ensure that the resource group can be targeted for instance launches
- `AWS::ResourceGroups::Generic` with `allowed-resource-types` set to `AWS::EC2::CapacityReservation` to ensure that the resource group accepts Capacity Reservations only

For example, the following command creates a group named `MyCRGroup`.

```
$ aws resource-groups create-group --name MyCRGroup --configuration '{"Type":"AWS::EC2::CapacityReservationPool"}', '{"Type":"AWS::ResourceGroups::Generic", "Parameters": [{"Name": "allowed-resource-types", "Values": ["AWS::EC2::CapacityReservation"]}]}
```

The following shows example output.

```
{
    "GroupConfiguration": {
        "Status": "UPDATE_COMPLETE",
        "Configuration": [
            {
                "Type": "AWS::EC2::CapacityReservationPool"
            },
            {
                "Type": "AWS::ResourceGroups::Generic",
                "Parameters": [
                    {
                        "Values": [
                            "AWS::EC2::CapacityReservation"
                        ],
                        "Name": "allowed-resource-types"
                    }
                ]
            }
        ]
    },
    "Group": {
        "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",
        "Name": "MyCRGroup"
    }
}
```

**To add a Capacity Reservation to a group**

Use the `group-resources` AWS CLI command. For `group`, specify the name of the group to which to add the Capacity Reservations, and for `resources`, specify ARNs of the Capacity Reservations to add. To add multiple Capacity Reservations, separate the ARNs with a space. To get the ARNs of the Capacity Reservations to add, use the `describe-capacity-reservations` AWS CLI command and specify the IDs of the Capacity Reservations.

For example, the following command adds two Capacity Reservations to a group named `MyCRGroup`.
The following shows example output.

```json
{
    "Failed": [],
    "Succeeded": [
    ]
}
```

**To view the Capacity Reservations in a specific group**

Use the `list-group-resources` AWS CLI command. For `group`, specify the name of the group.

For example, the following command lists the Capacity Reservations in a group named `MyCRGroup`.

```
$ aws resource-groups list-group-resources --group MyCRGroup
```

The following shows example output.

```json
{
    "QueryErrors": [],
    "ResourceIdentifiers": [
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1"
        },
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
        }
    ]
}
```

**To view the groups to which a specific Capacity Reservation has been added (AWS CLI)**

Use the `get-groups-for-capacity-reservation` AWS CLI command.

For example, the following command lists the groups to which Capacity Reservation `cr-1234567890abcdef1` has been added.

```
$ aws ec2 get-groups-for-capacity-reservation --capacity-reservation-id cr-1234567890abcdef1
```

The following shows example output.

```json
{
    "CapacityReservationGroups": [
        {
            "OwnerId": "123456789012",
            "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup"
        }
    ]
}
```
To view the groups to which a specific Capacity Reservation has been added (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Capacity Reservations, select the Capacity Reservation to view, and then choose View.

The groups to which the Capacity Reservation has been added are listed in the Groups card.

To remove a Capacity Reservation from a group

Use the ungroup-resources AWS CLI command. For group, specify the ARN of the group from which to remove the Capacity Reservation, and for resources specify the ARNs of the Capacity Reservations to remove. To remove multiple Capacity Reservations, separate the ARNs with a space.

The following example removes two Capacity Reservations from a group named MyCRGroup.

```
```

The following shows example output.

```
{
   "Failed": [],
   "Succeeded": [
      "arn:aws:ec2:sa-east-1:123456789012:capacity_reservation/cr-0e154d26a16094dd",
   ]
}
```

To delete a group

Use the delete-group AWS CLI command. For group, provide the name of the group to delete.

For example, the following command deletes a group named MyCRGroup.

```
$ aws resource-groups delete-group --group MyCRGroup
```

The following shows example output.

```
{
   "Group": {
      "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",
      "Name": "MyCRGroup"
   }
}
```

Launch instances into an existing Capacity Reservation

When you launch an instance, you can specify whether to launch the instance into any open Capacity Reservation, into a specific Capacity Reservation, or into a group of Capacity Reservations. You can only launch an instance into a Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and sufficient capacity. Alternatively, you can configure the instance to avoid running in a Capacity Reservation, even if you have an open Capacity Reservation that has matching attributes and available capacity.
Launching an instance into a Capacity Reservation reduces its available capacity by the number of instances launched. For example, if you launch three instances, the available capacity of the Capacity Reservation is reduced by three.

**To launch instances into an existing Capacity Reservation using the console**

1. Open the Launch Instance wizard by choosing **Launch Instances** from **Dashboard** or **Instances**.
2. Select an Amazon Machine Image (AMI) and an instance type.
3. Complete the **Configure Instance Details** page. For **Capacity Reservation**, choose one of the following options:
   - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
   - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
   - **Target by ID** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
   - **Target by group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.
4. Complete the remaining steps to launch the instances.

**To launch an instance into an existing Capacity Reservation using the AWS CLI**

Use the **run-instances** command and specify the **--capacity-reservation-specification** parameter.

The following example launches a `t2.micro` instance into any open Capacity Reservation that has matching attributes and available capacity:

```bash
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationPreference=open
```

The following example launches a `t2.micro` instance into a targeted Capacity Reservation:

```bash
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

The following example launches a `t2.micro` instance into a Capacity Reservation group:

```bash
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-west-1:123456789012:group/my-cr-group}
```

**Modify a Capacity Reservation**

You can change the attributes of an active Capacity Reservation after you have created it. You cannot modify a Capacity Reservation after it has expired or after you have explicitly canceled it.
When modifying a Capacity Reservation, you can only increase or decrease the quantity and change the way in which it is released. You cannot change the instance type, EBS optimization, instance store settings, platform, Availability Zone, or instance eligibility of a Capacity Reservation. If you need to modify any of these attributes, we recommend that you cancel the reservation, and then create a new one with the required attributes.

If you specify a new quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the update fails.

**To modify a Capacity Reservation using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations**, select the Capacity Reservation to modify, and then choose **Edit**.
3. Modify the **Quantity** or **Reservation ends** options as needed, and choose **Save changes**.

**To modify a Capacity Reservation using the AWS CLI**

Use the `modify-capacity-reservations` command:

For example, the following command modifies a Capacity Reservation to reserve capacity for eight instances.

```
aws ec2 modify-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0 --instance-count 8
```

**Modify an instance's Capacity Reservation settings**

You can modify the following Capacity Reservation settings for a stopped instance at any time:

- Start in any Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and available capacity.
- Start the instance in a specific Capacity Reservation.
- Start the in any Capacity Reservation that has matching attributes and available capacity in a Capacity Reservation group
- Prevent the instance from starting in a Capacity Reservation.

**To modify an instance's Capacity Reservation settings using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Instances** and select the instance to modify. Stop the instance if it is not already stopped.
3. Choose **Actions, Modify Capacity Reservation Settings**.
4. For **Capacity Reservation**, choose one of the following options:
   - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
   - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
   - **Specify Capacity Reservation** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
   - **Specify Capacity Reservation group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If
the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

To modify an instance's Capacity Reservation settings using the AWS CLI

Use the `modify-instance-capacity-reservation-attributes` command.

For example, the following command changes an instance's Capacity Reservation setting to `open` or `none`.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0
  --capacity-reservation-specification CapacityReservationPreference=none|open
```

For example, the following command modifies an instance to target a specific Capacity Reservation.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0
  --capacity-reservation-specification
  CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

For example, the following command modifies an instance to target a specific Capacity Reservation group.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0
  --capacity-reservation-specification
  CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-west-1:123456789012:group/my-cr-group}
```

View a Capacity Reservation

Capacity Reservations have the following possible states:

- **active**—The capacity is available for use.
- **expired**—The Capacity Reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.
- **cancelled**—The Capacity Reservation was canceled. The reserved capacity is no longer available for your use.
- **pending**—The Capacity Reservation request was successful but the capacity provisioning is still pending.
- **failed**—The Capacity Reservation request has failed. A request can fail due to invalid request parameters, capacity constraints, or instance limit constraints. You can view a failed request for 60 minutes.

To view your Capacity Reservations using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Capacity Reservations** and select a Capacity Reservation to view.
3. Choose **View launched instances for this reservation**.

To view your Capacity Reservations using the AWS CLI

Use the `describe-capacity-reservations` command:

For example, the following command describes all Capacity Reservations.
Cancel a Capacity Reservation

You can cancel a Capacity Reservation at any time if you no longer need the reserved capacity. When you cancel a Capacity Reservation, the capacity is released immediately, and it is no longer reserved for your use.

You can cancel empty Capacity Reservations and Capacity Reservations that have running instances. If you cancel a Capacity Reservation that has running instances, the instances continue to run normally outside of the capacity reservation at standard On-Demand Instance rates or at a discounted rate if you have a matching Savings Plan or regional Reserved Instance.

After you cancel a Capacity Reservation, instances that target it can no longer launch. Modify these instances so that they either target a different Capacity Reservation, launch into any open Capacity Reservation with matching attributes and sufficient capacity, or avoid launching into a Capacity Reservation. For more information, see Modify an instance's Capacity Reservation settings (p. 461).

To cancel a Capacity Reservation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Capacity Reservations and select the Capacity Reservation to cancel.
3. Choose Cancel reservation, Cancel reservation.

To cancel a Capacity Reservation using the AWS CLI

Use the cancel-capacity-reservation command:

For example, the following command cancels a Capacity Reservation with an ID of cr-1234567890abcdef0.

aws ec2 cancel-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0

Capacity Reservations in Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. Resources created in a Local Zone can serve local users with very low-latency communications. For more information, see AWS Local Zones.

You can extend a VPC from its parent AWS Region into a Local Zone by creating a new subnet in that Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as the other subnets in your VPC.

By using Local Zones, you can place Capacity Reservations in multiple locations that are closer to your users. You create and use Capacity Reservations in Local Zones in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply. For more information about the pricing models that are supported in Local Zones, see AWS Local Zones FAQs.

Considerations

You can't use Capacity Reservation groups in a Local Zone.

To use a Capacity Reservation in a Local Zone

1. Enable the Local Zone for use in your AWS account. For more information, see Enable Local Zones in the Amazon EC2 User Guide for Linux Instances.
2. Create a Capacity Reservation in the Local Zone. For Availability Zone, choose the Local Zone. The Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a. For more information, see Create a Capacity Reservation (p. 455).

3. Create a subnet in the Local Zone. For Availability Zone, choose the Local Zone. For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.

4. Launch an instance. For Subnet, choose the subnet in the Local Zone (for example subnet-123abc | us-west-2-lax-1a), and for Capacity Reservation, choose the specification (either open or target it by ID) that’s required for the Capacity Reservation that you created in the Local Zone. For more information, see Launch instances into an existing Capacity Reservation (p. 459).

Capacity Reservations in Wavelength Zones

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers’ 5G networks. You can extend a Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones. You can then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region. For more information, see AWS Wavelength Zones.

When you create On-Demand Capacity Reservations, you can choose the Wavelength Zone and you can launch instances into a Capacity Reservation in a Wavelength Zone by specifying the subnet associated with the Wavelength Zone. A Wavelength Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see Available Wavelength Zones in the AWS Wavelength Developer Guide.

Considerations

You can’t use Capacity Reservation groups in a Wavelength Zone.

To use a Capacity Reservation in a Wavelength Zone

1. Enable the Wavelength Zone for use in your AWS account. For more information, see Enable Wavelength Zones in the Amazon EC2 User Guide for Linux Instances.

2. Create a Capacity Reservation in the Wavelength Zone. For Availability Zone, choose the Wavelength. The Wavelength is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1. For more information, see Create a Capacity Reservation (p. 455).

3. Create a subnet in the Wavelength Zone. For Availability Zone, choose the Wavelength Zone. For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.

4. Launch an instance. For Subnet, choose the subnet in the Wavelength Zone (for example subnet-123abc | us-east-1-wl1-bos-wlz-1), and for Capacity Reservation, choose the specification (either open or target it by ID) that’s required for the Capacity Reservation that you created in the Wavelength. For more information, see Launch instances into an existing Capacity Reservation (p. 459).

Capacity Reservations on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.
An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create Capacity Reservations on Outposts that you have created in your account. This allows you to reserve compute capacity on an Outpost at your site. You create and use Capacity Reservations on Outposts in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply.

You can also share Capacity Reservations on Outposts with other AWS accounts within your organization using AWS Resource Access Manager. For more information about sharing Capacity Reservations, see Work with shared Capacity Reservations (p. 465).

**Prerequisite**

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the AWS Outposts User Guide.

**Considerations**

- You can't use Capacity Reservation groups on an Outpost.

**To use a Capacity Reservation on an Outpost**

1. Create a subnet on the Outpost. For more information, see Create a subnet in the AWS Outposts User Guide.
2. Create a Capacity Reservation on the Outpost.
   a. Open the AWS Outposts console at https://console.aws.amazon.com/outposts/.
   b. In the navigation pane, choose Outposts, and then choose Actions, Create Capacity Reservation.
   c. Configure the Capacity Reservation as needed and then choose Create. For more information, see Create a Capacity Reservation (p. 455).

   **Note**
   The Instance Type drop-down lists only instance types that are supported by the selected Outpost, and the Availability Zone drop-down lists only the Availability Zone with which the selected Outpost is associated.
3. Launch an instance into the Capacity Reservation. For Subnet choose the subnet that you created in Step 1, and for Capacity Reservation, select the Capacity Reservation that you created in Step 2. For more information, see Launch an instance on the Outpost in the AWS Outposts User Guide.

**Work with shared Capacity Reservations**

Capacity Reservation sharing enables Capacity Reservation owners to share their reserved capacity with other AWS accounts or within an AWS organization. This enables you to create and manage Capacity Reservations centrally, and share the reserved capacity across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Capacity Reservation (owner) shares it with other AWS accounts (consumers). Consumers can launch instances into Capacity Reservations that are shared with them in the same way that they launch instances into Capacity Reservations that they own in their own account. The Capacity Reservation owner is responsible for managing the Capacity Reservation and the instances that they launch into it. Owners cannot modify instances that consumers launch into Capacity Reservations that they have shared. Consumers are responsible for managing the instances that they launch into Capacity Reservations shared with them. Consumers cannot view or modify instances owned by other consumers or by the Capacity Reservation owner.
A Capacity Reservation owner can share a Capacity Reservation with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Contents

- Prerequisites for sharing Capacity Reservations (p. 466)
- Related services (p. 466)
- Share across Availability Zones (p. 466)
- Share a Capacity Reservation (p. 467)
- Stop sharing a Capacity Reservation (p. 467)
- Identify a shared Capacity Reservation (p. 468)
- View shared Capacity Reservation usage (p. 468)
- Shared Capacity Reservation permissions (p. 469)
- Billing and metering (p. 469)
- Instance limits (p. 469)

Prerequisites for sharing Capacity Reservations

- To share a Capacity Reservation, you must own it in your AWS account. You cannot share a Capacity Reservation that has been shared with you.
- You can only share Capacity Reservations for shared tenancy instances. You cannot share Capacity Reservations for dedicated tenancy instances.
- Capacity Reservation sharing is not available to new AWS accounts or AWS accounts that have a limited billing history.
- To share a Capacity Reservation with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see Enable Sharing with AWS Organizations in the AWS RAM User Guide.

Related services

Capacity Reservation sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a resource share. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the AWS RAM User Guide.

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone us-east-1a for your AWS account might not have the same location as us-east-1a for another AWS account.

To identify the location of your Capacity Reservations relative to your accounts, you must use the Availability Zone ID (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, use1-az1 is an AZ ID for the us-east-1 Region and it is the same location in every AWS account.
To view the AZ IDs for the Availability Zones in your account

2. The AZ IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Capacity Reservation

When you share a Capacity Reservation that you own with other AWS accounts, you enable them to launch instances into your reserved capacity. If you share an open Capacity Reservation, keep the following in mind as it could lead to unintended Capacity Reservation usage:

- If consumers have running instances that match the attributes of the Capacity Reservation, have the `CapacityReservationPreference` parameter set to `open`, and are not yet running in reserved capacity, they automatically use the shared Capacity Reservation.
- If consumers launch instances that have matching attributes (instance type, platform, and Availability Zone) and have the `CapacityReservationPreference` parameter set to `open`, they automatically launch into the shared Capacity Reservation.

To share a Capacity Reservation, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. When you share a Capacity Reservation using the Amazon EC2 console, you add it to an existing resource share. To add the Capacity Reservation to a new resource share, you must create the resource share using the AWS RAM console.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Capacity Reservation. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Capacity Reservation after accepting the invitation.

You can share a Capacity Reservation that you own using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

**To share a Capacity Reservation that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. Choose the Capacity Reservation to share and choose **Actions, Share reservation**.
4. Select the resource share to which to add the Capacity Reservation and choose **Share Capacity Reservation**.

   It could take a few minutes for consumers to get access to the shared Capacity Reservation.

**To share a Capacity Reservation that you own using the AWS RAM console**

**To share a Capacity Reservation that you own using the AWS CLI**

Use the `create-resource-share` command.

**Stop sharing a Capacity Reservation**

The Capacity Reservation owner can stop sharing a Capacity Reservation at any time. The following rules apply:
Instances owned by consumers that were running in the shared capacity at the time sharing stops continue to run normally outside of the reserved capacity, and the capacity is restored to the Capacity Reservation subject to Amazon EC2 capacity availability. Consumers with whom the Capacity Reservation was shared can no longer launch new instances into the reserved capacity.

To stop sharing a Capacity Reservation that you own, you must remove it from the resource share. You can do this using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

**To stop sharing a Capacity Reservation that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Capacity Reservation has been added. Select the resource share from which to remove the Capacity Reservation and choose **Remove from resource share**.

**To stop sharing a Capacity Reservation that you own using the AWS RAM console**

See **Updating a Resource Share** in the **AWS RAM User Guide**.

**To stop sharing a Capacity Reservation that you own using the AWS CLI**

Use the **disassociate-resource-share** command.

**Identify a shared Capacity Reservation**

Owners and consumers can identify shared Capacity Reservations using the Amazon EC2 console and AWS CLI.

**To identify a shared Capacity Reservation using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**. The screen lists Capacity Reservations that you own and Capacity Reservations that are shared with you. The **Owner** column shows the AWS account ID of the Capacity Reservation owner. *(me)* next to the AWS account ID indicates that you are the owner.

**To identify a shared Capacity Reservation using the AWS CLI**

Use the **describe-capacity-reservations** command. The command returns the Capacity Reservations that you own and Capacity Reservations that are shared with you. **OwnerId** shows the AWS account ID of the Capacity Reservation owner.

**View shared Capacity Reservation usage**

The owner of a shared Capacity Reservation can view its usage at any time using the Amazon EC2 console and the AWS CLI.

**To view Capacity Reservation usage using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation for which to view the usage and choose the **Usage** tab.
The AWS account ID column shows the account IDs of the consumers currently using the Capacity Reservation. The Launched instances column shows the number of instances each consumer currently has running in the reserved capacity.

To view Capacity Reservation usage using the AWS CLI

Use the get-capacity-reservation-usage command. AccountId shows the account ID of the account using the Capacity Reservation. UsedInstanceCount shows the number of instances the consumer currently has running in the reserved capacity.

Shared Capacity Reservation permissions

Permissions for owners

Owners are responsible for managing and canceling their shared Capacity Reservations. Owners cannot modify instances running in the shared Capacity Reservation that are owned by other accounts. Owners remain responsible for managing instances that they launch into the shared Capacity Reservation.

Permissions for consumers

Consumers are responsible for managing their instances that are running the shared Capacity Reservation. Consumers cannot modify the shared Capacity Reservation in any way, and they cannot view or modify instances that are owned by other consumers or the Capacity Reservation owner.

Billing and metering

There are no additional charges for sharing Capacity Reservations.

The Capacity Reservation owner is billed for instances that they run inside the Capacity Reservation and for unused reserved capacity. Consumers are billed for the instances that they run inside the shared Capacity Reservation.

Instance limits

All Capacity Reservation usage counts toward the Capacity Reservation owner's On-Demand Instance limits. This includes:

- Unused reserved capacity
- Usage by instances owned by the Capacity Reservation owner
- Usage by instances owned by consumers

Instances launched into the shared capacity by consumers count towards the Capacity Reservation owner's On-Demand Instance limit. Consumers' instance limits are a sum of their own On-Demand Instance limits and the capacity available in the shared Capacity Reservations to which they have access.

CloudWatch metrics for On-Demand Capacity Reservations

With CloudWatch metrics, you can efficiently monitor your Capacity Reservations and identify unused capacity by setting CloudWatch alarms to notify you when usage thresholds are met. This can help you maintain a constant Capacity Reservation volume and achieve a higher level of utilization.

On-Demand Capacity Reservations send metric data to CloudWatch every five minutes. Metrics are not supported for Capacity Reservations that are active for less than five minutes.

For more information about viewing metrics in the CloudWatch console, see Using Amazon CloudWatch Metrics. For more information about creating alarms, see Creating Amazon CloudWatch Alarms.

Contents
• Capacity Reservation usage metrics (p. 470)
• Capacity Reservation metric dimensions (p. 470)
• View CloudWatch metrics for Capacity Reservations (p. 470)

Capacity Reservation usage metrics

The AWS/EC2CapacityReservations namespace includes the following usage metrics you can use to monitor and maintain on-demand capacity within thresholds you specify for your reservation.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UsedInstanceCount</td>
<td>The number of instances that are currently in use.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>AvailableInstanceCount</td>
<td>The number of instances that are available.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>TotalInstanceCount</td>
<td>The total number of instances you have reserved.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>InstanceUtilization</td>
<td>The percentage of reserved capacity instances that are currently in use.</td>
</tr>
<tr>
<td></td>
<td>Unit: Percent</td>
</tr>
</tbody>
</table>

Capacity Reservation metric dimensions

You can use the following dimensions to refine the metrics listed in the previous table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CapacityReservationId</td>
<td>This globally unique dimension filters the data you request for the identified capacity reservation only.</td>
</tr>
</tbody>
</table>

View CloudWatch metrics for Capacity Reservations

Metrics are grouped first by the service namespace, and then by the supported dimensions. You can use the following procedures to view the metrics for your Capacity Reservations.

To view Capacity Reservation metrics using the CloudWatch console

2. If necessary, change the Region. From the navigation bar, select the Region where your Capacity Reservation resides. For more information, see Regions and Endpoints.
3. In the navigation pane, choose Metrics.
4. For All metrics, choose EC2 Capacity Reservations.
5. Choose the metric dimension By Capacity Reservation. Metrics will be grouped by CapacityReservationId.
6. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric.
To view Capacity Reservation metrics (AWS CLI)

Use the following list-metrics command:

```bash
aws cloudwatch list-metrics --namespace "AWS/EC2CapacityReservations"
```

**Instance lifecycle**

An Amazon EC2 instance transitions through different states from the moment you launch it through to its termination.

The following illustration represents the transitions between instance states. Notice that you can’t stop and start an instance store-backed instance. For more information about instance store-backed instances, see Storage for the root device (p. 73).

<table>
<thead>
<tr>
<th>Instance state</th>
<th>Description</th>
<th>Instance usage billing</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending</td>
<td>The instance is preparing to enter the running state. An</td>
<td>Not billed</td>
</tr>
</tbody>
</table>
Instance launch

When you launch an instance, it enters the pending state when it launches for the first time, or when it is started after being in the stopped state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the running state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance transitions to the running state, you're billed for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don’t connect to it.

For more information, see Launch your instance (p. 475) and Connect to your Linux instance (p. 499).

Instance stop and start (Amazon EBS-backed instances only)

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.
When you stop your instance, it enters the stopping state, and then the stopped state. We don't charge usage or data transfer fees for your instance after you stop it, but we do charge for the storage for any Amazon EBS volumes. While your instance is in the stopped state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host). When you stop and start your instance, you lose any data on the instance store volumes on the previous host computer.

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

Each time you transition an instance from stopped to running, we charge per second when the instance is running, with a minimum of one minute every time you start your instance.

For more information, see Stop and start your instance (p. 524).

Instance hibernate (Amazon EBS-backed instances only)

When you hibernate an instance, we signal the operating system to perform hibernation (suspend-to-disk), which saves the contents from the instance memory (RAM) to your Amazon EBS root volume. We persist the instance's Amazon EBS root volume and any attached Amazon EBS data volumes. When you start your instance, the Amazon EBS root volume is restored to its previous state and the RAM contents are reloaded. Previously attached data volumes are reattached and the instance retains its instance ID.

When you hibernate your instance, it enters the stopping state, and then the stopped state. We don't charge usage for a hibernated instance when it is in the stopped state, but we do charge while it is in the stopping state, unlike when you stop an instance (p. 472) without hibernating it. We don't charge usage for data transfer fees, but we do charge for the storage for any Amazon EBS volumes, including storage for the RAM data.

When you start your hibernated instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host).

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

For more information, see Hibernate your On-Demand or Reserved Linux instance (p. 528).

Instance reboot

You can reboot your instance using the Amazon EC2 console, a command line tool, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system. The instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing period; per second billing continues without a further one-minute minimum charge.

For more information, see Reboot your instance (p. 544).
Instance retirement

An instance is scheduled to be retired when AWS detects the irreparable failure of the underlying hardware hosting the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS. If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information, see Instance retirement (p. 544).

Instance termination

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to shutting-down or terminated, you stop incurring charges for that instance.

If you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You can also describe a terminated instance using the CLI and API. Resources (such as tags) are gradually disassociated from the terminated instance, therefore may no longer be visible on the terminated instance after a short while. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the InstanceInitiatedShutdownBehavior attribute, which controls whether the instance stops or terminates when you initiate shutdown from within the instance itself (for example, by using the shutdown command on Linux). The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the DeleteOnTermination attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to delete the root device volume and preserve any other EBS volumes.

For more information, see Terminate your instance (p. 547).

Differences between reboot, stop, hibernate, and terminate

The following table summarizes the key differences between rebooting, stopping, hibernating, and terminating your instance.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Reboot</th>
<th>Stop/start (Amazon EBS-backed instances only)</th>
<th>Hibernate (Amazon EBS-backed instances only)</th>
<th>Terminate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host computer</td>
<td>The instance stays on the same host computer</td>
<td>We move the instance to a new host computer (though in some cases, it remains on the current host).</td>
<td>We move the instance to a new host computer (though in some cases, it remains on the current host).</td>
<td>None</td>
</tr>
<tr>
<td>Private and public IPv4 addresses</td>
<td>These addresses stay the same</td>
<td>The instance keeps its private IPv4 address. The instance gets a new public IPv4</td>
<td>The instance keeps its private IPv4 address. The instance gets a new public IPv4</td>
<td>None</td>
</tr>
</tbody>
</table>
Operating system shutdown commands always terminate an instance store-backed instance. You can control whether operating system shutdown commands stop or terminate an Amazon EBS-backed instance. For more information, see Change the instance initiated shutdown behavior (p. 551).

Launch your instance

An instance is a virtual server in the AWS Cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.

When you sign up for AWS, you can get started with Amazon EC2 for free using the AWS Free Tier. You can use the free tier to launch and use a t2.micro instance for free for 12 months (in Regions where t2.micro is unavailable, you can use a t3.micro instance under the free tier). If you launch an instance
that is not within the free tier, you incur the standard Amazon EC2 usage fees for the instance. For more information, see Amazon EC2 pricing.

You can launch an instance using the following methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Amazon EC2 console] Use the launch instance wizard to specify the launch parameters.</td>
<td>Launch an instance using the Launch Instance Wizard (p. 477)</td>
</tr>
<tr>
<td>[Amazon EC2 console] Create a launch template and launch the instance from the launch template.</td>
<td>Launch an instance from a launch template (p. 483)</td>
</tr>
<tr>
<td>[Amazon EC2 console] Use an existing instance as the base.</td>
<td>Launch an instance using parameters from an existing instance (p. 496)</td>
</tr>
<tr>
<td>[Amazon EC2 console] Use an AMI that you purchased from the AWS Marketplace.</td>
<td>Launch an AWS Marketplace instance (p. 497)</td>
</tr>
<tr>
<td>[AWS CLI] Use an AMI that you select.</td>
<td>Using Amazon EC2 through the AWS CLI</td>
</tr>
<tr>
<td>[AWS CLI] Use EC2 Fleet to provision capacity across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchase models.</td>
<td>EC2 Fleet (p. 656)</td>
</tr>
<tr>
<td>[AWS CloudFormation] Use a AWS CloudFormation template to specify an instance.</td>
<td>AWS::EC2::Instance in the AWS CloudFormation User Guide</td>
</tr>
</tbody>
</table>
| [AWS SDK] Use a language-specific AWS SDK to launch an instance. | AWS SDK for .NET

AWS SDK for Python  
AWS SDK for Ruby V3 |

When you launch your instance, you can launch your instance in a subnet that is associated with one of the following resources:

- An Availability Zone - This option is the default.
- A Local Zone - To launch an instance in a Local Zone, you must opt in to the Local Zone, and then create a subnet in the zone. For more information, see Local Zones
- A Wavelength Zone - To launch an instance in a Wavelength Zone, you must opt in to the Wavelength Zone, and then create a subnet in the zone. For information about how to launch an instance in a Wavelength Zone, see Get started with AWS Wavelength in the AWS Wavelength Developer Guide.
• An Outpost - To launch an instance in an Outpost, you must create an Outpost. For information about how to create an Outpost, see Get Started with AWS Outposts in the AWS Outposts User Guide.

After you launch your instance, you can connect to it and use it. To begin, the instance state is pending. When the instance state is running, the instance has started booting. There might be a short time before you can connect to the instance. Note that bare metal instance types might take longer to launch. For more information about bare metal instances, see Instances built on the Nitro System (p. 199).

The instance receives a public DNS name that you can use to contact the instance from the internet. The instance also receives a private DNS name that other instances within the same VPC can use to contact the instance. For more information about connecting to your instance, see Connect to your Linux instance (p. 499).

When you are finished with an instance, be sure to terminate it. For more information, see Terminate your instance (p. 547).

Launch an instance using the Launch Instance Wizard

You can launch an instance using the launch instance wizard. The launch instance wizard specifies all the launch parameters required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. At the very least, you need to select an AMI and a key pair to launch an instance.

Before you launch your instance, be sure that you are set up. For more information, see Set up to use Amazon EC2 (p. 5).

Important
When you launch an instance that's not within the AWS Free Tier, you are charged for the time that the instance is running, even if it remains idle.

Steps to launch an instance:
- Initiate instance launch (p. 477)
- Step 1: Choose an Amazon Machine Image (AMI) (p. 477)
- Step 2: Choose an Instance Type (p. 478)
- Step 3: Configure Instance Details (p. 479)
- Step 4: Add Storage (p. 481)
- Step 5: Add Tags (p. 482)
- Step 6: Configure Security Group (p. 482)
- Step 7: Review Instance Launch and Select Key Pair (p. 482)

Initiate instance launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current Region is displayed (for example, US East (Ohio)). Select a Region for the instance that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see Resource locations (p. 1452).
3. From the Amazon EC2 console dashboard, choose Launch instance.

Step 1: Choose an Amazon Machine Image (AMI)

When you launch an instance, you must select a configuration, known as an Amazon Machine Image (AMI). An AMI contains the information required to create a new instance. For example, an AMI might contain the software required to act as a web server, such as Linux, Apache, and your website.
When you launch an instance, you can either select an AMI from the list, or you can select a Systems Manager parameter that points to an AMI ID. For more information, see Using a Systems Manager parameter to find an AMI.

On the Choose an Amazon Machine Image (AMI) page, use one of two options to choose an AMI. Either search the list of AMIs (p. 478), or search by Systems Manager parameter (p. 478).

**By searching the list of AMIs**

1. Select the type of AMI to use in the left pane:

   **Quick Start**
   
   A selection of popular AMIs to help you get started quickly. To select an AMI that is eligible for the free tier, choose Free tier only in the left pane. These AMIs are marked Free tier eligible.

   **My AMIs**
   
   The private AMIs that you own, or private AMIs that have been shared with you. To view AMIs that are shared with you, choose Shared with me in the left pane.

   **AWS Marketplace**
   
   An online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see Launch an AWS Marketplace instance (p. 497).

   **Community AMIs**
   
   The AMIs that AWS community members have made available for others to use. To filter the list of AMIs by operating system, choose the appropriate check box under Operating system. You can also filter by architecture and root device type.

2. Check the Root device type listed for each AMI. Notice which AMIs are the type that you need, either ebs (backed by Amazon EBS) or instance-store (backed by instance store). For more information, see Storage for the root device (p. 73).

3. Check the Virtualization type listed for each AMI. Notice which AMIs are the type that you need, either hvm or paravirtual. For example, some instance types require HVM. For more information, see Linux AMI virtualization types (p. 75).

4. Check the Boot mode listed for each AMI. Notice which AMIs use the boot mode that you need, either legacy-bios or uefi. For more information, see Boot modes (p. 77).

5. Choose an AMI that meets your needs, and then choose **Select**.

**By Systems Manager parameter**

1. Choose Search by Systems Manager parameter (at top right).

2. For Systems Manager parameter, select a parameter. The corresponding AMI ID appears next to Currently resolves to.

3. Choose Search. The AMIs that match the AMI ID appear in the list.

4. Select the AMI from the list, and choose **Select**.

**Step 2: Choose an Instance Type**

On the Choose an Instance Type page, select the hardware configuration and size of the instance to launch. Larger instance types have more CPU and memory. For more information, see Instance types (p. 193).
To remain eligible for the free tier, choose the `t2.micro` instance type (or the `t3.micro` instance type in Regions where `t2.micro` is unavailable). For more information, see Burstable performance instances (p. 216).

By default, the wizard displays current generation instance types, and selects the first available instance type based on the AMI that you selected. To view previous generation instance types, choose All generations from the filter list.

**Note**
To set up an instance quickly for testing purposes, choose Review and Launch to accept the default configuration settings, and launch your instance. Otherwise, to configure your instance further, choose Next: Configure Instance Details.

**Step 3: Configure Instance Details**

On the Configure Instance Details page, change the following settings as necessary (expand Advanced Details to see all the settings), and then choose Next: Add Storage:

- **Number of instances**: Enter the number of instances to launch.
  
  **Tip**
  To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose Launch into Auto Scaling Group to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the Amazon EC2 Auto Scaling User Guide.

  **Note**
  If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see Health Checks for Auto Scaling Instances in the Amazon EC2 Auto Scaling User Guide.

- **Purchasing option**: Choose Request Spot instances to launch a Spot Instance. This adds and removes options from this page. Set your maximum price, and optionally update the request type, interruption behavior, and request validity. For more information, see Create a Spot Instance request (p. 380).

- **Network**: Select the VPC, or to create a new VPC, choose Create new VPC to go the Amazon VPC console. When you have finished, return to the wizard and choose Refresh to load your VPC in the list.

- **Subnet**: You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone or Outpost.

To launch the instance in an Availability Zone, select the subnet into which to launch your instance. You can select No preference to let AWS choose a default subnet in any Availability Zone. To create a new subnet, choose Create new subnet to go to the Amazon VPC console. When you are done, return to the wizard and choose Refresh to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with an Outpost.

- **Auto-assign Public IP**: Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet do not. You can select Enable or Disable to override the subnet’s default setting. For more information, see Public IPv4 addresses and external DNS hostnames (p. 881).

- **Auto-assign IPv6 IP**: Specify whether your instance receives an IPv6 address from the range of the subnet. Select Enable or Disable to override the subnet’s default setting. This option is only available
if you’ve associated an IPv6 CIDR block with your VPC and subnet. For more information, see Your VPC and Subnets in the Amazon VPC User Guide.

- **Domain join directory**: Select the AWS Directory Service directory (domain) to which your Linux instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information, see Seamlessly Join a Linux EC2 Instance to Your AWS Managed Microsoft AD Directory.

- **Placement group**: A placement group determines the placement strategy of your instances. Select an existing placement group, or create a new one. This option is only available if you’ve selected an instance type that supports placement groups. For more information, see Placement groups (p. 1018).

- **Capacity Reservation**: Specify whether to launch the instance into shared capacity, any open Capacity Reservation, a specific Capacity Reservation, or a Capacity Reservation group. For more information, see Launch instances into an existing Capacity Reservation (p. 459).

- **IAM role**: Select an AWS Identity and Access Management (IAM) role to associate with the instance. For more information, see IAM roles for Amazon EC2 (p. 1125).

- **CPU options**: Choose Specify CPU options to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see Optimize CPU options (p. 575).

- **Shutdown behavior**: Select whether the instance should stop or terminate when shut down. For more information, see Change the instance initiated shutdown behavior (p. 551).

- **Stop - Hibernate behavior**: To enable hibernation, select this check box. This option is only available if your instance meets the hibernation prerequisites. For more information, see Hibernate your On-Demand or Reserved Linux instance (p. 528).

- **Enable termination protection**: To prevent accidental termination, select this check box. For more information, see Enable termination protection (p. 550).

- **Monitoring**: Select this check box to enable detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see Monitor your instances using CloudWatch (p. 818).

- **EBS-optimized instance**: An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, select this check box to enable it. Additional charges apply. For more information, see Amazon EBS–optimized instances (p. 1354).

- **Tenancy**: If you are launching your instance into a VPC, you can choose to run your instance on isolated, dedicated hardware (Dedicated) or on a Dedicated Host (Dedicated host). Additional charges may apply. For more information, see Dedicated Instances (p. 446) and Dedicated Hosts (p. 415).

- **T2/T3 Unlimited**: Select this check box to enable applications to burst beyond the baseline for as long as needed. Additional charges may apply. For more information, see Burstable performance instances (p. 216).

- **File systems**: To create a new file system to mount to your instance, choose Create new file system, enter a name for the new file system, and then choose Create. The file system is created using Amazon EFS Quick Create, which applies the service recommended settings. The security groups required to enable access to the file system are automatically created and attached to the instance and the mount targets of the file system. You can also choose to manually create and attach the required security groups. For more information, see Create an EFS file system using Amazon EFS Quick Create (p. 1427).

To mount one or more existing Amazon EFS file systems to your instance, choose Add file system and then choose the file systems to mount and the mount points to use. For more information, see Create an EFS file system and mount it to your instance (p. 1428).

- **Network interfaces**: If you selected a specific subnet, you can specify up to two network interfaces for your instance:
  - For **Network Interface**, select New network interface to let AWS create a new interface, or select an existing, available network interface.
  - For **Primary IP**, enter a private IPv4 address from the range of your subnet, or leave Auto-assign to let AWS choose a private IPv4 address for you.
• For **Secondary IP addresses**, choose Add IP to assign more than one private IPv4 address to the selected network interface.

• (IPv6-only) For **IPv6 IPs**, choose Add IP, and enter an IPv6 address from the range of the subnet, or leave Auto-assign to let AWS choose one for you.

• **Network Card Index**: The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.

• Choose Add Device to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces](p. 922). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using Auto-assign Public IP. For more information, see [Assign a public IPv4 address during instance launch](p. 885).

• **Kernel ID**: (Only valid for paravirtual (PV) AMIs) Select Use default unless you want to use a specific kernel.

• **RAM disk ID**: (Only valid for paravirtual (PV) AMIs) Select Use default unless you want to use a specific RAM disk. If you have selected a kernel, you may need to select a specific RAM disk with the drivers to support it.

• **Enclave**: Select Enable to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](aws-nitro-enclaves-user-guide) in the [AWS Nitro Enclaves User Guide](aws-nitro-enclaves-user-guide).

• **Metadata accessible**: You can enable or disable access to the instance metadata. For more information, see [Use IMDSv2](p. 607).

• **Metadata transport**: You can enable or disable the access method to the instance metadata service that's available for this EC2 instance based on the IP address type (IPv4, IPv6, or IPv4 and IPv6) of the instance. For more information, see [Retrieve instance metadata](p. 614).

• **Metadata version**: If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](p. 611).

• **Metadata token response hop limit**: If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Use IMDSv2](p. 607).

• **User data**: You can specify user data to configure an instance during launch, or to run a configuration script. To attach a file, select the As file option and browse for the file to attach.

---

**Step 4: Add Storage**

The AMI you selected includes one or more volumes of storage, including the root device volume. On the Add Storage page, you can specify additional volumes to attach to the instance by choosing Add New Volume. Configure each volume as follows, and then choose Next: Add Tags.

• **Type**: Select instance store or Amazon EBS volumes to associate with your instance. The types of volume available in the list depend on the instance type you've chosen. For more information, see [Amazon EC2 instance store](p. 1408) and [Amazon EBS volumes](p. 1177).

• **Device**: Select from the list of available device names for the volume.

• **Snapshot**: Enter the name or ID of the snapshot from which to restore a volume. You can also search for available shared and public snapshots by typing text into the Snapshot field. Snapshot descriptions are case-sensitive.

• **Size**: For EBS volumes, you can specify a storage size. Even if you have selected an AMI and instance that are eligible for the free tier, to stay within the free tier, you must stay under 30 GiB of total storage. For more information, see [Constraints on the size and configuration of an EBS volume](p. 1197).

• **Volume Type**: For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types](p. 1179).
• **IOPS**: If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.

• **Delete on Termination**: For Amazon EBS volumes, select this check box to delete the volume when the instance is terminated. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).

• **Encrypted**: If the instance type supports EBS encryption, you can specify the encryption state of the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or disable encryption. For more information, see Amazon EBS encryption (p. 1335).

**Step 5: Add Tags**

On the **Add Tags** page, specify tags (p. 1462) by providing key and value combinations. You can tag the instance, the volumes, or both. For Spot Instances, you can tag the Spot Instance request only. Choose **Add another tag** to add more than one tag to your resources. Choose **Next: Configure Security Group** when you are done.

**Step 6: Configure Security Group**

On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see Amazon EC2 security groups for Linux instances (p. 1152).) Select or create a security group as follows, and then choose **Review and Launch**.

- To select an existing security group, choose **Select an existing security group**, and select your security group. You can't edit the rules of an existing security group, but you can copy them to a new group by choosing **Copy to new**. Then you can add rules as described in the next step.

- To create a new security group, choose **Create a new security group**. The wizard automatically defines the launch-wizard-x security group and creates an inbound rule to allow you to connect to your instance over SSH (port 22).

- You can add rules to suit your needs. For example, if your instance is a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add Rule**, select the protocol to open to network traffic, and then specify the source. Choose **My IP** from the **Source** list to let the wizard add your computer's public IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

**Warning**

Rules that enable all IP addresses (0.0.0.0/0) to access your instance over SSH or RDP are acceptable for this short exercise, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

**Step 7: Review Instance Launch and Select Key Pair**

On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch**.

In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair you created when getting set up. For more information, see Amazon EC2 key pairs and Linux instances (p. 1137).
Important
If you choose the Proceed without key pair option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

To launch your instance, select the acknowledgment check box, then choose Launch Instances.

(Optional) You can create a status check alarm for the instance (additional fees may apply). (If you’re not sure, you can always add one later.) On the confirmation screen, choose Create status check alarms and follow the directions. For more information, see Create and edit status check alarms (p. 793).

If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot instance launch issues (p. 1477).

Launch an instance from a launch template

You can create a launch template that contains the configuration information to launch an instance. You can use launch templates to store launch parameters so that you do not have to specify them every time you launch an instance. For example, a launch template can contain the AMI ID, instance type, and network settings that you typically use to launch instances. When you launch an instance using the Amazon EC2 console, an AWS SDK, or a command line tool, you can specify the launch template to use.

For each launch template, you can create one or more numbered launch template versions. Each version can have different launch parameters. When you launch an instance from a launch template, you can use any version of the launch template. If you do not specify a version, the default version is used. You can set any version of the launch template as the default version—by default, it’s the first version of the launch template.

The following diagram shows a launch template with three versions. The first version specifies the instance type, AMI ID, subnet, and key pair to use to launch the instance. The second version is based on the first version and also specifies a security group for the instance. The third version uses different values for some of the parameters. Version 2 is set as the default version. If you launched an instance from this launch template, the launch parameters from version 2 would be used if no other version were specified.

Contents
- Launch template restrictions (p. 484)
- Use launch templates to control launch parameters (p. 484)
- Control the use of launch templates (p. 484)
- Create a launch template (p. 485)
- Modify a launch template (manage launch template versions) (p. 490)
- Launch an instance from a launch template (p. 493)
- Use launch templates with Amazon EC2 Auto Scaling (p. 494)
• Use launch templates with EC2 Fleet (p. 495)
• Use launch templates with Spot Fleet (p. 495)
• Delete a launch template (p. 496)

Launch template restrictions

The following rules apply to launch templates and launch template versions:

• You are limited to creating 5,000 launch templates per Region and 10,000 versions per launch template.
• Launch template parameters are optional. However, you must ensure that your request to launch an instance includes all required parameters. For example, if your launch template does not include an AMI ID, you must specify both the launch template and an AMI ID when you launch an instance.
• Launch template parameters are not fully validated when you create the launch template. If you specify incorrect values for parameters, or if you do not use supported parameter combinations, no instances can launch using this launch template. Ensure that you specify the correct values for the parameters and that you use supported parameter combinations. For example, to launch an instance in a placement group, you must specify a supported instance type.
• You can tag a launch template, but you cannot tag a launch template version.
• Launch templates are immutable. To modify a launch template, you must create a new version of the launch template.
• Launch template versions are numbered in the order in which they are created. When you create a launch template version, you cannot specify the version number yourself.

Use launch templates to control launch parameters

A launch template can contain all or some of the parameters to launch an instance. When you launch an instance using a launch template, you can override parameters that are specified in the launch template. Or, you can specify additional parameters that are not in the launch template.

Note
You cannot remove launch template parameters during launch (for example, you cannot specify a null value for the parameter). To remove a parameter, create a new version of the launch template without the parameter and use that version to launch the instance.

To launch instances, IAM users must have permissions to use the ec2:RunInstances action. IAM users must also have permissions to create or use the resources that are created or associated with the instance. You can use resource-level permissions for the ec2:RunInstances action to control the launch parameters that users can specify. Alternatively, you can grant users permissions to launch an instance using a launch template. This enables you to manage launch parameters in a launch template rather than in an IAM policy, and to use a launch template as an authorization vehicle for launching instances. For example, you can specify that users can only launch instances using a launch template, and that they can only use a specific launch template. You can also control the launch parameters that users can override in the launch template. For example policies, see Launch templates (p. 1100).

Control the use of launch templates

By default, IAM users do not have permissions to work with launch templates. You can create an IAM user policy that grants users permissions to create, modify, describe, and delete launch templates and launch template versions. You can also apply resource-level permissions to some launch template actions to control a user’s ability to use specific resources for those actions. For more information, see the following example policies: Example: Work with launch templates (p. 1112).

Take care when granting users permissions to use the ec2:CreateLaunchTemplate and ec2:CreateLaunchTemplateVersion actions. You cannot use resource-level permissions to control
which resources users can specify in the launch template. To restrict the resources that are used to launch an instance, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

Create a launch template

Create a new launch template using parameters that you define, or use an existing launch template or an instance as the basis for a new launch template.

Tasks

- Create a new launch template using parameters you define (p. 485)
- Create a launch template from an existing launch template (p. 489)
- Create a launch template from an instance (p. 489)

Create a new launch template using parameters you define

Console

To create a new launch template using defined parameters using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. For Launch template name, enter a descriptive name for the launch template.
4. For Template version description, provide a brief description of the launch template version.
5. To tag the launch template on creation, expand Template tags, choose Add tag, and then enter a tag key and value pair.
6. For Launch template contents, provide the following information:
   - **AMI**: An AMI from which to launch the instance. To search through all available AMIs, choose Search for AMI. To select a commonly used AMI, choose Quick Start. Or, choose AWS Marketplace or Community AMIs. You can use an AMI that you own or find a suitable AMI.
   - **Instance type**: Ensure that the instance type is compatible with the AMI that you’ve specified. For more information, see Instance types (p. 193).
   - **Key pair name**: The key pair for the instance. For more information, see Amazon EC2 key pairs and Linux instances (p. 1137).
   - **Network platform**: If applicable, whether to launch the instance into a VPC or EC2-Classic. If you choose VPC, specify the subnet in the Network interfaces section. If you choose Classic, ensure that the specified instance type is supported in EC2-Classic and specify the Availability Zone for the instance.
   - **Security groups**: One or more security groups to associate with the instance. If you add a network interface to the launch template, omit this setting and specify the security groups as part of the network interface specification. You cannot launch an instance from a launch template that specifies security groups and a network interface. For more information, see Amazon EC2 security groups for Linux instances (p. 1152).
7. For Storage (volumes), specify volumes to attach to the instance besides the volumes specified by the AMI (Volume 1 (AMI Root)). To add a new volume, choose Add new volume.
   - **Volume type**: The instance store or Amazon EBS volumes with which to associate your instance. The type of volume depends on the instance type that you’ve chosen. For more information, see Amazon EC2 instance store (p. 1408) and Amazon EBS volumes (p. 1177).
   - **Device name**: A device name for the volume.
   - **Snapshot**: The ID of the snapshot from which to create the volume.
   - **Size**: For Amazon EBS volumes, the storage size.
• **Volume type**: For Amazon EBS volumes, the volume type. For more information, see Amazon EBS volume types (p. 1179).

• **IOPS**: For the Provisioned IOPS SSD volume type, the number of I/O operations per second (IOPS) that the volume can support.

• **Delete on termination**: For Amazon EBS volumes, whether to delete the volume when the instance is terminated. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).

• **Encrypted**: If the instance type supports EBS encryption, you can enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see Amazon EBS encryption (p. 1335).

• **Key**: The customer managed key to use for EBS encryption. You can specify the ARN of any customer managed key that you created using the customer managed key. If you specify a customer managed key, you must also use Encrypted to enable encryption.

8. For **Resource tags**, specify tags (p. 1462) by providing key and value combinations. You can tag the instance, the volumes, Spot Instance requests, or all three.

9. For **Network interfaces**, you can specify up to two network interfaces (p. 922) for the instance.

• **Device index**: The device number for the network interface, for example, eth0 for the primary network interface. If you leave the field blank, AWS creates the primary network interface.

• **Network interface**: The ID of the network interface, or leave blank to let AWS create a new network interface.

• **Description**: (Optional) A description for the new network interface.

• **Subnet**: The subnet in which to create a new network interface. For the primary network interface (eth0), this is the subnet in which the instance is launched. If you've entered an existing network interface for eth0, the instance is launched in the subnet in which the network interface is located.

• **Auto-assign public IP**: Whether to automatically assign a public IP address to the network interface with the device index of eth0. This setting can only be enabled for a single, new network interface.

• **Primary IP**: A private IPv4 address from the range of your subnet. Leave blank to let AWS choose a private IPv4 address for you.

• **Secondary IP**: A secondary private IPv4 address from the range of your subnet. Leave blank to let AWS choose one for you.

• **(IPv6-only) IPv6 IPs**: An IPv6 address from the range of the subnet.

• **Security groups**: One or more security groups in your VPC with which to associate the network interface.

• **Delete on termination**: Whether the network interface is deleted when the instance is deleted.

• **Elastic Fabric Adapter**: Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see Elastic Fabric Adapter.

• **Network card index**: The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.

10. For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

• **Purchasing option**: The purchasing model. Choose Request Spot Instances to request Spot Instances at the Spot price, capped at the On-Demand price, and choose Customize to change the default Spot Instance settings. If you do not request a Spot Instance, EC2 launches an On-Demand Instance by default. For more information, see Spot Instances (p. 367).
IAM instance profile: An AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see IAM roles for Amazon EC2 (p. 1125).

Shutdown behavior: Whether the instance should stop or terminate when shut down. For more information, see Change the instance initiated shutdown behavior (p. 551).

Stop - Hibernate behavior: Whether the instance is enabled for hibernation. This field is only valid for instances that meet the hibernation prerequisites. For more information, see Hibernate your On-Demand or Reserved Linux instance (p. 528).

Termination protection: Whether to prevent accidental termination. For more information, see Enable termination protection (p. 550).

Detailed CloudWatch monitoring: Whether to enable detailed monitoring of the instance using Amazon CloudWatch. Additional charges apply. For more information, see Monitor your instances using CloudWatch (p. 818).

Elastic inference: An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see Working with Amazon Elastic Inference in the Amazon Elastic Inference Developer Guide.

T2/T3 Unlimited: Whether to enable applications to burst beyond the baseline for as long as needed. This field is only valid for T2, T3, and T3a instances. Additional charges may apply. For more information, see Burstable performance instances (p. 216).

Placement group name: Specify a placement group in which to launch the instance. Not all instance types can be launched in a placement group. For more information, see Placement groups (p. 1018).

EBS-optimized instance: Provides additional, dedicated capacity for Amazon EBS I/O. Not all instance types support this feature, and additional charges apply. For more information, see Amazon EBS-optimized instances (p. 1354).

Capacity Reservation: Specify whether to launch the instance into any open Capacity Reservation (open), a specific Capacity Reservation (Target by ID), or a Capacity Reservation group (Target by group). To specify that a Capacity Reservation should not be used, choose None. For more information, see Launch instances into an existing Capacity Reservation (p. 459).

Tenancy: Choose whether to run your instance on shared hardware (Shared), isolated, dedicated hardware (Dedicated), or on a Dedicated Host (Dedicated host). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see Dedicated Instances (p. 446) and Dedicated Hosts (p. 415).

RAM disk ID: (Only valid for paravirtual (PV) AMIs) A RAM disk for the instance. If you have specified a kernel, you may need to specify a specific RAM disk with the drivers to support it.

Kernel ID: (Only valid for paravirtual (PV) AMIs) A kernel for the instance.

License configurations: You can launch instances against the specified license configuration to track your license usage. For more information, see Create a License Configuration in the AWS License Manager User Guide.

Metadata accessible: Whether to enable or disable access to the instance metadata. For more information, see Use IMDSv2 (p. 607).

Metadata version: If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see Configure instance metadata options for new instances (p. 611).

Metadata response hop limit: If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see Use IMDSv2 (p. 607).

User data: You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see Run commands on your Linux instance at launch (p. 600).
11. Choose **Create launch template**.

**AWS CLI**

**To create a launch template using the AWS CLI**

- Use the `create-launch-template` command. The following example creates a launch template that specifies the following:
  - A tag for the launch template (purpose=production)
  - The instance type (r4.4xlarge) and AMI (ami-8c1be5f6) to launch
  - The number of cores (4) and threads per core (2) for a total of 8 vCPUs (4 cores x 2 threads)
  - The subnet in which to launch the instance (subnet-7b16de0c)

The template assigns a public IP address and an IPv6 address to the instance and creates a tag for the instance (Name=webserver).

```
aws ec2 create-launch-template \
  --launch-template-name TemplateForWebServer \
  --version-description WebVersion1 \
  --tag-specifications 'ResourceType=launch-template,Tags=[{Key=purpose,Value=production}]' \
  --launch-template-data file://template-data.json
```

The following is an example `template-data.json` file.

```json
{
  "NetworkInterfaces": [{
    "AssociatePublicIpAddress": true,
    "DeviceIndex": 0,
    "Ipv6AddressCount": 1,
    "SubnetId": "subnet-7b16de0c"
  }],
  "ImageId": "ami-8c1be5f6",
  "InstanceType": "r4.4xlarge",
  "TagSpecifications": [{
    "ResourceType": "instance",
    "Tags": [{
      "Key": "Name",
      "Value": "webserver"
    }]
  }],
  "CpuOptions": {
    "CoreCount": 4,
    "ThreadsPerCore": 2
  }
}
```

The following is example output.

```json
{
  "LaunchTemplate": {
    "LatestVersionNumber": 1,
    "LaunchTemplateId": "lt-01238c059e3466abc",
    "LaunchTemplateName": "TemplateForWebServer",
    "DefaultVersionNumber": 1,
    "CreatedBy": "arn:aws:iam::123456789012:root",
    "CreateTime": "2017-11-27T09:13:24.000Z"
  }
}
```
Create a launch template from an existing launch template

To create a launch template from an existing launch template using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. For Launch template name, enter a descriptive name for the launch template.
4. For Template version description, provide a brief description of the launch template version.
5. To tag the launch template on creation, expand Template tags, choose Add tag, and then enter a tag key and value pair.
6. Expand Source template, and for Launch template name choose a launch template on which to base the new launch template.
7. For Source template version, choose the launch template version on which to base the new launch template.
8. Adjust any launch parameters as required, and then choose Create launch template.

Create a launch template from an instance

Console

To create a launch template from an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, and choose Actions, Create template from instance.
4. Provide a name, description, and tags, and adjust the launch parameters as required.
   Note
   When you create a launch template from an instance, the instance's network interface IDs and IP addresses are not included in the template.
5. Choose Create launch template.

AWS CLI

You can use the AWS CLI to create a launch template from an existing instance by first getting the launch template data from an instance, and then creating a launch template using the launch template data.

To get launch template data from an instance using the AWS CLI

- Use the get-launch-template-data command and specify the instance ID. You can use the output as a base to create a new launch template or launch template version. By default, the output includes a top-level LaunchTemplateData object, which cannot be specified in your launch template data. Use the --query option to exclude this object.

```
aws ec2 get-launch-template-data \
  --instance-id i-0123d646e8048babc \
  --query "LaunchTemplateData"
```

The following is example output.
You can write the output directly to a file, for example:

```bash
aws ec2 get-launch-template-data \
  --instance-id i-0123d646e8048babc \
  --query "LaunchTemplateData" >> instance-data.json
```

**To create a launch template using launch template data**

Use the `create-launch-template` command to create a launch template using the output from the previous procedure. For more information about creating a launch template using the AWS CLI, see Create a new launch template using parameters you define (p. 485).

**Modify a launch template (manage launch template versions)**

Launch templates are immutable; after you create a launch template, you can't modify it. Instead, you can create a new version of the launch template that includes any changes you require.
You can create launch template versions for a specific launch template, set the default version, describe a launch template version, and delete versions that you no longer require.

**Tasks**
- Create a launch template version (p. 491)
- Set the default launch template version (p. 491)
- Describe a launch template version (p. 492)
- Delete a launch template version (p. 493)

**Create a launch template version**

When you create a launch template version, you can specify new launch parameters or use an existing version as the base for the new version. For more information about the launch parameters, see Create a launch template (p. 485).

**Console**

**To create a launch template version using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. Select a launch template, and then choose **Actions, Modify template (Create new version)**.
4. For **Template version description**, enter a description for the launch template version.
5. (Optional) Expand **Source template** and select a version of the launch template to use as a base for the new launch template version. The new launch template version inherits the launch parameters from this launch template version.
6. Modify the launch parameters as required, and choose **Create launch template**.

**AWS CLI**

**To create a launch template version using the AWS CLI**

- Use the `create-launch-template-version` command. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using `--launch-template-data`. The following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```bash
aws ec2 create-launch-template-version \
    --launch-template-id lt-0abcd290751193123 \
    --version-description WebVersion2 \
    --source-version 1 \
    --launch-template-data "ImageId=ami-c998b6b2"
```

**Set the default launch template version**

You can set the default version for the launch template. When you launch an instance from a launch template and do not specify a version, the instance is launched using the parameters of the default version.

**Console**

**To set the default launch template version using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Set default version**.
4. For **Template version**, select the version number to set as the default version and choose **Set as default version**.

**AWS CLI**

**To set the default launch template version using the AWS CLI**

- Use the `modify-launch-template` command and specify the version that you want to set as the default.

```
aws ec2 modify-launch-template \
    --launch-template-id lt-0abcd290751193123 \
    --default-version 2
```

**Describe a launch template version**

Using the console, you can view all the versions of the selected launch template, or get a list of the launch templates whose latest or default version matches a specific version number. Using the AWS CLI, you can describe all versions, individual versions, or a range of versions of a specified launch template. You can also describe all the latest versions or all the default versions of all the launch templates in your account.

**Console**

**To describe a launch template version using the console**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Launch Templates**.
3. You can view a version of a specific launch template, or get a list of the launch templates whose latest or default version matches a specific version number.
   - To view a version of a launch template: Select the launch template. On the **Versions** tab, from **Version**, select a version to view its details.
   - To get a list of all the launch templates whose latest version matches a specific version number: From the search bar, choose **Latest version**, and then choose a version number.
   - To get a list of all the launch templates whose default version matches a specific version number: From the search bar, choose **Default version**, and then choose a version number.

**AWS CLI**

**To describe a launch template version using the AWS CLI**

- Use the `describe-launch-template-versions` command and specify the version numbers. In the following example, versions 1 and 3 are specified.

```
aws ec2 describe-launch-template-versions \
    --launch-template-id lt-0abcd290751193123 \
    --versions 1 3
```
To describe all the latest and default launch template versions in your account using the AWS CLI

- Use the `describe-launch-template-versions` command and specify `$Latest`, `$Default`, or both. You must omit the launch template ID and name in the call. You cannot specify version numbers.

```
aws ec2 describe-launch-template-versions  
 --versions "$Latest,$Default"
```

Delete a launch template version

If you no longer require a launch template version, you can delete it. You cannot replace the version number after you delete it. You cannot delete the default version of the launch template; you must first assign a different version as the default.

Console

To delete a launch template version using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates.
3. Select the launch template and choose Actions, Delete template version.
4. Select the version to delete and choose Delete.

AWS CLI

To delete a launch template version using the AWS CLI

- Use the `delete-launch-template-versions` command and specify the version numbers to delete.

```
aws ec2 delete-launch-template-versions  
 --launch-template-id lt-0abcd290751193123  
 --versions 1
```

Launch an instance from a launch template

You can use the parameters contained in a launch template to launch an instance. You have the option to override or add launch parameters before you launch the instance.

Instances that are launched using a launch template are automatically assigned two tags with the keys `aws:ec2launchtemplate:id` and `aws:ec2launchtemplate:version`. You cannot remove or edit these tags.

Console

To launch an instance from a launch template using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates.
3. Select the launch template and choose Actions, Launch instance from template.
4. For Source template version, select the launch template version to use.
5. For Number of instances, specify the number of instances to launch.
6. (Optional) You can override or add launch template parameters by changing and adding parameters in the **Instance details** section.

7. Choose **Launch instance from template**.

**AWS CLI**

**To launch an instance from a launch template using the AWS CLI**

- Use the `run-instances` command and specify the `--launch-template` parameter. Optionally specify the launch template version to use. If you don’t specify the version, the default version is used.

```
aws ec2 run-instances \ 
    --launch-template LaunchTemplateId=lt-0abcd2907511931123,Version=1
```

- To override a launch template parameter, specify the parameter in the `run-instances` command. The following example overrides the instance type that’s specified in the launch template (if any).

```
aws ec2 run-instances \ 
    --launch-template LaunchTemplateId=lt-0abcd2907511931123 \ 
    --instance-type t2.small
```

- If you specify a nested parameter that’s part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag `Owner=TeamA` as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of `Owner`, the value is replaced with `TeamA`.

```
aws ec2 run-instances \ 
    --launch-template LaunchTemplateId=lt-0abcd2907511931123 \ 
    --tag-specifications "ResourceType=instance,Tags=[{Key=Owner,Value=TeamA}]"
```

In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

```
aws ec2 run-instances \ 
    --launch-template LaunchTemplateId=lt-0abcd2907511931123 \ 
    --block-device-mappings  "DeviceName=/dev/xvdb,Ebs={VolumeSize=20,VolumeType=gp2}"
```

If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see Troubleshoot instance launch issues (p. 1477).

**Use launch templates with Amazon EC2 Auto Scaling**

You can create an Auto Scaling group and specify a launch template to use for the group. When Amazon EC2 Auto Scaling launches instances in the Auto Scaling group, it uses the launch parameters defined in the associated launch template. For more information, see Creating an Auto Scaling Group Using a Launch Template in the Amazon EC2 Auto Scaling User Guide.

Before you can create an Auto Scaling group using a launch template, you must create a launch template that includes the parameters required to launch an instance in an Auto Scaling group, such as the ID
of the AMI. The console provides guidance to help you create a template that you can use with Auto
Scaling.

To create a launch template to use with Auto Scaling using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. For Launch template name, enter a descriptive name for the launch template.
4. For Template version description, provide a brief description of the launch template version.
5. Under Auto Scaling guidance, select the checkbox to have Amazon EC2 provide guidance to help
create a template to use with Auto Scaling.
6. Modify the launch parameters as required. Because you selected Auto Scaling guidance, some fields
are required and some fields are not available. For considerations to keep in mind when creating
a launch template, and for information about how to configure the launch parameters for Auto
Scaling, see Creating a Launch Template for an Auto Scaling Group in the Amazon EC2 Auto Scaling
User Guide.
7. Choose Create launch template.
8. (Optional) To create an Auto Scaling group using this launch template, in the Next steps page,
choose Create Auto Scaling group.

To create or update an Amazon EC2 Auto Scaling group with a launch template using the
AWS CLI

• Use the create-auto-scaling-group or the update-auto-scaling-group command and specify the --
launch-template parameter.

Use launch templates with EC2 Fleet

You can create an EC2 Fleet request and specify a launch template in the instance configuration. When
Amazon EC2 fulfills the EC2 Fleet request, it uses the launch parameters defined in the associated launch
template. You can override some of the parameters that are specified in the launch template.

For more information, see Create an EC2 Fleet (p. 693).

To create an EC2 Fleet with a launch template using the AWS CLI

• Use the create-fleet command. Use the --launch-template-configs parameter to specify the
launch template and any overrides for the launch template.

Use launch templates with Spot Fleet

You can create a Spot Fleet request and specify a launch template in the instance configuration. When
Amazon EC2 fulfills the Spot Fleet request, it uses the launch parameters defined in the associated
launch template. You can override some of the parameters that are specified in the launch template.

For more information, see Spot Fleet request types (p. 703).

To create a Spot Fleet request with a launch template using the AWS CLI

• Use the request-spot-fleet command. Use the LaunchTemplateConfigs parameter to specify the
launch template and any overrides for the launch template.
Delete a launch template

If you no longer require a launch template, you can delete it. Deleting a launch template deletes all of its versions.

Console

To delete a launch template (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates.
3. Select the launch template and choose Actions, Delete template.
4. Enter Delete to confirm deletion, and then choose Delete.

AWS CLI

To delete a launch template (AWS CLI)

- Use the delete-launch-template (AWS CLI) command and specify the launch template.

```bash
aws ec2 delete-launch-template --launch-template-id lt-01238c059e3466abc
```

Launch an instance using parameters from an existing instance

The Amazon EC2 console provides a Launch more like this wizard option that enables you to use a current instance as a base for launching other instances. This option automatically populates the Amazon EC2 launch wizard with certain configuration details from the selected instance.

**Note**

The Launch more like this wizard option does not clone your selected instance; it only replicates some configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI.

Alternatively, create a launch template (p. 483) to store the launch parameters for your instances.

The following configuration details are copied from the selected instance into the launch wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Public IPv4 address. If the selected instance currently has a public IPv4 address, the new instance receives a public IPv4 address - regardless of the selected instance's default public IPv4 address setting. For more information about public IPv4 addresses, see Public IPv4 addresses and external DNS hostnames (p. 881).
- Placement group, if applicable
- IAM role associated with the instance, if applicable
- Shutdown behavior setting (stop or terminate)
- Termination protection setting (true or false)
- CloudWatch monitoring (enabled or disabled)
- Amazon EBS-optimization setting (true or false)
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Kernel ID and RAM disk ID, if applicable
Launch

- User data, if specified
- Tags associated with the instance, if applicable
- Security groups associated with the instance

The following configuration details are not copied from your selected instance. Instead, the wizard applies their default settings or behavior:

- Number of network interfaces: The default is one network interface, which is the primary network interface (eth0).
- Storage: The default storage configuration is determined by the AMI and the instance type.

**New console**

**To use your current instance as a template**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance you want to use, and then choose **Actions, Images and templates, Launch more like this**.
4. The launch wizard opens on the **Review Instance Launch** page. You can make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch** to select a key pair and launch your instance.

5. If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see Troubleshoot instance launch issues (p. 1477).

**Old console**

**To use your current instance as a template**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance you want to use, and then choose **Actions, Launch More Like This**.
4. The launch wizard opens on the **Review Instance Launch** page. You can make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch** to select a key pair and launch your instance.

5. If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see Troubleshoot instance launch issues (p. 1477).

**Launch an AWS Marketplace instance**

You can subscribe to an AWS Marketplace product and launch an instance from the product's AMI using the Amazon EC2 launch wizard. For more information about paid AMIs, see Paid AMIs (p. 98). To cancel your subscription after launch, you first have to terminate all instances running from it. For more information, see Manage your AWS Marketplace subscriptions (p. 101).

**To launch an instance from the AWS Marketplace using the launch wizard**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Amazon EC2 dashboard, choose **Launch instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose the **AWS Marketplace** category on the left. Find a suitable AMI by browsing the categories, or using the search functionality. Choose **Select** to choose your product.

4. A dialog displays an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose **Continue**.

   **Note**
   You are not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type, as you will be prompted to select an instance type on the next page of the wizard. Additional taxes may also apply to the product.

5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. When you're done, choose **Next: Configure Instance Details**.

6. On the next pages of the wizard, you can configure your instance, add storage, and add tags. For more information about the different options you can configure, see Launch an instance using the Launch Instance Wizard (p. 477). Choose **Next** until you reach the **Configure Security Group** page.

   The wizard creates a new security group according to the vendor's specifications for the product. The security group may include rules that allow all IPv4 addresses (**0.0.0.0/0**) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.

   When you are ready, choose **Review and Launch**.

7. On the **Review Instance Launch** page, check the details of the AMI from which you're about to launch the instance, as well as the other configuration details you set up in the wizard. When you're ready, choose **Launch** to select or create a key pair, and launch your instance.

8. Depending on the product you've subscribed to, the instance may take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View Instances** to go to the Instances page.

   **Note**
   You are charged the subscription price as long as your instance is running, even if it is idle. If your instance is stopped, you may still be charged for storage.

9. When your instance is in the **running** state, you can connect to it. To do this, select your instance in the list and choose **Connect**. Follow the instructions in the dialog. For more information about connecting to your instance, see Connect to your Linux instance (p. 499).

   **Important**
   Check the vendor's usage instructions carefully, as you may need to use a specific user name to log in to the instance. For more information about accessing your subscription details, see Manage your AWS Marketplace subscriptions (p. 101).

10. If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see Troubleshoot instance launch issues (p. 1477).

### Launch an AWS Marketplace AMI instance using the API and CLI

To launch instances from AWS Marketplace products using the API or command line tools, first ensure that you are subscribed to the product. You can then launch an instance with the product's AMI ID using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS CLI</td>
<td>Use the <code>run-instances</code> command, or see the following topic for more information: Launching an Instance.</td>
</tr>
</tbody>
</table>
Connect to your Linux instance

Connect to the Linux instances that you launched and transfer files between your local computer and your instance.

To connect to a Windows instance, see Connect to your Windows instance in the Amazon EC2 User Guide for Windows Instances.

Connection options

The operating system of your local computer determines the options that you have to connect from your local computer to your Linux instance.

If your local computer operating system is Linux or macOS X

- SSH client (p. 502)
- EC2 Instance Connect (p. 505)
- AWS Systems Manager Session Manager

If your local computer operating system is Windows

- PuTTY (p. 515)
- SSH client (p. 502)
- AWS Systems Manager Session Manager
- Windows Subsystem for Linux (p. 520)

General prerequisites for connecting to your instance

Before you connect to your Linux instance, verify the following general prerequisites:

- Get information about your instance (p. 499)
- Enable inbound traffic to your instance (p. 501)
- Locate the private key (p. 501)
- (Optional) Get the instance fingerprint (p. 501)

Get information about your instance

- Get the ID of the instance.

You can get the ID of your instance using the Amazon EC2 console (from the Instance ID column). If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) command.

- Get the public DNS name of the instance.

You can get the public DNS for your instance using the Amazon EC2 console. Check the Public DNS (IPv4) column. If this column is hidden, choose the settings icon (
Connect

) in the top-right corner of the screen and select **Public DNS (IPv4)**. If you prefer, you can use the `describe-instances` (AWS CLI) or `Get-EC2Instance` (AWS Tools for Windows PowerShell) command.

- **(IPv6 only) Get the IPv6 address of the instance.**

  If you've assigned an IPv6 address to your instance, you can optionally connect to the instance using its IPv6 address instead of a public IPv4 address or public IPv4 DNS hostname. Your local computer must have an IPv6 address and must be configured to use IPv6. You can get the IPv6 address of your instance using the Amazon EC2 console. Check the **IPv6 IPs** field. If you prefer, you can use the `describe-instances` (AWS CLI) or `Get-EC2Instance` (AWS Tools for Windows PowerShell) command. For more information about IPv6, see **IPv6 addresses (p. 882).**

- **Get the user name for your instance.**

  You can connect to your instance using the user name for your user account or the default user name for the AMI that you used to launch your instance.

  - **Get the user name for your user account.**

    For more information about how to create a user account, see **Manage user accounts on your Amazon Linux instance (p. 561).**

  - **Get the default user name for the AMI that you used to launch your instance:**

    - For Amazon Linux 2 or the Amazon Linux AMI, the user name is `ec2-user`.
    - For a CentOS AMI, the user name is `centos` or `ec2-user`.
    - For a Fedora AMI, the user name is `fedora` or `ec2-user`.
    - For a RHEL AMI, the user name is `ec2-user` or `root`. 
• For a SUSE AMI, the user name is `ec2-user` or `root`.
• For an Ubuntu AMI, the user name is `ubuntu`.
• Otherwise, check with the AMI provider.

Enable inbound traffic to your instance

• **Enable inbound SSH traffic from your IP address to your instance.**

   Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard enables SSH traffic by default. For more information, see authorise inbound traffic for your Linux instances (p. 1134).

Locate the private key

• **Locate the private key**

   Get the fully-qualified path to the location on your computer of the `.pem` file for the key pair that you specified when you launched the instance. For more information, see identify the key pair that was specified at launch. If you can't find your private key file, see connect to your Linux instance if you lose your private key.

• **Set the permissions of your private key**

   If you will use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

   ```bash
   chmod 400 my-key-pair.pem
   ```

   If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file (p. 1487).

(Optional) Get the instance fingerprint

To protect yourself from man-in-the-middle attacks, you can verify the RSA key fingerprint when you connect to your instance. Verifying the fingerprint is useful if you've launched your instance from a public AMI from a third party.

First you get the instance fingerprint. Then, when you connect to the instance, you are prompted to verify the fingerprint. You can compare the fingerprint you obtained with the fingerprint displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to your instance.

Prerequisites for getting the instance fingerprint:

• To get the instance fingerprint, you must use the AWS CLI. For information about installing the AWS CLI, see installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

• The instance must not be in the pending state. The fingerprint is available only after the first boot of the instance is complete.

To get the instance fingerprint

1. On your local computer (not on the instance), use the `get-console-output` (AWS CLI) command as follows to obtain the fingerprint:
Connect to your Linux instance using SSH

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480). For more connection options, see Connect to your Linux instance (p. 499).

Prerequisites

Before you connect to your Linux instance, complete the following prerequisites.

Check your instance status

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the Status check column on the Instances page.

Get the public DNS name and user name to connect to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see Prerequisites for connecting to your instance (p. 499).

Install an SSH client on your local computer as needed

Your local computer might have an SSH client installed by default. You can verify this by typing ssh at the command line. If your computer doesn't recognize the command, you can install an SSH client.

• Recent versions of Windows Server 2019 and Windows 10 - OpenSSH is included as an installable component. For more information, see OpenSSH in Windows.
• Earlier versions of Windows - Download and install OpenSSH. For more information, see Win32-OpenSSH.
• Linux and macOS X - Download and install OpenSSH. For more information, see https://www.openssh.com.

Connect to your Linux instance using an SSH client

Use the following procedure to connect to your Linux instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).
To connect to your instance using SSH

1. In a terminal window, use the `ssh` command to connect to the instance. You specify the path and file name of the private key (`.pem`), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see Locate the private key (p. 501) and Get information about your instance (p. 499). To connect to your instance, use one of the following commands.

   - (Public DNS) To connect using your instance's public DNS name, enter the following command.
     
     ```
     ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-public-dns-name
     ```

   - (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter the following command.
     
     ```
     ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-IPv6-address
     ```

     You see a response like the following:

     ```
     The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)'
     can't be established.
     ECDSA key fingerprint is l4UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.
     Are you sure you want to continue connecting (yes/no)?
     ```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint (p. 501). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

3. Enter `yes`.

   You see a response like the following:

   ```
   Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to the
   list of known hosts.
   ```

Transfer files to Linux instances using an SCP client

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- Verify the general prerequisites for transferring files to your instance.

  The general prerequisites for transferring files to an instance are the same as the general prerequisites for connecting to an instance. For more information, see General prerequisites for connecting to your instance (p. 499).

- Install an SCP client

  Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see https://www.openssh.com.
The following procedure steps you through using SCP to transfer a file using the instance's public DNS name, or the IPv6 address if your instance has one.

To use SCP to transfer files between your computer and your instance

1. Determine the location of the source file on your computer and the destination path on the instance. In the following examples, the name of the private key file is `my-key-pair.pem`, the file to transfer is `my-file.txt`, the user name for the instance is `ec2-user`, the public DNS name of the instance is `my-instance-public-dns-name`, and the IPv6 address of the instance is `my-instance-IPv6-address`.

   - (Public DNS) To transfer a file to the destination on the instance, enter the following command from your computer.

     ```
     scp -i /path/my-key-pair.pem /path/my-file.txt ec2-user@my-instance-public-dns-name:/path/
     ```

   - (IPv6) To transfer a file to the destination on the instance if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([ ]), which must be escaped (\).

     ```
     scp -i /path/my-key-pair.pem /path/my-file.txt ec2-user@[my-instance-IPv6-address]:/path/
     ```

2. If you haven't already connected to the instance using SSH, you see a response like the following:

   ```
   The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
   Are you sure you want to continue connecting (yes/no)?
   ```

   (Optional) You can optionally verify that the fingerprint in the security alert matches the instance fingerprint. For more information, see (Optional) Get the instance fingerprint (p. 501).

   Enter `yes`.

3. If the transfer is successful, the response is similar to the following:

   ```
   Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
   my-file.txt                                100%   480     24.4KB/s   00:00
   ```

4. To transfer a file in the other direction (from your Amazon EC2 instance to your computer), reverse the order of the host parameters. For example, you can transfer `my-file.txt` from your EC2 instance to a destination on your local computer as `my-file2.txt`, as shown in the following examples.

   - (Public DNS) To transfer a file to a destination on your computer, enter the following command from your computer.

     ```
     scp -i /path/my-key-pair.pem ec2-user@my-instance-public-dns-name:/path/my-file.txt
     path/my-file2.txt
     ```

   - (IPv6) To transfer a file to a destination on your computer if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([ ]), which must be escaped (\).

     ```
     scp -i /path/my-key-pair.pem ec2-user@[my-instance-IPv6-address]:/path/my-file.txt
     path/my-file2.txt
     ```
Connect to your Linux instance using EC2 Instance Connect

Amazon EC2 Instance Connect provides a simple and secure way to connect to your Linux instances using Secure Shell (SSH). With EC2 Instance Connect, you use AWS Identity and Access Management (IAM) policies and principals to control SSH access to your instances, removing the need to share and manage SSH keys. All connection requests using EC2 Instance Connect are logged to AWS CloudTrail so that you can audit connection requests (p. 865).

You can use EC2 Instance Connect to connect to your instances using the Amazon EC2 console (browser-based client), the Amazon EC2 Instance Connect CLI, or the SSH client of your choice.

When you connect to an instance using EC2 Instance Connect, the Instance Connect API pushes a one-time-use SSH public key to the instance metadata (p. 606) where it remains for 60 seconds. An IAM policy attached to your IAM user authorizes your IAM user to push the public key to the instance metadata. The SSH daemon uses AuthorizedKeysCommand and AuthorizedKeysCommandUser, which are configured when Instance Connect is installed, to look up the public key from the instance metadata for authentication, and connects you to the instance.

You can use EC2 Instance Connect to connect to instances that have public or private IP addresses. For more information, see Connect using EC2 Instance Connect (p. 511).

Tip

If you are connecting to a Linux instance from a local computer running Windows, see the following documentation instead:

- Connect to your Linux instance from Windows using PuTTY (p. 515)
- Connect to your Linux instance using SSH (p. 502)
- Connect to your Linux instance from Windows using Windows Subsystem for Linux (p. 520)

Contents

- Set up EC2 Instance Connect (p. 505)
- Connect using EC2 Instance Connect (p. 511)
- Uninstall EC2 Instance Connect (p. 514)

Set up EC2 Instance Connect

To use EC2 Instance Connect to connect to an instance, you need to configure every instance that will support using Instance Connect (this is a one-time requirement for each instance), and you need to grant permission to every IAM principal that will use Instance Connect. After completing the following setup tasks, you can connect to your instance using EC2 Instance Connect (p. 511).

Tasks to set up EC2 Instance Connect

- Task 1: Configure network access to an instance (p. 506)
- Task 2: (Conditional) Install EC2 Instance Connect on an instance (p. 507)
- Task 3: (Optional) Install the EC2 Instance Connect CLI (p. 509)
- Task 4: Configure IAM permissions for EC2 Instance Connect (p. 509)

For more information about setting up EC2 Instance Connect, see Securing your bastion hosts with Amazon EC2 Instance Connect.

Limitations

- You can install EC2 Instance Connect on the following supported Linux distributions:
• Amazon Linux 2 (any version)
• Ubuntu 16.04 or later
• If you configured the AuthorizedKeysCommand and AuthorizedKeysCommandUser settings for SSH authentication, the EC2 Instance Connect installation will not update them. As a result, you cannot use Instance Connect.

Prerequisites for installing EC2 Instance Connect

• Verify the general prerequisites for connecting to your instance using SSH.
  For more information, see General prerequisites for connecting to your instance (p. 499).
• Install an SSH client on your local computer.
  Your local computer most likely has an SSH client installed by default. You can check for an SSH client by typing `ssh` at the command line. If your local computer doesn’t recognize the command, you can install an SSH client. For information about installing an SSH client on Linux or macOS X, see http://www.openssh.com. For information about installing an SSH client on Windows 10, see OpenSSH in Windows.
• Install the AWS CLI on your local computer.
  To configure the IAM permissions, you must use the AWS CLI. For more information about installing the AWS CLI, see Installing the AWS CLI in the AWS Command Line Interface User Guide.
• [Ubuntu] Install the AWS CLI on your instance.
  To install EC2 Instance Connect on an Ubuntu instance, you must use the AWS CLI on the instance. For more information about installing the AWS CLI, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

Task 1: Configure network access to an instance

You must configure the following network access so that your users can connect to your instance using EC2 Instance Connect:

• If your users will access your instance over the internet, then your instance must have a public IP address and be in a public subnet. For more information, see Enable internet access in the Amazon VPC User Guide.

• If your users will access your instance via the instance’s private IP address, then you must establish private network connectivity to your VPC, such as by using AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering, so that your users can reach the instance’s private IP address.

• Ensure that the security group associated with your instance allows inbound SSH traffic (p. 1135) on port 22 from your IP address or from your network. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch wizard allows incoming SSH traffic by default. For more information, see Authorize inbound traffic for your Linux instances (p. 1134).

• (Amazon EC2 console browser-based client) Ensure that the security group associated with your instance allows inbound SSH traffic from the IP address range for this service. To identify the address range, download the JSON file provided by AWS and filter for the subset for EC2 Instance Connect, using EC2_INSTANCE_CONNECT as the service value. For more information about downloading the JSON file and filtering by service, see AWS IP address ranges in the Amazon Web Services General Reference.
Task 2: (Conditional) Install EC2 Instance Connect on an instance

You can skip this task if you used one of the following AMIs to launch your instance because they come preinstalled with EC2 Instance Connect:

- Amazon Linux 2 2.0.20190618 or later
- Ubuntu 20.04 or later

For earlier versions of these AMIs, you must install Instance Connect on every instance that will support connecting using Instance Connect.

Installing Instance Connect configures the SSH daemon on the instance. The procedure for installing Instance Connect is different for instances launched using Amazon Linux 2 and Ubuntu.

Amazon Linux 2

To install EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH.
   
   Use the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Amazon Linux 2, the default user name is ec2-user.

   For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see Connect to your Linux instance using SSH (p. 502).

2. Install the EC2 Instance Connect package on your instance.
   
   For Amazon Linux 2, use the `yum install` command.

   ```
   [ec2-user ~]$ sudo yum install ec2-instance-connect
   ```

   You should see four new scripts in the `/opt/aws/bin/` folder:

   `eic_curl_authorized_keys`
   `eic_harvest_hostkeys`
   `eic_parse_authorized_keys`
   `eic_run_authorized_keys`

3. (Optional) Verify that Instance Connect was successfully installed on your instance.

   Use the `sudo less` command to check that the `/etc/ssh/sshd_config` file was correctly updated as follows:

   ```
   [ec2-user ~]$ sudo less /etc/ssh/sshd_config
   ```

   Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines in the `/etc/ssh/sshd_config` file contain the following values:
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect

- AuthorizedKeysCommand sets the eic_run_authorized_keys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

**Note**
If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the Instance Connect installation will not change the values and you will not be able to use Instance Connect.

**Ubuntu**

**To install EC2 Instance Connect on an instance launched with Ubuntu 16.04 or later**

1. Connect to your instance using SSH.

   Use the SSH key pair that was assigned to your instance when you launched it and use the default user name of the AMI that you used to launch your instance. For an Ubuntu AMI, the user name is `ubuntu`.

   If your instance was launched using Ubuntu, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

   ```
   $ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see [Connect to your Linux instance using SSH (p. 502)](#).

2. (Optional) Ensure your instance has the latest Ubuntu AMI.

   For Ubuntu, use the following commands to update all the packages on your instance.

   ```
   ubuntu:~$ sudo apt-get update
   ubuntu:~$ sudo apt-get upgrade
   ```

3. Install the Instance Connect package on your instance.

   For Ubuntu, use the `sudo apt-get` command.

   ```
   ubuntu:~$ sudo apt-get install ec2-instance-connect
   ```

   You should see four new scripts in the `/usr/share/ec2-instance-connect/` folder:

   ```
   eic_curl_authorized_keys
eic_harvest_hostkeys
eic_parse_authorized_keys
eic_run_authorized_keys
   ```

4. (Optional) Verify that Instance Connect was successfully installed on your instance.
Use the `sudo less` command to check that the `/lib/systemd/system/ssh.service.d/ec2-instance-connect.conf` was correctly updated as follows:

```
ubuntu:~$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines in the `/lib/systemd/system/ssh.service.d/ec2-instance-connect.conf` file contain the following values:

```
AuthorizedKeysCommand /usr/share/ec2-instance-connect/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

**Note**

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the Instance Connect installation will not change the values and you will not be able to use Instance Connect.

For more information about the EC2 Instance Connect package, see `aws/aws-ec2-instance-connect-config` on the GitHub website.

**Task 3: (Optional) Install the EC2 Instance Connect CLI**

The EC2 Instance Connect CLI provides a simplified experience to connect to EC2 instances through a single command, `mssh instance_id`. For more information, see Connect using the EC2 Instance Connect CLI (p. 512).

**Note**

There is no need to install the EC2 Instance Connect CLI if users will only use the Amazon EC2 console (browser-based client) or an SSH client to connect to an instance.

**To install the EC2 Instance Connect CLI package**

Use `pip` to install the `ec2instanceconnectcli` package. For more information, see `aws/aws-ec2-instance-connect-cli` on the GitHub website, and [https://pypi.org/project/ec2instanceconnectcli/](https://pypi.org/project/ec2instanceconnectcli/) on the Python Package Index (PyPI) website.

```
$ pip install ec2instanceconnectcli
```

**Task 4: Configure IAM permissions for EC2 Instance Connect**

For your IAM principals to connect to an instance using EC2 Instance Connect, you must grant them permission to push the public key to the instance. You grant them the permission by creating an IAM policy and attaching the policy to the IAM principals that require the permission. For more information, see Actions, resources, and condition keys for Amazon EC2 Instance Connect.

The following instructions explain how to create the policy and attach it to an IAM user using the AWS CLI. The same policy could be applied to other IAM principals, such as IAM roles. For instructions that use the AWS Management Console, see Creating IAM policies (console), Adding permissions by attaching policies directly to the user, and Creating IAM roles in the IAM User Guide.
To grant an IAM principal permission for EC2 Instance Connect (AWS CLI)

1. Create a JSON policy document that includes the following:

   - The `ec2-instance-connect:SendSSHPublicKey` action. This grants an IAM principal permission to push the public key to an instance. With `ec2-instance-connect:SendSSHPublicKey`, consider restricting access to specific EC2 instances. Otherwise, all IAM principals with this permission can connect to all EC2 instances. You can also restrict access by specifying resource ARNs or by using resource tags as condition keys.
   - The `ec2:osuser` condition. This specifies the name of the OS user that can push the public key to an instance. Use the default user name for the AMI that you used to launch the instance. The default user name for Amazon Linux 2 is `ec2-user`, and for Ubuntu it's `ubuntu`.
   - The `ec2:DescribeInstances` action. This is required when using the EC2 Instance Connect CLI because the wrapper calls this action. IAM principals might already have permission to call this action from another policy.

The following is an example policy document. You can omit the statement for the `ec2:DescribeInstances` action if your users will only use an SSH client to connect to your instances. You can replace the specified instances in `Resource` with the wildcard `*` to grant users access to all EC2 instances using EC2 Instance Connect.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "ec2-instance-connect:SendSSHPublicKey",
         "Resource": [
            "arn:aws:ec2:region:account-id:instance/i-1234567890abcdef0",
            "arn:aws:ec2:region:account-id:instance/i-0598c7d356eb048d7"
         ],
         "Condition": {
            "StringEquals": {
               "ec2:osuser": "ami-username"
            }
         }
      },
      {
         "Effect": "Allow",
         "Action": "ec2:DescribeInstances",
         "Resource": "*"
      }
   ]
}
```

The preceding policy allows access to specific instances, identified by their instance ID. Alternatively, you can use resource tags to control access to an instance. Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows an IAM user to access an instance only if that instance has a resource tag with `key=tag-key` and `value=tag-value`. For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the IAM User Guide.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "ec2-instance-connect:SendSSHPublicKey",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "ec2:osuser": "ami-username"
            }
         }
      }
   ]
}
```
2. Use the `create-policy` command to create a new managed policy, and specify the JSON document that you created to use as the content for the new policy.

```
$ aws iam create-policy --policy-name my-policy --policy-document file://JSON-file-name
```

3. Use the `attach-user-policy` command to attach the managed policy to the specified IAM user. For the `--user-name` parameter, specify the friendly name (not the ARN) of the IAM user.

```
$ aws iam attach-user-policy --policy-arn arn:aws:iam::account-id:policy/my-policy --user-name IAM-Friendly-name
```

## Connect using EC2 Instance Connect

The following instructions explain how to connect to your Linux instance using EC2 Instance Connect.

If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480) and How do I troubleshoot issues connecting to my EC2 instance using EC2 Instance Connect?.

### Topics
- Limitations (p. 511)
- Prerequisites (p. 511)
- Connect using EC2 Instance Connect (p. 512)

### Limitations
- The following Linux distributions are supported:
  - Amazon Linux 2 (any version)
  - Ubuntu 16.04 or later
- To connect using the Amazon EC2 console (browser-based client), the instance must have a public IPv4 address.
- If the instance does not have a public IP address, you can connect to the instance over a private network using an SSH client or the EC2 Instance Connect CLI. For example, you can connect from within the same VPC or through a VPN connection, transit gateway, or AWS Direct Connect.
- EC2 Instance Connect does not support connecting using an IPv6 address.

### Prerequisites
- Install Instance Connect on your instance.
For more information, see Set up EC2 Instance Connect (p. 505).

**• (Optional) Install an SSH client on your local computer.**

There is no need to install an SSH client if users only use the Amazon EC2 console (browser-based client) or the EC2 Instance Connect CLI to connect to an instance. Your local computer most likely has an SSH client installed by default. You can check for an SSH client by typing `ssh` at the command line. If your local computer doesn't recognize the command, you can install an SSH client. For information about installing an SSH client on Linux or macOS X, see [http://www.openssh.com](http://www.openssh.com). For information about installing an SSH client on Windows 10, see [OpenSSH in Windows](http://www.openssh.com).

**• (Optional) Install the EC2 Instance Connect CLI on your local computer.**

There is no need to install the EC2 Instance Connect CLI if users only use the Amazon EC2 console (browser-based client) or an SSH client to connect to an instance. For more information, see Task 3: (Optional) Install the EC2 Instance Connect CLI (p. 509). This connection method works for instances with public IP addresses.

**Connect using EC2 Instance Connect**

**Options**

- Connect using the Amazon EC2 console (browser-based client) (p. 512)
- Connect using the EC2 Instance Connect CLI (p. 512)
- Connect using your own key and SSH client (p. 513)

**Connect using the Amazon EC2 console (browser-based client)**

You can connect to an instance using the Amazon EC2 console (browser-based client) by selecting the instance from the console and choosing to connect using EC2 Instance Connect. Instance Connect handles the permissions and provides a successful connection.

**To connect to your instance using the browser-based client from the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. Choose **EC2 Instance Connect**.
5. Verify the user name and choose **Connect** to open a terminal window.

**Connect using the EC2 Instance Connect CLI**

You can connect to an instance using the EC2 Instance Connect CLI by providing only the instance ID, while the Instance Connect CLI performs the following three actions in one call: it generates a one-time-use SSH public key, pushes the key to the instance where it remains for 60 seconds, and connects the user to the instance. You can use basic SSH/SFTP commands with the Instance Connect CLI.

This connection method works for instances with public and private IP addresses. When connecting to an instance that only has private IP addresses, the local computer from which you are initiating the session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering.
Note

- `i` is not supported when using `mssh`. When using the `mssh` command to connect to your instance, you do not need to specify any kind of identity file because Instance Connect manages the key pair.

Amazon Linux 2

**To connect to an instance using the EC2 Instance Connect CLI**

Use the `mssh` command with the instance ID as follows. You do not need to specify the user name for the AMI.

```
$ mssh i-001234a4bf70dec41EXAMPLE
```

Ubuntu

**To connect to an instance using the EC2 Instance Connect CLI**

Use the `mssh` command with the instance ID and the default user name for the Ubuntu AMI as follows. You must specify the user name for the AMI or you get the following error: Authentication failed.

```
$ mssh ubuntu@i-001234a4bf70dec41EXAMPLE
```

**Connect using your own key and SSH client**

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the EC2 Instance Connect API. This enables you to benefit from the Instance Connect capability to push a public key to the instance. This connection method works for instances with public and private IP addresses.

**Requirements**

- The supported RSA key types are OpenSSH and SSH2. The supported lengths are 2048 and 4096. For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 1140).
- When connecting to an instance that only has private IP addresses, the local computer from which you are initiating the SSH session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address to establish the SSH session. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering.

**To connect to your instance using your own key and any SSH client**

1. **(Optional) Generate new SSH private and public keys**

   You can generate new SSH private and public keys, `my_rsa_key` and `my_rsa_key.pub`, using the following command:

   ```
   $ ssh-keygen -t rsa -f my_rsa_key
   ```

2. **Push your SSH public key to the instance**

   Use the `send-ssh-public-key` command to push your SSH public key to the instance. If you launched your instance using Amazon Linux 2, the default user name for the AMI is `ec2-user`. If you launched your instance using Ubuntu, the default user name for the AMI is `ubuntu`. 
The following example pushes the public key to the specified instance in the specified Availability Zone, to authenticate `ec2-user`:

```
$ aws ec2-instance-connect send-ssh-public-key
   --instance-id i-001234a4bf70dec41EXAMPLE
   --availability-zone us-west-2b
   --instance-os-user ec2-user
   --ssh-public-key file://my_rsa_key.pub
```

3. **Connect to the instance using your private key**

Use the `ssh` command to connect to the instance using the private key before the public key is removed from the instance metadata (you have 60 seconds before it is removed). Specify the private key that corresponds to the public key, the default user name for the AMI that you used to launch your instance, and the instance's public DNS name (if connecting over a private network, specify the private DNS name or IP address). Add the `IdentitiesOnly=yes` option to ensure that only the files in the ssh config and the specified key are used for the connection.

```
$ ssh -o "IdentitiesOnly=yes" -i my_rsa_key ec2-
user@ec2-198-51-100-1.compute-1.amazonaws.com
```

### Uninstall EC2 Instance Connect

To disable EC2 Instance Connect, connect to your instance and uninstall the `ec2-instance-connect` package that you installed on the OS. If the `sshd` configuration matches what it was set to when you installed EC2 Instance Connect, uninstalling `ec2-instance-connect` also removes the `sshd` configuration. If you modified the `sshd` configuration after installing EC2 Instance Connect, you must update it manually.

**Amazon Linux 2**

You can uninstall EC2 Instance Connect on Amazon Linux 2 2.0.20190618 or later, where EC2 Instance Connect is preconfigured.

**To uninstall EC2 Instance Connect on an instance launched with Amazon Linux 2**

1. **Connect to your instance using SSH.** Specify the SSH key pair you used for your instance when you launched it and the default user name for the Amazon Linux 2 AMI, which is `ec2-user`.

   For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

2. **Uninstall the `ec2-instance-connect` package using the `yum` command.**

   ```
   [ec2-user ~]# sudo yum remove ec2-instance-connect
   ```
To uninstall EC2 Instance Connect on an instance launched with an Ubuntu AMI

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the Ubuntu AMI, which is `ubuntu`.

   For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

   ```bash
   $ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

2. Uninstall the `ec2-instance-connect` package using the `apt-get` command.

   ```bash
   ubuntu:~$ sudo apt-get remove ec2-instance-connect
   ```

Connect to your Linux instance from Windows using PuTTY

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance using PuTTY, a free SSH client for Windows. If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).

Prerequisites

Before you connect to your Linux instance using PuTTY, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the Status check column on the Instances page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see General prerequisites for connecting to your instance (p. 499).

Install PuTTY on your local computer

Download and install PuTTY from the PuTTY download page. If you already have an older version of PuTTY installed, we recommend that you download the latest version. Be sure to install the entire suite.

Convert your private key using PuTTYgen

Locate the private key (.pem file) for the key pair that you specified when you launched the instance. Convert the .pem file to a .ppk file for use with PuTTY. For more information, follow the steps in the next section.

Convert your private key using PuTTYgen

PuTTY does not natively support the private key format for SSH keys. PuTTY provides a tool named PuTTYgen, which converts keys to the required format for PuTTY. You must convert your private key (.pem file) into this format (.ppk file) as follows in order to connect to your instance using PuTTY.
To convert your private key

1. From the Start menu, choose All Programs, PuTTY, PuTTYgen.

2. Under Type of key to generate, choose RSA. If your version of PuTTYgen does not include this option, choose SSH-2 RSA.

3. Choose Load. By default, PuTTYgen displays only files with the extension .ppk. To locate your .pem file, choose the option to display files of all types.

4. Select your .pem file for the key pair that you specified when you launched your instance and choose Open. PuTTYgen displays a notice that the .pem file was successfully imported. Choose OK.

5. To save the key in the format that PuTTY can use, choose Save private key. PuTTYgen displays a warning about saving the key without a passphrase. Choose Yes.

   Note
   A passphrase on a private key is an extra layer of protection. Even if your private key is discovered, it can’t be used without the passphrase. The downside to using a passphrase is that it makes automation harder because human intervention is needed to log on to an instance, or to copy files to an instance.

6. Specify the same name for the key that you used for the key pair (for example, my-key-pair) and choose Save. PuTTY automatically adds the .ppk file extension.

Your private key is now in the correct format for use with PuTTY. You can now connect to your instance using PuTTY's SSH client.

Connect to your Linux instance

Use the following procedure to connect to your Linux instance using PuTTY. You need the .ppk file that you created for your private key. For more information, see Convert your private key using PuTTYgen (p. 515) in the preceding section. If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).

To connect to your instance using PuTTY

1. Start PuTTY (from the Start menu, choose All Programs, PuTTY, PuTTY).

2. In the Category pane, choose Session and complete the following fields:
   a. In the Host Name box, do one of the following:
      • (Public DNS) To connect using your instance's public DNS name, enter my-instance-user-name@my-instance-public-dns-name.
      • (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter my-instance-user-name@my-instance-IPv6-address.

      For information about how to get the user name for your instance, and the public DNS name or IPv6 address of your instance, see Get information about your instance (p. 499).
   b. Ensure that the Port value is 22.
   c. Under Connection type, select SSH.
3. (Optional) You can configure PuTTY to automatically send 'keepalive' data at regular intervals to keep the session active. This is useful to avoid disconnecting from your instance due to session inactivity. In the Category pane, choose Connection, and then enter the required interval in the Seconds between keepalives field. For example, if your session disconnects after 10 minutes of inactivity, enter 180 to configure PuTTY to send keepalive data every 3 minutes.

4. In the Category pane, expand Connection, expand SSH, and then choose Auth. Complete the following:
   a. Choose Browse.
   b. Select the .ppk file that you generated for your key pair and choose Open.
   c. (Optional) If you plan to start this session again later, you can save the session information for future use. Under Category, choose Session, enter a name for the session in Saved Sessions, and then choose Save.
   d. Choose Open.

5. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host to which you are connecting.
   a. (Optional) Verify that the fingerprint in the security alert dialog box matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint (p. 501). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
   b. Choose Yes. A window opens and you are connected to your instance.

   **Note**
   If you specified a passphrase when you converted your private key to PuTTY's format, you must provide that passphrase when you log in to the instance.

If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).
Transfer files to your Linux instance using the PuTTY Secure Copy client

The PuTTY Secure Copy client (PSCP) is a command line tool that you can use to transfer files between your Windows computer and your Linux instance. If you prefer a graphical user interface (GUI), you can use an open source GUI tool named WinSCP. For more information, see Transfer files to your Linux instance using WinSCP (p. 518).

To use PSCP, you need the private key you generated in Convert your private key using PuTTYgen (p. 515). You also need the public DNS name of your Linux instance, or the IPv6 address if your instance has one.

The following example transfers the file Sample_file.txt from the C:\ drive on a Windows computer to the my-instance-user-name home directory on an Amazon Linux instance. To transfer a file, use one of the following commands.

- (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
pscp -i C:\path\my-key-pair.ppk C:\path\Sample_file.txt my-instance-user-name@my-instance-public-dns-name:/home/my-instance-user-name/Sample_file.txt
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to transfer a file using your instance's IPv6 address, enter the following command. The IPv6 address must be enclosed in square brackets ([ ]).

```
pscp -i C:\path\my-key-pair.ppk C:\path\Sample_file.txt my-instance-user-name@[my-instance-IPv6-address]:/home/my-instance-user-name/Sample_file.txt
```

Transfer files to your Linux instance using WinSCP

WinSCP is a GUI-based file manager for Windows that allows you to upload and transfer files to a remote computer using the SFTP, SCP, FTP, and FTPS protocols. WinSCP allows you to drag and drop files from your Windows computer to your Linux instance or synchronize entire directory structures between the two systems.

**Requirements**

- You must have the private key that you generated in Convert your private key using PuTTYgen (p. 515).
- You must have the public DNS name of your Linux instance.
- Your Linux instance must have scp installed. For some operating systems, you install the openssh-clients package. For others, such as the Amazon ECS-optimized AMI, you install the scp package. Check the documentation for your Linux distribution.

**To connect to your instance using WinSCP**

1. Download and install WinSCP from http://winscp.net/eng/download.php. For most users, the default installation options are OK.
2. Start WinSCP.
3. At the WinSCP login screen, for **Host name**, enter one of the following:
   - (Public DNS or IPv4 address) To log in using your instance's public DNS name or public IPv4 address, enter the public DNS name or public IPv4 address for your instance.
   - (IPv6) Alternatively, if your instance has an IPv6 address, to log in using your instance's IPv6 address, enter the IPv6 address for your instance.
4. For **User name**, enter the default user name for your AMI.
   - For Amazon Linux 2 or the Amazon Linux AMI, the user name is ec2-user.
• For a CentOS AMI, the user name is centos or ec2-user.
• For a Debian AMI, the user name is admin.
• For a Fedora AMI, the user name is fedora or ec2-user.
• For a RHEL AMI, the user name is ec2-user or root.
• For a SUSE AMI, the user name is ec2-user or root.
• For an Ubuntu AMI, the user name is ubuntu.
• Otherwise, check with the AMI provider.

5. Specify the private key for your instance. For Private key, enter the path to your private key, or choose the "..." button to browse for the file. To open the advanced site settings, for newer versions of WinSCP, choose Advanced. To find the Private key file setting, under SSH, choose Authentication.

Here is a screenshot from WinSCP version 5.9.4:

WinSCP requires a PuTTY private key file (.ppk). You can convert a .pem security key file to the .ppk format using PuTTYgen. For more information, see Convert your private key using PuTTYgen (p. 515).

6. (Optional) In the left panel, choose Directories. For Remote directory, enter the path for the directory to which to add files. To open the advanced site settings for newer versions of WinSCP, choose Advanced. To find the Remote directory setting, under Environment, choose Directories.
7. Choose **Login**. To add the host fingerprint to the host cache, choose **Yes**.

8. After the connection is established, in the connection window your Linux instance is on the right and your local machine is on the left. You can drag and drop files between the remote file system and your local machine. For more information on WinSCP, see the project documentation at [http://winscp.net/eng/docs/start](http://winscp.net/eng/docs/start).

   If you receive an error that you cannot run SCP to start the transfer, verify that you installed `scp` on the Linux instance.

**Connect to your Linux instance from Windows using Windows Subsystem for Linux**

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance using a Linux distribution on the Windows Subsystem for Linux (WSL). WSL is a free download and enables you to run native Linux command line tools directly on Windows, alongside your traditional Windows desktop, without the overhead of a virtual machine.

By installing WSL, you can use a native Linux environment to connect to your Linux EC2 instances instead of using PuTTY or PuTTYgen. The Linux environment makes it easier to connect to your Linux instances because it comes with a native SSH client that you can use to connect to your Linux instances and change the permissions of the .pem key file. The Amazon EC2 console provides the SSH command for connecting
to the Linux instance, and you can get verbose output from the SSH command for troubleshooting. For more information, see the Windows Subsystem for Linux Documentation.

**Note**
After you've installed the WSL, all the prerequisites and steps are the same as those described in Connect to your Linux instance using SSH (p. 502), and the experience is just like using native Linux.

If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).

**Contents**
- Prerequisites (p. 502)
- Connect to your Linux instance using WSL (p. 521)
- Transfer files to Linux instances from Linux using SCP (p. 522)
- Uninstall WSL (p. 524)

**Prerequisites**
Before you connect to your Linux instance, complete the following prerequisites.

**Verify that the instance is ready**
After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the Status check column on the Instances page.

**Verify the general prerequisites for connecting to your instance**
To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see General prerequisites for connecting to your instance (p. 499).

**Install the Windows Subsystem for Linux (WSL) and a Linux distribution on your local computer**
Install the WSL and a Linux distribution using the instructions in the Windows 10 Installation Guide. The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

**Copy the private key from Windows to WSL**
In a WSL terminal window, copy the .pem file (for the key pair that you specified when you launched the instance) from Windows to WSL. Note the fully-qualified path to the .pem file on WSL to use when connecting to your instance. For information about how to specify the path to your Windows hard drive, see How do I access my C drive?. For more information about key pairs and Windows instances, see Amazon EC2 key pairs and Windows instances.

```bash
cp /mnt/<Windows drive letter>/path/my-key-pair.pem ~/WSL-path/my-key-pair.pem
```

**Connect to your Linux instance using WSL**
Use the following procedure to connect to your Linux instance using the Windows Subsystem for Linux (WSL). If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance (p. 1480).

**To connect to your instance using SSH**
1. In a terminal window, use the `ssh` command to connect to the instance. You specify the path and file name of the private key (.pem), the user name for your instance, and the public DNS name or
IPV6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPV6 address for an instance, see Locate the private key (p. 501) and Get information about your instance (p. 499). To connect to your instance, use one of the following commands.

- (Public DNS) To connect using your instance's public DNS name, enter the following command.

  
  ```
  ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-public-dns-name
  ```

- (IPv6) Alternatively, if your instance has an IPV6 address, you can connect to the instance using its IPV6 address. Specify the `ssh` command with the path to the private key (.pem) file, the appropriate user name, and the IPV6 address.

  
  ```
  ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-IPv6-address
  ```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
Are you sure you want to continue connecting (yes/no)?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint (p. 501). If these fingerprints don’t match, someone might be attempting a “man-in-the-middle” attack. If they match, continue to the next step.

3. Enter yes.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
```

Transfer files to Linux instances from Linux using SCP

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- Verify the general prerequisites for transferring files to your instance.

  The general prerequisites for transferring files to an instance are the same as the general prerequisites for connecting to an instance. For more information, see General prerequisites for connecting to your instance (p. 499).

- Install an SCP client

  Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn’t, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see https://www.openssh.com.

The following procedure steps you through using SCP to transfer a file. If you’ve already connected to the instance with SSH and have verified its fingerprints, you can start with the step that contains the SCP command (step 4).
To use SCP to transfer a file

1. Transfer a file to your instance using the instance's public DNS name. For example, if the name of the private key file is `my-key-pair`, the file to transfer is `SampleFile.txt`, the user name is `my-instance-user-name`, and the public DNS name of the instance is `my-instance-public-dns-name` or the IPv6 address is `my-instance-IPv6-address`, use one of the following commands to copy the file to the `my-instance-user-name` home directory.

   - (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

     ```bash
     scp -i /path/my-key-pair.pem /path/SampleFile.txt my-instance-user-name@my-instance-public-dns-name:~
     ```

   - (IPv6) Alternatively, if your instance has an IPv6 address, you can transfer a file using the instance's IPv6 address. The IPv6 address must be enclosed in square brackets (`[ ]`), which must be escaped (`\`).

     ```bash
     scp -i /path/my-key-pair.pem /path/SampleFile.txt my-instance-user-name@[my-instance-IPv6-address]:~
     ```

     You see a response like the following:

     ```bash
     The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
     Are you sure you want to continue connecting (yes/no)?
     ```

     2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint (p. 501). If these fingerprints don’t match, someone might be attempting a “man-in-the-middle” attack. If they match, continue to the next step.

     3. Enter `yes`.

     You see a response like the following:

     ```bash
     Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
     Sending file modes: C0644 20 SampleFile.txt
     Sink: C0644 20 SampleFile.txt
     SampleFile.txt 100% 20 0.0KB/s 00:00
     ```

     If you receive a "bash: scp: command not found" error, you must first install `scp` on your Linux instance. For some operating systems, this is located in the `openssh-clients` package. For Amazon Linux variants, such as the Amazon ECS-optimized AMI, use the following command to install `scp`:

     ```bash
     [ec2-user ~]$ sudo yum install -y openssh-clients
     ```

     4. To transfer files in the other direction (from your Amazon EC2 instance to your local computer), reverse the order of the host parameters. For example, to transfer the `SampleFile.txt` file from your EC2 instance back to the home directory on your local computer as `SampleFile2.txt`, use one of the following commands on your local computer.

     - (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.
Stop and start

```
scp -i /path/my-key-pair.pem my-instance-user-name@ec2-198-51-100-1.compute-1.amazonaws.com:~/SampleFile.txt ~/SampleFile2.txt
```

• (IPv6) Alternatively, if your instance has an IPv6 address, to transfer files in the other direction using the instance's IPv6 address, enter the following command.

```
scp -i /path/my-key-pair.pem my-instance-user-name@[2001:db8:1234:1a00:9691:9503:25ad:1761]:~/SampleFile.txt ~/SampleFile2.txt
```

**Uninstall WSL**

For information about uninstalling Windows Subsystem for Linux, see How do I uninstall a WSL Distribution?

**Connect to your Linux instance using Session Manager**

Session Manager is a fully managed AWS Systems Manager capability that lets you manage your Amazon EC2 instances through an interactive one-click browser-based shell or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run bash commands as you would through any other connection type. For more information about Session Manager, see AWS Systems Manager Session Manager in the AWS Systems Manager User Guide.

Before attempting to connect to an instance using Session Manager, ensure that the necessary setup steps have been completed. For more information and instructions, see Getting Started with Session Manager.

**To connect to a Linux instance using Session Manager using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. For **Connection method**, choose **Session Manager**.
5. Choose **Connect**.

**Troubleshooting**

If you receive an error that you're not authorized to perform one or more Systems Manager actions (`ssm:command-name`), then you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information, see Quickstart Default IAM Policies for Session Manager in the AWS Systems Manager User Guide.

**Stop and start your instance**

You can stop and start your instance if it has an Amazon EBS volume as its root device. The instance retains its instance ID, but can change as described in the Overview (p. 525) section.

When you stop an instance, we shut it down. We don't charge usage for a stopped instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes. Each time you start a stopped instance we charge a minimum of one minute for usage. After one minute, we charge only for the seconds you use. For example, if you run an instance for 20 seconds and then stop it, we charge for a full one minute. If you run an instance for 3 minutes and 40 seconds, we charge for exactly 3 minutes and 40 seconds of usage.
While the instance is stopped, you can treat its root volume like any other volume, and modify it (for example, repair file system problems or update software). You just detach the volume from the stopped instance, attach it to a running instance, make your changes, detach it from the running instance, and then reattach it to the stopped instance. Make sure that you reattach it using the storage device name that’s specified as the root device in the block device mapping for the instance.

If you decide that you no longer need an instance, you can terminate it. As soon as the state of an instance changes to shutting-down or terminated, we stop charging for that instance. For more information, see Terminate your instance (p. 547). If you’d rather hibernate the instance, see Hibernate your On-Demand or Reserved Linux instance (p. 528). For more information, see Differences between reboot, stop, hibernate, and terminate (p. 474).

Contents
- Overview (p. 525)
- What happens when you stop an instance (p. 526)
- Stop and start your instances (p. 526)
- Modify a stopped instance (p. 527)
- Troubleshoot stopping your instance (p. 528)

Overview

You can only stop an Amazon EBS-backed instance. To verify the root device type of your instance, describe the instance and check whether the device type of its root volume is ebs (Amazon EBS-backed instance) or instance store (instance store-backed instance). For more information, see Determine the root device type of your AMI (p. 73).

When you stop a running instance, the following happens:

- The instance performs a normal shutdown and stops running; its status changes to stopping and then stopped.
- Any Amazon EBS volumes remain attached to the instance, and their data persists.
- Any data stored in the RAM of the host computer or the instance store volumes of the host computer is gone.
- In most cases, the instance is migrated to a new underlying host computer when it’s started (though in some cases, it remains on the current host).
- The instance retains its private IPv4 addresses and any IPv6 addresses when stopped and started. We release the public IPv4 address and assign a new one when you start it.
- The instance retains its associated Elastic IP addresses. You’re charged for any Elastic IP addresses associated with a stopped instance. With EC2-Classic, an Elastic IP address is dissociated from your instance when you stop it. For more information, see EC2-Classic (p. 1034).
- When you stop and start a Windows instance, the EC2Config service performs tasks on the instance, such as changing the drive letters for any attached Amazon EBS volumes. For more information about these defaults and how you can change them, see Configuring a Windows instance using the EC2Config service in the Amazon EC2 User Guide for Windows Instances.
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. For more information, see Health Checks for Auto Scaling Instances in the Amazon EC2 Auto Scaling User Guide.
- When you stop a ClassicLink instance, it’s unlinked from the VPC to which it was linked. You must link the instance to the VPC again after starting it. For more information about ClassicLink, see ClassicLink (p. 1041).

For more information, see Differences between reboot, stop, hibernate, and terminate (p. 474).
You can modify the following attributes of an instance only when it is stopped:

- Instance type
- User data
- Kernel
- RAM disk

If you try to modify these attributes while the instance is running, Amazon EC2 returns the IncorrectInstanceState error.

What happens when you stop an instance

When an EC2 instance is stopped using the `stop-instances` command, the following is registered at the OS level:

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.
- The instance shuts down when the graceful shutdown process exits. There is no configurable OS shutdown time.
- If the instance OS does not shut down cleanly within a few minutes, a hard shutdown is performed.

By default, when you initiate a shutdown from an Amazon EBS-backed instance (for example, using the `shutdown` or `poweroff` command), the instance stops. You can change this behavior so that it terminates instead. For more information, see Change the instance initiated shutdown behavior (p. 551).

Using the `halt` command from an instance does not initiate a shutdown. If used, the instance does not terminate; instead, it places the CPU into HLT and the instance remains running.

Stop and start your instances

You can stop and start your Amazon EBS-backed instance using the console or the command line.

New console

To stop and start an Amazon EBS-backed instance using the console

1. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. In the navigation pane, choose Instances and select the instance.
3. Choose Instance state, Stop instance. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.
5. (Optional) While your instance is stopped, you can modify certain instance attributes. For more information, see Modify a stopped instance (p. 527).
6. To start the stopped instance, select the instance, and choose Instance state, Start instance.
7. It can take a few minutes for the instance to enter the running state.
Old console

To stop and start an Amazon EBS-backed instance using the console

1. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you’ve copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. In the navigation pane, choose Instances and select the instance.
3. Choose Actions, Instance State, Stop. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose Yes, Stop. It can take a few minutes for the instance to stop.
5. (Optional) While your instance is stopped, you can modify certain instance attributes. For more information, see Modify a stopped instance (p. 527).
6. To start the stopped instance, select the instance, and choose Actions, Instance State, Start.
7. In the confirmation dialog box, choose Yes, Start. It can take a few minutes for the instance to enter the running state.

To stop and start an Amazon EBS-backed instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- stop-instances and start-instances (AWS CLI)
- Stop-EC2Instance and Start-EC2Instance (AWS Tools for Windows PowerShell)

Modify a stopped instance

You can change the instance type, user data, and EBS-optimization attributes of a stopped instance using the AWS Management Console or the command line interface. You can't use the AWS Management Console to modify the DeleteOnTermination, kernel, or RAM disk attributes.

To modify an instance attribute

- To change the instance type, see Change the instance type (p. 310).
- To change the user data for your instance, see Work with instance user data (p. 621).
- To enable or disable EBS-optimization for your instance, see Modifying EBS–Optimization (p. 1375).
- To change the DeleteOnTermination attribute of the root volume for your instance, see Update the block device mapping of a running instance (p. 1449). You are not required to stop the instance to change this attribute.

To modify an instance attribute using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- modify-instance-attribute (AWS CLI)
- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)
Troubleshoot stopping your instance

If you have stopped your Amazon EBS-backed instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see Troubleshoot stopping your instance (p. 1491).

Hibernate your On-Demand or Reserved Linux instance

When you hibernate an instance, Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). Hibernation saves the contents from the instance memory (RAM) to your Amazon Elastic Block Store (Amazon EBS) root volume. Amazon EC2 persists the instance's EBS root volume and any attached EBS data volumes. When you start your instance:

- The EBS root volume is restored to its previous state
- The RAM contents are reloaded
- The processes that were previously running on the instance are resumed
- Previously attached data volumes are reattached and the instance retains its instance ID

You can hibernate an instance only if it's enabled for hibernation (p. 537) and it meets the hibernation prerequisites (p. 529).

If an instance or application takes a long time to bootstrap and build a memory footprint in order to become fully productive, you can use hibernation to pre-warm the instance. To pre-warm the instance, you:

1. Launch it with hibernation enabled.
2. Bring it to a desired state.
3. Hibernate it so that it's ready to be resumed to the desired state whenever needed.

You're not charged for instance usage for a hibernated instance when it is in the stopped state. However, you are charged for instance usage while the instance is in the stopping state, while the contents of the RAM are transferred to the EBS root volume. (This is different from when you stop an instance (p. 524) without hibernating it.) You're not charged for data transfer. However, you are charged for storage of any EBS volumes, including storage for the RAM contents.

If you no longer need an instance, you can terminate it at any time, including when it is in a stopped (hibernated) state. For more information, see Terminate your instance (p. 547).

Note
For information about using hibernation on Windows instances, see Hibernate Your Windows Instance in the Amazon EC2 User Guide for Windows Instances.
For information about hibernating Spot Instances, see Hibernate interrupted Spot Instances (p. 404).

Contents
- Overview of hibernation (p. 529)
- Hibernation prerequisites (p. 529)
- Limitations (p. 532)
- Configure an existing AMI to support hibernation (p. 533)
- Enable hibernation for an instance (p. 537)
- Disable KASLR on an instance (Ubuntu only) (p. 539)
Overview of hibernation

The following diagram shows a basic overview of the hibernation process.

When you hibernate a running instance, the following happens:

- When you initiate hibernation, the instance moves to the stopping state. Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). The hibernation freezes all of the processes, saves the contents of the RAM to the EBS root volume, and then performs a regular shutdown.
- After the shutdown is complete, the instance moves to the stopped state.
- Any EBS volumes remain attached to the instance, and their data persists, including the saved contents of the RAM.
- Any Amazon EC2 instance store volumes remain attached to the instance, but the data on the instance store volumes is lost.
- In most cases, the instance is migrated to a new underlying host computer when it's started. This is also what happens when you stop and start an instance.
- When you start the instance, the instance boots up and the operating system reads in the contents of the RAM from the EBS root volume, before unfreezing processes to resume its state.
- The instance retains its private IPv4 addresses and any IPv6 addresses. When you start the instance, the instance continues to retain its private IPv4 addresses and any IPv6 addresses.
- Amazon EC2 releases the public IPv4 address. When you start the instance, Amazon EC2 assigns a new public IPv4 address to the instance.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses that are associated with a hibernated instance. With EC2-Classic, an Elastic IP address is disassociated from your instance when you hibernate it. For more information, see EC2-Classic (p. 1034).
- When you hibernate a ClassicLink instance, it's unlinked from the VPC to which it was linked. You must link the instance to the VPC again after starting it. For more information, see ClassicLink (p. 1041).

For information about how hibernation differs from reboot, stop, and terminate, see Differences between reboot, stop, hibernate, and terminate (p. 474).

Hibernation prerequisites

To hibernate an On-Demand Instance or Reserved Instance, the following prerequisites must be in place:
• Supported Linux AMIs (p. 530)
• Supported instance families (p. 531)
• Instance size (p. 531)
• Instance RAM size (p. 531)
• Root volume type (p. 531)
• EBS root volume size (p. 531)
• Supported EBS volume types (p. 532)
• EBS root volume encryption (p. 532)
• Enable hibernation at launch (p. 532)
• Purchasing options (p. 532)

**Supported Linux AMIs**

Must be an HVM AMI that supports hibernation:

<table>
<thead>
<tr>
<th>AMI</th>
<th>Xen - supported instance families only</th>
<th>Nitro - supported instance families only</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2 AMI released 2019.08.29 or later</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Amazon Linux AMI 2018.03 released 2018.11.16 or later</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>CentOS version 8 AMI* (Additional configuration (p. 534) is required)</td>
<td>Not supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Fedora version 34 or later AMI* (Additional configuration (p. 535) is required)</td>
<td>Not supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux (RHEL) 8 AMI* (Additional configuration (p. 535) is required)</td>
<td>Not supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Ubuntu 18.04 LTS - Bionic AMI released with serial number 20190722.1 or later †</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Ubuntu 16.04 LTS - Xenial AMI † (Additional configuration (p. 536) is required)</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

* For CentOS, Fedora, and Red Hat Enterprise Linux, hibernation is supported on Nitro-based instances only.

† We recommend disabling KASLR on instances with Ubuntu 18.04 LTS - Bionic and Ubuntu 16.04 LTS - Xenial. For more information, see Disable KASLR on an instance (Ubuntu only) (p. 539).
To configure your own AMI to support hibernation, see Configure an existing AMI to support hibernation (p. 533).

Support for other versions of Ubuntu and other operating systems is coming soon.

For information about the supported Windows AMIs, see Supported Windows AMIs in the Amazon EC2 User Guide for Windows Instances.

**Supported instance families**

- Xen: C3, C4, I3, M3, M4, R3, R4, T2
- Nitro: C5, C5d, M5, M5a, M5ad, M5d, R5, R5a, R5ad, R5d, T3, T3a

**To see the available instance types that support hibernation in a specific Region**

The available instance types vary by Region. To see the available instance types that support hibernation in a Region, use the `describe-instance-types` command with the `--region` parameter. Include the `--filters` parameter to see only the instance types that support hibernation.

```
$ aws ec2 describe-instance-types \
   --region us-east-2 \
   --filters Name=hibernation-supported,Values=true \
   --query "InstanceTypes[*].[InstanceType]" \
   --output table
```

**Example output**

```
<table>
<thead>
<tr>
<th>DescribeInstanceTypes</th>
</tr>
</thead>
<tbody>
<tr>
<td>r5a.xlarge</td>
</tr>
<tr>
<td>c4.4xlarge</td>
</tr>
<tr>
<td>m5ad.large</td>
</tr>
<tr>
<td>c5.4xlarge</td>
</tr>
<tr>
<td>m4.4xlarge</td>
</tr>
<tr>
<td>t3.2xlarge</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>
```

**Instance size**

Not supported for bare metal instances.

**Instance RAM size**

Must be less than 150 GB.

**Root volume type**

Must be an EBS volume, not an instance store volume.

**EBS root volume size**

Must be large enough to store the RAM contents and accommodate your expected usage, for example, OS or applications. If you enable hibernation, space is allocated on the root volume at launch to store the RAM.
Supported EBS volume types

- General Purpose SSD (gp2 and gp3)
- Provisioned IOPS SSD (io1 and io2)

If you choose a Provisioned IOPS SSD volume type, you must provision the EBS volume with the appropriate IOPS to achieve optimum performance for hibernation. For more information, see Amazon EBS volume types (p. 1179).

EBS root volume encryption

To use hibernation, the root volume must be encrypted to ensure the protection of sensitive content that is in memory at the time of hibernation. When RAM data is moved to the EBS root volume, it is always encrypted. Encryption of the root volume is enforced at instance launch.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see Encryption by default (p. 1338).

- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see Use encryption with EBS-backed AMIs (p. 156).

- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see Encrypt an unencrypted image during copy (p. 160) and Copy an AMI (p. 139).

Enable hibernation at launch

You cannot enable hibernation on an existing instance (running or stopped). For more information, see Enable hibernation for an instance (p. 537).

Purchasing options

This feature is available for On-Demand Instances and Reserved Instances. It is not available for Spot Instances. For information about hibernating a Spot Instance, see Hibernate interrupted Spot Instances (p. 404).

Limitations

- When you hibernate an instance, the data on any instance store volumes is lost.
- You can't hibernate an instance that has more than 150 GB of RAM.
- If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to the instance.
- You can't change the instance type or size of an instance when hibernation is enabled.
- You can't hibernate an instance that is in an Auto Scaling group or used by Amazon ECS. If your instance is in an Auto Scaling group and you try to hibernate it, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. For more information, see Health Checks for Auto Scaling Instances in the Amazon EC2 Auto Scaling User Guide.
• You can’t hibernate an instance that is configured to boot in UEFI mode.
• If you hibernate an instance that was launched into a Capacity Reservation, the Capacity Reservation does not ensure that the hibernated instance can resume after you try to start it.
• We do not support keeping an instance hibernated for more than 60 days. To keep the instance for longer than 60 days, you must start the hibernated instance, stop the instance, and start it.
• We constantly update our platform with upgrades and security patches, which can conflict with existing hibernated instances. We notify you about critical updates that require a start for hibernated instances so that we can perform a shutdown or a reboot to apply the necessary upgrades and security patches.

Configure an existing AMI to support hibernation

The following AMIs support hibernation, but to hibernate an instance that was launched with one of these AMIs, additional configuration is required before you can hibernate the instance.

Additional configuration required for:
- Amazon Linux 2 released before 2019.08.29 (p. 533)
- Amazon Linux released before 2018.11.16 (p. 534)
- CentOS version 8 or later (p. 534)
- Fedora version 34 or later (p. 535)
- Red Hat Enterprise Linux version 8 or later (p. 535)
- Ubuntu 18.04 - Bionic released before serial number 20190722.1 (p. 536)
- Ubuntu 16.04 - Xenial (p. 536)

For more information, see Update instance software on your Amazon Linux instance (p. 557).

No additional configuration is required for the following AMIs because they’re already configured to support hibernation:
- Amazon Linux 2 AMI released 2019.08.29 or later
- Amazon Linux AMI 2018.03 released 2018.11.16 or later
- Ubuntu 18.04 LTS - Bionic AMI released with serial number 20190722.1 or later

Amazon Linux 2 released before 2019.08.29

To configure an Amazon Linux 2 AMI released before 2019.08.29 to support hibernation

1. Update the kernel to 4.14.138-114.102 or later.

   [ec2-user ~]$ sudo yum update kernel

2. Install the ec2-hibinit-agent package from the repositories.

   [ec2-user ~]$ sudo yum install ec2-hibinit-agent

3. Reboot the instance.

   [ec2-user ~]$ sudo reboot

4. Confirm that the kernel version is updated to 4.14.138-114.102 or later.
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Hibernate

5. Stop the instance and create an AMI. For more information, see Create a Linux AMI from an instance (p. 103).

Amazon Linux released before 2018.11.16

To configure an Amazon Linux AMI released before 2018.11.16 to support hibernation

1. Update the kernel to 4.14.77-70.59 or later.

   `[ec2-user ~]# sudo yum update kernel`

2. Install the ec2-hibinit-agent package from the repositories.

   `[ec2-user ~]# sudo yum install ec2-hibinit-agent`

3. Reboot the instance.

   `[ec2-user ~]# sudo reboot`

4. Confirm that the kernel version is updated to 4.14.77-70.59 or greater.

   `[ec2-user ~]# uname -a`

5. Stop the instance and create an AMI. For more information, see Create a Linux AMI from an instance (p. 103).

CentOS version 8 or later

To configure a CentOS version 8 or later AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

   `[ec2-user ~]# sudo yum update kernel`

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

3. Install the ec2-hibinit-agent package from the repositories.

   `[ec2-user ~]# sudo yum install ec2-hibinit-agent`

4. Enable the hibernate agent to start on boot.

   `[ec2-user ~]# sudo systemctl enable hibinit-agent.service`

5. Reboot the instance.

   `[ec2-user ~]# sudo reboot`

6. Confirm that the kernel version is updated to 4.18.0-305.7.1.el8_4.x86_64 or later.
Fedora version 34 or later

To configure a Fedora version 34 or later AMI to support hibernation

1. Update the kernel to 5.12.10-300.fc34.x86_64 or later.

```
[ec2-user ~]# sudo yum update kernel
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]# sudo dnf install ec2-hibinit-agent
```

3. Enable the hibernate agent to start on boot.

```
[ec2-user ~]# sudo systemctl enable hibinit-agent.service
```

4. Reboot the instance.

```
[ec2-user ~]# sudo reboot
```

5. Confirm that the kernel version is updated to 5.12.10-300.fc34.x86_64 or later.

```
[ec2-user ~]# uname -a
```

Red Hat Enterprise Linux version 8 or later

To configure a Red Hat Enterprise Linux 8 AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]# sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

```
```

3. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]# sudo yum install ec2-hibinit-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]# sudo systemctl enable hibinit-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]# sudo reboot
```

6. Confirm that the kernel version is updated to 4.18.0-305.7.1.el8_4.x86_64 or later.
Ubuntu 18.04 - Bionic released before serial number 20190722.1

To configure an Ubuntu 18.04 LTS AMI released before serial number 20190722.1 to support hibernation

1. Update the kernel to 4.15.0-1044 or later.

   [ec2-user ~]$ sudo apt update
   [ec2-user ~]$ sudo apt dist-upgrade

2. Install the ec2-hibinit-agent package from the repositories.

   [ec2-user ~]$ sudo apt install ec2-hibinit-agent

3. Reboot the instance.

   [ec2-user ~]$ sudo reboot

4. Confirm that the kernel version is updated to 4.15.0-1044 or later.

   [ec2-user ~]$ uname -a

Ubuntu 16.04 - Xenial

To configure Ubuntu 16.04 LTS to support hibernation, you need to install the linux-aws-hwe kernel package version 4.15.0-1058-aws or later and the ec2-hibinit-agent.

To configure an Ubuntu 16.04 LTS AMI to support hibernation

1. Update the kernel to 4.15.0-1058-aws or later.

   [ec2-user ~]$ sudo apt update
   [ec2-user ~]$ sudo apt install linux-aws-hwe

   **Note**
   The `linux-aws-hwe` kernel package is fully supported by Canonical. The package will continue to receive regular updates until standard support for Ubuntu 16.04 LTS ends in April 2021, and will receive additional security updates until the Extended Security Maintenance support ends in 2024. For more information, see [Amazon EC2 Hibernation for Ubuntu 16.04 LTS now available](https://blog.canonical.com/2019/07/23/amazon-ec2-hibernation-for-ubuntu-16-04-lts-now-available/) on the Canonical Ubuntu Blog.

2. Install the ec2-hibinit-agent package from the repositories.

   [ec2-user ~]$ sudo apt install ec2-hibinit-agent

3. Reboot the instance.

   [ec2-user ~]$ sudo reboot

4. Confirm that the kernel version is updated to 4.15.0-1058-aws or later.
Enable hibernation for an instance

To hibernate an instance, you must first enable it for hibernation while launching the instance.

**Important**
You can't enable or disable hibernation for an instance after you launch it.

**Console**

**To enable hibernation using the console**

1. Follow the Launch an instance using the Launch Instance Wizard (p. 477) procedure.
2. On the **Choose an Amazon Machine Image (AMI)** page, select an AMI that supports hibernation. For more information about supported AMIs, see Hibernation prerequisites (p. 529).
3. On the **Choose an Instance Type** page, select a supported instance type, and choose **Next: Configure Instance Details**. For information about supported instance types, see Hibernation prerequisites (p. 529).
4. On the **Configure Instance Details** page, for **Stop - Hibernate Behavior**, select the **Enable hibernation as an additional stop behavior** check box.
5. On the **Add Storage** page, for the root volume, specify the following information:
   - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
   - For **Volume Type**, select a supported EBS volume type, General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).
   - For **Encryption**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see Hibernation prerequisites (p. 529).
6. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

**AWS CLI**

**To enable hibernation using the AWS CLI**

Use the **run-instances** command to launch an instance. Specify the EBS root volume parameters using the **--block-device-mappings** file://mapping.json parameter, and enable hibernation using the **--hibernation-options** Configured=true parameter.

```
aws ec2 run-instances \
   --image-id ami-0abcdef1234567890 \
   --instance-type m5.large \
   --block-device-mappings file://mapping.json \
   --hibernation-options Configured=true \
   --count 1 \
   --key-name MyKeyPair
```
Specify the following in mapping.json.

```
[
  {
    "DeviceName": "/dev/xvda",
    "Ebs": {
      "VolumeSize": 30,
      "VolumeType": "gp2",
      "Encrypted": true
    }
  }
]
```

**Note**
The value for DeviceName must match the root device name that's associated with the AMI. To find the root device name, use the `describe-images` command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

**PowerShell**

**To enable hibernation using the AWS Tools for Windows PowerShell**

Use the `New-EC2Instance` command to launch an instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the `-BlockDeviceMappings` parameter. Enable hibernation using the `-HibernationOptions_Configured` `$true` parameter.

```
PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true

PS C:\> New-EC2Instance `  `-ImageId ami-0abcdef1234567890 `  `-InstanceType m5.large`  `-BlockDeviceMappings $ebs_encrypt`  `-HibernationOptions_Configured $true`  `-MinCount 1`  `-MaxCount 1`  `-KeyName MyKeyPair`
```

**Note**
The value for DeviceName must match the root device name associated with the AMI. To find the root device name, use the `Get-EC2Image` command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit `Encrypted = $true` from the block device mapping.
New console

To view if an instance is enabled for hibernation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and, on the Details tab, in the Instance details section, inspect Stop- hibernate behavior. Enabled indicates that the instance is enabled for hibernation.

Old console

To view if an instance is enabled for hibernation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and, in the details pane, inspect Stop - Hibernation behavior. Enabled indicates that the instance is enabled for hibernation.

AWS CLI

To view if an instance is enabled for hibernation using the AWS CLI

Use the describe-instances command and specify the --filters "Name=hibernation- optionsconfigured,Values=true" parameter to filter instances that are enabled for hibernation.

```
aws ec2 describe-instances \n  --filters "Name=hibernation-optionsconfigured,Values=true"
```

The following field in the output indicates that the instance is enabled for hibernation.

```
"HibernationOptions": {
  "Configured": true
}
```

PowerShell

To view if an instance is enabled for hibernation using the AWS Tools for Windows PowerShell

Use the Get-EC2Instance command and specify the -Filter @\( Name="hibernation- optionsconfigured"; Value="true"\) parameter to filter instances that are enabled for hibernation.

```
Get-EC2Instance \n  -Filter @\( Name="hibernation-optionsconfigured"; Value="true"\)
```

The output lists the EC2 instances that are enabled for hibernation.

Disable KASLR on an instance (Ubuntu only)

To run hibernation on a newly launched instance with Ubuntu 16.04 LTS - Xenial or Ubuntu 18.04 LTS - Bionic released with serial 20190722.1 or later, we recommend disabling KASLR (Kernel Address Space Layout Randomization). On Ubuntu 16.04 LTS or Ubuntu 18.04 LTS, KASLR is enabled by default. KASLR is a standard Linux kernel security feature that helps to mitigate exposure to and ramifications of yet-
undiscovered memory access vulnerabilities by randomizing the base address value of the kernel. With KASLR enabled, there is a possibility that the instance might not resume after it has been hibernated.

To learn more about KASLR, see Ubuntu Features.

**To disable KASLR on an instance launched with Ubuntu**

1. Connect to your instance using SSH. For more information, see Connect to your Linux instance using SSH (p. 502).
2. Open the `/etc/default/grub.d/50-cloudimg-settings.cfg` file in your editor of choice. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line to append the `nokaslr` option to its end, as shown in the following example.

   ```bash
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0 nvme_core.io_timeout=4294967295 nokaslr"
   ```
3. Save the file and exit your editor.
4. Run the following command to rebuild the grub configuration.

   ```bash
   [ec2-user ~]# sudo update-grub
   ```
5. Reboot the instance.

   ```bash
   [ec2-user ~]# sudo reboot
   ```
6. Run the following command to confirm that `nokaslr` has been added.

   ```bash
   [ec2-user ~]# cat /proc/cmdline
   ```

   The output of the command should include the `nokaslr` option.

**Hibernate an instance**

You can hibernate an instance if the instance is enabled for hibernation (p. 537) and meets the hibernation prerequisites (p. 529). If an instance cannot hibernate successfully, a normal shutdown occurs.

**New console**

**To hibernate an Amazon EBS-backed instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select an instance, and choose Instance state, Hibernate instance. If Hibernate instance is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see Hibernation prerequisites (p. 529).
4. When prompted for confirmation, choose Hibernate. It can take a few minutes for the instance to hibernate. The instance state first changes to Stopping, and then changes to Stopped when the instance has hibernated.

**Old console**

**To hibernate an Amazon EBS-backed instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.

3. Select an instance, and choose **Actions, Instance State, Stop - Hibernate**. If **Stop - Hibernate** is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see Hibernation prerequisites (p. 529).

4. In the confirmation dialog box, choose **Yes, Stop - Hibernate**. It can take a few minutes for the instance to hibernate. The instance state first changes to **Stopping**, and then changes to **Stopped** when the instance has hibernated.

**AWS CLI**

**To hibernate an Amazon EBS-backed instance using the AWS CLI**

Use the **stop-instances** command and specify the **--hibernate** parameter.

```
aws ec2 stop-instances \
  --instance-ids i-1234567890abcdef0 \
  --hibernate
```

**PowerShell**

**To hibernate an Amazon EBS-backed instance using the AWS Tools for Windows PowerShell**

Use the **Stop-EC2Instance** command and specify the **-Hibernate $true** parameter.

```
Stop-EC2Instance \
  -InstanceId i-1234567890abcdef0 \
  -Hibernate $true
```

**New console**

**To view if hibernation was initiated on an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **State transition message**. The message **Client.UserInitiatedHibernate: User initiated hibernate** indicates that hibernation was initiated on the instance.

**Old console**

**To view if hibernation was initiated on an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and, in the details pane, inspect **State transition reason message**. The message **Client.UserInitiatedHibernate: User initiated hibernate** indicates that hibernation was initiated on the instance.

**AWS CLI**

**To view if hibernation was initiated on an instance using the AWS CLI**
Use the `describe-instances` command and specify the `state-reason-code` filter to see the instances on which hibernation was initiated.

```
aws ec2 describe-instances \\
   --filters "Name=state-reason-code,Values=Client.UserInitiatedHibernate"
```

The following field in the output indicates that hibernation was initiated on the instance.

```
"StateReason": {
   "Code": "Client.UserInitiatedHibernate"
}
```

PowerShell

To view if hibernation was initiated on an instance using the AWS Tools for Windows PowerShell

Use the `Get-EC2Instance` command and specify the `state-reason-code` filter to see the instances on which hibernation was initiated.

```
Get-EC2Instance `  
   -Filter @{Name="state-reason-code";Value="Client.UserInitiatedHibernate"}
```

The output lists the EC2 instances on which hibernation was initiated.

### Start a hibernated instance

Start a hibernated instance by starting it in the same way that you would start a stopped instance.

**New console**

**To start a hibernated instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Instance state**, **Start instance**. It can take a few minutes for the instance to enter the **running** state. During this time, the instance **status checks** (p. 789) show the instance in a failed state until the instance has started.

**Old console**

**To start a hibernated instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Actions, Instance State, Start**. It can take a few minutes for the instance to enter the **running** state. During this time, the instance **status checks** (p. 789) show the instance in a failed state until the instance has started.

**AWS CLI**

**To start a hibernated instance using the AWS CLI**

Use the `start-instances` command.
aws ec2 start-instances \ 
--instance-ids i-1234567890abcdef0

PowerShell

To start a hibernated instance using the AWS Tools for Windows PowerShell

Use the Start-EC2Instance command.

Start-EC2Instance ` 
-InstanceId i-1234567890abcdef0

Troubleshoot hibernation

Use this information to help diagnose and fix issues that you might encounter when hibernating an instance.

Can't hibernate immediately after launch

If you try to hibernate an instance too quickly after you've launched it, you get an error.

You must wait for about two minutes after launch before hibernating.

Takes too long to transition from stopping to stopped, and memory state not restored after start

If it takes a long time for your hibernating instance to transition from the stopping state to stopped, and if the memory state is not restored after you start, this could indicate that hibernation was not properly configured.

Check the instance system log and look for messages that are related to hibernation. To access the system log, connect (p. 499) to the instance or use the get-console-output command. Find the log lines from the hibinit-agent. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough:
hibinit-agent: Insufficient disk space. Cannot create setup for hibernation. Please allocate a larger root device.

If the last log line from the hibinit-agent is hibinit-agent: Running: swapoff /swap, hibernation was successfully configured.

If you do not see any logs from these processes, your AMI might not support hibernation. For information about supported AMIs, see Hibernation prerequisites (p. 529). If you used your own AMI, make sure that you followed the instructions for Configure an existing AMI to support hibernation (p. 533).

Instance "stuck" in the stopping state

If you hibernated your instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see Troubleshoot stopping your instance (p. 1491).
Reboot your instance

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it keeps its public DNS name (IPv4), private and public IPv4 address, IPv6 address (if applicable), and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and starting your instance.

We might schedule your instance for a reboot for necessary maintenance, such as to apply updates that require a reboot. No action is required on your part; we recommend that you wait for the reboot to occur within its scheduled window. For more information, see Scheduled events for your instances (p. 795).

We recommend that you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance instead of running the operating system reboot command from your instance. If you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance, we perform a hard reboot if the instance does not cleanly shut down within a few minutes. If you use AWS CloudTrail, then using Amazon EC2 to reboot your instance also creates an API record of when your instance was rebooted.

New console

**To reboot an instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Instance state, Reboot instance**.
4. Choose **Reboot** when prompted for confirmation. The instance remains in the running state.

Old console

**To reboot an instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Instance State, Reboot**.
4. Choose **Yes, Reboot** when prompted for confirmation. The instance remains in the running state.

**To reboot an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `reboot-instances` (AWS CLI)
- `Restart-EC2Instance` (AWS Tools for Windows PowerShell)

Instance retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware that hosts the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS.
• If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware.

• If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information about the types of instance events, see Scheduled events for your instances (p. 795).

Contents

• Identify instances scheduled for retirement (p. 545)
• Actions to take for EBS-backed instances scheduled for retirement (p. 546)
• Actions to take for instance-store backed instances scheduled for retirement (p. 547)

Identify instances scheduled for retirement

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date. You can also check for instances that are scheduled for retirement using the Amazon EC2 console or the command line.

Important

If an instance is scheduled for retirement, we recommend that you take action as soon as possible because the instance might be unreachable. (The email notification you receive states the following: “Due to this degradation your instance could already be unreachable.”) For more information about the recommended action you should take, see Check if your instance is reachable.

Ways to identify instances scheduled for retirement

• Email notification (p. 545)
• Console identification (p. 545)

Email notification

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date.

The email is sent to the primary account holder and the operations contact. For more information, see Adding, changing, or removing alternate contacts in the AWS Billing and Cost Management User Guide.

Console identification

If you use an email account that you do not check regularly for instance retirement notifications, you can use the Amazon EC2 console or the command line to determine if any of your instances are scheduled for retirement.

To identify instances scheduled for retirement using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose EC2 Dashboard. Under Scheduled events, you can see the events that are associated with your Amazon EC2 instances and volumes, organized by Region.
3. If you have an instance with a scheduled event listed, select its link below the Region name to go to the **Events** page.

4. The **Events** page lists all resources that have events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance stop or retirement** from the second filter list.

5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

**To identify instances scheduled for retirement using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `describe-instance-status` (AWS CLI)
- `Get-EC2InstanceStatus` (AWS Tools for Windows PowerShell)

**Actions to take for EBS-backed instances scheduled for retirement**

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

If you are not sure whether your instance is backed by EBS or instance store, see Determine the root device type of your instance (p. 1435).

**Check if your instance is reachable**

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either connecting (p. 499) to or pinging your instance.
- If your instance is reachable, you should plan to stop/start your instance at an appropriate time before the scheduled retirement date, when the impact is minimal. For more information about stopping and starting your instance, and what to expect when your instance is stopped, such as the effect on public, private, and Elastic IP addresses that are associated with your instance, see Stop and start your instance (p. 524). Note that data on instance store volumes is lost when you stop and start your instance.
- If your instance is unreachable, you should take immediate action and perform a stop/start (p. 524) to recover your instance.
- Alternatively, if you want to terminate (p. 547) your instance, plan to do so as soon as possible so that you stop incurring charges for the instance.

**Create a backup of your instance**

Create an EBS-backed AMI from your instance so that you have a backup. To ensure data integrity, stop the instance before you create the AMI. You can wait for the scheduled retirement date when the...
instance is stopped, or stop the instance yourself before the retirement date. You can start the instance again at any time. For more information, see Create an Amazon EBS-backed Linux AMI (p. 102).

Launch a replacement instance

After you create an AMI from your instance, you can use the AMI to launch a replacement instance. From the Amazon EC2 console, select your new AMI and then choose Actions, Launch. Follow the wizard to launch your instance. For more information about each step in the wizard, see Launch an instance using the Launch Instance Wizard (p. 477).

Actions to take for instance-store backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

**Warning**

If your instance store-backed instance passes its retirement date, it is terminated and you cannot recover the instance or any data that was stored on it. Regardless of the root device of your instance, the data on instance store volumes is lost when the instance is retired, even if the volumes are attached to an EBS-backed instance.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either connecting (p. 499) to or pinging your instance.
- If your instance is unreachable, there is likely very little that can be done to recover your instance. For more information, see Troubleshoot an unreachable instance (p. 1515). AWS will terminate your instance on the scheduled retirement date, so, for an unreachable instance, you can immediately terminate (p. 547) the instance yourself.

Launch a replacement instance

Create an instance store-backed AMI from your instance using the AMI tools, as described in Create an instance store-backed Linux AMI (p. 107). From the Amazon EC2 console, select your new AMI and then choose Actions, Launch. Follow the wizard to launch your instance. For more information about each step in the wizard, see Launch an instance using the Launch Instance Wizard (p. 477).

Convert your instance to an EBS-backed instance

Transfer your data to an EBS volume, take a snapshot of the volume, and then create AMI from the snapshot. You can launch a replacement instance from your new AMI. For more information, see Convert your instance store-backed AMI to an Amazon EBS-backed AMI (p. 118).

Terminate your instance

You can delete your instance when you no longer need it. This is referred to as terminating your instance. As soon as the state of an instance changes to shutting-down or terminated, you stop incurring charges for that instance.

You can't connect to or start an instance after you've terminated it. However, you can launch additional instances using the same AMI. If you'd rather stop and start your instance, or hibernate it, see Stop and
Instance termination

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You cannot delete the terminated instance entry yourself. After an instance is terminated, resources such as tags and volumes are gradually disassociated from the instance and may no longer be visible on the terminated instance after a short while.

When an instance terminates, the data on any instance store volumes associated with that instance is deleted.

By default, Amazon EBS root device volumes are automatically deleted when the instance terminates. However, by default, any additional EBS volumes that you attach at launch, or any EBS volumes that you attach to an existing instance persist even after the instance terminates. This behavior is controlled by the volume’s `DeleteOnTermination` attribute, which you can modify. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).

You can prevent an instance from being terminated accidentally by someone using the AWS Management Console, the CLI, and the API. This feature is available for both Amazon EC2 instance store-backed and Amazon EBS-backed instances. Each instance has a `DisableApiTermination` attribute with the default value of `false` (the instance can be terminated through Amazon EC2). You can modify this instance attribute while the instance is running or stopped (in the case of Amazon EBS-backed instances). For more information, see Enable termination protection (p. 550).

You can control whether an instance should stop or terminate when shutdown is initiated from the instance using an operating system command for system shutdown. For more information, see Change the instance initiated shutdown behavior (p. 551).

If you run a script on instance termination, your instance might have an abnormal termination, because we have no way to ensure that shutdown scripts run. Amazon EC2 attempts to shut an instance down cleanly and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.

Terminating multiple instances with termination protection across Availability Zones

If you terminate multiple instances across multiple Availability Zones, and one or more of the specified instances are enabled for termination protection, the request fails with the following results:

- The specified instances that are in the same Availability Zone as the protected instance are not terminated.
- The specified instances that are in different Availability Zones, where no other specified instances are protected, are successfully terminated.

For example, say you have the following instances:

<table>
<thead>
<tr>
<th>Instance</th>
<th>Availability Zone</th>
<th>Terminate protection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance A</td>
<td>us-east-1a</td>
<td>Disabled</td>
</tr>
<tr>
<td>Instance B</td>
<td></td>
<td>Disabled</td>
</tr>
<tr>
<td>Instance C</td>
<td>us-east-1b</td>
<td>Enabled</td>
</tr>
<tr>
<td>Instance D</td>
<td></td>
<td>Disabled</td>
</tr>
</tbody>
</table>

If you attempt to terminate all of these instances in the same request, the request reports failure with the following results:

- **Instance A** and **Instance B** are successfully terminated because none of the specified instances in `us-east-1a` are enabled for termination protection.
- **Instance C** and **Instance D** fail to terminate because at least one of the specified instances in `us-east-1b` (**Instance C**) is enabled for termination protection.

**What happens when you terminate an instance**

When an EC2 instance is terminated using the `terminate-instances` command, the following is registered at the OS level:

- The API request will send a button press event to the guest.
- Various system services will be stopped as a result of the button press event. `systemd` handles a graceful shutdown of the system. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown will be initiated.
- The instance will shut down when the graceful shutdown process exits. There is no configurable OS shutdown time.

**Terminate an instance**

You can terminate an instance using the AWS Management Console or the command line.

By default, when you initiate a shutdown from an Amazon EBS-backed instance (using the `shutdown` or `poweroff` commands), the instance stops. The `halt` command does not initiate a shutdown. If used, the instance does not terminate; instead, it places the CPU into HLT and the instance remains running.

**New console**

**To terminate an instance using the console**

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose Instances.
4. Select the instance, and choose Instance state, Terminate instance.
5. Choose Terminate when prompted for confirmation.

Old console

To terminate an instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose Instances.
4. Select the instance, and choose Actions, Instance State, Terminate.
5. Choose Yes, Terminate when prompted for confirmation.

To terminate an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- terminate-instances (AWS CLI)
- Stop-EC2Instance (AWS Tools for Windows PowerShell)

Enable termination protection

By default, you can terminate your instance using the Amazon EC2 console, command line interface, or API. To prevent your instance from being accidentally terminated using Amazon EC2, you can enable termination protection for the instance. The DisableApiTermination attribute controls whether the instance can be terminated using the console, CLI, or API. By default, termination protection is disabled for your instance. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped (for Amazon EBS-backed instances).

The DisableApiTermination attribute does not prevent you from terminating an instance by initiating shutdown from the instance (using an operating system command for system shutdown) when the InstanceInitiatedShutdownBehavior attribute is set. For more information, see Change the instance initiated shutdown behavior (p. 551).

Limitations

You can't enable termination protection for Spot Instances—a Spot Instance is terminated when the Spot price exceeds the amount you're willing to pay for Spot Instances. However, you can prepare your application to handle Spot Instance interruptions. For more information, see Spot Instance interruptions (p. 402).

The DisableApiTermination attribute does not prevent Amazon EC2 Auto Scaling from terminating an instance. For instances in an Auto Scaling group, use the following Amazon EC2 Auto Scaling features instead of Amazon EC2 termination protection:

- To prevent instances that are part of an Auto Scaling group from terminating on scale in, use instance protection. For more information, see Instance Protection in the Amazon EC2 Auto Scaling User Guide.
• To prevent Amazon EC2 Auto Scaling from terminating unhealthy instances, suspend the ReplaceUnhealthy process. For more information, see Suspending and Resuming Scaling Processes in the Amazon EC2 Auto Scaling User Guide.

• To specify which instances Amazon EC2 Auto Scaling should terminate first, choose a termination policy. For more information, see Customizing the Termination Policy in the Amazon EC2 Auto Scaling User Guide.

To enable termination protection for an instance at launch time

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the dashboard, choose Launch Instance and follow the directions in the wizard.
3. On the Configure Instance Details page, select the Enable termination protection check box.

To enable termination protection for a running or stopped instance

1. Select the instance, and choose Actions, Instance Settings, Change Termination Protection.
2. Choose Yes, Enable.

To disable termination protection for a running or stopped instance

1. Select the instance, and choose Actions, Instance Settings, Change Termination Protection.
2. Choose Yes, Disable.

To enable or disable termination protection using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

• modify-instance-attribute (AWS CLI)
• Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)

Change the instance initiated shutdown behavior

By default, when you initiate a shutdown from an Amazon EBS-backed instance (using a command such as shutdown or poweroff), the instance stops (Note that halt does not issue a poweroff command and, if used, the instance will not terminate; instead, it will place the CPU into HLT and the instance will remain running). You can change this behavior using the InstanceInitiatedShutdownBehavior attribute for the instance so that it terminates instead. You can update this attribute while the instance is running or stopped.

You can update the InstanceInitiatedShutdownBehavior attribute using the Amazon EC2 console or the command line. The InstanceInitiatedShutdownBehavior attribute only applies when you perform a shutdown from the operating system of the instance itself; it does not apply when you stop an instance using the StopInstances API or the Amazon EC2 console.

To change the shutdown behavior of an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
4. Choose Actions, Instance settings, Change shutdown behavior. The current behavior is selected.
5. To change the behavior, select Stop or Terminate from Shutdown behavior and then choose Apply.
To change the shutdown behavior of an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `modify-instance-attribute` (AWS CLI)
- `Edit-EC2InstanceAttribute` (AWS Tools for Windows PowerShell)

Preserve Amazon EBS volumes on instance termination

When an instance terminates, Amazon EC2 uses the value of the `DeleteOnTermination` attribute for each attached Amazon EBS volume to determine whether to preserve or delete the volume.

The default value for the `DeleteOnTermination` attribute differs depending on whether the volume is the root volume of the instance or a non-root volume attached to the instance.

Root volume

By default, the `DeleteOnTermination` attribute for the root volume of an instance is set to `true`. Therefore, the default is to delete the root volume of the instance when the instance terminates. The `DeleteOnTermination` attribute can be set by the creator of an AMI as well as by the person who launches an instance. When the attribute is changed by the creator of an AMI or by the person who launches an instance, the new setting overrides the original AMI default setting. We recommend that you verify the default setting for the `DeleteOnTermination` attribute after you launch an instance with an AMI.

Non-root volume

By default, when you attach a non-root EBS volume to an instance, its `DeleteOnTermination` attribute is set to `false`. Therefore, the default is to preserve these volumes. After the instance terminates, you can take a snapshot of the preserved volume or attach it to another instance. You must delete a volume to avoid incurring further charges. For more information, see Delete an Amazon EBS volume (p. 1226).

To verify the value of the `DeleteOnTermination` attribute for an EBS volume that is in use, look at the instance's block device mapping. For more information, see View the EBS volumes in an instance block device mapping (p. 1449).

You can change the value of the `DeleteOnTermination` attribute for a volume when you launch the instance or while the instance is running.

Examples

- Change the root volume to persist at launch using the console (p. 552)
- Change the root volume to persist at launch using the command line (p. 553)
- Change the root volume of a running instance to persist using the command line (p. 553)

Change the root volume to persist at launch using the console

Using the console, you can change the `DeleteOnTermination` attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

To change the root volume of an instance to persist at launch using the console

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. From the console dashboard, select Launch Instance.
3. On the Choose an Amazon Machine Image (AMI) page, choose an AMI and choose Select.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.

5. On the **Add Storage** page, deselect the **Delete On Termination** check box for the root volume.

6. Complete the remaining wizard pages, and then choose **Launch**.

You can verify the setting by viewing details for the root device volume on the instance's details pane. Next to **Block devices**, choose the entry for the root device volume. By default, **Delete on termination** is True. If you change the default behavior, **Delete on termination** is False.

### Change the root volume to persist at launch using the command line

When you launch an EBS-backed instance, you can use one of the following commands to change the root device volume to persist. For more information about these command line interfaces, see [Access Amazon EC2](p. 3).

- **run-instances** (AWS CLI)
- **New-EC2Instance** (AWS Tools for Windows PowerShell)

For example, add the following option to your `run-instances` command:

```bash
--block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`:

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false,
      "SnapshotId": "snap-1234567890abcdef0",
      "VolumeType": "gp2"
    }
  }
]
```

### Change the root volume of a running instance to persist using the command line

You can use one of the following commands to change the root device volume of a running EBS-backed instance to persist. For more information about these command line interfaces, see [Access Amazon EC2](p. 3).

- **modify-instance-attribute** (AWS CLI)
- **Edit-EC2InstanceAttribute** (AWS Tools for Windows PowerShell)

For example, use the following command:

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`:

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
```
Troubleshoot instance termination

If you terminate your instance and another instance starts, most likely you have configured automatic scaling through a feature like EC2 Fleet or Amazon EC2 Auto Scaling.

If your instance is in the shutting-down state for longer than usual, it should be cleaned up (terminated) by automated processes within the Amazon EC2 service. For more information, see Delayed instance termination (p. 1493).

Recover your instance

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. Terminated instances cannot be recovered.

A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata. If the impaired instance has a public IPv4 address, the instance retains the public IPv4 address after recovery. If the impaired instance is in a placement group, the recovered instance runs in the placement group.

When the StatusCheckFailed_System alarm is triggered, and the recover action is initiated, you will be notified by the Amazon SNS topic that you selected when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic will receive an email notification that includes the status of the recovery attempt and any further instructions. You will notice an instance reboot on the recovered instance.

Examples of problems that cause system status checks to fail include:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

Topics

- Requirements (p. 554)
- Create an Amazon CloudWatch alarm to recover an instance (p. 555)
- Troubleshoot instance recovery failures (p. 555)

Requirements

The recover action is supported only on instances with the following characteristics:

- Uses one of the following instance types: A1, C3, C4, C5, C5a, C5n, C6g, C6gn, Inf1, M3, M4, M5, M5a, M5n, M5zn, M6g, M6i, P3, P4, R3, R4, R5, R5a, R5b, R5n, R6g, T2, T3, T3a, T4g, high memory (virtualized only), X1, X1e
- Runs in a virtual private cloud (VPC)
- Uses default or dedicated instance tenancy
Configure instances

- Has only EBS volumes (do not configure instance store volumes)

Create an Amazon CloudWatch alarm to recover an instance

For information about creating an Amazon CloudWatch alarm to recover an instance, see Add recover actions to Amazon CloudWatch alarms (p. 847).

Troubleshoot instance recovery failures

The following issues can cause automatic recovery of your instance to fail:

- Temporary, insufficient capacity of replacement hardware.
- The instance has an attached instance store storage, which is an unsupported configuration for automatic instance recovery.
- There is an ongoing Service Health Dashboard event that prevented the recovery process from successfully executing. Refer to http://status.aws.amazon.com/ for the latest service availability information.
- The instance has reached the maximum daily allowance of three recovery attempts.

The automatic recovery process attempts to recover your instance for up to three separate failures per day. If the instance system status check failure persists, we recommend that you manually stop and start the instance. For more information, see Stop and start your instance (p. 524).

Your instance may subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause for the original system status check failure.

Configure your Amazon Linux instance

After you have successfully launched and logged into your Amazon Linux instance, you can make changes to it. There are many different ways you can configure an instance to meet the needs of a specific application. The following are some common tasks to help get you started.

Contents

- Common configuration scenarios (p. 555)
- Manage software on your Amazon Linux instance (p. 556)
- Manage user accounts on your Amazon Linux instance (p. 561)
- Processor state control for your EC2 instance (p. 564)
- Set the time for your Linux instance (p. 570)
- Optimize CPU options (p. 575)
- Change the hostname of your Amazon Linux instance (p. 596)
- Set up dynamic DNS on Your Amazon Linux instance (p. 599)
- Run commands on your Linux instance at launch (p. 600)
- Instance metadata and user data (p. 606)

Common configuration scenarios

The base distribution of Amazon Linux contains many software packages and utilities that are required for basic server operations. However, many more software packages are available in various software repositories, and even more packages are available for you to build from source code. For more
information on installing and building software from these locations, see Manage software on your Amazon Linux instance (p. 556).

Amazon Linux instances come pre-configured with an `ec2-user` account, but you may want to add other user accounts that do not have super-user privileges. For more information on adding and removing user accounts, see Manage user accounts on your Amazon Linux instance (p. 561).

The default time configuration for Amazon Linux instances uses Amazon Time Sync Service to set the system time on an instance. The default time zone is UTC. For more information on setting the time zone for an instance or using your own time server, see Set the time for your Linux instance (p. 570).

If you have your own network with a domain name registered to it, you can change the hostname of an instance to identify itself as part of that domain. You can also change the system prompt to show a more meaningful name without changing the hostname settings. For more information, see Change the hostname of your Amazon Linux instance (p. 596). You can configure an instance to use a dynamic DNS service provider. For more information, see Set up dynamic DNS on Your Amazon Linux instance (p. 599).

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: cloud-init directives and shell scripts. For more information, see Run commands on your Linux instance at launch (p. 600).

### Manage software on your Amazon Linux instance

The base distribution of Amazon Linux contains many software packages and utilities that are required for basic server operations. Many more software packages are available in various software repositories, and even more packages are available for you to build from source code.

**Contents**

- Update instance software on your Amazon Linux instance (p. 557)
- Add repositories on an Amazon Linux instance (p. 558)
- Find software packages on an Amazon Linux instance (p. 559)
- Install software packages on an Amazon Linux instance (p. 560)
- Prepare to compile software on an Amazon Linux instance (p. 561)

It is important to keep software up to date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. For more information, see Update instance software on your Amazon Linux instance (p. 557).

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: `amzn2-core` and `amzn2extra-docker`
- Amazon Linux AMI: `amzn-main` and `amzn-updates`

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository. For more information, see Add repositories on an Amazon Linux instance (p. 558). For help finding packages in enabled repositories, see Find software packages on an Amazon Linux instance (p. 559). For information about installing software on an Amazon Linux instance, see Install software packages on an Amazon Linux instance (p. 560).

Not all software is available in software packages stored in repositories; some software must be compiled on an instance from its source code. For more information, see Prepare to compile software on an Amazon Linux instance (p. 561).
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Manage software

Amazon Linux instances manage their software using the yum package manager. The yum package manager can install, remove, and update software, as well as manage all of the dependencies for each package. Debian-based Linux distributions, like Ubuntu, use the apt-get command and dpkg package manager, so the yum examples in the following sections do not work for those distributions.

Update instance software on your Amazon Linux instance

It is important to keep software up to date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. When you first launch and connect to an Amazon Linux instance, you might see a message asking you to update software packages for security purposes. This section shows how to update an entire system, or just a single package.

Important
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To update all packages on an Amazon Linux instance

1. (Optional) Start a screen session in your shell window. Sometimes you might experience a network interruption that can disconnect the SSH connection to your instance. If this happens during a long software update, it can leave the instance in a recoverable, although confused state. A screen session allows you to continue running the update even if your connection is interrupted, and you can reconnect to the session later without problems.

   a. Execute the screen command to begin the session.

      [ec2-user ~]$ screen

   b. If your session is disconnected, log back into your instance and list the available screens.

      [ec2-user ~]$ screen -ls

      There is a screen on:
      17793.pts-0.ip-12-34-56-78 (Detached)
      1 Socket in /var/run/screen/S-ec2-user.

   c. Reconnect to the screen using the screen -r command and the process ID from the previous command.

      [ec2-user ~]$ screen -r 17793

   d. When you are finished using screen, use the exit command to close the session.

      [ec2-user ~]$ exit
      [screen is terminating]

2. Run the yum update command. Optionally, you can add the --security flag to apply only security updates.

      [ec2-user ~]$ sudo yum update

3. Review the packages listed, enter y, and press Enter to accept the updates. Updating all of the packages on a system can take several minutes. The yum output shows the status of the update while it is running.

4. (Optional) Reboot your instance to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.
To update a single package on an Amazon Linux instance

Use this procedure to update a single package (and its dependencies) and not the entire system.

1. Run the **yum update** command with the name of the package to update.

   ```
   [ec2-user ~]# sudo yum update openssl
   ```

2. Review the package information listed, enter y, and press Enter to accept the update or updates.

   Sometimes there will be more than one package listed if there are package dependencies that must be resolved. The **yum** output shows the status of the update while it is running.

3. (Optional) Reboot your instance to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

Add repositories on an Amazon Linux instance

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: amzn2-core and amzn2extra-docker
- Amazon Linux AMI: amzn-main and amzn-updates

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository.

**Important**

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To install a package from a different repository with **yum**, you need to add the repository information to the `/etc/yum.conf` file or to its own `repository.repo` file in the `/etc/yum.repos.d` directory. You can do this manually, but most yum repositories provide their own `repository.repo` file at their repository URL.

To determine what yum repositories are already installed

- List the installed yum repositories with the following command:

  ```
  [ec2-user ~]# yum repolist all
  ```

  The resulting output lists the installed repositories and reports the status of each. Enabled repositories display the number of packages they contain.

To add a yum repository to `/etc/yum.repos.d`

1. Find the location of the `.repo` file. This will vary depending on the repository you are adding. In this example, the `.repo` file is at https://www.example.com/repository.repo.

2. Add the repository with the **yum-config-manager** command.

   ```
   [ec2-user ~]# sudo yum-config-manager --add-repo https://www.example.com/repository.repo
   ```
Manage software

grasping file https://www.example.com/repository.repo to /etc/yum.repos.d/repository.repo
repo saved to /etc/yum.repos.d/repository.repo

After you install a repository, you must enable it as described in the next procedure.

**To enable a yum repository in /etc/yum.repos.d**

- Use the `yum-config-manager` command with the `--enable` flag. The following command enables the Extra Packages for Enterprise Linux (EPEL) repository from the Fedora project. By default, this repository is present in /etc/yum.repos.d on Amazon Linux AMI instances, but it is not enabled.

```
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

*Note*
To enable the EPEL repository on Amazon Linux 2, use the following command:

```
```

For information on enabling the EPEL repository on other distributions, such as Red Hat and CentOS, see the EPEL documentation at https://fedoraproject.org/wiki/EPEL.

**Find software packages on an Amazon Linux instance**

You can use the `yum search` command to search the descriptions of packages that are available in your configured repositories. This is especially helpful if you don't know the exact name of the package you want to install. Simply append the keyword search to the command; for multiple word searches, wrap the search query with quotation marks.

*Important*
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

```
[ec2-user ~]$ sudo yum search "find"
```

The following is example output for Amazon Linux 2.

```
Loaded plugins: extras_suggestions, langpacks, priorities, update-motd
=================================================================== N/S matched: find  ==================================================
findutils.x86_64 : The GNU versions of find utilities (find and xargs)
gedit-plugin-findinfiles.x86_64 : gedit findinfiles plugin
ocaml-findlib-devel.x86_64 : Development files for ocaml-findlib
perl-File-Find-Rule.noarch : Perl module implementing an alternative interface to File::Find
robotfindskitten.x86_64 : A game/zen simulation. You are robot. Your job is to find kitten.
mlocate.x86_64 : An utility for finding files by name
ocaml-findlib.x86_64 : Objective CAML package manager and build helper
perl-Devel-Cycle.noarch : Find memory cycles in objects
perl-Devel-EnforceEncapsulation.noarch : Find access violations to blessed objects
perl-File-Find-Rule-Perl.noarch : Common rules for searching for Perl things
perl-File-HomeDir.noarch : Find your home and other directories on any platform
perl-IPC-Cmd.noarch : Finding and running system commands made easy
perl-Perl-MinimumVersion.noarch : Find a minimum required version of perl for Perl code
```

559
Manage software

Manage software

The following is example output for Amazon Linux.

```
Loaded plugins: priorities, security, update-motd, upgrade-helper
================================================ N/S Matched: find ===============================
findutils.x86_64 : The GNU versions of find utilities (find and xargs)
perl-File-Find-Rule.noarch : Perl module implementing an alternative interface to
  File::Find
perl-Module-Find.noarch : Find and use installed modules in a (sub)category
libpuzzle.i686 : Library to quickly find visually similar images (gif, png, jpg)
libpuzzle.x86_64 : Library to quickly find visually similar images (gif, png, jpg)
mlocate.x86_64 : An utility for finding files by name
```

Multiple word search queries in quotation marks only return results that match the exact query. If you don't see the expected package, simplify your search to one keyword and then scan the results. You can also try keyword synonyms to broaden your search.

For more information about packages for Amazon Linux 2 and Amazon Linux, see the following:

- Package repository (p. 167)
- Extras library (Amazon Linux 2) (p. 169)

Install software packages on an Amazon Linux instance

The yum package manager is a great tool for installing software, because it can search all of your enabled repositories for different software packages and also handle any dependencies in the software installation process.

**Important**
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To install a package from a repository

Use the `yum install` command, replacing `package` with the name of the software to install. For example, to install the `links` text-based web browser, enter the following command.

```
[ec2-user ~]# sudo yum install links
```

To install RPM package files that you have downloaded

You can also use `yum install` to install RPM package files that you have downloaded from the internet. To do this, append the path name of an RPM file to the installation command instead of a repository package name.

```
[ec2-user ~]# sudo yum install my-package.rpm
```

To list installed packages

To view a list of installed packages on your instance, use the following command.

```
[ec2-user ~]# yum list installed
```
Prepare to compile software on an Amazon Linux instance

There is a wealth of open-source software available on the internet that has not been pre-compiled and made available for download from a package repository. You might eventually discover a software package that you need to compile yourself, from its source code. For your system to be able to compile software, you need to install several development tools, such as `make`, `gcc`, and `autoconf`.

**Important**
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

Because software compilation is not a task that every Amazon EC2 instance requires, these tools are not installed by default, but they are available in a package group called "Development Tools" that is easily added to an instance with the `yum groupinstall` command.

```
[ec2-user ~]$ sudo yum groupinstall "Development Tools"
```

Software source code packages are often available for download (from websites such as https://github.com/ and http://sourceforge.net/) as a compressed archive file, called a tarball. These tarballs will usually have the `.tar.gz` file extension. You can decompress these archives with the `tar` command.

```
[ec2-user ~]$ tar -xzf software.tar.gz
```

After you have decompressed and unarchived the source code package, you should look for a `README` or `INSTALL` file in the source code directory that can provide you with further instructions for compiling and installing the source code.

**To retrieve source code for Amazon Linux packages**

Amazon Web Services provides the source code for maintained packages. You can download the source code for any installed packages with the `yumdownloader --source` command.

- Run the `yumdownloader --source package` command to download the source code for `package`. For example, to download the source code for the `htop` package, enter the following command.

```
[ec2-user ~]$ yumdownloader --source htop
```

The location of the source RPM is in the directory from which you ran the command.

Manage user accounts on your Amazon Linux instance

Each Linux instance launches with a default Linux system user account. The default user name is determined by the AMI that was specified when you launched the instance.
Manage users

- For Amazon Linux 2 or the Amazon Linux AMI, the user name is `ec2-user`.
- For a CentOS AMI, the user name is `centos` or `ec2-user`.
- For a Debian AMI, the user name is `admin`.
- For a Fedora AMI, the user name is `fedora` or `ec2-user`.
- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.
- Otherwise, check with the AMI provider.

**Note**

Linux system users should not be confused with AWS Identity and Access Management (IAM) users. For more information, see IAM users in the IAM User Guide.

Contents

- Considerations (p. 562)
- Create a user account (p. 562)
- Remove a user account (p. 564)

**Considerations**

Using the default user account is adequate for many applications. However, you may choose to add user accounts so that individuals can have their own files and workspaces. Furthermore, creating user accounts for new users is much more secure than granting multiple (possibly inexperienced) users access to the default user account, because the default user account can cause a lot of damage to a system when used improperly. For more information, see Tips for Securing Your EC2 Instance.

To enable users SSH access to your EC2 instance using a Linux system user account, you must share the SSH key with the user. Alternatively, you can use EC2 Instance Connect to provide access to users without the need to share and manage SSH keys. For more information, see Connect to your Linux instance using EC2 Instance Connect (p. 505).

**Create a user account**

First create the user account, and then add the SSH public key that allows the user to connect to and log into the instance.

**To create a user account**

1. Create a new key pair (p. 1138). You must provide the `.pem` file to the user for whom you are creating the user account. They must use this file to connect to the instance.
2. Retrieve the public key from the key pair that you created in the previous step.

   ```bash
   # ssh-keygen -y -f /path_to_key_pair/key-pair-name.pem
   ```

   The command returns the public key, as shown in the following example.

   ```plaintext
   ssh-rsa
   AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYbCe53pcjgF3maAhDFcvs7O6Vhz2ItxC1h +PnDShu+wMNGz/m2pTkT/aga/gUejEc0OWWkM4yxyb/w896bxbIFveSPJv0Q/d6RJhQ0l1pBxl6rLbItntckiI77FbtxJMXLvvwJrYDUlBMJytw8+QhYY UM02ce5Pjz5/i8SeJtjnV3iaOG/cQy+0FzQgaejAAHc0+CY/5wUBkrHmFjR6HeKxvJdWpkYQs3xqC0+FmU0ofz221CBt51MucxXQfx4rWi +z7wB3RbBQoQzd8v7yeb70zlPnWOyN0qFU0X2A46RA8QFYiCNYyW13f05p6KLLxEXAMPLE
   ```
3. Connect to the instance.
4. Use the `adduser` command to create the user account and add it to the system (with an entry in the `/etc/passwd` file). The command also creates a group and a home directory for the account. In this example, the user account is named `newuser`.

   - Amazon Linux and Amazon Linux 2
     ```
     [ec2-user ~]$ sudo adduser newuser
     ```

   - Ubuntu
     Include the `--disabled-password` parameter to create the user account without a password.
     ```
     [ubuntu ~]$ sudo adduser newuser --disabled-password
     ```

5. Switch to the new account so that the directory and file that you create will have the proper ownership.

   ```
   [ec2-user ~]$ sudo su - newuser
   ```
   The prompt changes from `ec2-user` to `newuser` to indicate that you have switched the shell session to the new account.

6. Add the SSH public key to the user account. First create a directory in the user's home directory for the SSH key file, then create the key file, and finally paste the public key into the key file, as described in the following sub-steps.

   a. Create a `.ssh` directory in the `newuser` home directory and change its file permissions to `700` (only the owner can read, write, or open the directory).
     ```
     [newuser ~]$ mkdir .ssh
     [newuser ~]$ chmod 700 .ssh
     ```
     **Important**
     Without these exact file permissions, the user will not be able to log in.

   b. Create a file named `authorized_keys` in the `.ssh` directory and change its file permissions to `600` (only the owner can read or write to the file).
     ```
     [newuser ~]$ touch .ssh/authorized_keys
     [newuser ~]$ chmod 600 .ssh/authorized_keys
     ```
     **Important**
     Without these exact file permissions, the user will not be able to log in.

   c. Open the `authorized_keys` file using your favorite text editor (such as `vim` or `nano`).
     ```
     [newuser ~]$ nano .ssh/authorized_keys
     ```
     Paste the public key that you retrieved in **Step 2** into the file and save the changes.
     **Important**
     Ensure that you paste the public key in one continuous line. The public key must not be split over multiple lines.
The user should now be able to log into the `newuser` account on your instance, using the private key that corresponds to the public key that you added to the `authorized_keys` file. For more information about the different methods of connecting to a Linux instance, see Connect to your Linux instance (p. 499).

**Remove a user account**

If a user account is no longer needed, you can remove that account so that it can no longer be used.

Use the `userdel` command to remove the user account from the system. When you specify the `-r` parameter, the user's home directory and mail spool are deleted. To keep the user's home directory and mail spool, omit the `-r` parameter.

```
[ec2-user ~]$ sudo userdel -r olduser
```

**Processor state control for your EC2 instance**

C-states control the sleep levels that a core can enter when it is idle. C-states are numbered starting with C0 (the shallowest state where the core is totally awake and executing instructions) and go to C6 (the deepest idle state where a core is powered off). P-states control the desired performance (in CPU frequency) from a core. P-states are numbered starting from P0 (the highest performance setting where the core is allowed to use Intel Turbo Boost Technology to increase frequency if possible), and they go from P1 (the P-state that requests the maximum baseline frequency) to P15 (the lowest possible frequency).

The following instance types provide the ability for an operating system to control processor C-states and P-states:

- **General purpose:** `m4.10xlarge | m4.16xlarge | m5.metal | m5d.metal`
- **Compute optimized:** `c4.8xlarge | c5.metal | c5n.metal`
- **Memory optimized:** `r4.8xlarge | r4.16xlarge | r5.metal | r5d.metal | u-6tb1.metal | u-9tb1.metal | u-12tb1.metal | u-18tb1.metal | u-24tb1.metal | x1.16xlarge | x1.32xlarge | x1e.8xlarge | x1e.16xlarge | x1e.32xlarge | x1d.metal`
- **Storage optimized:** `d2.8xlarge | i3.8xlarge | i3.16xlarge | i3.meta | i3n.meta | i3en.meta | h1.8xlarge | h1.16xlarge`
- **Accelerated computing:** `f1.16xlarge | g3.16xlarge | g4dn.meta | p2.16xlarge | p3.16xlarge`

The following instance types provide the ability for an operating system to control processor C-states:

- **General purpose:** `m5.12xlarge | m5.24xlarge | m5d.12xlarge | m5d.24xlarge | m5n.12xlarge | m5n.24xlarge | m5n.24xlarge | m5dn.12xlarge | m5dn.24xlarge`
- **Compute optimized:** `c5.9xlarge | c5.12xlarge | c5.18xlarge | c5.24xlarge | c5a.24xlarge | c5ad.24xlarge | c5d.9xlarge | c5d.12xlarge | c5d.18xlarge | c5d.24xlarge | c5n.9xlarge | c5n.18xlarge | c5n.24xlarge`
- **Memory optimized:** `r5.12xlarge | r5.24xlarge | r5d.12xlarge | r5d.24xlarge | r5n.12xlarge | r5n.24xlarge | r5dn.12xlarge | r5dn.24xlarge | z1d.6xlarge | z1d.12xlarge`
- **Storage optimized:** `d3en.12xlarge | i3en.12xlarge | i3en.24xlarge`
- **Accelerated computing:** `inf1.24xlarge | p3dn.24xlarge`

AWS Graviton processors have built-in power saving modes and operate at a fixed frequency. Therefore, they do not provide the ability for the operating system to control C-states and P-states.
You might want to change the C-state or P-state settings to increase processor performance consistency, reduce latency, or tune your instance for a specific workload. The default C-state and P-state settings provide maximum performance, which is optimal for most workloads. However, if your application would benefit from reduced latency at the cost of higher single- or dual-core frequencies, or from consistent performance at lower frequencies as opposed to bursty Turbo Boost frequencies, consider experimenting with the C-state or P-state settings that are available to these instances.

The following sections describe the different processor state configurations and how to monitor the effects of your configuration. These procedures were written for, and apply to Amazon Linux; however, they may also work for other Linux distributions with a Linux kernel version of 3.9 or newer. For more information about other Linux distributions and processor state control, see your system-specific documentation.

**Note**
The examples on this page use the `turbostat` utility (which is available on Amazon Linux by default) to display processor frequency and C-state information, and the `stress` command (which can be installed by running `sudo yum install -y stress`) to simulate a workload. If the output does not display the C-state information, include the `--debug` option in the command (`sudo turbostat --debug stress <options>`).

**Contents**
- Highest performance with maximum Turbo Boost frequency (p. 565)
- High performance and low latency by limiting deeper C-states (p. 566)
- Baseline performance with the lowest variability (p. 568)

### Highest performance with maximum Turbo Boost frequency

This is the default processor state control configuration for the Amazon Linux AMI, and it is recommended for most workloads. This configuration provides the highest performance with lower variability. Allowing inactive cores to enter deeper sleep states provides the thermal headroom required for single or dual core processes to reach their maximum Turbo Boost potential.

The following example shows a c4.8xlarge instance with two cores actively performing work reaching their maximum processor Turbo Boost frequency.

```
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10
stress: info: [30680] dispatching hogs: 2 cpu, 0 io, 0 vm, 0 hdd
stress: info: [30680] successful run completed in 10s

</table>
```

In this example, vCPUs 21 and 28 are running at their maximum Turbo Boost frequency because the other cores have entered the C6 sleep state to save power and provide both power and thermal...
headroom for the working cores. vCPUs 3 and 10 (each sharing a processor core with vCPUs 21 and 28) are in the C1 state, waiting for instruction.

In the following example, all 18 cores are actively performing work, so there is no headroom for maximum Turbo Boost, but they are all running at the "all core Turbo Boost" speed of 3.2 GHz.

```
[ec2-user ~]$ sudo turbostat stress -c 36 -t 10
stress: info: [30685] dispatching hogs: 36 cpu, 0 io, 0 vm, 0 hdd
stress: info: [30685] successful run completed in 10s

**High performance and low latency by limiting deeper C-states**

C-states control the sleep levels that a core may enter when it is inactive. You may want to control C-states to tune your system for latency versus performance. Putting cores to sleep takes time, and although a sleeping core allows more headroom for another core to boost to a higher frequency, it takes time for that sleeping core to wake back up and perform work. For example, if a core that is assigned to handle network packet interrupts is asleep, there may be a delay in servicing that interrupt. You can configure the system to not use deeper C-states, which reduces the processor reaction latency, but that in turn also reduces the headroom available to other cores for Turbo Boost.

A common scenario for disabling deeper sleep states is a Redis database application, which stores the database in system memory for the fastest possible query response time.

**To limit deeper sleep states on Amazon Linux 2**

1. Open the `/etc/default/grub` file with your editor of choice.
    ```bash
    [ec2-user ~]$ sudo vim /etc/default/grub
    ```

2. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line and add the `intel_idle.max_cstate=1` option to set C1 as the deepest C-state for idle cores.
    ```
    GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1"
    ```

3. Save the file and exit your editor.

4. Run the following command to rebuild the boot configuration.

```bash
...```
5. Reboot your instance to enable the new kernel option.

To limit deeper sleep states on Amazon Linux AMI

1. Open the `/boot/grub/grub.conf` file with your editor of choice.

2. Edit the `kernel` line of the first entry and add the `intel_idle.max_cstate=1` option to set C1 as the deepest C-state for idle cores.

3. Save the file and exit your editor.

4. Reboot your instance to enable the new kernel option.

The following example shows a `c4.8xlarge` instance with two cores actively performing work at the "all core Turbo Boost" core frequency.

In this example, the cores for vCPUs 19 and 28 are running at 3.2 GHz, and the other cores are in the C1 C-state, awaiting instruction. Although the working cores are not reaching their maximum Turbo Boost
frequency, the inactive cores will be much faster to respond to new requests than they would be in the deeper C6 C-state.

**Baseline performance with the lowest variability**

You can reduce the variability of processor frequency with P-states. P-states control the desired performance (in CPU frequency) from a core. Most workloads perform better in P0, which requests Turbo Boost. But you may want to tune your system for consistent performance rather than bursty performance that can happen when Turbo Boost frequencies are enabled.

Intel Advanced Vector Extensions (AVX or AVX2) workloads can perform well at lower frequencies, and AVX instructions can use more power. Running the processor at a lower frequency, by disabling Turbo Boost, can reduce the amount of power used and keep the speed more consistent. For more information about optimizing your instance configuration and workload for AVX, see [http://www.intel.com/content/dam/www/public/us/en/documents/white-papers/performance-xeon-e5-v3-advanced-vector-extensions-paper.pdf](http://www.intel.com/content/dam/www/public/us/en/documents/white-papers/performance-xeon-e5-v3-advanced-vector-extensions-paper.pdf).

This section describes how to limit deeper sleep states and disable Turbo Boost (by requesting the P1 P-state) to provide low-latency and the lowest processor speed variability for these types of workloads.

**To limit deeper sleep states and disable Turbo Boost on Amazon Linux 2**

1. Open the `/etc/default/grub` file with your editor of choice.

   ```bash
   [ec2-user ~]$ sudo vim /etc/default/grub
   ```

2. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line and add the `intel_idle.max_cstate=1` option to set C1 as the deepest C-state for idle cores.

   ```bash
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1"
   GRUB_TIMEOUT=0
   ```

3. Save the file and exit your editor.

4. Run the following command to rebuild the boot configuration.

   ```bash
   [ec2-user ~]$ grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

5. Reboot your instance to enable the new kernel option.

   ```bash
   [ec2-user ~]$ sudo reboot
   ```

6. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

   ```bash
   [ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
   ```

7. When your workload is finished, you can re-enable Turbo Boost with the following command.

   ```bash
   [ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
   ```

**To limit deeper sleep states and disable Turbo Boost on Amazon Linux AMI**

1. Open the `/boot/grub/grub.conf` file with your editor of choice.

   ```bash
   [ec2-user ~]$ sudo vim /boot/grub/grub.conf
   ```

   ```bash
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1"
   ```

   ```bash
   GRUB_TIMEOUT=0
   ```

   ```bash
   [ec2-user ~]$ grub2-mkconfig -o /boot/grub/grub.cfg
   ```

   ```bash
   [ec2-user ~]$ sudo reboot
   ```

   ```bash
   [ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
   ```

   ```bash
   [ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
   ```
2. Edit the kernel line of the first entry and add the `intel_idle.max_cstate=1` option to set C1 as the deepest C-state for idle cores.

```plaintext
# created by imagebuilder
default=0
timeout=1
hiddenmenu
title Amazon Linux 2014.09 (3.14.26-24.46.amzn1.x86_64)
root (/dev/sda0)
kernel /boot/vmlinuz-3.14.26-24.46.amzn1.x86_64 root=LABEL=/ console=ttyS0
intel_idle.max_cstate=1
initrd /boot/initramfs-3.14.26-24.46.amzn1.x86_64.img
```

3. Save the file and exit your editor.

4. Reboot your instance to enable the new kernel option.

```plaintext
[ec2-user ~]$ sudo reboot
```

5. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

```plaintext
[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

6. When your workload is finished, you can re-enable Turbo Boost with the following command.

```plaintext
[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

The following example shows a c4.8xlarge instance with two vCPUs actively performing work at the baseline core frequency, with no Turbo Boost.

```plaintext
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10
```

The cores for vCPUs 21 and 28 are actively performing work at the baseline processor speed of 2.9 GHz, and all inactive cores are also running at the baseline speed in the C1 C-state, ready to accept instructions.
Set the time for your Linux instance

A consistent and accurate time reference is crucial for many server tasks and processes. Most system logs include a time stamp that you can use to determine when problems occurred and in what order the events took place. If you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If your instance's date and time are not set correctly, the date in the signature may not match the date of the request, and AWS rejects the request.

Amazon provides the Amazon Time Sync Service, which is accessible from all EC2 instances, and is also used by other AWS services. This service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate current time readings of the Coordinated Universal Time (UTC) global standard through Network Time Protocol (NTP). The Amazon Time Sync Service automatically smooths any leap seconds that are added to UTC.

The Amazon Time Sync Service is available through NTP at the 169.254.169.123 IPv4 address or the fd00:ec2::123 IPv6 address for any instance running in a VPC. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199). Your instance does not require access to the internet, and you do not have to configure your security group rules or your network ACL rules to allow access. The latest versions of Amazon Linux 2 and Amazon Linux AMIs synchronize with the Amazon Time Sync Service by default.

Use the following procedures to configure the Amazon Time Sync Service on your instance using the `chrony` client. Alternatively, you can use external NTP sources. For more information about NTP and public time sources, see [http://www.ntp.org/](http://www.ntp.org/). An instance needs access to the internet for the external NTP time sources to work.

For Windows instances, see Set the time for a Windows instance.

Configure the time for EC2 instances with IPv4 addresses

This section describes how to set the time for EC2 instances with IPv4 addresses depending on the type of Linux distribution.

Topics
- Configure the Amazon Time Sync Service on Amazon Linux AMI (p. 570)
- Configure the Amazon Time Sync Service on Ubuntu (p. 572)
- Configure the Amazon Time Sync Service on SUSE Linux (p. 573)

Configure the Amazon Time Sync Service on Amazon Linux AMI

**Note**
On Amazon Linux 2, `chrony` is already installed and configured to use the Amazon Time Sync Service IP address.

With the Amazon Linux AMI, you must edit the `chrony` configuration file to add a server entry for the Amazon Time Sync Service.

**To configure your instance to use the Amazon Time Sync Service**

1. Connect to your instance and uninstall the NTP service.
Set the time

2. Install the chrony package.

```bash
[ec2-user -]# sudo yum install chrony
```

3. Open the /etc/chrony.conf file using a text editor (such as `vim` or `nano`). Verify that the file includes the following line:

```plaintext
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If the line is present, then the Amazon Time Sync Service is already configured and you can go to the next step. If not, add the line after any other `server` or `pool` statements that are already present in the file, and save your changes.

4. Restart the chrony daemon (`chronyd`).

```bash
[ec2-user -]# sudo service chronyd restart
```

Starting chronyd: [ OK ]

**Note**
On RHEL and CentOS (up to version 6), the service name is `chrony` instead of `chronyd`.

5. Use the `chkconfig` command to configure `chronyd` to start at each system boot.

```bash
[ec2-user -]# sudo chkconfig chronyd on
```

6. Verify that `chrony` is using the 169.254.169.123 IP address to synchronize the time.

```bash
[ec2-user -]# chronyc sources -v
```

In the output that's returned, `^*` indicates the preferred time source.

7. Verify the time synchronization metrics that are reported by `chrony`.

---

571
Configure the Amazon Time Sync Service on Ubuntu

You must edit the `chrony` configuration file to add a server entry for the Amazon Time Sync Service.

To configure your instance to use the Amazon Time Sync Service

1. Connect to your instance and use `apt` to install the `chrony` package.

   ```
   ubuntu:~$ sudo apt install chrony
   ```

   **Note**
   If necessary, update your instance first by running `sudo apt update`.

2. Open the `/etc/chrony/chrony.conf` file using a text editor (such as `vim` or `nano`). Add the following line before any other `server` or `pool` statements that are already present in the file, and save your changes:

   ```
   server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
   ```

3. Restart the `chrony` service.

   ```
   ubuntu:~$ sudo /etc/init.d/chrony restart
   ```

4. Verify that `chrony` is using the 169.254.169.123 IP address to synchronize the time.

   ```
   ubuntu:~$ chronyc sources -v
   ```

   210 Number of sources = 7

   ```
   .-- Source mode  '^' = server, '=' = peer, '#' = local clock.
   / .-- Source state ' '=' current synced, '+=' = combined , '-' = not
   combined,
   | /  '?' = unreachable, 'x=' = time may be in error, '-' = time too
   |   variable.
   || 
   || zzzz .- xxxx [ yyyy ] +/-
   ```
Set the time

In the output that's returned, ^* indicates the preferred time source.

5. Verify the time synchronization metrics that are reported by chrony.

```
ubuntu:~$ chronyc tracking
```

```

Configure the Amazon Time Sync Service on SUSE Linux

Install chrony from https://software.opensuse.org/package/chrony.

Open the /etc/chrony.conf file using a text editor (such as vim or nano). Verify that the file contains the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If this line is not present, add it. Comment out any other server or pool lines. Open yaST and enable the chrony service.
Configure the time for EC2 instances with IPv6 addresses

This section explains how the process described in Configure the time for EC2 instances with IPv4 addresses (p. 570) differs if you are configuring Amazon Time Sync Service for EC2 instances that use an IPv6 address. It doesn't explain the entire Amazon Time Sync Service configuration process. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

Note
We don't recommend using both the IPv4 address and the IPv6 address entries together in your chrony.conf file. The IPv4 and IPv6 NTP packets come from the same local server for your instance. You will likely get mixed results with some packets coming from the IPv4 endpoint and some from the IPv6 endpoint if you are using both at the same time.

Depending on the Linux distribution you are using, when you reach the step to edit the chrony.conf file, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (fd00:ec2::123) rather than the IPv4 endpoint (169.254.169.123):

```
server fd00:ec2::123 prefer iburst minpoll 4 maxpoll 4
```

Save the file and verify that chrony is using the fd00:ec2::123 IPv6 address to synchronize time:

```
[ec2-user ~]$ chronyc sources -v
```

In the output, if you see the fd00:ec2::123 IPv6 address, the configuration is complete.

Change the time zone on Amazon Linux

Amazon Linux instances are set to the UTC (Coordinated Universal Time) time zone by default. You can change the time on an instance to the local time or to another time zone in your network.

Important
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To change the time zone on an instance

1. Identify the time zone to use on the instance. The /usr/share/zoneinfo directory contains a hierarchy of time zone data files. Browse the directory structure at that location to find a file for your time zone.

```
[ec2-user ~]$ ls /usr/share/zoneinfo
Africa   Chile   GB   Indian   Mideast   posixrules   US
America  CST6CDT GB-Eire Iran   MST   PRC   UTC
Antarctica Cuba   GMT   iso3166.tab MST7MDT   PST8PDT   WET
Arctic   EET   GMT0   Israel   Navajo   right   W-SU
... 
```

Some of the entries at this location are directories (such as America), and these directories contain time zone files for specific cities. Find your city (or a city in your time zone) to use for the instance.

2. Update the /etc/sysconfig/clock file with the new time zone. In this example, we use the time zone data file for Los Angeles, /usr/share/zoneinfo/America/Los_Angeles.

```
a. Open the /etc/sysconfig/clock file with your favorite text editor (such as vim or nano). You need to use sudo with your editor command because /etc/sysconfig/clock is owned by root.
```

```
[ec2-user ~]$ sudo nano /etc/sysconfig/clock
```
b. Locate the ZONE entry, and change it to the time zone file (omitting the /usr/share/zoneinfo section of the path). For example, to change to the Los Angeles time zone, change the ZONE entry to the following:

```
ZONE="America/Los_Angeles"
```

**Note**
Do not change the UTC=true entry to another value. This entry is for the hardware clock, and does not need to be adjusted when you're setting a different time zone on your instance.

c. Save the file and exit the text editor.

3. Create a symbolic link between /etc/localtime and the time zone file so that the instance finds the time zone file when it references local time information.

```
[ec2-user ~]$
sudo ln -sf /usr/share/zoneinfo/America/Los_Angeles /etc/localtime
```

4. Reboot the system to pick up the new time zone information in all services and applications.

```
[ec2-user ~]$
sudo reboot
```

5. (Optional) Confirm that the current time zone is updated to the new time zone by using the `date` command. The current time zone appears in the output. In the following example, the current time zone is PDT, which refers to the Los Angeles time zone.

```
[ec2-user ~]$
date
Sun Aug 16 05:45:16 PDT 2020
```

## Optimize CPU options

Amazon EC2 instances support multithreading, which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an `m5.xlarge` instance type has two CPU cores and two threads per core by default—four vCPUs in total.

**Note**
Each vCPU is a thread of a CPU core, except for T2 instances and instances powered by AWS Graviton2 processors.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, you can specify the following CPU options to optimize your instance for specific workloads or business needs:

- **Number of CPU cores**: You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core**: You can disable multithreading by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

You can specify these CPU options during instance launch. There is no additional or reduced charge for specifying CPU options. You're charged the same as instances that are launched with default CPU options.

**Contents**
- Rules for specifying CPU options (p. 576)
• CPU cores and threads per CPU core per instance type (p. 576)
• Specify CPU options for your instance (p. 593)
• View the CPU options for your instance (p. 595)

Rules for specifying CPU options

To specify the CPU options for your instance, be aware of the following rules:

• CPU options can only be specified during instance launch and cannot be modified after launch.
• When you launch an instance, you must specify both the number of CPU cores and threads per core in the request. For example requests, see Specify CPU options for your instance (p. 593).
• The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see CPU cores and threads per CPU core per instance type (p. 576).
• To disable multithreading, specify one thread per core.
• When you change the instance type (p. 310) of an existing instance, the CPU options automatically change to the default CPU options for the new instance type.
• The specified CPU options persist after you stop, start, or reboot an instance.

CPU cores and threads per CPU core per instance type

The following tables list the instance types that support specifying CPU options.

Contents
• Accelerated computing instances (p. 576)
• Compute optimized instances (p. 578)
• General purpose instances (p. 581)
• Memory optimized instances (p. 587)
• Storage optimized instances (p. 592)

### Specify CPU options for your instance

You can specify CPU options during instance launch. The following examples are for an r4.4xlarge instance type, which has the following default values (p. 587):

- Default CPU cores: 8
- Default threads per core: 2
- Default vCPUs: 16 (8 * 2)
- Valid number of CPU cores: 1, 2, 3, 4, 5, 6, 7, 8
- Valid number of threads per core: 1, 2
Disable multithreading

To disable multithreading, specify one thread per core.

To disable multithreading during instance launch (console)

1. Follow the Launch an instance using the Launch Instance Wizard (p. 477) procedure.
2. On the Configure Instance Details page, for CPU options, choose Specify CPU options.
3. For Core count, choose the number of required CPU cores. In this example, to specify the default CPU core count for an r4.4xlarge instance, choose 8.
4. To disable multithreading, for Threads per core, choose 1.
5. Continue as prompted by the wizard. When you've finished reviewing your options on the Review Instance Launch page, choose Launch. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

To disable multithreading during instance launch (AWS CLI)

Use the run-instances AWS CLI command and specify a value of 1 for ThreadsPerCore for the --cpu-options parameter. For CoreCount, specify the number of CPU cores. In this example, to specify the default CPU core count for an r4.4xlarge instance, specify a value of 8.

```bash
aws ec2 run-instances --image-id ami-1a2b3c4d --instance-type r4.4xlarge --cpu-options "CoreCount=8,ThreadsPerCore=1" --key-name MyKeyPair
```

Specify a custom number of vCPUs

You can customize the number of CPU cores and threads per core for the instance.

To specify a custom number of vCPUs during instance launch (console)

The following example launches an r4.4xlarge instance with six vCPUs.

1. Follow the Launch an instance using the Launch Instance Wizard (p. 477) procedure.
2. On the Configure Instance Details page, for CPU options, choose Specify CPU options.
3. To get six vCPUs, specify three CPU cores and two threads per core, as follows:
   - For Core count, choose 3.
   - For Threads per core, choose 2.
4. Continue as prompted by the wizard. When you've finished reviewing your options on the Review Instance Launch page, choose Launch. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

To specify a custom number of vCPUs during instance launch (AWS CLI)

The following example launches an r4.4xlarge instance with six vCPUs.

Use the run-instances AWS CLI command and specify the number of CPU cores and number of threads in the --cpu-options parameter. You can specify three CPU cores and two threads per core to get six vCPUs.

```bash
aws ec2 run-instances --image-id ami-1a2b3c4d --instance-type r4.4xlarge --cpu-options "CoreCount=3,ThreadsPerCore=2" --key-name MyKeyPair
```

Alternatively, specify six CPU cores and one thread per core (disable multithreading) to get six vCPUs:
**View the CPU options for your instance**

You can view the CPU options for an existing instance in the Amazon EC2 console or by describing the instance using the AWS CLI.

**New console**

To view the CPU options for an instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Instances** and select the instance.
3. On the **Details** tab, under **Host and placement group**, find **Number of vCPUs**.
4. To view core count and threads per core, choose the value for **Number of vCPUs**.

**Old console**

To view the CPU options for an instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Instances** and select the instance.
3. Choose **Description** and find **Number of vCPUs**.
4. To view core count and threads per core, choose the value for **Number of vCPUs**.

**To view the CPU options for an instance (AWS CLI)**

Use the **describe-instances** command.

```bash
aws ec2 describe-instances --instance-ids i-123456789abcdef123
```

```json
...
"Instances": [
  {
    "Monitoring": {
      "State": "disabled"
    },
    "PublicDnsName": "ec2-198-51-100-5.eu-central-1.compute.amazonaws.com",
    "State": {
      "Code": 16,
      "Name": "running"
    },
    "EbsOptimized": false,
    "LaunchTime": "2018-05-08T13:40:33.000Z",
    "PublicIpAddress": "198.51.100.5",
    "PrivateIpAddress": "172.31.2.206",
    "ProductCodes": [],
    "VpcId": "vpc-1a2b3c4d",
    "CpuOptions": {
      "CoreCount": 34,
      "ThreadsPerCore": 1
    },
    "StateTransitionReason": "",
    ...
  }
...
In the output that's returned, the `CoreCount` field indicates the number of cores for the instance. The `ThreadsPerCore` field indicates the number of threads per core.

Alternatively, connect to your instance and use a tool such as `lscpu` to view the CPU information for your instance.

You can use AWS Config to record, assess, audit, and evaluate configuration changes for instances, including terminated instances. For more information, see Getting Started with AWS Config in the AWS Config Developer Guide.

### Change the hostname of your Amazon Linux instance

When you launch an instance, it is assigned a hostname that is a form of the private, internal IPv4 address. A typical Amazon EC2 private DNS name looks something like this: `ip-12-34-56-78.us-west-2.compute.internal`, where the name consists of the internal domain, the service (in this case, `compute`), the region, and a form of the private IPv4 address. Part of this hostname is displayed at the shell prompt when you log into your instance (for example, `ip-12-34-56-78`). Each time you stop and restart your Amazon EC2 instance (unless you are using an Elastic IP address), the public IPv4 address changes, and so does your public DNS name, system hostname, and shell prompt.

**Important**

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

### Change the system hostname

If you have a public DNS name registered for the IP address of your instance (such as `webserver.mydomain.com`), you can set the system hostname so your instance identifies itself as a part of that domain. This also changes the shell prompt so that it displays the first portion of this name instead of the hostname supplied by AWS (for example, `ip-12-34-56-78`). If you do not have a public DNS name registered, you can still change the hostname, but the process is a little different.

In order for your hostname update to persist, you must verify that the `preserve_hostname` cloud-init setting is set to `true`. You can run the following command to edit or add this setting:

```
sudo vi /etc/cloud/cloud.cfg
```

If the `preserve_hostname` setting is not listed, add the following line of text to the end of the file:

```
preserve_hostname: true
```

**To change the system hostname to a public DNS name**

Follow this procedure if you already have a public DNS name registered.

1. For Amazon Linux 2: Use the `hostnamectl` command to set your hostname to reflect the fully qualified domain name (such as `webserver.mydomain.com`).

   ```
   [ec2-user ~]$ sudo hostnamectl set-hostname webserver.mydomain.com
   ```

2. For Amazon Linux AMI: On your instance, open the `/etc/sysconfig/network` configuration file in your favorite text editor and change the `HOSTNAME` entry to reflect the fully qualified domain name (such as `webserver.mydomain.com`).

596
2. Reboot the instance to pick up the new hostname.

```
[ec2-user ~]$ sudo reboot
```

Alternatively, you can reboot using the Amazon EC2 console (on the Instances page, select the instance and choose Instance state, Reboot instance).

3. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the hostname command should show the fully-qualified domain name.

```
[ec2-user@webserver ~]$ hostname
webserver.mydomain.com
```

To change the system hostname without a public DNS name

1. • For Amazon Linux 2: Use the hostnamectl command to set your hostname to reflect the desired system hostname (such as webserver).

```
[ec2-user ~]$ sudo hostnamectl set-hostname webserver.localdomain
```

• For Amazon Linux AMI: On your instance, open the /etc/sysconfig/network configuration file in your favorite text editor and change the HOSTNAME entry to reflect the desired system hostname (such as webserver).

```
HOSTNAME=webserver.localdomain
```

2. Open the /etc/hosts file in your favorite text editor and change the entry beginning with 127.0.0.1 to match the example below, substituting your own hostname.

```
127.0.0.1 webserver.localdomain webserver localhost4 localhost4.localdomain4
```

3. Reboot the instance to pick up the new hostname.

```
[ec2-user ~]$ sudo reboot
```

Alternatively, you can reboot using the Amazon EC2 console (on the Instances page, select the instance and choose Instance state, Reboot instance).

4. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the hostname command should show the fully-qualified domain name.

```
[ec2-user@webserver ~]$ hostname
webserver.localdomain
```

Change the shell prompt without affecting the hostname

If you do not want to modify the hostname for your instance, but you would like to have a more useful system name (such as webserver) displayed than the private name supplied by AWS (for example,
ip-12-34-56-78), you can edit the shell prompt configuration files to display your system nickname instead of the hostname.

To change the shell prompt to a host nickname

1. Create a file in /etc/profile.d that sets the environment variable called NICKNAME to the value you want in the shell prompt. For example, to set the system nickname to webserver, run the following command.

   ```bash
   [ec2-user ~]# sudo sh -c 'echo "export NICKNAME=webserver" > /etc/profile.d/prompt.sh'
   ```

2. Open the /etc/bashrc (Red Hat) or /etc/bash.bashrc (Debian/Ubuntu) file in your favorite text editor (such as vim or nano). You need to use sudo with the editor command because /etc/bashrc and /etc/bash.bashrc are owned by root.

3. Edit the file and change the shell prompt variable (PS1) to display your nickname instead of the hostname. Find the following line that sets the shell prompt in /etc/bashrc or /etc/bash.bashrc (several surrounding lines are shown below for context; look for the line that starts with [ "$PS1"):

   ```bash
   # Turn on checkwinsize
   shopt -s checkwinsize
   [ "$PS1" = "\s-\v\$ " ] && PS1="[\u@
   # You might want to have e.g. tty in prompt (e.g. more virtual machines)
   # and console windows
   \h \W\]\$ "
   # Turn on checkwinsize
   shopt -s checkwinsize
   [ "$PS1" = "\s-\v\$ " ] && PS1="[\u@NICKNAME \W]\$ "
   # You might want to have e.g. tty in prompt (e.g. more virtual machines)
   # and console windows
   ``

   Change the \h (the symbol for hostname) in that line to the value of the NICKNAME variable.

   ```bash
   # Turn on checkwinsize
   shopt -s checkwinsize
   [ "$PS1" = "\s-\v\$ " ] && PS1="[\u@NICKNAME \W]\$ "
   # You might want to have e.g. tty in prompt (e.g. more virtual machines)
   # and console windows
   ``

4. (Optional) To set the title on shell windows to the new nickname, complete the following steps.

   a. Create a file named /etc/sysconfig/bash-prompt-xterm.

   ```bash
   [ec2-user ~]# sudo touch /etc/sysconfig/bash-prompt-xterm
   ```

   b. Make the file executable using the following command.

   ```bash
   [ec2-user ~]# sudo chmod +x /etc/sysconfig/bash-prompt-xterm
   ```

   c. Open the /etc/sysconfig/bash-prompt-xterm file in your favorite text editor (such as vim or nano). You need to use sudo with the editor command because /etc/sysconfig/bash-prompt-xterm is owned by root.

   ```bash
   echo -ne "\033[033]0;@\$(USER)@\$(NICKNAME)@\$(PWD)@\$HOME/\007"
   ```

5. Log out and then log back in to pick up the new nickname value.

Change the hostname on other Linux distributions

The procedures on this page are intended for use with Amazon Linux only. For more information about other Linux distributions, see their specific documentation and the following articles:
Set up dynamic DNS on Your Amazon Linux instance

When you launch an EC2 instance, it is assigned a public IP address and a public DNS (Domain Name System) name that you can use to reach it from the internet. Because there are so many hosts in the Amazon Web Services domain, these public names must be quite long for each name to remain unique. A typical Amazon EC2 public DNS name looks something like this: ec2-12-34-56-78.us-west-2.compute.amazonaws.com, where the name consists of the Amazon Web Services domain, the service (in this case, compute), the region, and a form of the public IP address.

Dynamic DNS services provide custom DNS host names within their domain area that can be easy to remember and that can also be more relevant to your host’s use case; some of these services are also free of charge. You can use a dynamic DNS provider with Amazon EC2 and configure the instance to update the IP address associated with a public DNS name each time the instance starts. There are many different providers to choose from, and the specific details of choosing a provider and registering a name with them are outside the scope of this guide.

**Important**
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To use dynamic DNS with Amazon EC2

1. Sign up with a dynamic DNS service provider and register a public DNS name with their service. This procedure uses the free service from noip.com/free as an example.

2. Configure the dynamic DNS update client. After you have a dynamic DNS service provider and a public DNS name registered with their service, point the DNS name to the IP address for your instance. Many providers (including noip.com) allow you to do this manually from your account page on their website, but many also support software update clients. If an update client is running on your EC2 instance, your dynamic DNS record is updated each time the IP address changes, as after a shutdown and restart. In this example, you install the noip2 client, which works with the service provided by noip.com.

   a. Enable the Extra Packages for Enterprise Linux (EPEL) repository to gain access to the noip2 client.

      **Note**
      Amazon Linux instances have the GPG keys and repository information for the EPEL repository installed by default; however, Red Hat and CentOS instances must first install the epel-release package before you can enable the EPEL repository. For more information and to download the latest version of this package, see [https://fedoraproject.org/wiki/EPEL](https://fedoraproject.org/wiki/EPEL).

      - For Amazon Linux 2:

        ```bash
        ```

      - For Amazon Linux AMI:

        ```bash
        [ec2-user ~]$ sudo yum-config-manager --enable epel
        ```

     b. Install the noip package.

        ```bash
        [ec2-user ~]$ sudo yum install -y noip
        ```
c. Create the configuration file. Enter the login and password information when prompted and answer the subsequent questions to configure the client.

```
[ec2-user ~]$ sudo noip2 -C
```

3. Enable the noip service.
   - For Amazon Linux 2:
     ```
     [ec2-user ~]$ sudo systemctl enable noip.service
     ```
   - For Amazon Linux AMI:
     ```
     [ec2-user ~]$ sudo chkconfig noip on
     ```

4. Start the noip service.
   - For Amazon Linux 2:
     ```
     [ec2-user ~]$ sudo systemctl start noip.service
     ```
   - For Amazon Linux AMI:
     ```
     [ec2-user ~]$ sudo service noip start
     ```

This command starts the client, which reads the configuration file (/etc/no-ip2.conf) that you created earlier and updates the IP address for the public DNS name that you chose.

5. Verify that the update client has set the correct IP address for your dynamic DNS name. Allow a few minutes for the DNS records to update, and then try to connect to your instance using SSH with the public DNS name that you configured in this procedure.

### Run commands on your Linux instance at launch

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common automated configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: shell scripts and cloud-init directives. You can also pass this data into the launch wizard as plain text, as a file (this is useful for launching instances using the command line tools), or as base64-encoded text (for API calls).

If you are interested in more complex automation scenarios, consider using AWS CloudFormation and AWS OpsWorks. For more information, see the AWS CloudFormation User Guide and the AWS OpsWorks User Guide.

For information about running commands on your Windows instance at launch, see Run commands on your Windows instance at launch and Manage Windows instance configuration in the Amazon EC2 User Guide for Windows Instances.

In the following examples, the commands from the Install a LAMP Web Server on Amazon Linux 2 (p. 15) are converted to a shell script and a set of cloud-init directives that run when the instance launches. In each example, the following tasks are performed by the user data:

- The distribution software packages are updated.
- The necessary web server, php, and mariadb packages are installed.
- The httpd service is started and turned on via systemctl.
Run commands at launch

- The ec2-user is added to the apache group.
- The appropriate ownership and file permissions are set for the web directory and the files contained within it.
- A simple web page is created to test the web server and PHP engine.

Contents

- Prerequisites (p. 601)
- User data and shell scripts (p. 601)
- User data and the console (p. 602)
- User data and cloud-init directives (p. 603)
- User data and the AWS CLI (p. 604)

Prerequisites

The following examples assume that your instance has a public DNS name that is reachable from the internet. For more information, see Step 1: Launch an instance (p. 10). You must also configure your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see Set up to use Amazon EC2 (p. 5).

Also, these instructions are intended for use with Amazon Linux 2, and the commands and directives may not work for other Linux distributions. For more information about other distributions, such as their support for cloud-init, see their specific documentation.

User data and shell scripts

If you are familiar with shell scripting, this is the easiest and most complete way to send instructions to an instance at launch. Adding these tasks at boot time adds to the amount of time it takes to boot the instance. You should allow a few minutes of extra time for the tasks to complete before you test that the user script has finished successfully.

**Important**

By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance? in the AWS Knowledge Center.

User data shell scripts must start with the `#!` characters and the path to the interpreter you want to read the script (commonly `/bin/bash`). For a great introduction on shell scripting, see the BASH Programming HOW-TO at the Linux Documentation Project (tldp.org).

Scripts entered as user data are run as the root user, so do not use the `sudo` command in the script. Remember that any files you create will be owned by root; if you need non-root users to have file access, you should modify the permissions accordingly in the script. Also, because the script is not run interactively, you cannot include commands that require user feedback (such as `yum update` without the `-y` flag).

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to issue the API call. For more information, see Using instance profiles in the IAM User Guide. The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see IAM roles for Amazon EC2.

The cloud-init output log file (`/var/log/cloud-init-output.log`) captures console output so it is easy to debug your scripts following a launch if the instance does not behave the way you intended.
When a user data script is processed, it is copied to and run from `/var/lib/cloud/instances/instance-id/`. The script is not deleted after it is run. Be sure to delete the user data scripts from `/var/lib/cloud/instances/instance-id/` before you create an AMI from the instance. Otherwise, the script will exist in this directory on any instance launched from the AMI.

### User data and the console

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.

#### Specify instance user data at launch

Follow the procedure for launching an instance at [Launch an instance using the Launch Instance Wizard](p. 477), but when you get to the section called "Step 3: Configure Instance Details" (p. 479) in that procedure, copy your shell script in the **User data** field, and then complete the launch procedure.

In the example script below, the script creates and configures our web server.

```bash
#!/bin/bash
yum update -y
amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
yum install -y httpd mariadb-server
systemctl start httpd
systemctl enable httpd
usermod -a -G apache ec2-user
chown -R ec2-user:apache /var/www
chmod 2775 /var/www
find /var/www -type d -exec chmod 2775 {} \;
find /var/www -type f -exec chmod 0664 {} \;
```

Allow enough time for the instance to launch and run the commands in your script, and then check to see that your script has completed the tasks that you intended.

For our example, in a web browser, enter the URL of the PHP test file the script created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see [Add rules to a security group](p. 1160).

(Optional) If your script did not accomplish the tasks you were expecting it to, or if you just want to verify that your script completed without errors, examine the cloud-init output log file at `/var/log/cloud-init-output.log` and look for error messages in the output.

For additional debugging information, you can create a Mime multipart archive that includes a cloud-init data section with the following directive:

```bash
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends command output from your script to `/var/log/cloud-init-output.log`. For more information about cloud-init data formats and creating Mime multipart archive, see [cloud-init Formats](p. 1160).

#### View and update the instance user data

To update the instance user data, you must first stop the instance. If the instance is running, you can view the user data but you cannot modify it.
Warning
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

New console

To modify instance user data
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Instance state, Stop instance. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose Actions, Instance settings, Edit user data.
6. Modify the user data as needed, and then choose Save.
7. Restart the instance. The new user data is visible on your instance after you restart it; however, user data scripts are not run.

Old console

To modify instance user data
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Instance State, Stop. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose Yes, Stop. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose Actions, Instance Settings, View/Change User Data.
6. In the View/Change User Data dialog box, update the user data, and then choose Save.
7. Restart the instance. The new user data is visible on your instance after you restart it; however, user data scripts are not run.

User data and cloud-init directives
The cloud-init package configures specific aspects of a new Amazon Linux instance when it is launched; most notably, it configures the .ssh/authorized_keys file for the ec2-user so you can log in with your own private key. For more information, see cloud-init (p. 170).

The cloud-init user directives can be passed to an instance at launch the same way that a script is passed, although the syntax is different. For more information about cloud-init, go to http://cloudinit.readthedocs.org/en/latest/index.html.

Important
By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance? in the AWS Knowledge Center.

Adding these tasks at boot time adds to the amount of time it takes to boot an instance. You should allow a few minutes of extra time for the tasks to complete before you test that your user data directives have completed.
To pass cloud-init directives to an instance with user data

1. Follow the procedure for launching an instance at Launch an instance using the Launch Instance Wizard (p. 477), but when you get to the section called “Step 3: Configure Instance Details” (p. 479) in that procedure, enter your cloud-init directive text in the User data field, and then complete the launch procedure.

   In the example below, the directives create and configure a web server on Amazon Linux 2. The #cloud-config line at the top is required in order to identify the commands as cloud-init directives.

```
#cloud-config
repo_update: true
repo_upgrade: all
packages:
- httpd
- mariadb-server
runcmd:
- [ sh, -c, "amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2" ]
- systemctl start httpd
- sudo systemctl enable httpd
- [ sh, -c, "usermod -a -G apache ec2-user" ]
- [ sh, -c, "chown -R ec2-user:apache /var/www" ]
- chmod 2775 /var/www
- [ find, /var/www, -type, d, -exec, chmod, 2775, {}, \; ]
- [ find, /var/www, -type, f, -exec, chmod, 0664, {}, \; ]
```

2. Allow enough time for the instance to launch and run the directives in your user data, and then check to see that your directives have completed the tasks you intended.

   For our example, in a web browser, enter the URL of the PHP test file the directives created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

   `http://my.public.dns.amazonaws.com/phpinfo.php`

   You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see Add rules to a security group (p. 1160).

3. (Optional) If your directives did not accomplish the tasks you were expecting them to, or if you just want to verify that your directives completed without errors, examine the output log file at /var/log/cloud-init-output.log and look for error messages in the output. For additional debugging information, you can add the following line to your directives:

   ```
   output : { all : '| tee -a /var/log/cloud-init-output.log' }
   ```

   This directive sends runcmd output to /var/log/cloud-init-output.log.

User data and the AWS CLI

You can use the AWS CLI to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see Retrieve instance user data (p. 622).
On Windows, you can use the AWS Tools for Windows PowerShell instead of using the AWS CLI. For more information, see User data and the Tools for Windows PowerShell in the Amazon EC2 User Guide for Windows Instances.

**Example: Specify user data at launch**

To specify user data when you launch your instance, use the `run-instances` command with the `--user-data` parameter. With `run-instances`, the AWS CLI performs base64 encoding of the user data for you.

The following example shows how to specify a script as a string on the command line:

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 --user-data echo user data
```

The following example shows how to specify a script using a text file. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 --user-data file://my_script.txt
```

The following is an example text file with a shell script.

```bash
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

**Example: Modify the user data of a stopped instance**

You can modify the user data of a stopped instance using the `modify-instance-attribute` command. With `modify-instance-attribute`, the AWS CLI does not perform base64 encoding of the user data for you.

- On a **Linux** computer, use the `base64` command to encode the user data.

  ```
  base64 my_script.txt >my_script_base64.txt
  ```

- On a **Windows** computer, use the `certutil` command to encode the user data. Before you can use this file with the AWS CLI, you must remove the first (BEGIN CERTIFICATE) and last (END CERTIFICATE) lines.

  ```
  certutil -encode my_script.txt my_script_base64.txt 
  notepad my_script_base64.txt
  ```

Use the `--attribute` and `--value` parameters to use the encoded text file to specify the user data. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --value file:///my_script_base64.txt
```

**Example: Clear the user data of a stopped instance**

To delete the existing user data, use the `modify-instance-attribute` command as follows:
Instance metadata and user data

Example: View user data

To retrieve the user data for an instance, use the `describe-instance-attribute` command. With `describe-instance-attribute`, the AWS CLI does not perform base64 decoding of the user data for you.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData
```

The following is example output with the user data base64 encoded.

```
{
   "UserData": {
      "Value": "IyEvYmluL2Jhc2gKeXVtIHVwZGF0ZSAteQpzZXJ2aWNlIGh0dHBkIHNOYXJ0CmNoa2NvbmZpZyBodHRwZCBvbgs=",  
   "InstanceId": "i-1234567890abcdef0"
}
```

- On a Linux computer, use the `--query` option to get the encoded user data and the base64 command to decode it.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --output text --query "UserData.Value" | base64 --decode
```

- On a Windows computer, use the `--query` option to get the coded user data and the certutil command to decode it. Note that the encoded output is stored in a file and the decoded output is stored in another file.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --output text --query "UserData.Value" >my_output.txt
certutil -decode my_output.txt my_output_decoded.txt
type my_output_decoded.txt
```

The following is example output.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Instance metadata and user data

*Instance metadata* is data about your instance that you can use to configure or manage the running instance. Instance metadata is divided into categories (p. 623), for example, host name, events, and security groups.

You can also use instance metadata to access *user data* that you specified when launching your instance. For example, you can specify parameters for configuring your instance, or include a simple script. You can build generic AMIs and use user data to modify the configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same generic AMI and retrieve their content from the Amazon S3 bucket that you specify in the user data at launch. To add a new customer at any time, create a bucket for the customer, add their content, and launch your AMI with
the unique bucket name provided to your code in the user data. If you launch more than one instance at the same time, the user data is available to all instances in that reservation. Each instance that is part of the same reservation has a unique `ami-launch-index` number, allowing you to write code that controls what to do. For example, the first host might elect itself as the original node in a cluster. For a detailed AMI launch example, see Example: AMI launch index value (p. 631).

EC2 instances can also include **dynamic data**, such as an instance identity document that is generated when the instance is launched. For more information, see Dynamic data categories (p. 630).

**Important**
Although you can only access instance metadata and user data from within the instance itself, the data is not protected by authentication or cryptographic methods. Anyone who has direct access to the instance, and potentially any software running on the instance, can view its metadata. Therefore, you should not store sensitive data, such as passwords or long-lived encryption keys, as user data.

**Note**
The examples in this section use the IPv4 address of the instance metadata service: `169.254.169.254`. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: `fd00:ec2::254`. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

### Contents
- Use IMDSv2 (p. 607)
- Configure the instance metadata options (p. 611)
- Retrieve instance metadata (p. 614)
- Work with instance user data (p. 621)
- Retrieve dynamic data (p. 623)
- Instance metadata categories (p. 623)
- Example: AMI launch index value (p. 631)
- Instance identity documents (p. 634)

### Use IMDSv2
You can access instance metadata from a running instance using one of the following methods:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

By default, you can use either IMDSv1 or IMDSv2, or both. The instance metadata service distinguishes between IMDSv1 and IMDSv2 requests based on whether, for any given request, either the `PUT` or `GET` headers, which are unique to IMDSv2, are present in that request.

You can configure the instance metadata service on each instance such that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works. For more information, see Configure the instance metadata options (p. 611).

To retrieve instance metadata, see Retrieve instance metadata (p. 614).

**Note**
The examples in this section use the IPv4 address of the instance metadata service: `169.254.169.254`. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: `fd00:ec2::254`. The IPv6
address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

How Instance Metadata Service Version 2 works

IMDSv2 uses session-oriented requests. With session-oriented requests, you create a session token that defines the session duration, which can be a minimum of one second and a maximum of six hours. During the specified duration, you can use the same session token for subsequent requests. After the specified duration expires, you must create a new session token to use for future requests.

The following example uses a Linux shell script and IMDSv2 to retrieve the top-level instance metadata items. The example:

- Creates a session token lasting six hours (21,600 seconds) using the `PUT` request
- Stores the session token header in a variable named `TOKEN`
- Requests the top-level metadata items using the token

You can run two separate commands, or combine them.

**Separate commands**

First, generate a token using the following command.

```
```

Then, use the token to generate top-level metadata items using the following command.

```
```

**Combined commands**

You can store the token and combine the commands. The following example combines the above two commands and stores the session token header in a variable named `TOKEN`.

```
```

**Note**

If there is an error in creating the token, instead of a valid token, an error message is stored in the variable, and the command will not work.

```
```

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in `$TOKEN` in the previous example is reused.

```
```

When you use IMDSv2 to request instance metadata, the request must include the following:

1. Use a `PUT` request to initiate a session to the instance metadata service. The `PUT` request returns a token that must be included in subsequent `GET` requests to the instance metadata service. The token is required to access metadata using IMDSv2.
2. Include the token in all GET requests to the instance metadata service. When token usage is set to required, requests without a valid token or with an expired token receive a 401 - Unauthorized HTTP error code. For information about changing the token usage requirement, see modify-instance-metadata-options in the AWS CLI Command Reference.

- The token is an instance-specific key. The token is not valid on other EC2 instances and will be rejected if you attempt to use it outside of the instance on which it was generated.

- The PUT request must include a header that specifies the time to live (TTL) for the token, in seconds, up to a maximum of six hours (21,600 seconds). The token represents a logical session. The TTL specifies the length of time that the token is valid and, therefore, the duration of the session.

- After a token expires, to continue accessing instance metadata, you must create a new session using another PUT.

- You can choose to reuse a token or create a new token with every request. For a small number of requests, it might be easier to generate and immediately use a token each time you need to access the instance metadata service. But for efficiency, you can specify a longer duration for the token and reuse it rather than having to write a PUT request every time you need to request instance metadata. There is no practical limit on the number of concurrent tokens, each representing its own session. IMDSv2 is, however, still constrained by normal instance metadata service connection and throttling limits. For more information, see Query throttling (p. 620).

HTTP GET and HEAD methods are allowed in IMDSv2 instance metadata requests. PUT requests are rejected if they contain an X-Forwarded-For header.

By default, the response to PUT requests has a response hop limit (time to live) of 1 at the IP protocol level. You can adjust the hop limit using the modify-instance-metadata-options command if you need to make it larger. For example, you might need a larger hop limit for backward compatibility with container services running on the instance. For more information, see modify-instance-metadata-options in the AWS CLI Command Reference.

**Transition to using Instance Metadata Service Version 2**

Use of Instance Metadata Service Version 2 (IMDSv2) is optional. Instance Metadata Service Version 1 (IMDSv1) will continue to be supported indefinitely. If you choose to migrate to using IMDSv2, we recommend that you use the following tools and transition path.

**Tools for helping with the transition to IMDSv2**

If your software uses IMDSv1, use the following tools to help reconfigure your software to use IMDSv2.

- **AWS software**: The latest versions of the AWS SDKs and CLIs support IMDSv2. To use IMDSv2, make sure that your EC2 instances have the latest versions of the AWS SDKs and CLIs. For information about updating the CLI, see Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide.

- **CloudWatch**: IMDSv2 uses token-backed sessions, while IMDSv1 does not. The MetadataNoToken CloudWatch metric tracks the number of calls to the instance metadata service that are using IMDSv1. By tracking this metric to zero, you can determine if and when all of your software has been upgraded to use IMDSv2. For more information, see Instance metrics (p. 821).

- **Updates to EC2 APIs and CLIs**: For existing instances, you can use the modify-instance-metadata-options CLI command (or the ModifyInstanceMetadataOptions API) to require the use of IMDSv2. For new instances, you can use the run-instances CLI command (or the RunInstances API) and the metadata-options parameter to launch new instances that require the use of IMDSv2.

To require the use of IMDSv2 on all new instances launched by Auto Scaling groups, your Auto Scaling groups can use either a launch template or a launch configuration. When you create a launch template or create a launch configuration, you must configure the MetadataOptions parameters to require the use of IMDSv2. After you configure the launch template or launch configuration, the Auto Scaling
group launches new instances using the new launch template or launch configuration, but existing
instances are not affected.

Use the `modify-instance-metadata-options` CLI command (or the `ModifyInstanceMetadataOptions
API`) to require the use of IMDSv2 on the existing instances, or terminate the instances and the Auto
Scaling group will launch new replacement instances with the instance metadata options settings that
are defined in the launch template or launch configuration.

- **IAM policies and SCPs**: You can use an IAM condition to enforce that IAM users can't launch an
instance unless it uses IMDSv2. You can also use IAM conditions to enforce that IAM users can't modify
running instances to re-enable IMDSv1, and to enforce that the instance metadata service is available
on the instance.

The `ec2:MetadataHttpTokens`, `ec2:MetadataHttpPutResponseHopLimit`, and
`ec2:MetadataHttpEndpoint` IAM condition keys can be used to control the use of the `RunInstances`
and the `ModifyInstanceMetadataOptions` API and corresponding CLI. If a policy is created, and a
parameter in the API call does not match the state specified in the policy using the condition key, the
API or CLI call fails with an `UnauthorizedOperation` response. These condition keys can be used
either in IAM policies or AWS Organizations service control policies (SCPs).

Furthermore, you can choose an additional layer of protection to enforce the change from IMDSv1
to IMDSv2. At the access management layer with respect to the APIs called via EC2 Role credentials,
you can use a new condition key in either IAM policies or AWS Organizations service control
policies (SCPs). Specifically, by using the policy condition key `ec2:RoleDelivery` with a value of
2.0 in your IAM policies, API calls made with EC2 Role credentials obtained from IMDSv1 will
receive an `UnauthorizedOperation` response. The same thing can be achieved more broadly
with that condition required by an SCP. This ensures that credentials delivered via IMDSv1 cannot
actually be used to call APIs because any API calls not matching the specified condition will
receive an `UnauthorizedOperation` error. For example IAM policies, see Work with instance
metadata (p. 1112). For more information, see Service Control Policies in the AWS Organizations User
Guide.

**Recommended path to requiring IMDSv2 access**

Using the above tools, we recommend that you follow this path for transitioning to IMDSv2:

**Step 1: At the start**

Update the SDKs, CLIs, and your software that use Role credentials on their EC2 instances to IMDSv2-
compatible versions. For information about updating the CLI, see Upgrading to the latest version of the
AWS CLI in the AWS Command Line Interface User Guide.

Then, change your software that directly accesses instance metadata (in other words, that does not use
an SDK) using the IMDSv2 requests.

**Step 2: During the transition**

Track your transition progress by using the CloudWatch metric `MetadataNoToken`. This metric shows
the number of calls to the instance metadata service that are using IMDSv1 on your instances. For more
information, see Instance metrics (p. 821).

**Step 3: When everything is ready on all instances**

Everything is ready on all instances when the CloudWatch metric `MetadataNoToken` records zero
IMDSv1 usage. At this stage, you can do the following:

- For existing instances: You can require IMDSv2 use through the `modify-instance-metadata-options
command. You can make these changes on running instances; you do not need to restart your
instances.
 Instance metadata and user data

- For new instances: When launching a new instance, you can do one of the following:
  - In the Amazon EC2 console launch instance wizard, set Metadata accessible to Enabled and Metadata version to V2. For more information, see Step 3: Configure Instance Details (p. 479).
  - Use the run-instances command to specify that only IMDSv2 is to be used.

Updating instance metadata options for existing instances is available only through the API or AWS CLI. It is currently not available in the Amazon EC2 console. For more information, see Configure the instance metadata options (p. 611).

Step 4: When all of your instances are transitioned to IMDSv2

The ec2:MetadataHttpTokens, ec2:MetadataHttpPutResponseHopLimit, and ec2:MetadataHttpEndpoint IAM condition keys can be used to control the use of the RunInstances and the ModifyInstanceMetadataOptions API and corresponding CLI. If a policy is created, and a parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an UnauthorizedOperation response. For example IAM policies, see Work with instance metadata (p. 1112).

Configure the instance metadata options

Instance metadata options allow you to configure new or existing instances to do the following:

- Require the use of IMDSv2 when requesting instance metadata
- Specify the PUT response hop limit
- Turn off access to instance metadata

You can also use IAM condition keys in an IAM policy or SCP to do the following:

- Allow an instance to launch only if it's configured to require the use of IMDSv2
- Restrict the number of allowed hops
- Turn off access to instance metadata

**Note**

You should proceed cautiously and conduct careful testing before making any changes. Take note of the following:

- If you enforce the use of IMDSv2, applications or agents that use IMDSv1 for instance metadata access will break.
- If you turn off all access to instance metadata, applications or agents that rely on instance metadata access to function will break.
- For IMDSv2, you must use /latest/api/ token when retrieving the token.

**Topics**

- Configure instance metadata options for new instances (p. 611)
- Modify instance metadata options for existing instances (p. 613)

Configure instance metadata options for new instances

You can require the use of IMDSv2 on an instance when you launch it. You can also create an IAM policy that prevents users from launching new instances unless they require IMDSv2 on the new instance.
Console

To require the use of IMDSv2 on a new instance

- When launching a new instance in the Amazon EC2 console, select the following options on the Configure Instance Details page:
  - Under Advanced Details, for Metadata accessible, select Enabled.
  - For Metadata version, select V2 (token required).

For more information, see Step 3: Configure Instance Details (p. 479).

AWS CLI

To require the use of IMDSv2 on a new instance

The following run-instances example launches a c3.large instance with --metadata-options set to HttpTokens=required. When you specify a value for HttpTokens, you must also set HttpEndpoint to enabled. Because the secure token header is set to required for metadata retrieval requests, this opts in the instance to require using IMDSv2 when requesting instance metadata.

```bash
aws ec2 run-instances
  --image-id ami-0abcdef1234567890
  --instance-type c3.large
  ...
  --metadata-options "HttpEndpoint=enabled,HttpTokens=required"
```

To enforce the use of IMDSv2 on all new instances

To ensure that IAM users can only launch instances that require the use of IMDSv2 when requesting instance metadata, you can specify that the condition to require IMDSv2 must be met before an instance can be launched. For the example IAM policy, see Work with instance metadata (p. 1112).

Console

To turn off access to instance metadata

- To ensure that access to your instance metadata is turned off, regardless of which version of the instance metadata service you are using, launch the instance in the Amazon EC2 console with the following option selected on the Configure Instance Details page:
  - Under Advanced Details, for Metadata accessible, select Disabled.

For more information, see Step 3: Configure Instance Details (p. 479).

AWS CLI

To turn off access to instance metadata

To ensure that access to your instance metadata is turned off, regardless of which version of the instance metadata service you are using, launch the instance with --metadata-options set to HttpEndpoint=disabled. You can turn access on later by using the modify-instance-metadata-options command.

```bash
aws ec2 run-instances
  --image-id ami-0abcdef1234567890
  --instance-type c3.large
```
Modify instance metadata options for existing instances

You can require the use IMDSv2 on an existing instance. You can also change the PUT response hop limit and turn off access to instance metadata on an existing instance. You can also create an IAM policy that prevents users from modifying the instance metadata options on an existing instance.

Currently only the AWS SDK or AWS CLI support modifying the instance metadata options on existing instances. You can’t use the Amazon EC2 console for modifying instance metadata options.

To require the use of IMDSv2

You can opt in to require that IMDSv2 is used when requesting instance metadata. Use the `modify-instance-metadata-options` CLI command and set the `http-tokens` parameter to `required`. When you specify a value for `http-tokens`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-1234567898abcdef0 \
  --http-tokens required \
  --http-endpoint enabled
```

To change the PUT response hop limit

For existing instances, you can change the settings of the PUT response hop limit. Use the `modify-instance-metadata-options` CLI command and set the `http-put-response-hop-limit` parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for `http-put-response-hop-limit`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-1234567898abcdef0 \
  --http-put-response-hop-limit 3 \
  --http-endpoint enabled
```

To restore the use of IMDSv1 on an instance using IMDSv2

You can use the `modify-instance-metadata-options` CLI command with `http-tokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-1234567898abcdef0 \
  --http-tokens optional \
  --http-endpoint enabled
```

To turn off access to instance metadata

You can turn off access to your instance metadata by disabling the HTTP endpoint of the instance metadata service, regardless of which version of the instance metadata service you are using. You can reverse this change at any time by enabling the HTTP endpoint. Use the `modify-instance-metadata-options` CLI command and set the `http-endpoint` parameter to `disabled`.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-1234567898abcdef0 \
  --http-endpoint disabled
To control the use of `modify-instance-metadata-options`

To control which IAM users can modify the instance metadata options, specify a policy that prevents all users other than users with a specified role to use the `ModifyInstanceMetadataOptions` API. For the example IAM policy, see Work with instance metadata (p. 1112).

Retrieve instance metadata

Because your instance metadata is available from your running instance, you do not need to use the Amazon EC2 console or the AWS CLI. This can be helpful when you're writing scripts to run from your instance. For example, you can access the local IP address of your instance from instance metadata to manage a connection to an external application.

Instance metadata is divided into categories. For a description of each instance metadata category, see Instance metadata categories (p. 623).

To view all categories of instance metadata from within a running instance, use the following IPv4 or IPv6 URIs:

```
```

```
http://[fd00:ec2::254]/latest/meta-data/
```

The IP addresses are link-local address and are valid only from the instance. For more information, see Link-local address on Wikipedia.

**Note**
The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

The command format is different, depending on whether you use IMDSv1 or IMDSv2. By default, you can use both instance metadata services. To require the use of IMDSv2, see Use IMDSv2 (p. 607).

You can use a tool such as cURL, as shown in the following example.

**IMDSv2**

```
```

**IMDSv1**

```
```

Note that you are not billed for HTTP requests used to retrieve instance metadata and user data.

**Considerations**

To avoid problems with instance metadata retrieval, consider the following:

- The AWS SDKs use IMDSv2 calls by default. If the IMDSv2 call receives no response, the SDK retries the call and, if still unsuccessful, uses IMDSv1. This can result in a delay. In a container environment, if
the hop limit is 1, the IMDSv2 response does not return because going to the container is considered an additional network hop. To avoid the process of falling back to IMDSv1 and the resultant delay, in a container environment we recommend that you set the hop limit to 2. For more information, see Configure the instance metadata options (p. 611).

- For IMDSv2, you must use /latest/api/token when retrieving the token. Issuing PUT requests to any version-specific path, for example /2021-03-23/api/token, will result in the metadata service returning 403 Forbidden errors. This behavior is intended.

**Responses and error messages**

All instance metadata is returned as text (HTTP content type text/plain).

A request for a specific metadata resource returns the appropriate value, or a 404 - Not Found HTTP error code if the resource is not available.

A request for a general metadata resource (the URI ends with a /) returns a list of available resources, or a 404 - Not Found HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

For requests made using Instance Metadata Service Version 2, the following HTTP error codes can be returned:

- 400 - Missing or Invalid Parameters – The PUT request is not valid.
- 401 - Unauthorized – The GET request uses an invalid token. The recommended action is to generate a new token.
- 403 - Forbidden – The request is not allowed or the instance metadata service is turned off.

**Examples of retrieving instance metadata**

**Examples**

- Get the available versions of the instance metadata (p. 615)
- Get the top-level metadata items (p. 616)
- Get the list of available public keys (p. 618)
- Show the formats in which public key 0 is available (p. 618)
- Get public key 0 (in the OpenSSH key format) (p. 619)
- Get the subnet ID for an instance (p. 619)

**Get the available versions of the instance metadata**

This example gets the available versions of the instance metadata. These versions do not necessarily correlate with an Amazon EC2 API version. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

Get the list of available public keys

This example gets the list of available public keys.

IMDSv2

0=my-public-key

IMDSv1

0=my-public-key

Show the formats in which public key 0 is available

This example shows the formats in which public key 0 is available.
Get public key 0 (in the OpenSSH key format)

This example gets public key 0 (in the OpenSSH key format).

Get the subnet ID for an instance

This example gets the subnet ID for an instance.
IMDSv2

```
subnet-be9b61d7
```

IMDSv1

```
subnet-be9b61d7
```

Query throttling

We throttle queries to the instance metadata service on a per-instance basis, and we place limits on the number of simultaneous connections from an instance to the instance metadata service.

If you're using the instance metadata service to retrieve AWS security credentials, avoid querying for credentials during every transaction or concurrently from a high number of threads or processes, as this might lead to throttling. Instead, we recommend that you cache the credentials until they start approaching their expiry time.

If you are throttled while accessing the instance metadata service, retry your query with an exponential backoff strategy.

Limit instance metadata service access

You can consider using local firewall rules to disable access from some or all processes to the instance metadata service.

**Note**

For Instances built on the Nitro System (p. 199), IMDS can be reached from your own network when a network appliance within your VPC, such as a virtual router, forwards packets to the IMDS address, and the default source/destination check on the instance is disabled. To prevent a source from outside your VPC reaching IMDS, we recommend that you modify the configuration of the network appliance to drop packets with the destination IPv4 address of IMDS 169.254.169.254 and, if you enabled the IPv6 endpoint, the IPv6 address of IMDS fd00:ec2::254.

Using iptables to limit access

The following example uses Linux iptables and its `owner` module to prevent the Apache webserver (based on its default installation user ID of `apache`) from accessing 169.254.169.254. It uses a deny rule to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner --uid-owner apache --jump REJECT
```

Or, you can consider only allowing access to particular users or groups, by using allow rules. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use allow rules, it's less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with
allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.

The following example prevents access to the instance metadata service by all processes, except for processes running in the user account trustworthy-user.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner ! --uid-owner trustworthy-user --jump REJECT
```

**Note**

- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
- By default, iptables rules are not persistent across system reboots. They can be made to be persistent by using OS features, not described here.
- The iptables owner module only matches group membership if the group is the primary group of a given local user. Other groups are not matched.

### Using PF or IPFW to limit access

If you are using FreeBSD or OpenBSD, you can also consider using PF or IPFW. The following examples limit access to the instance metadata service to just the root user.

**PF**

```
$ block out inet proto tcp from any to 169.254.169.254

$ pass out inet proto tcp from any to 169.254.169.254 user root
```

**IPFW**

```
$ allow tcp from any to 169.254.169.254 uid root

$ deny tcp from any to 169.254.169.254
```

**Note**

The order of the PF and IPFW commands matter. PF defaults to last matching rule and IPFW defaults to first matching rule.

### Work with instance user data

When working with instance user data, keep the following in mind:

- User data must be base64-encoded. The Amazon EC2 console can perform the base64-encoding for you or accept base64-encoded input.
- User data is limited to 16 KB, in raw form, before it is base64-encoded. The size of a string of length $n$ after base64-encoding is ceil($n/3$)*4.
- User data must be base64-decoded when you retrieve it. If you retrieve the data using instance metadata or the console, it's decoded for you automatically.
- User data is treated as opaque data: what you give is what you get back. It is up to the instance to be able to interpret it.
• If you stop an instance, modify its user data, and start the instance, the updated user data is not run when you start the instance.

Specify instance user data at launch

You can specify user data when you launch an instance. For more information, see Launch an instance using the Launch Instance Wizard (p. 477) and Run commands on your Linux instance at launch (p. 600).

Modify instance user data

You can modify user data for an instance in the stopped state if the root volume is an EBS volume. For more information, see View and update the instance user data (p. 602).

Retrieve instance user data

Note
The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

To retrieve user data from within a running instance, use the following URI.

```
http://169.254.169.254/latest/user-data
```

A request for user data returns the data as it is (content type application/octet-stream).

This example returns user data that was provided as comma-separated text.

IMDSv2

```
1234,john,reboot,true | 4512,richard, | 173,\
```

IMDSv1

```
1234,john,reboot,true | 4512,richard, | 173,\
```

This example returns user data that was provided as a script.

IMDSv2

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```
IMDSv1

#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on

To retrieve user data for an instance from your own computer, see User data and the AWS CLI (p. 604).

Retrieve dynamic data

To retrieve dynamic data from within a running instance, use the following URI.

Note
The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

This example shows how to retrieve the high-level instance identity categories.

IMDSv2

rsa2048
pkcs7
document
signature
dsa2048

IMDSv1

rsa2048
pkcs7
document
signature
dsa2048

For more information about dynamic data and examples of how to retrieve it, see Instance identity documents (p. 634).

Instance metadata categories

Instance metadata is divided into categories. When you retrieve instance metadata, these are the top-level items.

When Amazon EC2 releases a new instance metadata category, the instance metadata for the new category might not be available for existing instances. With instances built on the Nitro system (p. 199),
you can retrieve instance metadata only for the categories that were available at launch. For instances
with the Xen hypervisor, you can stop and then start (p. 524) the instance to update the categories that
are available for the instance.

The following table lists the categories of instance metadata. Some of the category names include
placeholders for data that is unique to your instance. For example, mac represents the MAC address
for the network interface. You must replace the placeholders with actual values when you retrieve the
instance metadata.

<table>
<thead>

</table>
Example: AMI launch index value

This example demonstrates how you can use both user data and instance metadata to configure your instances.

**Note**

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

Alice wants to launch four instances of her favorite database AMI, with the first acting as the original instance and the remaining three acting as replicas. When she launches them, she wants to add user data about the replication strategy for each replica. She is aware that this data will be available to all four instances, so she needs to structure the user data in a way that allows each instance to recognize which parts are applicable to it. She can do this using the `ami-launch-index` instance metadata value, which will be unique for each instance. If she starts more than one instance at the same time, the `ami-launch-index` indicates the order in which the instances were launched. The value of the first instance launched is 0.

Here is the user data that Alice has constructed.

```
replicate-every=1min | replicate-every=5min | replicate-every=10min
```

The `replicate-every=1min` data defines the first replica's configuration, `replicate-every=5min` defines the second replica's configuration, and so on. Alice decides to provide this data as an ASCII string with a pipe symbol (`|`) delimiting the data for the separate instances.

Alice launches four instances using the `run-instances` command, specifying the user data.

```
aws ec2 run-instances
  --image-id ami-0abcdef1234567890
  --count 4
  --instance-type t2.micro
  --user-data "replicate-every=1min | replicate-every=5min | replicate-every=10min"
```

After they're launched, all instances have a copy of the user data and the common metadata shown here:

- AMI ID: ami-0abcdef1234567890
- Reservation ID: r-1234567890abcabc0
- Public keys: none
- Security group name: default
- Instance type: t2.micro

However, each instance has certain unique metadata.

Alice can use the ami-launch-index value to determine which portion of the user data is applicable to a particular instance.
1. She connects to one of the instances, and retrieves the `ami-launch-index` for that instance to ensure it is one of the replicas:

    **IMDSv2**

    ```bash
    -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"`
    ``

    For the following steps, the IMDSv2 requests use the stored token from the preceding IMDSv2 command, assuming the token has not expired.

    **IMDSv1**

    ```bash
    ``

2. She saves the `ami-launch-index` as a variable.

    **IMDSv2**

    ```bash
    [ec2-user ~]$ ami_launch_index=`curl -H "X-aws-ec2-metadata-token: $TOKEN" -v

    **IMDSv1**

    ```bash

3. She saves the user data as a variable.

    **IMDSv2**

    ```bash
    [ec2-user ~]$ user_data=`curl -H "X-aws-ec2-metadata-token: $TOKEN" -v
    http://169.254.169.254/latest/user-data``

    **IMDSv1**

    ```bash

4. Finally, Alice uses the `cut` command to extract the portion of the user data that is applicable to that instance.

    **IMDSv2**

    ```bash
    [ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index"`  
    replicate-every=5min

    **IMDSv1**

    ```bash
    [ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index"`  
    replicate-every=5min
Instance identity documents

Each instance that you launch has an instance identity document that provides information about the instance itself. You can use the instance identity document to validate the attributes of the instance.

The instance identity document is generated when the instance is launched and it is exposed (in plaintext JSON format) through the Instance Metadata Service. The IPv4 address 169.254.169.254 is a link-local address and is valid only from the instance. For more information, see Link-local address on Wikipedia. The IPv6 address fd00:ec2::254 is a unique local address and is valid only from the instance. For more information, see Unique local address on Wikipedia.

Note
The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 199).

You can retrieve the instance identity document from a running instance at any time. The instance identity document includes the following information:

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>devpayProductCodes</td>
<td>Deprecated.</td>
</tr>
<tr>
<td>marketplaceProductCodes</td>
<td>The AWS Marketplace product code of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>availabilityZone</td>
<td>The Availability Zone in which the instance is running.</td>
</tr>
<tr>
<td>privateIp</td>
<td>The private IPv4 address of the instance.</td>
</tr>
<tr>
<td>version</td>
<td>The version of the instance identity document format.</td>
</tr>
<tr>
<td>instanceId</td>
<td>The ID of the instance.</td>
</tr>
<tr>
<td>billingProducts</td>
<td>The billing product code of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>instanceType</td>
<td>The instance type of the instance.</td>
</tr>
<tr>
<td>accountId</td>
<td>The ID of the AWS account that launched the instance.</td>
</tr>
<tr>
<td>imageId</td>
<td>The ID of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>pendingTime</td>
<td>The date and time that the instance was launched.</td>
</tr>
<tr>
<td>architecture</td>
<td>The architecture of the AMI used to launch the instance (i386</td>
</tr>
<tr>
<td>kernelId</td>
<td>The ID of the kernel associated with the instance, if applicable.</td>
</tr>
<tr>
<td>ramdiskId</td>
<td>The ID of the RAM disk associated with the instance, if applicable.</td>
</tr>
<tr>
<td>region</td>
<td>The Region in which the instance is running.</td>
</tr>
</tbody>
</table>

Retrieve the plaintext instance identity document

To retrieve the plaintext instance identity document

Connect to the instance and run one of the following commands depending on the Instance Metadata Service (IMDS) version used by the instance.
Verify the instance identity document

If you intend to use the contents of the instance identity document for an important purpose, you should verify its contents and authenticity before using it.

The plaintext instance identity document is accompanied by three hashed and encrypted signatures. You can use these signatures to verify the origin and authenticity of the instance identity document and the information that it includes. The following signatures are provided:

- Base64-encoded signature—This is a base64-encoded SHA256 hash of the instance identity document that is encrypted using an RSA key pair.
- PKCS7 signature—This is a SHA1 hash of the instance identity document that is encrypted using a DSA key pair.
- RSA-2048 signature—This is a SHA256 hash of the instance identity document that is encrypted using an RSA-2048 key pair.

Each signature is available at a different endpoint in the instance metadata. You can use any one of these signatures depending on your hashing and encryption requirements. To verify the signatures, you must use the corresponding AWS public certificate.

**Important**

To validate the instance identity document using the base64-encoded signature or RSA2048 signature, you must request the corresponding AWS public certificate from [AWS Support](https://aws.amazon.com/support/).
Use the PKCS7 signature to verify the instance identity document (p. 636)
Use the base64-encoded signature to verify the instance identity document (p. 639)
Use the RSA-2048 signature to verify the instance identity document (p. 643)

Use the PKCS7 signature to verify the instance identity document

This topic explains how to verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate.

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.
2. Retrieve the PKCS7 signature from the instance metadata and add it to a new file named `pkcs7` along with the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

   **IMDSv2**
   
   ```bash
   $ echo "-----BEGIN PKCS7-----" >> pkcs7
   && echo "" >> pkcs7 
   && echo "-----END PKCS7-----" >> pkcs7
   
   **IMDSv1**
   
   ```bash
   $ echo "-----BEGIN PKCS7-----" >> pkcs7
   && echo "" >> pkcs7 
   && echo "-----END PKCS7-----" >> pkcs7
   ```

3. Add the contents of the instance identity document from the instance metadata to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

   **IMDSv2**
   
   ```bash
   
   **IMDSv1**
   
   ```bash
   ```

4. Add the AWS DSA public certificate to a new file named `certificate`. Use one of the following commands depending on the Region of your instance.

   **Other AWS Regions**
   
   The following AWS public certificate is for all AWS Regions, except Hong Kong, Bahrain, China, and GovCloud.
$ echo "-----BEGIN CERTIFICATE-----
MIIC7cCAQ4GCCQ窝k25V4a2zAJBgcqjkoOAQMDFWxCzAJBgNVBAATVMRkwFwYDVQQIEExBYXNoaW5ndquIFNOYXIRMAwgdYDQQHEwdTW0dghxkMSAwHgYD

VQQExdbdWbf6b24q2V2I1FNln2p2Yz10MQzAeFw0x02JAYMDMwMj1XJFafVw0
-----END CERTIFICATE-----" >> certificate
Cape Town Region

The AWS public certificate for the Cape Town Region is as follows.

```bash
$ echo "-----BEGIN CERTIFICATE-----
MIIC7DCCAgwCQQCCnbcCQgJyMzIwMAYGALAwM5g5/gw0AwRg4AQQIAQCB8BMAsAwHgYD
VQQEExdBWF6dB24gZ2V1IFNlcn5pZ2lvIExMQzoA5s6QzQkN/5/5HR41/Wc+N6QXoR8
8CAwCAQEEBQgCQYDQgEJH3Mxj7l5w0B+b+j8538dYmkEJKAR2ufL71p0gE1xdj/SkUc
--- END CERTIFICATE-----" > certificate
```

Milan Region

The AWS public certificate for the Milan Region is as follows.

```bash
$ echo "-----BEGIN CERTIFICATE-----
MIIC7DCCAgwCQQCCnbcCQgJyMzIwMAYGALAwM5g5/gw0AwRg4AQQIAQCB8BMAsAwHgYD
VQQEExdBWF6dB24gZ2V1IFNlcn5pZ2lvIExMQzoA5s6QzQkN/5/5HR41/Wc+N6QXoR8
8CAwCAQEEBQgCQYDQgEJH3Mxj7l5w0B+b+j8538dYmkEJKAR2ufL71p0gE1xdj/SkUc
--- END CERTIFICATE-----" > certificate
```

China Regions

The AWS public certificate for the China (Beijing) and China (Ningxia) Regions is as follows.

```bash
$ echo "-----BEGIN CERTIFICATE-----
MIDN5CCAgwCQQCCnbcCQgJyMzIwMAYGALAwM5g5/gw0AwRg4AQQIAQCB8BMAsAwHgYD
VQQEExdBWF6dB24gZ2V1IFNlcn5pZ2lvIExMQzoA5s6QzQkN/5/5HR41/Wc+N6QXoR8
8CAwCAQEEBQgCQYDQgEJH3Mxj7l5w0B+b+j8538dYmkEJKAR2ufL71p0gE1xdj/SkUc
--- END CERTIFICATE-----" > certificate
```
5. Use the OpenSSL smime command to verify the signature. Include the -verify option to indicate that the signature needs to be verified, and the -noverify option to indicate that the certificate does not need to be verified.

```bash
openssl smime -verify -in pkcs7 -inform PEM -content document -certfile certificate -noverify
```

If the signature is valid, the Verification successful message appears. If the signature cannot be verified, contact AWS Support.

Use the base64-encoded signature to verify the instance identity document

This topic explains how to verify the instance identity document using the base64-encoded signature and the AWS RSA public certificate.

To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate

1. Connect to the instance.
2. Retrieve the base64-encoded signature from the instance metadata, convert it to binary, and add it to a file named signature. Use one of the following commands depending on the IMDS version used by the instance.

```bash
<base64-encoded signature>
```

-----END CERTIFICATE-----
3. Retrieve the plaintext instance identity document from the instance metadata and add it to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```bash
```

**IMDSv1**

```bash
```

4. Add the AWS RSA public certificate to a new file named `certificate`. Use one of the following commands, depending on the Region of your instance.

**Other AWS Regions**

The following AWS public certificate is for all AWS Regions, except Hong Kong, Bahrain, China, and GovCloud.

```bash
$ echo "-----BEGIN CERTIFICATE-----

```
5. Extract the public key from the certificate that you received from AWS Support and save it to a file named key.

```
$ openssl x509 -pubkey -noout -in certificate >> key
```

6. Use OpenSSL dgst command to verify the instance identity document.

```
$ openssl dgst -sha256 -verify key -signature signature document
```

If the signature is valid, the Verified OK message appears. If the signature cannot be verified, contact AWS Support.

**Use the RSA-2048 signature to verify the instance identity document**

This topic explains how to verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate.

**To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate**

1. Connect to the instance.
2. Retrieve the RSA-2048 signature from the instance metadata and add it to a file named rsa2048 along the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```
$ echo "-----BEGIN PKCS7-----" >> rsa2048
&& echo "" >> rsa2048
&& echo "-----END PKCS7-----" >> rsa2048
```

**IMDSv1**

```
$ echo "-----BEGIN PKCS7-----" >> rsa2048
&& echo "" >> rsa2048
&& echo "-----END PKCS7-----" >> rsa2048
```

3. Add the contents of the instance identity document from the instance metadata to a file named document. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```
```
4. Add the AWS RSA-2048 public certificate for your Region to a new file named certificate. Use one of the following commands depending on the Region of your instance.

5. Use the OpenSSL `smime` command to verify the signature. Include the `-verify` option to indicate that the signature needs to be verified, and the `-noverify` option to indicate that the certificate does not need to be verified.

```bash
$ openssl smime -verify -in rsa2048 -inform PEM -content document -certfile certificate -noverify
```

If the signature is valid, the `Verification successful` message appears. If the signature cannot be verified, contact AWS Support.

---

**Amazon Elastic Inference**

Amazon Elastic Inference (EI) is a resource you can attach to your Amazon EC2 CPU instances to accelerate your deep learning (DL) inference workloads. Amazon EI accelerators come in multiple sizes and are a cost-effective method to build intelligent capabilities into applications running on Amazon EC2 instances.

Amazon EI distributes model operations defined by TensorFlow, Apache MXNet, and the Open Neural Network Exchange (ONNX) format through MXNet between low-cost, DL inference accelerators and the CPU of the instance.

For more information about Amazon Elastic Inference, see the [Amazon EI Developer Guide](https://aws.amazon.com/ei).

---

**Identify EC2 Linux instances**

Your application might need to determine whether it is running on an EC2 instance.

---

**Inspect the instance identity document**

For a definitive and cryptographically verified method of identifying an EC2 instance, check the instance identity document, including its signature. These documents are available on every EC2 instance at the local, non-routable address `http://169.254.169.254/latest/dynamic/instance-identity/`. For more information, see [Instance identity documents](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/identify-ebs-optimized-instances.html) (p. 634).

---

**Inspect the system UUID**

You can get the system UUID and look for the presence of the characters "ec2" or "EC2" in the beginning octet of the UUID. This method to determine whether a system is an EC2 instance is quick but potentially inaccurate because there is a small chance that a system that is not an EC2 instance could have a UUID that starts with these characters. Furthermore, for EC2 instances that are not using Amazon Linux 2, the distribution's implementation of SMBIOS might represent the UUID in little-endian format, therefore the "EC2" characters do not appear at the beginning of the UUID.

**Example : Get the UUID from DMI (HVM AMIs only)**

Use the following command to get the UUID using the Desktop Management Interface (DMI):

```
[ec2-user ~]$ sudo dmidecode --string system-uuid
```
In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.

```
EC2E1916-9099-7CAF-FD21-012345ABCDEF
```

In the following example output, the UUID is represented in little-endian format.

```
45E12AEC-DCD1-B213-94ED-012345ABCDEF
```

Alternatively, for instances built on the Nitro system, you can use the following command:

```
[ec2-user ~]$ cat /sys/devices/virtual/dmi/id/board_asset_tag
```

If the output is an instance ID, as the following example output, the system is an EC2 instance:

```
i-0af01c0123456789a
```

**Example: Get the UUID from the hypervisor (PV AMIs only)**

Use the following command to get the UUID from the hypervisor:

```
[ec2-user ~]$ cat /sys/hypervisor/uuid
```

In the following example output, the UUID starts with "ec2", which indicates that the system is probably an EC2 instance.

```
ec2e1916-9099-7cafe-d21-012345abcdef
```
EC2 Fleet and Spot Fleet

You can use an EC2 Fleet or a Spot Fleet to launch a fleet of instances. In a single API call, a fleet can launch multiple instance types across multiple Availability Zones, using the On-Demand Instance, Reserved Instance, and Spot Instance purchasing options together.

Topics
- EC2 Fleet (p. 656)
- Spot Fleet (p. 703)
- Monitor fleet events using Amazon EventBridge (p. 738)
- Tutorials for EC2 Fleet and Spot Fleet (p. 752)
- Example configurations for EC2 Fleet and Spot Fleet (p. 758)
- Fleet quotas (p. 783)

EC2 Fleet

An EC2 Fleet contains the configuration information to launch a fleet—or group—of instances. In a single API call, a fleet can launch multiple instance types across multiple Availability Zones, using the On-Demand Instance, Reserved Instance, and Spot Instance purchasing options together. Using EC2 Fleet, you can:

- Define separate On-Demand and Spot capacity targets and the maximum amount you’re willing to pay per hour
- Specify the instance types that work best for your applications
- Specify how Amazon EC2 should distribute your fleet capacity within each purchasing option

You can also set a maximum amount per hour that you’re willing to pay for your fleet, and EC2 Fleet launches instances until it reaches the maximum amount. When the maximum amount you’re willing to pay is reached, the fleet stops launching instances even if it hasn’t met the target capacity.

The EC2 Fleet attempts to launch the number of instances that are required to meet the target capacity specified in your request. If you specified a total maximum price per hour, it fulfills the capacity until it reaches the maximum amount that you’re willing to pay. The fleet can also attempt to maintain its target Spot capacity if your Spot Instances are interrupted. For more information, see How Spot Instances work (p. 372).
You can specify an unlimited number of instance types per EC2 Fleet. Those instance types can be provisioned using both On-Demand and Spot purchasing options. You can also specify multiple Availability Zones, specify different maximum Spot prices for each instance, and choose additional Spot options for each fleet. Amazon EC2 uses the specified options to provision capacity when the fleet launches.

While the fleet is running, if Amazon EC2 reclaims a Spot Instance because of a price increase or instance failure, EC2 Fleet can try to replace the instances with any of the instance types that you specify. This makes it easier to regain capacity during a spike in Spot pricing. You can develop a flexible and elastic resourcing strategy for each fleet. For example, within specific fleets, your primary capacity can be On-Demand supplemented with less-expensive Spot capacity if available.

If you have Reserved Instances and you specify On-Demand Instances in your fleet, EC2 Fleet uses your Reserved Instances. For example, if your fleet specifies an On-Demand Instance as c4.large, and you have Reserved Instances for c4.large, you receive the Reserved Instance pricing.

There is no additional charge for using EC2 Fleet. You pay only for the EC2 instances that the fleet launches for you.

Contents

- EC2 Fleet limitations (p. 657)
- Burstable performance instances (p. 657)
- EC2 Fleet request types (p. 658)
- EC2 Fleet configuration strategies (p. 676)
- Work with EC2 Fleets (p. 684)

EC2 Fleet limitations

The following limitations apply to EC2 Fleet:

- EC2 Fleet is available only through the API or AWS CLI.
- An EC2 Fleet request can't span AWS Regions. You need to create a separate EC2 Fleet for each Region.
- An EC2 Fleet request can't span different subnets from the same Availability Zone.

Burstable performance instances

If you launch your Spot Instances using a burstable performance instance type (p. 216), and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in Standard mode (p. 232) to avoid paying higher costs. If you launch burstable performance Spot Instances in Unlimited mode (p. 225) and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see When to use unlimited mode versus fixed CPU (p. 226).

Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use Unlimited mode (p. 225) for T2 Spot Instances, or use an instance type with dedicated CPU.
EC2 Fleet request types

There are three types of EC2 Fleet requests:

**instant**

If you configure the request type as `instant`, EC2 Fleet places a synchronous one-time request for your desired capacity. In the API response, it returns the instances that launched, along with errors for those instances that could not be launched. For more information, see Use an EC2 Fleet of type 'instant' (p. 658).

**request**

If you configure the request type as `request`, EC2 Fleet places an asynchronous one-time request for your desired capacity. Thereafter, if capacity is diminished because of Spot interruptions, the fleet does not attempt to replenish Spot Instances, nor does it submit requests in alternative Spot capacity pools if capacity is unavailable.

**maintain**

(Default) If you configure the request type as `maintain`, EC2 Fleet places an asynchronous request for your desired capacity, and maintains capacity by automatically replenishing any interrupted Spot Instances.

All three types of requests benefit from an allocation strategy. For more information, see Allocation strategies for Spot Instances (p. 677).

Use an EC2 Fleet of type 'instant'

The EC2 Fleet of type `instant` is a synchronous one-time request that makes only one attempt to launch your desired capacity. The API response lists the instances that launched, along with errors for those instances that could not be launched. There are several benefits to using an EC2 Fleet of type `instant`, which are described in this article. Example configurations are provided at the end of the article.

For workloads that need a launch-only API to launch EC2 instances, you can use the RunInstances API. However, with RunInstances, you can only launch On-Demand Instances or Spot Instances, but not both in the same request. Furthermore, when you use RunInstances to launch Spot Instances, your Spot Instance request is limited to one instance type and one Availability Zone. This targets a single Spot capacity pool (a set of unused instances with the same instance type and Availability Zone). If the Spot capacity pool does not have sufficient Spot Instance capacity for your request, the RunInstances call fails.

Instead of using RunInstances to launch Spot Instances, we recommend that you rather use the CreateFleet API with the `type` parameter set to `instant` for the following benefits:

- **Launch On-Demand Instances and Spot Instances in one request.** An EC2 Fleet can launch On-Demand Instances, Spot Instances, or both. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price.

- **Increase the availability of Spot Instances.** By using an EC2 Fleet of type `instant`, you can launch Spot Instances following Spot best practices with the resulting benefits:
  - **Spot best practice: Be flexible about instance types and Availability Zones.**
  
  Benefit: By specifying several instance types and Availability Zones, you increase the number of Spot capacity pools. This gives the Spot service a better chance of finding and allocating your desired Spot compute capacity. A good rule of thumb is to be flexible across at least 10 instance types for each workload and make sure that all Availability Zones are configured for use in your VPC.

  - **Spot best practice: Use the capacity-optimized allocation strategy.**
Benefit: The capacity-optimized allocation strategy automatically provisions instances from the most-available Spot capacity pools. Because your Spot instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances will be interrupted when Amazon EC2 needs the capacity back.

- **Get access to a wider set of capabilities.** For workloads that need a launch-only API, and where you prefer to manage the lifecycle of your instance rather than let EC2 Fleet manage it for you, use the EC2 Fleet of type `instant` instead of the `RunInstances` API. EC2 Fleet provides a wider set of capabilities than RunInstances, as demonstrated in the following examples. For all other workloads, you should use Amazon EC2 Auto Scaling because it supplies a more comprehensive feature set for a wide variety of workloads, like ELB-backed applications, containerized workloads, and queue processing jobs.

AWS services like Amazon EC2 Auto Scaling and Amazon EMR use EC2 Fleet of type `instant` to launch EC2 instances.

**Prerequisites for EC2 Fleet of type instant**

For the prerequisites for creating an EC2 Fleet, see [EC2 Fleet prerequisites](p. 685).

**How instant EC2 Fleet works**

When working with an EC2 Fleet of type `instant`, the sequence of events is as follows:

1. Configure the `CreateFleet` request type as `instant`. For more information, see [Create an EC2 Fleet](p. 693). Note that after you make the API call, you can't modify it.
2. When you make the API call, EC2 Fleet places a synchronous one-time request for your desired capacity.
3. The API response lists the instances that launched, along with errors for those instances that could not be launched.
4. You can describe your EC2 Fleet, list the instances associated with your EC2 Fleet, and view the history of your EC2 Fleet.
5. After your instances have launched, you can delete the fleet request. When deleting the fleet request, you can also choose to terminate the associated instances, or leave them running.
6. You can terminate the instances at any time.

**Examples**

The following examples show how to use EC2 Fleet of type `instant` for different use cases. For more information about using the EC2 CreateFleet API parameters, see [CreateFleet](p. 693) in the Amazon EC2 API Reference.

**Examples**

- **Example 1:** Launch Spot Instances with the capacity-optimized allocation strategy (p. 660)
- **Example 2:** Launch a single Spot Instance with the capacity-optimized allocation strategy (p. 661)
- **Example 3:** Launch Spot Instances using instance weighting (p. 662)
- **Example 4:** Launch Spot Instances within single Availability zone (p. 664)
- **Example 5:** Launch Spot Instances of single instance type within single Availability zone (p. 665)
- **Example 6:** Launch Spot Instances only if minimum target capacity can be launched (p. 666)
- **Example 7:** Launch Spot Instances only if minimum target capacity can be launched of same Instance Type in a single Availability Zone (p. 668)
- **Example 8:** Launch instances with multiple Launch Templates (p. 669)
- **Example 9:** Launch Spot Instance with a base of On-Demand Instances (p. 671)
Example 1: Launch Spot Instances with the capacity-optimized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type `instant`:

- The launch template is identified by its launch template name and version number.
- The 12 launch template overrides specify 4 different instance types and 3 different subnets, each in a separate Availability Zone. Each instance type and subnet combination defines a Spot capacity pool, resulting in 12 Spot capacity pools.
- The target capacity for the fleet is 20 instances.
- The default purchasing option is `spot`, which results in the fleet attempting to launch 20 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateName": "ec2-fleet-lt1",
            "Version": "$Latest"
        },
        {
            "InstanceType": "c5.large",
            "SubnetId": "subnet-fae8c380"
        },
        {
            "InstanceType": "c5.large",
            "SubnetId": "subnet-e7188bab"
        },
        {
            "InstanceType": "c5.large",
            "SubnetId": "subnet-49e41922"
        },
        {
            "InstanceType": "c5d.large",
            "SubnetId": "subnet-fae8c380"
        },
        {
            "InstanceType": "c5d.large",
            "SubnetId": "subnet-e7188bab"
        },
        {
            "InstanceType": "c5d.large",
            "SubnetId": "subnet-49e41922"
        },
        {
            "InstanceType": "m5.large",
            "SubnetId": "subnet-fae8c380"
        },
        {
            "InstanceType": "m5.large",
            "SubnetId": "subnet-e7188bab"
        }
    ]
}
```
Example 2: Launch a single Spot Instance with the capacity-optimized allocation strategy

You can optimally launch one Spot Instance at a time by making multiple EC2 Fleet API calls of type instant, by setting the TotalTargetCapacity to 1.

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch template overrides have 4 different instance types and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 1 instance, and the default purchasing option is spot, which results in the fleet attempting to launch a Spot Instance from one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy, to launch a Spot Instance from the most-available capacity pool.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "ec2-fleet-lt1",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c5.large",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "c5.large",
                    "SubnetId": "subnet-e7188bab"
                },

                    "SubnetId": "subnet-49e41922"
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 1,
        "DefaultTargetCapacityType": "spot"
    }
}
```
Example 3: Launch Spot Instances using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight based on how many units of the workload can run on the instance assuming a unit of the workload requires a 15 GB of memory and 4 vCPUs. For example an m5.xlarge (4 vCPUs and 16 GB of memory) can run one unit and is weighted 1, m5.2xlarge (8 vCPUs and 32 GB of memory) can run 2 units and is weighted 2, and so on. The total target capacity is set to 40 units. The default purchasing option is spot, and the allocation strategy is capacity-optimized, which results in either 40 m5.xlarge (40 divided by 1), 20 m5.2xlarge (40 divided by 2), 10 m5.4xlarge (40 divided by 4), 5 m5.8xlarge (40 divided by 8), or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

For more information, see EC2 Fleet instance weighting (p. 682).

Example 4: Launch Spot Instances within single Availability zone

You can configure a fleet to launch all instances in a single Availability Zone by setting the Spot options SingleAvailabilityZone to true.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity is 20 instances, the default purchasing option is spot, and the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances all in a single AZ, from the Spot capacity pool(s) with optimal capacity using the launch specifications.

```json
{
  "SpotOptions": {
    "AllocationStrategy": "capacity-optimized",
    "SingleAvailabilityZone": true
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "ec2-fleet-lt1",
        "Version": "$Latest"
      },
      "Overrides": [
        {
          "InstanceType": "c5.4xlarge",
          "SubnetId": "subnet-fae8c380"
        },
        {
          "InstanceType": "c5.4xlarge",
          "SubnetId": "subnet-e7188bab"
        },
        {
          "InstanceType": "c5.4xlarge",
          "SubnetId": "subnet-49e41922"
        },
        {
          "InstanceType": "c5d.4xlarge",
          "SubnetId": "subnet-fae8c380"
        },
        {
          "InstanceType": "c5d.4xlarge",
          "SubnetId": "subnet-e7188bab"
        },
        {
          "InstanceType": "c5d.4xlarge",
          "SubnetId": "subnet-49e41922"
        },
        {
          "InstanceType": "m5.4xlarge",
          "SubnetId": "subnet-fae8c380"
        }
      ]
    }
  ]
}
```
Example 5: Launch Spot Instances of single instance type within single Availability zone

You can configure a fleet to launch all instances of the same instance type and in a single Availability Zone by setting the SpotOptions SingleInstanceType to true and SingleAvailabilityZone to true.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity is 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances of the same instance type all in a single AZ from the Spot Instance pool with optimal capacity using the launch specifications.
Example 6: Launch Spot Instances only if minimum target capacity can be launched

You can configure a fleet to launch instances only if the minimum target capacity can be launched by setting the Spot options MinTargetCapacity to the minimum target capacity you want to launch together.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity and the minimum target capacity are both set to 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances from the Spot capacity pool with optimal capacity using the launch template overrides, only if it can launch all 20 instances at the same time.

```json
{
    "SpotOptions": {
        "MinTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    }
}
```
"AllocationStrategy": "capacity-optimized",
"MinTargetCapacity": 20,

Example 7: Launch Spot Instances only if minimum target capacity can be launched of same Instance Type in a single Availability Zone

You can configure a fleet to launch instances only if the minimum target capacity can be launched with a single instance type in a single Availability Zone by setting the Spot options MinTargetCapacity to the minimum target capacity you want to launch together along with SingleInstanceType and SingleAvailabilityZone options.

The 12 launch specifications which override the launch template, have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity and the minimum target capacity are both set to 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized, the SingleInstanceType is true and SingleAvailabilityZone is true. The EC2 Fleet launches 20 Spot Instances of the same Instance type all in a single AZ from the Spot capacity pool with optimal capacity using the launch specifications, only if it can launch all 20 instances at the same time.

```json
{
   "SpotOptions": {
      "AllocationStrategy": "capacity-optimized",
      "SingleInstanceType": true,
      "SingleAvailabilityZone": true,
      "MinTargetCapacity": 20
   },
   "LaunchTemplateConfigs": [
      {
         "LaunchTemplateName": "ec2-fleet-lt1",
         "Version": "$Latest"
      },
      {
         "Overrides": [
            {
               "InstanceType": "c5.4xlarge",
               "SubnetId": "subnet-fae8c380"
            },
            {
               "InstanceType": "c5.4xlarge",

               "InstanceType": "m5.4xlarge",
               "SubnetId": "subnet-e7188bab"
            }
      ]
   }
}
```
Example 8: Launch instances with multiple Launch Templates

You can configure a fleet to launch instances with different launch specifications for different instance types or a group of instance types, by specifying multiple launch templates. In this example we want different EBS volume sizes for different instance types and we have that configured in the launch templates ec2-fleet-lt-4xl, ec2-fleet-lt-9xl and ec2-fleet-lt-18xl.

In this example, we are using 3 different launch templates for the 3 instance types based on their size. The launch specification overrides on all the launch templates use instance weights based on the vCPUs on the instance type. The total target capacity is 144 units, the default purchasing option is spot, and the Spot allocation strategy is capacity-optimized. The EC2 Fleet can either launch 9 c5n.4xlarge (144 divided by 16) using the launch template ec2-fleet-lt-4xl or 4 c5n.9xlarge (144 divided by 36) using the launch template ec2-fleet-lt-9xl or 2 c5n.18xlarge (144 divided by 72) using the launch template ec2-fleet-lt-18xl, or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

Example 9: Launch Spot Instance with a base of On-Demand Instances

The following example specifies the total target capacity of 20 instances for the fleet, and a target capacity of 5 On-Demand Instances. The default purchasing option is spot. The fleet launches 5 On-Demand Instance as specified, but needs to launch 15 more instances to fulfill the total target capacity. The purchasing option for the difference is calculated as TotalTargetCapacity – OnDemandTargetCapacity = DefaultTargetCapacityType, which results in the fleet launching 15 Spot Instances form one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy.

                }
            ]
        }
    ]
}
```
Example 10: Launch Spot Instances using capacity-optimized allocation strategy with a base of On-Demand Instances using Capacity Reservations and the prioritized allocation strategy

You can configure a fleet to use On-Demand Capacity Reservations first when launching a base of On-Demand Instances with the default target capacity type as spot by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if multiple instance pools have unused Capacity Reservations, the chosen On-Demand allocation strategy is applied. In this example, the On-Demand allocation strategy is prioritized.

In this example, there are 6 available unused Capacity Reservations. This is less than the fleet's target On-Demand capacity of 10 On-Demand Instances.

The account has the following 6 unused Capacity Reservations in 2 pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is prioritized, and the usage strategy for Capacity Reservations is use-capacity-reservations-first. The Spot allocation strategy is capacity-optimized. The total target capacity is 20, the On-Demand target capacity is 10, and the default target capacity type is spot.

After you create the instant fleet using the preceding configuration, the following 20 instances are launched to meet the target capacity:

- 7 c5.large On-Demand Instances in us-east-1a – c5.large in us-east-1a is prioritized first, and there are 3 available unused c5.large Capacity Reservations. The Capacity Reservations are used first to launch 3 On-Demand Instances plus 4 additional On-Demand Instances are launched according to the On-Demand allocation strategy, which is prioritized in this example.
- 3 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is prioritized second, and there are 3 available unused c5.large Capacity Reservations.
- 10 Spot Instances from one of the 12 Spot capacity pools that has the optimal capacity according to the capacity-optimized-prioritized allocation strategy.

After the fleet is launched, you can run `describe-capacity-reservations` to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the c5.large and m5.large Capacity Reservations were used.

```

```

```

```

Example 11: Launch Spot Instances using capacity-optimized-prioritized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch specifications which override the launch template have 4 different instance types with a priority assigned, and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 20 instances, and the default purchasing option is spot, which results in the fleet attempting to launch 20 Spot Instances from one of the 12 Spot capacity pools based on the capacity-optimized-prioritized allocation strategy, which implements priorities on a best-effort basis, but optimizes for capacity first.

EC2 Fleet configuration strategies

An EC2 Fleet is a group of On-Demand Instances and Spot Instances.

The EC2 Fleet attempts to launch the number of instances that are required to meet the target capacity that you specify in the fleet request. The fleet can comprise only On-Demand Instances, only Spot Instances, or a combination of both On-Demand Instances and Spot Instances. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price. The fleet also attempts to maintain its target capacity if your Spot Instances are interrupted.

You can also set a maximum amount per hour that you’re willing to pay for your fleet, and EC2 Fleet launches instances until it reaches the maximum amount. When the maximum amount you’re willing to pay is reached, the fleet stops launching instances even if it hasn’t met the target capacity.

A Spot capacity pool is a set of unused EC2 instances with the same instance type and Availability Zone. When you create an EC2 Fleet, you can include multiple launch specifications, which vary by instance type, Availability Zone, subnet, and maximum price. The fleet selects the Spot capacity pools that are used to fulfill the request, based on the launch specifications included in your request, and the configuration of the request. The Spot Instances come from the selected pools.

An EC2 Fleet enables you to provision large amounts of EC2 capacity that makes sense for your application based on number of cores or instances, or amount of memory. For example, you can specify an EC2 Fleet to launch a target capacity of 200 instances, of which 130 are On-Demand Instances and the rest are Spot Instances.

Use the appropriate configuration strategies to create an EC2 Fleet that meets your needs.

Contents

- Plan an EC2 Fleet (p. 676)
- Allocation strategies for Spot Instances (p. 677)
- Configure EC2 Fleet for On-Demand backup (p. 679)
- Capacity Rebalancing (p. 680)
- Maximum price overrides (p. 682)
- Control spending (p. 682)
- EC2 Fleet instance weighting (p. 682)

Plan an EC2 Fleet

When planning your EC2 Fleet, we recommend that you do the following:

- Determine whether you want to create an EC2 Fleet that submits a synchronous or asynchronous one-time request for the desired target capacity, or one that maintains a target capacity over time. For more information, see EC2 Fleet request types (p. 658).
EC2 Fleet configuration strategies

- Determine the instance types that meet your application requirements.
- If you plan to include Spot Instances in your EC2 Fleet, review Spot Best Practices before you create the fleet. Use these best practices when you plan your fleet so that you can provision the instances at the lowest possible price.
- Determine the target capacity for your EC2 Fleet. You can set target capacity in instances or in custom units. For more information, see EC2 Fleet instance weighting (p. 682).
- Determine what portion of the EC2 Fleet target capacity must be On-Demand capacity and Spot capacity. You can specify 0 for On-Demand capacity or Spot capacity, or both.
- Determine your price per unit, if you are using instance weighting. To calculate the price per unit, divide the price per instance hour by the number of units (or weight) that this instance represents. If you are not using instance weighting, the default price per unit is the price per instance hour.
- Determine the maximum amount per hour that you’re willing to pay for your fleet. For more information, see Control spending (p. 682).
- Review the possible options for your EC2 Fleet. For more information, see the EC2 Fleet JSON configuration file reference (p. 690). For EC2 Fleet configuration examples, see EC2 Fleet example configurations (p. 758).

Allocation strategies for Spot Instances

The allocation strategy for your EC2 Fleet determines how it fulfills your request for Spot Instances from the possible Spot capacity pools represented by its launch specifications. The following are the allocation strategies that you can specify in your fleet:

lowest-price

The Spot Instances come from the Spot capacity pool with the lowest price. This is the default strategy.

diversified

The Spot Instances are distributed across all Spot capacity pools.

capacity-optimized

The Spot Instances come from the Spot capacity pool with optimal capacity for the number of instances that are launching. You can optionally set a priority for each instance type in your fleet using capacity-optimized-prioritized. EC2 Fleet optimizes for capacity first, but honors instance type priorities on a best-effort basis.

With Spot Instances, pricing changes slowly over time based on long-term trends in supply and demand, but capacity fluctuates in real time. The capacity-optimized strategy automatically launches Spot Instances into the most available pools by looking at real-time capacity data and predicting which are the most available. This works well for workloads such as big data and analytics, image and media rendering, machine learning, and high performance computing that may have a higher cost of interruption associated with restarting work and checkpointing. By offering the possibility of fewer interruptions, the capacity-optimized strategy can lower the overall cost of your workload.

Alternatively, you can use the capacity-optimized-prioritized allocation strategy with a priority parameter to order instance types from highest to lowest priority. You can set the same priority for different instance types. EC2 Fleet will optimize for capacity first, but will honor instance type priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect EC2 Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters. Using priorities is supported only if your fleet uses a launch template. Note that when you set the priority for capacity-optimized-prioritized, the same priority is also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized.
InstancePoolsToUseCount

The Spot Instances are distributed across the number of Spot capacity pools that you specify. This parameter is valid only when used in combination with lowest-price.

Maintaining target capacity

After Spot Instances are terminated due to a change in the Spot price or available capacity of a Spot capacity pool, an EC2 Fleet of type maintain launches replacement Spot Instances. If the allocation strategy is lowest-price, the fleet launches replacement instances in the pool where the Spot price is currently the lowest. If the allocation strategy is lowest-price in combination with InstancePoolsToUseCount, the fleet selects the Spot capacity pools with the lowest price and launches Spot Instances across the number of Spot capacity pools that you specify. If the allocation strategy is capacity-optimized, the fleet launches replacement instances in the pool that has the most available Spot Instance capacity. If the allocation strategy is diversified, the fleet distributes the replacement Spot Instances across the remaining pools.

Choose the appropriate allocation strategy

You can optimize your fleet based on your use case.

If your fleet runs workloads that may have a higher cost of interruption associated with restarting work and checkpointing, then use the capacity-optimized strategy. This strategy offers the possibility of fewer interruptions, which can lower the overall cost of your workload. Use the capacity-optimized-prioritized strategy for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

If your fleet is small or runs for a short time, the probability that your Spot Instances will be interrupted is low, even with all of the instances in a single Spot capacity pool. Therefore, the lowest-price strategy is likely to meet your needs while providing the lowest cost.

If your fleet is large or runs for a long time, you can improve the availability of your fleet by distributing the Spot Instances across multiple pools using the diversified strategy. For example, if your EC2 Fleet specifies 10 pools and a target capacity of 100 instances, the fleet launches 10 Spot Instances in each pool. If the Spot price for one pool exceeds your maximum price for this pool, only 10% of your fleet is affected. Using this strategy also makes your fleet less sensitive to increases in the Spot price in any one pool over time. With the diversified strategy, the EC2 Fleet does not launch Spot Instances into any pools with a Spot price that is equal to or higher than the On-Demand price.

To create a cheap and diversified fleet, use the lowest-price strategy in combination with InstancePoolsToUseCount. You can use a low or high number of Spot capacity pools across which to allocate your Spot Instances. For example, if you run batch processing, we recommend specifying a low number of Spot capacity pools (for example, InstancePoolsToUseCount=2) to ensure that your queue always has compute capacity while maximizing savings. If you run a web service, we recommend specifying a high number of Spot capacity pools (for example, InstancePoolsToUseCount=10) to minimize the impact if a Spot capacity pool becomes temporarily unavailable.

Configure EC2 Fleet for cost optimization

To optimize the costs for your use of Spot Instances, specify the lowest-price allocation strategy so that EC2 Fleet automatically deploys the least expensive combination of instance types and Availability Zones based on the current Spot price.

For On-Demand Instance target capacity, EC2 Fleet always selects the cheapest instance type based on the public On-Demand price, while continuing to follow the allocation strategy (either lowest-price, capacity-optimized, or diversified) for Spot Instances.
Configure EC2 Fleet for cost optimization and diversification

To create a fleet of Spot Instances that is both cheap and diversified, use the lowest-price allocation strategy in combination with InstancePoolsToUseCount. EC2 Fleet automatically deploys the least expensive combination of instance types and Availability Zones based on the current Spot price across the number of Spot capacity pools that you specify. This combination can be used to avoid the most expensive Spot Instances.

For example, if your target capacity is 10 Spot Instances, and you specify 2 Spot capacity pools (for InstancePoolsToUseCount), EC2 Fleet will draw on the two cheapest pools to fulfill your Spot capacity.

Note that EC2 Fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, EC2 Fleet will continue to fulfill your request by drawing from the next cheapest pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.

Configure EC2 Fleet for capacity optimization

To launch Spot Instances into the most-available Spot capacity pools, use the capacity-optimized allocation strategy. For an example configuration, see Example 10: Launch Spot Instances in a capacity-optimized fleet (p. 771).

You can also express your pool priorities by using the capacity-optimized-prioritized allocation strategy and then setting the order of instance types to use from highest to lowest priority. Using priorities is supported only if your fleet uses a launch template. Note that when you set priorities for capacity-optimized-prioritized, the same priorities are also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized. For an example configuration, see Example 11: Launch Spot Instances in a capacity-optimized fleet with priorities (p. 771).

Configure EC2 Fleet for On-Demand backup

If you have urgent, unpredictable scaling needs, such as a news website that must scale during a major news event or game launch, we recommend that you specify alternative instance types for your On-Demand Instances, in the event that your preferred option does not have sufficient available capacity. For example, you might prefer c5.2xlarge On-Demand Instances, but if there is insufficient available capacity, you’d be willing to use some c4.2xlarge instances during peak load. In this case, EC2 Fleet attempts to fulfill all of your target capacity using c5.2xlarge instances, but if there is insufficient capacity, it automatically launches c4.2xlarge instances to fulfill the target capacity.

Prioritize instance types for On-Demand capacity

When EC2 Fleet attempts to fulfill your On-Demand capacity, it defaults to launching the lowest-priced instance type first. If AllocationStrategy is set to prioritized, EC2 Fleet uses priority to determine which instance type to use first in fulfilling On-Demand capacity. The priority is assigned to the launch template override, and the highest priority is launched first.

For example, you have configured three launch template overrides, each with a different instance type: c3.large, c4.large, and c5.large. The On-Demand price for c5.large is less than the price for c4.large. c3.large is the cheapest. If you do not use priority to determine the order, the fleet fulfills On-Demand capacity by starting with c3.large, and then c5.large. Because you often have unused Reserved Instances for c4.large, you can set the launch template override priority so that the order is c4.large, c3.large, and then c5.large.
Use Capacity Reservations for On-Demand Instances

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. You can use this setting in conjunction with the allocation strategy for On-Demand Instances (lowest-price or prioritized).

When unused Capacity Reservations are used to fulfil On-Demand capacity:

- The fleet uses unused Capacity Reservations to fulfill On-Demand capacity up to the target On-Demand capacity.
- If multiple instance pools have unused Capacity Reservations, the On-Demand allocation strategy (lowest-price or prioritized) is applied.
- If the number of unused Capacity Reservations is less than the On-Demand target capacity, the remaining On-Demand target capacity is launched according to the On-Demand allocation strategy (lowest-price or prioritized).

You can only use unused On-Demand Capacity Reservations for fleets of type instant.

For examples of how to configure a fleet to use Capacity Reservations to fulfil On-Demand capacity, see EC2 Fleet example configurations (p. 758). For more information, see On-Demand Capacity Reservations (p. 451) and the On-Demand Capacity Reservation FAQs.

Capacity Rebalancing

You can configure EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation to notify you that a Spot Instance is at an elevated risk of interruption. Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance is interrupted by Amazon EC2. For more information, see EC2 instance rebalance recommendations (p. 399).

To configure EC2 Fleet to launch a replacement Spot Instance, use the create-fleet (AWS CLI) command and the relevant parameters in the MaintenanceStrategies structure. For more information, see the example launch configuration (p. 770).

Limitations

- Only available for fleets of type maintain.
- When the fleet is running, you can't modify the Capacity Rebalancing setting. To change the Capacity Rebalancing setting, you must delete the fleet and create a new fleet.

Considerations

If you configure an EC2 Fleet for Capacity Rebalancing, consider the following:

**EC2 Fleet can launch new replacement Spot Instances until fulfilled capacity is double target capacity**

When an EC2 Fleet is configured for Capacity Rebalancing, the fleet attempts to launch a new replacement Spot Instance for every Spot Instance that receives a rebalance recommendation. After a Spot Instance receives a rebalance recommendation, it is no longer counted as part of the fulfilled capacity, and EC2 Fleet does not automatically terminate the instance. This gives you the opportunity to perform rebalancing actions (p. 400) on the instance. Thereafter, you can terminate the instance, or you can leave it running.

If your fleet reaches double its target capacity, it stops launching new replacement instances even if the replacement instances themselves receive a rebalance recommendation.
For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. All the Spot Instances receive a rebalance recommendation, which causes EC2 Fleet to launch 100 replacement Spot Instances. This raises the number of fulfilled Spot Instances to 200, which is double the target capacity. Some of the replacement instances receive a rebalance recommendation, but no more replacement instances are launched because the fleet cannot exceed double its target capacity.

Note that you are charged for all of the instances while they are running.

**We recommend that you manually terminate Spot Instances that receive a rebalance recommendation**

If you configure your EC2 Fleet for Capacity Rebalancing, we recommend that you monitor the rebalance recommendation signal that is received by the Spot Instances in the fleet. By monitoring the signal, you can quickly perform rebalancing actions (p. 400) on the affected instances before Amazon EC2 interrupts them, and then you can manually terminate them. If you do not terminate the instances, you continue paying for them while they are running. EC2 Fleet does not automatically terminate the instances that receive a rebalance recommendation.

You can set up notifications using Amazon EventBridge or instance metadata. For more information, see Monitor rebalance recommendation signals (p. 400).

**EC2 Fleet does not count instances that receive a rebalance recommendation when calculating fulfilled capacity during scale in or out**

If your EC2 Fleet is configured for Capacity Rebalancing, and you change the target capacity to either scale in or scale out, the fleet does not count the instances that are marked for rebalance as part of the fulfilled capacity, as follows:

- **Scale in** – If you decrease your desired target capacity, the fleet terminates instances that are not marked for rebalance until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

  For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then reduce the target capacity to 50 (scale in), but the fulfilled capacity is actually 60 instances because the 10 instances that are marked for rebalance are not terminated by the fleet. You need to manually terminate these instances, or you can leave them running.

- **Scale out** – If you increase your desired target capacity, the fleet launches new instances until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

  For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then increase the target capacity to 200 (scale out), but the fulfilled capacity is actually 210 instances because the 10 instances that are marked for rebalance are not counted by the fleet as part of the target capacity. You need to manually terminate these instances, or you can leave them running.

**Provide as many Spot capacity pools in the request as possible**

Configure your EC2 Fleet to use multiple instance types and Availability Zones. This provides the flexibility to launch Spot Instances in various Spot capacity pools. For more information, see Be flexible about instance types and Availability Zones (p. 371).

**Configure your EC2 Fleet to use the most optimal Spot capacity pools**

Use the capacity-optimized allocation strategy to ensure that replacement Spot Instances are launched in the most optimal Spot capacity pools. For more information, see Use the capacity optimized allocation strategy (p. 371).
Maximum price overrides

Each EC2 Fleet can either include a global maximum price, or use the default (the On-Demand price). The fleet uses this as the default maximum price for each of its launch specifications.

You can optionally specify a maximum price in one or more launch specifications. This price is specific to the launch specification. If a launch specification includes a specific price, the EC2 Fleet uses this maximum price, overriding the global maximum price. Any other launch specifications that do not include a specific maximum price still use the global maximum price.

Control spending

EC2 Fleet stops launching instances when it has met one of the following parameters: the TotalTargetCapacity or the MaxTotalPrice (the maximum amount you're willing to pay). To control the amount you pay per hour for your fleet, you can specify the MaxTotalPrice. When the maximum total price is reached, EC2 Fleet stops launching instances even if it hasn't met the target capacity.

The following examples show two different scenarios. In the first, EC2 Fleet stops launching instances when it has met the target capacity. In the second, EC2 Fleet stops launching instances when it has reached the maximum amount you're willing to pay (MaxTotalPrice).

Example: Stop launching instances when target capacity is reached

Given a request for m4.large On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- OnDemandTargetCapacity: 10
- MaxTotalPrice: $1.50

EC2 Fleet launches 10 On-Demand Instances because the total of $1.00 (10 instances x $0.10) does not exceed the MaxTotalPrice of $1.50 for On-Demand Instances.

Example: Stop launching instances when maximum total price is reached

Given a request for m4.large On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- OnDemandTargetCapacity: 10
- MaxTotalPrice: $0.80

If EC2 Fleet launches the On-Demand target capacity (10 On-Demand Instances), the total cost per hour would be $1.00. This is more than the amount ($0.80) specified for MaxTotalPrice for On-Demand Instances. To prevent spending more than you're willing to pay, EC2 Fleet launches only 8 On-Demand Instances (below the On-Demand target capacity) because launching more would exceed the MaxTotalPrice for On-Demand Instances.

EC2 Fleet instance weighting

When you create an EC2 Fleet, you can define the capacity units that each instance type would contribute to your application's performance. You can then adjust your maximum price for each launch specification by using instance weighting.

By default, the price that you specify is per instance hour. When you use the instance weighting feature, the price that you specify is per unit hour. You can calculate your price per unit hour by dividing your price for an instance type by the number of units that it represents. EC2 Fleet calculates the number of instances to launch by dividing the target capacity by the instance weight. If the result isn't an integer,
the fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity. The fleet can select any pool that you specify in your launch specification, even if the capacity of the instances launched exceeds the requested target capacity.

The following table includes examples of calculations to determine the price per unit for an EC2 Fleet with a target capacity of 10.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance weight</th>
<th>Target capacity</th>
<th>Number of instances launched</th>
<th>Price per instance hour</th>
<th>Price per unit hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.xlarge</td>
<td>2</td>
<td>10</td>
<td>5</td>
<td>$0.05</td>
<td>$0.025</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(10 divided by 2)</td>
<td></td>
<td>(.05 divided by 2)</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>8</td>
<td>10</td>
<td>2</td>
<td>$0.10</td>
<td>$0.0125</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(10 divided by 8, result rounded up)</td>
<td></td>
<td>(.10 divided by 8)</td>
</tr>
</tbody>
</table>

Use EC2 Fleet instance weighting as follows to provision the target capacity that you want in the pools with the lowest price per unit at the time of fulfillment:

1. Set the target capacity for your EC2 Fleet either in instances (the default) or in the units of your choice, such as virtual CPUs, memory, storage, or throughput.
2. Set the price per unit.
3. For each launch specification, specify the weight, which is the number of units that the instance type represents toward the target capacity.

**Instance weighting example**

Consider an EC2 Fleet request with the following configuration:

- A target capacity of 24
- A launch specification with an instance type `r3.2xlarge` and a weight of 6
- A launch specification with an instance type `c3.xlarge` and a weight of 5

The weights represent the number of units that instance type represents toward the target capacity. If the first launch specification provides the lowest price per unit (price for `r3.2xlarge` per instance hour divided by 6), the EC2 Fleet would launch four of these instances (24 divided by 6).

If the second launch specification provides the lowest price per unit (price for `c3.xlarge` per instance hour divided by 5), the EC2 Fleet would launch five of these instances (24 divided by 5, result rounded up).

**Instance weighting and allocation strategy**

Consider an EC2 Fleet request with the following configuration:

- A target capacity of 30 Spot Instances
- A launch specification with an instance type `c3.2xlarge` and a weight of 8
- A launch specification with an instance type `m3.xlarge` and a weight of 8
- A launch specification with an instance type `r3.xlarge` and a weight of 8
The EC2 Fleet would launch four instances (30 divided by 8, result rounded up). With the lowest-price strategy, all four instances come from the pool that provides the lowest price per unit. With the diversified strategy, the fleet launches one instance in each of the three pools, and the fourth instance in whichever of the three pools provides the lowest price per unit.

**Work with EC2 Fleets**

To start using an EC2 Fleet, you create a request that includes the total target capacity, On-Demand capacity, Spot capacity, one or more launch specifications for the instances, and the maximum price that you are willing to pay. The fleet request must include a launch template that defines the information that the fleet needs to launch an instance, such as an AMI, instance type, subnet or Availability Zone, and one or more security groups. You can specify launch specification overrides for the instance type, subnet, Availability Zone, and maximum price you're willing to pay, and you can assign weighted capacity to each launch specification override.

If your fleet includes Spot Instances, Amazon EC2 can attempt to maintain your fleet target capacity as Spot prices change.

An EC2 Fleet request of type maintain or request remains active until it expires or you delete it. When you delete a fleet of type maintain or request, you can specify whether deletion terminates the instances in that fleet.

**Contents**

- EC2 Fleet request states (p. 684)
- EC2 Fleet prerequisites (p. 685)
- EC2 Fleet health checks (p. 688)
- Generate an EC2 Fleet JSON configuration file (p. 688)
- Create an EC2 Fleet (p. 693)
- Tag an EC2 Fleet (p. 695)
- Monitor your EC2 Fleet (p. 697)
- Modify an EC2 Fleet (p. 698)
- Delete an EC2 Fleet (p. 699)

**EC2 Fleet request states**

An EC2 Fleet request can be in one of the following states:

**submitted**

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances. The request can include On-Demand Instances, Spot Instances, or both.

**active**

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances. The request remains in this state until it is modified or deleted.

**modifying**

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed or the request is deleted. Only a maintain fleet type can be modified. This state does not apply to other request types.

**deleted_running**

The EC2 Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated manually. The request remains in this state
until all instances are interrupted or terminated. Only an EC2 Fleet of type maintain or request can have running instances after the EC2 Fleet request is deleted. A deleted instant fleet with running instances is not supported. This state does not apply to instant fleets.

**deleted**

The EC2 Fleet is deleted and has no running instances. The request is deleted two days after its instances are terminated.

The following illustration represents the transitions between the EC2 Fleet request states. If you exceed your fleet limits, the request is deleted immediately.

---

**EC2 Fleet prerequisites**

**To create an EC2 Fleet, the following prerequisites must be in place:**

- Launch template (p. 685)
- Service-linked role for EC2 Fleet (p. 685)
- Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots (p. 686)
- Permissions for EC2 Fleet IAM users (p. 687)

**Launch template**

A launch template includes information about the instances to launch, such as the instance type, Availability Zone, and the maximum price that you are willing to pay. For more information, see Launch an instance from a launch template (p. 483).

**Service-linked role for EC2 Fleet**

The AWSServiceRoleForEC2Fleet role grants the EC2 Fleet permission to request, launch, terminate, and tag instances on your behalf. Amazon EC2 uses this service-linked role to complete the following actions:
• `ec2:RunInstances` – Launch instances.
• `ec2:RequestSpotInstances` – Request Spot Instances.
• `ec2:TerminateInstances` – Terminate instances.
• `ec2:DescribeImages` – Describe Amazon Machine Images (AMIs) for the Spot Instances.
• `ec2:DescribeInstanceStatus` – Describe the status of the Spot Instances.
• `ec2:DescribeSubnets` – Describe the subnets for Spot Instances.
• `ec2:CreateTags` – Add tags to the EC2 Fleet, instances, and volumes.

Ensure that this role exists before you use the AWS CLI or an API to create an EC2 Fleet.

**Note**
An instant EC2 Fleet does not require this role.

To create the role, use the IAM console as follows.

**To create the AWSServiceRoleForEC2Fleet role for EC2 Fleet**

2. In the navigation pane, choose Roles, and then choose Create role.
3. For Select type of trusted entity, choose AWS service.
4. For Choose the service that will use this role, choose EC2 - Fleet, and then choose Next: Permissions, Next: Tags, and Next: Review.
5. On the Review page, choose Create role.

If you no longer need to use EC2 Fleet, we recommend that you delete the AWSServiceRoleForEC2Fleet role. After this role is deleted from your account, you can create the role again if you create another fleet.

For more information, see Using service-linked roles in the IAM User Guide.

**Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots**

If you specify an encrypted AMI (p. 156) or an encrypted Amazon EBS snapshot (p. 1335) in your EC2 Fleet and you use an AWS KMS key for encryption, you must grant the AWSServiceRoleForEC2Fleet role permission to use the customer managed key so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using grants and Using key policies in AWS KMS in the AWS Key Management Service Developer Guide.

**To grant the AWSServiceRoleForEC2Fleet role permissions to use the customer managed key**

1. Use the create-grant command to add a grant to the customer managed key and to specify the principal (the AWSServiceRoleForEC2Fleet service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the key-id parameter and the ARN of the customer managed key. The principal is specified by the grantee-principal parameter and the ARN of the AWSServiceRoleForEC2Fleet service-linked role.

```
aws kms create-grant \
    --region us-east-1 \
    --key-id arn:aws:kms:us-east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
    --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2Fleet \
    --operations "Decrypt" "Encrypt" "GenerateDataKey" "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom" "ReEncryptTo"
```

686
Permissions for EC2 Fleet IAM users

If your IAM users will create or manage an EC2 Fleet, be sure to grant them the required permissions as follows.

To grant an IAM user permissions for EC2 Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Create policy page, choose the JSON tab, replace the text with the following, and choose Review policy.

```json
{"Version": "2012-10-17",
 "Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ec2:*"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": [
      "iam:ListRoles",
      "iam:PassRole",
      "iam:ListInstanceProfiles"
    ],
    "Resource": "*"
  }
]
}
```

The `ec2:*` grants an IAM user permission to call all Amazon EC2 API actions. To limit the user to specific Amazon EC2 API actions, specify those actions instead.

An IAM user must have permission to call the `iam:ListRoles` action to enumerate existing IAM roles, the `iam:PassRole` action to specify the EC2 Fleet role, and the `iam:ListInstanceProfiles` action to enumerate existing instance profiles.

(Optional) To enable an IAM user to create roles or instance profiles using the IAM console, you must also add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
- `iam:AttachRolePolicy`
- `iam:CreateInstanceProfile`
- `iam:CreateRole`
- `iam:GetRole`
- `iam:ListPolicies`

5. On the Review policy page, enter a policy name and description, and choose Create policy.
6. In the navigation pane, choose Users and select the user.
7. On the Permissions tab, choose Add permissions.
8. Choose Attach existing policies directly. Select the policy that you created earlier and choose Next: Review.
9. Choose **Add permissions**.

### EC2 Fleet health checks

EC2 Fleet checks the health status of the instances in the fleet every two minutes. The health status of an instance is either healthy or unhealthy.

EC2 Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as unhealthy when the status of either the instance status check or the system status check is impaired for three consecutive health status checks. For more information, see [Status checks for your instances (p. 788)](https://docs.aws.amazon.com/en_us EC2 Fleet health checks)

You can configure your fleet to replace unhealthy Spot Instances. After setting `ReplaceUnhealthyInstances` to `true`, a Spot Instance is replaced when it is reported as unhealthy. The fleet can go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

**Requirements**

- Health check replacement is supported only for EC2 Fleets that maintain a target capacity (fleets of type `maintain`), and not for fleets of type `request` or `instant`.
- Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.
- You can configure your EC2 Fleet to replace unhealthy instances only when you create it.
- IAM users can use health check replacement only if they have permission to call the `ec2:DescribeInstanceStatus` action.

**To configure an EC2 Fleet to replace unhealthy Spot Instances**

1. Follow the steps for creating an EC2 Fleet. For more information, see [Create an EC2 Fleet (p. 693)](https://docs.aws.amazon.com/en_us EC2 Fleet health checks)

2. To configure the fleet to replace unhealthy Spot Instances, in the JSON file, for `ReplaceUnhealthyInstances`, enter `true`.

### Generate an EC2 Fleet JSON configuration file

To create an EC2 Fleet, you need only specify the launch template, total target capacity, and whether the default purchasing option is On-Demand or Spot. If you do not specify a parameter, the fleet uses the default value. To view the full list of fleet configuration parameters, you can generate a JSON file as follows.

**To generate a JSON file with all possible EC2 Fleet parameters using the command line**

- Use the `create-fleet` (AWS CLI) command and the `--generate-cli-skeleton` parameter to generate an EC2 Fleet JSON file:

```
aws ec2 create-fleet \  
  --generate-cli-skeleton
```

The following EC2 Fleet parameters are available:

```json
{
  "DryRun": true,
  "ClientToken": "",
```

---

688
"SpotOptions": {  "AllocationStrategy": "lowest-price",  "InstanceInterruptionBehavior": "hibernate",  "InstancePoolsToUseCount": 0,  "SingleInstanceType": true,  "SingleAvailabilityZone": true,  "MaxTotalPrice": 0,  "MinTargetCapacity": 0},  "OnDemandOptions": {  "AllocationStrategy": "prioritized",  "SingleInstanceType": true,  "SingleAvailabilityZone": true,  "MaxTotalPrice": 0,  "MinTargetCapacity": 0},  "ExcessCapacityTerminationPolicy": "termination",  "LaunchTemplateConfigs": [  {  "LaunchTemplateSpecification": {  "LaunchTemplateId": "",  "LaunchTemplateName": "",  "Version": ""  },  "Overrides": [  {  "InstanceType": "t2.micro",  "MaxPrice": "",  "SubnetId": "",  "AvailabilityZone": "",  "WeightedCapacity": null,  "Priority": null,  "Placement": {  "AvailabilityZone": "",  "Affinity": "",  "GroupName": "",  "PartitionNumber": 0,  "HostId": "",  "Tenancy": "dedicated",  "SpreadDomain": ""  }  }  ]  }  ],  "TargetCapacitySpecification": {  "TotalTargetCapacity": 0,  "OnDemandTargetCapacity": 0,  "SpotTargetCapacity": 0,  "DefaultTargetCapacityType": "spot"  },  "TerminateInstancesWithExpiration": true,  "Type": "maintain",  "ValidFrom": "1970-01-01T00:00:00",  "ValidUntil": "1970-01-01T00:00:00",  "ReplaceUnhealthyInstances": true,  "TagSpecifications": [  {  "ResourceType": "fleet",  "Tags": [  {  "Key": "",  "Value": ""  }  ]  }  ]  }
EC2 Fleet JSON configuration file reference

**Note**
Use lowercase for all parameter values; otherwise, you get an error when Amazon EC2 uses the JSON file to launch the EC2 Fleet.

**AllocationStrategy (for SpotOptions)**

(Optional) Indicates how to allocate the Spot Instance target capacity across the Spot capacity pools specified by the EC2 Fleet. Valid values are `lowest-price`, `diversified`, `capacity-optimized`, `capacity-optimized-prioritized`. The default is `lowest-price`. Specify the allocation strategy that meets your needs. For more information, see Allocation strategies for Spot Instances (p. 677).

**InstanceInterruptionBehavior**

(Optional) The behavior when a Spot Instance is interrupted. Valid values are `hibernate`, `stop`, and `terminate`. By default, the Spot service terminates Spot Instances when they are interrupted. If the fleet type is `maintain`, you can specify that the Spot service hibernates or stops Spot Instances when they are interrupted.

**InstancePoolsToUseCount**

The number of Spot capacity pools across which to allocate your target Spot capacity. Valid only when Spot AllocationStrategy is set to `lowest-price`. EC2 Fleet selects the cheapest Spot capacity pools and evenly allocates your target Spot capacity across the number of Spot capacity pools that you specify.

**SingleInstanceType**

Indicates that the fleet uses a single instance type to launch all Spot Instances in the fleet.

**SingleAvailabilityZone**

Indicates that the fleet launches all Spot Instances into a single Availability Zone.

**MaxTotalPrice**

The maximum amount per hour for Spot Instances that you're willing to pay.

**MinTargetCapacity**

The minimum target capacity for Spot Instances in the fleet. If the minimum target capacity is not reached, the fleet launches no instances.

**AllocationStrategy (for OnDemandOptions)**

The order of the launch template overrides to use in fulfilling On-Demand capacity. If you specify `lowest-price`, EC2 Fleet uses price to determine the order, launching the lowest price first. If you specify `prioritized`, EC2 Fleet uses the priority that you assigned to each launch template override, launching the highest priority first. If you do not specify a value, EC2 Fleet defaults to `lowest-price`.

**SingleInstanceType**

Indicates that the fleet uses a single instance type to launch all On-Demand Instances in the fleet.

**SingleAvailabilityZone**

Indicates that the fleet launches all On-Demand Instances into a single Availability Zone.

**MaxTotalPrice**

The maximum amount per hour for On-Demand Instances that you're willing to pay.
MinTargetCapacity

The minimum target capacity for On-Demand Instances in the fleet. If the minimum target capacity is not reached, the fleet launches no instances.

ExcessCapacityTerminationPolicy

(Optional) Indicates whether running instances should be terminated if the total target capacity of the EC2 Fleet is decreased below the current size of the EC2 Fleet. Valid values are no-termination and termination.

LaunchTemplateId

The ID of the launch template to use. You must specify either the launch template ID or launch template name. The launch template must specify an Amazon Machine Image (AMI). For information about creating launch templates, see Launch an instance from a launch template (p. 483).

LaunchTemplateName

The name of the launch template to use. You must specify either the launch template ID or launch template name. The launch template must specify an Amazon Machine Image (AMI). For more information, see Launch an instance from a launch template (p. 483).

Version

The launch template version number, $Latest, or $Default. You must specify a value, otherwise the request fails. If the value is $Latest, Amazon EC2 uses the latest version of the launch template. If the value is $Default, Amazon EC2 uses the default version of the launch template. For more information, see Modify a launch template (manage launch template versions) (p. 490).

InstanceType

(Optional) The instance type. If entered, this value overrides the launch template. The instance types must have the minimum hardware specifications that you need (vCPUs, memory, or storage).

MaxPrice

(Optional) The maximum price per unit hour that you are willing to pay for a Spot Instance. If entered, this value overrides the launch template. You can use the default maximum price (the On-Demand price) or specify the maximum price that you are willing to pay. Your Spot Instances are not launched if your maximum price is lower than the Spot price for the instance types that you specified.

SubnetId

(Optional) The ID of the subnet in which to launch the instances. If entered, this value overrides the launch template.

To create a new VPC, go the Amazon VPC console. When you are done, return to the JSON file and enter the new subnet ID.

AvailabilityZone

(Optional) The Availability Zone in which to launch the instances. The default is to let AWS choose the zones for your instances. If you prefer, you can specify specific zones. If entered, this value overrides the launch template.

Specify one or more Availability Zones. If you have more than one subnet in a zone, specify the appropriate subnet. To add subnets, go to the Amazon VPC console. When you are done, return to the JSON file and enter the new subnet ID.

WeightedCapacity

(Optional) The number of units provided by the specified instance type. If entered, this value overrides the launch template.
Priority

The priority for the launch template override. The highest priority is launched first.

If the On-Demand AllocationStrategy is set to prioritized, EC2 Fleet uses priority to determine which launch template override to use first in fulfilling On-Demand capacity.

If the Spot AllocationStrategy is set to capacity-optimized-prioritized, EC2 Fleet uses priority on a best-effort basis to determine which launch template override to use first in fulfilling Spot capacity, but optimizes for capacity first.

Valid values are whole numbers starting at 0. The lower the number, the higher the priority. If no number is set, the launch template override has the lowest priority. You can set the same priority for different launch template overrides.

TotalTargetCapacity

The number of instances to launch. You can choose instances or performance characteristics that are important to your application workload, such as vCPUs, memory, or storage. If the request type is maintain, you can specify a target capacity of 0 and add capacity later.

OnDemandTargetCapacity

(Optional) The number of On-Demand Instances to launch. This number must be less than the TotalTargetCapacity.

SpotTargetCapacity

(Optional) The number of Spot Instances to launch. This number must be less than the TotalTargetCapacity.

DefaultTargetCapacityType

If the value for TotalTargetCapacity is higher than the combined values for OnDemandTargetCapacity and SpotTargetCapacity, the difference is launched as the instance purchasing option specified here. Valid values are on-demand or spot.

TerminateInstancesWithExpiration

(Optional) By default, Amazon EC2 terminates your instances when the EC2 Fleet request expires. The default value is true. To keep them running after your request expires, do not enter a value for this parameter.

Type

(Optional) The type of request. Valid values are instant, request, and maintain. The default value is maintain.

• instant – The EC2 Fleet submits a synchronous one-time request for your desired capacity, and returns errors for any instances that could not be launched.
• request – The EC2 Fleet submits an asynchronous one-time request for your desired capacity, but does submit Spot requests in alternative Spot capacity pools if Spot capacity is unavailable, and does not maintain Spot capacity if Spot Instances are interrupted.
• maintain – The EC2 Fleet submits an asynchronous request for your desired capacity, and continues to maintain your desired Spot capacity by replenishing interrupted Spot Instances.

For more information, see EC2 Fleet request types (p. 658).

ValidFrom

(Optional) To create a request that is valid only during a specific time period, enter a start date.

ValidUntil

(Optional) To create a request that is valid only during a specific time period, enter an end date.
ReplaceUnhealthyInstances

(Optional) To replace unhealthy instances in an EC2 Fleet that is configured to maintain the fleet, enter true. Otherwise, leave this parameter empty.

TagSpecifications

(Optional) The key-value pair for tagging the EC2 Fleet request on creation. The value for ResourceType must be fleet, otherwise the fleet request fails. To tag instances at launch, specify the tags in the launch template (p. 485). For information about tagging after launch, see Tag your resources (p. 1463).

Create an EC2 Fleet

When you create an EC2 Fleet, you must specify a launch template that includes information about the instances to launch, such as the instance type, Availability Zone, and the maximum price you are willing to pay.

You can create an EC2 Fleet that includes multiple launch specifications that override the launch template. The launch specifications can vary by instance type, Availability Zone, subnet, and maximum price, and can include a different weighted capacity.

When you create an EC2 Fleet, use a JSON file to specify information about the instances to launch. For more information, see EC2 Fleet JSON configuration file reference (p. 690).

EC2 Fleets can only be created using the AWS CLI.

To create an EC2 Fleet (AWS CLI)

• Use the create-fleet (AWS CLI) command to create an EC2 Fleet.

```bash
aws ec2 create-fleet \
--cli-input-json file://file_name.json
```

For example configuration files, see EC2 Fleet example configurations (p. 758).

The following is example output for a fleet of type request or maintain.

```json
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE"
}
```

The following is example output for a fleet of type instant that launched the target capacity.

```json
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [],
  "Instances": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a"
        }
      }
    }
  ]
}
```
The following is example output for a fleet of type `instant` that launched part of the target capacity with errors for instances that were not launched.

```
{
    "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
    "Errors": [
    {
        "LaunchTemplateAndOverrides": {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
                "Version": "1"
            },
            "Overrides": {
                "InstanceType": "c4.xlarge",
                "AvailabilityZone": "us-east-1a"
            },
            "Lifecycle": "on-demand",
            "InstanceIds": [
                "i-5678901234abcdef0",
                "i-5432109876abcdef9"
            ],
            "InstanceType": "c4.xlarge",
            "Platform": null
        },
        "Lifecycle": "on-demand",
        "InstanceIds": [
            "i-1234567890abcdef0",
            "i-9876543210abcdef9"
        ],
        "InstanceType": "c5.large",
        "Platform": null
    },
    {
        "LaunchTemplateAndOverrides": {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
                "Version": "1"
            },
            "Overrides": {
                "InstanceType": "c4.large",
                "AvailabilityZone": "us-east-1a"
            },
            "Lifecycle": "on-demand",
            "InstanceIds": [
                "i-5678901234abcdef0",
                "i-5432109876abcdef9"
            ],
            "InstanceType": "c4.large",
            "Platform": null
        },
        "Lifecycle": "on-demand",
        "InstanceIds": [
            "i-1234567890abcdef0",
            "i-9876543210abcdef9"
        ],
        "InstanceType": "c5.large",
        "Platform": null
    }
}
```

The following is example output for a fleet of type `instant` that launched no instances.

```
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c4.xlarge",
          "AvailabilityZone": "us-east-1a",
        },
        "Lifecycle": "on-demand",
        "ErrorCode": "InsufficientCapacity",
        "ErrorMessage": "",
        "InstanceType": "c4.xlarge",
        "Platform": null
      },
    },
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a",
        },
        "Lifecycle": "on-demand",
        "ErrorCode": "InsufficientCapacity",
        "ErrorMessage": "",
        "InstanceType": "c5.large",
        "Platform": null
      },
    },
  ],
  "Instances": []
}
```

### Tag an EC2 Fleet

To help categorize and manage your EC2 Fleet requests, you can tag them with custom metadata. You can assign a tag to an EC2 Fleet request when you create it, or afterward.
When you tag a fleet request, the instances and volumes that are launched by the fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the fleet. You can choose to assign tags to only the fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all three.

**Note**
For instant fleet types, you can tag volumes that are attached to On-Demand Instances and Spot Instances. For request or maintain fleet types, you can only tag volumes that are attached to On-Demand Instances.

For more information about how tags work, see Tag your Amazon EC2 resources (p. 1462).

**Prerequisite**
Grant the IAM user the permission to tag resources. For more information, see Example: Tag resources (p. 1108).

**To grant an IAM user the permission to tag resources**
Create a IAM policy that includes the following:

- The ec2:CreateTags action. This grants the IAM user permission to create tags.
- The ec2:CreateFleet action. This grants the IAM user permission to create an EC2 Fleet request.
- For Resource, we recommend that you specify "*". This allows users to tag all resource types.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TagEC2FleetRequest",
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags",
        "ec2:CreateFleet"
      ],
      "Resource": "*"
    }
  ]
}
```

**Important**
We currently do not support resource-level permissions for the create-fleet resource. If you specify create-fleet as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how not to set the policy.

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateTags",
    "ec2:CreateFleet"
  ],
}
```

**To tag a new EC2 Fleet request**
To tag an EC2 Fleet request when you create it, specify the key-value pair in the JSON file (p. 688) used to create the fleet. The value for ResourceType must be fleet. If you specify another value, the fleet request fails.

**To tag instances and volumes launched by an EC2 Fleet**
To tag instances and volumes when they are launched by the fleet, specify the tags in the launch template (p. 485) that is referenced in the EC2 Fleet request.

**Note**
You can't tag volumes attached to Spot Instances that are launched by a request or maintain fleet type.

**To tag an existing EC2 Fleet request, instance, and volume (AWS CLI)**

Use the `create-tags` command to tag existing resources.

```bash
aws ec2 create-tags
  --resources fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE i-1234567890abcdef0 vol-1234567890EXAMPLE
  --tags Key=purpose,Value=test
```

**Monitor your EC2 Fleet**

The EC2 Fleet launches On-Demand Instances when there is available capacity, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available. The On-Demand Instances run until you terminate them, and the Spot Instances run until they are interrupted or you terminate them.

The returned list of running instances is refreshed periodically and might be out of date.

**To monitor your EC2 Fleet (AWS CLI)**

Use the `describe-fleets` command to describe your EC2 Fleets.

```bash
aws ec2 describe-fleets
```

The following is example output.

```json
{
  "Fleets": [
    {
      "Type": "maintain",
      "FulfilledCapacity": 2.0,
      "LaunchTemplateConfigs": [
        {
          "LaunchTemplateSpecification": {
            "Version": "2",
            "LaunchTemplateId": "lt-07b3bc7625cdab851"
          }
        }
      ],
      "TerminateInstancesWithExpiration": false,
      "TargetCapacitySpecification": {
        "OnDemandTargetCapacity": 0,
        "SpotTargetCapacity": 2,
        "TotalTargetCapacity": 2,
        "DefaultTargetCapacityType": "spot"
      },
      "FulfilledOnDemandCapacity": 0.0,
      "ActivityStatus": "fulfilled",
      "FleetId": "fleet-76e13e99-01ef-4bd6-ba9b-9208de883e7f",
      "ReplaceUnhealthyInstances": false,
      "SpotOptions": {
        "InstanceInterruptionBehavior": "terminate",
        "InstancePoolsToUseCount": 1,
        "AllocationStrategy": "lowest-price"
      }
    }
  ]
}
```
Use the `describe-fleet-instances` command to describe the instances for the specified EC2 Fleet.

```bash
aws ec2 describe-fleet-instances \
  --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

```json
{
  "ActiveInstances": [
    {
      "InstanceId": "i-0cd595998cb3765e",
      "InstanceHealth": "healthy",
      "InstanceType": "m4.large",
      "SpotInstanceRequestId": "sir-86k84j6p"
    },
    {
      "InstanceId": "i-0cf95167ca219f17",
      "InstanceHealth": "healthy",

    }
  ],
  "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE"
}
```

Use the `describe-fleet-history` command to describe the history for the specified EC2 Fleet for the specified time.

```bash
aws ec2 describe-fleet-history --fleet-request-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE --start-time 2018-04-10T00:00:00Z
```

```json
{
  "HistoryRecords": [],
  "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
  "LastEvaluatedTime": "1970-01-01T00:00:00.000Z",
  "StartTime": "2018-04-09T23:53:20.000Z"
}
```

### Modify an EC2 Fleet

You can modify an EC2 Fleet that is in the submitted or active state. When you modify a fleet, it enters the modifying state.

You can only modify an EC2 Fleet that is of type `maintain`. You cannot modify an EC2 Fleet of type request or instant.

You can modify the following parameters of an EC2 Fleet:

- **target-capacity-specification** – Increase or decrease the target capacity for `TotalTargetCapacity`, `OnDemandTargetCapacity`, and `SpotTargetCapacity`.
- **excess-capacity-termination-policy** – Whether running instances should be terminated if the total target capacity of the EC2 Fleet is decreased below the current size of the fleet. Valid values are `no-termination` and `termination`.
When you increase the target capacity, the EC2 Fleet launches the additional instances according to the instance purchasing option specified for DefaultTargetCapacityType, which are either On-Demand Instances or Spot Instances.

If the DefaultTargetCapacityType is spot, the EC2 Fleet launches the additional Spot Instances according to its allocation strategy. If the allocation strategy is lowest-price, the fleet launches the instances from the lowest-priced Spot capacity pool in the request. If the allocation strategy is diversified, the fleet distributes the instances across the pools in the request.

When you decrease the target capacity, the EC2 Fleet deletes any open requests that exceed the new target capacity. You can request that the fleet terminate instances until the size of the fleet reaches the new target capacity. If the allocation strategy is lowest-price, the fleet terminates the instances with the highest price per unit. If the allocation strategy is diversified, the fleet terminates instances across the pools. Alternatively, you can request that EC2 Fleet keep the fleet at its current size, but not replace any Spot Instances that are interrupted or any instances that you terminate manually.

When an EC2 Fleet terminates a Spot Instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

To modify an EC2 Fleet (AWS CLI)

Use the modify-fleet command to update the target capacity of the specified EC2 Fleet.

```bash
aws ec2 modify-fleet \
--fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
--target-capacity-specification TotalTargetCapacity=20
```

If you are decreasing the target capacity but want to keep the fleet at its current size, you can modify the previous command as follows.

```bash
aws ec2 modify-fleet \
--fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
--target-capacity-specification TotalTargetCapacity=10 \
--excess-capacity-termination-policy no-termination
```

Delete an EC2 Fleet

If you no longer require an EC2 Fleet, you can delete it. After you delete a fleet, it launches no new instances.

When you delete an EC2 Fleet, you must specify if you want to also terminate its instances. If you specify that the instances must be terminated when the fleet is deleted, it enters the deleted_terminating state. Otherwise, it enters the deleted_running state, and the instances continue to run until they are interrupted or you terminate them manually.

Restrictions

- You can delete up to 25 instant fleets in a single request. If you exceed this number, no instant fleets are deleted and an error is returned. There is no restriction on the number of fleets of type maintain or request that can be deleted in a single request.
- Up to 1000 instances can be terminated in a single request to delete instant fleets.

To delete an EC2 Fleet and terminate its instances (AWS CLI)

Use the delete-fleets command and the --terminate-instances parameter to delete the specified EC2 Fleet and terminate the instances.
aws ec2 delete-fleets \
  --fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --terminate-instances

The following is example output.

```
{
  "UnsuccessfulFleetDeletions": [],
  "SuccessfulFleetDeletions": [
    {
      "CurrentFleetState": "deleted_terminating",
      "PreviousFleetState": "active",
      "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE"
    }
  ]
}
```

**To delete an EC2 Fleet without terminating the instances (AWS CLI)**

You can modify the previous command using the `--no-terminate-instances` parameter to delete the specified EC2 Fleet without terminating the instances.

**Note**

`--no-terminate-instances` is not supported for instant fleets.

aws ec2 delete-fleets \
  --fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --no-terminate-instances

The following is example output.

```
{
  "UnsuccessfulFleetDeletions": [],
  "SuccessfulFleetDeletions": [
    {
      "CurrentFleetState": "deleted_running",
      "PreviousFleetState": "active",
      "FleetId": "fleet-4b8aaae8-dfb5-436d-a4c6-3dafa4c6b7dcEXAMPLE"
    }
  ]
}
```

**Troubleshoot when a fleet fails to delete**

If an EC2 Fleet fails to delete, `UnsuccessfulFleetDeletions` in the output returns the ID of the EC2 Fleet, an error code, and an error message.

The error codes are:

- ExceededInstantFleetNumForDeletion
- fleetIdDoesNotExist
- fleetIdMalformed
- fleetNotInDeletableState
- NoTerminateInstancesNotSupported
- UnauthorizedOperation
- unexpectedError
Troubleshooting ExceededInstantFleetNumForDeletion

If you try to delete more than 25 instant fleets in a single request, the ExceededInstantFleetNumForDeletion error is returned. The following is example output for this error.

```json
{
    "UnsuccessfulFleetDeletions": [
        {
            "FleetId": "fleet-5d130460-0c26-bfd9-2c32-0100a098f625",
            "Error": {
                "Message": "Can't delete more than 25 instant fleets in a single request.",
                "Code": "ExceededInstantFleetNumForDeletion"
            }
        },
        {
            "FleetId": "fleet-9a941b23-0286-5bf4-2430-03a029a07e31",
            "Error": {
                "Message": "Can't delete more than 25 instant fleets in a single request.",
                "Code": "ExceededInstantFleetNumForDeletion"
            }
        }
    ],
    "SuccessfulFleetDeletions": []
}
```

Troubleshoot NoTerminateInstancesNotSupported

If you specify that the instances in an instant fleet must not be terminated when you delete the fleet, the NoTerminateInstancesNotSupported error is returned. --no-terminate-instances is not supported for instant fleets. The following is example output for this error.

```json
{
    "UnsuccessfulFleetDeletions": [
        {
            "FleetId": "fleet-5d130460-0c26-bfd9-2c32-0100a098f625",
            "Error": {
                "Message": "NoTerminateInstances option is not supported for instant fleet",
                "Code": "NoTerminateInstancesNotSupported"
            }
        }
    ],
    "SuccessfulFleetDeletions": []
}
```

Troubleshoot UnauthorizedOperation

If you do not have permission to terminate instances, you get the UnauthorizedOperation error when deleting a fleet that must terminate its instances. The following is the error response.

```xml
<Response>
<Errors>
<Error>
<Code>UnauthorizedOperation</Code>
<Message>You are not authorized to perform this operation. Encoded authorization failure message: VvuncIxj7Z_CPGNYXWqnuFV-YjByeAU66Q9752NtQ-I3-qnDLWs6JLPdKnSMMiq5s6CcOqijjPteDpnsnGHszzyHasHFOaRY3paDVrav0W25azn6KNkUQQlFw8hjyuJ7zt2dNcdduJfrqcFYAj1EiRMkfDHT7N638Klwe8HTurzDR5A560Y2nDSU1MmAbly9UNtqaZJ9SNe5aNkRMq2aqKrjRbk02Rzu5V2vn9VMk6f2m2aMVHbY9JhLwGypLcMUjt7J6H9ytg2zR</Message>
</Error>
</Errors>
</Response>
```
To resolve the error, you must add the ec2:TerminateInstances action to the IAM policy, as shown in the following example.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DeleteFleetsAndTerminateInstances",
            "Effect": "Allow",
            "Action": [
                "ec2:DeleteFleets",
                "ec2:TerminateInstances"
            ],
            "Resource": "*"
        }
    ]
}
```
Spot Fleet

A Spot Fleet is set of Spot Instances and optionally On-Demand Instances that is launched based on criteria that you specify. The Spot Fleet selects the Spot capacity pools that meet your needs and launches Spot Instances to meet the target capacity for the fleet. By default, Spot Fleets are set to maintain target capacity by launching replacement instances after Spot Instances in the fleet are terminated. You can submit a Spot Fleet as a one-time request, which does not persist after the instances have been terminated. You can include On-Demand Instance requests in a Spot Fleet request.

Topics

• Spot Fleet request types (p. 703)
• Spot Fleet configuration strategies (p. 703)
• Work with Spot Fleets (p. 711)
• CloudWatch metrics for Spot Fleet (p. 730)
• Automatic scaling for Spot Fleet (p. 732)

Spot Fleet request types

There are two types of Spot Fleet requests:

request

If you configure the request type as request, Spot Fleet places an asynchronous one-time request for your desired capacity. Thereafter, if capacity is diminished because of Spot interruptions, the fleet does not attempt to replenish Spot Instances, nor does it submit requests in alternative Spot capacity pools if capacity is unavailable.

maintain

If you configure the request type as maintain, Spot Fleet places an asynchronous request for your desired capacity, and maintains capacity by automatically replenishing any interrupted Spot Instances.

To specify the type of request in the Amazon EC2 console, do the following when creating a Spot Fleet request:

• To create a Spot Fleet of type request, clear the Maintain target capacity check box.
• To create a Spot Fleet of type maintain, select the Maintain target capacity check box.

For more information, see Create a Spot Fleet request using defined parameters (console) (p. 718).

Both types of requests benefit from an allocation strategy. For more information, see Allocation strategy for Spot Instances (p. 704).

Spot Fleet configuration strategies

A Spot Fleet is a collection, or fleet, of Spot Instances, and optionally On-Demand Instances.

The Spot Fleet attempts to launch the number of Spot Instances and On-Demand Instances to meet the target capacity that you specified in the Spot Fleet request. The request for Spot Instances is fulfilled if there is available capacity and the maximum price you specified in the request exceeds the current Spot price. The Spot Fleet also attempts to maintain its target capacity fleet if your Spot Instances are interrupted.
You can also set a maximum amount per hour that you’re willing to pay for your fleet, and Spot Fleet launches instances until it reaches the maximum amount. When the maximum amount you’re willing to pay is reached, the fleet stops launching instances even if it hasn’t met the target capacity.

A **Spot capacity pool** is a set of unused EC2 instances with the same instance type (for example, `m5.large`), operating system, Availability Zone, and network platform. When you make a Spot Fleet request, you can include multiple launch specifications, that vary by instance type, AMI, Availability Zone, or subnet. The Spot Fleet selects the Spot capacity pools that are used to fulfill the request, based on the launch specifications included in your Spot Fleet request, and the configuration of the Spot Fleet request. The Spot Instances come from the selected pools.

**Contents**

- Plan a Spot Fleet request (p. 704)
- Allocation strategy for Spot Instances (p. 704)
- On-Demand in Spot Fleet (p. 706)
- Capacity Rebalancing (p. 707)
- Spot price overrides (p. 709)
- Control spending (p. 709)
- Spot Fleet instance weighting (p. 709)

**Plan a Spot Fleet request**

Before you create a Spot Fleet request, review Spot Best Practices. Use these best practices when you plan your Spot Fleet request so that you can provision the type of instances you want at the lowest possible price. We also recommend that you do the following:

- Determine whether you want to create a Spot Fleet that submits a one-time request for the desired target capacity, or one that maintains a target capacity over time.
- Determine the instance types that meet your application requirements.
- Determine the target capacity for your Spot Fleet request. You can set the target capacity in instances or in custom units. For more information, see Spot Fleet instance weighting (p. 709).
- Determine what portion of the Spot Fleet target capacity must be On-Demand capacity. You can specify 0 for On-Demand capacity.
- Determine your price per unit, if you are using instance weighting. To calculate the price per unit, divide the price per instance hour by the number of units (or weight) that this instance represents. If you are not using instance weighting, the default price per unit is the price per instance hour.
- Review the possible options for your Spot Fleet request. For more information, see the request-spot-fleet command in the AWS CLI Command Reference. For additional examples, see Spot Fleet example configurations (p. 772).

**Allocation strategy for Spot Instances**

The allocation strategy for the Spot Instances in your Spot Fleet determines how it fulfills your Spot Fleet request from the possible Spot capacity pools represented by its launch specifications. The following are the allocation strategies that you can specify in your Spot Fleet request:

- `lowestPrice`
  
  The Spot Instances come from the pool with the lowest price. This is the default strategy.

- `diversified`
  
  The Spot Instances are distributed across all pools.
capacityOptimized

The Spot Instances come from the pools with optimal capacity for the number of instances that are launching. You can optionally set a priority for each instance type in your fleet using capacityOptimizedPrioritized. Spot Fleet optimizes for capacity first, but honors instance type priorities on a best-effort basis.

With Spot Instances, pricing changes slowly over time based on long-term trends in supply and demand, but capacity fluctuates in real time. The capacityOptimized strategy automatically launches Spot Instances into the most available pools by looking at real-time capacity data and predicting which are the most available. This works well for workloads such as big data and analytics, image and media rendering, machine learning, and high performance computing that may have a higher cost of interruption associated with restarting work and checkpointing. By offering the possibility of fewer interruptions, the capacityOptimized strategy can lower the overall cost of your workload.

Alternatively, you can use the capacityOptimizedPrioritized allocation strategy with a priority parameter to order instance types from highest to lowest priority. You can set the same priority for different instance types. Spot Fleet will optimize for capacity first, but will honor instance type priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect Spot Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters. Using priorities is supported only if your fleet uses a launch template. Note that when you set the priority for capacityOptimizedPrioritized, the same priority is also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized.

InstancePoolsToUseCount

The Spot Instances are distributed across the number of Spot pools that you specify. This parameter is valid only when used in combination with lowestPrice.

Maintain target capacity

After Spot Instances are terminated due to a change in the Spot price or available capacity of a Spot capacity pool, a Spot Fleet of type maintain launches replacement Spot Instances. If the allocation strategy is lowestPrice, the fleet launches replacement instances in the pool where the Spot price is currently the lowest. If the allocation strategy is diversified, the fleet distributes the replacement Spot Instances across the remaining pools. If the allocation strategy is lowestPrice in combination with InstancePoolsToUseCount, the fleet selects the Spot pools with the lowest price and launches Spot Instances across the number of Spot pools that you specify.

Choose an appropriate allocation strategy

You can optimize your Spot Fleets based on your use case.

If your fleet runs workloads that may have a higher cost of interruption associated with restarting work and checkpointing, then use the capacityOptimized strategy. This strategy offers the possibility of fewer interruptions, which can lower the overall cost of your workload. This is the recommended strategy. Use the capacityOptimizedPrioritized strategy for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

If your fleet is small or runs for a short time, the probability that your Spot Instances may be interrupted is low, even with all the instances in a single Spot capacity pool. Therefore, the lowestPrice strategy is likely to meet your needs while providing the lowest cost.

If your fleet is large or runs for a long time, you can improve the availability of your fleet by distributing the Spot Instances across multiple pools. For example, if your Spot Fleet request specifies 10 pools and a target capacity of 100 instances, the fleet launches 10 Spot Instances in each pool. If the Spot price for one pool exceeds your maximum price for this pool, only 10% of your fleet is affected. Using this
strategy also makes your fleet less sensitive to increases in the Spot price in any one pool over time. With the diversified strategy, the Spot Fleet does not launch Spot Instances into any pools with a Spot price that is equal to or higher than the On-Demand price.

To create a cheap and diversified fleet, use the lowestPrice strategy in combination with InstancePoolsToUseCount. You can use a low or high number of Spot pools across which to allocate your Spot Instances. For example, if you run batch processing, we recommend specifying a low number of Spot pools (for example, InstancePoolsToUseCount=2) to ensure that your queue always has compute capacity while maximizing savings. If you run a web service, we recommend specifying a high number of Spot pools (for example, InstancePoolsToUseCount=10) to minimize the impact if a Spot capacity pool becomes temporarily unavailable.

Configure Spot Fleet for cost optimization

To optimize the costs for your use of Spot Instances, specify the lowestPrice allocation strategy so that Spot Fleet automatically deploys the least expensive combination of instance types and Availability Zones based on the current Spot price.

For On-Demand Instance target capacity, Spot Fleet always selects the least expensive instance type based on the public On-Demand price, while continuing to follow the allocation strategy (either lowestPrice, capacityOptimized, or diversified) for Spot Instances.

Configure Spot Fleet for cost optimization and diversification

To create a fleet of Spot Instances that is both cheap and diversified, use the lowestPrice allocation strategy in combination with InstancePoolsToUseCount. Spot Fleet automatically deploys the cheapest combination of instance types and Availability Zones based on the current Spot price across the number of Spot pools that you specify. This combination can be used to avoid the most expensive Spot Instances.

For example, if your target capacity is 10 Spot Instances, and you specify 2 Spot capacity pools (for InstancePoolsToUseCount), Spot Fleet will draw on the two cheapest pools to fulfill your Spot capacity.

Note that Spot Fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, Spot Fleet will continue to fulfill your request by drawing from the next cheapest pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.

Configure Spot Fleet for capacity optimization

To launch Spot Instances into the most-available Spot capacity pools, use the capacityOptimized allocation strategy. For an example configuration, see Example 9: Launch Spot Instances in a capacity-optimized fleet (p. 782).

You can also express your pool priorities by using the capacityOptimizedPrioritized allocation strategy and then setting the order of instance types to use from highest to lowest priority. Using priorities is supported only if your fleet uses a launch template. Note that when you set priorities for capacityOptimizedPrioritized, the same priorities are also applied to your On-Demand Instances if the OnDemandAllocationStrategy is set to prioritized. For an example configuration, see Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities (p. 782).

On-Demand in Spot Fleet

To ensure that you always have instance capacity, you can include a request for On-Demand capacity in your Spot Fleet request. In your Spot Fleet request, you specify your desired target capacity and how
much of that capacity must be On-Demand. The balance comprises Spot capacity, which is launched if there is available Amazon EC2 capacity and availability. For example, if in your Spot Fleet request you specify target capacity as 10 and On-Demand capacity as 8, Amazon EC2 launches 8 capacity units as On-Demand, and 2 capacity units (10-8=2) as Spot.

Prioritize instance types for On-Demand capacity

When Spot Fleet attempts to fulfill your On-Demand capacity, it defaults to launching the lowest-priced instance type first. If OnDemandAllocationStrategy is set to prioritized, Spot Fleet uses priority to determine which instance type to use first in fulfilling On-Demand capacity. The priority is assigned to the launch template override, and the highest priority is launched first.

For example, you have configured three launch template overrides, each with a different instance type: c3.large, c4.large, and c5.large. The On-Demand price for c5.large is less than for c4.large. c3.large is the cheapest. If you do not use priority to determine the order, the fleet fulfills On-Demand capacity by starting with c3.large, and then c5.large. Because you often have unused Reserved Instances for c4.large, you can set the launch template override priority so that the order is c4.large, c3.large, and then c5.large.

Capacity Rebalancing

You can configure Spot Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation to notify you that a Spot Instance is at an elevated risk of interruption. Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance is interrupted by Amazon EC2. For more information, see EC2 instance rebalance recommendations (p. 399).

To configure Spot Fleet to launch a replacement Spot Instance, you can use the Amazon EC2 console or the AWS CLI.

- Amazon EC2 console: You must select the Capacity rebalance check box when you create the Spot Fleet. For more information, see step 6.d. in Create a Spot Fleet request using defined parameters (console) (p. 718).
- AWS CLI: Use the request-spot-fleet command and the relevant parameters in the SpotMaintenanceStrategies structure. For more information, see the example launch configuration (p. 781).

Limitations

- Only available for fleets of type maintain.
- When the fleet is running, you can't modify the Capacity Rebalancing setting. To change the Capacity Rebalancing setting, you must delete the fleet and create a new fleet.

Considerations

If you configure a Spot Fleet for Capacity Rebalancing, consider the following:

Spot Fleet can launch new replacement Spot Instances until fulfilled capacity is double target capacity

When a Spot Fleet is configured for Capacity Rebalancing, the fleet attempts to launch a new replacement Spot Instance for every Spot Instance that receives a rebalance recommendation. After a Spot Instance receives a rebalance recommendation, it is no longer counted as part of the fulfilled capacity, and Spot Fleet does not automatically terminate the instance. This gives you the opportunity to perform rebalancing actions (p. 400) on the instance. Thereafter, you can terminate the instance, or you can leave it running.
If your fleet reaches double its target capacity, it stops launching new replacement instances even if the replacement instances themselves receive a rebalance recommendation.

For example, you create a Spot Fleet with a target capacity of 100 Spot Instances. All the Spot Instances receive a rebalance recommendation, which causes Spot Fleet to launch 100 replacement Spot Instances. This raises the number of fulfilled Spot Instances to 200, which is double the target capacity. Some of the replacement instances receive a rebalance recommendation, but no more replacement instances are launched because the fleet cannot exceed double its target capacity.

Note that you are charged for all of the instances while they are running.

**We recommend that you manually terminate Spot Instances that receive a rebalance recommendation**

If you configure your Spot Fleet for Capacity Rebalancing, we recommend that you monitor the rebalance recommendation signal that is received by the Spot Instances in the fleet. By monitoring the signal, you can quickly perform rebalancing actions (p. 400) on the affected instances before Amazon EC2 interrupts them, and then you can manually terminate them. If you do not terminate the instances, you continue paying for them while they are running. Spot Fleet does not automatically terminate the instances that receive a rebalance recommendation.

You can set up notifications using Amazon EventBridge or instance metadata. For more information, see Monitor rebalance recommendation signals (p. 400).

**Spot Fleet does not count instances that receive a rebalance recommendation when calculating fulfilled capacity during scale in or out**

If your Spot Fleet is configured for Capacity Rebalancing, and you change the target capacity to either scale in or scale out, the fleet does not count the instances that are marked for rebalance as part of the fulfilled capacity, as follows:

- **Scale in** – If you decrease your desired target capacity, the fleet terminates instances that are not marked for rebalance until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

For example, you create a Spot Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then reduce the target capacity to 50 (scale in), but the fulfilled capacity is actually 60 instances because the 10 instances that are marked for rebalance are not terminated by the fleet. You need to manually terminate these instances, or you can leave them running.

- **Scale out** – If you increase your desired target capacity, the fleet launches new instances until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

For example, you create a Spot Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then increase the target capacity to 200 (scale out), but the fulfilled capacity is actually 210 instances because the 10 instances that are marked for rebalance are not counted by the fleet as part of the target capacity. You need to manually terminate these instances, or you can leave them running.

**Provide as many Spot capacity pools in the request as possible**

Configure your Spot Fleet to use multiple instance types and Availability Zones. This provides the flexibility to launch Spot Instances in various Spot capacity pools. For more information, see Be flexible about instance types and Availability Zones (p. 371).

**Configure your Spot Fleet to use the most optimal Spot capacity pools**

Use the capacity-optimized allocation strategy to ensure that replacement Spot Instances are launched in the most optimal Spot capacity pools. For more information, see Use the capacity optimized allocation strategy (p. 371).
Spot price overrides

Each Spot Fleet request can include a global maximum price, or use the default (the On-Demand price). Spot Fleet uses this as the default maximum price for each of its launch specifications.

You can optionally specify a maximum price in one or more launch specifications. This price is specific to the launch specification. If a launch specification includes a specific price, the Spot Fleet uses this maximum price, overriding the global maximum price. Any other launch specifications that do not include a specific maximum price still use the global maximum price.

Control spending

Spot Fleet stops launching instances when it has either reached the target capacity or the maximum amount you’re willing to pay. To control the amount you pay per hour for your fleet, you can specify the SpotMaxTotalPrice for Spot Instances and the OnDemandMaxTotalPrice for On-Demand Instances. When the maximum total price is reached, Spot Fleet stops launching instances even if it hasn’t met the target capacity.

The following examples show two different scenarios. In the first, Spot Fleet stops launching instances when it has met the target capacity. In the second, Spot Fleet stops launching instances when it has reached the maximum amount you’re willing to pay.

Example: Stop launching instances when target capacity is reached

Given a request for m4.large On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- OnDemandTargetCapacity: 10
- OnDemandMaxTotalPrice: $1.50

Spot Fleet launches 10 On-Demand Instances because the total of $1.00 (10 instances x $0.10) does not exceed the OnDemandMaxTotalPrice of $1.50.

Example: Stop launching instances when maximum total price is reached

Given a request for m4.large On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- OnDemandTargetCapacity: 10
- OnDemandMaxTotalPrice: $0.80

If Spot Fleet launches the On-Demand target capacity (10 On-Demand Instances), the total cost per hour would be $1.00. This is more than the amount ($0.80) specified for OnDemandMaxTotalPrice. To prevent spending more than you're willing to pay, Spot Fleet launches only 8 On-Demand Instances (below the On-Demand target capacity) because launching more would exceed the OnDemandMaxTotalPrice.

Spot Fleet instance weighting

When you request a fleet of Spot Instances, you can define the capacity units that each instance type would contribute to your application’s performance, and adjust your maximum price for each Spot capacity pool accordingly using instance weighting.

By default, the price that you specify is per instance hour. When you use the instance weighting feature, the price that you specify is per unit hour. You can calculate your price per unit hour by dividing your price for an instance type by the number of units that it represents. Spot Fleet calculates the number of Spot Instances to launch by dividing the target capacity by the instance weight. If the result isn’t an
integer, the Spot Fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity. Spot Fleet can select any pool that you specify in your launch specification, even if the capacity of the instances launched exceeds the requested target capacity.

The following tables provide examples of calculations to determine the price per unit for a Spot Fleet request with a target capacity of 10.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance weight</th>
<th>Price per instance hour</th>
<th>Price per unit hour</th>
<th>Number of instances launched</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.xlarge</td>
<td>2</td>
<td>$0.05</td>
<td>.025 (.05 divided by 2)</td>
<td>5 (10 divided by 2)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance weight</th>
<th>Price per instance hour</th>
<th>Price per unit hour</th>
<th>Number of instances launched</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.8xlarge</td>
<td>8</td>
<td>$0.10</td>
<td>.0125 (.10 divided by 8)</td>
<td>2 (10 divided by 8, result rounded up)</td>
</tr>
</tbody>
</table>

Use Spot Fleet instance weighting as follows to provision the target capacity that you want in the pools with the lowest price per unit at the time of fulfillment:

1. Set the target capacity for your Spot Fleet either in instances (the default) or in the units of your choice, such as virtual CPUs, memory, storage, or throughput.
2. Set the price per unit.
3. For each launch configuration, specify the weight, which is the number of units that the instance type represents toward the target capacity.

**Instance weighting example**

Consider a Spot Fleet request with the following configuration:

- A target capacity of 24
- A launch specification with an instance type r3.2xlarge and a weight of 6
- A launch specification with an instance type c3.xlarge and a weight of 5

The weights represent the number of units that instance type represents toward the target capacity. If the first launch specification provides the lowest price per unit (price for r3.2xlarge per instance hour divided by 6), the Spot Fleet would launch four of these instances (24 divided by 6).

If the second launch specification provides the lowest price per unit (price for c3.xlarge per instance hour divided by 5), the Spot Fleet would launch five of these instances (24 divided by 5, result rounded up).

**Instance weighting and allocation strategy**

Consider a Spot Fleet request with the following configuration:

- A target capacity of 30
- A launch specification with an instance type c3.2xlarge and a weight of 8

710
• A launch specification with an instance type `m3.xlarge` and a weight of 8
• A launch specification with an instance type `r3.xlarge` and a weight of 8

The Spot Fleet would launch four instances (30 divided by 8, result rounded up). With the `lowestPrice` strategy, all four instances come from the pool that provides the lowest price per unit. With the `diversified` strategy, the Spot Fleet launches one instance in each of the three pools, and the fourth instance in whichever pool provides the lowest price per unit.

**Work with Spot Fleets**

To start using a Spot Fleet, you create a Spot Fleet request that includes the target capacity, an optional On-Demand portion, one or more launch specifications for the instances, and the maximum price that you are willing to pay. The fleet request must include a launch specification that defines the information that the fleet needs to launch an instance, such as an AMI, instance type, subnet or Availability Zone, and one or more security groups.

If your fleet includes Spot Instances, Amazon EC2 can attempt to maintain your fleet target capacity as Spot prices change.

It is not possible to modify the target capacity of a one-time request after it's been submitted. To change the target capacity, cancel the request and submit a new one.

A Spot Fleet request remains active until it expires or you cancel it. When you cancel a fleet request, you can specify whether canceling the request terminates the Spot Instances in that fleet.

**Contents**

- Spot Fleet request states (p. 711)
- Spot Fleet health checks (p. 712)
- Spot Fleet permissions (p. 713)
- Create a Spot Fleet request (p. 717)
- Tag a Spot Fleet (p. 721)
- Monitor your Spot Fleet (p. 727)
- Modify a Spot Fleet request (p. 727)
- Cancel a Spot Fleet request (p. 729)

**Spot Fleet request states**

A Spot Fleet request can be in one of the following states:

- **submitted** – The Spot Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.
- **active** – The Spot Fleet has been validated and Amazon EC2 is attempting to maintain the target number of running Spot Instances. The request remains in this state until it is modified or canceled.
- **modifying** – The Spot Fleet request is being modified. The request remains in this state until the modification is fully processed or the Spot Fleet is canceled. A one-time request cannot be modified, and this state does not apply to such Spot requests.
- **cancelled_running** – The Spot Fleet is canceled and does not launch additional Spot Instances. Its existing Spot Instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.
- **cancelled_terminating** – The Spot Fleet is canceled and its Spot Instances are terminating. The request remains in this state until all instances are terminated.
- **cancelled** – The Spot Fleet is canceled and has no running Spot Instances. The Spot Fleet request is deleted two days after its instances were terminated.
The following illustration represents the transitions between the request states. If you exceed your Spot Fleet limits, the request is canceled immediately.

Spot Fleet health checks

Spot Fleet checks the health status of the Spot Instances in the fleet every two minutes. The health status of an instance is either healthy or unhealthy.

Spot Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as unhealthy when the status of either the instance status check or the system status check is impaired for three consecutive health checks. For more information, see Status checks for your instances (p. 788).

You can configure your fleet to replace unhealthy Spot Instances. After enabling health check replacement, a Spot Instance is replaced when it is reported as unhealthy. The fleet could go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

Requirements

- Health check replacement is supported only for Spot Fleets that maintain a target capacity (fleets of type maintain), not for one-time Spot Fleets (fleets of type request).
- Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.
- You can configure your Spot Fleet to replace unhealthy instances only when you create it.
- IAM users can use health check replacement only if they have permission to call the ec2:DescribeInstanceStatus action.

Console

To configure a Spot Fleet to replace unhealthy Spot Instances using the console

1. Follow the steps for creating a Spot Fleet. For more information, see Create a Spot Fleet request using defined parameters (console) (p. 718).
2. To configure the fleet to replace unhealthy Spot Instances, for Health check, choose Replace unhealthy instances. To enable this option, you must first choose Maintain target capacity.
To configure a Spot Fleet to replace unhealthy Spot Instances using the AWS CLI

1. Follow the steps for creating a Spot Fleet. For more information, see Create a Spot Fleet using the AWS CLI (p. 720).
2. To configure the fleet to replace unhealthy Spot Instances, for ReplaceUnhealthyInstances, enter true.

Spot Fleet permissions

If your IAM users will create or manage a Spot Fleet, you need to grant them the required permissions.

If you use the Amazon EC2 console to create a Spot Fleet, it creates two service-linked roles named AWSServiceRoleForEC2SpotFleet and AWSServiceRoleForEC2Spot, and a role named aws-ec2-spot-fleet-tagging-role that grant the Spot Fleet the permissions to request, launch, terminate, and tag resources on your behalf. If you use the AWS CLI or an API, you must ensure that these roles exist.

Use the following instructions to grant the required permissions and create the roles.

Permissions and roles

- Grant permission to IAM users for Spot Fleet (p. 713)
- Service-linked role for Spot Fleet (p. 715)
- Service-linked role for Spot Instances (p. 717)
- IAM role for tagging a Spot Fleet (p. 717)

Grant permission to IAM users for Spot Fleet

If your IAM users will create or manage a Spot Fleet, be sure to grant them the required permissions as follows.

To grant an IAM user permissions for Spot Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies, Create policy.
3. On the Create policy page, choose JSON, and replace the text with the following.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "ec2:RunInstances",
            "ec2:CreateTags",
            "ec2:RequestSpotFleet",
            "ec2:ModifySpotFleetRequest",
            "ec2:CancelSpotFleetRequests",
            "ec2:DescribeSpotFleetRequests",
            "ec2:DescribeSpotFleetInstances",
            "ec2:DescribeSpotFleetRequestHistory"
        ],
        "Resource": "*
    },
    ],
    "Resource": "*
}
```
The preceding example policy grants an IAM user the permissions required for most Spot Fleet use cases. To limit the user to specific API actions, specify only those API actions instead.

**Required EC2 and IAM APIs**

The following APIs must be included in the policy:

- `ec2:RunInstances` – Required to launch instances in a Spot Fleet
- `ec2:CreateTags` – Required to tag the Spot Fleet request, instances, or volumes
- `iam:PassRole` – Required to specify the Spot Fleet role
- `iam:CreateServiceLinkedRole` – Required to create the service-linked role
- `iam:ListRoles` – Required to enumerate existing IAM roles
- `iam:ListInstanceProfiles` – Required to enumerate existing instance profiles

**Important**

If you specify a role for the IAM instance profile in the launch specification or launch template, you must grant the IAM user the permission to pass the role to the service. To do this, in the IAM policy include `"arn:aws:iam::*:role/IamInstanceProfile-role"` as a resource for the `iam:PassRole` action. For more information, see [Granting a user permissions to pass a role to an AWS service](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_ec2.html) in the IAM User Guide.

**Spot Fleet APIs**

Add the following Spot Fleet API actions to your policy, as needed:

- `ec2:RequestSpotFleet`
- `ec2:ModifySpotFleetRequest`
- `ec2:CancelSpotFleetRequests`
- `ec2:DescribeSpotFleetRequests`
- `ec2:DescribeSpotFleetInstances`
- `ec2:DescribeSpotFleetRequestHistory`

**Optional IAM APIs**

(Optional) To enable an IAM user to create roles or instance profiles using the IAM console, you must add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
- `iam:AttachRolePolicy`
- `iam:CreateInstanceProfile`
4. Choose **Review policy**.
5. On the **Review policy** page, enter a policy name and description, and choose **Create policy**.
6. In the navigation pane, choose **Users** and select the user.
7. Choose **Permissions, Add permissions**.
8. Choose **Attach existing policies directly**. Select the policy that you created earlier and choose **Next: Review**.
9. Choose **Add permissions**.

**Service-linked role for Spot Fleet**

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see **Using Service-Linked Roles** in the **IAM User Guide**.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2SpotFleet** to launch and manage instances on your behalf.

**Important**
If you specify an encrypted AMI (p. 156) or an encrypted Amazon EBS snapshot (p. 1335) in your Spot Fleet, you must grant the **AWSServiceRoleForEC2SpotFleet** role permission to use the CMK so that Amazon EC2 can launch instances on your behalf. For more information, see **Grant access to CMKs for use with encrypted AMIs and EBS snapshots** (p. 716).

**Permissions granted by AWSServiceRoleForEC2SpotFleet**

Amazon EC2 uses **AWSServiceRoleForEC2SpotFleet** to complete the following actions:

- **ec2:RequestSpotInstances** - Request Spot Instances
- **ec2:RunInstances** - Launch instances
- **ec2:TerminateInstances** - Terminate instances
- **ec2:DescribeImages** - Describe Amazon Machine Images (AMIs) for the instances
- **ec2:DescribeInstanceStatus** - Describe the status of the instances
- **ec2:DescribeSubnets** - Describe the subnets for the instances
- **ec2:CreateTags** - Add tags to the Spot Fleet request, instances, and volumes
- **elasticloadbalancing:RegisterInstancesWithLoadBalancer** - Add the specified instances to the specified load balancer
- **elasticloadbalancing:RegisterTargets** - Register the specified targets with the specified target group

**Create the service-linked role**

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2SpotFleet** service-linked role the first time you create a Spot Fleet using the console.

If you had an active Spot Fleet request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2SpotFleet** role in your AWS account. For more information, see **A new role appeared in my AWS account** in the **IAM User Guide**.
If you use the AWS CLI or an API to create a Spot Fleet, you must first ensure that this role exists.

To create AWSServiceRoleForEC2SpotFleet using the console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. For Select type of trusted entity, choose AWS service.
5. Under Choose a use case, or select a service to view its use cases, choose EC2.
6. Under Select your use case, choose EC2 - Spot Fleet.
7. Choose Next: Permissions.
8. On the next page, choose Next: Tags.

To create AWSServiceRoleForEC2SpotFleet using the AWS CLI

Use the create-service-linked-role command as follows.

```bash
aws iam create-service-linked-role --aws-service-name spotfleet.amazonaws.com
```

If you no longer need to use Spot Fleet, we recommend that you delete the AWSServiceRoleForEC2SpotFleet role. After this role is deleted from your account, Amazon EC2 will create the role again if you request a Spot Fleet using the console. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Grant access to CMKs for use with encrypted AMIs and EBS snapshots

If you specify an encrypted AMI (p. 156) or an encrypted Amazon EBS snapshot (p. 1335) in your Spot Fleet request and you use a customer managed customer master key (CMK) for encryption, you must grant the AWSServiceRoleForEC2SpotFleet role permission to use the CMK so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the CMK, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using Grants and Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide.

To grant the AWSServiceRoleForEC2SpotFleet role permissions to use the CMK

- Use the create-grant command to add a grant to the CMK and to specify the principal (the AWSServiceRoleForEC2SpotFleet service-linked role) that is given permission to perform the operations that the grant permits. The CMK is specified by the key-id parameter and the ARN of the CMK. The principal is specified by the grantee-principal parameter and the ARN of the AWSServiceRoleForEC2SpotFleet service-linked role.

```bash
aws kms create-grant \
   --region us-east-1 \
   --key-id arn:aws:kms:us-east-1:123456789012:key/12345678901234567890123456789012 \
   --grantee-principal arn:aws:iam::123456789012:role/AWSServiceRoleForEC2SpotFleet \
   --operations "Decrypt" "Encrypt" "GenerateDataKey" "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom" "ReEncryptTo"
```
Service-linked role for Spot Instances

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests (p. 379).

IAM role for tagging a Spot Fleet

The **aws-ec2-spot-fleet-tagging-role** IAM role grants the Spot Fleet permission to tag the Spot Fleet request, instances, and volumes. For more information, see Tag a Spot Fleet (p. 721).

**Important**
If you choose to tag instances in the fleet and you choose to maintain target capacity (the Spot Fleet request is of type maintain), the differences in permissions of the IAM user and the **IamFleetRole** might lead to inconsistent tagging behavior of instances in the fleet. If the **IamFleetRole** does not include the **CreateTags** permission, some of the instances launched by the fleet might not be tagged. While we are working to fix this inconsistency, to ensure that all instances launched by the fleet are tagged, we recommend that you use the **aws-ec2-spot-fleet-tagging-role** for the **IamFleetRole**. Alternatively, to use an existing role, attach the **AmazonEC2SpotFleetTaggingRole** AWS Managed Policy to the existing role. Otherwise, you need to manually add the **CreateTags** permission to your existing policy.

**To create the IAM role for tagging a Spot Fleet**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Choose Create roles.
4. On the Select type of trusted entity page, choose AWS service.
5. Under Choose a use case, Or select a service to view its use cases, choose EC2.
6. Under Select your use case, choose EC2 - Spot Fleet Tagging.
7. Choose Next: Permissions.
8. On the next page, choose Next: Tags.
10. On the Review page, enter a name for the role (for example, **aws-ec2-spot-fleet-tagging-role**) and choose Create role.

Create a Spot Fleet request

Using the AWS Management Console, quickly create a Spot Fleet request by choosing only your application or task need and minimum compute specs. Amazon EC2 configures a fleet that best meets your needs and follows Spot best practice. For more information, see Quickly create a Spot Fleet request (console) (p. 717). Otherwise, you can modify any of the default settings. For more information, see Create a Spot Fleet request using defined parameters (console) (p. 718) and Create a Spot Fleet using the AWS CLI (p. 720).

**Options for creating a Spot Fleet**

- Quickly create a Spot Fleet request (console) (p. 717)
- Create a Spot Fleet request using defined parameters (console) (p. 718)
- Create a Spot Fleet using the AWS CLI (p. 720)

**Quickly create a Spot Fleet request (console)**

Follow these steps to quickly create a Spot Fleet request.
To create a Spot Fleet request using the recommended settings (console)

2. If you are new to Spot, you see a welcome page; choose Get started. Otherwise, choose Request Spot Instances.
3. For Tell us your application or task need, choose Load balancing workloads, Flexible workloads, or Big data workloads.
4. Under Configure your instances, for Minimum compute unit, choose the minimum hardware specifications (vCPUs, memory, and storage) that you need for your application or task, either as specs or as an instance type.
   - For as specs, specify the required number of vCPUs and amount of memory.
   - For as an instance type, accept the default instance type, or choose Change instance type to choose a different instance type.
5. Under Tell us how much capacity you need, for Total target capacity, specify the number of units to request for target capacity. You can choose instances or vCPUs.
6. Review the recommended Fleet request settings based on your application or task selection, and choose Launch.

Create a Spot Fleet request using defined parameters (console)

You can create a Spot Fleet using the parameters that you define.

To create a Spot Fleet request using defined parameters (console)

2. If you are new to Spot, you see a welcome page; choose Get started. Otherwise, choose Request Spot Instances.
3. For Tell us your application or task need, choose Load balancing workloads, Flexible workloads, or Big data workloads.
4. For Configure your instances, do the following:
   a. (Optional) For Launch template, choose a launch template. The launch template must specify an Amazon Machine Image (AMI), as you cannot override the AMI using Spot Fleet if you specify a launch template.
      Important
      If you intend to specify Optional On-Demand portion, you must choose a launch template.
   b. For AMI, choose one of the basic AMIs provided by AWS, or choose Search for AMI to use an AMI from our user community, the AWS Marketplace, or one of your own.
   c. For Minimum compute unit, choose the minimum hardware specifications (vCPUs, memory, and storage) that you need for your application or task, either as specs or as an instance type.
      - For as specs, specify the required number of vCPUs and amount of memory.
      - For as an instance type, accept the default instance type, or choose Change instance type to choose a different instance type.
   d. For Network, choose an existing VPC or create a new one.
      [Existing VPC] Choose the VPC.
      [New VPC] Choose Create new VPC to go the Amazon VPC console. When you are done, return to the wizard and refresh the list.
   e. (Optional) For Availability Zone, let AWS choose the Availability Zones for your Spot Instances, or specify one or more Availability Zones.
If you have more than one subnet in an Availability Zone, choose the appropriate subnet from Subnet. To add subnets, choose Create new subnet to go to the Amazon VPC console. When you are done, return to the wizard and refresh the list.

f. (Optional) For Key pair name, choose an existing key pair or create a new one.

[Existing key pair] Choose the key pair.

[New key pair] Choose Create new key pair to go the Amazon VPC console. When you are done, return to the wizard and refresh the list.

5. (Optional) For Additional configurations, do the following:

   a. (Optional) To enable Amazon EBS optimization, for EBS-optimized, choose Launch EBS-optimized instances.

   b. (Optional) To add temporary block-level storage for your instances, for Instance store, choose Attach at launch.

   c. (Optional) To add storage, specify additional instance store volumes or Amazon EBS volumes, depending on the instance type.

   d. (Optional) By default, basic monitoring is enabled for your instances. To enable detailed monitoring, for Monitoring, choose Enable CloudWatch detailed monitoring.

   e. (Optional) To replace unhealthy Spot Instances, for Health check, choose Replace unhealthy instances. To enable this option, you must first choose Maintain target capacity.

   f. (Optional) To run a Dedicated Spot Instance, for Tenancy, choose Dedicated - run a dedicated instance.

   g. (Optional) For Security groups, choose one or more security groups or create a new one.

[Existing security group] Choose one or more security groups.

[New security group] Choose Create new security group to go the Amazon VPC console. When you are done, return to the wizard and refresh the list.

h. (Optional) To make your instances reachable from the internet, for Auto-assign IPv4 Public IP, choose Enable.

i. (Optional) To launch your Spot Instances with an IAM role, for IAM instance profile, choose the role.

j. (Optional) To run a start-up script, copy it to User data.

k. (Optional) To add a tag, choose Add new tag and enter the key and value for the tag. Repeat for each tag.

   For each tag, to tag the instances and the Spot Fleet request with the same tag, ensure that both Instance and Fleet are selected. To tag only the instances launched by the fleet, clear Fleet. To tag only the Spot Fleet request, clear Instance.

6. For Tell us how much capacity you need, do the following:

   a. For Total target capacity, specify the number of units to request for target capacity. You can choose instances or vCPUs. To specify a target capacity of 0 so that you can add capacity later, choose Maintain target capacity.

   b. (Optional) For Optional On-Demand portion, specify the number of On-Demand units to request. The number must be less than the Total target capacity. Amazon EC2 calculates the difference, and allocates the difference to Spot units to request.

     Important
     To specify an optional On-Demand portion, you must first choose a launch template.

   c. (Optional) By default, the Spot service terminates Spot Instances when they are interrupted. To maintain the target capacity, select Maintain target capacity. You can then specify that the
Spot service terminates, stops, or hibernates Spot Instances when they are interrupted. To do so, choose the corresponding option from **Interruption behavior**.

d. **(Optional)** To allow Spot Fleet to launch a replacement Spot Instance when an instance rebalance notification is emitted for an existing Spot Instance in the fleet, select **Capacity rebalance**. For more information, see Capacity Rebalancing (p. 707).

   **Note**
   When a replacement instance is launched, the instance marked for rebalance is not automatically terminated. You can terminate it, or you can leave it running. You are charged for both instances while they are running.
   The instance marked for rebalance is at an elevated risk of interruption, and you will receive a two-minute Spot Instance interruption notice before Amazon EC2 interrupts it.

e. **(Optional)** To control the amount you pay per hour for all the Spot Instances in your fleet, select **Set maximum cost for Spot Instances** and then enter the maximum total amount you're willing to pay per hour. When the maximum total amount is reached, Spot Fleet stops launching Spot Instances even if it hasn't met the target capacity. For more information, see Control spending (p. 709).

7. For **Fleet request settings**, do the following:

   a. Review the fleet request and fleet allocation strategy based on your application or task selection. To change the instance types or allocation strategy, clear **Apply recommendations**.

   b. **(Optional)** For **Fleet allocation strategy**, choose the strategy that meets your needs. For more information, see Allocation strategy for Spot Instances (p. 704).

   c. **(Optional)** To remove instance types, for **Fleet request**, select the instance types to remove and then choose **Delete**. To add instance types, choose **Select instance types**.

8. For **Additional request details**, do the following:

   a. Review the additional request details. To make changes, clear **Apply defaults**.

   b. **(Optional)** For **IAM fleet role**, you can use the default role or choose a different role. To use the default role after changing the role, choose **Use default role**.

   c. **(Optional)** For **Maximum price**, you can use the default maximum price (the On-Demand price) or specify the maximum price you are willing to pay. If your maximum price is lower than the Spot price for the instance types that you selected, your Spot Instances are not launched.

   d. **(Optional)** To create a request that is valid only during a specific time period, edit **Request valid from** and **Request valid until**.

   e. **(Optional)** By default, we terminate your Spot Instances when the request expires. To keep them running after your request expires, clear **Terminate the instances when the request expires**.

   f. **(Optional)** To register your Spot Instances with a load balancer, choose **Receive traffic from one or more load balancers** and choose one or more Classic Load Balancers or target groups.

9. **(Optional)** To download a copy of the launch configuration for use with the AWS CLI, choose **JSON config**.

10. Choose **Launch**.

    The Spot Fleet request type is **fleet**. When the request is fulfilled, requests of type **instance** are added, where the state is **active** and the status is **fulfilled**.

**Create a Spot Fleet using the AWS CLI**

**To create a Spot Fleet request using the AWS CLI**

- Use the **request-spot-fleet** command to create a Spot Fleet request.
aws ec2 request-spot-fleet --spot-fleet-request-config file://config.json

For example configuration files, see Spot Fleet example configurations (p. 772).

The following is example output:

```
{
  "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1ce4EXAMPLE"
}
```

**Tag a Spot Fleet**

To help categorize and manage your Spot Fleet requests, you can tag them with custom metadata. You can assign a tag to a Spot Fleet request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Fleet request, the instances and volumes that are launched by the Spot Fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Fleet. You can choose to assign tags to only the Spot Fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all three.

**Note**

Volume tags are only supported for volumes that are attached to On-Demand Instances. You can't tag volumes that are attached to Spot Instances.

For more information about how tags work, see Tag your Amazon EC2 resources (p. 1462).

**Contents**

- Prerequisite (p. 721)
- Tag a new Spot Fleet (p. 722)
- Tag a new Spot Fleet and the instances and volumes that it launches (p. 723)
- Tag an existing Spot Fleet (p. 725)
- View Spot Fleet request tags (p. 726)

**Prerequisite**

Grant the IAM user the permission to tag resources. For more information, see Example: Tag resources (p. 1108).

**To grant an IAM user the permission to tag resources**

Create a IAM policy that includes the following:

- The `ec2:CreateTags` action. This grants the IAM user permission to create tags.
- The `ec2:RequestSpotFleet` action. This grants the IAM user permission to create a Spot Fleet request.
- For `Resource`, you must specify "*". This allows users to tag all resource types.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TagSpotFleetRequest",
```
Important

We currently do not support resource-level permissions for the spot-fleet-request resource. If you specify spot-fleet-request as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how not to set the policy.

```
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateTags",
    "ec2:RequestSpotFleet"
  ],
}
```

Tag a new Spot Fleet

To tag a new Spot Fleet request using the console

1. Follow the Create a Spot Fleet request using defined parameters (console) (p. 718) procedure.
2. To add a tag, expand Additional configurations, choose Add new tag, and enter the key and value for the tag. Repeat for each tag.

   For each tag, you can tag the Spot Fleet request and the instances with the same tag. To tag both, ensure that both Instance tags and Fleet tags are selected. To tag only the Spot Fleet request, clear Instance tags. To tag only the instances launched by the fleet, clear Fleet tags.
3. Complete the required fields to create a Spot Fleet request, and then choose Launch. For more information, see Create a Spot Fleet request using defined parameters (console) (p. 718).

To tag a new Spot Fleet request using the AWS CLI

To tag a Spot Fleet request when you create it, configure the Spot Fleet request configuration as follows:

- Specify the tags for the Spot Fleet request in SpotFleetRequestConfig.
- For ResourceType, specify spot-fleet-request. If you specify another value, the fleet request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the Spot Fleet request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123.

```
{
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "lowestPrice",
    "ExcessCapacityTerminationPolicy": "default",
    "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
      {
        "ImageId": "ami-0123456789EXAMPLE",
```
"InstanceType": "c4.large"
},
"SpotPrice": "$5",
"TargetCapacity": 2,
"TerminateInstancesWithExpiration": true,
"Type": "maintain",
"ReplaceUnhealthyInstances": true,
"InstanceInterruptionBehavior": "terminate",
"InstancePoolsToUseCount": 1,
"TagSpecifications": [
  {
    "ResourceType": "spot-fleet-request",
    "Tags": [
      {
        "Key": "Environment",
        "Value": "Production"
      },
      {
        "Key": "Cost-Center",
        "Value": "123"
      }
    ]
  }
]}
}

Tag a new Spot Fleet and the instances and volumes that it launches

To tag a new Spot Fleet request and the instances and volumes that it launches using the AWS CLI

To tag a Spot Fleet request when you create it, and to tag the instances and volumes when they are launched by the fleet, configure the Spot Fleet request configuration as follows:

Spot Fleet request tags:

- Specify the tags for the Spot Fleet request in SpotFleetRequestConfig.
- For ResourceType, specify spot-fleet-request. If you specify another value, the fleet request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

Instance tags:

- Specify the tags for the instances in LaunchSpecifications.
- For ResourceType, specify instance. If you specify another value, the fleet request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

Alternatively, you can specify the tags for the instance in the launch template (p. 485) that is referenced in the Spot Fleet request.

Volume tags:

- Specify the tags for the volumes in the launch template (p. 485) that is referenced in the Spot Fleet request. Volume tagging in LaunchSpecifications is not supported.

In the following example, the Spot Fleet request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123. The instances that are launched by the fleet are
tagged with one tag (which is the same as one of the tags for the Spot Fleet request): Key=Cost-Center and Value=123.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "lowestPrice",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-role",
        "LaunchSpecifications": [
            {
                "ImageId": "ami-0123456789EXAMPLE",
                "InstanceType": "c4.large",
                "TagSpecifications": [
                    {
                        "ResourceType": "instance",
                        "Tags": [
                            {
                                "Key": "Cost-Center",
                                "Value": "123"
                            }
                        ]
                    }
                ],
                "SpotPrice": "5",
                "TargetCapacity": 2,
                "TerminateInstancesWithExpiration": true,
                "Type": "maintain",
                "ReplaceUnhealthyInstances": true,
                "InstanceInterruptionBehavior": "terminate",
                "InstancePoolsToUseCount": 1,
                "TagSpecifications": [
                    {
                        "ResourceType": "spot-fleet-request",
                        "Tags": [
                            {
                                "Key": "Environment",
                                "Value": "Production"
                            },
                            {
                                "Key": "Cost-Center",
                                "Value": "123"
                            }
                        ]
                    }
                ]
            }
        ],
        "SpotPrice": "5",
        "TargetCapacity": 2,
        "TerminateInstancesWithExpiration": true,
        "Type": "maintain",
        "ReplaceUnhealthyInstances": true,
        "InstanceInterruptionBehavior": "terminate",
        "InstancePoolsToUseCount": 1,
        "TagSpecifications": [
            {
                "ResourceType": "spot-fleet-request",
                "Tags": [
                    {
                        "Key": "Environment",
                        "Value": "Production"
                    },
                    {
                        "Key": "Cost-Center",
                        "Value": "123"
                    }
                ]
            }
        ]
    }
}
```

**To tag instances launched by a Spot Fleet using the AWS CLI**

To tag instances when they are launched by the fleet, you can either specify the tags in the launch template (p. 485) that is referenced in the Spot Fleet request, or you can specify the tags in the Spot Fleet request configuration as follows:

- Specify the tags for the instances in LaunchSpecifications.
- For ResourceType, specify instance. If you specify another value, the fleet request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the instances that are launched by the fleet are tagged with one tag: Key=Cost-Center and Value=123.
To tag volumes attached to On-Demand Instances launched by a Spot Fleet using the AWS CLI

To tag volumes when they are created by the fleet, you must specify the tags in the launch template (p. 485) that is referenced in the Spot Fleet request.

Note
Volume tags are only supported for volumes that are attached to On-Demand Instances. You can't tag volumes that are attached to Spot Instances.
Volume tagging in LaunchSpecifications is not supported.

Tag an existing Spot Fleet

To tag an existing Spot Fleet request using the console

After you have created a Spot Fleet request, you can add tags to the fleet request using the console.

2. Select your Spot Fleet request.
3. Choose the Tags tab and choose Create Tag.

To tag an existing Spot Fleet request using the AWS CLI

You can use the create-tags command to tag existing resources. In the following example, the existing Spot Fleet request is tagged with Key=purpose and Value=test.

```bash
aws ec2 create-tags \
--resources sfr-1112222-3333-4444-5555-66666EXAMPLE \
--tags Key=purpose,Value=test
```
View Spot Fleet request tags

To view Spot Fleet request tags using the console
2. Select your Spot Fleet request and choose the Tags tab.

To describe Spot Fleet request tags
Use the describe-tags command to view the tags for the specified resource. In the following example, you describe the tags for the specified Spot Fleet request.

```
aws ec2 describe-tags \
  --filters "Name=resource-id,Values=sfr-11112222-3333-4444-5555-66666EXAMPLE"
```

```
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-fleet-request",
      "Value": "Production"
    },
    {
      "Key": "Another key",
      "ResourceId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-fleet-request",
      "Value": "Another value"
    }
  ]
}
```

You can also view the tags of a Spot Fleet request by describing the Spot Fleet request.

Use the describe-spot-fleet-requests command to view the configuration of the specified Spot Fleet request, which includes any tags that were specified for the fleet request.

```
aws ec2 describe-spot-fleet-requests \
  --spot-fleet-request-ids sfr-11112222-3333-4444-5555-66666EXAMPLE
```

```
{
  "SpotFleetRequestConfigs": [
    {
      "ActivityStatus": "fulfilled",
      "CreateTime": "2020-02-13T02:49:19.709Z",
      "SpotFleetRequestConfig": {
        "AllocationStrategy": "capacityOptimized",
        "OnDemandAllocationStrategy": "lowestPrice",
        "ExcessCapacityTerminationPolicy": "Default",
        "FulfilledCapacity": 2.0,
        "OnDemandFulfilledCapacity": 0.0,
        "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-role",
        "LaunchSpecifications": [
          {
            "ImageId": "ami-0123456789EXAMPLE",
            "InstanceType": "c4.large"
          }
        ]
      }
    }
  ]
}```
Monitor your Spot Fleet

The Spot Fleet launches Spot Instances when your maximum price exceeds the Spot price and capacity is available. The Spot Instances run until they are interrupted or you terminate them.

**To monitor your Spot Fleet (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request. To see the configuration details, choose **Description**.
4. To list the Spot Instances for the Spot Fleet, choose **Instances**.
5. To view the history for the Spot Fleet, choose **History**.

**To monitor your Spot Fleet (AWS CLI)**

Use the `describe-spot-fleet-requests` command to describe your Spot Fleet requests.

```
aws ec2 describe-spot-fleet-requests
```

Use the `describe-spot-fleet-instances` command to describe the Spot Instances for the specified Spot Fleet.

```
aws ec2 describe-spot-fleet-instances \
    --spot-fleet-request-id sfr-73fbd2ce-a030-494c-8788-1cee4EXAMPLE
```

Use the `describe-spot-fleet-request-history` command to describe the history for the specified Spot Fleet request.

```
aws ec2 describe-spot-fleet-request-history \
    --spot-fleet-request-id sfr-73fbd2ce-a030-494c-8788-1cee4EXAMPLE \
    --start-time 2015-05-18T00:00:00Z
```

**Modify a Spot Fleet request**

You can modify an active Spot Fleet request to complete the following tasks:
• Increase the target capacity and On-Demand portion
• Decrease the target capacity and On-Demand portion

Note
You can’t modify a one-time Spot Fleet request. You can only modify a Spot Fleet request if you selected **Maintain target capacity** when you created the Spot Fleet request.

When you increase the target capacity, the Spot Fleet launches additional Spot Instances. When you increase the On-Demand portion, the Spot Fleet launches additional On-Demand Instances.

When you increase the target capacity, the Spot Fleet launches the additional Spot Instances according to the allocation strategy for its Spot Fleet request. If the allocation strategy is **lowestPrice**, the Spot Fleet launches the instances from the lowest-priced Spot capacity pool in the Spot Fleet request. If the allocation strategy is **diversified**, the Spot Fleet distributes the instances across the pools in the Spot Fleet request.

When you decrease the target capacity, the Spot Fleet cancels any open requests that exceed the new target capacity. You can request that the Spot Fleet terminate Spot Instances until the size of the fleet reaches the new target capacity. If the allocation strategy is **lowestPrice**, the Spot Fleet terminates the instances with the highest price per unit. If the allocation strategy is **diversified**, the Spot Fleet terminates instances across the pools. Alternatively, you can request that the Spot Fleet keep the fleet at its current size, but not replace any Spot Instances that are interrupted or that you terminate manually.

When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

**To modify a Spot Fleet request (console)**

2. Select your Spot Fleet request.
3. Choose **Actions, Modify target capacity**.
4. In **Modify target capacity**, do the following:
   a. Enter the new target capacity and On-Demand portion.
   b. (Optional) If you are decreasing the target capacity but want to keep the fleet at its current size, clear **Terminate instances**.
   c. Choose **Submit**.

**To modify a Spot Fleet request using the AWS CLI**

Use the `modify-spot-fleet-request` command to update the target capacity of the specified Spot Fleet request.

```bash
aws ec2 modify-spot-fleet-request \   --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \   --target-capacity 20
```

You can modify the previous command as follows to decrease the target capacity of the specified Spot Fleet without terminating any Spot Instances as a result.

```bash
aws ec2 modify-spot-fleet-request \   --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \   --target-capacity 10 \   --excess-capacity-termination-policy NoTermination
```
Cancel a Spot Fleet request

When you are finished using your Spot Fleet, you can cancel the Spot Fleet request. This cancels all Spot requests associated with the Spot Fleet, so that no new Spot Instances are launched for your Spot Fleet. You must specify whether the Spot Fleet should terminate its Spot Instances. If you terminate the instances, the Spot Fleet request enters the `cancelled_terminating` state. Otherwise, the Spot Fleet request enters the `cancelled_running` state and the instances continue to run until they are interrupted or you terminate them manually.

To cancel a Spot Fleet request (console)

2. Select your Spot Fleet request.
3. Choose Actions, Cancel spot request.
4. In Cancel spot request, verify that you want to cancel the Spot Fleet. To keep the fleet at its current size, clear Terminate instances. When you are ready, choose Confirm.

To cancel a Spot Fleet request using the AWS CLI

Use the cancel-spot-fleet-requests command to cancel the specified Spot Fleet request and terminate the instances.

```
aws ec2 cancel-spot-fleet-requests \\
  --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \\
  --terminate-instances
```

The following is example output:

```
{
  "SuccessfulFleetRequests": [
    {
      "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
      "CurrentSpotFleetRequestState": "cancelled_terminating",
      "PreviousSpotFleetRequestState": "active"
    }
  ],
  "UnsuccessfulFleetRequests": []
}
```

You can modify the previous command as follows to cancel the specified Spot Fleet request without terminating the instances.

```
aws ec2 cancel-spot-fleet-requests \\
  --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \\
  --no-terminate-instances
```

The following is example output:

```
{
  "SuccessfulFleetRequests": [
    {
      "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
      "CurrentSpotFleetRequestState": "cancelled_running",
      "PreviousSpotFleetRequestState": "active"
    }
  ],
  "UnsuccessfulFleetRequests": []
}
```
CloudWatch metrics for Spot Fleet

Amazon EC2 provides Amazon CloudWatch metrics that you can use to monitor your Spot Fleet.

**Important**
To ensure accuracy, we recommend that you enable detailed monitoring when using these metrics. For more information, see Enable or turn off detailed monitoring for your instances (p. 819).

For more information about CloudWatch metrics provided by Amazon EC2, see Monitor your instances using CloudWatch (p. 818).

**Spot Fleet metrics**

The AWS/EC2Spot namespace includes the following metrics, plus the CloudWatch metrics for the Spot Instances in your fleet. For more information, see Instance metrics (p. 821).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailableInstancePoolsCount</td>
<td>The Spot capacity pools specified in the Spot Fleet request.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>BidsSubmittedForCapacity</td>
<td>The capacity for which Amazon EC2 has submitted Spot Fleet requests.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>EligibleInstancePoolCount</td>
<td>The Spot capacity pools specified in the Spot Fleet request where Amazon EC2 can fulfill requests. Amazon EC2 does not fulfill requests in pools where the maximum price you're willing to pay for Spot Instances is less than the Spot price or the Spot price is greater than the price for On-Demand Instances.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>FulfilledCapacity</td>
<td>The capacity that Amazon EC2 has fulfilled.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>MaxPercentCapacityAllocation</td>
<td>The maximum value of PercentCapacityAllocation across all Spot Fleet pools specified in the Spot Fleet request.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>PendingCapacity</td>
<td>The difference between TargetCapacity and FulfilledCapacity.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>PercentCapacityAllocation</td>
<td>The capacity allocated for the Spot capacity pool for the specified dimensions. To get the maximum value recorded across all Spot capacity pools, use MaxPercentCapacityAllocation.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
</tbody>
</table>
CloudWatch metrics for Spot Fleet

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TargetCapacity</td>
<td>The target capacity of the Spot Fleet request.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>TerminatingCapacity</td>
<td>The capacity that is being terminated because the provisioned capacity is greater than the target capacity.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
</tbody>
</table>

If the unit of measure for a metric is Count, the most useful statistic is Average.

**Spot Fleet dimensions**

To filter the data for your Spot Fleet, use the following dimensions.

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailabilityZone</td>
<td>Filter the data by Availability Zone.</td>
</tr>
<tr>
<td>FleetRequestId</td>
<td>Filter the data by Spot Fleet request.</td>
</tr>
<tr>
<td>InstanceType</td>
<td>Filter the data by instance type.</td>
</tr>
</tbody>
</table>

**View the CloudWatch metrics for your Spot Fleet**

You can view the CloudWatch metrics for your Spot Fleet using the Amazon CloudWatch console. These metrics are displayed as monitoring graphs. These graphs show data points if the Spot Fleet is active.

Metrics are grouped first by namespace, and then by the various combinations of dimensions within each namespace. For example, you can view all Spot Fleet metrics or Spot Fleet metrics groups by Spot Fleet request ID, instance type, or Availability Zone.

**To view Spot Fleet metrics**

2. In the navigation pane, choose Metrics.
3. Choose the EC2 Spot namespace.

**Note**

If the EC2 Spot namespace is not displayed, there are two reasons for this. Either you've not yet used Spot Fleet—only the AWS services that you're using send metrics to Amazon CloudWatch. Or, if you've not used Spot Fleet for the past two weeks, the namespace does not appear.

4. (Optional) To filter the metrics by dimension, select one of the following:

   - **Fleet Request Metrics** – Group by Spot Fleet request
   - **By Availability Zone** – Group by Spot Fleet request and Availability Zone
   - **By Instance Type** – Group by Spot Fleet request and instance type
   - **By Availability Zone/Instance Type** – Group by Spot Fleet request, Availability Zone, and instance type

5. To view the data for a metric, select the check box next to the metric.
Automatic scaling for Spot Fleet

Automatic scaling is the ability to increase or decrease the target capacity of your Spot Fleet automatically based on demand. A Spot Fleet can either launch instances (scale out) or terminate instances (scale in), within the range that you choose, in response to one or more scaling policies.

Spot Fleet supports the following types of automatic scaling:

- **Target tracking scaling (p. 734)** – Increase or decrease the current capacity of the fleet based on a target value for a specific metric. This is similar to the way that your thermostat maintains the temperature of your home—you select temperature and the thermostat does the rest.
- **Step scaling (p. 735)** – Increase or decrease the current capacity of the fleet based on a set of scaling adjustments, known as step adjustments, that vary based on the size of the alarm breach.
- **Scheduled scaling (p. 736)** – Increase or decrease the current capacity of the fleet based on the date and time.

If you are using instance weighting (p. 709), keep in mind that Spot Fleet can exceed the target capacity as needed. Fulfilled capacity can be a floating-point number but target capacity must be an integer, so Spot Fleet rounds up to the next integer. You must take these behaviors into account when you look at the outcome of a scaling policy when an alarm is triggered. For example, suppose that the target capacity is 30, the fulfilled capacity is 30.1, and the scaling policy subtracts 1. When the alarm is triggered, the automatic scaling process subtracts 1 from 30.1 to get 29.1 and then rounds it up to 30, so no scaling action is taken. As another example, suppose that you selected instance weights of 2, 4, and 8, and a target capacity of 10, but no weight 2 instances were available so Spot Fleet provisioned instances of weights 4 and 8 for a fulfilled capacity of 12. If the scaling policy decreases target capacity by 20% and an alarm is triggered, the automatic scaling process subtracts 12*0.2 from 12 to get 9.6 and then rounds it up to 10, so no scaling action is taken.

The scaling policies that you create for Spot Fleet support a cooldown period. This is the number of seconds after a scaling activity completes where previous trigger-related scaling activities can influence future scaling events. For scale-out policies, while the cooldown period is in effect, the capacity that has been added by the previous scale-out event that initiated the cooldown is calculated as part of the desired capacity for the next scale out. The intention is to continuously (but not excessively) scale out. For scale in policies, the cooldown period is used to block subsequent scale in requests until it has expired. The intention is to scale in conservatively to protect your application's availability. However, if another alarm triggers a scale-out policy during the cooldown period after a scale-in, automatic scaling scales out your scalable target immediately.
We recommend that you scale based on instance metrics with a 1-minute frequency because that ensures a faster response to utilization changes. Scaling on metrics with a 5-minute frequency can result in slower response time and scaling on stale metric data. To send metric data for your instances to CloudWatch in 1-minute periods, you must specifically enable detailed monitoring. For more information, see Enable or turn off detailed monitoring for your instances (p. 819) and Create a Spot Fleet request using defined parameters (console) (p. 718).

For more information about configuring scaling for Spot Fleet, see the following resources:

- application-autoscaling section of the AWS CLI Command Reference
- Application Auto Scaling API Reference
- Application Auto Scaling User Guide

**IAM permissions required for Spot Fleet automatic scaling**

Automatic scaling for Spot Fleet is made possible by a combination of the Amazon EC2, Amazon CloudWatch, and Application Auto Scaling APIs. Spot Fleet requests are created with Amazon EC2, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling.

In addition to the IAM permissions for Spot Fleet (p. 713) and Amazon EC2, the IAM user that accesses fleet scaling settings must have the appropriate permissions for the services that support dynamic scaling. IAM users must have permissions to use the actions shown in the following example policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "application-autoscaling:*",
            "ec2:DescribeSpotFleetRequests",
            "ec2:ModifySpotFleetRequest",
            "cloudwatch:DeleteAlarms",
            "cloudwatch:DescribeAlarmHistory",
            "cloudwatch:DescribeAlarms",
            "cloudwatch:DescribeAlarmsForMetric",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:ListMetrics",
            "cloudwatch:PutMetricAlarm",
            "cloudwatch:DisableAlarmActions",
            "cloudwatch:EnableAlarmActions",
            "iam:CreateServiceLinkedRole",
            "sns:CreateTopic",
            "sns:Subscribe",
            "sns:Get*",
            "sns:List*
         ],
         "Resource": "*"
      }
   ]
}
```

You can also create your own IAM policies that allow more fine-grained permissions for calls to the Application Auto Scaling API. For more information, see Authentication and Access Control in the Application Auto Scaling User Guide.

The Application Auto Scaling service also needs permission to describe your Spot Fleet and CloudWatch alarms, and permissions to modify your Spot Fleet target capacity on your behalf. If you enable automatic scaling for your Spot Fleet, it creates a service-linked role named
AWS SERVICE ROLE FOR APPLICATION AUTO SCALING. EC2 SPOT FLEET REQUEST. THIS SERVICE-LINKED ROLE GRANTS APPLICATION AUTO SCALING PERMISSION TO DESCRIBE THE ALARMS FOR YOUR POLICIES, TO MONITOR THE CURRENT CAPACITY OF THE FLEET, AND TO MODIFY THE CAPACITY OF THE FLEET. THE ORIGINAL MANAGED SPOT FLEET ROLE FOR APPLICATION AUTO SCALING WAS AWS-EC2-SPOT-FLEET-AUTOSCALE-ROLE, BUT IT IS NO LONGER REQUIRED. THE SERVICE-LINKED ROLE IS THE DEFAULT ROLE FOR APPLICATION AUTO SCALING. FOR MORE INFORMATION, SEE SERVICE-LINKED ROLES IN THE APPLICATION AUTO SCALING USER GUIDE.

SCALE SPOT FLEET USING A TARGET TRACKING POLICY

With target tracking scaling policies, you select a metric and set a target value. Spot Fleet creates and manages the CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and the target value. The scaling policy adds or removes capacity as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the capacity of the fleet.

You can create multiple target tracking scaling policies for a Spot Fleet, provided that each of them uses a different metric. The fleet scales based on the policy that provides the largest fleet capacity. This enables you to cover multiple scenarios and ensure that there is always enough capacity to process your application workloads.

To ensure application availability, the fleet scales out proportionally to the metric as fast as it can, but scales in more gradually.

When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

Do not edit or delete the CloudWatch alarms that Spot Fleet manages for a target tracking scaling policy. Spot Fleet deletes the alarms automatically when you delete the target tracking scaling policy.

LIMITATION

The Spot Fleet request must have a request type of maintain. Automatic scaling is not supported for requests of type request, or Spot blocks.

TO CONFIGURE A TARGET TRACKING POLICY (CONSOLE)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose Auto Scaling.
4. If automatic scaling is not configured, choose Configure.
5. Use Scale capacity between to set the minimum and maximum capacity for your fleet. Automatic scaling does not scale your fleet below the minimum capacity or above the maximum capacity.
6. For Policy name, enter a name for the policy.
7. Choose a Target metric.
8. Enter a Target value for the metric.
9. (Optional) Set Cooldown period to modify the default cooldown period.
10. (Optional) Select Disable scale-in to omit creating a scale-in policy based on the current configuration. You can create a scale-in policy using a different configuration.
11. Choose Save.

TO CONFIGURE A TARGET TRACKING POLICY USING THE AWS CLI

1. Register the Spot Fleet request as a scalable target using the register-scalable-target command.
2. Create a scaling policy using the put-scaling-policy command.
Scale Spot Fleet using step scaling policies

With step scaling policies, you specify CloudWatch alarms to trigger the scaling process. For example, if you want to scale out when CPU utilization reaches a certain level, create an alarm using the CPUUtilization metric provided by Amazon EC2.

When you create a step scaling policy, you must specify one of the following scaling adjustment types:

- **Add** – Increase the target capacity of the fleet by a specified number of capacity units or a specified percentage of the current capacity.
- **Remove** – Decrease the target capacity of the fleet by a specified number of capacity units or a specified percentage of the current capacity.
- **Set to** – Set the target capacity of the fleet to the specified number of capacity units.

When an alarm is triggered, the automatic scaling process calculates the new target capacity using the fulfilled capacity and the scaling policy, and then updates the target capacity accordingly. For example, suppose that the target capacity and fulfilled capacity are 10 and the scaling policy adds 1. When the alarm is triggered, the automatic scaling process adds 1 to 10 to get 11, so Spot Fleet launches 1 instance.

When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

**Limitation**

The Spot Fleet request must have a request type of maintain. Automatic scaling is not supported for requests of type request, or Spot blocks.

**Prerequisites**

- Consider which CloudWatch metrics are important to your application. You can create CloudWatch alarms based on metrics provided by AWS or your own custom metrics.
- For the AWS metrics that you will use in your scaling policies, enable CloudWatch metrics collection if the service that provides the metrics does not enable it by default.

**To create a CloudWatch alarm**

2. In the navigation pane, choose Alarms.
3. Choose Create alarm.
4. On the Specify metric and conditions page, choose Select metric.
5. Choose EC2 Spot, Fleet Request Metrics, select a metric (for example, TargetCapacity), and then choose Select metric.

   The Specify metric and conditions page appears, showing a graph and other information about the metric you selected.
6. For Period, choose the evaluation period for the alarm, for example, 1 minute. When evaluating the alarm, each period is aggregated into one data point.

   **Note**
   A shorter period creates a more sensitive alarm.
7. For Conditions, define the alarm by defining the threshold condition. For example, you can define a threshold to trigger the alarm whenever the value of the metric is greater than or equal to 80 percent.
8. Under **Additional configuration**, for **Datapoints to alarm**, specify how many datapoints (evaluation periods) must be in the ALARM state to trigger the alarm, for example, 1 evaluation period or 2 out of 3 evaluation periods. This creates an alarm that goes to ALARM state if that many consecutive periods are breaching. For more information, see Evaluating an Alarm in the Amazon CloudWatch User Guide.

9. For **Missing data treatment**, choose one of the options (or leave the default of Treat missing data as missing). For more information, see Configuring How CloudWatch Alarms Treat Missing Data in the Amazon CloudWatch User Guide.

10. Choose **Next**.

11. (Optional) To receive notification of a scaling event, for **Notification**, you can choose or create the Amazon SNS topic you want to use to receive notifications. Otherwise, you can delete the notification now and add one later as needed.

12. Choose **Next**.

13. Under **Add a description**, enter a name and description for the alarm and choose **Next**.

14. Choose **Create alarm**.

**To configure a step scaling policy for your Spot Fleet (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request and choose **Auto Scaling**.
4. If automatic scaling is not configured, choose **Configure**.
5. Use **Scale capacity between** to set the minimum and maximum capacity for your fleet. Automatic scaling does not scale your fleet below the minimum capacity or above the maximum capacity.
6. Initially, **Scaling policies** contains policies named ScaleUp and ScaleDown. You can complete these policies, or choose **Remove policy** to delete them. You can also choose **Add policy**.
7. To define a policy, do the following:
   a. For **Policy name**, enter a name for the policy.
   b. For **Policy trigger**, select an existing alarm or choose **Create new alarm** to open the Amazon CloudWatch console and create an alarm.
   c. For **Modify capacity**, select a scaling adjustment type, select a number, and select a unit.
   d. (Optional) To perform step scaling, choose **Define steps**. By default, an add policy has a lower bound of -infinity and an upper bound of the alarm threshold. By default, a remove policy has a lower bound of the alarm threshold and an upper bound of +infinity. To add another step, choose **Add step**.
   e. (Optional) To modify the default value for the cooldown period, select a number from **Cooldown period**.
8. Choose **Save**.

**To configure step scaling policies for your Spot Fleet using the AWS CLI**

1. Register the Spot Fleet request as a scalable target using the `register-scalable-target` command.
2. Create a scaling policy using the `put-scaling-policy` command.
3. Create an alarm that triggers the scaling policy using the `put-metric-alarm` command.

**Scale Spot Fleet using scheduled scaling**

Scaling based on a schedule enables you to scale your application in response to predictable changes in demand. To use scheduled scaling, you create **scheduled actions**, which tell Spot Fleet to perform scaling...
activities at specific times. When you create a scheduled action, you specify an existing Spot Fleet, when
the scaling activity should occur, minimum capacity, and maximum capacity. You can create scheduled
actions that scale one time only or that scale on a recurring schedule.

You can only create a scheduled action for Spot Fleets that already exist. You can’t create a scheduled
action at the same time that you create a Spot Fleet.

Limitation

The Spot Fleet request must have a request type of maintain. Automatic scaling is not supported for
requests of type request, or Spot blocks.

To create a one-time scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose the Scheduled Scaling tab near the bottom of the screen.
5. For Name, specify a name for the scheduled action.
6. Enter a value for Minimum capacity, Maximum capacity, or both.
7. For Recurrence, choose Once.
8. (Optional) Choose a date and time for Start time, End time, or both.
9. Choose Submit.

To scale on a recurring schedule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose the Scheduled Scaling tab near the bottom of the screen.
4. For Recurrence, choose one of the predefined schedules (for example, Every day), or choose
   Custom and enter a cron expression. For more information about the cron expressions supported by
   scheduled scaling, see Cron Expressions in the Amazon CloudWatch Events User Guide.
5. (Optional) Choose a date and time for Start time, End time, or both.
6. Choose Submit.

To edit a scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose the Scheduled Scaling tab near the bottom of the screen.
4. Select the scheduled action and choose Actions, Edit.
5. Make the needed changes and choose Submit.

To delete a scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose the Scheduled Scaling tab near the bottom of the screen.
4. Select the scheduled action and choose Actions, Delete.
5. When prompted for confirmation, choose Delete.
To manage scheduled scaling using the AWS CLI

Use the following commands:

- put-scheduled-action
- describe-scheduled-actions
- delete-scheduled-action

Monitor fleet events using Amazon EventBridge

When the state of an EC2 Fleet or Spot Fleet changes, the fleet emits a notification. The notification is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). Events are emitted on a best effort basis.

With Amazon EventBridge, you can create rules that trigger programmatic actions in response to an event. For example, you can create two EventBridge rules, one that's triggered when a fleet state changes, and one that's triggered when an instance in the fleet is terminated. You can configure the first rule so that, if the fleet state changes, the rule invokes an SNS topic to send an email notification to you. You can configure the second rule so that, if an instance is terminated, the rule invokes a Lambda function to launch a new instance.

Topics
- EC2 Fleet event types (p. 738)
- Spot Fleet event types (p. 743)
- Create Amazon EventBridge rules (p. 747)

EC2 Fleet event types

Note
Only fleets of type maintain and request emit events. Fleets of type instant do not emit events because they submit synchronous one-time requests, and the state of the fleet is known immediately in the response.

There are five EC2 Fleet event types. For each event type, there are several sub-types.

The events are sent to EventBridge in JSON format. The following fields in the event form the event pattern that is defined in the rule, and which trigger an action:

"source": "aws.ec2fleet"

Identifies that the event is from EC2 Fleet.

"detail-type": "EC2 Fleet State Change"

Identifies the event type.

"detail": { "sub-type": "submitted" }

Identifies the event sub-type.

Event types
- EC2 Fleet State Change (p. 739)
- EC2 Fleet Spot Instance Request Change (p. 740)
- EC2 Fleet Instance Change (p. 740)
EC2 Fleet State Change

EC2 Fleet sends an EC2 Fleet State Change event to Amazon EventBridge when an EC2 Fleet changes state.

The following is example data for this event.

```
{
  "version": "0",
  "id": "715ed6b3-b8fc-27fe-fad6-528c7b8bf8a2",
  "detail-type": "EC2 Fleet State Change",
  "source": "aws.ec2fleet",
  "account": "123456789012",
  "time": "2020-11-09T09:00:20Z",
  "region": "us-east-1",
  "resources": ["arn:aws:ec2:us-east-1:123456789012:fleet/fleet-598fb973-87b7-422d-be4d-6b0809bfff0a"],
  "detail": {
    "sub-type": "active"
  }
}
```

The possible values for sub-type are:

**submitted**

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.

**active**

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running Spot Instances.

**progress**

The EC2 Fleet request is in the process of being fulfilled.

**cancelled_terminating**

The EC2 Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

**cancelled_running**

The EC2 Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

**cancelled**

The EC2 Fleet request is deleted and has no running instances. The EC2 Fleet will be deleted two days after its instances are terminated.

**modify_in_progress**

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed or the EC2 Fleet request is deleted.
modify_succeeded

The EC2 Fleet request was modified. This state does not apply to instant fleets because instant fleets cannot be modified.

expired

The EC2 Fleet request has expired. If the request was created with TerminateInstancesWithExpiration set, a subsequent event indicates that the instances are terminated.

EC2 Fleet Spot Instance Request Change

EC2 Fleet sends an EC2 Fleet Spot Instance Request Change event to Amazon EventBridge when a Spot Instance request in the fleet changes state.

The following is example data for this event.

```json
{
    "version": "0",
    "id": "1931f74-bf4b-a3dd-0f1b-ddb1422032b9",
    "detail-type": "EC2 Fleet Spot Instance Request Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:05Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-83fd4e48-552a-40ef-9532-82a3acca5f10"
    ],
    "detail": {
        "spot-instance-request-id": "sir-rmqske6h",
        "description": "SpotInstanceRequestId sir-rmqske6h, PreviousState: cancelled_running",
        "sub-type": "cancelled"
    }
}
```

The possible values for sub-type are:

submitted

The request is submitted.

disabled

You stopped the Spot Instance.

active

The request is fulfilled and has an associated Spot Instance.

cancelled

You cancelled the request, or the request expired.

EC2 Fleet Instance Change

EC2 Fleet sends an EC2 Fleet Instance Change event to Amazon EventBridge when an instance in the fleet changes state.
The following is example data for this event.

```
{
    "version": "0",
    "id": "542ce428-c8f1-0608-c015-e8ed6522c5bc",
    "detail-type": "EC2 Fleet Instance Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:23Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-598fb973-87b7-422d-be4d-6b0809bfff0a"
    ],
    "detail": {
        "instance-id": "i-0c594155dd5ff1829",
        "description": "{\"instanceType\":\"c5.large\",\"image\":\"ami-6057e21a\",\"productDescription\":\"Linux/UNIX\",\"availabilityZone\":\"us-east-1\"}",
        "sub-type": "launched"
    }
}
```

The possible values for `sub-type` are:

- launched
  - A new instance was launched.
- terminated
  - The instance was terminated.
- termination_notified
  - An instance termination notification was sent.

### EC2 Fleet Information

EC2 Fleet sends an EC2 Fleet Information event to Amazon EventBridge when there is an error during fulfillment. The information event does not block the fleet from attempting to fulfill its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "76529817-d605-4571-7224-d36cc1b2c0c4",
    "detail-type": "EC2 Fleet Information",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T08:17:07Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-8becf5fe-bb9e-415d-8f54-3fa5a8628b91"
    ],
    "detail": {
        "description": "r3.8xlarge, ami-032930428bf1abbff, Linux/UNIX, us-east-1a, Spot bid price is less than Spot market price $0.5291",
        "sub-type": "launchSpecUnusable"
    }
}
```
The possible values for sub-type are:

**launchSpecUnusable**

The price in a launch specification is not valid because it is below the Spot price or the Spot price is above the On-Demand price.

**fleetProgressHalted**

The price in every launch specification is not valid. A launch specification might become valid if the Spot price changes.

**registerWithLoadBalancersFailed**

An attempt to register instances with load balancers failed. For more information, see the description of the event.

**launchSpecTemporarilyBlacklisted**

The configuration is not valid and several attempts to launch instances have failed. For more information, see the description of the event.

### EC2 Fleet Error

EC2 Fleet sends an EC2 Fleet Error event to Amazon EventBridge when there is an error during fulfillment. The error event blocks the fleet from attempting to fulfill its target capacity.

The following is example data for this event.

```json
{
   "version": "0",
   "id": "69849a22-6d0f-d4ce-602b-b47c1c98240e",
   "detail-type": "EC2 Fleet Error",
   "source": "aws.ec2fleet",
   "account": "123456789012",
   "time": "2020-10-07T01:44:24Z",
   "region": "us-east-1",
   "resources": [
      "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-9bb19bc6-60d3-4fd2-ae47-d33e68eafa08"
   ],
   "detail": {
      "description": "m3.large, ami-00068cd7555f543ds, Linux/UNIX: IPV6 is not supported for the instance type 'm3.large'. ",
      "sub-type": "spotFleetRequestConfigurationInvalid"
   }
}
```

The possible values for sub-type are:

**allLaunchSpecsTemporarilyBlacklisted**

None of the configurations are valid, and several attempts to launch instances have failed. For more information, see the description of the event.

**spotFleetRequestConfigurationInvalid**

The configuration is not valid. For more information, see the description of the event.

**spotInstanceCountLimitExceeded**

You've reached the limit on the number of Spot Instances that you can launch.
Spot Fleet event types

There are five Spot Fleet event types. For each event type, there are several sub-types.

The events are sent to EventBridge in JSON format. The following fields in the event form the event pattern that is defined in the rule, and which trigger an action:

"source": "aws.ec2spotfleet"

Identifies that the event is from Spot Fleet.

"detail-type": "EC2 Spot Fleet State Change"

Identifies the event type.

"detail": { "sub-type": "submitted" }

Identifies the event sub-type.

**Event types**

- EC2 Spot Fleet State Change (p. 743)
- EC2 Spot Fleet Spot Instance Request Change (p. 744)
- EC2 Spot Fleet Instance Change (p. 745)
- EC2 Spot Fleet Information (p. 746)
- EC2 Spot Fleet Error (p. 746)

**EC2 Spot Fleet State Change**

Spot Fleet sends an EC2 Spot Fleet State Change event to Amazon EventBridge when a Spot Fleet changes state.

The following is example data for this event.

```json
{
   "version": "0",
   "id": "d1af1091-6cc3-2e24-203a-3b870e455d5b",
   "detail-type": "EC2 Spot Fleet State Change",
   "source": "aws.ec2spotfleet",
   "account": "123456789012",
   "time": "2020-11-09T08:57:06Z",
   "region": "us-east-1",
   "resources": [
      "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-4b6d274d-0cea-4b2c-b3be-9dc627ad1f55"
   ],
   "detail": {
      "sub-type": "submitted"
   }
}
```

The possible values for **sub-type** are:

- submitted

The Spot Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.

743
Spot Fleet event types

**active**

The Spot Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running Spot Instances.

**progress**

The Spot Fleet request is in the process of being fulfilled.

**cancelled_terminating**

The Spot Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

**cancelled_running**

The Spot Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

**cancelled**

The Spot Fleet request is deleted and has no running instances. The Spot Fleet will be deleted two days after its instances are terminated.

**modify_in_progress**

The Spot Fleet request is being modified. The request remains in this state until the modification is fully processed or the Spot Fleet request is deleted.

**modify_succeeded**

The Spot Fleet request was modified.

**expired**

The Spot Fleet request has expired. If the request was created with TerminateInstancesWithExpiration set, a subsequent event indicates that the instances are terminated.

**EC2 Spot Fleet Spot Instance Request Change**

Spot Fleet sends an EC2 Spot Fleet Spot Instance Request Change event to Amazon EventBridge when a Spot Instance request in the fleet changes state.

The following is example data for this event.

```json
{
    "version": "0",
    "id": "cd141ef0-14af-d670-a71d-fe46e9971bd2",
    "detail-type": "EC2 Spot Fleet Spot Instance Request Change",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T08:53:21Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-a98d2133-941a-47dc-8b03-0f94c6852ad1"
    ],
    "detail": {
        "spot-instance-request-id": "sir-a2w9gc5h",
        "description": "SpotInstanceRequestId sir-a2w9gc5h, PreviousState: cancelled_running",
```
The possible values for \texttt{sub-type} are:

\begin{itemize}
  \item \texttt{submitted} \quad The request is submitted.
  \item \texttt{disabled} \quad You stopped the Spot Instance.
  \item \texttt{active} \quad The request is fulfilled and has an associated Spot Instance.
  \item \texttt{cancelled} \quad You cancelled the request, or the request expired.
\end{itemize}

\section*{EC2 Spot Fleet Instance Change}

Spot Fleet sends an EC2 Spot Fleet Instance Change event to Amazon EventBridge when an instance in the fleet changes state.

The following is example data for this event.

\begin{verbatim}
{
  "version": "0",
  "id": "11591686-5bd7-bbbaa-eb40-d46529c2710f",
  "detail-type": "EC2 Spot Fleet Instance Change",
  "source": "aws.ec2spotfleet",
  "account": "123456789012",
  "time": "2020-11-09T07:25:02Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-c8a764a4-bedc-4b62-af9c-0095e6e3ba61"
  ],
  "detail": {
    "instance-id": "i-08b90df1e09c30c9b",
    "description": "{\"instanceType\":\"r4.2xlarge\",\"image\":\"ami-032930428bf1abbff \",\"productDescription\":\"Linux/UNIX\",\"availabilityZone\":\"us-east-1\"}",
    "sub-type": "launched"
  }
}
\end{verbatim}

The possible values for \texttt{sub-type} are:

\begin{itemize}
  \item \texttt{launched} \quad A new instance was launched.
  \item \texttt{terminated} \quad The instance was terminated.
  \item \texttt{termination_notified} \quad An instance termination notification was sent.
\end{itemize}
EC2 Spot Fleet Information

Spot Fleet sends an EC2 Spot Fleet Information event to Amazon EventBridge when there is an error during fulfillment. The information event does not block the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "73a60f70-3409-a66c-635c-7f66c5f5b669",
    "detail-type": "EC2 Spot Fleet Information",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-08T20:56:12Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-2531ea06-af18-4647-8757-7d69c94971b1"
    ],
    "detail": {
        "description": "r3.8xlarge, ami-032930428bf1abbff, Linux/UNIX, us-east-1a, Spot bid price is less than Spot market price $0.5291",
        "sub-type": "launchSpecUnusable"
    }
}
```

The possible values for sub-type are:

- **launchSpecUnusable**
  
  The price in a launch specification is not valid because it is below the Spot price or the Spot price is above the On-Demand price.

- **fleetProgressHalted**
  
  The price in every launch specification is not valid. A launch specification might become valid if the Spot price changes.

- **registerWithLoadBalancersFailed**
  
  An attempt to register instances with load balancers failed. For more information, see the description of the event.

- **launchSpecTemporarilyBlacklisted**
  
  The configuration is not valid and several attempts to launch instances have failed. For more information, see the description of the event.

EC2 Spot Fleet Error

Spot Fleet sends an EC2 Spot Fleet Error event to Amazon EventBridge when there is an error during fulfillment. The error event blocks the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "10adc4e7-675c-643e-125c-5bfa1b1ba5d2",
    "detail-type": "EC2 Spot Fleet Error",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-08T20:56:12Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-2531ea06-af18-4647-8757-7d69c94971b1"
    ],
    "detail": {
        "description": "r3.8xlarge, ami-032930428bf1abbff, Linux/UNIX, us-east-1a, Spot bid price is less than Spot market price $0.5291",
        "sub-type": "launchSpecUnusable"
    }
}
```
The possible values for sub-type are:

- allLaunchSpecsTemporarilyBlacklisted
  None of the configurations are valid, and several attempts to launch instances have failed. For more information, see the description of the event.

- spotFleetRequestConfigurationInvalid
  The configuration is not valid. For more information, see the description of the event.

- spotInstanceCountLimitExceeded
  You've reached the limit on the number of Spot Instances that you can launch.

### Create Amazon EventBridge rules

When a notification of a state change is emitted for an EC2 Fleet or Spot Fleet, the event for the notification is sent to Amazon EventBridge in the form of a JSON file. You can write an EventBridge rule to automate what actions to take when the event pattern matches the rule. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes the target (or targets) specified in the rule.

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

**Topics**
- Create Amazon EventBridge rules to monitor EC2 Fleet events (p. 747)
- Create Amazon EventBridge rules to monitor Spot Fleet events (p. 750)

### Create Amazon EventBridge rules to monitor EC2 Fleet events

When a notification of a state change is emitted for an EC2 Fleet, the event for the notification is sent to Amazon EventBridge in the form of a JSON file. You can write an EventBridge rule to automate what actions to take when an event pattern matches the rule. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes the target (or targets) specified in the rule.

The following fields form the event pattern that is defined in the rule:

- "source": "aws.ec2fleet"
  Identifies that the event is from EC2 Fleet.

- "detail-type": "EC2 Fleet State Change"
  Identifies the event type.
"detail": { "sub-type": "submitted" }

Identifies the event sub-type.

For the list of EC2 Fleet events and example event data, see the section called "EC2 Fleet event types" (p. 738).

**Examples**

- Create an EventBridge rule to send a notification (p. 748)
- Create an EventBridge rule to trigger a Lambda function (p. 749)

Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time that Amazon EC2 emits an EC2 Fleet state change notification. The signal in this example is emitted as an EC2 Fleet State Change event, which triggers the action defined by the rule. Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

**To create an EventBridge rule to send a notification when an EC2 Fleet state changes**

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose **Create rule**.
3. Enter a **Name** for the rule, and, optionally, a description.
   
   A rule can't have the same name as another rule in the same Region and on the same event bus.
4. For **Define pattern**, choose **Event pattern**.
5. Under **Event matching pattern**, you can choose **Pre-defined pattern by service** or **Custom pattern**. The **Custom pattern** allows you to create a more detailed rule.
   
   a. If you choose **Pre-defined pattern by service**, do the following:
      
      i. For **Service provider**, choose AWS.
      ii. For **Service name**, choose EC2 Fleet.
      iii. For **Event type**, select the required event type. For this example, choose EC2 Fleet Instance Change.
   
   b. If you choose **Custom pattern**, do the following:
      
      • In the **Event pattern** box, add the following pattern to match the EC2 Fleet Instance Change event for this example, and then choose **Save**.

```json
{
    "source": ["aws.ec2fleet"],
    "detail-type": ["EC2 Fleet Instance Change"]
}
```

6. For **Select event bus**, choose **AWS default event bus**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
7. Confirm that **Enable the rule on the selected event bus** is toggled on.
8. For **Target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
9. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
For more information, see Amazon EventBridge rules and Amazon EventBridge event patterns in the Amazon EventBridge User Guide

Create an EventBridge rule to trigger a Lambda function

The following example creates an EventBridge rule to trigger a Lambda function every time that Amazon EC2 emits an EC2 Fleet instance change notification for when an instance is launched. The signal in this example is emitted as an EC2 Fleet Instance Change event, sub-type launched, which triggers the action defined by the rule. Before creating the EventBridge rule, you must create the Lambda function.

To create an EventBridge rule to trigger a Lambda function when an instance in an EC2 Fleet changes state

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create function.
3. Enter a name for your function, configure the code, and then choose Create function.
   For more information about using Lambda, see Create a Lambda function with the console in the AWS Lambda Developer Guide.
4. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
5. Choose Create rule.
6. Enter a Name for the rule, and, optionally, a description.
   A rule can’t have the same name as another rule in the same Region and on the same event bus.
7. For Define pattern, choose Event pattern.
8. Under Event matching pattern, you can choose Pre-defined pattern by service or Custom pattern. The Custom pattern allows you to create a more detailed rule.
   a. If you choose Pre-defined pattern by service, do the following:
      i. For Service provider, choose AWS.
      ii. For Service name, choose EC2 Fleet.
      iii. For Event type, select the required event type. For this example, choose EC2 Fleet Instance Change.
   b. If you choose Custom pattern, do the following:
      • In the Event pattern box, add the following pattern to match the EC2 Fleet Instance Change event and launched sub-type for this example, and then choose Save.

   ```json
   {
      "source": ["aws.ec2fleet"],
      "detail-type": ["EC2 Fleet Instance Change"],
      "detail": {
        "sub-type": ["launched"]
      }
   }
   ```
9. For Target, choose Lambda function, and for Function, choose the function that you created to respond when the event occurs.
10. Choose Create.
   In this example, the Lambda function will be triggered when the EC2 Fleet Instance Change event with the sub-type launched occurs.
Create Amazon EventBridge rules to monitor Spot Fleet events

When a notification of a state change is emitted for a Spot Fleet, the event for the notification is sent to Amazon EventBridge in the form of a JSON file. You can write an EventBridge rule to automate what actions to take when an event pattern matches the rule. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes the target (or targets) specified in the rule.

The following fields form the event pattern that is defined in the rule:

- "source": "aws.ec2spotfleet"
  - Identifies that the event is from Spot Fleet.
- "detail-type": "EC2 Spot Fleet State Change"
  - Identifies the event type.
- "detail": { "sub-type": "submitted" }
  - Identifies the event sub-type.

For the list of Spot Fleet events and example event data, see the section called “Spot Fleet event types” (p. 743).

Examples
- Create an EventBridge rule to send a notification (p. 748)
- Create an EventBridge rule to trigger a Lambda function (p. 749)

Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time that Amazon EC2 emits a Spot Fleet state change notification. The signal in this example is emitted as an EC2 Spot Fleet State Change event, which triggers the action defined by the rule. Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule to send a notification when a Spot Fleet state changes

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. Enter a Name for the rule, and, optionally, a description.
   - A rule can't have the same name as another rule in the same Region and on the same event bus.
4. For Define pattern, choose Event pattern.
5. Under Event matching pattern, you can choose Pre-defined pattern by service or Custom pattern. The Custom pattern allows you to create a more detailed rule.
   a. If you choose Pre-defined pattern by service, do the following:
      i. For Service provider, choose AWS.
      ii. For Service name, choose EC2 Spot Fleet.
      iii. For Event type, select the required event type. For this example, choose EC2 Spot Fleet Instance Change.
Create EventBridge rules

b. If you choose Custom pattern, do the following:
   • In the Event pattern box, add the following pattern to match the EC2 Spot Fleet Instance Change event for this example, and then choose Save.

   ```
   {
     "source": ["aws.ec2spotfleet"],
     "detail-type": ["EC2 Spot Fleet Instance Change"]
   }
   ```

6. For Select event bus, choose AWS default event bus. When an AWS service in your account emits an event, it always goes to your account’s default event bus.

7. Confirm that Enable the rule on the selected event bus is toggled on.

8. For Target, choose SNS topic to send an email, text message, or mobile push notification when the event occurs.

9. For Topic, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.

10. For Configure input, choose the input for the email, text message, or mobile push notification.

11. Choose Create.

For more information, see Amazon EventBridge rules and Amazon EventBridge event patterns in the Amazon EventBridge User Guide

Create an EventBridge rule to trigger a Lambda function

The following example creates an EventBridge rule to trigger a Lambda function every time that Amazon EC2 emits a Spot Fleet instance change notification for when an instance is launched. The signal in this example is emitted as an EC2 Spot Fleet Instance Change event, sub-type launched, which triggers the action defined by the rule. Before creating the EventBridge rule, you must create the Lambda function.

To create an EventBridge rule to trigger a Lambda function when an instance in a Spot Fleet changes state

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create function.
3. Enter a name for your function, configure the code, and then choose Create function.

   For more information about using Lambda, see Create a Lambda function with the console in the AWS Lambda Developer Guide.

4. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
5. Choose Create rule.
6. Enter a Name for the rule, and, optionally, a description.

   A rule can't have the same name as another rule in the same Region and on the same event bus.

7. For Define pattern, choose Event pattern.
8. Under Event matching pattern, you can choose Pre-defined pattern by service or Custom pattern. The Custom pattern allows you to create a more detailed rule.

   a. If you choose Pre-defined pattern by service, do the following:

      i. For Service provider, choose AWS.

      ii. For Service name, choose EC2 Spot Fleet.
iii. For Event type, select the required event type. For this example, choose EC2 Spot Fleet Instance Change.

b. If you choose Custom pattern, do the following:

• In the Event pattern box, add the following pattern to match the EC2 Spot Fleet Instance Change event and launched sub-type for this example, and then choose Save.

```json
{
    "source": ["aws.ec2spotfleet"],
    "detail-type": ["EC2 Spot Fleet Instance Change"],
    "detail": {
        "sub-type": ["launched"]
    }
}
```

9. For Target, choose Lambda function, and for Function, choose the function that you created to respond when the event occurs.

10. Choose Create.

   In this example, the Lambda function will be triggered when the EC2 Fleet Instance Change event with the sub-type launched occurs.

For a tutorial on how to create a Lambda function and an EventBridge rule that runs the Lambda function, see Tutorial: Log the State of an Amazon EC2 Instance Using EventBridge in the AWS Lambda Developer Guide.

Tutorials for EC2 Fleet and Spot Fleet

The following tutorials take you through the common processes for creating EC2 Fleets and Spot Fleets.

Tutorials

• Tutorial: Use EC2 Fleet with instance weighting (p. 752)
• Tutorial: Use EC2 Fleet with On-Demand as the primary capacity (p. 755)
• Tutorial: Use Spot Fleet with instance weighting (p. 756)

Tutorial: Use EC2 Fleet with instance weighting

This tutorial uses a fictitious company called Example Corp to illustrate the process of requesting an EC2 Fleet using instance weighting.

Objective

Example Corp, a pharmaceutical company, wants to use the computational power of Amazon EC2 for screening chemical compounds that might be used to fight cancer.

Planning

Example Corp first reviews Spot Best Practices. Next, Example Corp determines the requirements for their EC2 Fleet.

Instance types

Example Corp has a compute- and memory-intensive application that performs best with at least 60 GB of memory and eight virtual CPUs (vCPUs). They want to maximize these resources for the application at
the lowest possible price. Example Corp decides that any of the following EC2 instance types would meet their needs:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Memory (GiB)</th>
<th>vCPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xlarge</td>
<td>61</td>
<td>8</td>
</tr>
<tr>
<td>r3.4xlarge</td>
<td>122</td>
<td>16</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>244</td>
<td>32</td>
</tr>
</tbody>
</table>

**Target capacity in units**

With instance weighting, target capacity can equal a number of instances (the default) or a combination of factors such as cores (vCPUs), memory (GiBs), and storage (GBs). By considering the base for their application (60 GB of RAM and eight vCPUs) as one unit, Example Corp decides that 20 times this amount would meet their needs. So the company sets the target capacity of their EC2 Fleet request to 20.

**Instance weights**

After determining the target capacity, Example Corp calculates instance weights. To calculate the instance weight for each instance type, they determine the units of each instance type that are required to reach the target capacity as follows:

- r3.2xlarge (61.0 GB, 8 vCPUs) = 1 unit of 20
- r3.4xlarge (122.0 GB, 16 vCPUs) = 2 units of 20
- r3.8xlarge (244.0 GB, 32 vCPUs) = 4 units of 20

Therefore, Example Corp assigns instance weights of 1, 2, and 4 to the respective launch configurations in their EC2 Fleet request.

**Price per unit hour**

Example Corp uses the On-Demand price per instance hour as a starting point for their price. They could also use recent Spot prices, or a combination of the two. To calculate the price per unit hour, they divide their starting price per instance hour by the weight. For example:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>On-Demand price</th>
<th>Instance weight</th>
<th>Price per unit hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xLarge</td>
<td>$0.7</td>
<td>1</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.4xLarge</td>
<td>$1.4</td>
<td>2</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.8xLarge</td>
<td>$2.8</td>
<td>4</td>
<td>$0.7</td>
</tr>
</tbody>
</table>

Example Corp could use a global price per unit hour of $0.7 and be competitive for all three instance types. They could also use a global price per unit hour of $0.7 and a specific price per unit hour of $0.9 in the r3.8xlarge launch specification.

**Verify permissions**

Before creating an EC2 Fleet, Example Corp verifies that it has an IAM role with the required permissions. For more information, see EC2 Fleet prerequisites (p. 685).
Create a launch template

Next, Example Corp creates a launch template. The launch template ID is used in the following step. For more information, see Create a launch template (p. 485).

Create the EC2 Fleet

Example Corp creates a file, config.json, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-07b3bc7625cdab851",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r3.2xlarge",
          "SubnetId": "subnet-482e4972",
          "WeightedCapacity": 1
        },
        {
          "InstanceType": "r3.4xlarge",
          "SubnetId": "subnet-482e4972",
          "WeightedCapacity": 2
        },
        {
          "InstanceType": "r3.8xlarge",
          "MaxPrice": "0.90",
          "SubnetId": "subnet-482e4972",
          "WeightedCapacity": 4
        }
      ]
    },
    "TargetCapacitySpecification": {
      "TotalTargetCapacity": 20,
      "DefaultTargetCapacityType": "spot"
    }
  ]
}
```

Example Corp creates the EC2 Fleet using the following create-fleet command.

```
aws ec2 create-fleet \
  --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet (p. 693).

Fulfillment

The allocation strategy determines which Spot capacity pools your Spot Instances come from.

With the lowest-price strategy (which is the default strategy), the Spot Instances come from the pool with the lowest price per unit at the time of fulfillment. To provide 20 units of capacity, the EC2 Fleet launches either 20 r3.2xlarge instances (20 divided by 1), 10 r3.4xlarge instances (20 divided by 2), or 5 r3.8xlarge instances (20 divided by 4).
If Example Corp used the diversified strategy, the Spot Instances would come from all three pools. The EC2 Fleet would launch 6 \( r3.2xlarge \) instances (which provide 6 units), 3 \( r3.4xlarge \) instances (which provide 6 units), and 2 \( r3.8xlarge \) instances (which provide 8 units), for a total of 20 units.

**Tutorial: Use EC2 Fleet with On-Demand as the primary capacity**

This tutorial uses a fictitious company called ABC Online to illustrate the process of requesting an EC2 Fleet with On-Demand as the primary capacity, and Spot capacity if available.

**Objective**

ABC Online, a restaurant delivery company, wants to be able to provision Amazon EC2 capacity across EC2 instance types and purchasing options to achieve their desired scale, performance, and cost.

**Plan**

ABC Online requires a fixed capacity to operate during peak periods, but would like to benefit from increased capacity at a lower price. ABC Online determines the following requirements for their EC2 Fleet:

- On-Demand Instance capacity – ABC Online requires 15 On-Demand Instances to ensure that they can accommodate traffic at peak periods.
- Spot Instance capacity – ABC Online would like to improve performance, but at a lower price, by provisioning 5 Spot Instances.

**Verify permissions**

Before creating an EC2 Fleet, ABC Online verifies that it has an IAM role with the required permissions. For more information, see EC2 Fleet prerequisites (p. 685).

**Create a launch template**

Next, ABC Online creates a launch template. The launch template ID is used in the following step. For more information, see Create a launch template (p. 485).

**Create the EC2 Fleet**

ABC Online creates a file, `config.json`, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```json
{
   "LaunchTemplateConfigs": [
   {
      "LaunchTemplateSpecification": {
         "LaunchTemplateId": "lt-07b3bc7625cdab851",
         "Version": "2"
      }
   },
   "TargetCapacitySpecification": {
      "TotalTargetCapacity": 20,
      "OnDemandTargetCapacity": 15,
      "DefaultTargetCapacityType": "spot"
   }
}
```
ABC Online creates the EC2 Fleet using the following create-fleet command.

```
aws ec2 create-fleet \
   --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet (p. 693).

**Fulfillment**

The allocation strategy determines that the On-Demand capacity is always fulfilled, while the balance of the target capacity is fulfilled as Spot if there is capacity and availability.

**Tutorial: Use Spot Fleet with instance weighting**

This tutorial uses a fictitious company called Example Corp to illustrate the process of requesting a Spot Fleet using instance weighting.

**Objective**

Example Corp, a pharmaceutical company, wants to leverage the computational power of Amazon EC2 for screening chemical compounds that might be used to fight cancer.

**Planning**

Example Corp first reviews Spot Best Practices. Next, Example Corp determines the following requirements for their Spot Fleet.

**Instance types**

Example Corp has a compute- and memory-intensive application that performs best with at least 60 GB of memory and eight virtual CPUs (vCPUs). They want to maximize these resources for the application at the lowest possible price. Example Corp decides that any of the following EC2 instance types would meet their needs:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Memory (GiB)</th>
<th>vCPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xlarge</td>
<td>61</td>
<td>8</td>
</tr>
<tr>
<td>r3.4xlarge</td>
<td>122</td>
<td>16</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>244</td>
<td>32</td>
</tr>
</tbody>
</table>

**Target capacity in units**

With instance weighting, target capacity can equal a number of instances (the default) or a combination of factors such as cores (vCPUs), memory (GiBs), and storage (GBs). By considering the base for their application (60 GB of RAM and eight vCPUs) as 1 unit, Example Corp decides that 20 times this amount would meet their needs. So the company sets the target capacity of their Spot Fleet request to 20.

**Instance weights**

After determining the target capacity, Example Corp calculates instance weights. To calculate the instance weight for each instance type, they determine the units of each instance type that are required to reach the target capacity as follows:
• r3.2xlarge (61.0 GB, 8 vCPUs) = 1 unit of 20
• r3.4xlarge (122.0 GB, 16 vCPUs) = 2 units of 20
• r3.8xlarge (244.0 GB, 32 vCPUs) = 4 units of 20

Therefore, Example Corp assigns instance weights of 1, 2, and 4 to the respective launch configurations in their Spot Fleet request.

Price per unit hour

Example Corp uses the On-Demand price per instance hour as a starting point for their price. They could also use recent Spot prices, or a combination of the two. To calculate the price per unit hour, they divide their starting price per instance hour by the weight. For example:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>On-Demand price</th>
<th>Instance weight</th>
<th>Price per unit hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xLarge</td>
<td>$0.7</td>
<td>1</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.4xLarge</td>
<td>$1.4</td>
<td>2</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.8xLarge</td>
<td>$2.8</td>
<td>4</td>
<td>$0.7</td>
</tr>
</tbody>
</table>

Example Corp could use a global price per unit hour of $0.7 and be competitive for all three instance types. They could also use a global price per unit hour of $0.7 and a specific price per unit hour of $0.9 in the r3.8xlarge launch specification.

Verify permissions

Before creating a Spot Fleet request, Example Corp verifies that it has an IAM role with the required permissions. For more information, see Spot Fleet permissions (p. 713).

Create the request

Example Corp creates a file, config.json, with the following configuration for its Spot Fleet request:

```json
{
  "SpotPrice": "0.70",
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "r3.2xlarge",
      "SubnetId": "subnet-482e4972",
      "WeightedCapacity": 1
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "r3.4xlarge",
      "SubnetId": "subnet-482e4972",
      "WeightedCapacity": 2
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "r3.8xlarge",
      "SubnetId": "subnet-482e4972",
      "SpotPrice": "0.90",
      "WeightedCapacity": 4
    }
  ]
}
```
Example Corp creates the Spot Fleet request using the `request-spot-fleet` command.

```
aws ec2 request-spot-fleet --spot-fleet-request-config file://config.json
```

For more information, see Spot Fleet request types (p. 703).

**Fulfillment**

The allocation strategy determines which Spot capacity pools your Spot Instances come from.

With the `lowestPrice` strategy (which is the default strategy), the Spot Instances come from the pool with the lowest price per unit at the time of fulfillment. To provide 20 units of capacity, the Spot Fleet launches either 20 `r3.2xlarge` instances (20 divided by 1), 10 `r3.4xlarge` instances (20 divided by 2), or 5 `r3.8xlarge` instances (20 divided by 4).

If Example Corp used the `diversified` strategy, the Spot Instances would come from all three pools. The Spot Fleet would launch 6 `r3.2xlarge` instances (which provide 6 units), 3 `r3.4xlarge` instances (which provide 6 units), and 2 `r3.8xlarge` instances (which provide 8 units), for a total of 20 units.

**Example configurations for EC2 Fleet and Spot Fleet**

The following examples show launch configurations that you can use to create EC2 Fleets and Spot Fleets.

**Topics**
- EC2 Fleet example configurations (p. 758)
- Spot Fleet example configurations (p. 772)

**EC2 Fleet example configurations**

The following examples show launch configurations that you can use with the `create-fleet` command to create an EC2 Fleet. For more information about the `create-fleet` parameters, see the EC2 Fleet JSON configuration file reference (p. 690).

**Examples**
- Example 1: Launch Spot Instances as the default purchasing option (p. 759)
- Example 2: Launch On-Demand Instances as the default purchasing option (p. 759)
- Example 3: Launch On-Demand Instances as the primary capacity (p. 760)
- Example 4: Launch Spot Instances using the lowest-price allocation strategy (p. 760)
- Example 5: Launch On-Demand Instances using Capacity Reservations and the prioritized allocation strategy (p. 761)
- Example 6: Launch On-Demand Instances using Capacity Reservations and the prioritized allocation strategy when the total target capacity is more than the number of unused Capacity Reservations (p. 763)
Example 1: Launch Spot Instances as the default purchasing option

The following example specifies the minimum parameters required in an EC2 Fleet: a launch template, target capacity, and default purchasing option. The launch template is identified by its launch template ID and version number. The target capacity for the fleet is 2 instances, and the default purchasing option is spot, which results in the fleet launching 2 Spot Instances.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 2,
        "DefaultTargetCapacityType": "spot"
    }
}
```

Example 2: Launch On-Demand Instances as the default purchasing option

The following example specifies the minimum parameters required in an EC2 Fleet: a launch template, target capacity, and default purchasing option. The launch template is identified by its launch template ID and version number. The target capacity for the fleet is 2 instances, and the default purchasing option is on-demand, which results in the fleet launching 2 On-Demand Instances.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 2,
        "DefaultTargetCapacityType": "on-demand"
    }
}
```
Example 3: Launch On-Demand Instances as the primary capacity

The following example specifies the total target capacity of 2 instances for the fleet, and a target capacity of 1 On-Demand Instance. The default purchasing option is spot. The fleet launches 1 On-Demand Instance as specified, but needs to launch one more instance to fulfill the total target capacity. The purchasing option for the difference is calculated as $\text{TotalTargetCapacity} - \text{OnDemandTargetCapacity} = \text{DefaultTargetCapacityType}$, which results in the fleet launching 1 Spot Instance.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-0e8c754449b27161c",
        "Version": "1"
      }
    },
    "TargetCapacitySpecification": {
      "TotalTargetCapacity": 2,
      "OnDemandTargetCapacity": 1,
      "DefaultTargetCapacityType": "spot"
    }
  }
}
```

Example 4: Launch Spot Instances using the lowest-price allocation strategy

If the allocation strategy for Spot Instances is not specified, the default allocation strategy, which is lowest-price, is used. The following example uses the lowest-price allocation strategy. The three launch specifications, which override the launch template, have different instance types but the same weighted capacity and subnet. The total target capacity is 2 instances and the default purchasing option is spot. The EC2 Fleet launches 2 Spot Instances using the instance type of the launch specification with the lowest price.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-0e8c754449b27161c",
        "Version": "1"
      }
    },
    "Overrides": [
      {
        "InstanceType": "c4.large",
        "WeightedCapacity": 1,
        "SubnetId": "subnet-a4f6c5d3"
      },
      {
        "InstanceType": "c3.large",
        "WeightedCapacity": 1,
        "SubnetId": "subnet-a4f6c5d3"
      },
      {
        "InstanceType": "c5.large",
```
Example 5: Launch On-Demand Instances using Capacity Reservations and the prioritized allocation strategy

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if multiple instance pools have unused Capacity Reservations, the chosen On-Demand allocation strategy is applied. In this example, the On-Demand allocation strategy is prioritized.

In this example, there are 15 available unused Capacity Reservations. This is more than the fleet's target On-Demand capacity of 12 On-Demand Instances.

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```
{
   "CapacityReservationId": "cr-111",
   "InstanceType": "c4.large",
   "InstancePlatform": "Linux/UNIX",
   "AvailabilityZone": "us-east-1a",
   "AvailableInstanceCount": 5,
   "InstanceMatchCriteria": "open",
   "State": "active"
}

{
   "CapacityReservationId": "cr-222",
   "InstanceType": "c3.large",
   "InstancePlatform": "Linux/UNIX",
   "AvailabilityZone": "us-east-1a",
   "AvailableInstanceCount": 5,
   "InstanceMatchCriteria": "open",
   "State": "active"
}

{
   "CapacityReservationId": "cr-333",
   "InstanceType": "c5.large",
   "InstancePlatform": "Linux/UNIX",
   "AvailabilityZone": "us-east-1a",
   "AvailableInstanceCount": 5,
   "InstanceMatchCriteria": "open",
   "State": "active"
}
```

The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is prioritized, and the usage strategy for Capacity Reservations is use-capacity-reservations-first. The total target capacity is 12, and the default target capacity type is on-demand.
Note
The fleet type must be instant. use-capacity-reservations-first is not supported for other fleet types.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-1234567890abcdefg",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "c4.large",
          "AvailabilityZone": "us-east-1a",
          "WeightedCapacity": 1,
          "Priority": 1.0
        },
        {
          "InstanceType": "c3.large",
          "AvailabilityZone": "us-east-1a",
          "WeightedCapacity": 1,
          "Priority": 2.0
        },
        {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a",
          "WeightedCapacity": 1,
          "Priority": 3.0
        }
      ]
    }
  ],
  "TargetCapacitySpecification": {
    "TotalTargetCapacity": 12,
    "DefaultTargetCapacityType": "on-demand"
  },
  "OnDemandOptions": {
    "AllocationStrategy": "prioritized",
    "CapacityReservationOptions": {
      "UsageStrategy": "use-capacity-reservations-first"
    }
  },
  "Type": "instant",
}
```

After you create the instant fleet using the preceding configuration, the following 12 instances are launched to meet the target capacity:

- 5 c4.large On-Demand Instances in us-east-1a – c4.large in us-east-1a is prioritized first, and there are 5 available unused c4.large Capacity Reservations
- 5 c3.large On-Demand Instances in us-east-1a – c3.large in us-east-1a is prioritized second, and there are 5 available unused c3.large Capacity Reservations
- 2 c5.large On-Demand Instances in us-east-1a – c5.large in us-east-1a is prioritized third, and there are 5 available unused c5.large Capacity Reservations of which only 2 are needed to meet the target capacity

After the fleet is launched, you can run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the c4.large and c3.large Capacity Reservations were used, with 3 c5.large Capacity Reservations remaining unused.
Example 6: Launch On-Demand Instances using Capacity Reservations and the prioritized allocation strategy when the total target capacity is more than the number of unused Capacity Reservations

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to `use-capacity-reservations-first`. And if the number of unused Capacity Reservations is less than the On-Demand target capacity, the remaining On-Demand target capacity is launched according to the chosen On-Demand allocation strategy. In this example, the On-Demand allocation strategy is prioritized.

In this example, there are 15 available unused Capacity Reservations. This is less than the fleet's On-Demand target capacity of 16 On-Demand Instances.

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by `AvailableInstanceCount`.

```json
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "c4.large",
  "AvailableInstanceCount": 5,
  "InstanceMatchCriteria": "open",
  "State": "active"
}
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "c3.large",
  "AvailableInstanceCount": 5,
  "InstanceMatchCriteria": "open",
  "State": "active"
}
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "c5.large",
  "AvailableInstanceCount": 3
}
```
The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is prioritized, and the usage strategy for Capacity Reservations is use-capacity-reservations-first. The total target capacity is 16, and the default target capacity type is on-demand.

**Note**

The fleet type must be instant. use-capacity-reservations-first is not supported for other fleet types.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-0e8ec754449b27161c",
        "Version": "1"
      }
    },
    {
      "Overrides": [
        {
          "InstanceType": "c4.large",
          "AvailabilityZone": "us-east-1a",
          "WeightedCapacity": 1,
          "Priority": 1.0
        },
        {
          "InstanceType": "c3.large",
          "AvailabilityZone": "us-east-1a",
          "WeightedCapacity": 1,
          "Priority": 2.0
        },
        {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a",
          "WeightedCapacity": 1,
          "Priority": 3.0
        }
      ]
    },
    {
      "TargetCapacitySpecification": {
        "TotalTargetCapacity": 16,
        "DefaultTargetCapacityType": "on-demand"
      },
      "OnDemandOptions": {
        "AllocationStrategy": "prioritized"
      }
    }]
}
```

After you create the instant fleet using the preceding configuration, the following 16 instances are launched to meet the target capacity:

- 6 c4.large On-Demand Instances in us-east-1a – c4.large in us-east-1a is prioritized first, and there are 5 available unused c4.large Capacity Reservations. The Capacity Reservations are used first to launch
5 On-Demand Instances plus an additional On-Demand Instance is launched according to the On-Demand allocation strategy, which is prioritized in this example.

- 5 c3.large On-Demand Instances in us-east-1a – c3.large in us-east-1a is prioritized second, and there are 5 available unused c3.large Capacity Reservations
- 5 c5.large On-Demand Instances in us-east-1a – c5.large in us-east-1a is prioritized third, and there are 5 available unused c5.large Capacity Reservations

After the fleet is launched, you can run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "c4.large",
    "AvailableInstanceCount": 0
}
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "c3.large",
    "AvailableInstanceCount": 0
}
{
    "CapacityReservationId": "cr-333",
    "InstanceType": "c5.large",
    "AvailableInstanceCount": 0
}
```

Example 7: Launch On-Demand Instances using Capacity Reservations and the lowest-price allocation strategy

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if multiple instance pools have unused Capacity Reservations, the chosen On-Demand allocation strategy is applied. In this example, the On-Demand allocation strategy is lowest-price.

In this example, there are 15 available unused Capacity Reservations. This is more than the fleet's target On-Demand capacity of 12 On-Demand Instances.

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 0
}
```
The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is **lowest-price**, and the usage strategy for Capacity Reservations is **use-capacity-reservations-first**. The total target capacity is 12, and the default target capacity type is **on-demand**.

In this example, the On-Demand Instance price is:

- m5.large – $0.096 per hour
- m4.xlarge – $0.20 per hour
- m4.2xlarge – $0.40 per hour

**Note**
The fleet type must be **instant**. **use-capacity-reservations-first** is not supported for other fleet types.
After you create the instant fleet using the preceding configuration, the following 12 instances are launched to meet the target capacity:

- 5 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is the lowest price, and there are 5 available unused m5.large Capacity Reservations
- 5 m4.xlarge On-Demand Instances in us-east-1a – m4.xlarge in us-east-1a is the next lowest price, and there are 5 available unused m4.xlarge Capacity Reservations
- 2 m4.2xlarge On-Demand Instances in us-east-1a – m4.2xlarge in us-east-1a is the third lowest price, and there are 5 available unused m4.2xlarge Capacity Reservations of which only 2 are needed to meet the target capacity

After the fleet is launched, you can run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the m5.large and m4.xlarge Capacity Reservations were used, with 3 m4.2xlarge Capacity Reservations remaining unused.

```
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "m5.large",
  "AvailableInstanceCount": 0
}
{
  "CapacityReservationId": "cr-222",
  "InstanceType": "m4.xlarge",
  "AvailableInstanceCount": 0
}
{
  "CapacityReservationId": "cr-333",
  "InstanceType": "m4.2xlarge",
  "AvailableInstanceCount": 3
}
```

**Example 8: Launch On-Demand Instances using Capacity Reservations and the lowest-price allocation strategy when the total target capacity is more than the number of unused Capacity Reservations**

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if the number of unused Capacity Reservations is less than the On-Demand target capacity, the remaining On-Demand target capacity is launched according to the chosen On-Demand allocation strategy. In this example, the On-Demand allocation strategy is lowest-price.

In this example, there are 15 available unused Capacity Reservations. This is less than the fleet's On-Demand target capacity of 16 On-Demand Instances.
The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by `AvailableInstanceCount`.

```json
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
{
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is `lowest-price`, and the usage strategy for Capacity Reservations is `use-capacity-reservations-first`. The total target capacity is 16, and the default target capacity type is `on-demand`.

In this example, the On-Demand Instance price is:

- m5.large – $0.096 per hour
- m4.xlarge – $0.20 per hour
- m4.2xlarge – $0.40 per hour

**Note**
The fleet type must be `instant`. `use-capacity-reservations-first` is not supported for other fleet types.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }
        }
    ]
}
```
After you create the **instant** fleet using the preceding configuration, the following 16 instances are launched to meet the target capacity:

- 6 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is the lowest price, and there are 5 available unused m5.large Capacity Reservations. The Capacity Reservations are used first to launch 5 On-Demand Instances plus an additional On-Demand Instance is launched according to the On-Demand allocation strategy, which is **lowest-price** in this example.
- 5 m4.xlarge On-Demand Instances in us-east-1a – m4.xlarge in us-east-1a is the next lowest price, and there are 5 available unused m4.xlarge Capacity Reservations
- 5 m4.2xlarge On-Demand Instances in us-east-1a – m4.2xlarge in us-east-1a is the third lowest price, and there are 5 available unused m4.2xlarge Capacity Reservations

After the fleet is launched, you can run `describe-capacity-reservations` to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```json
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "m5.large",
  "AvailableInstanceCount": 0
}
{
  "CapacityReservationId": "cr-222",
  "InstanceType": "m4.xlarge",
  "AvailableInstanceCount": 0
}
{
  "CapacityReservationId": "cr-333",
  "InstanceType": "m4.2xlarge",
  "AvailableInstanceCount": 0
}
```
Example 9: Configure Capacity Rebalancing to launch replacement Spot Instances

The following example configures the EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation for a Spot Instance in the fleet. To configure the automatic replacement of Spot Instances, for `ReplacementStrategy`, specify `launch`.

**Note**

When a replacement instance is launched, the instance marked for rebalance is not automatically terminated. You can terminate it, or you can leave it running. You are charged for both instances while they are running.

The effectiveness of the Capacity Rebalancing strategy depends on the number of Spot capacity pools specified in the EC2 Fleet request. We recommend that you configure the fleet with a diversified set of instance types and Availability Zones, and for `AllocationStrategy`, specify `capacity-optimized`. For more information about what you should consider when configuring an EC2 Fleet for Capacity Rebalancing, see Capacity Rebalancing (p. 680).

```json
{
    "ExcessCapacityTerminationPolicy": "termination",
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "LaunchTemplate",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "c3.large",
                    "WeightedCapacity": 1,
                    "Placement": {
                        "AvailabilityZone": "us-east-1a"
                    }
                },
                {
                    "InstanceType": "c4.large",
                    "WeightedCapacity": 1,
                    "Placement": {
                        "AvailabilityZone": "us-east-1a"
                    }
                },
                {
                    "InstanceType": "c5.large",
                    "WeightedCapacity": 1,
                    "Placement": {
                        "AvailabilityZone": "us-east-1a"
                    }
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 5,
        "DefaultTargetCapacityType": "spot"
    },
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "MaintenanceStrategies": {
            "CapacityRebalance": {
                "ReplacementStrategy": "launch"
            }
        }
    }
}
```
Example 10: Launch Spot Instances in a capacity-optimized fleet

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for capacity. To optimize for capacity, you must set AllocationStrategy to capacity-optimized.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "r4.2xlarge",
                    "Placement": {
                        "AvailabilityZone": "us-west-2a"
                    },
                },
                {
                    "InstanceType": "m4.2xlarge",
                    "Placement": {
                        "AvailabilityZone": "us-west-2b"
                    },
                },
                {
                    "InstanceType": "c5.2xlarge",
                    "Placement": {
                        "AvailabilityZone": "us-west-2b"
                    }
                }
            ]
        },
        "TargetCapacitySpecification": {
            "TotalTargetCapacity": 50,
            "DefaultTargetCapacityType": "spot"
        }
    }
}
```

Example 11: Launch Spot Instances in a capacity-optimized fleet with priorities

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for capacity while using priority on a best-effort basis.

When using the capacity-optimized-prioritized allocation strategy, you can use the Priority parameter to specify the priorities of the Spot capacity pools, where the lower the number the higher priority. You can also set the same priority for several Spot capacity pools if you favor them equally. If you do not set a priority for a pool, the pool will be considered last in terms of priority.
To prioritize Spot capacity pools, you must set `AllocationStrategy` to `capacity-optimized-prioritized`. EC2 Fleet will optimize for capacity first, but will honor the priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect EC2 Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

In the following example, the three launch specifications specify three Spot capacity pools. Each pool is prioritized, where the lower the number the higher priority. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with the highest priority on a best-effort basis, but optimizes for capacity first.

```json
{
  "SpotOptions": {
    "AllocationStrategy": "capacity-optimized-prioritized"
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateName": "my-launch-template",
      "Version": "1"
    },
    "Overrides": [
      {
        "InstanceType": "r4.2xlarge",
        "Priority": 1
      },
      {
        "InstanceType": "m4.2xlarge",
        "Priority": 2
      },
      {
        "InstanceType": "c5.2xlarge",
        "Priority": 3
      }
    ],
    "TargetCapacitySpecification": {
      "TotalTargetCapacity": 50,
      "DefaultTargetCapacityType": "spot"
    }
  }
}
```

### Spot Fleet example configurations

The following examples show launch configurations that you can use with the `request-spot-fleet` command to create a Spot Fleet request. For more information, see Create a Spot Fleet request (p. 717).

**Note**

For Spot Fleet, you can't specify an network interface ID in a launch specification. Make sure you omit the `NetworkInterfaceID` parameter in your launch specification.

**Examples**

772
Example 1: Launch Spot Instances using the lowest-priced Availability Zone or subnet in the Region (p. 773)

The following example specifies a single launch specification without an Availability Zone or subnet. The Spot Fleet launches the instances in the lowest-priced Availability Zone that has a default subnet. The price you pay does not exceed the On-Demand price.

```
{
    "TargetCapacity": 20,
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
            "KeyName": "my-key-pair",
            "SecurityGroups": [
                {
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "InstanceType": "m3.medium",
            "IamInstanceProfile": {
                "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
            }
        }
    ]
}
```

Example 2: Launch Spot Instances using the lowest-priced Availability Zone or subnet in a specified list (p. 773)

The following examples specify two launch specifications with different Availability Zones or subnets, but the same instance type and AMI.

**Availability Zones**

The Spot Fleet launches the instances in the default subnet of the lowest-priced Availability Zone that you specified.

```
{
    "TargetCapacity": 20,
```
Spot Fleet example configurations

```
"IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
"LaunchSpecifications": [
  
  {  
    "ImageId": "ami-1a2b3c4d",
    "KeyName": "my-key-pair",
    "SecurityGroups": [  
      
    
      {  
        "GroupId": "sg-1a2b3c4d"
      }
    ],
    "InstanceType": "m3.medium",
    "Placement": {
      "AvailabilityZone": "us-west-2a, us-west-2b"
    },
    "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
    }
  }
]
```

Subnets

You can specify default subnets or nondefault subnets, and the nondefault subnets can be from a default VPC or a nondefault VPC. The Spot service launches the instances in whichever subnet is in the lowest-priced Availability Zone.

You can't specify different subnets from the same Availability Zone in a Spot Fleet request.

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
    
    {  
      "ImageId": "ami-1a2b3c4d",
      "KeyName": "my-key-pair",
      "SecurityGroups": [  
        
        {  
          "GroupId": "sg-1a2b3c4d"
        }
      ],
      "InstanceType": "m3.medium",
      "SubnetId": "subnet-a61dafcf, subnet-65e5f08",
      "IamInstanceProfile": {
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
      }
    }
  ]
}
```

If the instances are launched in a default VPC, they receive a public IPv4 address by default. If the instances are launched in a nondefault VPC, they do not receive a public IPv4 address by default. Use a network interface in the launch specification to assign a public IPv4 address to instances launched in a nondefault VPC. When you specify a network interface, you must include the subnet ID and security group ID using the network interface.

```
...
{
  "ImageId": "ami-1a2b3c4d",
  "KeyName": "my-key-pair",
  "InstanceType": "m3.medium",
  "NetworkInterfaces": [

```
Example 3: Launch Spot Instances using the lowest-priced instance type in a specified list

The following examples specify two launch configurations with different instance types, but the same AMI and Availability Zone or subnet. The Spot Fleet launches the instances using the specified instance type with the lowest price.

**Availability Zone**

```json
{
    "TargetCapacity": 20,
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
            "SecurityGroups": [
                {
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "InstanceType": "cc2.8xlarge",
            "Placement": {
                "AvailabilityZone": "us-west-2b"
            }
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "SecurityGroups": [
                {
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "InstanceType": "r3.xlarge",
            "Placement": {
                "AvailabilityZone": "us-west-2b"
            }
        }
    ]
}
```

**Subnet**

```json
{
    "TargetCapacity": 20,
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
```
Example 4. Override the price for the request

We recommended that you use the default maximum price, which is the On-Demand price. If you prefer, you can specify a maximum price for the fleet request and maximum prices for individual launch specifications.

The following examples specify a maximum price for the fleet request and maximum prices for two of the three launch specifications. The maximum price for the fleet request is used for any launch specification that does not specify a maximum price. The Spot Fleet launches the instances using the instance type with the lowest price.

Availability Zone

{  "SpotPrice": "1.00",  "TargetCapacity": 30,  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",  "LaunchSpecifications": [    {      "ImageId": "ami-1a2b3c4d",      "InstanceId": "c3.2xlarge",      "Placement": {        "AvailabilityZone": "us-west-2b"      },      "SpotPrice": "0.10"    },    {      "ImageId": "ami-1a2b3c4d",      "InstanceId": "c3.4xlarge",      "Placement": {        "AvailabilityZone": "us-west-2b"      },      "SpotPrice": "0.20"    },    {      "ImageId": "ami-1a2b3c4d",      "InstanceId": "c3.8xlarge",      "Placement": {        "AvailabilityZone": "us-west-2b"      }    }  ]}
Example 5: Launch a Spot Fleet using the diversified allocation strategy

The following example uses the diversified allocation strategy. The launch specifications have different instance types but the same AMI and Availability Zone or subnet. The Spot Fleet distributes the 30 instances across the three launch specifications, such that there are 10 instances of each type. For more information, see Allocation strategy for Spot Instances (p. 704).

Availability Zone

```json
{
  "SpotPrice": "0.70",
  "TargetCapacity": 30,
  "AllocationStrategy": "diversified",
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "c4.2xlarge",
      "Placement": {
        "AvailabilityZone": "us-west-2b"
      }
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "m3.2xlarge",
      "Placement": {
        "AvailabilityZone": "us-west-2b"
      }
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "c4.2xlarge",
      "Placement": {
        "AvailabilityZone": "us-west-2b"
      }
    }
  ]
}
```
A best practice to increase the chance that a spot request can be fulfilled by EC2 capacity in the event of an outage in one of the Availability Zones is to diversify across zones. For this scenario, include each Availability Zone available to you in the launch specification. And, instead of using the same subnet each time, use three unique subnets (each mapping to a different zone).

**Availability Zone**

```json
{
   "SpotPrice": "0.70",
   "TargetCapacity": 30,
   "AllocationStrategy": "diversified",
   "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
   "LaunchSpecifications": [
      {
         "ImageId": "ami-1a2b3c4d",
         "InstanceType": "c4.2xlarge",
         "Placement": { "AvailabilityZone": "us-west-2a"
      }
      },
      {
         "ImageId": "ami-1a2b3c4d",
         "InstanceType": "m3.2xlarge",
         "Placement": { "AvailabilityZone": "us-west-2b"
      }
      },
      {
         "ImageId": "ami-1a2b3c4d",
         "InstanceType": "r3.2xlarge",
         "Placement": { "AvailabilityZone": "us-west-2b"
      }
      }]
```
Example 6: Launch a Spot Fleet using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight. The Spot Fleet selects the instance type with the lowest price per unit hour. The Spot Fleet calculates the number of Spot Instances to launch by dividing the target capacity by the instance weight. If the result isn’t an integer, the Spot Fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity.

If the r3.2xlarge request is successful, Spot provisions 4 of these instances. Divide 20 by 6 for a total of 3.33 instances, then round up to 4 instances.

If the c3.xlarge request is successful, Spot provisions 7 of these instances. Divide 20 by 3 for a total of 6.66 instances, then round up to 7 instances.

For more information, see Spot Fleet instance weighting (p. 709).

Availability Zone

```json
{
    "SpotPrice": "0.70",
    "TargetCapacity": 20,
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "c4.2xlarge",
            "SubnetId": "subnet-1a2b3c4d"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "m3.2xlarge",
            "SubnetId": "subnet-2a2b3c4d"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "r3.2xlarge",
            "SubnetId": "subnet-3a2b3c4d"
        }
    ]
}
```
"Placement": {
    "AvailabilityZone": "us-west-2b"
},
"WeightedCapacity": 6
},
{
    "ImageId": "ami-1a2b3c4d",
    "InstanceType": "c3.xlarge",
    "Placement": {
        "AvailabilityZone": "us-west-2b"
    },
    "WeightedCapacity": 3
}]
}

Subnet

{
    "SpotPrice": "0.70",
    "TargetCapacity": 20,
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "r3.2xlarge",
            "SubnetId": "subnet-1a2b3c4d",
            "WeightedCapacity": 6
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "c3.xlarge",
            "SubnetId": "subnet-1a2b3c4d",
            "WeightedCapacity": 3
        }
    ]
}

Example 7: Launch a Spot Fleet with On-Demand capacity

To ensure that you always have instance capacity, you can include a request for On-Demand capacity in your Spot Fleet request. If there is capacity, the On-Demand request is always fulfilled. The balance of the target capacity is fulfilled as Spot if there is capacity and availability.

The following example specifies the desired target capacity as 10, of which 5 must be On-Demand capacity. Spot capacity is not specified; it is implied in the balance of the target capacity minus the On-Demand capacity. Amazon EC2 launches 5 capacity units as On-Demand, and 5 capacity units (10-5=5) as Spot if there is available Amazon EC2 capacity and availability.

For more information, see On-Demand in Spot Fleet (p. 706).

{  
    "IamFleetRole": "arn:aws:iam::781603563322:role/aws-ec2-spot-fleet-tagging-role",
    "AllocationStrategy": "lowestPrice",
    "TargetCapacity": 10,
    "SpotPrice": null,
    "ValidFrom": "2018-04-04T15:58:13Z",
    "ValidUntil": "2019-04-04T15:58:13Z",
    "TerminateInstancesWithExpiration": true,
    "LaunchSpecifications": [],
    "Type": "maintain",
    "OnDemandTargetCapacity": 5,
}
Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances

The following example configures the Spot Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation for a Spot Instance in the fleet. To configure the automatic replacement of Spot Instances, for `ReplacementStrategy`, specify `launch`.

**Note**
When a replacement instance is launched, the instance marked for rebalance is not automatically terminated. You can terminate it, or you can leave it running. You are charged for both instances while they are running.

The effectiveness of the Capacity Rebalancing strategy depends on the number of Spot capacity pools specified in the Spot Fleet request. We recommend that you configure the fleet with a diversified set of instance types and Availability Zones, and for `AllocationStrategy`, specify `capacityOptimized`. For more information about what you should consider when configuring a Spot Fleet for Capacity Rebalancing, see Capacity Rebalancing (p. 707).

```json
{"SpotFleetRequestConfig": {
   "AllocationStrategy": "capacityOptimized",
   "IamFleetRole": "arn:aws:iam::000000000000:role/aws-ec2-spot-fleet-tagging-role",
   "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification": {
            "LaunchTemplateName": "LaunchTemplate",
            "Version": "1"
         },
         "Overrides": [
            {
               "InstanceType": "c3.large",
               "WeightedCapacity": 1,
               "Placement": {
                  "AvailabilityZone": "us-east-1a"
               }
            },
            {
               "InstanceType": "c4.large",
               "WeightedCapacity": 1,
               "Placement": {
                  "AvailabilityZone": "us-east-1a"
               }
            },
            {
               "InstanceType": "c5.large",
               "WeightedCapacity": 1,
               "Placement": {
                  "AvailabilityZone": "us-east-1a"
               }
            }
         ]
      }
   ]
}
```
Example 9: Launch Spot Instances in a capacity-optimized fleet

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for capacity. To optimize for capacity, you must set AllocationStrategy to capacityOptimized.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```
{
  "TargetCapacity": "50",
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "capacityOptimized",
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r4.2xlarge",
          "AvailabilityZone": "us-west-2a"
        },
        {
          "InstanceType": "m4.2xlarge",
          "AvailabilityZone": "us-west-2b"
        },
        {
          "InstanceType": "c5.2xlarge",
          "AvailabilityZone": "us-west-2b"
        }
      ]
    }
  ]
}
```

Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for capacity while using priority on a best-effort basis.
When using the `capacityOptimizedPrioritized` allocation strategy, you can use the `Priority` parameter to specify the priorities of the Spot capacity pools, where the lower the number the higher priority. You can also set the same priority for several Spot capacity pools if you favor them equally. If you do not set a priority for a pool, the pool will be considered last in terms of priority.

To prioritize Spot capacity pools, you must set `AllocationStrategy` to `capacityOptimizedPrioritized`. Spot Fleet will optimize for capacity first, but will honor the priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect Spot Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

In the following example, the three launch specifications specify three Spot capacity pools. Each pool is prioritized, where the lower the number the higher priority. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with the highest priority on a best-effort basis, but optimizes for capacity first.

```
{
  "TargetCapacity": "50",
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "capacityOptimizedPrioritized"
  },
  "LaunchTemplateConfig": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r4.2xlarge",
          "Priority": 1,
          "AvailabilityZone": "us-west-2a"
        },
        {
          "InstanceType": "m4.2xlarge",
          "Priority": 2,
          "AvailabilityZone": "us-west-2b"
        },
        {
          "InstanceType": "c5.2xlarge",
          "Priority": 3,
          "AvailabilityZone": "us-west-2b"
        }
      ]
    }
  ]
}
```

**Fleet quotas**

The usual Amazon EC2 quotas apply to instances launched by an EC2 Fleet or a Spot Fleet, such as Spot Instance limits (p. 413) and volume limits (p. 1431). In addition, the following limits apply:

- The number of active EC2 Fleets and Spot Fleets per Region: 1,000* †
- The number of Spot capacity pools (unique combination of instance type and subnet): 300* ‡
- The size of the user data in a launch specification: 16 KB †
- The target capacity per EC2 Fleet or Spot Fleet: 10,000
- The target capacity across all EC2 Fleets and Spot Fleets in a Region: 100,000*
• An EC2 Fleet request or a Spot Fleet request can't span Regions.
• An EC2 Fleet request or a Spot Fleet request can't span different subnets from the same Availability Zone.

* These limits apply to both your EC2 Fleets and your Spot Fleets.
† These are hard limits. You cannot request a limit increase for these limits.
‡ This limit only applies to fleets of type request or maintain. This limit does not apply to instant fleets.

To request a limit increase for target capacity

If you need more than the default limits for target capacity, complete the AWS Support Center Create case form to request a limit increase. For Limit type, choose EC2 Fleet, choose a Region, and then choose Target Fleet Capacity per Fleet (in units) or Target Fleet Capacity per Region (in units), or both.
Monitor Amazon EC2

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon Elastic Compute Cloud (Amazon EC2) instances and your AWS solutions. You should collect monitoring data from all of the parts in your AWS solutions so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon EC2, however, you should create a monitoring plan that should include:

- What are your goals for monitoring?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

After you have defined your monitoring goals and have created your monitoring plan, the next step is to establish a baseline for normal Amazon EC2 performance in your environment. You should measure Amazon EC2 performance at various times and under different load conditions. As you monitor Amazon EC2, you should store a history of monitoring data that you collect. You can compare current Amazon EC2 performance to this historical data to help you to identify normal performance patterns and performance anomalies, and devise methods to address them. For example, you can monitor CPU utilization, disk I/O, and network utilization for your EC2 instances. When performance falls outside your established baseline, you might need to reconfigure or optimize the instance to reduce CPU utilization, improve disk I/O, or reduce network traffic.

To establish a baseline you should, at a minimum, monitor the following items:

<table>
<thead>
<tr>
<th>Item to monitor</th>
<th>Amazon EC2 metric</th>
<th>Monitoring agent/CloudWatch Logs</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU utilization</td>
<td>CPUUtilization (p. 821)</td>
<td></td>
</tr>
<tr>
<td>Network utilization</td>
<td>NetworkIn (p. 821)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>NetworkOut (p. 821)</td>
<td></td>
</tr>
<tr>
<td>Disk performance</td>
<td>DiskReadOps (p. 821)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DiskWriteOps (p. 821)</td>
<td></td>
</tr>
<tr>
<td>Disk Reads/Writes</td>
<td>DiskReadBytes (p. 821)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DiskWriteBytes (p. 821)</td>
<td></td>
</tr>
<tr>
<td>Memory utilization, disk swap utilization, disk space utilization, page file utilization, log collection</td>
<td>Collect Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent</td>
<td></td>
</tr>
</tbody>
</table>
Automated and manual monitoring

AWS provides various tools that you can use to monitor Amazon EC2. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention.

Monitoring tools
- Automated monitoring tools (p. 786)
- Manual monitoring tools (p. 787)

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon EC2 and report back to you when something is wrong:

- **System status checks** – monitor the AWS systems required to use your instance to ensure that they are working properly. These checks detect problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue or you can resolve it yourself (for example, by stopping and restarting or terminating and replacing an instance). Examples of problems that cause system status checks to fail include:
  - Loss of network connectivity
  - Loss of system power
  - Software issues on the physical host
  - Hardware issues on the physical host that impact network reachability

For more information, see Status checks for your instances (p. 788).

- **Instance status checks** – monitor the software and network configuration of your individual instance. These checks detect problems that require your involvement to repair. When an instance status check fails, typically you will need to address the problem yourself (for example, by rebooting the instance or by making modifications in your operating system). Examples of problems that may cause instance status checks to fail include:
  - Failed system status checks
  - Misconfigured networking or startup configuration
  - Exhausted memory
  - Corrupted file system
  - Incompatible kernel

For more information, see Status checks for your instances (p. 788).

- **Amazon CloudWatch alarms** – watch a single metric over a time period you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. Alarms invoke actions for sustained state changes only.
CloudWatch alarms will not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitor your instances using CloudWatch (p. 818).

- **Amazon EventBridge** – automate your AWS services and respond automatically to system events. Events from AWS services are delivered to EventBridge in near real time, and you can specify automated actions to take when an event matches a rule you write. For more information, see What is Amazon EventBridge?.

- **Amazon CloudWatch Logs** – monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, or other sources. For more information, see the Amazon CloudWatch Logs User Guide.

- **CloudWatch agent** – collect logs and system-level metrics from both hosts and guests on your EC2 instances and on-premises servers. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

- **AWS Management Pack for Microsoft System Center Operations Manager** – links Amazon EC2 instances and the Windows or Linux operating systems running inside them. The AWS Management Pack is an extension to Microsoft System Center Operations Manager. It uses a designated computer in your datacenter (called a watcher node) and the Amazon Web Services APIs to remotely discover and collect information about your AWS resources. For more information, see AWS Management Pack for Microsoft System Center.

### Manual monitoring tools

Another important part of monitoring Amazon EC2 involves manually monitoring those items that the monitoring scripts, status checks, and CloudWatch alarms don't cover. The Amazon EC2 and CloudWatch console dashboards provide an at-a-glance view of the state of your Amazon EC2 environment.

- **Amazon EC2 Dashboard shows:**
  - Service Health and Scheduled Events by Region
  - Instance state
  - Status checks
  - Alarm status
  - Instance metric details (In the navigation pane choose *Instances*, select an instance, and choose the *Monitoring* tab)
  - Volume metric details (In the navigation pane choose *Volumes*, select a volume, and choose the *Monitoring* tab)

- **Amazon CloudWatch Dashboard shows:**
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:

- Graph Amazon EC2 monitoring data to troubleshoot issues and discover trends
- Search and browse all your AWS resource metrics
- Create and edit alarms to be notified of problems
- See at-a-glance overviews of your alarms and AWS resources

### Best practices for monitoring

Use the following best practices for monitoring to help you with your Amazon EC2 monitoring tasks.
• Make monitoring a priority to head off small problems before they become big ones.
• Create and implement a monitoring plan that collects monitoring data from all of the parts in your AWS solution so that you can more easily debug a multi-point failure if one occurs. Your monitoring plan should address, at a minimum, the following questions:
  • What are your goals for monitoring?
  • What resources you will monitor?
  • How often you will monitor these resources?
  • What monitoring tools will you use?
  • Who will perform the monitoring tasks?
  • Who should be notified when something goes wrong?
• Automate monitoring tasks as much as possible.
• Check the log files on your EC2 instances.

Monitor the status of your instances

You can monitor the status of your instances by viewing status checks and scheduled events for your instances.

A status check gives you the information that results from automated checks performed by Amazon EC2. These automated checks detect whether specific issues are affecting your instances. The status check information, together with the data provided by Amazon CloudWatch, gives you detailed operational visibility into each of your instances.

You can also see status of specific events that are scheduled for your instances. The status of events provides information about upcoming activities that are planned for your instances, such as rebooting or retirement. They also provide the scheduled start and end time of each event.

Contents

• Status checks for your instances (p. 788)
• Scheduled events for your instances (p. 795)

Status checks for your instances

With instance status monitoring, you can quickly determine whether Amazon EC2 has detected any problems that might prevent your instances from running applications. Amazon EC2 performs automated checks on every running EC2 instance to identify hardware and software issues. You can view the results of these status checks to identify specific and detectable problems. The event status data augments the information that Amazon EC2 already provides about the state of each instance (such as pending, running, stopping) and the utilization metrics that Amazon CloudWatch monitors (CPU utilization, network traffic, and disk activity).

Status checks are performed every minute, returning a pass or a fail status. If all checks pass, the overall status of the instance is OK. If one or more checks fail, the overall status is impaired. Status checks are built into Amazon EC2, so they cannot be disabled or deleted.

When a status check fails, the corresponding CloudWatch metric for status checks is incremented. For more information, see Status check metrics (p. 827). You can use these metrics to create CloudWatch alarms that are triggered based on the result of the status checks. For example, you can create an alarm to warn you if status checks fail on a specific instance. For more information, see Create and edit status check alarms (p. 793).
You can also create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying issue. For more information, see Recover your instance (p. 554).

Contents

- Types of status checks (p. 789)
- View status checks (p. 790)
- Report instance status (p. 792)
- Create and edit status check alarms (p. 793)

Types of status checks

There are two types of status checks: system status checks and instance status checks.

System status checks

System status checks monitor the AWS systems on which your instance runs. These checks detect underlying problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue, or you can resolve it yourself. For instances backed by Amazon EBS, you can stop and start the instance yourself, which in most cases results in the instance being migrated to a new host. For Linux instances backed by instance store, you can terminate and replace the instance. For Windows instances, the root volume must be an Amazon EBS volume; instance store is not supported for the root volume. Note that instance store volumes are ephemeral and all data is lost when the instance is stopped.

The following are examples of problems that can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

Note

If you perform a restart from the operating system on a bare metal instance, the system status check might temporarily return a fail status. When the instance becomes available, the system status check should return a pass status.

Instance status checks

Instance status checks monitor the software and network configuration of your individual instance. Amazon EC2 checks the health of the instance by sending an address resolution protocol (ARP) request to the network interface (NIC). These checks detect problems that require your involvement to repair. When an instance status check fails, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes).

The following are examples of problems that can cause instance status checks to fail:

- Failed system status checks
- Incorrect networking or startup configuration
- Exhausted memory
- Corrupted file system
- Incompatible kernel
Note
If you perform a restart from the operating system on a bare metal instance, the instance status check might temporarily return a fail status. When the instance becomes available, the instance status check should return a pass status.

View status checks

Amazon EC2 provides you with several ways to view and work with status checks.

View status using the console

You can view status checks by using the AWS Management Console.

New console

To view status checks (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. On the Instances page, the Status check column lists the operational status of each instance.
4. To view the status of a specific instance, select the instance, and then choose the Status checks tab.

If your instance has a failed status check, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes). However, if your instance has a failed status check and has been unreachable for over 20 minutes, choose Open support case to submit a request for assistance. To troubleshoot system or instance status check failures yourself, see Troubleshoot instances with failed status checks (p. 1494).

5. To review the CloudWatch metrics for status checks, select the instance, and then choose the Monitoring tab. Scroll until you see the graphs for the following metrics:

- Status check failed (any)
- Status check failed (instance)
• **Status check failed (system)**

Old console

**To view status checks (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. On the **Instances** page, the **Status Checks** column lists the operational status of each instance.
4. To view the status of a specific instance, select the instance, and then choose the **Status Checks** tab.

If you have an instance with a failed status check and the instance has been unreachable for over 20 minutes, choose **AWS Support** to submit a request for assistance. To troubleshoot system or instance status check failures yourself, see **Troubleshoot instances with failed status checks** (p. 1494).

5. To review the CloudWatch metrics for status checks, select the instance, and then choose the **Monitoring** tab. Scroll until you see the graphs for the following metrics:

- **Status Check Failed (Any)**
- **Status Check Failed (Instance)**
- **Status Check Failed (System)**

**View status using the command line**

You can view status checks for running instances by using the **describe-instance-status** (AWS CLI) command.

To view the status of all instances, use the following command.

```
aws ec2 describe-instance-status
```

To get the status of all instances with an instance status of **impaired**, use the following command.

```
aws ec2 describe-instance-status \
  --filters Name=instance-status.status,Values=impaired
```

To get the status of a single instance, use the following command.

```
aws ec2 describe-instance-status \
  --instance-ids i-1234567890abcdef0
```
Alternatively, use the following commands:

- Get-EC2InstanceStatus (AWS Tools for Windows PowerShell)
- DescribeInstanceStatus (Amazon EC2 Query API)

If you have an instance with a failed status check, see Troubleshoot instances with failed status checks (p. 1494).

**Report instance status**

You can provide feedback if you are having problems with an instance whose status is not shown as impaired, or if you want to send AWS additional details about the problems you are experiencing with an impaired instance.

We use reported feedback to identify issues impacting multiple customers, but do not respond to individual account issues. Providing feedback does not change the status check results that you currently see for the instance.

**Report status feedback using the console**

New console

To report instance status (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose the Status Checks tab, choose Actions (the second Actions menu in the bottom half of the page), and then choose Report instance status.
4. Complete the Report instance status form, and then choose Submit.

Old console

To report instance status (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose the Status Checks tab, and choose Submit feedback.
4. Complete the Report Instance Status form, and then choose Submit.

**Report status feedback using the command line**

Use the report-instance-status (AWS CLI) command to send feedback about the status of an impaired instance.

```
aws ec2 report-instance-status \
    --instances i-1234567890abcdef0 \
    --status impaired \
    --reason-codes code
```

Alternatively, use the following commands:

- Send-EC2InstanceStatus (AWS Tools for Windows PowerShell)
- ReportInstanceStatus (Amazon EC2 Query API)
Create and edit status check alarms

You can use the status check metrics (p. 827) to create CloudWatch alarms to notify you when an instance has a failed status check.

Create a status check alarm using the console

Use the following procedure to configure an alarm that sends you a notification by email, or stops, terminates, or recovers an instance when it fails a status check.

New console

To create a status check alarm (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose the Status Checks tab, and choose Actions, Create status check alarm.
4. On the Manage CloudWatch alarms page, under Add or edit alarm, choose Create an alarm.
5. For Alarm notification, turn the toggle on to configure Amazon Simple Notification Service (Amazon SNS) notifications. Select an existing Amazon SNS topic or enter a name to create a new topic.

If you add an email address to the list of recipients or created a new topic, Amazon SNS sends a subscription confirmation email message to each new address. Each recipient must confirm the subscription by choosing the link contained in that message. Alert notifications are sent only to confirmed addresses.
6. For Alarm action, turn the toggle on to specify an action to take when the alarm is triggered. Select the action.
7. For Alarm thresholds, specify the metric and criteria for the alarm.

You can leave the default settings for Group samples by (Average) and Type of data to sample (Status check failed:either), or you can change them to suit your needs.

For Consecutive period, set the number of periods to evaluate and, in Period, enter the evaluation period duration before triggering the alarm and sending an email.
8. (Optional) For Sample metric data, choose Add to dashboard.
9. Choose Create.

Old console

To create a status check alarm (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose the Status Checks tab, and choose Create Status Check Alarm.
4. Select Send a notification to. Choose an existing SNS topic, or choose create topic to create a new one. If creating a new topic, in With these recipients, enter your email address and the addresses of any additional recipients, separated by commas.
5. (Optional) Select Take the action, and then select the action that you'd like to take.
6. In Whenever, select the status check that you want to be notified about.

If you selected Recover this instance in the previous step, select Status Check Failed (System).
7. In **For at least**, set the number of periods you want to evaluate and in **consecutive periods**, select the evaluation period duration before triggering the alarm and sending an email.

8. (Optional) In **Name of alarm**, replace the default name with another name for the alarm.

9. Choose **Create Alarm**.

**Important**
If you added an email address to the list of recipients or created a new topic, Amazon SNS sends a subscription confirmation email message to each new address. Each recipient must confirm the subscription by choosing the link contained in that message. Alert notifications are sent only to confirmed addresses.

If you need to make changes to an instance status alarm, you can edit it.

**New console**

**To edit a status check alarm using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitoring**, **Manage CloudWatch alarms**.
4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Edit an alarm**.
5. For **Search for alarm**, choose the alarm.
6. When you are finished making changes, choose **Update**.

**Old console**

**To edit a status check alarm using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **CloudWatch Monitoring**, **Add/Edit Alarms**.
4. In the **Alarm Details** dialog box, choose the name of the alarm.
5. In the **Edit Alarm** dialog box, make the desired changes, and then choose **Save**.

**Create a status check alarm using the AWS CLI**

In the following example, the alarm publishes a notification to an SNS topic, `arn:aws:sns:us-west-2:111122223333:my-sns-topic`, when the instance fails either the instance check or system status check for at least two consecutive periods. The CloudWatch metric used is `StatusCheckFailed`.

**To create a status check alarm using the AWS CLI**

1. Select an existing SNS topic or create a new one. For more information, see [Using the AWS CLI with Amazon SNS](https://docs.aws.amazon.com/cli/latest/all/sns.html) in the **AWS Command Line Interface User Guide**.
2. Use the following `list-metrics` command to view the available Amazon CloudWatch metrics for Amazon EC2.

   ```bash
   aws cloudwatch list-metrics --namespace AWS/EC2
   ```

3. Use the following `put-metric-alarm` command to create the alarm.

   ```bash
   aws cloudwatch put-metric-alarm --alarm-name StatusCheckFailed-Alarm-for-i-1234567890abcdef0 --metric-name StatusCheckFailed --namespace AWS/EC2 --
   ```
### Scheduled events for your instances

AWS can schedule events for your instances, such as a reboot, stop/start, or retirement. These events do not occur frequently. If one of your instances will be affected by a scheduled event, AWS sends an email to the email address that’s associated with your AWS account prior to the scheduled event. The email provides details about the event, including the start and end date. Depending on the event, you might be able to take action to control the timing of the event. AWS also sends an AWS Health event, which you can monitor and manage by using Amazon CloudWatch Events. For more information about monitoring AWS Health events with CloudWatch, see Monitoring AWS Health events with CloudWatch Events.

Scheduled events are managed by AWS; you cannot schedule events for your instances. You can view the events scheduled by AWS, customize scheduled event notifications to include or remove tags from the email notification, perform actions when an instance is scheduled to reboot, retire, or stop.

To update the contact information for your account so that you can be sure to be notified about scheduled events, go to the Account Settings page.

### Contents

- Types of scheduled events (p. 795)
- View scheduled events (p. 796)
- Customize scheduled event notifications (p. 800)
- Work with instances scheduled to stop or retire (p. 802)
- Work with instances scheduled for reboot (p. 802)
- Work with instances scheduled for maintenance (p. 804)
- Reschedule a scheduled event (p. 804)
- Define event windows for scheduled events (p. 806)

### Types of scheduled events

Amazon EC2 can create the following types of events for your instances, where the event occurs at a scheduled time:

- **Instance stop**: At the scheduled time, the instance is stopped. When you start it again, it’s migrated to a new host. Applies only to instances backed by Amazon EBS.
- **Instance retirement**: At the scheduled time, the instance is stopped if it is backed by Amazon EBS, or terminated if it is backed by instance store.
- **Instance reboot**: At the scheduled time, the instance is rebooted.
- **System reboot**: At the scheduled time, the host for the instance is rebooted.
- **System maintenance**: At the scheduled time, the instance might be temporarily affected by network maintenance or power maintenance.
View scheduled events

In addition to receiving notification of scheduled events in email, you can check for scheduled events by using one of the following methods.

New console

To view scheduled events for your instances using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. You can view scheduled events in the following screens:
   - In the navigation pane, choose Events. Any resources with an associated event are displayed. You can filter by Resource ID, Resource type, Availability zone, Event status, or Event type.
   - Alternatively, in the navigation pane, choose EC2 Dashboard. Any resources with an associated event are displayed under Scheduled events.

Old console

To view scheduled events for your instances using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. You can view scheduled events in the following screens:
   - In the navigation pane, choose Events. Any resources with an associated event are displayed. You can filter by resource type, or by specific event types. You can select the resource to view details.
Scheduled events

• Alternatively, in the navigation pane, choose EC2 Dashboard. Any resources with an associated event are displayed under Scheduled Events.

• Some events are also shown for affected resources. For example, in the navigation pane, choose Instances and select an instance. If the instance has an associated instance stop or instance retirement event, it is displayed in the lower pane.

AWS CLI

To view scheduled events for your instances using the AWS CLI

Use the describe-instance-status command.

```
aws ec2 describe-instance-status \
  --instance-id i-1234567890abcdef0 \
  --query "InstanceStatuses[].Events"
```

The following example output shows a reboot event.

```
[   
  "Events": [   
    {   
      "InstanceEventId": "instance-event-0d59937288b749b32",   
      "Code": "system-reboot",   
      "Description": "The instance is scheduled for a reboot",   
      "NotAfter": "2019-03-15T22:00:00.000Z",   
      "NotBefore": "2019-03-14T20:00:00.000Z",   
      "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"
    }
  ]
```
The following example output shows an instance retirement event.

```
["Events": [
{
  "InstanceEventId": "instance-event-0e439355b779n26",
  "Code": "instance-stop",
  "Description": "The instance is running on degraded hardware",
  "NotBefore": "2015-05-23T00:00:00.000Z"
}
]
```

**PowerShell**

To view scheduled events for your instances using the AWS Tools for Windows PowerShell

Use the following `Get-EC2InstanceStatus` command.

```
PS C:\> (Get-EC2InstanceStatus -InstanceId i-1234567890abcdef0).Events
```

The following example output shows an instance retirement event.

```
Code         : instance-stop
Description  : The instance is running on degraded hardware
NotBefore    : 5/23/2015 12:00:00 AM
```

**Instance metadata**

To view scheduled events for your instances using instance metadata

You can retrieve information about active maintenance events for your instances from the instance metadata (p. 606) by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

**IMDSv2**

```
```

**IMDSv1**

```
```

The following is example output with information about a scheduled system reboot event, in JSON format.

```
[
```
To view event history about completed or canceled events for your instances using instance metadata

You can retrieve information about completed or canceled events for your instances from instance metadata (p. 606) by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

**IMDSv2**

```
```

**IMDSv1**

```
```

The following is example output with information about a system reboot event that was canceled, and a system reboot event that was completed, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Canceled] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "21 Jan 2019 09:17:23 GMT",
    "State" : "canceled"
  },
  {
    "NotBefore" : "29 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Completed] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",

]
```

AWS Health

You can use the AWS Personal Health Dashboard to learn about events that can affect your instance. The AWS Personal Health Dashboard organizes issues in three groups: open issues, scheduled changes, and other notifications. The scheduled changes group contains items that are ongoing or upcoming.

For more information, see Getting started with the AWS Personal Health Dashboard in the AWS Health User Guide.
Customize scheduled event notifications

You can customize scheduled event notifications to include tags in the email notification. This makes it easier to identify the affected resource (instances or Dedicated Hosts) and to prioritize actions for the upcoming event.

When you customize event notifications to include tags, you can choose to include:

- All of the tags that are associated with the affected resource
- Only specific tags that are associated with the affected resource

For example, suppose that you assign application, costcenter, project, and owner tags to all of your instances. You can choose to include all of the tags in event notifications. Alternatively, if you'd like to see only the owner and project tags in event notifications, then you can choose to include only those tags.

After you select the tags to include, the event notifications will include the resource ID (instance ID or Dedicated Host ID) and the tag key and value pairs that are associated with the affected resource.

Topics

- Include tags in event notifications (p. 800)
- Remove tags from event notifications (p. 801)
- View the tags to be included in event notifications (p. 801)

Include tags in event notifications

The tags that you choose to include apply to all resources (instances and Dedicated Hosts) in the selected Region. To customize event notifications in other Regions, first select the required Region and then perform the following steps.

You can include tags in event notifications by using one of the following methods.

New console

To include tags in event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event notifications.
4. Select Include resource tags in event notifications.
5. Do one of the following, depending on the tags that you want to include in event notifications:
   - To include all of the tags associated with the affected instance or Dedicated Host, select Include all resource tags.
   - To manually select the tags to include, select Choose the tags to include, and then for Choose the tags to include, enter the tag key and press Enter.
6. Choose Save.

AWS CLI

To include all tags in event notifications

Use the register-instance-event-notification-attributes AWS CLI command and set the IncludeAllTagsOfInstance parameter to true.
To include specific tags in event notifications

Use the `register-instance-event-notification-attributes` AWS CLI command and specify the tags to include by using the `InstanceTagKeys` parameter.

```bash
aws ec2 register-instance-event-notification-attributes --instance-tag-attribute 'InstanceTagKeys=["tag_key_1", "tag_key_2", "tag_key_3"]'
```

Remove tags from event notifications

You can remove tags from event notifications by using one of the following methods.

**New console**

**To remove tags from event notifications**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions, Manage event notifications**.
4. Do one of the following, depending on the tag that you want to remove from event notifications.
   - To remove all tags from event notifications, clear **Include resource tags in event notifications**.
   - To remove specific tags from event notifications, choose **Remove (X)** for the tags listed below the **Choose the tags to include** field.
5. Choose **Save**.

**AWS CLI**

**To remove all tags from event notifications**

Use the `deregister-instance-event-notification-attributes` AWS CLI command and set the `IncludeAllTagsOfInstance` parameter to false.

```bash
aws ec2 deregister-instance-event-notification-attributes --instance-tag-attribute "IncludeAllTagsOfInstance=false"
```

**To remove specific tags from event notifications**

Use the `deregister-instance-event-notification-attributes` AWS CLI command and specify the tags to remove by using the `InstanceTagKeys` parameter.

```bash
aws ec2 deregister-instance-event-notification-attributes --instance-tag-attribute 'InstanceTagKeys=["tag_key_1", "tag_key_2", "tag_key_3"]'
```

View the tags to be included in event notifications

You can view the tags that are to be included in event notifications by using one of the following methods.
New console

To view the tags that are to be included in event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event notifications.

AWS CLI

To view the tags that are to be included in event notifications

Use the describe-instance-event-notification-attributes AWS CLI command.

```
aws ec2 describe-instance-event-notification-attributes
```

Work with instances scheduled to stop or retire

When AWS detects irreparable failure of the underlying host for your instance, it schedules the instance to stop or terminate, depending on the type of root device for the instance. If the root device is an EBS volume, the instance is scheduled to stop. If the root device is an instance store volume, the instance is scheduled to terminate. For more information, see Instance retirement (p. 544).

Important

Any data stored on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. Be sure to save data from your instance store volumes that you might need later before the instance is stopped, hibernated, or terminated.

Actions for Instances Backed by Amazon EBS

You can wait for the instance to stop as scheduled. Alternatively, you can stop and start the instance yourself, which migrates it to a new host. For more information about stopping your instance, in addition to information about the changes to your instance configuration when it's stopped, see Stop and start your instance (p. 524).

You can automate an immediate stop and start in response to a scheduled instance stop event. For more information, see Automating Actions for EC2 Instances in the AWS Health User Guide.

Actions for Instances Backed by Instance Store

We recommend that you launch a replacement instance from your most recent AMI and migrate all necessary data to the replacement instance before the instance is scheduled to terminate. Then, you can terminate the original instance, or wait for it to terminate as scheduled.

Work with instances scheduled for reboot

When AWS must perform tasks such as installing updates or maintaining the underlying host, it can schedule the instance or the underlying host for a reboot. You can reschedule most reboot events (p. 804) so that your instance is rebooted at a specific date and time that suits you.

If you stop your linked EC2-Classic instance (p. 1044), it is automatically unlinked from the VPC and the VPC security groups are no longer associated with the instance. You can link your instance to the VPC again after you've restarted it.
View the reboot event type

You can view whether a reboot event is an instance reboot or a system reboot by using one of the following methods.

New console

To view the type of scheduled reboot event using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Resource type: instance from the filter list.
4. For each instance, view the value in the Event type column. The value is either system-reboot or instance-reboot.

Old console

To view the type of scheduled reboot event using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Instance resources from the filter list.
4. For each instance, view the value in the Event Type column. The value is either system-reboot or instance-reboot.

AWS CLI

To view the type of scheduled reboot event using the AWS CLI

Use the describe-instance-status command.

```bash
cmd
aws ec2 describe-instance-status --instance-id i-1234567890abcdef0
```

For scheduled reboot events, the value for Code is either system-reboot or instance-reboot. The following example output shows a system-reboot event.

```json
[  
  "Events": [    
    {      
      "InstanceEventId": "instance-event-0d59937288b749b32",      
      "Code": "system-reboot",      
      "Description": "The instance is scheduled for a reboot",      
      "NotAfter": "2019-03-14T22:00:00.000Z",      
      "NotBefore": "2019-03-14T20:00:00.000Z",      
      "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"    
    }  
  ]
]
```

Actions for instance reboot

You can wait for the instance reboot to occur within its scheduled maintenance window, reschedule (p. 804) the instance reboot to a date and time that suits you, or reboot (p. 544) the instance yourself at a time that is convenient for you.
After your instance is rebooted, the scheduled event is cleared and the event’s description is updated. The pending maintenance to the underlying host is completed, and you can begin using your instance again after it has fully booted.

**Actions for system reboot**

It is not possible for you to reboot the system yourself. You can wait for the system reboot to occur during its scheduled maintenance window, or you can reschedule (p. 804) the system reboot to a date and time that suits you. A system reboot typically completes in a matter of minutes. After the system reboot has occurred, the instance retains its IP address and DNS name, and any data on local instance store volumes is preserved. After the system reboot is complete, the scheduled event for the instance is cleared, and you can verify that the software on your instance is operating as expected.

Alternatively, if it is necessary to maintain the instance at a different time and you can’t reschedule the system reboot, then you can stop and start an Amazon EBS-backed instance, which migrates it to a new host. However, the data on the local instance store volumes is not preserved. You can also automate an immediate instance stop and start in response to a scheduled system reboot event. For more information, see Automating Actions for EC2 Instances in the AWS Health User Guide. For an instance store-backed instance, if you can’t reschedule the system reboot, then you can launch a replacement instance from your most recent AMI, migrate all necessary data to the replacement instance before the scheduled maintenance window, and then terminate the original instance.

**Work with instances scheduled for maintenance**

When AWS must maintain the underlying host for an instance, it schedules the instance for maintenance. There are two types of maintenance events: network maintenance and power maintenance.

During network maintenance, scheduled instances lose network connectivity for a brief period of time. Normal network connectivity to your instance is restored after maintenance is complete.

During power maintenance, scheduled instances are taken offline for a brief period, and then rebooted. When a reboot is performed, all of your instance’s configuration settings are retained.

After your instance has rebooted (this normally takes a few minutes), verify that your application is working as expected. At this point, your instance should no longer have a scheduled event associated with it, or if it does, the description of the scheduled event begins with [Completed]. It sometimes takes up to 1 hour for the instance status description to refresh. Completed maintenance events are displayed on the Amazon EC2 console dashboard for up to a week.

**Actions for Instances Backed by Amazon EBS**

You can wait for the maintenance to occur as scheduled. Alternatively, you can stop and start the instance, which migrates it to a new host. For more information about stopping your instance, in addition to information about the changes to your instance configuration when it’s stopped, see Stop and start your instance (p. 524).

You can automate an immediate stop and start in response to a scheduled maintenance event. For more information, see Automating Actions for EC2 Instances in the AWS Health User Guide.

**Actions for instances backed by instance store**

You can wait for the maintenance to occur as scheduled. Alternatively, if you want to maintain normal operation during a scheduled maintenance window, you can launch a replacement instance from your most recent AMI, migrate all necessary data to the replacement instance before the scheduled maintenance window, and then terminate the original instance.

**Reschedule a scheduled event**

You can reschedule an event so that it occurs at a specific date and time that suits you. Only events that have a deadline date can be rescheduled. There are other limitations for rescheduling an event (p. 806).
You can reschedule an event by using one of the following methods.

New console

To reschedule an event using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Resource type: instance from the filter list.
4. Select one or more instances, and then choose Actions, Schedule event.

Only events that have an event deadline date, indicated by a value for Deadline, can be rescheduled. If one of the selected events does not have a deadline date, Actions, Schedule event is disabled.
5. For New start time, enter a new date and time for the event. The new date and time must occur before the Event deadline.
6. Choose Save.

It might take a minute or 2 for the updated event start time to be reflected in the console.

Old console

To reschedule an event using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Instance resources from the filter list.
4. Select one or more instances, and then choose Actions, Schedule Event.

Only events that have an event deadline date, indicated by a value for Event Deadline, can be rescheduled.
5. For Event start time, enter a new date and time for the event. The new date and time must occur before the Event Deadline.

It might take a minute or 2 for the updated event start time to be reflected in the console.

AWS CLI

To reschedule an event using the AWS CLI

1. Only events that have an event deadline date, indicated by a value for NotBeforeDeadline, can be rescheduled. Use the describe-instance-status command to view the NotBeforeDeadline parameter value.

```bash
aws ec2 describe-instance-status --instance-id i-1234567890abcdef0
```

The following example output shows a system-reboot event that can be rescheduled because NotBeforeDeadline contains a value.

```
[
  "Events": [
    
    
    "InstanceEventId": "instance-event-0d59937288b749b32",

```
Scheduled events

"Code": "system-reboot",
"Description": "The instance is scheduled for a reboot",
"NotAfter": "2019-03-14T22:00:00.000Z",
"NotBefore": "2019-03-14T20:00:00.000Z",
"NotBeforeDeadline": "2019-04-05T11:00:00.000Z"
}
]
]

2. To reschedule the event, use the modify-instance-event-start-time command. Specify the new event start time by using the not-before parameter. The new event start time must fall before the NotBeforeDeadline.

```bash
aws ec2 modify-instance-event-start-time --instance-id i-1234567890abcdef0
--instance-event-id instance-event-0d59937288b749b32 --not-before
2019-03-25T10:00:00.000
```

It might take a minute or 2 before the describe-instance-status command returns the updated not-before parameter value.

Limitations

- Only events with an event deadline date can be rescheduled. The event can be rescheduled up to the event deadline date. The Deadline column in the console and the NotBeforeDeadline field in the AWS CLI indicate if the event has a deadline date.
- Only events that have not yet started can be rescheduled. The Start time column in the console and the NotBefore field in the AWS CLI indicate the event start time. Events that are scheduled to start in the next 5 minutes cannot be rescheduled.
- The new event start time must be at least 60 minutes from the current time.
- If you reschedule multiple events using the console, the event deadline date is determined by the event with the earliest event deadline date.

Define event windows for scheduled events

You can define custom event windows that recur weekly for scheduled events that reboot, stop, or terminate your Amazon EC2 instances. You can associate one or more instances with an event window. If a scheduled event for those instances is planned, AWS will schedule the events within the associated event window.

You can use event windows to maximize workload availability by specifying event windows that occur during off-peak periods for your workload. You can also align the event windows with your internal maintenance schedules.

You define an event window by specifying a set of time ranges. The minimum time range is 2 hours. The combined time ranges must total at least 4 hours.

You can associate one or more instances with an event window by using either instance IDs or instance tags. You can also associate Dedicated Hosts with an event window by using the host ID.

Warning

Event windows are applicable only for scheduled events that stop, reboot, or terminate instances. Event windows are not applicable for:

- Expedited scheduled events and network maintenance events.
- Unscheduled maintenance such as AutoRecovery and unplanned reboots.
Work with event windows

- Considerations (p. 807)
- View event windows (p. 807)
- Create event windows (p. 809)
- Modify event windows (p. 813)
- Delete event windows (p. 817)
- Tag event windows (p. 818)

Considerations

- All event window times are in UTC.
- The minimum weekly event window duration is 4 hours.
- The time ranges within an event window must each be at least 2 hours.
- Only one target type (instance ID, Dedicated Host ID, or instance tag) can be associated with an event window.
- A target (instance ID, Dedicated Host ID, or instance tag) can only be associated with one event window.
- A maximum of 100 instance IDs, or 50 Dedicated Host IDs, or 50 instance tags can be associated with an event window. The instance tags can be associated with any number of instances.
- A maximum of 200 event windows can be created per AWS Region.
- Multiple instances that are associated with event windows can potentially have scheduled events occur at the same time.
- If AWS has already scheduled an event, modifying an event window won't change the time of the scheduled event. If the event has a deadline date, you can reschedule the event (p. 804).
- You can stop and start an instance prior to the scheduled event, which migrates the instance to a new host, and the scheduled event will no longer take place.

View event windows

You can view event windows by using one of the following methods.

Console

To view event windows using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event windows.
4. Select an event window to view its details.

AWS CLI

To describe all event windows using the AWS CLI

Use the describe-instance-event-windows command.

```
aws ec2 describe-instance-event-windows \
  --region us-east-1
```

Expected output
To describe a specific event window using the AWS CLI

Use the describe-instance-event-windows command with the --instance-event-window-id parameter to describe a specific event window.

```
aws ec2 describe-instance-event-windows \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890
```

To describe event windows that match one or more filters using the AWS CLI

Use the describe-instance-event-windows command with the --filters parameter. In the following example, the instance-id filter is used to describe all of the event windows that are associated with the specified instance.

When a filter is used, it performs a direct match. However, the instance-id filter is different. If there is no direct match to the instance ID, then it falls back to indirect associations with the event window, such as the instance's tags or Dedicated Host ID (if the instance is on a Dedicated Host).

For the list of supported filters, see describe-instance-event-windows in the AWS CLI Reference.

```
aws ec2 describe-instance-event-windows \
  --region us-east-1 \
  --filters Name=instance-id,Values=i-1234567890abcdef0 \
  --max-results 100 \
  --next-token <next-token-value>
```

Expected output

In the following example, the instance is on a Dedicated Host, which is associated with the event window.

```
{   "InstanceEventWindows": [     {       "InstanceEventWindowId": "iew-0dbcd0adb66f135982",       "TimeRanges": [     ]   }   ]}
```
Create event windows

You can create one or more event windows. For each event window, you specify one or more blocks of time. For example, you can create an event window with blocks of time that occur every day at 4 AM for 2 hours. Or you can create an event window with blocks of time that occur on Sundays from 2 AM to 4 AM and on Wednesdays from 3 AM to 5 AM.

For the event window constraints, see Considerations (p. 807) earlier in this topic.

Event windows recur weekly until you delete them.

Use one of the following methods to create an event window.

Console

**To create an event window using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Create instance event window.
4. For Event window name, enter a descriptive name for the event window.
5. For Event window schedule, choose to specify the blocks of time in the event window by using the cron schedule builder or by specifying time ranges.

   - If you choose Cron schedule builder, specify the following:
     1. For Days (UTC), specify the days of the week on which the event window occurs.
     2. For Start time (UTC), specify the time when the event window begins.
     3. For Duration, specify the duration of the blocks of time in the event window. The minimum duration per block of time is 2 hours. The minimum duration of the event window must equal or exceed 4 hours in total. All times are in UTC.

   - If you choose Time ranges, choose Add new time range and specify the start day and time and the end day and time. Repeat for each time range. The minimum duration per time range is 2 hours. The minimum duration for all time ranges combined must equal or exceed 4 hours in total.

6. (Optional) For Target details, associate one or more instances with the event window so that if the instances are scheduled for maintenance, the scheduled event will occur during the
associated event window. You can associate one or more instances with an event window by using instance IDs or instance tags. You can associate Dedicated Hosts with an event window by using the host ID.

Note that you can create the event window without associating a target with the window. Later, you can modify the window to associate one or more targets.

7. (Optional) For **Event window tags**, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

8. Choose **Create event window**.

**AWS CLI**

To create an event window using the AWS CLI, you first create the event window, and then you associate one or more targets with the event window.

**Create an event window**

You can define either a set of time ranges or a cron expression when creating the event window, but not both.

**To create an event window with a time range using the AWS CLI**

Use the `create-instance-event-window` command and specify the `--time-range` parameter. You can't also specify the `--cron-expression` parameter.

```
aws ec2 create-instance-event-window \
  --region us-east-1 \
  --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8 \
  --tag-specifications "ResourceType=instance-event-window,Tags=[{Key=K1,Value=V1}]" \
  --name myEventWindowName
```

**Expected output**

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "TimeRanges": [
      {
        "StartWeekDay": "monday",
        "StartHour": 2,
        "EndWeekDay": "wednesday",
        "EndHour": 8
      }
    ],
    "Name": "myEventWindowName",
    "State": "creating",
    "Tags": [
      {
        "Key": "K1",
        "Value": "V1"
      }
    ]
  }
}
```

**To create an event window with a cron expression using the AWS CLI**

Use the `create-instance-event-window` command and specify the `--cron-expression` parameter. You can't also specify the `--time-range` parameter.
aws ec2 create-instance-event-window
   --region us-east-1
   --cron-expression "* 21-23 * * 2,3"
   --tag-specifications "ResourceType=instance-event-window,Tags=[{Key=K1,Value=V1}]"
   --name myEventWindowName

Expected output

```json
{
   "InstanceEventWindow": {
      "InstanceEventWindowId": "iew-0abcdef1234567890",
      "Name": "myEventWindowName",
      "CronExpression": "* 21-23 * * 2,3",
      "State": "creating",
      "Tags": [
         {
            "Key": "K1",
            "Value": "V1"
         }
      ]
   }
}
```

Associate a target with an event window

You can associate only one type of target (instance IDs, Dedicated Host IDs, or instance tags) with an event window.

To associate instance tags with an event window using the AWS CLI

Use the `associate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To associate instance tags, specify the `--association-target` parameter, and for the parameter values, specify one or more tags.

aws ec2 associate-instance-event-window
   --region us-east-1
   --instance-event-window-id iew-0abcdef1234567890
   --association-target "InstanceTags=[{Key=k2,Value=v2},{Key=k1,Value=v1}]"

Expected output

```json
{
   "InstanceEventWindow": {
      "InstanceEventWindowId": "iew-0abcdef1234567890",
      "Name": "myEventWindowName",
      "CronExpression": "* 21-23 * * 2,3",
      "AssociationTarget": {
         "InstanceIds": [],
         "Tags": [
            {
               "Key": "k2",
               "Value": "v2"
            },
            {
               "Key": "k1",
               "Value": "v1"
            }
         ],
         "DedicatedHostIds": []
      }
   }
}
```
To associate one or more instances with an event window using the AWS CLI

Use the `associate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To associate instances, specify the `--association-target` parameter, and for the parameter values, specify one or more instance IDs.

```bash
aws ec2 associate-instance-event-window
  --region us-east-1
  --instance-event-window-id iew-0abcdef1234567890
  --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356ebo48d7"
```

Expected output

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "AssociationTarget": {
      "InstanceIds": [
        "i-1234567890abcdef0",
        "i-0598c7d356ebo48d7"
      ],
      "Tags": [],
      "DedicatedHostIds": []
    },
    "State": "creating"
  }
}
```

To associate a Dedicated Host with an event window using the AWS CLI

Use the `associate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To associate a Dedicated Host, specify the `--association-target` parameter, and for the parameter values, specify one or more Dedicated Host IDs.

```bash
aws ec2 associate-instance-event-window
  --region us-east-1
  --instance-event-window-id iew-0abcdef1234567890
  --association-target "DedicatedHostIds=h-029fa35a02b99801d"
```

Expected output

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "AssociationTarget": {
      "InstanceIds": [],
      "Tags": [],
      "DedicatedHostIds": ["h-029fa35a02b99801d"]
    }
  }
}
```
Modify event windows

You can modify all of the fields of an event window except its ID. For example, when daylight savings begin, you might want to modify the event window schedule. For existing event windows, you might want to add or remove targets.

Use one of the following methods to modify an event window.

Console

To modify an event window using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event windows.
4. Select the event window to modify, and then choose Actions, Modify instance event window.
5. Modify the fields in the event window, and then choose Modify event window.

AWS CLI

To modify an event window using the AWS CLI, you can modify the time range or cron expression, and associate or disassociate one or more targets with the event window.

Modify the event window time

You can modify either a time range or a cron expression when modifying the event window, but not both.

To modify the time range of an event window using the AWS CLI

Use the modify-instance-event-window command and specify the event window to modify. Specify the --time-range parameter to modify the time range. You can't also specify the --cron-expression parameter.

```
aws ec2 modify-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id ievent-0abcdef1234567890 \
  --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8
```

Expected output

```
{
  "InstanceEventWindow": { 
    "InstanceEventWindowId": "iet-0abcdef1234567890",
    "TimeRanges": [ 
      { 
        "StartWeekDay": "monday",
        "StartHour": 2,
        "EndWeekDay": "wednesday",
        "EndHour": 8
      }
    ]
  }
}
```
Scheduled events

To modify a set of time ranges for an event window using the AWS CLI

Use the `modify-instance-event-window` command and specify the event window to modify. Specify the `--time-range` parameter to modify the time range. You can't also specify the `--cron-expression` parameter in the same call.

```
aws ec2 modify-instance-event-window
  --region us-east-1
  --instance-event-window-id iev-0abcdef1234567890
  --time-range '[
    {
      "StartWeekDay": "monday",
      "StartHour": 2,
      "EndWeekDay": "wednesday",
      "EndHour": 8
    },
    {
      "StartWeekDay": "thursday",
      "StartHour": 2,
      "EndWeekDay": "friday",
      "EndHour": 8
    }
  ]'
```

Expected output

```
{}
```

To modify the cron expression of an event window using the AWS CLI

Use the `modify-instance-event-window` command and specify the event window to modify. Specify the `--cron-expression` parameter to modify the cron expression. You can't also specify the `--time-range` parameter.

```
aws ec2 modify-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --cron-expression "* 21-23 * * 2,3"
```

Expected output

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "AssociationTarget": {
      "InstanceIds": [
        "i-0abcdef1234567890",
        "i-0be35f9acbf01f0"
      ],
      "Tags": [],
      "DedicatedHostIds": []
    },
    "State": "creating",
    "Tags": [
      {
        "Key": "K1",
        "Value": "V1"
      }
    ]
  }
}
```

Modify the targets associated with an event window

You can associate additional targets with an event window. You can also disassociate existing targets from an event window. However, only one type of target (instance IDs, Dedicated Host IDs, or instance tags) can be associated with an event window.

To associate additional targets with an event window

For the instructions on how to associate targets with an event window, see Associate a target with an event window.

To disassociate instance tags from an event window using the AWS CLI

Use the `disassociate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To disassociate instance tags, specify the `--association-target` parameter, and for the parameter values, specify one or more tags.
To disassociate one or more instances from an event window using the AWS CLI

Use the `disassociate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To disassociate instances, specify the `--association-target` parameter, and for the parameter values, specify one or more instance IDs.

```bash
aws ec2 disassociate-instance-event-window
  --region us-east-1
  --instance-event-window-id iew-0abcdef1234567890
  --association-target "InstanceIds=[i-1234567890abcdef0,i-0598c7d356eba48d7]"
```

Expected output

```json
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "AssociationTarget": {
      "InstanceIds": [],
      "Tags": [],
      "DedicatedHostIds": []
    }
  },
  "State": "creating"
}
```

To disassociate a Dedicated Host from an event window using the AWS CLI

Use the `disassociate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To disassociate a Dedicated Host, specify the `--association-target` parameter, and for the parameter values, specify one or more Dedicated Host IDs.

```bash
aws ec2 disassociate-instance-event-window
  --region us-east-1
  --instance-event-window-id iew-0abcdef1234567890
  --association-target DedicatedHostIds=h-029fa350a02b99801d
```

Expected output

```json
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "AssociationTarget": {
      "InstanceIds": [],
      "Tags": [],
      "DedicatedHostIds": []
    }
  },
  "State": "creating"
}
```
Delete event windows

You can delete one event window at a time by using one of the following methods.

Console

To delete an event window using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event windows.
4. Select the event window to delete, and then choose Actions, Delete instance event window.
5. When prompted, enter delete, and then choose Delete.

AWS CLI

To delete an event window using the AWS CLI

Use the delete-instance-event-window command and specify the event window to delete.

```
aws ec2 delete-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890
```

To force delete an event window using the AWS CLI

Use the --force-delete parameter if the event window is currently associated with targets.

```
aws ec2 delete-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --force-delete
```

Expected output

```
{
  "InstanceEventWindowState": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "State": "deleting"
  }
}
```
Tag event windows

You can tag an event window when you create it, or afterwards.

To tag an event window when you create it, see Create event windows (p. 809).

Use one of the following methods to tag an event window.

Console

To tag an existing event window using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event windows.
4. Select the event window to tag, and then choose Actions, Manage instance event window tags.
5. Choose Add tag to add a tag. Repeat for each tag.
6. Choose Save.

AWS CLI

To tag an existing event window using the AWS CLI

Use the create-tags command to tag existing resources. In the following example, the existing event window is tagged with Key=purpose and Value=test.

```bash
aws ec2 create-tags \
  --resources i-0abcdef1234567890 \
  --tags Key=purpose,Value=test
```

Monitor your instances using CloudWatch

You can monitor your instances using Amazon CloudWatch, which collects and processes raw data from Amazon EC2 into readable, near real-time metrics. These statistics are recorded for a period of 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing.

By default, Amazon EC2 sends metric data to CloudWatch in 5-minute periods. To send metric data for your instance to CloudWatch in 1-minute periods, you can enable detailed monitoring on the instance. For more information, see Enable or turn off detailed monitoring for your instances (p. 819).

The Amazon EC2 console displays a series of graphs based on the raw data from Amazon CloudWatch. Depending on your needs, you might prefer to get data for your instances from Amazon CloudWatch instead of the graphs in the console.

For more information about Amazon CloudWatch, see the Amazon CloudWatch User Guide.

Contents

- Enable or turn off detailed monitoring for your instances (p. 819)
- List the available CloudWatch metrics for your instances (p. 821)
Enable or turn off detailed monitoring for your instances

By default, your instance is enabled for basic monitoring. You can optionally enable detailed monitoring. After you enable detailed monitoring, the Amazon EC2 console displays monitoring graphs with a 1-minute period for the instance.

The following describes the data interval and charge for basic and detailed monitoring for instances.

<table>
<thead>
<tr>
<th>Monitoring type</th>
<th>Description</th>
<th>Charges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic monitoring</td>
<td>Data is available automatically in 5-minute periods.</td>
<td>No charge</td>
</tr>
<tr>
<td>Detailed monitoring</td>
<td>Data is available in 1-minute periods. To get this level of data, you must specifically enable it for the instance. For the instances where you've enabled detailed monitoring, you can also get aggregated data across groups of similar instances.</td>
<td>You are charged per metric that is sent to CloudWatch. You are not charged for data storage. For more information, see Paid tier and Example 1 - EC2 Detailed Monitoring on the Amazon CloudWatch pricing page.</td>
</tr>
</tbody>
</table>

Topics

- Required IAM permissions (p. 819)
- Enable detailed monitoring (p. 819)
- Turn off detailed monitoring (p. 820)

Required IAM permissions

To enable detailed monitoring for an instance, your IAM user must have permission to use the MonitorInstances API action. To turn off detailed monitoring for an instance, your IAM user must have permission to use the UnmonitorInstances API action.

Enable detailed monitoring

You can enable detailed monitoring on an instance as you launch it or after the instance is running or stopped. Enabling detailed monitoring on an instance does not affect the monitoring of the EBS volumes attached to the instance. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 1391).

New console

To enable detailed monitoring for an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitoring, Manage detailed monitoring**.
4. On the **Detailed monitoring** detail page, for **Detailed monitoring**, select the **Enable** check box.
5. Choose **Save**.

**To enable detailed monitoring when launching an instance**

When launching an instance using the AWS Management Console, select the **Monitoring** check box on the **Configure Instance Details** page.

**Old console**

**To enable detailed monitoring for an existing instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, CloudWatch Monitoring, Enable Detailed Monitoring**.
4. In the **Enable Detailed Monitoring** dialog box, choose **Yes, Enable**.
5. Choose **Close**.

**To enable detailed monitoring when launching an instance (console)**

When launching an instance using the AWS Management Console, select the **Monitoring** check box on the **Configure Instance Details** page.

**AWS CLI**

**To enable detailed monitoring for an existing instance**

Use the following `monitor-instances` command to enable detailed monitoring for the specified instances.

```bash
aws ec2 monitor-instances --instance-ids i-1234567890abcdef0
```

**To enable detailed monitoring when launching an instance**

Use the `run-instances` command with the --monitoring flag to enable detailed monitoring.

```bash
aws ec2 run-instances --image-id ami-09092360 --monitoring Enabled=true...
```

**Turn off detailed monitoring**

You can turn off detailed monitoring on an instance as you launch it or after the instance is running or stopped.

**New console**

**To turn off detailed monitoring**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitoring, Manage detailed monitoring**.
4. On the **Detailed monitoring** detail page, for **Detailed monitoring**, clear the **Enable** check box.
5. Choose **Save**.

**Old console**

To turn off detailed monitoring

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, CloudWatch Monitoring, Disable Detailed Monitoring**.
4. In the **Disable Detailed Monitoring** dialog box, choose **Yes, Disable**.
5. Choose **Close**.

**AWS CLI**

To turn off detailed monitoring

Use the following `unmonitor-instances` command to turn off detailed monitoring for the specified instances.

```
aws ec2 unmonitor-instances --instance-ids i-1234567890abcdef0
```

**List the available CloudWatch metrics for your instances**

Amazon EC2 sends metrics to Amazon CloudWatch. You can use the AWS Management Console, the AWS CLI, or an API to list the metrics that Amazon EC2 sends to CloudWatch. By default, each data point covers the 5 minutes that follow the start time of activity for the instance. If you've enabled detailed monitoring, each data point covers the next minute of activity from the start time. Note that for the Minimum, Maximum, and Average statistics, the minimum granularity for the metrics that EC2 provides is 1 minute.

For information about getting the statistics for these metrics, see [Get statistics for metrics for your instances](p. 832).

**Contents**

- Instance metrics (p. 821)
- CPU credit metrics (p. 824)
- Amazon EBS metrics for Nitro-based instances (p. 825)
- Status check metrics (p. 827)
- Traffic mirroring metrics (p. 828)
- Amazon EC2 metric dimensions (p. 828)
- Amazon EC2 usage metrics (p. 828)
- List metrics using the console (p. 829)
- List metrics using the AWS CLI (p. 831)

**Instance metrics**

The AWS/EC2 namespace includes the following instance metrics.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of allocated EC2 compute units that are currently in use on the instance. This metric identifies the processing power required to run an application on a selected instance.</td>
</tr>
<tr>
<td></td>
<td>Depending on the instance type, tools in your operating system can show a lower percentage than CloudWatch when the instance is not allocated a full processor core.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>DiskReadOps</td>
<td>Completed read operations from all instance store volumes available to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period.</td>
</tr>
<tr>
<td></td>
<td>If there are no instance store volumes, either the value is 0 or the metric is not reported.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>DiskWriteOps</td>
<td>Completed write operations to all instance store volumes available to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period.</td>
</tr>
<tr>
<td></td>
<td>If there are no instance store volumes, either the value is 0 or the metric is not reported.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>DiskReadBytes</td>
<td>Bytes read from all instance store volumes available to the instance.</td>
</tr>
<tr>
<td></td>
<td>This metric is used to determine the volume of the data the application reads from the hard disk of the instance. This can be used to determine the speed of the application.</td>
</tr>
<tr>
<td></td>
<td>The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60.</td>
</tr>
<tr>
<td></td>
<td>If there are no instance store volumes, either the value is 0 or the metric is not reported.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td>DiskWriteBytes</td>
<td>Bytes written to all instance store volumes available to the instance.</td>
</tr>
<tr>
<td></td>
<td>This metric is used to determine the volume of the data the application writes onto the hard disk of the instance. This can be used to determine the speed of the application.</td>
</tr>
</tbody>
</table>
|                | The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide

</thead>
<tbody>
<tr>
<td></td>
<td>this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60.</td>
</tr>
<tr>
<td></td>
<td>If there are no instance store volumes, either the value is 0 or the metric is not reported.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td>MetadataNoToken</td>
<td>The number of times the instance metadata service was successfully accessed using a method that does not use a token.</td>
</tr>
<tr>
<td></td>
<td>This metric is used to determine if there are any processes accessing instance metadata that are using Instance Metadata Service Version 1, which does not use a token. If all requests use token-backed sessions, i.e., Instance Metadata Service Version 2, the value is 0. For more information, see Transition to using Instance Metadata Service Version 2 (p. 609).</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>NetworkIn</td>
<td>The number of bytes received by the instance on all network interfaces. This metric identifies the volume of incoming network traffic to a single instance.</td>
</tr>
<tr>
<td></td>
<td>The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td>NetworkOut</td>
<td>The number of bytes sent out by the instance on all network interfaces. This metric identifies the volume of outgoing network traffic from a single instance.</td>
</tr>
<tr>
<td></td>
<td>The number reported is the number of bytes sent during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td>NetworkPacketsIn</td>
<td>The number of packets received by the instance on all network interfaces. This metric identifies the volume of incoming traffic in terms of the number of packets on a single instance.</td>
</tr>
<tr>
<td></td>
<td>This metric is available for basic monitoring only (5-minute periods). To calculate the number of packets per second (PPS) your instance received for the 5 minutes, divide the Sum statistic value by 300.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
</tbody>
</table>
### List available metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| NetworkPacketsOut | The number of packets sent out by the instance on all network interfaces. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single instance.  
This metric is available for basic monitoring only (5-minute periods). To calculate the number of packets per second (PPS) your instance received for the 5 minutes, divide the Sum statistic value by 300.  
Units: Count                                                                                                      |

### CPU credit metrics

The AWS/EC2 namespace includes the following CPU credit metrics for your burstable performance instances (p. 216).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| CPUCreditUsage   | The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).  
CPU credit metrics are available at a 5-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.  
Units: Credits (vCPU-minutes)                                                                                           |
| CPUCreditBalance | The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.  
Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.  
The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.  
When an instance is running, credits in the CPUCreditBalance do not expire. When a T3 or T3a instance stops, the CPUCreditBalance value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the CPUCreditBalance value does not persist, and all accrued credits are lost.  
CPU credit metrics are available at a 5-minute frequency only. |

---

824
List available metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUSurplusCreditBalance</td>
<td>The number of surplus credits that have been spent by an unlimited instance when its CPUCreditBalance value is zero. The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. CPU credit metrics are available at a 5-minute frequency only.</td>
</tr>
</tbody>
</table>
| CPUSurplusCreditsCharged | The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when any of the following occurs:  
  • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.  
  • The instance is stopped or terminated.  
  • The instance is switched from unlimited to standard.  
  CPU credit metrics are available at a 5-minute frequency only. |

Amazon EBS metrics for Nitro-based instances

The AWS/EC2 namespace includes the following Amazon EBS metrics for the Nitro-based instances that are not bare metal instances. For the list of Nitro-based instance types, see Instances built on the Nitro System (p. 199).

Metric values for Nitro-based instances will always be integers (whole numbers), whereas values for Xen-based instances support decimals. Therefore, low instance CPU utilization on Nitro-based instances may appear to be rounded down to 0.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBSReadOps</td>
<td>Completed read operations from all Amazon EBS volumes attached to the instance in a specified period of time. To calculate the average read I/O operations per second (Read IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Read IOPS. If you have detailed (1-minute) monitoring, divide it by 60.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

For information about the metrics provided for your EBS volumes, see Amazon EBS metrics (p. 1391). For information about the metrics provided for your Spot fleets, see CloudWatch metrics for Spot Fleet (p. 730).

Status check metrics

The AWS/EC2 namespace includes the following status check metrics. By default, status check metrics are available at a 1-minute frequency at no charge. For a newly-launched instance, status check metric data is only available after the instance has completed the initialization state (within a few minutes of the instance entering the running state). For more information about EC2 status checks, see Status checks for your instances (p. 788).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StatusCheckFailed</td>
<td>Reports whether the instance has passed both the instance status check and the system status check in the last minute.</td>

</table>
Traffic mirroring metrics

The AWS/EC2 namespace includes metrics for mirrored traffic. For more information, see Monitoring mirrored traffic using Amazon CloudWatch in the Amazon VPC Traffic Mirroring Guide.

Amazon EC2 metric dimensions

You can use the following dimensions to refine the metrics listed in the previous tables.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoScalingGroupName</td>
<td>This dimension filters the data you request for all instances in a specified capacity group. An Auto Scaling group is a collection of instances you define if you're using Auto Scaling. This dimension is available only for Amazon EC2 metrics when the instances are in such an Auto Scaling group. Available for instances with Detailed or Basic Monitoring enabled.</td>
</tr>
<tr>
<td>ImageId</td>
<td>This dimension filters the data you request for all instances running this Amazon EC2 Amazon Machine Image (AMI). Available for instances with Detailed Monitoring enabled.</td>
</tr>
<tr>
<td>InstanceId</td>
<td>This dimension filters the data you request for the identified instance only. This helps you pinpoint an exact instance from which to monitor data.</td>
</tr>
<tr>
<td>InstanceType</td>
<td>This dimension filters the data you request for all instances running with this specified instance type. This helps you categorize your data by the type of instance running. For example, you might compare data from an m1.small instance and an m1.large instance to determine which has the better business value for your application. Available for instances with Detailed Monitoring enabled.</td>
</tr>
</tbody>
</table>

Amazon EC2 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon EC2 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see Service Quotas Integration and Usage Metrics.

Amazon EC2 publishes the following metrics in the AWS/Usage namespace.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceCount</td>
<td>The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric. The most useful statistic for this metric is MAXIMUM, which represents the maximum number of resources used during the 1-minute period.</td>
</tr>
</tbody>
</table>
The following dimensions are used to refine the usage metrics that are published by Amazon EC2.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>The name of the AWS service containing the resource. For Amazon EC2 usage metrics, the value for this dimension is EC2.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of entity that is being reported. Currently, the only valid value for Amazon EC2 usage metrics is Resource.</td>
</tr>
<tr>
<td>Resource</td>
<td>The type of resource that is running. Currently, the only valid value for Amazon EC2 usage metrics is vCPU, which returns information on instances that are running.</td>
</tr>
<tr>
<td>Class</td>
<td>The class of resource being tracked. For Amazon EC2 usage metrics with vCPU as the value of the Resource dimension, the valid values are Standard/OnDemand, F/OnDemand, G/OnDemand, Inf/OnDemand, P/OnDemand, and X/OnDemand. The values for this dimension define the first letter of the instance types that are reported by the metric. For example, Standard/OnDemand returns information about all running instances with types that start with A, C, D, H, I, M, R, T, and Z, and G/OnDemand returns information about all running instances with types that start with G.</td>
</tr>
</tbody>
</table>

List metrics using the console

Metrics are grouped first by namespace, and then by the various dimension combinations within each namespace. For example, you can view all metrics provided by Amazon EC2, or metrics grouped by instance ID, instance type, image (AMI) ID, or Auto Scaling group.

To view available metrics by category (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 metric namespace.
4. Select a metric dimension (for example, **Per-Instance Metrics**).
List available metrics

5. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric. To filter by resource, choose the resource ID and then choose Add to search. To filter by metric, choose the metric name and then choose Add to search.

List metrics using the AWS CLI

Use the list-metrics command to list the CloudWatch metrics for your instances.

To list all the available metrics for Amazon EC2 (AWS CLI)

The following example specifies the AWS/EC2 namespace to view all the metrics for Amazon EC2.

```
aws cloudwatch list-metrics --namespace AWS/EC2
```

The following is example output:

```json
{
  "Metrics": [
    {
      "Namespace": "AWS/EC2",
      "Dimensions": [
        {
          "Name": "InstanceId",
          "Value": "i-1234567890abcdef0"
        }
      ],
      "MetricName": "NetworkOut"
    },
    {
      "Namespace": "AWS/EC2",
      "Dimensions": [
        {
          "Name": "InstanceId",
          "Value": "i-1234567890abcdef0"
        }
      ],
      "MetricName": "NetworkIn"
    }
  ]
}
```
To list all the available metrics for an instance (AWS CLI)

The following example specifies the AWS/EC2 namespace and the InstanceId dimension to view the results for the specified instance only.

```bash
aws cloudwatch list-metrics --namespace AWS/EC2 --dimensions Name=InstanceId,Value=i-1234567890abcdef0
```

To list a metric across all instances (AWS CLI)

The following example specifies the AWS/EC2 namespace and a metric name to view the results for the specified metric only.

```bash
aws cloudwatch list-metrics --namespace AWS/EC2 --metric-name CPUUtilization
```

Get statistics for metrics for your instances

You can get statistics for the CloudWatch metrics for your instances.

Contents

- Statistics overview (p. 832)
- Get statistics for a specific instance (p. 833)
- Aggregate statistics across instances (p. 836)
- Aggregate statistics by Auto Scaling group (p. 838)
- Aggregate statistics by AMI (p. 839)

Statistics overview

Statistics are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other services in AWS to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify. The following table describes the available statistics.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum</td>
<td>The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.</td>
</tr>
</tbody>
</table>
## Get statistics for metrics

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum</td>
<td>The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.</td>
</tr>
<tr>
<td>Sum</td>
<td>All values submitted for the matching metric added together. This statistic can be useful for determining the total volume of a metric.</td>
</tr>
<tr>
<td>Average</td>
<td>The value of (\text{Sum} / \text{SampleCount}) during the specified period. By comparing this statistic with the Minimum and Maximum, you can determine the full scope of a metric and how close the average use is to the Minimum and Maximum. This comparison helps you to know when to increase or decrease your resources as needed.</td>
</tr>
<tr>
<td>SampleCount</td>
<td>The count (number) of data points used for the statistical calculation.</td>
</tr>
<tr>
<td>pNN.NN</td>
<td>The value of the specified percentile. You can specify any percentile, using up to two decimal places (for example, p95.45).</td>
</tr>
</tbody>
</table>

### Get statistics for a specific instance

The following examples show you how to use the AWS Management Console or the AWS CLI to determine the maximum CPU utilization of a specific EC2 instance.

#### Requirements

- You must have the ID of the instance. You can get the instance ID using the AWS Management Console or the `describe-instances` command.
- By default, basic monitoring is enabled, but you can enable detailed monitoring. For more information, see Enable or turn off detailed monitoring for your instances (p. 819).

#### To display the CPU utilization for a specific instance (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 metric namespace.
4. Choose the **Per-Instance Metrics** dimension.
5. In the search field, enter **CPUUtilization** and press Enter. Choose the row for the specific instance, which displays a graph for the **CPUUtilization** metric for the instance. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.

![Graph of CPUUtilization](image)

6. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

**To get the CPU utilization for a specific instance (AWS CLI)**

Use the following `get-metric-statistics` command to get the **CPUUtilization** metric for the specified instance, using the specified period and time interval:

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization --period 3600 --statistics Maximum --dimensions Name=InstanceId,Value=i-1234567890abcdef0 --start-time 2016-10-18T23:18:00 --end-time 2016-10-19T23:18:00
```
The following is example output. Each value represents the maximum CPU utilization percentage for a single EC2 instance.

```json
{
  "Datapoints": [
    {
      "Timestamp": "2016-10-19T00:18:00Z",
      "Maximum": 0.33000000000000002,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2016-10-19T03:18:00Z",
      "Maximum": 99.670000000000002,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2016-10-19T07:18:00Z",
      "Maximum": 0.34000000000000002,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2016-10-19T12:18:00Z",
      "Maximum": 0.34000000000000002,
      "Unit": "Percent"
    },
    ...,
    "Label": "CPUUtilization"
  ]
}
```

**Aggregate statistics across instances**

Aggregate statistics are available for instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics aggregated across instances, you must enable detailed monitoring (p. 819) (at an additional charge), which provides data in 1-minute periods.

Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to use detailed monitoring to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the AWS/EC2 namespace.

**Important**

This technique for retrieving all dimensions across an AWS namespace does not work for custom namespaces that you publish to Amazon CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

**To display average CPU utilization across your instances (console)**

2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **Across All Instances**.
4. Choose the row that contains **CPUUtilization**, which displays a graph for the metric for all your EC2 instances. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.
5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get average CPU utilization across your instances (AWS CLI)

Use the `get-metric-statistics` command as follows to get the average of the `CPUUtilization` metric across your instances.

```
aws cloudwatch get-metric-statistics \
  --namespace AWS/EC2 \
  --metric-name CPUUtilization \
  --period 3600 --statistics "Average" "SampleCount" \
  --start-time 2016-10-11T23:18:00 \
  --end-time 2016-10-12T23:18:00
```

The following is example output:

```
{
  "Datapoints": [
    {
      "SampleCount": 238.0,
      "Timestamp": "2016-10-12T07:18:00Z",
      "Average": 0.038235294117647062,
      "Unit": "Percent"
    },
    {
      "SampleCount": 240.0,
      "Timestamp": "2016-10-12T09:18:00Z",
      "Average": 0.16670833333333332
    }
  ]
}
```
Aggregate statistics by Auto Scaling group

You can aggregate statistics for the EC2 instances in an Auto Scaling group. Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to retrieve the total bytes written to disk for one Auto Scaling group. The total is computed for 1-minute periods for a 24-hour interval across all EC2 instances in the specified Auto Scaling group.

To display DiskWriteBytes for the instances in an Auto Scaling group (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose By Auto Scaling Group.
4. Choose the row for the DiskWriteBytes metric and the specific Auto Scaling group, which displays a graph for the metric for the instances in the Auto Scaling group. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic or the period for the metric, choose the Graphed metrics tab. Choose the column heading or an individual value, and then choose a different value.

To display DiskWriteBytes for the instances in an Auto Scaling group (AWS CLI)

Use the get-metric-statistics command as follows.

```bash
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name DiskWriteBytes --period 360 --statistics "Sum" "SampleCount" --dimensions Name=AutoScalingGroupName,Value=my-asg --start-time 2016-10-16T23:18:00 --end-time 2016-10-18T23:18:00
```

The following is example output:

```json
{
   "Datapoints": [
      {
         "SampleCount": 18.0,
         "Timestamp": "2016-10-19T21:36:00Z",
         "Sum": 0.0,
         "Unit": "Bytes"
      },
      {
         "SampleCount": 5.0,
         "Timestamp": "2016-10-19T21:42:00Z",
         "Sum": 0.0,
         "Unit": "Bytes"
      }
   ],
   "Label": "CPUUtilization"
}
```
Aggregate statistics by AMI

You can aggregate statistics for your instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics aggregated across instances, you must enable detailed monitoring (p. 819) (at an additional charge), which provides data in 1-minute periods.

Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to determine average CPU utilization for all instances that use a specific Amazon Machine Image (AMI). The average is over 60-second time intervals for a one-day period.

To display the average CPU utilization by AMI (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose By Image (AMI) Id.
4. Choose the row for the CPUUtilization metric and the specific AMI, which displays a graph for the metric for the specified AMI. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic or the period for the metric, choose the Graphed metrics tab. Choose the column heading or an individual value, and then choose a different value.

To get the average CPU utilization for an image ID (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization --period 3600 --statistics Average --dimensions Name=ImageId,Value=ami-3c47a355 --start-time 2016-10-10T00:00:00 --end-time 2016-10-11T00:00:00
```

The following is example output. Each value represents an average CPU utilization percentage for the EC2 instances running the specified AMI.

```json
{
    "Datapoints": [
        {
            "Timestamp": "2016-10-10T07:00:02Z",
            "Average": 0.041000000000000009,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2016-10-10T14:00:02Z",
            "Average": 0.079579831932773085,
            "Unit": "Percent"
        },
        {
```
Graph metrics for your instances

After you launch an instance, you can open the Amazon EC2 console and view the monitoring graphs for the instance on the Monitoring tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs are available:

- Average CPU Utilization (Percent)
- Average Disk Reads (Bytes)
- Average Disk Writes (Bytes)
- Maximum Network In (Bytes)
- Maximum Network Out (Bytes)
- Summary Disk Read Operations (Count)
- Summary Disk Write Operations (Count)
- Summary Status (Any)
- Summary Status Instance (Count)
- Summary Status System (Count)

For more information about the metrics and the data they provide to the graphs, see List the available CloudWatch metrics for your instances (p. 821).

Graph Metrics Using the CloudWatch Console

You can also use the CloudWatch console to graph metric data generated by Amazon EC2 and other AWS services. For more information, see Graph Metrics in the Amazon CloudWatch User Guide.

Create a CloudWatch alarm for an instance

You can create a CloudWatch alarm that monitors CloudWatch metrics for one of your instances. CloudWatch will automatically send you a notification when the metric reaches a threshold you specify.

You can create a CloudWatch alarm using the Amazon EC2 console, or using the more advanced options provided by the CloudWatch console.

To create an alarm using the CloudWatch console

For examples, see Creating Amazon CloudWatch Alarms in the Amazon CloudWatch User Guide.

New console

To create an alarm using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose **Actions, Monitor and troubleshoot, Manage CloudWatch alarms**.

4. On the **Manage CloudWatch alarms** detail page, under **Add or edit alarm**, select **Create an alarm**.

5. For **Alarm notification**, choose whether to turn the toggle on or off to configure Amazon Simple Notification Service (Amazon SNS) notifications. Enter an existing Amazon SNS topic or enter a name to create a new topic.

6. For **Alarm action**, choose whether to turn the toggle on or off to specify an action to take when the alarm is triggered. Select an action from the dropdown.

7. For **Alarm thresholds**, select the metric and criteria for the alarm. For example, you can leave the default settings for **Group samples by (Average)** and **Type of data to sample (CPU utilization)**. For **Alarm when**, choose >= and enter 0.80. For **Consecutive period**, enter 1. For **Period**, select 5 minutes.

8. (Optional) For **Sample metric data**, choose **Add to dashboard**.

9. Choose **Create**.

**Old console**

**To create an alarm using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. In the navigation pane, choose **Instances**.

3. Select the instance.

4. On the **Monitoring** tab located at the bottom of the page, choose **Create Alarm**. Or, from the **Actions** dropdown, choose **CloudWatch Monitoring, Add/Edit Alarm**.

5. In the **Create Alarm** dialog box, do the following:

   a. Choose **create topic**. For **Send a notification to**, enter a name for the SNS topic. For **With these recipients**, enter one or more email addresses to receive notification.

   b. Specify the metric and the criteria for the policy. For example, you can leave the default settings for **Whenever** (Average of CPU Utilization). For **Is**, choose >= and enter 80 percent. For **For at least**, enter 1 consecutive period of 5 minutes.

   c. Choose **Create Alarm**.
Create alarms that stop, terminate, reboot, or recover an instance

You can edit your CloudWatch alarm settings from the Amazon EC2 console or the CloudWatch console. If you want to delete your alarm, you can do so from the CloudWatch console. For more information, see Editing or Deleting a CloudWatch Alarm in the Amazon CloudWatch User Guide.

You can edit your CloudWatch alarm settings from the Amazon EC2 console or the CloudWatch console. If you want to delete your alarm, you can do so from the CloudWatch console. For more information, see Editing or Deleting a CloudWatch Alarm in the Amazon CloudWatch User Guide.

Create alarms that stop, terminate, reboot, or recover an instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

The AWSServiceRoleForCloudWatchEvents service-linked role enables AWS to perform alarm actions on your behalf. The first time you create an alarm in the AWS Management Console, the IAM CLI, or the IAM API, CloudWatch creates the service-linked role for you.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which can help you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily start a stopped instance if you need to run it again later, and you can keep the same instance...
Add stop actions to Amazon CloudWatch alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an Amazon Simple Notification Service (Amazon SNS) notification so that you receive an email when the alarm is triggered.

Instances that use an Amazon EBS volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated.

New console

To create an alarm to stop an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, Manage CloudWatch alarms.

Alternatively, you can choose the plus sign (+) in the Alarm status column.

4. On the Manage CloudWatch alarms page, do the following:
   a. Choose Create an alarm.
Create alarms that stop, terminate, reboot, or recover an instance

b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see *Using Amazon SNS for application-to-person (A2P) messaging* in the *Amazon Simple Notification Service Developer Guide*.

c. Toggle on **Alarm action**, and choose **Stop**.

d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **CPU utilization**.

e. For **Alarm When** and **Percent**, specify the metric threshold. In this example, specify <= and 10 percent.

f. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, specify 1 consecutive period of **5 Minutes**.

g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

**Note**
You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

h. Choose **Create**.

Old console

**To create an alarm to stop an idle instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance. On the **Monitoring** tab, choose **Create Alarm**.
4. In the **Create Alarm** dialog box, do the following:

   a. To receive an email when the alarm is triggered, for **Send a notification to**, choose an existing Amazon SNS topic, or choose **create topic** to create a new one.

      To create a new topic, for **Send a notification to**, enter a name for the topic, and then for **With these recipients**, enter the email addresses of the recipients (separated by commas). After you create the alarm, you will receive a subscription confirmation email that you must accept before you can get notifications for this topic.

   b. Choose **Take the action, Stop this instance**.

c. For **Whenever**, choose the statistic you want to use and then choose the metric. In this example, choose **Average** and **CPU Utilization**.

d. For **Is**, specify the metric threshold. In this example, enter **10** percent.

e. For **For at least**, specify the evaluation period for the alarm. In this example, enter **24** consecutive period(s) of **1 Hour**.

f. To change the name of the alarm, for **Name of alarm**, enter a new name. Alarm names must contain only ASCII characters.

   If you don’t enter a name for the alarm, Amazon CloudWatch automatically creates one for you.

**Note**
You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.
Create alarms that stop, terminate, reboot, or recover an instance

Add terminate actions to Amazon CloudWatch alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don’t need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. For information on enabling and disabling termination protection for an instance, see Enable termination protection (p. 550).

New console

**To create an alarm to terminate an idle instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitor and troubleshoot, Manage CloudWatch alarms**.

Alternatively, you can choose the plus sign (✚) in the **Alarm status** column.

4. On the **Manage CloudWatch alarms** page, do the following:
   a. Choose **Create an alarm**.
   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
   c. Toggle on **Alarm action**, and choose **Terminate**.
   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **CPU utilization**.
   e. For **Alarm When** and **Percent**, specify the metric threshold. In this example, specify `=>` and **10** percent.
   f. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, specify **24** consecutive periods of **1 Hour**.
   g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

   **Note**
   You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.
   h. Choose **Create**.

Old console

**To create an alarm to terminate an idle instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance. On the **Monitoring** tab, choose **Create Alarm**.
4. In the **Create Alarm** dialog box, do the following:

   a. To receive an email when the alarm is triggered, for **Send a notification to**, choose an existing Amazon SNS topic, or choose **create topic** to create a new one.

      To create a new topic, for **Send a notification to**, enter a name for the topic, and then for **With these recipients**, enter the email addresses of the recipients (separated by commas). After you create the alarm, you will receive a subscription confirmation email that you must accept before you can get notifications for this topic.

   b. Choose **Take the action**, **Terminate this instance**.

   c. For **Whenever**, choose a statistic and then choose the metric. In this example, choose **Average** and **CPU Utilization**.

   d. For **Is**, specify the metric threshold. In this example, enter 10 percent.

   e. For **For at least**, specify the evaluation period for the alarm. In this example, enter 24 consecutive period(s) of **1 Hour**.

   f. To change the name of the alarm, for **Name of alarm**, enter a new name. Alarm names must contain only ASCII characters.

      If you don't enter a name for the alarm, Amazon CloudWatch automatically creates one for you.

      **Note**
      You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

   g. Choose **Create Alarm**.

---

**Add reboot actions to Amazon CloudWatch alarms**

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and restarting your instance. For more information, see Reboot your instance (p. 544).

**Important**
To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each. For more information, see Evaluating an alarm in the Amazon CloudWatch User Guide.

**New console**

**To create an alarm to reboot an instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitor and troubleshoot, Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (➕) in the **Alarm status** column.
4. On the Manage CloudWatch alarms page, do the following:

   a. Choose Create an alarm.
   b. To receive an email when the alarm is triggered, for Alarm notification, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
   c. Toggle on Alarm action, and choose Reboot.
   d. For Group samples by and Type of data to sample, choose a statistic and a metric. In this example, choose Average and Status check failed: instance.
   e. For Consecutive period and Period, specify the evaluation period for the alarm. In this example, enter 3 consecutive periods of 5 Minutes.
   f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for Alarm name, enter a new name. Alarm names must contain only ASCII characters.
   g. Choose Create.

Old console

To create an alarm to reboot an instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
4. In the Create Alarm dialog box, do the following:

   a. To receive an email when the alarm is triggered, for Send a notification to, choose an existing Amazon SNS topic, or choose create topic to create a new one.
      To create a new topic, for Send a notification to, enter a name for the topic, and for With these recipients, enter the email addresses of the recipients (separated by commas). After you create the alarm, you will receive a subscription confirmation email that you must accept before you can get notifications for this topic.
   b. Select Take the action, Reboot this instance.
   c. For Whenever, choose Status Check Failed (Instance).
   d. For For at least, specify the evaluation period for the alarm. In this example, enter 3 consecutive period(s) of 5 Minutes.
   e. To change the name of the alarm, for Name of alarm, enter a new name. Alarm names must contain only ASCII characters.
      If you don’t enter a name for the alarm, Amazon CloudWatch automatically creates one for you.
   f. Choose Create Alarm.

Add recover actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance. If the instance becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair, you can automatically recover the instance. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

CloudWatch prevents you from adding a recovery action to an alarm that is on an instance which does not support recovery actions.
When the `StatusCheckFailed_System` alarm is triggered, and the recover action is initiated, you are notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you’ve configured for the alarm. Anyone who is subscribed to this SNS topic receives an email notification that includes the status of the recovery attempt and any further instructions. You notice an instance reboot on the recovered instance.

The recover action can be used only with `StatusCheckFailed_System`, not with `StatusCheckFailed_Instance`.

The following problems can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

The recover action is supported only on instances with the following characteristics:

- Use one of the following instance types: A1, C3, C4, C5, C5a, C5n, C6g, C6gn, Inf1, M3, M4, M5, M5a, M5n, M5zn, M6g, M6i, P3, P4, R3, R4, R5, R5a, R5b, R5n, R6g, T2, T3, T3a, T4g, high memory (virtualized only), X1, X1e
- Use default or dedicated instance tenancy
- Use EBS volumes only (do not configure instance store volumes). For more information, see ‘Recover this instance’ is disabled.

If your instance has a public IP address, it retains the public IP address after recovery.

**Important**

To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each. For more information, see Evaluating an Alarm in the Amazon CloudWatch User Guide.

**New console**

**To create an alarm to recover an instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitor and troubleshoot, Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (+) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.
   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
Create alarms that stop, terminate, reboot, or recover an instance

**Note**

Users must subscribe to the specified SNS topic to receive email notifications when the alarm is triggered. The AWS account root user always receives email notifications when automatic instance recovery actions occur, even if an SNS topic is not specified or the root user is not subscribed to the specified SNS topic.

c. Toggle on **Alarm action**, and choose **Recover**.

d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **Status check failed: system**.

e. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, enter 2 consecutive periods of **5 Minutes**.

f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

g. Choose **Create**.

**Old console**

**To create an alarm to recover an instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance. On the **Monitoring** tab, choose **Create Alarm**.
4. In the **Create Alarm** dialog box, do the following:

   a. To receive an email when the alarm is triggered, for **Send a notification to**, choose an existing Amazon SNS topic, or choose **create topic** to create a new one.

   To create a new topic, for **Send a notification to**, enter a name for the topic, and for **With these recipients**, enter the email addresses of the recipients (separated by commas). After you create the alarm, you will receive a subscription confirmation email that you must accept before you can get email for this topic.

   **Note**

   - Users must subscribe to the specified SNS topic to receive email notifications when the alarm is triggered.
   - The AWS account root user always receives email notifications when automatic instance recovery actions occur, even if an SNS topic is not specified.
   - The AWS account root user always receives email notifications when automatic instance recovery actions occur, even if it is not subscribed to the specified SNS topic.

   b. Select **Take the action**, **Recover this instance**.

   c. For **Whenever**, choose **Status Check Failed (System)**.

   d. For **For at least**, specify the evaluation period for the alarm. In this example, enter 2 consecutive period(s) of **5 Minutes**.

   e. To change the name of the alarm, for **Name of alarm**, enter a new name. Alarm names must contain only ASCII characters.

   If you don’t enter a name for the alarm, Amazon CloudWatch automatically creates one for you.

   f. Choose **Create Alarm**.
Use the Amazon CloudWatch console to view alarm and action history

You can view alarm and action history in the Amazon CloudWatch console. Amazon CloudWatch keeps the last two weeks' worth of alarm and action history.

To view the history of triggered alarms and actions (CloudWatch console)
2. In the navigation pane, choose Alarms.
3. Select an alarm.
4. The Details tab shows the most recent state transition along with the time and metric values.
5. Choose the History tab to view the most recent history entries.

Amazon CloudWatch alarm action scenarios

You can use the Amazon EC2 console to create alarm actions that stop or terminate an Amazon EC2 instance when certain conditions are met. In the following screen capture of the console page where you set the alarm actions, we've numbered the settings. We've also numbered the settings in the scenarios that follow, to help you create the appropriate actions.
Create alarms that stop, terminate, reboot, or recover an instance.

**Alarm notification**
Configure the alarm to send notifications to an Amazon SNS topic when it is triggered.

**Alarm action**
Specify the action to take when the alarm is triggered.

**Alarm thresholds**
Specify the metric thresholds for the alarm.

- **Group samples by**: average
- **Alarm When**:
- **Consecutive Period**
- **Alarm name**
Create alarms that stop, terminate, reboot, or recover an instance

Scenario 1: Stop idle development and test instances

Create an alarm that stops an instance used for software development or testing when it has been idle for at least an hour.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop</td>
</tr>
<tr>
<td>2</td>
<td>Maximum</td>
</tr>
<tr>
<td>3</td>
<td>CPU Utilization</td>
</tr>
<tr>
<td>4</td>
<td>&lt;=</td>
</tr>
<tr>
<td>5</td>
<td>10%</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>
Scenario 2: Stop idle instances

Create an alarm that stops an instance and sends an email when the instance has been idle for 24 hours.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop and email</td>
</tr>
<tr>
<td>2</td>
<td>Average</td>
</tr>
<tr>
<td>3</td>
<td>CPU Utilization</td>
</tr>
<tr>
<td>4</td>
<td>&lt;=</td>
</tr>
<tr>
<td>5</td>
<td>5%</td>
</tr>
<tr>
<td>6</td>
<td>24</td>
</tr>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>

Scenario 3: Send email about web servers with unusually high traffic

Create an alarm that sends email when an instance exceeds 10 GB of outbound network traffic per day.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Email</td>
</tr>
<tr>
<td>2</td>
<td>Sum</td>
</tr>
<tr>
<td>3</td>
<td>Network Out</td>
</tr>
<tr>
<td>4</td>
<td>&gt;</td>
</tr>
<tr>
<td>5</td>
<td>10 GB</td>
</tr>
<tr>
<td>6</td>
<td>24</td>
</tr>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>

Scenario 4: Stop web servers with unusually high traffic

Create an alarm that stops an instance and send a text message (SMS) if outbound traffic exceeds 1 GB per hour.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop and send SMS</td>
</tr>
<tr>
<td>2</td>
<td>Sum</td>
</tr>
<tr>
<td>3</td>
<td>Network Out</td>
</tr>
<tr>
<td>4</td>
<td>&gt;</td>
</tr>
<tr>
<td>5</td>
<td>1 GB</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
</tbody>
</table>
### Scenario 5: Stop an impaired instance

Create an alarm that stops an instance that fails three consecutive status checks (performed at 5-minute intervals).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>

### Scenario 6: Terminate instances when batch processing jobs are complete

Create an alarm that terminates an instance that runs batch jobs when it is no longer sending results data.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop</td>
</tr>
<tr>
<td>2</td>
<td>Average</td>
</tr>
<tr>
<td>3</td>
<td>Status Check Failed: System</td>
</tr>
<tr>
<td>4</td>
<td>&lt;=</td>
</tr>
<tr>
<td>5</td>
<td>100,000 bytes</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>5 Minutes</td>
</tr>
</tbody>
</table>

---

**Automate Amazon EC2 with EventBridge**

Amazon EventBridge enables you to automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and the automated actions to take when an event matches a rule. The actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
Monitor memory and disk metrics for Amazon EC2 Linux instances

You can use Amazon CloudWatch to collect metrics and logs from the operating systems for your EC2 instances.

**Important**
The CloudWatch monitoring scripts are deprecated. We recommend that you use the CloudWatch agent to collect metrics and logs. For more information, see Collect Metrics from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

If you are still migrating from the deprecated monitoring scripts to the agent, and require information about the monitoring scripts, see Deprecated: Collect metrics using the CloudWatch monitoring scripts (p. 855).

Collect metrics using the CloudWatch agent

You can use the CloudWatch agent to collect both system metrics and log files from Amazon EC2 instances and on-premises servers. The agent supports both Windows Server and Linux, and enables you to select the metrics to be collected, including sub-resource metrics such as per-CPU core. We recommend that you use the agent to collect metrics and logs instead of using the deprecated monitoring scripts. For more information, see Collect Metrics from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

Deprecated: Collect metrics using the CloudWatch monitoring scripts

**Important**
The CloudWatch monitoring scripts are deprecated. We provide information about the monitoring scripts for customers who have not yet migrated from the deprecated monitoring scripts to the CloudWatch agent.

We recommend that you use the CloudWatch agent to collect metrics and logs. For more information, see Collect Metrics from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

The monitoring scripts demonstrate how to produce and consume custom metrics for Amazon CloudWatch. These sample Perl scripts comprise a fully functional example that reports memory, swap, and disk space utilization metrics for a Linux instance.
Standard Amazon CloudWatch usage charges for custom metrics apply to your use of these scripts. For more information, see the Amazon CloudWatch pricing page.

Contents
- Supported systems (p. 856)
- Required permissions (p. 856)
- Install required packages (p. 856)
- Install monitoring scripts (p. 858)
- mon-put-instance-data.pl (p. 858)
- mon-get-instance-stats.pl (p. 861)
- View your custom metrics in the console (p. 862)
- Troubleshoot (p. 863)

Supported systems

The monitoring scripts were tested on instances using the following systems. Using the monitoring scripts on any other operating system is unsupported.

- Amazon Linux 2
- Amazon Linux AMI 2014.09.2 and later
- Red Hat Enterprise Linux 6.9 and 7.4
- SUSE Linux Enterprise Server 12
- Ubuntu Server 14.04 and 16.04

Required permissions

Ensure that the scripts have permission to call the following actions by associating an IAM role with your instance:

- cloudwatch:PutMetricData
- cloudwatch:GetMetricStatistics
- cloudwatch:ListMetrics
- ec2:DescribeTags

For more information, see Work with IAM roles (p. 1127).

Install required packages

With some versions of Linux, you must install additional Perl modules before you can use the monitoring scripts.

To install the required packages on Amazon Linux 2 and Amazon Linux AMI

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 499).
2. At a command prompt, install packages as follows:

```
sudo yum install -y perl-Switch perl-DateTime perl-Sys-Syslog perl-LWP-Protocol-https perl-Digest-SHA.x86_64
```
To install the required packages on Ubuntu

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 499).
2. At a command prompt, install packages as follows:

   ```
sudo apt-get update
sudo apt-get install unzip
sudo apt-get install libwww-perl libdatetime-perl
   ```

To install the required packages on Red Hat Enterprise Linux 7

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 499).
2. At a command prompt, install packages as follows:

   ```
sudo yum install perl-Switch perl-DateTime perl-Syslog perl-LWP-Protocol-https
perl-Digest-SHA --enablerepo="rhui-REGION-rhel-server-optional" -y
sudo yum install zip unzip
   ```

To install the required packages on Red Hat Enterprise Linux 6.9

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 499).
2. At a command prompt, install packages as follows:

   ```
sudo yum install perl-DateTime perl-CPAN perl-Net-SSLeay perl-IO-Socket-SSL perl-
Digest-SHA gcc -y
sudo yum install zip unzip
   ```
3. Run CPAN as an elevated user:

   ```
sudo cpan
   ```

   Press ENTER through the prompts until you see the following prompt:

   ```
cpan[1]>
   ```
4. At the CPAN prompt, run each of the below commands: run one command and it installs, and when you return to the CPAN prompt, run the next command. Press ENTER like before when prompted to continue through the process:

   ```
cpan[1]> install YAML
   ```
   ```
cpan[2]> install LWP::Protocol::https
   ```
   ```
cpan[3]> install Sys::Syslog
   ```
   ```
cpan[4]> install Switch
   ```

To install the required packages on SUSE

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 499).
2. On servers running SUSE Linux Enterprise Server 12, you might need to download the perl-Switch package. You can download and install this package using the following commands:

   ```
wget http://download.opensuse.org/repositories/devel:/languages:/perl/SLE_12_SP3/
oarch/perl-Switch-2.17-32.1.noarch.rpm
   ```
Install monitoring scripts

The following steps show you how to download, uncompress, and configure the CloudWatch Monitoring Scripts on an EC2 Linux instance.

To download, install, and configure the monitoring scripts

1. At a command prompt, move to a folder where you want to store the monitoring scripts and run the following command to download them:

```bash
curl https://aws-cloudwatch.s3.amazonaws.com/downloads/CloudWatchMonitoringScripts-1.2.2.zip -O
```

2. Run the following commands to install the monitoring scripts you downloaded:

```bash
unzip CloudWatchMonitoringScripts-1.2.2.zip &&
rm CloudWatchMonitoringScripts-1.2.2.zip &&
cd aws-scripts-mon
```

The package for the monitoring scripts contains the following files:

- **CloudWatchClient.pm** – Shared Perl module that simplifies calling Amazon CloudWatch from other scripts.
- **mon-put-instance-data.pl** – Collects system metrics on an Amazon EC2 instance (memory, swap, disk space utilization) and sends them to Amazon CloudWatch.
- **mon-get-instance-stats.pl** – Queries Amazon CloudWatch and displays the most recent utilization statistics for the EC2 instance on which this script is run.
- **awscreds.template** – File template for AWS credentials that stores your access key ID and secret access key.
- **LICENSE.txt** – Text file containing the Apache 2.0 license.
- **NOTICE.txt** – Copyright notice.

**mon-put-instance-data.pl**

This script collects memory, swap, and disk space utilization data on the current system. It then makes a remote call to Amazon CloudWatch to report the collected data as custom metrics.

**Options**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--mem-util</td>
<td>Collects and sends the MemoryUtilization metrics in percentages. This metric counts memory allocated by applications and the operating system as used, and also includes cache and buffer memory as used if you specify the --mem-used-incl-cache-buff option.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
--mem-used | Collects and sends the MemoryUsed metrics, reported in megabytes. This metric counts memory allocated by applications and the operating system as used, and also includes cache and buffer memory as used if you specify the --mem-used-incl-cache-buff option.

--mem-used-incl-cache-buff | If you include this option, memory currently used for cache and buffers is counted as "used" when the metrics are reported for --mem-util, --mem-used, and --mem-avail.

--mem-avail | Collects and sends the MemoryAvailable metrics, reported in megabytes. This metric counts memory allocated by applications and the operating system as used, and also includes cache and buffer memory as used if you specify the --mem-used-incl-cache-buff option.

--swap-util | Collects and sends SwapUtilization metrics, reported in percentages.

--swap-used | Collects and sends SwapUsed metrics, reported in megabytes.

--disk-path=PATH | Selects the disk on which to report.

PATH can specify a mount point or any file located on a mount point for the filesystem that needs to be reported. For selecting multiple disks, specify a --disk-path=PATH for each one of them.

To select a disk for the filesystems mounted on / and /home, use the following parameters:

--disk-path=/ --disk-path=/home

--disk-space-util | Collects and sends the DiskSpaceUtilization metric for the selected disks. The metric is reported in percentages.

Note that the disk utilization metrics calculated by this script differ from the values calculated by the df -k -l command. If you find the values from df -k -l more useful, you can change the calculations in the script.

--disk-space-used | Collects and sends the DiskSpaceUsed metric for the selected disks. The metric is reported by default in gigabytes.

Due to reserved disk space in Linux operating systems, disk space used and disk space available might not accurately add up to the amount of total disk space.

--disk-space_avail | Collects and sends the DiskSpaceAvailable metric for the selected disks. The metric is reported in gigabytes.

Due to reserved disk space in the Linux operating systems, disk space used and disk space available might not accurately add up to the amount of total disk space.

--memory-units=UNITS | Specifies units in which to report memory usage. If not specified, memory is reported in megabytes. UNITS may be one of the following: bytes, kilobytes, megabytes, gigabytes.
Name | Description
--- | ---
--disk-space-units=UNITS | Specifies units in which to report disk space usage. If not specified, disk space is reported in gigabytes. UNITS may be one of the following: bytes, kilobytes, megabytes, gigabytes.
--aws-credential-file=PATH | Provides the location of the file containing AWS credentials. This parameter cannot be used with the --aws-access-key-id and --aws-secret-key parameters.
--aws-access-key-id=VALUE | Specifies the AWS access key ID to use to identify the caller. Must be used together with the --aws-secret-key option. Do not use this option with the --aws-credential-file parameter.
--aws-secret-key=VALUE | Specifies the AWS secret access key to use to sign the request to CloudWatch. Must be used together with the --aws-access-key-id option. Do not use this option with --aws-credential-file parameter.
--aws-iam-role=VALUE | Specifies the IAM role used to provide AWS credentials. The value =VALUE is required. If no credentials are specified, the default IAM role associated with the EC2 instance is applied. Only one IAM role can be used. If no IAM roles are found, or if more than one IAM role is found, the script will return an error. Do not use this option with the --aws-credential-file, --aws-access-key-id, or --aws-secret-key parameters.
--aggregated[=only] | Adds aggregated metrics for instance type, AMI ID, and overall for the Region. The value =only is optional; if specified, the script reports only aggregated metrics.
--auto-scaling[=only] | Adds aggregated metrics for the Auto Scaling group. The value =only is optional; if specified, the script reports only Auto Scaling metrics. The IAM policy associated with the IAM account or role using the scripts need to have permissions to call the EC2 action DescribeTags.
--verify | Performs a test run of the script that collects the metrics, prepares a complete HTTP request, but does not actually call CloudWatch to report the data. This option also checks that credentials are provided. When run in verbose mode, this option outputs the metrics that will be sent to CloudWatch.
--from-cron | Use this option when calling the script from cron. When this option is used, all diagnostic output is suppressed, but error messages are sent to the local system log of the user account.
--verbose | Displays detailed information about what the script is doing.
--help | Displays usage information.
--version | Displays the version number of the script.

Examples
The following examples assume that you provided an IAM role or awscreds.conf file. Otherwise, you must provide credentials using the --aws-access-key-id and --aws-secret-key parameters for these commands.

The following example performs a simple test run without posting data to CloudWatch.

```
./mon-put-instance-data.pl --mem-util --verify --verbose
```

The following example collects all available memory metrics and sends them to CloudWatch, counting cache and buffer memory as used.

```
./mon-put-instance-data.pl --mem-used-incl-cache-buff --mem-util --mem-used --mem-avail
```

The following example collects aggregated metrics for an Auto Scaling group and sends them to Amazon CloudWatch without reporting individual instance metrics.

```
./mon-put-instance-data.pl --mem-util --mem-used --mem-avail --auto-scaling=only
```

The following example collects aggregated metrics for instance type, AMI ID and region, and sends them to Amazon CloudWatch without reporting individual instance metrics.

```
./mon-put-instance-data.pl --mem-util --mem-used --mem-avail --aggregated=only
```

To set a cron schedule for metrics reported to CloudWatch, start editing the crontab using the `crontab -e` command. Add the following command to report memory and disk space utilization to CloudWatch every five minutes:

```
*/5 * * * * ~/aws-scripts-mon/mon-put-instance-data.pl --mem-used-incl-cache-buff --mem-util --disk-space-util --disk-path=/ --from-cron
```

If the script encounters an error, it writes the error message in the system log.

**mon-get-instance-stats.pl**

This script queries CloudWatch for statistics on memory, swap, and disk space metrics within the time interval provided using the number of most recent hours. This data is provided for the Amazon EC2 instance on which this script is run.

**Options**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--recent-hours=N</td>
<td>Specifies the number of recent hours to report on, as represented by \ N where N is an integer.</td>
</tr>
<tr>
<td>--aws-credential-file=PATH</td>
<td>Provides the location of the file containing AWS credentials.</td>
</tr>
<tr>
<td>--aws-access-key-id=VALUE</td>
<td>Specifies the AWS access key ID to use to identify the caller. Must be used together with the --aws-secret-key option. Do not use this option with the --aws-credential-file option.</td>
</tr>
<tr>
<td>--aws-secret-key=VALUE</td>
<td>Specifies the AWS secret access key to use to sign the request to CloudWatch. Must be used together with the --aws-access-key-</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>id option. Do not use this option with --aws-credential-file option.</td>
<td></td>
</tr>
<tr>
<td>--aws-iam-role=VALUE</td>
<td>Specifies the IAM role used to provide AWS credentials. The value=VALUE is required. If no credentials are specified, the default IAM role associated with the EC2 instance is applied. Only one IAM role can be used. If no IAM roles are found, or if more than one IAM role is found, the script will return an error. Do not use this option with the --aws-credential-file, --aws-access-key-id, or --aws-secret-key parameters.</td>
</tr>
<tr>
<td>--verify</td>
<td>Performs a test run of the script. This option also checks that credentials are provided.</td>
</tr>
<tr>
<td>--verbose</td>
<td>Displays detailed information about what the script is doing.</td>
</tr>
<tr>
<td>--help</td>
<td>Displays usage information.</td>
</tr>
<tr>
<td>--version</td>
<td>Displays the version number of the script.</td>
</tr>
</tbody>
</table>

**Example**

To get utilization statistics for the last 12 hours, run the following command:

```
./mon-get-instance-stats.pl --recent-hours=12
```

The following is an example response:

<table>
<thead>
<tr>
<th>Instance metric statistics for the last 12 hours.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU Utilization</td>
</tr>
<tr>
<td>Average: 1.06%, Minimum: 0.00%, Maximum: 15.22%</td>
</tr>
<tr>
<td>Memory Utilization</td>
</tr>
<tr>
<td>Average: 6.84%, Minimum: 6.82%, Maximum: 6.89%</td>
</tr>
<tr>
<td>Swap Utilization</td>
</tr>
<tr>
<td>Average: N/A, Minimum: N/A, Maximum: N/A</td>
</tr>
<tr>
<td>Disk Space Utilization on /dev/xvda1 mounted as /</td>
</tr>
<tr>
<td>Average: 9.69%, Minimum: 9.69%, Maximum: 9.69%</td>
</tr>
</tbody>
</table>

**View your custom metrics in the console**

After you successfully run the mon-put-instance-data.pl script, you can view your custom metrics in the Amazon CloudWatch console.

**To view custom metrics**

1. Run mon-put-instance-data.pl as described previously.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. Choose View Metrics.
4. For Viewing, your custom metrics posted by the script are displayed with the prefix System/Linux.
Troubleshoot

The CloudWatchClient.pm module caches instance metadata locally. If you create an AMI from an instance where you have run the monitoring scripts, any instances launched from the AMI within the cache TTL (default: six hours, 24 hours for Auto Scaling groups) emit metrics using the instance ID of the original instance. After the cache TTL time period passes, the script retrieves fresh data and the monitoring scripts use the instance ID of the current instance. To immediately correct this, remove the cached data using the following command:

```
rm /var/tmp/aws-mon/instance-id
```

Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail

Amazon EC2 and Amazon EBS are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EC2 and Amazon EBS. CloudTrail captures all API calls for Amazon EC2 and Amazon EBS as events, including calls from the console and from code calls to the APIs. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon EC2 and Amazon EBS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon EC2 and Amazon EBS, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon EC2 and Amazon EBS information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon EC2 and Amazon EBS, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon EC2 and Amazon EBS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Amazon EC2 actions, and Amazon EBS management actions, are logged by CloudTrail and are documented in the Amazon EC2 API Reference. For example, calls to the RunInstances, DescribeInstances, or CreateImage actions generate entries in the CloudTrail log files.
Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail `userIdentity` Element.

**Understand Amazon EC2 and Amazon EBS log file entries**

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following log file record shows that a user terminated an instance.

```json
{
  "Records": [  
    {
      "eventVersion": "1.03",
      "userIdentity": {
        "type": "Root",
        "principalId": "123456789012",
        "arn": "arn:aws:iam::123456789012:root",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "userName": "user"
      },
      "eventTime": "2016-05-20T08:27:45Z",
      "eventSource": "ec2.amazonaws.com",
      "eventName": "TerminateInstances",
      "awsRegion": "us-west-2",
      "sourceIPAddress": "198.51.100.1",
      "userAgent": "aws-cli/1.10.10 Python/2.7.9 Windows/7botocore/1.4.1",
      "requestParameters": {
        "instancesSet": {
          "items": [
            {

              "currentState": {
                "code": 32,
                "name": "shutting-down"
              },
              "previousState": {
                "code": 16,
                "name": "running"
              }
            }
          ]
        }
      }
    }
  ]
}
```
Use AWS CloudTrail to audit users that connect via EC2 Instance Connect

Use AWS CloudTrail to audit the users that connect to your instances via EC2 Instance Connect.

To audit SSH activity via EC2 Instance Connect using the AWS CloudTrail console

1. Open the AWS CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. Verify that you are in the correct Region.
3. In the navigation pane, choose Event history.
5. (Optional) For Time range, select a time range.
6. Choose the Refresh events icon.
7. The page displays the events that correspond to the SendSSHPublicKey API calls. Expand an event using the arrow to view additional details, such as the user name and AWS access key that was used to make the SSH connection, and the source IP address.
8. To display the full event information in JSON format, choose View event. The requestParameters field contains the destination instance ID, OS user name, and public key that were used to make the SSH connection.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "ABCDEFGHIJKLMNOPQRSTUVWXYZ01234567890EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/IAM-friendly-name",
        "accountId": "123456789012",
        "accessKeyId": "ABCDEFGHIJKLMNOPQRSTUVWXYZ01234567890EXAMPLE",
        "userName": "IAM-friendly-name",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2018-09-21T21:37:58Z"
            }
        }
    },
    "eventTime": "2018-09-21T21:38:00Z",
    "eventSource": "ec2-instance-connect.amazonaws.com",
    "eventName": "SendSSHPublicKey",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "123.456.789.012",
    "userAgent": "aws-cli/1.15.61 Python/2.7.10 Darwin/16.7.0 botocore/1.10.60",
    "requestParameters": {
        "instanceId": "i-0123456789EXAMPLE",
        "osUser": "ec2-user",
        "SSHKey": {
            "publicKey": "ssh-rsa ABCDEFGHIJKLMNOPQRSTUVWXYZ01234567890EXAMPLE"
        }
    },
    "responseElements": null,
    "requestID": "1a2b3c4d5e6f7g8h9i0j1k2l3m4n5o6p7q8r9s0t1u2v3w4x5y6z7890EXAMPLE"
}
```
If you have configured your AWS account to collect CloudTrail events in an S3 bucket, you can download and audit the information programmatically. For more information, see Getting and Viewing Your CloudTrail Log Files in the AWS CloudTrail User Guide.
Networking in Amazon EC2

Amazon VPC enables you to launch AWS resources, such as Amazon EC2 instances, into a virtual network dedicated to your AWS account, known as a virtual private cloud (VPC). When you launch an instance, you can select a subnet from the VPC. The instance is configured with a primary network interface, which is a logical virtual network card. The instance receives a primary private IP address from the IPv4 address of the subnet, and it is assigned to the primary network interface.

You can control whether the instance receives a public IP address from Amazon's pool of public IP addresses. The public IP address of an instance is associated with your instance only until it is stopped or terminated. If you require a persistent public IP address, you can allocate an Elastic IP address for your AWS account and associate it with an instance or a network interface. An Elastic IP address remains associated with your AWS account until you release it, and you can move it from one instance to another as needed. You can bring your own IP address range to your AWS account, where it appears as an address pool, and then allocate Elastic IP addresses from your address pool.

To increase network performance and reduce latency, you can launch instances in a placement group. You can get significantly higher packet per second (PPS) performance using enhanced networking. You can accelerate high performance computing and machine learning applications using an Elastic Fabric Adapter (EFA), which is a network device that you can attach to a supported instance type.

Features

- Regions and Zones (p. 867)
- Amazon EC2 instance IP addressing (p. 880)
- Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 896)
- Assigning prefixes to Amazon EC2 network interfaces (p. 905)
- Elastic IP addresses (p. 914)
- Elastic network interfaces (p. 922)
- Amazon EC2 instance network bandwidth (p. 951)
- Enhanced networking on Linux (p. 952)
- Elastic Fabric Adapter (p. 980)
- Placement groups (p. 1018)
- Network maximum transmission unit (MTU) for your EC2 instance (p. 1030)
- Virtual private clouds (p. 1033)
- EC2-Classic (p. 1034)

Regions and Zones

Amazon EC2 is hosted in multiple locations world-wide. These locations are composed of Regions, Availability Zones, Local Zones, AWS Outposts, and Wavelength Zones. Each Region is a separate geographic area.

- Availability Zones are multiple, isolated locations within each Region.
- Local Zones provide you the ability to place resources, such as compute and storage, in multiple locations closer to your end users.
- AWS Outposts brings native AWS services, infrastructure, and operating models to virtually any data center, co-location space, or on-premises facility.
- Wavelength Zones allow developers to build applications that deliver ultra-low latencies to 5G devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers’ 5G networks.
AWS operates state-of-the-art, highly available data centers. Although rare, failures can occur that affect the availability of instances that are in the same location. If you host all of your instances in a single location that is affected by a failure, none of your instances would be available.

To help you determine which deployment is best for you, see AWS Wavelength FAQs.

Contents
- Regions (p. 868)
- Availability Zones (p. 872)
- Local Zones (p. 874)
- Wavelength Zones (p. 877)
- AWS Outposts (p. 879)

Regions

Each Amazon EC2 Region is designed to be isolated from the other Amazon EC2 Regions. This achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the Region that you specified. This is because Regions are isolated from each other, and we don't automatically replicate resources across Regions.

When you launch an instance, you must select an AMI that's in the same Region. If the AMI is in another Region, you can copy the AMI to the Region you're using. For more information, see Copy an AMI (p. 138).

Note that there is a charge for data transfer between Regions. For more information, see Amazon EC2 Pricing - Data Transfer.

Contents
- Available Regions (p. 868)
- Regions and endpoints (p. 869)
- Describe your Regions (p. 870)
- Get the Region name (p. 871)
- Specify the Region for a resource (p. 871)

Available Regions

Your account determines the Regions that are available to you.

- An AWS account provides multiple Regions so that you can launch Amazon EC2 instances in locations that meet your requirements. For example, you might want to launch instances in Europe to be closer to your European customers or to meet legal requirements.
- An AWS GovCloud (US-West) account provides access to the AWS GovCloud (US-West) Region and the AWS GovCloud (US-East) Region. For more information, see AWS GovCloud (US).
- An Amazon AWS (China) account provides access to the Beijing and Ningxia Regions only. For more information, see AWS in China.

The following table lists the Regions provided by an AWS account. You can't describe or access additional Regions from an AWS account, such as AWS GovCloud (US) Region or the China Regions. To use a Region introduced after March 20, 2019, you must enable the Region. For more information, see Managing AWS Regions in the AWS General Reference.
For information about available Wavelength Zones, see Available Wavelength Zones in the AWS Wavelength Developer Guide. For information about available Local Zones, see the section called “Available Local Zones” (p. 875).

For more information, see AWS Global Infrastructure.

The number and mapping of Availability Zones per Region may vary between AWS accounts. To get a list of the Availability Zones that are available to your account, you can use the Amazon EC2 console or the command line interface. For more information, see Describe your Regions (p. 870).

**Regions and endpoints**

When you work with an instance using the command line interface or API actions, you must specify its Regional endpoint. For more information about the Regions and endpoints for Amazon EC2, see Amazon EC2 endpoints and quotas in the Amazon Web Services General Reference.
Describe your Regions

You can use the Amazon EC2 console or the command line interface to determine which Regions are available for your account. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

To find your Regions using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, view the options in the Region selector.
3. Your EC2 resources for this Region are displayed on the EC2 Dashboard in the Resources section.

To find your Regions using the AWS CLI

- Use the describe-regions command as follows to describe the Regions that are enabled for your account.

  ```
  aws ec2 describe-regions
  ```

  To describe all Regions, including any Regions that are disabled for your account, add the --all-regions option as follows.

  ```
  aws ec2 describe-regions --all-regions
  ```

To find your Regions using the AWS Tools for Windows PowerShell

- Use the Get-EC2Region command as follows to describe the Regions for your account.
Get the Region name

You can use the Amazon Lightsail API to view the name of a Region.

To view the Region name using the AWS CLI

- Use the `get-regions` command as follows to describe the name of the specified Region.

  ```bash
  aws lightsail get-regions --query "regions[?name=='region-name'].displayName" --output text
  ```

  The following example returns the name of the `us-east-2` Region.

  ```bash
  aws lightsail get-regions --query "regions[?name=='us-east-2'].displayName" --output text
  ```

  The following is the output:

  ```
  Ohio
  ```

Specify the Region for a resource

Every time you create an Amazon EC2 resource, you can specify the Region for the resource. You can specify the Region for a resource using the AWS Management Console or the command line.

Considerations

Some AWS resources might not be available in all Regions. Ensure that you can create the resources that you need in the desired Regions before you launch an instance.

To specify the Region for a resource using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Use the Region selector in the navigation bar.

To specify the default Region using the command line

You can set the value of an environment variable to the desired Regional endpoint (for example, https://ec2.us-east-2.amazonaws.com):

- **AWS_DEFAULT_REGION** (AWS CLI)
- **Set-AWSDefaultRegion** (AWS Tools for Windows PowerShell)

Alternatively, you can use the `--region` (AWS CLI) or `-Region` (AWS Tools for Windows PowerShell) command line option with each individual command. For example, `--region us-east-2`.

For more information about the endpoints for Amazon EC2, see Amazon Elastic Compute Cloud Endpoints.
Availability Zones

Each Region has multiple, isolated locations known as Availability Zones. When you launch an instance, you can select an Availability Zone or let us choose one for you. If you distribute your instances across multiple Availability Zones and one instance fails, you can design your application so that an instance in another Availability Zone can handle requests.

The following diagram illustrates multiple Availability Zones in an AWS Region.

You can also use Elastic IP addresses to mask the failure of an instance in one Availability Zone by rapidly remapping the address to an instance in another Availability Zone. For more information, see Elastic IP addresses (p. 914).

An Availability Zone is represented by a Region code followed by a letter identifier; for example, us-east-1a. To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each AWS account. For example, the Availability Zone us-east-1a for your AWS account might not be the same location as us-east-1a for another AWS account.

To coordinate Availability Zones across accounts, you must use the AZ ID, which is a unique and consistent identifier for an Availability Zone. For example, use1-az1 is an AZ ID for the us-east-1 Region and it has the same location in every AWS account.

You can view AZ IDs to determine the location of resources in one account relative to the resources in another account. For example, if you share a subnet in the Availability Zone with the AZ ID use-az2 with another account, this subnet is available to that account in the Availability Zone whose AZ ID is also use-az2. The AZ ID for each VPC and subnet is displayed in the Amazon VPC console. For more information, see Working with Shared VPCs in the Amazon VPC User Guide.

As Availability Zones grow over time, our ability to expand them can become constrained. If this happens, we might restrict you from launching an instance in a constrained Availability Zone unless you already have an instance in that Availability Zone. Eventually, we might also remove the constrained Availability Zone from the list of Availability Zones for new accounts. Therefore, your account might have a different number of available Availability Zones in a Region than another account.

Contents

- Describe your Availability Zones (p. 872)
- Launch instances in an Availability Zone (p. 873)
- Migrate an instance to another Availability Zone (p. 873)

Describe your Availability Zones

You can use the Amazon EC2 console or the command line interface to determine which Availability Zones are available for your account. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

To find your Availability Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, view the options in the Region selector.
3. On the navigation pane, choose **EC2 Dashboard**.
4. The Availability Zones are listed under **Service health, Zone status**.

**To find your Availability Zones using the AWS CLI**

1. Use the `describe-availability-zones` command as follows to describe the Availability Zones within the specified Region.
   
   ```bash
   aws ec2 describe-availability-zones --region region-name
   ```
2. Use the `describe-availability-zones` command as follows to describe the Availability Zones regardless of the opt-in status.
   
   ```bash
   aws ec2 describe-availability-zones --all-availability-zones
   ```

**To find your Availability Zones using the AWS Tools for Windows PowerShell**

Use the `Get-EC2AvailabilityZone` command as follows to describe the Availability Zones within the specified Region.

```powershell
PS C:\> Get-EC2AvailabilityZone -Region region-name
```

**Launch instances in an Availability Zone**

When you launch an instance, select a Region that puts your instances closer to specific customers, or meets the legal or other requirements that you have. By launching your instances in separate Availability Zones, you can protect your applications from the failure of a single location.

When you launch an instance, you can optionally specify an Availability Zone in the Region that you are using. If you do not specify an Availability Zone, we select an Availability Zone for you. When you launch your initial instances, we recommend that you accept the default Availability Zone, because this allows us to select the best Availability Zone for you based on system health and available capacity. If you launch additional instances, specify a Zone only if your new instances must be close to, or separated from, your running instances.

**Migrate an instance to another Availability Zone**

If necessary, you can migrate an instance from one Availability Zone to another. For example, let's say you are trying to modify the instance type of your instance and we can't launch an instance of the new instance type in the current Availability Zone. In this case, you can migrate the instance to an Availability Zone where we are able to launch an instance of that instance type.

The migration process involves:

- Creating an AMI from the original instance
- Launching an instance in the new Availability Zone
- Updating the configuration of the new instance, as shown in the following procedure

**To migrate an instance to another Availability Zone**

1. Create an AMI from the instance. The procedure depends on your operating system and the type of root device volume for the instance. For more information, see the documentation that corresponds to your operating system and root device volume:
• Create an Amazon EBS-backed Linux AMI
• Create an instance store-backed Linux AMI
• Create a custom Windows AMI

2. If you need to preserve the private IPv4 address of the instance, you must delete the subnet in the current Availability Zone and then create a subnet in the new Availability Zone with the same IPv4 address range as the original subnet. Note that you must terminate all instances in a subnet before you can delete it. Therefore, you should create AMIs from all of the instances in your subnet so that you can move all instances from the current subnet to the new subnet.

3. Launch an instance from the AMI that you just created, specifying the new Availability Zone or subnet. You can use the same instance type as the original instance, or select a new instance type. For more information, see Launch instances in an Availability Zone (p. 873).

4. If the original instance has an associated Elastic IP address, associate it with the new instance. For more information, see Disassociate an Elastic IP address (p. 919).

5. If the original instance is a Reserved Instance, change the Availability Zone for your reservation. (If you also changed the instance type, you can also change the instance type for your reservation.) For more information, see Submit modification requests (p. 359).

6. (Optional) Terminate the original instance. For more information, see Terminate an instance (p. 549).

### Local Zones

A Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect, so that resources created in a Local Zone can serve local users with low-latency communications. For more information, see AWS Local Zones.

A Local Zone is represented by a Region code followed by an identifier that indicates the location, for example, us-west-2-lax-1a. For more information, see Available Local Zones (p. 875).

To use a Local Zone, you must first enable it. For more information, see the section called “Opt in to Local Zones” (p. 876). Next, create a subnet in the Local Zone. Finally, launch any of the following resources in the Local Zone subnet, so that your applications are close to your end users:

• Amazon EC2 instances
• Amazon EBS volumes
• Amazon ECS
• Amazon EKS
• Internet gateways

In addition to the preceding list, the following resources are available in the Los Angeles Local Zones:
• Amazon FSx file servers
• Elastic Load Balancing
• Amazon EMR
• Amazon ElastiCache
• Amazon Relational Database Service
• Dedicated Hosts

Contents
• Available Local Zones (p. 875)
• Describe your Local Zones (p. 876)
• Opt in to Local Zones (p. 876)
• Launch instances in a Local Zone (p. 877)

Available Local Zones
The following tables list the available Local Zones by parent Regions. For information about how to opt in, see the section called “Opt in to Local Zones” (p. 876).

US East (N. Virginia) Local Zones
This table lists Local Zones in US East (N. Virginia):

<table>
<thead>
<tr>
<th>Parent Region</th>
<th>Zone Name</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-bos-1a</td>
<td>Boston</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-chi-1a</td>
<td>Chicago</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-dfw-1a</td>
<td>Dallas</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-iah-1a</td>
<td>Houston</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-mci-1a</td>
<td>Kansas City</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-mia-1a</td>
<td>Miami</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-msp-1a</td>
<td>Minneapolis</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-phl-1a</td>
<td>Philadelphia</td>
</tr>
</tbody>
</table>

US West (Oregon) Local Zones
This table lists Local Zones in US West (Oregon):

<table>
<thead>
<tr>
<th>Parent Region</th>
<th>Zone Name</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2-den-1a</td>
<td>Denver</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2-lax-1a</td>
<td>Los Angeles</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2-lax-1b</td>
<td>Los Angeles</td>
</tr>
</tbody>
</table>
Describe your Local Zones

You can use the Amazon EC2 console or the command line interface to determine which Local Zones are available for your account. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

To find your Local Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, view the options in the Region selector.
3. On the navigation pane, choose EC2 Dashboard.
4. The Local Zones are listed under Service health, Zone status.

To find your Local Zones using the AWS CLI

1. Use the describe-availability-zones command as follows to describe the Local Zones in the specified Region.

   ```
   aws ec2 describe-availability-zones --region region-name
   ```

2. Use the describe-availability-zones command as follows to describe the Local Zones regardless of whether they are enabled.

   ```
   aws ec2 describe-availability-zones --all-availability-zones
   ```

To find your Local Zones using the AWS Tools for Windows PowerShell

Use the Get-EC2AvailabilityZone command as follows to describe the Local Zones in the specified Region.

```powershell
PS C:\> Get-EC2AvailabilityZone -Region region-name
```

Opt in to Local Zones

Before you can specify a Local Zone for a resource or service, you must opt in to Local Zones.

Consideration

Some AWS resources might not be available in all Regions. Make sure that you can create the resources that you need in the desired Regions or Local Zones before launching an instance in a specific Local Zone.

To opt in to Local Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-left corner of the page, select New EC2 Experience. You cannot complete this task using the old console experience.
3. From the Region selector in the navigation bar, select the Region for the Local Zone.
4. On the navigation pane, choose EC2 Dashboard.
5. In the upper-right corner of the page, choose Account attributes, Zones.
6. Choose Manage.
7. For Zone group, choose Enabled.
8. Choose **Update zone group**.

**To opt in to Local Zones using the AWS CLI**

- Use the `modify-availability-zone-group` command.

**Launch instances in a Local Zone**

When you launch an instance, you can specify a subnet that is in a Local Zone. You also allocate an IP address from a network border group. A network border group is a unique set of Availability Zones, Local Zones, or Wavelength Zones from which AWS advertises IP addresses, for example, `us-west-2-lax-1a`.

You can allocate the following IP addresses from a network border group:

- Amazon-provided Elastic IPv4 addresses
- Amazon-provided IPv6 VPC addresses

**To launch an instance in a Local Zone:**

1. Enable Local Zones. For more information, see Opt in to Local Zones (p. 876).
2. Create a VPC in a Region that supports the Local Zone. For more information, see Creating a VPC in the Amazon VPC User Guide.
3. Create a subnet. Select the Local Zone when you create the subnet. For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.
4. Launch an instance, and select the subnet that you created in the Local Zone. For more information, see Launch your instance (p. 475).

**Wavelength Zones**

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. Developers can extend a virtual private cloud (VPC) to one or more Wavelength Zones, and then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region.

A Wavelength Zone is an isolated zone in the carrier location where the Wavelength infrastructure is deployed. Wavelength Zones are tied to a Region. A Wavelength Zone is a logical extension of a Region, and is managed by the control plane in the Region.

A Wavelength Zone is represented by a Region code followed by an identifier that indicates the Wavelength Zone, for example, `us-east-1-wl1-bos-wlz-1`. 
To use a Wavelength Zone, you must first opt in to the Zone. For more information, see the section called “Enable Wavelength Zones” (p. 878). Next, create a subnet in the Wavelength Zone. Finally, launch your resources in the Wavelength Zones subnet, so that your applications are closer to your end users.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see Available Wavelength Zones in the AWS Wavelength Developer Guide.

Contents

- Describe your Wavelength Zones (p. 878)
- Enable Wavelength Zones (p. 878)
- Launch instances in a Wavelength Zone (p. 879)

Describe your Wavelength Zones

You can use the Amazon EC2 console or the command line interface to determine which Wavelength Zones are available for your account. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

To find your Wavelength Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, view the options in the Region selector.
3. On the navigation pane, choose EC2 Dashboard.
4. The Wavelength Zones are listed under Service health, Zone status.

To find your Wavelength Zones using the AWS CLI

1. Use the describe-availability-zones command as follows to describe the Wavelength Zones within the specified Region.
   
   ```bash
   aws ec2 describe-availability-zones --region region-name
   ```

2. Use the describe-availability-zones command as follows to describe the Wavelength Zones regardless of the opt-in status.
   
   ```bash
   aws ec2 describe-availability-zones --all-availability-zones
   ```

To find your Wavelength Zone using the AWS Tools for Windows PowerShell

Use the Get-EC2AvailabilityZone command as follows to describe the Wavelength Zone within the specified Region.

```
PSC: > Get-EC2AvailabilityZone -Region region-name
```

Enable Wavelength Zones

Before you specify a Wavelength Zone for a resource or service, you must opt in to Wavelength Zones.

Considerations

- Some AWS resources are not available in all Regions. Make sure that you can create the resources that you need in the desired Region or Wavelength Zone before launching an instance in a specific Wavelength Zone.
To opt in to Wavelength Zone using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-left corner of the page, select New EC2 Experience. You cannot complete this task using the old console experience.
3. From the Region selector in the navigation bar, select the Region for the Wavelength Zone.
4. On the navigation pane, choose EC2 Dashboard.
5. In the upper-right corner of the page, choose Account attributes, Zones.
6. Under Wavelength Zones, choose Manage for the Wavelength Zone.
7. Choose Enable.
8. Choose Update zone group.

To enable Wavelength Zones using the AWS CLI

Use the modify-availability-zone-group command.

Launch instances in a Wavelength Zone

When you launch an instance, you can specify a subnet which is in a Wavelength Zone. You also allocate a carrier IP address from a network border group, which is a unique set of Availability Zones, Local Zones, or Wavelength Zones from which AWS advertises IP addresses, for example, us-east-1-wl1-bos-wlz-1.

For information about how to launch an instance in a Wavelength Zone, see Get started with AWS Wavelength in the AWS Wavelength Developer Guide.

AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region. You can create subnets on your Outpost and specify them when you create AWS resources such as EC2 instances, EBS volumes, ECS clusters, and RDS instances. Instances in Outpost subnets communicate with other instances in the AWS Region using private IP addresses, all within the same VPC.

To begin using AWS Outposts, you must create an Outpost and order Outpost capacity. For more information about Outposts configurations, see our catalog. After your Outpost equipment is installed, the compute and storage capacity is available for you when you launch Amazon EC2 instances and create Amazon EBS volumes on your Outpost.

Launch instances on an Outpost

You can launch EC2 instances in the Outpost subnet that you created. Security groups control inbound and outbound traffic for instances in an Outpost subnet, as they do for instances in an Availability Zone subnet. To connect to an EC2 instance in an Outpost subnet, you can specify a key pair when you launch the instance, as you do for instances in an Availability Zone subnet.

The root volume must be 30 GB or smaller. You can specify data volumes in the block device mapping of the AMI or the instance to provide additional storage. To trim unused blocks from the boot volume, see How to Build Sparse EBS Volumes in the AWS Partner Network Blog.
We recommend that you increase the NVMe timeout for the root volume. For more information, see I/O operation timeout (p. 1354).

For information about how to create an Outpost, see Get started with AWS Outposts in the AWS Outposts User Guide.

Create a volume on an Outpost

You can create EBS volumes in the Outpost subnet that you created. When you create the volume, specify the Amazon Resource Name (ARN) of the Outpost.

The following create-volume command creates an empty 50 GB volume on the specified Outpost.

```bash
aws ec2 create-volume --availability-zone us-east-2a --outpost-arn arn:aws:outposts:us-east-2:123456789012:outpost/op-03e6fecad652a6138 --size 50
```

You can dynamically modify the size of your Amazon EBS gp2 volumes without detaching them. For more information about modifying a volume without detaching it, see Request modifications to your EBS volumes (p. 1325).

Amazon EC2 instance IP addressing

Amazon EC2 and Amazon VPC support both the IPv4 and IPv6 addressing protocols. By default, Amazon EC2 and Amazon VPC use the IPv4 addressing protocol; you can't disable this behavior. When you create a VPC, you must specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to instances in your subnet. IPv6 addresses are reachable over the Internet. For more information about IPv6, see IP Addressing in Your VPC in the Amazon VPC User Guide.

**Contents**

- Private IPv4 addresses and internal DNS hostnames (p. 880)
- Public IPv4 addresses and external DNS hostnames (p. 881)
- Elastic IP addresses (IPv4) (p. 882)
- Amazon DNS server (p. 882)
- IPv6 addresses (p. 882)
- Work with the IPv4 addresses for your instances (p. 883)
- Work with the IPv6 addresses for your instances (p. 886)
- Multiple IP addresses (p. 888)

**Private IPv4 addresses and internal DNS hostnames**

A private IPv4 address is an IP address that's not reachable over the Internet. You can use private IPv4 addresses for communication between instances in the same VPC. For more information about the standards and specifications of private IPv4 addresses, see RFC 1918. We allocate private IPv4 addresses to instances using DHCP.

**Note**

You can create a VPC with a publicly routable CIDR block that falls outside of the private IPv4 address ranges specified in RFC 1918. However, for the purposes of this documentation, we refer
Public IPv4 addresses and external DNS hostnames

A public IPv4 address is an IPv4 address that's reachable from the Internet. You can use public addresses for communication between your instances and the Internet.

Each instance that receives a public IPv4 address is also given an external DNS hostname; for example, ec2-203-0-113-25.compute-1.amazonaws.com. We resolve an external DNS hostname to the public IP address of the instance from outside its VPC, and to the private IPv4 address of the instance from inside its VPC. The public IP address is mapped to the primary private IPv4 address through network address translation (NAT). For more information, see RFC 1631: The IP Network Address Translator (NAT).

When you launch an instance in a default VPC, we assign it a public IP address by default. When you launch an instance into a nondefault VPC, the subnet has an attribute that determines whether instances launched into that subnet receive a public IP address from the public IPv4 address pool. By default, we don't assign a public IP address to instances launched in a nondefault subnet.

You can control whether your instance receives a public IP address as follows:

- Modifying the public IP addressing attribute of your subnet. For more information, see Modifying the public IPv4 addressing attribute for your subnet in the Amazon VPC User Guide.
- Enabling or disabling the public IP addressing feature during launch, which overrides the subnet's public IPv4 addressing attribute. For more information, see Assign a public IPv4 address during instance launch (p. 885).

A public IP address is assigned to your instance from Amazon's pool of public IPv4 addresses, and is not associated with your AWS account. When a public IP address is disassociated from your instance, it is released back into the public IPv4 address pool, and you cannot reuse it.

You cannot manually associate or disassociate a public IP (IPv4) address from your instance. Instead, in certain cases, we release the public IP address from your instance, or assign it a new one:

- We release your instance's public IP address when it is stopped, hibernated, or terminated. Your stopped or hibernated instance receives a new public IP address when it is started.
- We release your instance's public IP address when you associate an Elastic IP address with it. When you disassociate the Elastic IP address from your instance, it receives a new public IP address.
- If the public IP address of your instance in a VPC has been released, it will not receive a new one if there is more than one network interface attached to your instance.
• If your instance's public IP address is released while it has a secondary private IP address that is associated with an Elastic IP address, the instance does not receive a new public IP address.

If you require a persistent public IP address that can be associated to and from instances as you require, use an Elastic IP address instead.

If you use dynamic DNS to map an existing DNS name to a new instance's public IP address, it might take up to 24 hours for the IP address to propagate through the Internet. As a result, new instances might not receive traffic while terminated instances continue to receive requests. To solve this problem, use an Elastic IP address. You can allocate your own Elastic IP address, and associate it with your instance. For more information, see Elastic IP addresses (p. 914).

If you assign an Elastic IP address to an instance, it receives an IPv4 DNS hostname if DNS hostnames are enabled. For more information, see Using DNS with your VPC in the Amazon VPC User Guide.

Note
Instances that access other instances through their public NAT IP address are charged for regional or Internet data transfer, depending on whether the instances are in the same Region.

Elastic IP addresses (IPv4)

An Elastic IP address is a public IPv4 address that you can allocate to your account. You can associate it to and disassociate it from instances as you require. It's allocated to your account until you choose to release it. For more information about Elastic IP addresses and how to use them, see Elastic IP addresses (p. 914).

We do not support Elastic IP addresses for IPv6.

Amazon DNS server

Amazon provides a DNS server that resolves Amazon-provided IPv4 DNS hostnames to IPv4 addresses. The Amazon DNS server is located at the base of your VPC network range plus two. For more information, see Amazon DNS server in the Amazon VPC User Guide.

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC, and associate IPv6 CIDR blocks with your subnets. The IPv6 CIDR block for your VPC is automatically assigned from Amazon’s pool of IPv6 addresses; you cannot choose the range yourself. For more information, see the following topics in the Amazon VPC User Guide:

• VPC and subnet sizing for IPv6
• Associating an IPv6 CIDR block with your VPC
• Associating an IPv6 CIDR block with your subnet

IPv6 addresses are globally unique, and therefore reachable over the Internet. Your instance receives an IPv6 address if an IPv6 CIDR block is associated with your VPC and subnet, and if one of the following is true:

• Your subnet is configured to automatically assign an IPv6 address to an instance during launch. For more information, see Modifying the IPv6 addressing attribute for your subnet.
• You assign an IPv6 address to your instance during launch.
• You assign an IPv6 address to the primary network interface of your instance after launch.
• You assign an IPv6 address to a network interface in the same subnet, and attach the network interface to your instance after launch.
When your instance receives an IPv6 address during launch, the address is associated with the primary network interface (eth0) of the instance. You can disassociate the IPv6 address from the network interface. We do not support IPv6 DNS hostnames for your instance.

An IPv6 address persists when you stop and start, or hibernate and start, your instance, and is released when you terminate your instance. You cannot reassign an IPv6 address while it's assigned to another network interface—you must first unassign it.

You can assign additional IPv6 addresses to your instance by assigning them to a network interface attached to your instance. The number of IPv6 addresses you can assign to a network interface and the number of network interfaces you can attach to an instance varies per instance type. For more information, see IP addresses per network interface per instance type (p. 924).

Work with the IPv4 addresses for your instances

You can assign a public IPv4 address to your instance when you launch it. You can view the IPv4 addresses for your instance in the console through either the Instances page or the Network Interfaces page.

Contents
- View the IPv4 addresses (p. 883)
- Assign a public IPv4 address during instance launch (p. 885)

View the IPv4 addresses

You can use the Amazon EC2 console to view the private IPv4 addresses, public IPv4 addresses, and Elastic IP addresses of your instances. You can also determine the public IPv4 and private IPv4 addresses of your instance from within your instance by using instance metadata. For more information, see Instance metadata and user data (p. 606).

The public IPv4 address is displayed as a property of the network interface in the console, but it's mapped to the primary private IPv4 address through NAT. Therefore, if you inspect the properties of your network interface on your instance, for example, through `ifconfig` (Linux) or `ipconfig` (Windows), the public IPv4 address is not displayed. To determine your instance's public IPv4 address from an instance, use instance metadata.

New console

To view the IPv4 addresses for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select your instance.
3. The following information is available on the Networking tab:
   - **Public IPv4 address** — The public IPv4 address. If you associated an Elastic IP address with the instance or the primary network interface, this is the Elastic IP address.
   - **Public IPv4 DNS** — The external DNS hostname.
   - **Private IPv4 addresses** — The private IPv4 address.
   - **Private IPv4 DNS** — The internal DNS hostname.
   - **Secondary private IPv4 addresses** — Any secondary private IPv4 addresses.
   - **Elastic IP addresses** — Any associated Elastic IP addresses.
4. Alternatively, under Network interfaces on the Networking tab, choose the interface ID for the primary network interface (for example, eni-123abc456def78901). The following information is available:
   - **Private DNS (IPv4)** — The internal DNS hostname.
• **Primary private IPv4 IP** — The primary private IPv4 address.
• **Secondary private IPv4 IPs** — Any secondary private IPv4 addresses.
• **Public DNS** — The external DNS hostname.
• **IPv4 Public IP** — The public IPv4 address. If you associated an Elastic IP address with the instance or the primary network interface, this is the Elastic IP address.
• **Elastic IPs** — Any associated Elastic IP addresses.

**Old console**

To view the IPv4 addresses for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select your instance.
3. The following information is available on the **Description** tab:
   • **Private DNS** — The internal DNS hostname.
   • **Private IPs** — The private IPv4 address.
   • **Secondary private IPs** — Any secondary private IPv4 addresses.
   • **Public DNS** — The external DNS hostname.
   • **IPv4 Public IP** — The public IPv4 address. If you associated an Elastic IP address with the instance or the primary network interface, this is the Elastic IP address.
   • **Elastic IPs** — Any associated Elastic IP addresses.
4. Alternatively, you can view the IPv4 addresses for the instance using the primary network interface. Under **Network interfaces** on the **Description** tab, choose **eth0**, and then choose the interface ID (for example, eni-123abc456def78901). The following information is available:
   • **Private DNS (IPv4)** — The internal DNS hostname.
   • **Primary private IPv4 IP** — The primary private IPv4 address.
   • **Secondary private IPv4 IPs** — Any secondary private IPv4 addresses.
   • **Public DNS** — The external DNS hostname.
   • **IPv4 Public IP** — The public IPv4 address. If you associated an Elastic IP address with the instance or the primary network interface, this is the Elastic IP address.
   • **Elastic IPs** — Any associated Elastic IP addresses.

**To view the IPv4 addresses for an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2 (p. 3)**.

- **describe-instances** (AWS CLI)

**To determine your instance's IPv4 addresses using instance metadata**

1. Connect to your instance. For more information, see **Connect to your Linux instance (p. 499)**.
2. Use the following command to access the private IP address:

   ```bash
   ```
Work with the IPv4 addresses for your instances

### Assign a public IPv4 address during instance launch

Each subnet has an attribute that determines whether instances launched into that subnet are assigned a public IPv4 address. By default, nondefault subnets have this attribute set to false, and default subnets have this attribute set to true. When you launch an instance, a public IPv4 addressing feature is also available for you to control whether your instance is assigned a public IPv4 address; you can override the default behavior of the subnet’s IP addressing attribute. The public IPv4 address is assigned from Amazon’s pool of public IPv4 addresses, and is assigned to the network interface with the device index of eth0. This feature depends on certain conditions at the time you launch your instance.

### Considerations

- You can’t manually disassociate the public IP address from your instance after launch. Instead, it’s automatically released in certain cases, after which you cannot reuse it. For more information, see Public IPv4 addresses and external DNS hostnames (p. 881). If you require a persistent public IP address that you can associate or disassociate at will, assign an Elastic IP address to the instance after launch instead. For more information, see Elastic IP addresses (p. 914).
- You cannot auto-assign a public IP address if you specify more than one network interface. Additionally, you cannot override the subnet setting using the auto-assign public IP feature if you specify an existing network interface for eth0.
- The public IP addressing feature is only available during launch. However, whether you assign a public IP address to your instance during launch or not, you can associate an Elastic IP address with your instance after it’s launched. For more information, see Elastic IP addresses (p. 914). You can also modify your subnet’s public IPv4 addressing behavior. For more information, see Modifying the public IPv4 addressing attribute for your subnet.

### To enable or disable the public IP addressing feature using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. Select an AMI and an instance type, and then choose Next: Configure Instance Details.
4. On the Configure Instance Details page, for Network, select a VPC. The Auto-assign Public IP list is displayed. Choose Enable or Disable to override the default setting for the subnet.
5. Follow the steps on the next pages of the wizard to complete your instance's setup. For more information about the wizard configuration options, see Launch an instance using the Launch Instance Wizard (p. 477). On the final Review Instance Launch page, review your settings, and then choose Launch to choose a key pair and launch your instance.
6. On the Instances page, select your new instance and view its public IP address in IPv4 Public IP field in the details pane.

To enable or disable the public IP addressing feature using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- Use the --associate-public-ip-address or the --no-associate-public-ip-address option with the run-instances command (AWS CLI)
- Use the -AssociatePublicIp parameter with the New-EC2Instance command (AWS Tools for Windows PowerShell)

Work with the IPv6 addresses for your instances

You can view the IPv6 addresses assigned to your instance, assign a public IPv6 address to your instance, or unassign an IPv6 address from your instance. You can view these addresses in the console through either the Instances page or the Network Interfaces page.

Contents

- View the IPv6 addresses (p. 886)
- Assign an IPv6 address to an instance (p. 887)
- Unassign an IPv6 address from an instance (p. 888)

View the IPv6 addresses

You can use the Amazon EC2 console, AWS CLI, and instance metadata to view the IPv6 addresses for your instances.

New console

To view the IPv6 addresses for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
5. Alternatively, under Network interfaces on the Networking tab, choose the interface ID for the network interface (for example, eni-123abc456def78901). Locate IPv6 IPs.

Old console

To view the IPv6 addresses for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Networking** tab, locate **IPv6 IPs**.
5. Alternatively, under **Network interfaces** on the **Description** tab, choose **eth0**, and then choose the interface ID (for example, eni-123abc456def78901). Locate **IPv6 IPs**.

**To view the IPv6 addresses for an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 3).

- **describe-instances** (AWS CLI)

**To view the IPv6 addresses for an instance using instance metadata**

1. Connect to your instance. For more information, see [Connect to your Linux instance](p. 499).
2. Use the following command to view the IPv6 address (you can get the MAC address from [http://169.254.169.254/latest/meta-data/network/interfaces/macs/](http://169.254.169.254/latest/meta-data/network/interfaces/macs/)).

IMDSv2

```
```

IMDSv1

```
```

**Assign an IPv6 address to an instance**

If your VPC and subnet have IPv6 CIDR blocks associated with them, you can assign an IPv6 address to your instance during or after launch. The IPv6 address is assigned from the IPv6 address range of the subnet, and is assigned to the network interface with the device index of eth0.

**To assign an IPv6 address to an instance during launch**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Select an AMI and an instance type that supports IPv6, and choose **Next: Configure Instance Details**.
3. On the **Configure Instance Details** page, for **Network**, select a VPC and for **Subnet**, select a subnet. For **Auto-assign IPv6 IP**, choose **Enable**.
4. Follow the remaining steps in the wizard to launch your instance.

**To assign an IPv6 address to an instance after launch**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance, and choose Actions, Networking, Manage IP addresses.
4. Expand the network interface. Under IPv6 addresses, choose Assign new IP address. Enter an IPv6 address from the range of the subnet or leave the field blank to let Amazon choose an IPv6 address for you.
5. Choose Save.

To assign an IPv6 address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- Use the --ipv6-addresses option with the run-instances command (AWS CLI)
- Use the IPv6Addresses property for -NetworkInterface in the New-EC2Instance command (AWS Tools for Windows PowerShell)
- assign-ipv6-addresses (AWS CLI)
- Register-EC2Ipv6AddressList (AWS Tools for Windows PowerShell)

Unassign an IPv6 address from an instance

You can unassign an IPv6 address from an instance at any time.

To unassign an IPv6 address from an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, and choose Actions, Networking, Manage IP addresses.
4. Expand the network interface. Under IPv6 addresses, choose Unassign next to the IPv6 address.
5. Choose Save.

To unassign an IPv6 address from an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- unassign-ipv6-addresses (AWS CLI)

Multiple IP addresses

You can specify multiple private IPv4 and IPv6 addresses for your instances. The number of network interfaces and private IPv4 and IPv6 addresses that you can specify for an instance depends on the instance type. For more information, see IP addresses per network interface per instance type (p. 924).

It can be useful to assign multiple IP addresses to an instance in your VPC to do the following:

- Host multiple websites on a single server by using multiple SSL certificates on a single server and associating each certificate with a specific IP address.
- Operate network appliances, such as firewalls or load balancers, that have multiple IP addresses for each network interface.
- Redirect internal traffic to a standby instance in case your instance fails, by reassigning the secondary IP address to the standby instance.
Contents

• How multiple IP addresses work (p. 889)
• Work with multiple IPv4 addresses (p. 889)
• Work with multiple IPv6 addresses (p. 893)

How multiple IP addresses work

The following list explains how multiple IP addresses work with network interfaces:

• You can assign a secondary private IPv4 address to any network interface. The network interface need not be attached to the instance.
• You can assign multiple IPv6 addresses to a network interface that's in a subnet that has an associated IPv6 CIDR block.
• You must choose a secondary IPv4 address from the IPv4 CIDR block range of the subnet for the network interface.
• You must choose IPv6 addresses from the IPv6 CIDR block range of the subnet for the network interface.
• You associate security groups with network interfaces, not individual IP addresses. Therefore, each IP address you specify in a network interface is subject to the security group of its network interface.
• Multiple IP addresses can be assigned and unassigned to network interfaces attached to running or stopped instances.
• Secondary private IPv4 addresses that are assigned to a network interface can be reassigned to another one if you explicitly allow it.
• An IPv6 address cannot be reassigned to another network interface; you must first unassign the IPv6 address from the existing network interface.
• When assigning multiple IP addresses to a network interface using the command line tools or API, the entire operation fails if one of the IP addresses can't be assigned.
• Primary private IPv4 addresses, secondary private IPv4 addresses, Elastic IP addresses, and IPv6 addresses remain with a secondary network interface when it is detached from an instance or attached to an instance.
• Although you can't detach the primary network interface from an instance, you can reassign the secondary private IPv4 address of the primary network interface to another network interface.

The following list explains how multiple IP addresses work with Elastic IP addresses (IPv4 only):

• Each private IPv4 address can be associated with a single Elastic IP address, and vice versa.
• When a secondary private IPv4 address is reassigned to another interface, the secondary private IPv4 address retains its association with an Elastic IP address.
• When a secondary private IPv4 address is unassigned from an interface, an associated Elastic IP address is automatically disassociated from the secondary private IPv4 address.

Work with multiple IPv4 addresses

You can assign a secondary private IPv4 address to an instance, associate an Elastic IPv4 address with a secondary private IPv4 address, and unassign a secondary private IPv4 address.

Contents

• Assign a secondary private IPv4 address (p. 890)
Multiple IP addresses

• Configure the operating system on your instance to recognize secondary private IPv4 addresses (p. 891)
• Associate an Elastic IP address with the secondary private IPv4 address (p. 892)
• View your secondary private IPv4 addresses (p. 892)
• Unassign a secondary private IPv4 address (p. 892)

Assign a secondary private IPv4 address

You can assign the secondary private IPv4 address to the network interface for an instance as you launch the instance, or after the instance is running. This section includes the following procedures.

• To assign a secondary private IPv4 address when launching an instance (p. 890)
• To assign a secondary IPv4 address during launch using the command line (p. 891)
• To assign a secondary private IPv4 address to a network interface (p. 891)
• To assign a secondary private IPv4 to an existing instance using the command line (p. 891)

To assign a secondary private IPv4 address when launching an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. Select an AMI, then choose an instance type and choose Next: Configure Instance Details.
4. On the Configure Instance Details page, for Network, select a VPC and for Subnet, select a subnet.
5. In the Network Interfaces section, do the following, and then choose Next: Add Storage:

   • To add another network interface, choose Add Device. The console enables you to specify up to two network interfaces when you launch an instance. After you launch the instance, choose Network Interfaces in the navigation pane to add additional network interfaces. The total number of network interfaces that you can attach varies by instance type. For more information, see IP addresses per network interface per instance type (p. 924).
   
   Important
   When you add a second network interface, the system can no longer auto-assign a public IPv4 address. You will not be able to connect to the instance over IPv4 unless you assign an Elastic IP address to the primary network interface (eth0). You can assign the Elastic IP address after you complete the Launch wizard. For more information, see Work with Elastic IP addresses (p. 915).

   • For each network interface, under Secondary IP addresses, choose Add IP, and then enter a private IP address from the subnet range, or accept the default Auto-assign value to let Amazon select an address.

6. On the next Add Storage page, you can specify volumes to attach to the instance besides the volumes specified by the AMI (such as the root device volume), and then choose Next: Add Tags.
7. On the Add Tags page, specify tags for the instance, such as a user-friendly name, and then choose Next: Configure Security Group.
8. On the Configure Security Group page, select an existing security group or create a new one. Choose Review and Launch.
9. On the Review Instance Launch page, review your settings, and then choose Launch to choose a key pair and launch your instance. If you're new to Amazon EC2 and haven't created any key pairs, the wizard prompts you to create one.

   Important
   After you have added a secondary private IP address to a network interface, you must connect to the instance and configure the secondary private IP address on the instance itself. For more
To assign a secondary IPv4 address during launch using the command line

- You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).
  - The --secondary-private-ip-addresses option with the run-instances command (AWS CLI)
  - Define --NetworkInterface and specify the PrivateIpAddresses parameter with the New-EC2Instance command (AWS Tools for Windows PowerShell).

To assign a secondary private IPv4 address to a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces, and then select the network interface attached to the instance.
3. Choose Actions, Manage IP Addresses.
4. Under IPv4 Addresses, choose Assign new IP.
5. Enter a specific IPv4 address that's within the subnet range for the instance, or leave the field blank to let Amazon select an IP address for you.
6. (Optional) Choose Allow reassignment to allow the secondary private IP address to be reassigned if it is already assigned to another network interface.
7. Choose Yes, Update.

Alternatively, you can assign a secondary private IPv4 address to an instance. Choose Instances in the navigation pane, select the instance, and then choose Actions, Networking, Manage IP Addresses. You can configure the same information as you did in the steps above. The IP address is assigned to the primary network interface (eth0) for the instance.

To assign a secondary private IPv4 to an existing instance using the command line

- You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).
  - assign-private-ip-addresses (AWS CLI)
  - Register-EC2PrivateIpAddress (AWS Tools for Windows PowerShell)

Configure the operating system on your instance to recognize secondary private IPv4 addresses

After you assign a secondary private IPv4 address to your instance, you need to configure the operating system on your instance to recognize the secondary private IP address.

- If you are using Amazon Linux, the ec2-net-utils package can take care of this step for you. It configures additional network interfaces that you attach while the instance is running, refreshes secondary IPv4 addresses during DHCP lease renewal, and updates the related routing rules. You can immediately refresh the list of interfaces by using the command sudo service network restart and then view the up-to-date list using ip addr li. If you require manual control over your network configuration, you can remove the ec2-net-utils package. For more information, see Configure your network interface using ec2-net-utils (p. 949).
- If you are using another Linux distribution, see the documentation for your Linux distribution. Search for information about configuring additional network interfaces and secondary IPv4 addresses. If the
instance has two or more interfaces on the same subnet, search for information about using routing rules to work around asymmetric routing.

For information about configuring a Windows instance, see Configuring a secondary private IP address for your Windows instance in a VPC in the Amazon EC2 User Guide for Windows Instances.

**Associate an Elastic IP address with the secondary private IPv4 address**

**To associate an Elastic IP address with a secondary private IPv4 address**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Choose Actions, and then select Associate address.
4. For Network interface, select the network interface, and then select the secondary IP address from the Private IP list.
5. Choose Associate.

**To associate an Elastic IP address with a secondary private IPv4 address using the command line**

- You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).
  - associate-address (AWS CLI)
  - Register-EC2Address (AWS Tools for Windows PowerShell)

**View your secondary private IPv4 addresses**

**To view the private IPv4 addresses assigned to a network interface**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface with private IP addresses to view.
4. On the Details tab in the details pane, check the Primary private IPv4 IP and Secondary private IPv4 IPs fields for the primary private IPv4 address and any secondary private IPv4 addresses assigned to the network interface.

**To view the private IPv4 addresses assigned to an instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance with private IPv4 addresses to view.
4. On the Description tab in the details pane, check the Private IPs and Secondary private IPs fields for the primary private IPv4 address and any secondary private IPv4 addresses assigned to the instance through its network interface.

**Unassign a secondary private IPv4 address**

If you no longer require a secondary private IPv4 address, you can unassign it from the instance or the network interface. When a secondary private IPv4 address is unassigned from a network interface, the Elastic IP address (if it exists) is also disassociated.
To unassign a secondary private IPv4 address from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, choose **Actions, Networking, Manage IP Addresses**.
4. Under **IPv4 Addresses**, choose **Unassign** for the IPv4 address to unassign.
5. Choose **Yes, Update**.

To unassign a secondary private IPv4 address from a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface, choose **Actions, Manage IP Addresses**.
4. Under **IPv4 Addresses**, choose **Unassign** for the IPv4 address to unassign.
5. Choose **Yes, Update**.

To unassign a secondary private IPv4 address using the command line

- You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).
  - `unassign-private-ip-addresses` (AWS CLI)
  - `Unregister-EC2PrivateIpAddress` (AWS Tools for Windows PowerShell)

Work with multiple IPv6 addresses

You can assign multiple IPv6 addresses to your instance, view the IPv6 addresses assigned to your instance, and unassign IPv6 addresses from your instance.

Contents

- Assign multiple IPv6 addresses (p. 893)
- View your IPv6 addresses (p. 895)
- Unassign an IPv6 address (p. 895)

Assign multiple IPv6 addresses

You can assign one or more IPv6 addresses to your instance during launch or after launch. To assign an IPv6 address to an instance, the VPC and subnet in which you launch the instance must have an associated IPv6 CIDR block. For more information, see VPCs and Subnets in the Amazon VPC User Guide.

To assign multiple IPv6 addresses during launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the dashboard, choose **Launch Instance**.
3. Select an AMI, choose an instance type, and choose **Next: Configure Instance Details**. Ensure that you choose an instance type that support IPv6. For more information, see Instance types (p. 193).
4. On the **Configure Instance Details** page, select a VPC from the **Network** list, and a subnet from the **Subnet** list.
5. In the **Network Interfaces** section, do the following, and then choose **Next: Add Storage**:
• To assign a single IPv6 address to the primary network interface (eth0), under IPv6 IPs, choose Add IP. To add a secondary IPv6 address, choose Add IP again. You can enter an IPv6 address from the range of the subnet, or leave the default Auto-assign value to let Amazon choose an IPv6 address from the subnet for you.

• Choose Add Device to add another network interface and repeat the steps above to add one or more IPv6 addresses to the network interface. The console enables you to specify up to two network interfaces when you launch an instance. After you launch the instance, choose Network Interfaces in the navigation pane to add additional network interfaces. The total number of network interfaces that you can attach varies by instance type. For more information, see IP addresses per network interface per instance type (p. 924).

6. Follow the next steps in the wizard to attach volumes and tag your instance.

7. On the Configure Security Group page, select an existing security group or create a new one. If you want your instance to be reachable over IPv6, ensure that your security group has rules that allow access from IPv6 addresses. For more information, see Security group rules for different use cases (p. 1167). Choose Review and Launch.

8. On the Review Instance Launch page, review your settings, and then choose Launch to choose a key pair and launch your instance. If you're new to Amazon EC2 and haven't created any key pairs, the wizard prompts you to create one.

You can use the Instances screen Amazon EC2 console to assign multiple IPv6 addresses to an existing instance. This assigns the IPv6 addresses to the primary network interface (eth0) for the instance. To assign a specific IPv6 address to the instance, ensure that the IPv6 address is not already assigned to another instance or network interface.

To assign multiple IPv6 addresses to an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, choose Actions, Networking, Manage IP Addresses.
4. Under IPv6 Addresses, choose Assign new IP for each IPv6 address you want to add. You can specify an IPv6 address from the range of the subnet, or leave the Auto-assign value to let Amazon choose an IPv6 address for you.
5. Choose Yes, Update.

Alternatively, you can assign multiple IPv6 addresses to an existing network interface. The network interface must have been created in a subnet that has an associated IPv6 CIDR block. To assign a specific IPv6 address to the network interface, ensure that the IPv6 address is not already assigned to another network interface.

To assign multiple IPv6 addresses to a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select your network interface, choose Actions, Manage IP Addresses.
4. Under IPv6 Addresses, choose Assign new IP for each IPv6 address you want to add. You can specify an IPv6 address from the range of the subnet, or leave the Auto-assign value to let Amazon choose an IPv6 address for you.
5. Choose Yes, Update.
CLI overview

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- **Assign an IPv6 address during launch:**
  - Use the `--ipv6-addresses` or `--ipv6-address-count` options with the `run-instances` command (AWS CLI)
  - Define `--NetworkInterface` and specify the `Ipv6Addresses` or `Ipv6AddressCount` parameters with the `New-EC2Instance` command (AWS Tools for Windows PowerShell).

- **Assign an IPv6 address to a network interface:**
  - `assign-ipv6-addresses` (AWS CLI)
  - `Register-EC2Ipv6AddressList` (AWS Tools for Windows PowerShell)

View your IPv6 addresses

You can view the IPv6 addresses for an instance or for a network interface.

**To view the IPv6 addresses assigned to an instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance. In the details pane, review the **IPv6 IPs** field.

**To view the IPv6 addresses assigned to a network interface**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select your network interface. In the details pane, review the **IPv6 IPs** field.

CLI overview

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- **View the IPv6 addresses for an instance:**
  - `describe-instances` (AWS CLI)

- **View the IPv6 addresses for a network interface:**
  - `describe-network-interfaces` (AWS CLI)
  - `Get-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

Unassign an IPv6 address

You can unassign an IPv6 address from the primary network interface of an instance, or you can unassign an IPv6 address from a network interface.

**To unassign an IPv6 address from an instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
In the navigation pane, choose **Instances**.
3. Select your instance, choose **Actions, Networking, Manage IP Addresses**.
4. Under **IPv6 Addresses**, choose **Unassign** for the IPv6 address to unassign.
5. Choose **Yes, Update**.

### To unassign an IPv6 address from a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select your network interface, choose **Actions, Manage IP Addresses**.
4. Under **IPv6 Addresses**, choose **Unassign** for the IPv6 address to unassign.
5. Choose **Save**.

### CLI overview

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- **unassign-ipv6-addresses** (AWS CLI)
- **Unregister-EC2Ipv6AddressList** (AWS Tools for Windows PowerShell).

### Bring your own IP addresses (BYOIP) in Amazon EC2

You can bring part or all of your publicly routable IPv4 or IPv6 address range from your on-premises network to your AWS account. You continue to own the address range, but AWS advertises it on the internet by default. After you bring the address range to AWS, it appears in your AWS account as an address pool.

BYOIP is not available in all Regions and for all resources. For a list of supported Regions and resources, see the FAQ for Bring Your Own IP.

**Note**

The following steps describe how to bring your own IP address range for use in Amazon EC2 only. For steps to bring your own IP address range for use in AWS Global Accelerator, see Bring your own IP addresses (BYOIP) in the AWS Global Accelerator Developer Guide.

### Contents

- Requirements and quotas (p. 896)
- Configure your BYOIP address range (p. 897)
- Work with your address range (p. 904)
- Learn more (p. 905)

### Requirements and quotas

- The address range must be registered with your regional internet registry (RIR), such as the American Registry for Internet Numbers (ARIN), Réseaux IP Européens Network Coordination Centre (RIPE), or
Configure your BYOIP address range

The process to configure BYOIP has these phases:

• **Preparation**

  For authentication purposes, create an RSA key pair and use it to generate a self-signed X.509 certificate.

• **RIR configuration**

  Register with the Resource Public Key Infrastructure (RPKI) of your RIR, and file a Route Origin Authorization (ROA) that defines the desired address range, the autonomous system numbers (ASNs) allowed to advertise the address range, and an expiration date. Upload the self-signed certificate to your RDAP record comments.

• **Amazon configuration**

  Sign a CIDR authorization context message with the private RSA key that you created, and upload the message and signature to Amazon using the AWS Command Line Interface.

To bring on multiple address ranges, you must repeat this process with each address range. Bringing on an address range has no effect on any address ranges that you brought on previously.

To configure BYOIP, complete the following tasks. For some tasks, you run Linux commands. On Windows, you can use the Windows Subsystem for Linux to run the Linux commands.

**Tasks**

• Create a key pair and certificate (p. 898)
• Create an ROA object in your RIR (p. 901)
• Update the RDAP record in your RIR (p. 901)
• Provision the address range in AWS (p. 901)
• Advertise the address range through AWS (p. 903)
• Deprovision the address range (p. 903)
Create a key pair and certificate

Use the following procedure to create a self-signed X.509 certificate and add it to the RDAP record for your RIR. The `openssl` commands require OpenSSL version 1.0.2 or later.

Copy the commands below and replace only the placeholder values (in colored italic text).

To create a self-signed X.509 certificate and add it to the RDAP record

This procedure follows the best practice of encrypting your private RSA key and requiring a pass phrase to access it.

1. Generate an RSA 2048-bit key pair as shown in the following.

   ```bash
   $ openssl genpkey -aes256 -algorithm RSA -pkeyopt rsa_keygen_bits:2048 -out private-key.pem
   ```

   The `-aes256` parameter specifies the algorithm used to encrypt the private key. The command returns the following output, including prompts to set a pass phrase:

   ```text
   .......+++ .+++ Enter PEM pass phrase: **********
   Verifying - Enter PEM pass phrase: **********
   ```

   You can inspect the key using the following command:

   ```bash
   $ openssl pkey -in private-key.pem -text
   ```

   This returns a pass-phrase prompt and the contents of the key, which should be similar to the following:

   ```text
   Enter pass phrase for private-key.pem: **********
   ...

Keep your private key in a secure location when it is not in use.

2. Generate your public key from the private key as follows. You will use this later to test that your signed authorization message validates correctly.

```bash
# openssl rsa -in private-key.pem -pubout > public-key.pem
```

On inspection, your public key should look like this:

```
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAxQVx0SOB1SgIYd7HonIqKISwtkU2YxmLMTU4u2F8isqVRiBVgxw0BOBQh5Tzj16sfjaj++MPEqDwzot8aPZGkMqZ9MkDhAaAe0J2HyU0Eum8G8yI0t5Vfj5yBGRD+Zf/4n37XIEzr7Y3aX1gS/PZrOC7gJY+buQ4WNkgKJw/4kQ7JZldwK8y5aJKbC3NC/al3W4g3X6kG7r0nB8A9dluaM6x4Lr89rF/9B9VRrlh7H2WFQ96h277C4cW6A5U7fjL97wCzXqZmMhX9k86X7Q1lO/cH7yJrRdnvZ9qyM82/6Yd7Hy7uTz2Q1w7Tjo07dB+Y/9RswC7iFNH2vo1S2vJgX9U9i0O8V1A4Y97T68G319W98H8zUJbOjZU6jGcXYcSjCjUrQjQsJkT877/73:00:ce:76:61:6d:04:44:67:2d:ff:

9a:77:5a:5e:87:d5:4f:01
```

3. Generate an X.509 certificate using the key pair created in the previous. In this example, the certificate expires in 365 days, after which time it cannot be trusted. Be sure to set the expiration appropriately. The `tr -d "\n"` command strips newline characters (line breaks) from the output. You need to provide a Common Name when prompted, but the other fields can be left blank.

```bash
# openssl req -new -x509 -key private-key.pem -days 365 | tr -d "\n" > certificate.pem
```

This results in output similar to the following:

```
Enter pass phrase for private-key.pem: xxxxxxxx
You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
```

There are quite a few fields but you can leave some blank
Configure your BYOIP address range

For some fields there will be a default value, if you enter ".", the field will be left blank.

Country Name (2 letter code) []:
State or Province Name (full name) []:
Locality Name (eg, city) []:
Organization Name (eg, company) []:
Organizational Unit Name (eg, section) []:
Common Name (eg, fully qualified host name) []: example.com
Email Address []:

You can inspect the certificate with the following command:

```
# cat certificate.pem
```

The output should be a long, PEM-encoded string without line breaks, prefaced by `-----BEGIN CERTIFICATE-----` and followed by `-----END CERTIFICATE-----`.

Create an ROA object in your RIR

Create an ROA object to authorize Amazon ASNs 16509 and 14618 to advertise your address range, as well as the ASNs that are currently authorized to advertise the address range. You must set the maximum length to the size of the smallest prefix that you want to bring (for example, /24). It might take up to 24 hours for the ROA to become available to Amazon. For more information, consult your RIR:

- ARIN — ROA Requests
- RIPE — Managing ROAs
- APNIC — Route Management

Update the RDAP record in your RIR

Add the certificate that you previously created to the RDAP record for your RIR. Be sure to include the `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` strings before and after the encoded portion. All of this content must be on a single, long line. The procedure for updating RDAP depends on your RIR:

- For ARIN, add the certificate in the "Public Comments" section for your address range. Do not add it to the comments section for your organization.
- For RIPE, add the certificate as a new "descr" field for your address range. Do not add it to the comments section for your organization.
- For APNIC, email the public key to helpdesk@apnic.net to manually add it to the "remarks" field for your address range. Send the email using the APNIC authorized contact for the IP addresses.

Provision the address range in AWS

When you provision an address range for use with AWS, you are confirming that you own the address range and are authorizing Amazon to advertise it. We also verify that you own the address range through a signed authorization message. This message is signed with the self-signed X.509 key pair that you used when updating the RDAP record with the X.509 certificate. AWS requires a cryptographically signed authorization message that it presents to the RIR. The RIR authenticates the signature against the certificate that you added to RDAP, and checks the authorization details against the ROA.
To provision the address range

1. **Compose message**

   Compose the plaintext authorization message. The format of the message is as follows, where the date is the expiry date of the message:

   ```
   1|aws|account|cidr|YYYYMMDD|SHA256|RSAPSS
   ```

   Replace the account number, address range, and expiry date with your own values to create a message resembling the following:

   ```
   1|aws|0123456789AB|198.51.100.0/24|20211231|SHA256|RSAPSS
   ```

   This is not to be confused with an ROA message, which has a similar appearance.

2. **Sign message**

   Sign the plaintext message using the private key that you created previously. The signature returned by this command is a long string that you need to use in the next step.

   ```
   Important
   We recommend that you copy and paste this command. Except for the message content, do not modify or replace any of the values.
   ```

   ```
   # echo -n "1|aws|123456789012|198.51.100.0/24|20211231|SHA256|RSAPSS" | openssl dgst -sha256 -sigopt rsa_padding_mode:pss -sigopt rsa_pss_saltlen:-1 -sign private-key.pem -keyform PEM | openssl base64 | tr -- '+=/' '-_~' | tr -d "\n"
   ```

3. **Provision address**

   Use the AWS CLI `provision-byoip-cidr` command to provision the address range. The `--cidr-authorization-context` option uses the message and signature strings that you created previously.

   ```
   aws ec2 provision-byoip-cidr --cidr address-range --cidr-authorization-context Message="message",Signature="signature"
   ```

   Provisioning an address range is an asynchronous operation, so the call returns immediately, but the address range is not ready to use until its status changes from pending-provision to provisioned.

4. **Monitor progress**

   It can take up to three weeks to complete the provisioning process for publicly advertisable ranges. Use the `describe-byoip-cidrs` command to monitor progress, as in this example:

   ```
   aws ec2 describe-byoip-cidrs --max-results 5
   ```

   If there are issues during provisioning and the status goes to `failed-provision`, you must run the `provision-byoip-cidr` command again after the issues have been resolved.

**Provision an IPv6 address range that's not publicly advertised**

By default, an address range is provisioned to be publicly advertised to the internet. You can provision an IPv6 address range that will not be publicly advertised. For routes that are not publicly advertisable, the provisioning process generally completes within minutes. When you associate an IPv6 CIDR block from a
Configure your BYOIP address range

non-public address range with a VPC, the IPv6 CIDR can only be accessed through an AWS Direct Connect connection.

An ROA is not required to provision a non-public address range.

**Important**
You can only specify whether an address range is publicly advertised during provisioning. You cannot change the advertisable status later on.

To provision an IPv6 address range that will not be publicly advertised, use the following provision-
byoip-cidr command.

```bash
aws ec2 provision-byoip-cidr --cidr address-range --cidr-authorization-context Message="$text_message",Signature="$signed_message" --no-publicly-advertisable
```

**Advertise the address range through AWS**

After the address range is provisioned, it is ready to be advertised. You must advertise the exact address range that you provisioned. You can't advertise only a portion of the provisioned address range.

If you provisioned an IPv6 address range that will not be publicly advertised, you do not need to complete this step.

We recommend that you stop advertising the address range from other locations before you advertise it through AWS. If you keep advertising your IP address range from other locations, we can't reliably support it or troubleshoot issues. Specifically, we can't guarantee that traffic to the address range will enter our network.

To minimize down time, you can configure your AWS resources to use an address from your address pool before it is advertised, and then simultaneously stop advertising it from the current location and start advertising it through AWS. For more information about allocating an Elastic IP address from your address pool, see Allocate an Elastic IP address (p. 915).

**Limitations**

- You can run the advertise-byoip-cidr command at most once every 10 seconds, even if you specify different address ranges each time.
- You can run the withdraw-byoip-cidr command at most once every 10 seconds, even if you specify different address ranges each time.

To advertise the address range, use the following advertise-byoip-cidr command.

```bash
aws ec2 advertise-byoip-cidr --cidr address-range
```

To stop advertising the address range, use the following withdraw-byoip-cidr command.

```bash
aws ec2 withdraw-byoip-cidr --cidr address-range
```

**Deprovision the address range**

To stop using your address range with AWS, first release any Elastic IP addresses and disassociate any IPv6 CIDR blocks that are still allocated from the address pool. Then stop advertising the address range, and finally, deprovision the address range.
Work with your address range

You cannot deprovision a portion of the address range. If you want to use a more specific address range with AWS, deprovision the entire address range and provision a more specific address range.

(IPV4) To release each Elastic IP address, use the following `release-address` command.

```
aws ec2 release-address --allocation-id eipalloc-12345678abcabcabc
```

(IPV6) To disassociate an IPv6 CIDR block, use the following `disassociate-vpc-cidr-block` command.

```
aws ec2 disassociate-vpc-cidr-block --association-id vpc-cidr-assoc-12345abcd1234abc1
```

To stop advertising the address range, use the following `withdraw-byoip-cidr` command.

```
aws ec2 withdraw-byoip-cidr --cidr address-range
```

To deprovision the address range, use the following `deprovision-byoip-cidr` command.

```
aws ec2 deprovision-byoip-cidr --cidr address-range
```

It can take up to a day to deprovision an address range.

**Work with your address range**

You can view and use the IPv4 and IPv6 address ranges that you've provisioned in your account.

**IPv4 address ranges**

You can create an Elastic IP address from your IPv4 address pool and use it with your AWS resources, such as EC2 instances, NAT gateways, and Network Load Balancers.

To view information about the IPv4 address pools that you've provisioned in your account, use the following `describe-public-ipv4-pools` command.

```
aws ec2 describe-public-ipv4-pools
```

To create an Elastic IP address from your IPv4 address pool, use the `allocate-address` command. You can use the `--public-ipv4-pool` option to specify the ID of the address pool returned by `describe-byoip-cidrs`. Or you can use the `--address` option to specify an address from the address range that you provisioned.

**IPv6 address ranges**

To view information about the IPv6 address pools that you've provisioned in your account, use the following `describe-ipv6-pools` command.

```
aws ec2 describe-ipv6-pools
```

To create a VPC and specify an IPv6 CIDR from your IPv6 address pool, use the following `create-vpc` command. To let Amazon choose the IPv6 CIDR from your IPv6 address pool, omit the `--ipv6-cidr-block` option.

```
aws ec2 create-vpc --cidr-block 10.0.0.0/16 --ipv6-cidr-block ipv6-cidr --ipv6-pool pool-id
```
To associate an IPv6 CIDR block from your IPv6 address pool with a VPC, use the following `associate-vpc-cidr-block` command. To let Amazon choose the IPv6 CIDR from your IPv6 address pool, omit the `--ipv6-cidr-block` option.

```
aws ec2 associate-vpc-cidr-block --vpc-id vpc-123456789abc123ab --ipv6-cidr-block ipv6-cidr --ipv6-pool pool-id
```

To view your VPCs and the associated IPv6 address pool information, use the `describe-vpcs` command. To view information about associated IPv6 CIDR blocks from a specific IPv6 address pool, use the following `get-associated-ipv6-pool-cidrs` command.

```
aws ec2 get-associated-ipv6-pool-cidrs --pool-id pool-id
```

If you disassociate the IPv6 CIDR block from your VPC, it's released back into your IPv6 address pool.

For more information about working with IPv6 CIDR blocks in the VPC console, see Working with VPCs and Subnets in the Amazon VPC User Guide.

### Learn more

For more information, see the AWS Online Tech talk Deep Dive on Bring Your Own IP.

### Assigning prefixes to Amazon EC2 network interfaces

You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces. By assigning prefixes, you scale and simplify the management of applications, including container and networking applications that require multiple IP addresses on an instance.

The following assignment options are available:

- **Automatic assignment** — AWS chooses the prefix from your VPC subnet's IPv4 or IPv6 CIDR and assigns to your network interface.
- **Manual Assignment** — You specify the prefix from your VPC subnet's IPv4 and IPv6 CIDRs, and AWS verifies that the prefix is not already assigned to other resources before assigning it to your network interface.

Assigning prefixes has the following benefits:

- **Increased IP addresses on a network interface** — When you use a prefix, you assign a block of IP addresses as opposed to individual IP addresses. This increases the number of IP addresses on a network interface.
- **Simplified VPC management for containers** — In container applications, each container requires a unique IP address. Assigning prefixes to your instance simplifies the management of your VPCs, as you can launch and terminate containers without having to call Amazon EC2 APIs for individual IP assignments.

### Topics

- Basics for assigning prefixes (p. 906)
Basics for assigning prefixes

- You can assign a prefix to new or existing network interfaces.
- To use prefixes, you first assign a prefix to your network interface, then attach the network interface to your instance, and then configure your operating system.
- When you choose the option to specify a prefix, the prefix must meet the following requirements:
  - The IPv4 prefix that you can specify is /28.
  - The IPv6 prefix that you can specify is /80.
  - The prefix is in the subnet CIDR of the network interface, and it does not overlap with other prefixes or IP addresses assigned to existing resources in the subnet.
- You can assign a prefix to the primary or secondary network interface.
- You can assign an Elastic IP address to a network interface that has a prefix assigned to it.
- We resolve the private DNS host name of an instance to the primary private IPv4 address.
- We assign each private IPv4 address on a network interface, including those from prefixes, with the following forms:
  - us-east-1 Region
    
    ```text
    ip-private-ipv4-address.ec2.internal
    ```
  - All other Regions
    
    ```text
    ip-private-ipv4-address.region.compute.internal
    ```

Considerations and limits for prefixes

Take the following into consideration when you use prefixes:

- Network interfaces with prefixes are supported with nitro-based instances.
- Prefixes for network interfaces are limited to private IPv4 and IPv6 addresses.
- See IP addresses per network interface per instance type (p. 924) for limitations.
- The number of prefixes and IP addresses on a network interface must be less than the limit on the instance that the network interface is associated with. For example, if you have a c5.large instance, the limit is 10 IPv4 addresses and 10 IPv6 addresses on a network interface, and the total number of /28 and /80 prefixes must be less than 10.
- Prefixes are included in source/destination checks.

Work with prefixes

Topics

- Assign prefixes during network interface creation (p. 907)
- Assign prefixes to existing network interfaces (p. 910)
- Configure your operating system for network interfaces with prefixes (p. 912)
- View the prefixes assigned your network interfaces (p. 912)
- Remove prefixes from your network interfaces (p. 913)
Assign prefixes during network interface creation

You can use the create-network-interface AWS CLI command to assign prefixes to a new network interface during creation.

If you use the automatic assignment option, you can reserve a block of IP addresses in your subnet. AWS chooses the prefixes from this block. For more information, see Subnet CIDR reservations in the Amazon VPC User Guide.

After you have created the network interface, use the attach-network-interface AWS CLI command to attach the network interface to your instance, and you must configure your operating system to work with network interfaces with prefixes. For more information, see Configure your operating system for network interfaces with prefixes (p. 912).

Topics

- Assign automatic prefixes during network interface creation (p. 907)
- Assign specific prefixes during network interface creation (p. 908)

Assign automatic prefixes during network interface creation

To assign automatic IPv4 prefixes during network interface creation

Use the create-network-interface command and set --ipv4-prefix-count to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 prefix.

```bash
$ aws ec2 create-network-interface \\   --subnet-id subnet-047cfed18eEXAMPLE \\   --description "IPv4 automatic example" \\   --ipv4-prefix-count 1
```

Example output

```json
{
   "NetworkInterface": {
      "AvailabilityZone": "us-west-2a",
      "Description": "IPv4 automatic example",
      "Groups": [
         {
            "GroupName": "default",
            "GroupId": "sg-044c2de2c4EXAMPLE"
         }
      ],
      "InterfaceType": "interface",
      "Ipv6Addresses": [],
      "MacAddress": "02:98:65:dd:18:47",
      "NetworkInterfaceId": "eni-02b80b4668EXAMPLE",
      "OwnerId": "123456789012",
      "PrivateIpAddress": "10.0.0.62",
      "PrivateIpAddresses": [
         {
            "Primary": true,
            "PrivateIpAddress": "10.0.0.62"
         }
      ],
      "Ipv4Prefixes": [
         {
            "Ipv4Prefix": "10.0.0.208/28"
         }
      ]
   }
}
```
To assign automatic IPv6 prefixes during network interface creation

Use the `create-network-interface` command and set `--ipv6-prefix-count` to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 prefix.

$ aws ec2 create-network-interface \
--subnet-id subnet-047cfed18eEXAMPLE \
--description "IPv6 automatic example" \
--ipv6-prefix-count 1

Example output

```json
{
  "NetworkInterface": {
    "AvailabilityZone": "us-west-2a",
    "Description": "IPv6 automatic example",
    "Groups": [
      {
        "GroupName": "default",
        "GroupId": "sg-044c2de2c4EXAMPLE"
      }
    ],
    "InterfaceType": "interface",
    "Ipv6Addresses": [],
    "MacAddress": "02:bb:e4:31:fe:09",
    "NetworkInterfaceId": "eni-006edbcfa4EXAMPLE",
    "OwnerId": "123456789012",
    "PrivateIpAddress": "10.0.0.73",
    "PrivateIpAddresses": [
      {
        "Primary": true,
        "PrivateIpAddress": "10.0.0.73"
      }
    ],
    "Ipv6Prefixes": [
      {
        "Ipv6Prefix": "2600:1f13:fc2:a700:1768::/80"
      }
    ],
    "RequesterId": "AIDAIV5AJI5LXF5XXDFCO",
    "RequesterManaged": false,
    "SourceDestCheck": true,
    "Status": "pending",
    "SubnetId": "subnet-047cfed18eEXAMPLE",
    "TagSet": [],
    "VpcId": "vpc-0e12f52b21EXAMPLE"
  }
}
```

Assign specific prefixes during network interface creation

To assign specific IPv4 prefixes during network interface creation
Use the `create-network-interface` command and set `--ipv4-prefixes` to the prefixes. AWS selects IP addresses from this range. In the following example, the prefix CIDR is `10.0.0.208/28`.

```bash
$ aws ec2 create-network-interface \\
--subnet-id subnet-047cfed18eEXAMPLE \\
--description "IPv4 manual example" \\
--ipv4-prefixes Ipv4Prefix=10.0.0.208/28
```

Example output

```
{
   "NetworkInterface": {
      "AvailabilityZone": "us-west-2a",
      "Description": "IPv4 manual example",
      "Groups": [
         {
            "GroupName": "default",
            "GroupId": "sg-044c2de2c4EXAMPLE"
         }
      ],
      "InterfaceType": "interface",
      "Ipv6Addresses": [],
      "MacAddress": "02:98:65:dd:18:47",
      "NetworkInterfaceId": "eni-02b80b4668EXAMPLE",
      "OwnerId": "123456789012",
      "PrivateIpAddress": "10.0.0.62",
      "PrivateIpAddresses": [
         {
            "Primary": true,
            "PrivateIpAddress": "10.0.0.62"
         }
      ],
      "Ipv4Prefixes": [
         {
            "Ipv4Prefix": "10.0.0.208/28"
         }
      ],
      "RequesterId": "AIDAIV5AJI5LXF5XXDPCO",
      "RequesterManaged": false,
      "SourceDestCheck": true,
      "Status": "pending",
      "SubnetId": "subnet-047cfed18eEXAMPLE",
      "TagSet": [],
      "VpcId": "vpc-0e12f52b21EXAMPLE"
   }
}
```

To assign specific IPv6 prefixes during network interface creation

Use the `create-network-interface` command and set `--ipv6-prefixes` to the prefixes. AWS selects IP addresses from this range. In the following example, the prefix CIDR is `2600:1f13:fc2:a700:1768::/80`.

```bash
$ aws ec2 create-network-interface \\
--subnet-id subnet-047cfed18eEXAMPLE \\
--description "IPv6 manual example" \\
--ipv6-prefixes Ipv6Prefix=2600:1f13:fc2:a700:1768::/80
```

Example output

```
{
```
Assign prefixes to existing network interfaces

You can use the `assign-ipv6-addresses` command to assign IPv6 prefixes and the `assign-private-ip-addresses` command to assign IPv4 prefixes to existing network interfaces.

After you have assigned the prefixes, use the `attach-network-interface` AWS CLI command to attach the network interface to your instance, and you must configure your operating system to work with network interfaces with prefixes. For more information, see Configure your operating system for network interfaces with prefixes (p. 912).

Assign automatic prefixes to an existing network interface

To assign automatic IPv4 prefixes to an existing network interface

Use the `assign-private-ip-addresses` command and set `--ipv4-prefix-count` to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 IPv4 prefix.

```
$ aws ec2 assign-private-ip-addresses \
--network-interface-id eni-081fbb4095EXAMPLE \
--ipv4-prefix-count 1
```

Example output

```
{
  "NetworkInterfaceId": "eni-081fbb4095EXAMPLE",
```
To assign automatic IPv6 prefixes to an existing network interface

Use the `assign-ipv6-addresses` command and set `--ipv6-prefix-count` to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 IPv6 prefix.

```
$ aws ec2 assign-ipv6-addresses 
   --network-interface-id eni-00d577338cEXAMPLE 
   --ipv6-prefix-count 1
```

Example output

```
{
   "AssignedIpv6Prefixes": [
      "2600:1f13:fc2:a700:18bb::/80"
   ],
   "NetworkInterfaceId": "eni-00d577338cEXAMPLE"
}
```

Assign specific prefixes to an existing network interface

Assign specific IPv4 prefixes to an existing network interface

Use the `assign-private-ip-addresses` command and set `--ipv4-prefixes` to the prefix. AWS selects IPv4 addresses from this range. In the following example, the prefix CIDR is `10.0.0.208/28`.

```
$ aws ec2 assign-private-ip-addresses 
   --network-interface-id eni-081fbb4095EXAMPLE 
   --ipv4-prefixes 10.0.0.208/28
```

Example output

```
{
   "NetworkInterfaceId": "eni-081fbb4095EXAMPLE",
   "AssignedIpv4Prefixes": [
      "10.0.0.208/28"
   ]
}
```

Assign specific IPv6 prefixes to an existing network interface

Use the `assign-ipv6-addresses` command and set `--ipv6-prefixes` to the prefix. AWS selects IPv6 addresses from this range. In the following example, the prefix CIDR is `2600:1f13:fc2:a700:18bb::/80`.

```
$ aws ec2 assign-ipv6-addresses 
   --network-interface-id eni-00d577338cEXAMPLE 
   --ipv6-prefixes 2600:1f13:fc2:a700:18bb::/80
```

Example output
Configure your operating system for network interfaces with prefixes

Amazon Linux AMIs might contain additional scripts installed by AWS, known as `ec2-net-utils`. These scripts optionally automate the configuration of your network interfaces. They are available for Amazon Linux only.

If you are not using Amazon Linux, you can use a Container Network Interface (CNI) for Kubernetes plugin, or `dockerd` if you use Docker to manage your containers.

View the prefixes assigned your network interfaces

You can use the `describe-network-interfaces` AWS CLI command to view the prefixes assigned to your network interfaces.

```bash
# aws ec2 describe-network-interfaces
```

Example output

```
{
   "NetworkInterfaces": [
      {
         "AvailabilityZone": "us-west-2a",
         "Description": "IPv4 automatic example",
         "Groups": [
            {
               "GroupName": "default",
               "GroupId": "sg-044c2de2c4EXAMPLE"
            }
         ],
         "InterfaceType": "interface",
         "Ipv6Addresses": [],
         "MacAddress": "02:98:65:dd:18:47",
         "NetworkInterfaceId": "eni-02b80b4668EXAMPLE",
         "OwnerId": "123456789012",
         "PrivateIpAddress": "10.0.0.62",
         "PrivateIpAddresses": [
            {
               "Primary": true,
               "PrivateIpAddress": "10.0.0.62"
            }
         ],
         "Ipv4Prefixes": [
            {
               "Ipv4Prefix": "10.0.0.208/28"
            }
         ],
         "Ipv6Prefixes": [
            {
               "Ipv6Prefix": "2600:1f13:fc2:a700:18bb::/80"
            }
         ],
         "RequesterId": "AIDAIV5AJI5LXF5XXDCO",
         "RequesterManaged": false,
         "SourceDestCheck": true,
      }
   ]
}
```
Remove prefixes from your network interfaces

You can use the `unassign-ipv6-addresses` command to remove IPv6 prefixes and the `unassign-private-ip-addresses` commands to remove IPv4 prefixes from your existing network interfaces.

To remove IPv4 prefixes from a network interface

Use the `unassign-private-ip-addresses` command and set `--ipv4-prefix` to the address that you want to remove.

```
$ aws ec2 unassign-private-ip-addresses
  --network-interface-id eni-081fbb4095EXAMPLE
  --ipv4-prefixes 10.0.0.176/28
```

To remove IPv6 prefixes from a network interface

Use the `unassign-ipv6-addresses` command and set `--ipv6-prefix` to the address that you want to remove.
Elastic IP addresses

An Elastic IP address is a static IPv4 address designed for dynamic cloud computing. An Elastic IP address is allocated to your AWS account, and is yours until you release it. By using an Elastic IP address, you can mask the failure of an instance or software by rapidly remapping the address to another instance in your account. Alternatively, you can specify the Elastic IP address in a DNS record for your domain, so that your domain points to your instance. For more information, see the documentation for your domain registrar, or Set up dynamic DNS on Your Amazon Linux instance (p. 599).

An Elastic IP address is a public IPv4 address, which is reachable from the internet. If your instance does not have a public IPv4 address, you can associate an Elastic IP address with your instance to enable communication with the internet. For example, this allows you to connect to your instance from your local computer.

We currently do not support Elastic IP addresses for IPv6.

Contents
- Elastic IP address pricing (p. 914)
- Elastic IP address basics (p. 914)
- Work with Elastic IP addresses (p. 915)
- Use reverse DNS for email applications (p. 921)
- Elastic IP address limit (p. 922)

Elastic IP address pricing

To ensure efficient use of Elastic IP addresses, we impose a small hourly charge if an Elastic IP address is not associated with a running instance, or if it is associated with a stopped instance or an unattached network interface. While your instance is running, you are not charged for one Elastic IP address associated with the instance, but you are charged for any additional Elastic IP addresses associated with the instance.

For more information, see Elastic IP Addresses on the Amazon EC2 Pricing, On-Demand Pricing page.

Elastic IP address basics

The following are the basic characteristics of an Elastic IP address:

- An Elastic IP address is static; it does not change over time.
- To use an Elastic IP address, you first allocate one to your account, and then associate it with your instance or a network interface.
- When you associate an Elastic IP address with an instance, it is also associated with the instance's primary network interface. When you associate an Elastic IP address with a network interface that is attached to an instance, it is also associated with the instance.
- When you associate an Elastic IP address with an instance or its primary network interface, the instance's public IPv4 address (if it had one) is released back into Amazon's pool of public IPv4 addresses. You cannot reuse a public IPv4 address, and you cannot convert a public IPv4 address to an Elastic IP address. For more information, see Public IPv4 addresses and external DNS hostnames (p. 881).
Work with Elastic IP addresses

Tasks

- Allocate an Elastic IP address (p. 915)
- Describe your Elastic IP addresses (p. 916)
- Tag an Elastic IP address (p. 917)
- Associate an Elastic IP address with an instance or network interface (p. 918)
- Disassociate an Elastic IP address (p. 919)
- Release an Elastic IP address (p. 920)
- Recover an Elastic IP address (p. 920)

Allocate an Elastic IP address

You can allocate an Elastic IP address from Amazon's pool of public IPv4 addresses, or from a custom IP address pool that you have brought to your AWS account. For more information about bringing your own IP address range to your AWS account, see Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 896).

You can allocate an Elastic IP address using one of the following methods.

New console

To allocate an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network & Security, Elastic IPs.
3. Choose Allocate Elastic IP address.
4. For **Public IPv4 address pool**, choose one of the following:
   - **Amazon's pool of IPv4 addresses**—If you want an IPv4 address to be allocated from Amazon's pool of IPv4 addresses.
   - **My pool of public IPv4 addresses**—If you want to allocate an IPv4 address from an IP address pool that you have brought to your AWS account. This option is disabled if you do not have any IP address pools.
   - **Customer owned pool of IPv4 addresses**—If you want to allocate an IPv4 address from a pool created from your on-premises network for use with an AWS Outpost. This option is disabled if you do not have an AWS Outpost.

5. (Optional) Add or remove a tag.
   - [Add a tag] Choose **Add new tag** and do the following:
     - For **Key**, enter the key name.
     - For **Value**, enter the key value.
   - [Remove a tag] Choose **Remove** to the right of the tag’s Key and Value.

6. Choose **Allocate**.

Old console

**To allocate an Elastic IP address**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Choose **Allocate new address**.
4. For **IPv4 address pool**, choose **Amazon pool**.
5. Choose **Allocate**, and close the confirmation screen.

AWS CLI

**To allocate an Elastic IP address**

Use the **allocate-address** AWS CLI command.

PowerShell

**To allocate an Elastic IP address**

Use the **New-EC2Address** AWS Tools for Windows PowerShell command.

**Describe your Elastic IP addresses**

You can describe an Elastic IP address using one of the following methods.

New console

**To describe your Elastic IP addresses**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to view and choose **Actions, View details**.
Old console

**To describe your Elastic IP addresses**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select a filter from the Resource Attribute list to begin searching. You can use multiple filters in a single search.

AWS CLI

**To describe your Elastic IP addresses**

Use the `describe-addresses` AWS CLI command.

PowerShell

**To describe your Elastic IP addresses**

Tag an Elastic IP address

You can assign custom tags to your Elastic IP addresses to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Elastic IP address based on the custom tags that you assigned to it.

Cost allocation tracking using Elastic IP address tags is not supported.

You can tag an Elastic IP address using one of the following methods.

New console

**To tag an Elastic IP address**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to tag and choose **Actions**, **View details**.
4. In the **Tags** section, choose **Manage tags**.
5. Specify a tag key and value pair.
6. (Optional) Choose **Add tag** to add additional tags.
7. Choose **Save**.

Old console

**To tag an Elastic IP address**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to tag and choose **Tags**.
4. Choose **Add/Edit Tags**.
5. In the **Add/Edit Tags** dialog box, choose **Create Tag**, and then specify the key and value for the tag.
6. (Optional) Choose **Create Tag** to add additional tags to the Elastic IP address.
7. Choose **Save**.

**AWS CLI**

**To tag an Elastic IP address**

Use the `create-tags` AWS CLI command.

```
aws ec2 create-tags --resources eipalloc-12345678 --tags Key=Owner,Value=TeamA
```

**PowerShell**

**To tag an Elastic IP address**

Use the `New-EC2Tag` AWS Tools for Windows PowerShell command.

The `New-EC2Tag` command needs a `Tag` parameter, which specifies the key and value pair to be used for the Elastic IP address tag. The following commands create the `Tag` parameter.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

Associate another Elastic IP address with an instance or network interface

If you're associating an Elastic IP address with your instance to enable communication with the internet, you must also ensure that your instance is in a public subnet. For more information, see Internet Gateways in the Amazon VPC User Guide.

You can associate an Elastic IP address with an instance or network interface using one of the following methods.

**New console**

**To associate an Elastic IP address with an instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to associate and choose **Actions, Associate Elastic IP address**.
4. For **Resource type**, choose **Instance**.
5. For instance, choose the instance with which to associate the Elastic IP address. You can also enter text to search for a specific instance.
6. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
7. Choose **Associate**.

**To associate an Elastic IP address with a network interface**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to associate and choose **Actions, Associate Elastic IP address**.
4. For **Resource type**, choose **Network interface**.
5. For **Network interface**, choose the network interface with which to associate the Elastic IP address. You can also enter text to search for a specific network interface.
6. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
7. Choose **Associate**.

**Old console**

**To associate an Elastic IP address with an instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select an Elastic IP address and choose **Actions, Associate address**.
4. Select the instance from **Instance** and then choose **Associate**.

**AWS CLI**

**To associate an Elastic IP address**

Use the **associate-address** AWS CLI command.

**PowerShell**

**To associate an Elastic IP address**

Use the **Register-EC2Address** AWS Tools for Windows PowerShell command.

**Disassociate an Elastic IP address**

You can disassociate an Elastic IP address from an instance or network interface at any time. After you disassociate the Elastic IP address, you can reassociate it with another resource.

You can disassociate an Elastic IP address using one of the following methods.

**New console**

**To disassociate and reassociate an Elastic IP address**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to disassociate, choose **Actions, Disassociate Elastic IP address**.
4. Choose **Disassociate**.

**Old console**

**To disassociate and reassociate an Elastic IP address**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address, choose **Actions**, and then select **Disassociate address**.
4. Choose **Disassociate address**.
Work with Elastic IP addresses

AWS CLI

To disassociate an Elastic IP address

Use the disassociate-address AWS CLI command.

PowerShell

To disassociate an Elastic IP address

Use the Unregister-EC2Address AWS Tools for Windows PowerShell command.

Release an Elastic IP address

If you no longer need an Elastic IP address, we recommend that you release it using one of the following methods. The address to release must not be currently associated with an AWS resource, such as an EC2 instance, NAT gateway, or Network Load Balancer.

New console

To release an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address to release and choose Actions, Release Elastic IP addresses.

Old console

To release an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address, choose Actions, and then select Release addresses. Choose Release when prompted.

AWS CLI

To release an Elastic IP address

Use the release-address AWS CLI command.

PowerShell

To release an Elastic IP address

Use the Remove-EC2Address AWS Tools for Windows PowerShell command.

Recover an Elastic IP address

If you have released your Elastic IP address, you might be able to recover it. The following rules apply:

- You cannot recover an Elastic IP address if it has been allocated to another AWS account, or if it will result in your exceeding your Elastic IP address limit.
- You cannot recover tags associated with an Elastic IP address.
• You can recover an Elastic IP address using the Amazon EC2 API or a command line tool only.

AWS CLI

To recover an Elastic IP address

Use the `allocate-address` AWS CLI command and specify the IP address using the `--address` parameter as follows.

```
aws ec2 allocate-address --domain vpc --address 203.0.113.3
```

PowerShell

To recover an Elastic IP address

Use the `New-EC2Address` AWS Tools for Windows PowerShell command and specify the IP address using the `-Address` parameter as follows.

```
PS C:\> New-EC2Address -Address 203.0.113.3 -Domain vpc -Region us-east-1
```

Use reverse DNS for email applications

If you intend to send email to third parties from an instance, we recommend that you provision one or more Elastic IP addresses and assign static reverse DNS records to the Elastic IP addresses that you use to send email. This can help you avoid having your email flagged as spam by some anti-spam organizations. AWS works with ISPs and internet anti-spam organizations to reduce the chance that your email sent from these addresses will be flagged as spam.

Considerations

• Before you create a reverse DNS record, you must set a corresponding forward DNS record (record type A) that points to your Elastic IP address.
• If a reverse DNS record is associated with an Elastic IP address, the Elastic IP address is locked to your account and cannot be released from your account until the record is removed.

Console

To create a reverse DNS record for your Elastic IP address

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`
2. Choose Elastic IPs from the navigation pane.
3. Select the Elastic IP address and choose Actions, Update reverse DNS.
4. For Reverse DNS domain name, enter the domain name to associate with the Elastic IP address.
5. Enter **update** to confirm.
6. Choose **Update**.

AWS CLI

To create a reverse DNS record for your Elastic IP address

• Use the `modify-address-attribute` AWS CLI command to associate your domain name to your Elastic IP address.
AWS GovCloud (US) Region and China Regions

For these Regions, you can't create a reverse DNS record using the methods above. AWS must assign the static reverse DNS records for you. Open Request to remove reverse DNS and email sending limitations and provide us with your Elastic IP addresses and reverse DNS records.

Elastic IP address limit

By default, all AWS accounts are limited to five (5) Elastic IP addresses per Region, because public (IPv4) internet addresses are a scarce public resource. We strongly encourage you to use an Elastic IP address primarily for the ability to remap the address to another instance in the case of instance failure, and to use DNS hostnames for all other inter-node communication.

To verify how many Elastic IP addresses are in use

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/ and choose Elastic IPs from the navigation pane.

To verify your current account limit for Elastic IP addresses

You can verify your limit in either the Amazon EC2 console or the Service Quotas console. Do one of the following:

• Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
  Choose Limits from the navigation pane, and then enter IP in the search field. The limit is EC2-VPC Elastic IPs. If you have access to EC2-Classic, there is an additional limit, EC2-Classic Elastic IPs.
• Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.
  On the Dashboard, choose Amazon Elastic Compute Cloud (Amazon EC2). If Amazon Elastic Compute Cloud (Amazon EC2) is not listed on the Dashboard, choose AWS services, enter EC2 in the search field, and then choose Amazon Elastic Compute Cloud (Amazon EC2).
  On the Amazon EC2 service quotas page, enter IP in the search field. The limit is EC2-VPC Elastic IPs. If you have access to EC2-Classic, there is an additional limit, EC2-Classic Elastic IPs. For more information, choose the limit.

If you think your architecture warrants additional Elastic IP addresses, you can request a quota increase directly from the Service Quotas console.

Elastic network interfaces

An elastic network interface is a logical networking component in a VPC that represents a virtual network card. It can include the following attributes:

• A primary private IPv4 address from the IPv4 address range of your VPC
• One or more secondary private IPv4 addresses from the IPv4 address range of your VPC
• One Elastic IP address (IPv4) per private IPv4 address
• One public IPv4 address
• One or more IPv6 addresses
• One or more security groups
• A MAC address
• A source/destination check flag
• A description
You can create and configure network interfaces and attach them to instances in the same Availability Zone. Your account might also have requestor-managed network interfaces, which are created and managed by AWS services to enable you to use other resources and services. You cannot manage these network interfaces yourself. For more information, see Requester-managed network interfaces (p. 950).

This AWS resource is referred to as a network interface in the AWS Management Console and the Amazon EC2 API. Therefore, we use "network interface" in this documentation instead of "elastic network interface". The term "network interface" in this documentation always means "elastic network interface".

Contents

• Network interface basics (p. 923)
• Network cards (p. 924)
• IP addresses per network interface per instance type (p. 924)
• Work with network interfaces (p. 939)
• Scenarios for network interfaces (p. 946)
• Best practices for configuring network interfaces (p. 948)
• Requester-managed network interfaces (p. 950)

Network interface basics

You can create a network interface, attach it to an instance, detach it from an instance, and attach it to another instance. The attributes of a network interface follow it as it's attached or detached from an instance and reattached to another instance. When you move a network interface from one instance to another, network traffic is redirected to the new instance.

Primary network interface

Each instance has a default network interface, called the primary network interface. You cannot detach a primary network interface from an instance. You can create and attach additional network interfaces. The maximum number of network interfaces that you can use varies by instance type. For more information, see IP addresses per network interface per instance type (p. 924).

Public IPv4 addresses for network interfaces

In a VPC, all subnets have a modifiable attribute that determines whether network interfaces created in that subnet (and therefore instances launched into that subnet) are assigned a public IPv4 address. For more information, see IP addressing behavior for your subnet in the Amazon VPC User Guide. The public IPv4 address is assigned from Amazon's pool of public IPv4 addresses. When you launch an instance, the IP address is assigned to the primary network interface that's created.

When you create a network interface, it inherits the public IPv4 addressing attribute from the subnet. If you later modify the public IPv4 addressing attribute of the subnet, the network interface keeps the setting that was in effect when it was created. If you launch an instance and specify an existing network interface as the primary network interface, the public IPv4 address attribute is determined by this network interface.

For more information, see Public IPv4 addresses and external DNS hostnames (p. 881).

Elastic IP addresses for network interface

If you have an Elastic IP address, you can associate it with one of the private IPv4 addresses for the network interface. You can associate one Elastic IP address with each private IPv4 address.

If you disassociate an Elastic IP address from a network interface, you can release it back to the address pool. This is the only way to associate an Elastic IP address with an instance in a different subnet or VPC, as network interfaces are specific to subnets.

IPv6 addresses for network interfaces
If you associate IPv6 CIDR blocks with your VPC and subnet, you can assign one or more IPv6 addresses from the subnet range to a network interface. Each IPv6 address can be assigned to one network interface.

All subnets have a modifiable attribute that determines whether network interfaces created in that subnet (and therefore instances launched into that subnet) are automatically assigned an IPv6 address from the range of the subnet. For more information, see IP addressing behavior for your subnet in the Amazon VPC User Guide. When you launch an instance, the IPv6 address is assigned to the primary network interface that's created.

For more information, see IPv6 addresses (p. 882).

Prefix Delegation

A Prefix Delegation prefix is a reserved private IPv4 or IPv6 CIDR range that you allocate for automatic or manual assignment to network interfaces that are associated with an instance. By using Delegated Prefixes, you can launch services faster by assigning a range of IP addresses as a single prefix.

Termination behavior

You can set the termination behavior for a network interface that's attached to an instance. You can specify whether the network interface should be automatically deleted when you terminate the instance to which it's attached.

Source/destination checking

You can enable or disable source/destination checks, which ensure that the instance is either the source or the destination of any traffic that it receives. Source/destination checks are enabled by default. You must disable source/destination checks if the instance runs services such as network address translation, routing, or firewalls.

Monitoring IP traffic

You can enable a VPC flow log on your network interface to capture information about the IP traffic going to and from a network interface. After you've created a flow log, you can view and retrieve its data in Amazon CloudWatch Logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

Network cards

Instances with multiple network cards provide higher network performance, including bandwidth capabilities above 100 Gbps and improved packet rate performance. Each network interface is attached to a network card. The primary network interface must be assigned to network card index 0.

If you enable Elastic Fabric Adapter (EFA) when you launch an instance that supports multiple network cards, all network cards are available. You can assign up to one EFA per network card. An EFA counts as a network interface.

The following instances support multiple network cards. All other instance types support one network card.

<table>

You can use the `describe-instance-types` AWS CLI command to display information about an instance type, such as the supported network interfaces and IP addresses per interface. The following example displays this information for all C5 instances.

```bash
aws ec2 describe-instance-types --filters "Name=instance-type,Values=c5.*" --query "InstanceTypes[].{Type: InstanceType, MaxENI: NetworkInfo.MaximumNetworkInterfaces, IPv4addr: NetworkInfo.Ipv4AddressesPerInterface}" --output table
```
Work with network interfaces

You can work with network interfaces using the Amazon EC2 console or the command line.

Contents

- Create a network interface (p. 939)
- View details about a network interface (p. 940)
- Attach a network interface to an instance (p. 941)
- Detach a network interface from an instance (p. 942)
- Manage IP addresses (p. 943)
- Modify network interface attributes (p. 944)
- Add or edit tags (p. 945)
- Delete a network interface (p. 946)

Create a network interface

You can create a network interface in a subnet. You can't move the network interface to another subnet after it’s created. You must attach a network interface to an instance in the same Availability Zone.

New console

To create a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose Create network interface.
4. (Optional) For Description, enter a descriptive name.
5. For Subnet, select a subnet.
6. For Private IPv4 address, do one of the following:
   - Choose Auto-assign to allow Amazon EC2 to select an IPv4 address from the subnet.
   - Choose Custom and enter an IPv4 address that you select from the subnet.
7. (Subnets with IPv6 addresses only) For IPv6 address, do one of the following:
   - Choose None if you do not want to assign an IPv6 address to the network interface.
   - Choose Auto-assign to allow Amazon EC2 to select an IPv6 address from the subnet.
   - Choose Custom and enter an IPv6 address that you select from the subnet.
8. (Optional) To create an Elastic Fabric Adapter, choose Elastic Fabric Adapter, Enable.
9. For Security groups, select one or more security groups.
10. (Optional) For each tag, choose Add new tag and enter a tag key and an optional tag value.
11. Choose Create network interface.

Old console

To create a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose Create Network Interface.
4. For Description, enter a descriptive name.
5. For Subnet, select the subnet.
6. For Private IP (or IPv4 Private IP), enter the primary private IPv4 address. If you don't specify an IPv4 address, we select an available private IPv4 address from within the selected subnet.
7. (IPv6 only) If you selected a subnet that has an associated IPv6 CIDR block, you can optionally specify an IPv6 address in the IPv6 IP field.
8. To create an Elastic Fabric Adapter, select Elastic Fabric Adapter.
9. For Security groups, select one or more security groups.
10. (Optional) Choose Add Tag and enter a tag key and a tag value.
11. Choose Yes, Create.

To create a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- create-network-interface (AWS CLI)
- New-EC2NetworkInterface (AWS Tools for Windows PowerShell)

View details about a network interface

You can view all the network interfaces in your account.

New console

To describe a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. To view the details page for a network interface, select the ID of the network interface. Alternatively, to view information without leaving the network interfaces page, select the checkbox for the network interface.

Old console

To describe a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface.
4. To view the details, choose **Details**.

**To describe a network interface using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `describe-network-interfaces` (AWS CLI)
- `Get-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

**To describe a network interface attribute using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `describe-network-interface-attribute` (AWS CLI)

**Attach a network interface to an instance**

You can attach a network interface to any instance in the same Availability Zone as the network interface, using either the **Instances** or **Network Interfaces** page of the Amazon EC2 console. Alternatively, you can specify existing network interfaces when you launch instances (p. 477).

If the public IPv4 address on your instance is released, it does not receive a new one if there is more than one network interface attached to the instance. For more information about the behavior of public IPv4 addresses, see Public IPv4 addresses and external DNS hostnames (p. 881).

**Instances page**

**To attach a network interface to an instance using the Instances page**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the checkbox for the instance.
4. Choose **Actions**, **Networking**, **Attach network interface**.
5. Select a network interface. If the instance supports multiple network cards, you can choose a network card.
6. Choose **Attach**.

**Network Interfaces page**

**To attach a network interface to an instance using the Network Interfaces page**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface.
4. Choose **Actions**, **Attach**.
5. Choose an instance. If the instance supports multiple network cards, you can choose a network card.
6. Choose Attach.

To attach a network interface to an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- attach-network-interface (AWS CLI)
- Add-EC2NetworkInterface (AWS Tools for Windows PowerShell)

Detach a network interface from an instance

You can detach a secondary network interface that is attached to an EC2 instance at any time, using either the Instances or Network Interfaces page of the Amazon EC2 console.

If you try to detach a network interface that is attached to a resource from another service, such as an Elastic Load Balancing load balancer, a Lambda function, a WorkSpace, or a NAT gateway, you get an error that you do not have permission to access the resource. To find which service created the resource attached to a network interface, check the description of the network interface. If you delete the resource, then its network interface is deleted.

Instances page

To detach a network interface from an instance using the Instances page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the checkbox for the instance. Check the Network interfaces section of the Networking tab to verify that the network interface is attached to an instance as a secondary network interface.
5. Select the network interface and choose Detach.

Network Interfaces page

To detach a network interface from an instance using the Network Interfaces page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface. Check the Instance details section of the Details tab to verify that the network interface is attached to an instance as a secondary network interface.
4. Choose Actions, Detach.
5. When prompted for confirmation, choose Detach.
6. If the network interface fails to detach from the instance, choose Force detachment, Enable and then try again. We recommend that force detachment only as a last resort. Forcing a detachment can prevent you from attaching a different network interface on the same index until you restart the instance. It can also prevent the instance metadata from reflecting that the network interface was detached until you restart the instance.
To detach a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- detach-network-interface (AWS CLI)
- Dismount-EC2NetworkInterface (AWS Tools for Windows PowerShell)

Manage IP addresses

You can manage the following IP addresses for your network interfaces:

- Elastic IP addresses (one per private IPv4 address)
- IPv4 addresses
- IPv6 addresses

To manage the Elastic IP addresses of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. To associate an Elastic IP address, do the following:
   a. Choose Actions, Associate address.
   b. For Elastic IP address, select the Elastic IP address.
   c. For Private IPv4 address, select the private IPv4 address to associate with the Elastic IP address.
   d. (Optional) Choose Allow the Elastic IP address to be reassigned if the network interface is currently associated with another instance or network interface.
   e. Choose Associate.
5. To disassociate an Elastic IP address, do the following:
   a. Choose Actions, Disassociate address.
   b. For Public IP address, select the Elastic IP address.
   c. Choose Disassociate.

To manage the IPv4 and IPv6 addresses of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface.
4. Choose Actions, Manage IP addresses.
5. Expand the network interface.
6. For IPv4 addresses, modify the IP addresses as needed. To assign an IPv4 address, choose Assign new IP address and then specify an IPv4 address from the subnet range or let AWS choose one for you. To unassign an IPv4 address, choose Unassign next to the address.
7. For IPv6 addresses, modify the IP addresses as needed. To assign an IPv6 address, choose Assign new IP address and then specify an IPv6 address from the subnet range or let AWS choose one for you. To unassign an IPv6 address, choose Unassign next to the address.
8. Choose Save.
To manage the IP addresses of a network interface using the AWS CLI

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- assign-ipv6-addresses
- associate-address
- disassociate-address
- unassign-ipv6-addresses

To manage the IP addresses of a network interface using the Tools for Windows PowerShell

You can use one of the following commands.

- Register-EC2Address
- Register-EC2Ipv6AddressList
- Unregister-EC2Address
- Unregister-EC2Ipv6AddressList

Modify network interface attributes

You can change the following network interface attributes:

- Description (p. 944)
- Security groups (p. 944)
- Delete on termination (p. 945)
- Source/destination check (p. 945)

To change the description of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
5. For Description, enter a description for the network interface.
6. Choose Save.

To change the security groups of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. Choose Actions, Change security groups.
5. For Associated security groups, select the security groups to use, and then choose Save.

   The security group and network interface must be created for the same VPC. To change the security group for interfaces owned by other services, such as Elastic Load Balancing, do so through that service.
To change the termination behavior of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. Choose Actions, Change termination behavior.
5. Select or clear Delete on termination, Enable as needed, and then choose Save.

To change source/destination checking for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
5. Select or clear Source/destination check, Enable as needed, and then choose Save.

To modify network interface attributes using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- modify-network-interface-attribute (AWS CLI)
- Edit-EC2NetworkInterfaceAttribute (AWS Tools for Windows PowerShell)

Add or edit tags

Tags are metadata that you can add to a network interface. Tags are private and are only visible to your account. Each tag consists of a key and an optional value. For more information about tags, see Tag your Amazon EC2 resources (p. 1462).

New console

To add or edit tags for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. In Tags tab, choose Manage tags.
5. For each tag to create, choose Add new tag and enter a key and optional value. When you're done, choose Save.

Old console

To add or edit tags for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface.
4. In the details pane, choose Tags, Add/Edit Tags.
5. In the Add/Edit Tags dialog box, choose Create Tag for each tag to create, and enter a key and optional value. When you're done, choose Save.

To add or edit tags for a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- create-tags (AWS CLI)
- New-EC2Tag (AWS Tools for Windows PowerShell)

Delete a network interface

Deleting a network interface releases all attributes associated with the interface and releases any private IP addresses or Elastic IP addresses to be used by another instance.

You cannot delete a network interface that is in use. First, you must detach the network interface (p. 942).

New console

To delete a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface, and then choose Actions, Delete.
4. When prompted for confirmation, choose Delete.

Old console

To delete a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select a network interface and choose Delete.
4. In the Delete Network Interface dialog box, choose Yes, Delete.

To delete a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- delete-network-interface (AWS CLI)
- Remove-EC2NetworkInterface (AWS Tools for Windows PowerShell)

Scenarios for network interfaces

Attaching multiple network interfaces to an instance is useful when you want to:

- Create a management network.
- Use network and security appliances in your VPC.
• Create dual-homed instances with workloads/roles on distinct subnets.
• Create a low-budget, high-availability solution.

Create a management network

You can create a management network using network interfaces. In this scenario, as illustrated in the following image:

• The primary network interface (eth0) on the instance handles public traffic.
• The secondary network interface (eth1) handles backend management traffic, and is connected to a separate subnet in your VPC that has more restrictive access controls.

The public interface, which may or may not be behind a load balancer, has an associated security group that allows access to the server from the internet (for example, allow TCP port 80 and 443 from 0.0.0.0/0, or from the load balancer).

The private facing interface has an associated security group allowing SSH access only from an allowed range of IP addresses, either within the VPC, or from the internet, a private subnet within the VPC, or a virtual private gateway.

To ensure failover capabilities, consider using a secondary private IPv4 for incoming traffic on a network interface. In the event of an instance failure, you can move the interface and/or secondary private IPv4 address to a standby instance.
Best practices for configuring network interfaces

- You can attach a network interface to an instance when it's running (hot attach), when it's stopped (warm attach), or when the instance is being launched (cold attach).
- You can detach secondary network interfaces when the instance is running or stopped. However, you can't detach the primary network interface.
- You can move a network interface from one instance to another, if the instances are in the same Availability Zone and VPC but in different subnets.
- When launching an instance using the CLI, API, or an SDK, you can specify the primary network interface and additional network interfaces.
- Launching an Amazon Linux or Windows Server instance with multiple network interfaces automatically configures interfaces, private IPv4 addresses, and route tables on the operating system of the instance.
- A warm or hot attach of an additional network interface might require you to manually bring up the second interface, configure the private IPv4 address, and modify the route table accordingly. Instances running Amazon Linux or Windows Server automatically recognize the warm or hot attach and configure themselves.
- You cannot attach another network interface to an instance (for example, a NIC teaming configuration) to increase or double the network bandwidth to or from the dual-homed instance.
- If you attach two or more network interfaces from the same subnet to an instance, you might encounter networking issues such as asymmetric routing. If possible, use a secondary private IPv4 address on the primary network interface instead.
Configure your network interface using ec2-net-utils

Amazon Linux AMIs may contain additional scripts installed by AWS, known as ec2-net-utils. These scripts optionally automate the configuration of your network interfaces. These scripts are available for Amazon Linux only.

Use the following command to install the package on Amazon Linux if it's not already installed, or update it if it's installed and additional updates are available:

```
$ yum install ec2-net-utils
```

The following components are part of ec2-net-utils:

udev rules (/etc/udev/rules.d)

Identifies network interfaces when they are attached, detached, or reattached to a running instance, and ensures that the hotplug script runs (53-ec2-network-interfaces.rules). Maps the MAC address to a device name (75-persistent-net-generator.rules, which generates 70-persistent-net.rules).

hotplug script

DHCP script

Whenever the network interface receives a new DHCP lease, this script queries the instance metadata for Elastic IP addresses. For each Elastic IP address, it adds a rule to the routing policy database to ensure that outbound traffic from that address uses the correct network interface. It also adds each private IP address to the network interface as a secondary address.

`ec2ifup` ethN

Extends the functionality of the standard `ifup`. After this script rewrites the configuration files `ifcfg-ethN` and `route-ethN`, it runs `ifup`.

`ec2ifdown` ethN

Extends the functionality of the standard `ifdown`. After this script removes any rules for the network interface from the routing policy database, it runs `ifdown`.

`ec2ifscan`

Checks for network interfaces that have not been configured and configures them.

This script isn't available in the initial release of ec2-net-utils.

To list any configuration files that were generated by ec2-net-utils, use the following command:

```
$ ls -l /etc/sysconfig/network-scripts/*-eth?
```

To disable the automation on a per-instance basis, you can add `EC2SYNC=no` to the corresponding `ifcfg-ethN` file. For example, use the following command to disable the automation for the eth1 interface:

```
$ sed -i -e 's/^EC2SYNC=yes/EC2SYNC=no/ ' /etc/sysconfig/network-scripts/ifcfg-eth1
```

To disable the automation completely, you can remove the package using the following command:
Requester-managed network interfaces

A requester-managed network interface is a network interface that an AWS service creates in your VPC. This network interface can represent an instance for another service, such as an Amazon RDS instance, or it can enable you to access another service or resource, such as an AWS PrivateLink service, or an Amazon ECS task.

You cannot modify or detach a requester-managed network interface. If you delete the resource that the network interface represents, the AWS service detaches and deletes the network interface for you. To change the security groups for a requester-managed network interface, you might have to use the console or command line tools for that service. For more information, see the service-specific documentation.

You can tag a requester-managed network interface. For more information, see Add or edit tags (p. 945).

You can view the requester-managed network interfaces that are in your account.

To view requester-managed network interfaces using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface and view the following information on the details pane:
   - **Attachment owner**: If you created the network interface, this field displays your AWS account ID. Otherwise, it displays an alias or ID for the principal or service that created the network interface.
   - **Description**: Provides information about the purpose of the network interface; for example, "VPC Endpoint Interface".

To view requester-managed network interfaces using the command line

1. Use the describe-network-interfaces AWS CLI command to describe the network interfaces in your account.
   ```bash
   aws ec2 describe-network-interfaces
   ```
2. In the output, the RequesterManaged field displays true if the network interface is managed by another AWS service.

```json
{
   "Status": "in-use",
   ...
   "Description": "VPC Endpoint Interface vpce-089f2123488812123",
   "NetworkInterfaceId": "eni-c8fbc27e",
   "VpcId": "vpc-1a2b3c4d",
   "PrivateIpAddresses": [
     {
       "PrivateDnsName": "ip-10-0-2-227.ec2.internal",
       "Primary": true,
       "PrivateIpAddress": "10.0.2.227"
     }
   ],
   "RequesterManaged": true,
   ...
}
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Network bandwidth

Amazon EC2 instance network bandwidth

The network bandwidth available to an EC2 instance depends on several factors.

Bandwidth for aggregate multi-flow traffic available to an instance depends on the destination of the traffic.

Within the Region

Traffic can utilize the full network bandwidth available to the instance.

To other Regions, an internet gateway, or Direct Connect

Traffic can utilize up to 50% of the network bandwidth available to a current generation instance (p. 194) with a minimum of 32 vCPUs. Bandwidth for a current generation instance with less than 32 vCPUs is limited to 5 Gbps.

Bandwidth for single-flow (5-tuple) traffic is limited to 5 Gbps, regardless of the destination of the traffic. For use cases that require low latency and high single-flow bandwidth, use a cluster placement group (p. 1019) to achieve up to 10 Gbps for instances in the same placement group. Alternatively, set up multiple paths between two endpoints to achieve higher bandwidth using Multipath TCP (MPTCP).

Available instance bandwidth

The available network bandwidth of an instance depends on the number of vCPUs that it has. For example, an m5.8xlarge instance has 32 vCPUs and 10 Gbps network bandwidth, and an m5.16xlarge instance has 64 vCPUs and 20 Gbps network bandwidth. However, instances might not achieve this bandwidth; for example, if they exceed network allowances at the instance level, such as packet per second or number of tracked connections. How much of the available bandwidth the traffic can utilize depends on the number of vCPUs and the destination. For example, an m5.6xlarge instance has 64 vCPUs, so traffic to another instance in the Region can utilize the full bandwidth available (20 Gbps). However, traffic to another instance in a different Region can utilize only 50% of the bandwidth available (10 Gbps).

Typically, instances with 16 vCPUs or fewer (size 4xlarge and smaller) are documented as having “up to” a specified bandwidth; for example, “up to 10 Gbps”. These instances have a baseline bandwidth. To meet additional demand, they can use a network I/O credit mechanism to burst beyond their baseline bandwidth. Instances can use burst bandwidth for a limited time, typically from 5 to 60 minutes, depending on the instance size.

An instance receives the maximum number of network I/O credits at launch. If the instance exhausts its network I/O credits, it returns to its baseline bandwidth. A running instance earns network I/O credits whenever it uses less network bandwidth than its baseline bandwidth. A stopped instance does not earn network I/O credits. Instance burst is on a best effort basis, even when the instance has credits available, as burst bandwidth is a shared resource.

The following documentation describes the network performance for all instances, plus the baseline network bandwidth available for instances that can use burst bandwidth.

- General purpose instances (p. 209)
- Compute optimized instances (p. 258)
- Memory optimized instances (p. 267)
- Storage optimized instances (p. 281)
- Accelerated computing instances (p. 294)
To view network performance using the AWS CLI

You can use the `describe-instance-types` AWS CLI command to display information about an instance type. The following example displays network performance information for all C5 instances.

```
aws ec2 describe-instance-types --filters "Name=instance-type,Values=c5.*" --query "InstanceTypes[].[InstanceType, NetworkInfo.NetworkPerformance]" --output table
```

<table>
<thead>
<tr>
<th>DescribeInstanceTypes</th>
<th></th>

</table>

Monitor instance bandwidth

You can use CloudWatch metrics to monitor instance network bandwidth and the packets sent and received. You can use the network performance metrics provided by the Elastic Network Adapter (ENA) driver to monitor when traffic exceeds the network allowances that Amazon EC2 defines at the instance level.

You can configure whether Amazon EC2 sends metric data for the instance to CloudWatch using one-minute periods or five-minute periods. It is possible that the network performance metrics would show that an allowance was exceeded and packets were dropped while the CloudWatch instance metrics do not. This can happen when the instance has a short spike in demand for network resources (known as a microburst), but the CloudWatch metrics are not granular enough to reflect these microsecond spikes.

- Instance metrics (p. 821)
- Network performance metrics (p. 969)

Enhanced networking on Linux

Enhanced networking uses single root I/O virtualization (SR-IOV) to provide high-performance networking capabilities on supported instance types (p. 953). SR-IOV is a method of device virtualization that provides higher I/O performance and lower CPU utilization when compared to traditional virtualized network interfaces. Enhanced networking provides higher bandwidth, higher packet per second (PPS) performance, and consistently lower inter-instance latencies. There is no additional charge for using enhanced networking.

For information about the supported network speed for each instance type, see Amazon EC2 Instance Types.

Contents

- Enhanced networking support (p. 953)
- Enable enhanced networking on your instance (p. 953)
- Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances (p. 953)
- Enable enhanced networking with the Intel 82599 VF interface on Linux instances (p. 963)
Enhanced networking support

All current generation (p. 194) instance types support enhanced networking, except for T2 instances.

You can enable enhanced networking using one of the following mechanisms:

- **Elastic Network Adapter (ENA)**
  
  The Elastic Network Adapter (ENA) supports network speeds of up to 100 Gbps for supported instance types.
  
  The current generation instances use ENA for enhanced networking, except for C4, D2, and M4 instances smaller than m4.16xlarge.

- **Intel 82599 Virtual Function (VF) interface**
  
  The Intel 82599 Virtual Function interface supports network speeds of up to 10 Gbps for supported instance types.
  
  The following instance types use the Intel 82599 VF interface for enhanced networking: C3, C4, D2, I2, M4 (excluding m4.16xlarge), and R3.

For a summary of the enhanced networking mechanisms by instance type, see Summary of networking and storage features (p. 200).

Enable enhanced networking on your instance

If your instance type supports the Elastic Network Adapter for enhanced networking, follow the procedures in Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances (p. 953).

If your instance type supports the Intel 82599 VF interface for enhanced networking, follow the procedures in Enable enhanced networking with the Intel 82599 VF interface on Linux instances (p. 963).

Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances

Amazon EC2 provides enhanced networking capabilities through the Elastic Network Adapter (ENA). To use enhanced networking, you must install the required ENA module and enable ENA support.

Contents

- Requirements (p. 954)
- Enhanced networking performance (p. 954)
- Test whether enhanced networking is enabled (p. 954)
- Enable enhanced networking on the Amazon Linux AMI (p. 956)
- Enable enhanced networking on Ubuntu (p. 957)
- Enable enhanced networking on Linux (p. 959)
- Enable enhanced networking on Ubuntu with DKMS (p. 961)
- Driver release notes (p. 962)
Requirements

To prepare for enhanced networking using the ENA, set up your instance as follows:

- Launch the instance using a current generation (p. 194) instance type, other than C4, D2, M4 instances smaller than m4.16xlarge, or T2.
- Launch the instance using a supported version of the Linux kernel and a supported distribution, so that ENA enhanced networking is enabled for your instance automatically. For more information, see ENA Linux Kernel Driver Release Notes.
- Ensure that the instance has internet connectivity.
- Use AWS CloudShell from the AWS Management Console, or install and configure the AWS CLI or the AWS Tools for Windows PowerShell on any computer you choose, preferably your local desktop or laptop. For more information, see Access Amazon EC2 (p. 3) or the AWS CloudShell User Guide. Enhanced networking cannot be managed from the Amazon EC2 console.
- If you have important data on the instance that you want to preserve, you should back that data up now by creating an AMI from your instance. Updating kernels and kernel modules, as well as enabling the enaSupport attribute, might render incompatible instances or operating systems unreachable. If you have a recent backup, your data will still be retained if this happens.

Enhanced networking performance

The following documentation provides a summary of the network performance for the instance types that support ENA enhanced networking:

- Network Performance for Accelerated Computing Instances (p. 294)
- Network Performance for Compute Optimized Instances (p. 262)
- Network Performance for General Purpose Instances (p. 209)
- Network Performance for Memory Optimized Instances (p. 274)
- Network Performance for Storage Optimized Instances (p. 284)

Test whether enhanced networking is enabled

The following AMIs include the required ENA module and have ENA support enabled:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with linux-aws kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

To test whether enhanced networking is already enabled, verify that the ena module is installed on your instance and that the enaSupport attribute is set. If your instance satisfies these two conditions, then the ethtool -i ethn command should show that the module is in use on the network interface.

Kernel module (ena)
To verify that the ena module is installed, use the `modinfo` command as shown in the following example.

```
[ec2-user ~]$ modinfo ena
version:        1.5.0g
license:        GPL
description:    Elastic Network Adapter (ENA)
author:         Amazon.com, Inc. or its affiliates
srcversion:     692C7C68B8A9001CB3F31D0
alias:          pci:v00001D0Fd0000EC21sv*sd*bc*sc*i*
alias:          pci:v00001D0Fd0000EC20sv*sd*bc*sc*i*
alias:          pci:v00001D0Fd00001EC2sv*sd*bc*sc*i*
alias:          pci:v00001D0Fd00000EC2sv*sd*bc*sc*i*
depends:        
retpoline:      Y
intree:         Y
name:           ena
...
```

In the above Amazon Linux case, the ena module is installed.

```
ubuntu:~$ modinfo ena
ERROR: modinfo: could not find module ena
```

In the above Ubuntu instance, the module is not installed, so you must first install it. For more information, see Enable enhanced networking on Ubuntu (p. 957).

**Instance attribute (enaSupport)**

To check whether an instance has the enhanced networking enaSupport attribute set, use one of the following commands. If the attribute is set, the response is true.

- **describe-instances** (AWS CLI/AWS CloudShell)

  ```
  aws ec2 describe-instances --instance-ids instance_id --query "Reservations[].Instances[].EnaSupport"
  ```

- **Get-EC2Instance** (Tools for Windows PowerShell)

  ```
  (Get-EC2Instance -InstanceId instance-id).Instances.EnaSupport
  ```

**Image attribute (enaSupport)**

To check whether an AMI has the enhanced networking enaSupport attribute set, use one of the following commands. If the attribute is set, the response is true.

- **describe-images** (AWS CLI/AWS CloudShell)

  ```
  aws ec2 describe-images --image-id ami_id --query "Images[].EnaSupport"
  ```

- **Get-EC2Image** (Tools for Windows PowerShell)

  ```
  (Get-EC2Image -ImageId ami_id).EnaSupport
  ```

**Network interface driver**
Use the following command to verify that the `ena` module is being used on a particular interface, substituting the interface name that you want to check. If you are using a single interface (default), it is `eth0`. If the operating system supports predictable network names (p. 959), this could be a name like `en5`.

In the following example, the `ena` module is not loaded, because the listed driver is `vif`.

```
[ec2-user ~]$ ethtool -i eth0
driver: vif
version:
firmware-version:
bus-info: vif-0
supports-statistics: yes
supports-test: no
supports-eprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

In this example, the `ena` module is loaded and at the minimum recommended version. This instance has enhanced networking properly configured.

```
[ec2-user ~]$ ethtool -i eth0
driver: ena
version: 1.5.0g
firmware-version:
expansion-rom-version:
bus-info: 0000:00:05.0
supports-statistics: yes
supports-test: no
supports-eprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

**Enable enhanced networking on the Amazon Linux AMI**

Amazon Linux 2 and the latest versions of the Amazon Linux AMI include the module required for enhanced networking with ENA installed and have ENA support enabled. Therefore, if you launch an instance with an HVM version of Amazon Linux on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled (p. 954).

If you launched your instance using an older Amazon Linux AMI and it does not have enhanced networking enabled already, use the following procedure to enable enhanced networking.

**To enable enhanced networking on Amazon Linux AMI**

1. Connect to your instance.
2. From the instance, run the following command to update your instance with the newest kernel and kernel modules, including `ena`:

   ```
   [ec2-user ~]$ sudo yum update
   ```

3. From your local computer, reboot your instance using the Amazon EC2 console or one of the following commands: `reboot-instances` (AWS CLI), `Restart-EC2Instance` (AWS Tools for Windows PowerShell).
4. Connect to your instance again and verify that the `ena` module is installed and at the minimum recommended version using the `modinfo ena` command from Test whether enhanced networking is enabled (p. 954).
5. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

[Instance store-backed instance] You can’t stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Amazon Linux AMI (instance store-backed instances) (p. 957).

6. From your local computer, enable the enhanced networking attribute using one of the following commands:

   • `modify-instance-attribute` (AWS CLI)

     ```bash
daemon aws ec2 modify-instance-attribute --instance-id instance_id --ena-support
```

   • `Edit-EC2InstanceAttribute` (Tools for Windows PowerShell)

     ```powershell
daemon Edit-EC2InstanceAttribute -InstanceId instance_id -EnaSupport $true
```

7. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 102). The AMI inherits the enhanced networking `enaSupport` attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

8. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI), `Start-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

9. Connect to your instance and verify that the `ena` module is installed and loaded on your network interface using the `ethtool -i ethn` command from Test whether enhanced networking is enabled (p. 954).

   If you are unable to connect to your instance after enabling enhanced networking, see Troubleshoot the Elastic Network Adapter (ENA) (p. 972).

To enable enhanced networking on Amazon Linux AMI (instance store-backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed Linux AMI (p. 107), making sure to enable the enhanced networking attribute when you register the AMI.

   • `register-image` (AWS CLI)

     ```bash
daemon aws ec2 register-image --ena-support ...
```

   • `Register-EC2Image` (AWS Tools for Windows PowerShell)

     ```powershell
daemon Register-EC2Image -EnaSupport $true ...
```

Enable enhanced networking on Ubuntu

The latest Ubuntu HVM AMIs include the module required for enhanced networking with ENA installed and have ENA support enabled. Therefore, if you launch an instance with the latest Ubuntu HVM AMI on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled (p. 954).
If you launched your instance using an older AMI and it does not have enhanced networking enabled already, you can install the `linux-aws` kernel package to get the latest enhanced networking drivers and update the required attribute.

**To install the `linux-aws` kernel package (Ubuntu 16.04 or later)**

Ubuntu 16.04 and 18.04 ship with the Ubuntu custom kernel (`linux-aws` kernel package). To use a different kernel, contact AWS Support.

**To install the `linux-aws` kernel package (Ubuntu Trusty 14.04)**

1. Connect to your instance.
2. Update the package cache and packages.

```
ubuntu:~$ sudo apt-get update && sudo apt-get upgrade -y linux-aws
```

**Important**

If during the update process you are prompted to install `grub`, use `/dev/xvda` to install `grub` onto, and then choose to keep the current version of `/boot/grub/menu.lst`.

3. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: **To enable enhanced networking on Ubuntu (instance store-backed instances)** (p. 958).

4. From your local computer, enable the enhanced networking attribute using one of the following commands:
   - `modify-instance-attribute` (AWS CLI)
     ```
     aws ec2 modify-instance-attribute --instance-id instance_id --ena-support
     ```
   - `Edit-EC2InstanceAttribute` (Tools for Windows PowerShell)
     ```
     Edit-EC2InstanceAttribute -InstanceId instance_id -EnaSupport $true
     ```

5. (Optional) Create an AMI from the instance, as described in **Create an Amazon EBS-backed Linux AMI** (p. 102). The AMI inherits the enhanced networking `enaSupport` attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

6. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI), `Start-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

**To enable enhanced networking on Ubuntu (instance store-backed instances)**

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in **Create an instance store-backed Linux AMI** (p. 107), making sure to enable the enhanced networking attribute when you register the AMI.

- `register-image` (AWS CLI)

```
aws ec2 register-image --ena-support ...
```
Enable enhanced networking on Linux

The latest AMIs for Red Hat Enterprise Linux, SUSE Linux Enterprise Server, and CentOS include the module required for enhanced networking with ENA and have ENA support enabled. Therefore, if you launch an instance with the latest AMI on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled (p. 954).

The following procedure provides the general steps for enabling enhanced networking on a Linux distribution other than Amazon Linux AMI or Ubuntu. For more information, such as detailed syntax for commands, file locations, or package and tool support, see the documentation for your Linux distribution.

To enable enhanced networking on Linux

1. Connect to your instance.
2. Clone the source code for the ena module on your instance from GitHub at https://github.com/amzn/amzn-drivers. (SUSE Linux Enterprise Server 12 SP2 and later include ENA 2.02 by default, so you are not required to download and compile the ENA driver. For SUSE Linux Enterprise Server 12 SP2 and later, you should file a request to add the driver version you want to the stock kernel).

```bash
git clone https://github.com/amzn/amzn-drivers
```

3. Compile and install the ena module on your instance. These steps depend on the Linux distribution. For more information about compiling the module on Red Hat Enterprise Linux, see the AWS Knowledge Center article.
4. Run the `sudo depmod` command to update module dependencies.
5. Update `initramfs` on your instance to ensure that the new module loads at boot time. For example, if your distribution supports `dracut`, you can use the following command.

```bash
dracut -f -v
```

6. Determine if your system uses predictable network interface names by default. Systems that use `systemd` or `udev` versions 197 or greater can rename Ethernet devices and they do not guarantee that a single network interface will be named `eth0`. This behavior can cause problems connecting to your instance. For more information and to see other configuration options, see Predictable Network Interface Names on the freedesktop.org website.

a. You can check the `systemd` or `udev` versions on RPM-based systems with the following command.

```bash
rpm -qa | grep -e '^systemd-[0-9]\+\|^udev-[0-9]\+'
```

In the above Red Hat Enterprise Linux 7 example, the `systemd` version is 208, so predictable network interface names must be disabled.

b. Disable predictable network interface names by adding the `net.ifnames=0` option to the `GRUB_CMDLINE_LINUX` line in `/etc/default/grub`.

```bash
sudo sed -i '/^GRUB\_CMDLINE\_LINUX/s/"$/\ net\.ifnames\=0"/' /etc/default/grub
```
c. Rebuild the grub configuration file.

```
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

7. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

[Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Linux (instance store–backed instances) (p. 960).

8. From your local computer, enable the enhanced networking `enaSupport` attribute using one of the following commands:

- `modify-instance-attribute` (AWS CLI)

```
aws ec2 modify-instance-attribute –instance-id instance_id –ena-support
```

- `Edit-EC2InstanceAttribute` (Tools for Windows PowerShell)

```
Edit-EC2InstanceAttribute –InstanceId instance-id –EnaSupport $true
```

9. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 102). The AMI inherits the enhanced networking `enaSupport` attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

**Important**

If your instance operating system contains an `/etc/udev/rules.d/70-persistent-net.rules` file, you must delete it before creating the AMI. This file contains the MAC address for the Ethernet adapter of the original instance. If another instance boots with this file, the operating system will be unable to find the device and `eth0` might fail, causing boot issues. This file is regenerated at the next boot cycle, and any instances launched from the AMI create their own version of the file.

10. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI), `Start-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

11. (Optional) Connect to your instance and verify that the module is installed.

If you are unable to connect to your instance after enabling enhanced networking, see Troubleshoot the Elastic Network Adapter (ENA) (p. 972).

**To enable enhanced networking on Linux (instance store–backed instances)**

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed Linux AMI (p. 107), making sure to enable the enhanced networking attribute when you register the AMI.

- `register-image` (AWS CLI)

```
aws ec2 register-image --ena-support ...
```

- `Register-EC2Image` (AWS Tools for Windows PowerShell)
Enable enhanced networking on Ubuntu with DKMS

This method is for testing and feedback purposes only. It is not intended for use with production deployments. For production deployments, see Enable enhanced networking on Ubuntu (p. 957).

Important
Using DKMS voids the support agreement for your subscription. It should not be used for production deployments.

To enable enhanced networking with ENA on Ubuntu (EBS-backed instances)

1. Follow steps 1 and 2 in Enable enhanced networking on Ubuntu (p. 957).
2. Install the `build-essential` packages to compile the kernel module and the `dkms` package so that your `ena` module is rebuilt every time your kernel is updated.

   ```bash
   ubuntu:~$ sudo apt-get install -y build-essential dkms
   ```

3. Clone the source for the `ena` module on your instance from GitHub at https://github.com/amzn/amzn-drivers.

   ```bash
   ubuntu:~$ git clone https://github.com/amzn/amzn-drivers
   ```

4. Move the `amzn-drivers` package to the `/usr/src/` directory so DKMS can find it and build it for each kernel update. Append the version number (you can find the current version number in the release notes) of the source code to the directory name. For example, version `1.0.0` is shown in the following example.

   ```bash
   ubuntu:~$ sudo mv amzn-drivers /usr/src/amzn-drivers-1.0.0
   ```

5. Create the DKMS configuration file with the following values, substituting your version of `ena`.

   Create the file.

   ```bash
   ubuntu:~$ sudo touch /usr/src/amzn-drivers-1.0.0/dkms.conf
   ```

   Edit the file and add the following values.

   ```bash
   ubuntu:~$ sudo vim /usr/src/amzn-drivers-1.0.0/dkms.conf
   PACKAGE_NAME="ena"
   PACKAGE_VERSION="1.0.0"
   CLEAN="make -C kernel/linux/ena clean"
   MAKE="make -C kernel/linux/ena/ BUILD_KERNEL=${kernelver}"
   BUILT_MODULE_NAME[0]="ena"
   BUILT_MODULE_LOCATION="kernel/linux/ena"
   DEST_MODULE_LOCATION[0]="/updates"
   DEST_MODULE_NAME[0]="ena"
   AUTOINSTALL="yes"
   ```

6. Add, build, and install the `ena` module on your instance using DKMS.

   Add the module to DKMS.

   ```bash
   ubuntu:~$ sudo dkms add -m amzn-drivers -v 1.0.0
   ```
Build the module using the `dkms` command.

```bash
ubuntu:~$ sudo dkms build -m amzn-drivers -v 1.0.0
```

Install the module using `dkms`.

```bash
ubuntu:~$ sudo dkms install -m amzn-drivers -v 1.0.0
```

7. Rebuild `initramfs` so the correct module is loaded at boot time.

```bash
ubuntu:~$ sudo update-initramfs -u -k all
```

8. Verify that the `ena` module is installed using the `modinfo ena` command from Test whether enhanced networking is enabled (p. 954).

```bash
ubuntu:~$ modinfo ena
filename:       /lib/modules/3.13.0-74-generic/updates/dkms/ena.ko
version:        1.0.0
license:        GPL
description:    Elastic Network Adapter (ENA)
author:         Amazon.com, Inc. or its affiliates
srcversion:     9693879dc47c82418f0cb0
alias:          pci:v00001D0Fd0000EC21sv*sd*bc*sc*i*
alias:          pci:v00001D0Fd0000EC20sv*sd*bc*sc*i*
alias:          pci:v00001D0Fd00001EC2sv*sd*bc*sc*i*
alias:          pci:v00001D0Fd00000EC2sv*sd*bc*sc*i*
deps:
vermagic:       3.13.0-74-generic SMP mod_unload modversions
parm:           debug:Debug level (0=none,...,16=all) (int)
parm:           push_mode:Descriptor / header push mode
                (0=automatic,1=disable,3=enable)
                0 - Automatically choose according to device capability (default)
                1 - Don't push anything to device memory
                3 - Push descriptors and header buffer to device memory (default)
parm:           enable_wd:Enable keepalive watchdog (0=disable,1=enable,default=1)
                (int)
parm:           enable_missing_tx_detection:Enable missing Tx completions. (default=1)
                (int)
parm:           numa_node_override_array:Numa node override map
                (array of int)
parm:           numa_node_override:Enable/Disable numa node override (0=disable)
                (int)
```

9. Continue with Step 3 in Enable enhanced networking on Ubuntu (p. 957).

**Driver release notes**

For information about the versions of the Linux ENA driver, see the ENA Linux kernel driver release notes.

**Troubleshoot**

For troubleshooting information, see Troubleshoot the Elastic Network Adapter (ENA) (p. 972).
Enable enhanced networking with the Intel 82599 VF interface on Linux instances

Amazon EC2 provides enhanced networking capabilities through the Intel 82599 VF interface, which uses the Intel ixgbevf driver.

Contents
- Requirements (p. 963)
- Test whether enhanced networking is enabled (p. 963)
- Enable enhanced networking on Amazon Linux (p. 965)
- Enable enhanced networking on Ubuntu (p. 966)
- Enable enhanced networking on other Linux distributions (p. 966)
- Troubleshoot connectivity issues (p. 968)

Requirements

To prepare for enhanced networking using the Intel 82599 VF interface, set up your instance as follows:

- Select from the following supported instance types: C3, C4, D2, I2, M4 (excluding m4.16xlarge), and R3.
- Launch the instance from an HVM AMI using Linux kernel version of 2.6.32 or later. The latest Amazon Linux HVM AMIs have the modules required for enhanced networking installed and have the required attributes set. Therefore, if you launch an Amazon EBS–backed, enhanced networking–supported instance using a current Amazon Linux HVM AMI, enhanced networking is already enabled for your instance.

  **Warning**
  Enhanced networking is supported only for HVM instances. Enabling enhanced networking with a PV instance can make it unreachable. Setting this attribute without the proper module or module version can also make your instance unreachable.

- Ensure that the instance has internet connectivity.
- Use AWS CloudShell from the AWS Management Console, or install and configure the AWS CLI or the AWS Tools for Windows PowerShell on any computer you choose, preferably your local desktop or laptop. For more information, see Access Amazon EC2 (p. 3) or the AWS CloudShell User Guide. Enhanced networking cannot be managed from the Amazon EC2 console.
- If you have important data on the instance that you want to preserve, you should back that data up now by creating an AMI from your instance. Updating kernels and kernel modules, as well as enabling the sriovNetSupport attribute, might render incompatible instances or operating systems unreachable. If you have a recent backup, your data will still be retained if this happens.

Test whether enhanced networking is enabled

Enhanced networking with the Intel 82599 VF interface is enabled if the ixgbevf module is installed on your instance and the sriovNetSupport attribute is set.

**Instance attribute (sriovNetSupport)**

To check whether an instance has the enhanced networking sriovNetSupport attribute set, use one of the following commands:

- `describe-instance-attribute` (AWS CLI/AWS CloudShell)
aws ec2 describe-instance-attribute --instance-id instance_id --attribute sriovNetSupport

**Get-EC2InstanceAttribute** (AWS Tools for Windows PowerShell)

Get-EC2InstanceAttribute -InstanceId instance_id -Attribute sriovNetSupport

If the attribute isn’t set, `SriovNetSupport` is empty. If the attribute is set, the value is simple, as shown in the following example output.

```
"SriovNetSupport": {
  "Value": "simple"
},
```

**Image attribute (sriovNetSupport)**

To check whether an AMI already has the enhanced networking `sriovNetSupport` attribute set, use one of the following commands:

- **describe-images** (AWS CLI/AWS CloudShell)

  ```
  aws ec2 describe-images --image-id ami_id --query "Images[].SriovNetSupport"
  ```

- **Get-EC2Image** (AWS Tools for Windows PowerShell)

  ```
  (Get-EC2Image -ImageId ami-id).SriovNetSupport
  ```

If the attribute isn’t set, `SriovNetSupport` is empty. If the attribute is set, the value is simple.

**Network interface driver**

Use the following command to verify that the module is being used on a particular interface, substituting the interface name that you want to check. If you are using a single interface (default), this is `eth0`. If the operating system supports predictable network names (p. 967), this could be a name like `ens5`.

In the following example, the `ixgbevf` module is not loaded, because the listed driver is `vif`.

```
[ec2-user ~]$ ethtool -i eth0
driver: vif
version:
firmware-version:
bus-info: vif-0
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

In this example, the `ixgbevf` module is loaded. This instance has enhanced networking properly configured.

```
[ec2-user ~]$ ethtool -i eth0
driver: ixgbevf
version: 4.0.3
firmware-version: N/A
```
Enable enhanced networking on Amazon Linux

The latest Amazon Linux HVM AMIs have the `ixgbevf` module required for enhanced networking installed and have the required `sriovNetSupport` attribute set. Therefore, if you launch an instance type using a current Amazon Linux HVM AMI, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled (p. 963).

If you launched your instance using an older Amazon Linux AMI and it does not have enhanced networking enabled already, use the following procedure to enable enhanced networking.

**Warning**
There is no way to disable the enhanced networking attribute after you've enabled it.

**To enable enhanced networking**

1. Connect to your instance.
2. From the instance, run the following command to update your instance with the newest kernel and kernel modules, including `ixgbevf`:

   ```bash
   $ sudo yum update
   ```

3. From your local computer, reboot your instance using the Amazon EC2 console or one of the following commands: `reboot-instances` (AWS CLI), `Restart-EC2Instance` (AWS Tools for Windows PowerShell).

4. Connect to your instance again and verify that the `ixgbevf` module is installed and at the minimum recommended version using the `modinfo ixgbevf` command from Test whether enhanced networking is enabled (p. 963).

5. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking (instance store-backed instances) (p. 966).

6. From your local computer, enable the enhanced networking attribute using one of the following commands:

   - `modify-instance-attribute` (AWS CLI/AWS CloudShell)

     ```bash
     aws ec2 modify-instance-attribute --instance-id instance_id --sriov-net-support simple
     ```

   - `Edit-EC2InstanceAttribute` (AWS Tools for Windows PowerShell)

     ```powershell
     Edit-EC2InstanceAttribute -InstanceId instance_id -SriovNetSupport "simple"
     ```

7. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 102). The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.
8. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI), `Start-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

9. Connect to your instance and verify that the `ixgbevf` module is installed and loaded on your network interface using the `ethtool -i ethn` command from Test whether enhanced networking is enabled (p. 963).

**To enable enhanced networking (instance store-backed instances)**

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed Linux AMI (p. 107), making sure to enable the enhanced networking attribute when you register the AMI.

- **register-image** (AWS CLI/AWS CloudShell)

  ```
  aws ec2 register-image --sriov-net-support simple ...
  ```

- **Register-EC2Image** (AWS Tools for Windows PowerShell)

  ```
  Register-EC2Image -SriovNetSupport "simple" ...
  ```

**Enable enhanced networking on Ubuntu**

Before you begin, check if enhanced networking is already enabled (p. 963) on your instance.

The Quick Start Ubuntu HVM AMIs include the necessary drivers for enhanced networking. If you have a version of `ixgbevf` earlier than 2.16.4, you can install the `linux-aws` kernel package to get the latest enhanced networking drivers.

The following procedure provides the general steps for compiling the `ixgbevf` module on an Ubuntu instance.

**To install the `linux-aws` kernel package**

1. Connect to your instance.
2. Update the package cache and packages.

   ```
   ubuntu:~$ sudo apt-get update && sudo apt-get upgrade -y linux-aws
   ```

   **Important**
   If during the update process, you are prompted to install `grub`, use `/dev/xvda` to install `grub`, and then choose to keep the current version of `/boot/grub/menu.lst`.

**Enable enhanced networking on other Linux distributions**

Before you begin, check if enhanced networking is already enabled (p. 963) on your instance. The latest Quick Start HVM AMIs include the necessary drivers for enhanced networking, therefore you do not need to perform additional steps.

The following procedure provides the general steps if you need to enable enhanced networking with the Intel 82599 VF interface on a Linux distribution other than Amazon Linux or Ubuntu. For more
information, such as detailed syntax for commands, file locations, or package and tool support, see the specific documentation for your Linux distribution.

**To enable enhanced networking on Linux**

1. Connect to your instance.
2. Download the source for the `ixgbevf` module on your instance from Sourceforge at https://sourceforge.net/projects/e1000/files/ixgbevf%20stable/.

   Versions of `ixgbevf` earlier than 2.16.4, including version 2.14.2, do not build properly on some Linux distributions, including certain versions of Ubuntu.

3. Compile and install the `ixgbevf` module on your instance.

   **Warning**
   If you compile the `ixgbevf` module for your current kernel and then upgrade your kernel without rebuilding the driver for the new kernel, your system might revert to the distribution-specific `ixgbevf` module at the next reboot. This could make your system unreachable if the distribution-specific version is incompatible with enhanced networking.

4. Run the `sudo depmod` command to update module dependencies.
5. Update `initramfs` on your instance to ensure that the new module loads at boot time.
6. Determine if your system uses predictable network interface names by default. Systems that use `systemd` or `udev` versions 197 or greater can rename Ethernet devices and they do not guarantee that a single network interface will be named `eth0`. This behavior can cause problems connecting to your instance. For more information and to see other configuration options, see Predictable Network Interface Names on the freedesktop.org website.

   a. You can check the `systemd` or `udev` versions on RPM-based systems with the following command:

   ```bash
   [ec2-user ~]# rpm -qa | grep -e '^systemd-[0-9]\+\|^udev-[0-9]\+'
   systemd-208-11.el7_0.2.x86_64
   ```

   In the above Red Hat Enterprise Linux 7 example, the `systemd` version is 208, so predictable network interface names must be disabled.

   b. Disable predictable network interface names by adding the `net.ifnames=0` option to the `GRUB_CMDLINE_LINUX` line in `/etc/default/grub`.

   ```bash
   [ec2-user ~]# sudo sed -i '/^GRUB_COMMAND_LINE_LINUX/s/"$/\ net\.ifnames\=0"/' /etc/default/grub
   ```

   c. Rebuild the grub configuration file.

   ```bash
   [ec2-user ~]# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

7. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI/AWS CloudShell), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking (instance store–backed instances) (p. 968).

8. From your local computer, enable the enhanced networking attribute using one of the following commands:

   - `modify-instance-attribute` (AWS CLI/AWS CloudShell)
Operating system optimizations

To achieve the maximum network performance on instances with enhanced networking, you might need to modify the default operating system configuration. For more information, see ENA Linux Driver Best Practices and Performance Optimization Guide on github.
Monitor network performance for your EC2 instance

The Elastic Network Adapter (ENA) driver publishes network performance metrics from the instances where they are enabled. You can use these metrics to troubleshoot instance performance issues, choose the right instance size for a workload, plan scaling activities proactively, and benchmark applications to determine whether they maximize the performance available on an instance.

Amazon EC2 defines network maximums at the instance level to ensure a high-quality networking experience, including consistent network performance across instance sizes. AWS provides maximums for the following for each instance:

- **Bandwidth capability** – Each EC2 instance has a maximum bandwidth for aggregate inbound and outbound traffic, based on instance type and size. Some instances use a network I/O credit mechanism to allocate network bandwidth based on average bandwidth utilization. Amazon EC2 also has maximum bandwidth for traffic to AWS Direct Connect and the internet.
- **Packet-per-second (PPS) performance** – Each EC2 instance has a maximum PPS performance, based on instance type and size.
- **Connections tracked** – The security group tracks each connection established to ensure that return packets are delivered as expected. There is a maximum number of connections that can be tracked per instance.
- **Link-local service access** – Amazon EC2 provides a maximum PPS per network interface for traffic to services such as the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.

When the network traffic for an instance exceeds a maximum, AWS shapes the traffic that exceeds the maximum by queueing and then dropping network packets. You can monitor when traffic exceeds a maximum using the network performance metrics. These metrics inform you, in real time, of impact to network traffic and possible network performance issues.

Contents
- Requirements (p. 969)
- Metrics for the ENA driver (p. 970)
- View the network performance metrics for your Linux instance (p. 970)
- Network performance metrics with the DPDK driver for ENA (p. 970)
- Metrics on instances running FreeBSD (p. 972)

Requirements

The following requirements apply to Linux instances.

- Install ENA driver version 2.2.10 or later. To verify the installed version, use the `ethtool` command. In the following example, the version meets the minimum requirement.

```
[ec2-user ~]# ethtool -i eth0 | grep version
version: 2.2.10
```

To upgrade your ENA driver, see Enhanced networking (p. 953).
- To import these metrics to Amazon CloudWatch, install the CloudWatch agent. For more information, see Collect network performance metrics in the Amazon CloudWatch User Guide.
Metrics for the ENA driver

The ENA driver delivers the following metrics to the instance in real time. They provide the cumulative number of packets queued or dropped on each network interface since the last driver reset.

The following metrics are available on Linux instances, FreeBSD instances, and DPDK environments.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bw_in_allowance_exceeded</td>
<td>The number of packets queued or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance.</td>
</tr>
<tr>
<td>bw_out_allowance_exceeded</td>
<td>The number of packets queued or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance.</td>
</tr>
<tr>
<td>conntrack_allowance_exceeded</td>
<td>The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance.</td>
</tr>
<tr>
<td>linklocal_allowance_exceeded</td>
<td>The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.</td>
</tr>
<tr>
<td>pps_allowance_exceeded</td>
<td>The number of packets queued or dropped because the bidirectional PPS exceeded the maximum for the instance.</td>
</tr>
</tbody>
</table>

View the network performance metrics for your Linux instance

You can publish metrics to your favorite tools to visualize the metric data. For example, you can publish the metrics to Amazon CloudWatch using the CloudWatch agent. The agent enables you to select individual metrics and control publication.

You can also use the `ethtool` to retrieve the metrics for each network interface, such as eth0, as follows.

```
[ec2-user ~]$ ethtool -S eth0
bw_in_allowance_exceeded: 0
bw_out_allowance_exceeded: 0
pps_allowance_exceeded: 0
conntrack_allowance_exceeded: 0
linklocal_allowance_exceeded: 0
```

Network performance metrics with the DPDK driver for ENA

The ENA driver version 2.2.0 and later supports network metrics reporting. DPDK 20.11 includes the ENA driver 2.2.0 and is the first DPDK version to support this feature.

You can use an example application to view DPDK statistics. To start an interactive version of the example application, run the following command.

```
./app/dpdk-testpmd -- -i
```
Within this interactive session, you can enter a command to retrieve extended statistics for a port. The following example command retrieves the statistics for port 0.

```
show port xstats 0
```

The following is an example of an interactive session with the DPDK example application.

```
[root@ip-192.0.2.0 build]# ./app/dpdk-testpmd -- -i
EAL: Detected 4 lcore(s)
EAL: Detected 1 NUMA nodes
EAL: Multi-process socket /var/run/dpdk/rte/mp_socket

971
For more information about the example application and using it to retrieve extended statistics, see Testpmd Application User Guide in the DPDK documentation.

## Metrics on instances running FreeBSD

Starting with version 2.3.0, the ENA FreeBSD driver supports collecting network performance metrics on instances running FreeBSD. To enable the collection of FreeBSD metrics, enter the following command and set `interval` to a value between 1 and 3600. This specifies how often, in seconds, to collect FreeBSD metrics.

```
sysctl dev.ena.network_interface.eni_metrics.sample_interval=interval
```

For example, the following command sets the driver to collect FreeBSD metrics on network interface 1 every 10 seconds:

```
sysctl dev.ena.1.eni_metrics.sample_interval=10
```

To turn off the collection of FreeBSD metrics, you can run the preceding command and specify 0 as the `interval`.

Once you are collecting FreeBSD metrics, you can retrieve the latest set of collected metrics by running the following command.

```
sysctl dev.ena.network_interface.eni_metrics
```

## Troubleshoot the Elastic Network Adapter (ENA)

The Elastic Network Adapter (ENA) is designed to improve operating system health and reduce the chances of long-term disruption because of unexpected hardware behavior and or failures. The ENA architecture keeps device or driver failures as transparent to the system as possible. This topic provides troubleshooting information for ENA.

If you are unable to connect to your instance, start with the Troubleshoot connectivity issues (p. 973) section.

If you are able to connect to your instance, you can gather diagnostic information by using the failure detection and recovery mechanisms that are covered in the later sections of this topic.

### Contents

- Troubleshoot connectivity issues (p. 973)
- Keep-alive mechanism (p. 974)
- Register read timeout (p. 975)
Troubleshoot connectivity issues

If you lose connectivity while enabling enhanced networking, the ena module might be incompatible with your instance's current running kernel. This can happen if you install the module for a specific kernel version (without dkms, or with an improperly configured dkms.conf file) and then your instance kernel is updated. If the instance kernel that is loaded at boot time does not have the ena module properly installed, your instance will not recognize the network adapter and your instance becomes unreachable.

If you enable enhanced networking for a PV instance or AMI, this can also make your instance unreachable.

If your instance becomes unreachable after enabling enhanced networking with ENA, you can disable the enaSupport attribute for your instance and it will fall back to the stock network adapter.

To disable enhanced networking with ENA (EBS-backed instances)

1. From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI), Stop-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   Important
   If you are using an instance store-backed instance, you can't stop the instance.
   Instead, proceed to To disable enhanced networking with ENA (instance store-backed instances) (p. 973).

2. From your local computer, disable the enhanced networking attribute using the following command.

   • modify-instance-attribute (AWS CLI)

   ```
   $ aws ec2 modify-instance-attribute --instance-id instance_id --no-ena-support
   ```

3. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI), Start-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

4. (Optional) Connect to your instance and try reinstalling the ena module with your current kernel version by following the steps in Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances (p. 953).

To disable enhanced networking with ENA (instance store-backed instances)

If your instance is an instance store-backed instance, create a new AMI as described in Create an instance store-backed Linux AMI (p. 107). Be sure to disable the enhanced networking enaSupport attribute when you register the AMI.

• register-image (AWS CLI)

   ```
   $ aws ec2 register-image --no-ena-support ...
   ```

• Register-EC2Image (AWS Tools for Windows PowerShell)

   ```
   C:\> Register-EC2Image -EnaSupport $false ...
   ```

973
Keep-alive mechanism

The ENA device posts keep-alive events at a fixed rate (usually once every second). The ENA driver implements a watchdog mechanism, which checks for the presence of these keep-alive messages. If a message or messages are present, the watchdog is rearmed, otherwise the driver concludes that the device experienced a failure and then does the following:

- Dumps its current statistics to syslog
- Resets the ENA device
- Resets the ENA driver state

The above reset procedure may result in some traffic loss for a short period of time (TCP connections should be able to recover), but should not otherwise affect the user.

The ENA device may also indirectly request a device reset procedure, by not sending a keep-alive notification, for example, if the ENA device reaches an unknown state after loading an irrecoverable configuration.

Below is an example of the reset procedure:

```
[18509.800135] ena 0000:00:07.0 eth1: Keep alive watchdog timeout. // The watchdog process initiates a reset
[18509.815244] ena 0000:00:07.0 eth1: Trigger reset is on
[18509.825589] ena 0000:00:07.0 eth1: tx_timeout: 0 // The driver logs the current statistics
[18509.834253] ena 0000:00:07.0 eth1: io_suspend: 0
[18509.842674] ena 0000:00:07.0 eth1: io_resume: 0
[18509.850275] ena 0000:00:07.0 eth1: wd_expired: 1
[18509.857855] ena 0000:00:07.0 eth1: interface_up: 1
[18509.865415] ena 0000:00:07.0 eth1: interface_down: 0

[18512.775945] ena 0000:00:07.0: Device reset completed successfully // The reset process is complete
```
Register read timeout

The ENA architecture suggests a limited usage of memory mapped I/O (MMIO) read operations. MMIO registers are accessed by the ENA device driver only during its initialization procedure. If the driver logs (available in **dmesg** output) indicate failures of read operations, this may be caused by an incompatible or incorrectly compiled driver, a busy hardware device, or hardware failure. Intermittent log entries that indicate failures on read operations should not be considered an issue; the driver will retry them in this case. However, a sequence of log entries containing read failures indicate a driver or hardware problem. Below is an example of driver log entry indicating a read operation failure due to a timeout:

```
[ 47.113698] [ENA_COM: ena_com_reg_bar_read32] reading reg failed for timeout. expected:
  req id[1] offset[88] actual: req id[57006] offset[0]
[ 47.333715] [ENA_COM: ena_com_reg_bar_read32] reading reg failed for timeout. expected:
[ 47.346221] [ENA_COM: ena_com_dev_reset] Reg read32 timeout occurred
```

Statistics

If you experience insufficient network performance or latency issues, you should retrieve the device statistics and examine them. These statistics can be obtained using **ethtool** as follows.

```
[ec2-user ~]$ ethtool -S ethN
NIC statistics:
  tx_timeout: 0
  suspend: 0
  resume: 0
  wd_expired: 0
  interface_up: 1
  interface_down: 0
  admin_q_pause: 0
  bw_in_allowance_exceeded: 0
  bw_out_allowance_exceeded: 0
  pps_allowance_exceeded: 0
  conntrack_allowance_exceeded: 0
  linklocal_allowance_exceeded: 0
  queue_0_tx_bytes: 1075749
  queue_0_tx_queue_stop: 0
  ...
```

The following command output parameters are described below:

- **tx_timeout:** \( N \)
  The number of times that the Netdev watchdog was activated.
- **suspend:** \( N \)
  The number of times the driver performed a suspend operation.
- **resume:** \( N \)
  The number of times the driver performed a resume operation.
- **wd_expired:** \( N \)
  The number of times that the driver did not receive the keep-alive event in the preceding three seconds.
interface_up: N
   The number of times that the ENA interface was brought up.
interface_down: N
   The number of times that the ENA interface was brought down.
admin_q_pause: N
   The number of times the admin queue was not found in a running state.
bw_in_allowance_exceeded: N
   The number of rx packets dropped because the bandwidth allowance limit was exceeded.
bw_out_allowance_exceeded: N
   The number of tx packets dropped because the bandwidth allowance limit was exceeded.
pps_allowance_exceeded: N
   The number of packets dropped because the pps (packets per second) allowance limit was exceeded.
connttrack_allowance_exceeded: N
   The number of packets dropped because the connection count allowance limit was exceeded.
linklocal_allowance_exceeded: N
   The number of proxy packets dropped because the pps (packets per second) allowance limit was exceeded.
queue_N_tx_cnt: N
   The number of transmitted packets for this queue.
queue_N_tx_bytes: N
   The number of transmitted bytes for this queue.
queue_N_tx_queue_stop: N
   The number of times that queue N was full and stopped.
queue_N_tx_queue_wakeup: N
   The number of times that queue N resumed after being stopped.
queue_N_tx_dma_mapping_err: N
   Direct memory access error count. If this value is not 0, it indicates low system resources.
queue_N_tx_linearize: N
   The number of times SKB linearization was attempted for this queue.
queue_N_tx_linearize_failed: N
   The number of times SKB linearization failed for this queue.
queue_N_tx_napi_comp: N
   The number of times the napi handler called napi_complete for this queue.
queue_N_tx_rx_poll: N
   The number of times the napi handler was scheduled for this queue.
queue_N_tx_doorbells: N
   The number of transmission doorbells for this queue.
queue_N_tx_prepare_ctx_err: N
   The number of times ena_com_prepare_tx failed for this queue.
queue_N_tx_bad_req_id: N

Invalid req_id for this queue. The valid req_id is zero, minus the queue_size, minus 1.

queue_N_tx_llq_buffer_copy: N

The number of packets whose headers size are larger than llq entry for this queue.

queue_N_tx_missed_tx: N

The number of packets that were left uncompleted for this queue.

queue_N_tx_unmask_interrupt: N

The number of times the tx interrupt was unmasked for this queue.

queue_N_rx_cnt: N

The number of received packets for this queue.

queue_N_rx_bytes: N

The number of received bytes for this queue.

queue_N_rx_copybreak_pkt: N

The number of times the rx queue received a packet that is less than the rx_copybreak packet size for this queue.

queue_N_rx_csum_good: N

The number of times the rx queue received a packet where the checksum was checked and was correct for this queue.

queue_N_rx_refil_partial: N

The number of times the driver did not succeed in refilling the empty portion of the rx queue with the buffers for this queue. If this value is not zero, it indicates low memory resources.

queue_N_rx_bad_csum: N

The number of times the rx queue had a bad checksum for this queue (only if rx checksum offload is supported).

queue_N_rx_page_alloc_fail: N

The number of time that page allocation failed for this queue. If this value is not zero, it indicates low memory resources.

queue_N_rx_skb_alloc_fail: N

The number of time that SKB allocation failed for this queue. If this value is not zero, it indicates low system resources.

queue_N_rx_dma_mapping_err: N

Direct memory access error count. If this value is not 0, it indicates low system resources.

queue_N_rx_bad_desc_num: N

Too many buffers per packet. If this value is not 0, it indicates the use of very small buffers.

queue_N_rx_bad_req_id: N

The req_id for this queue is not valid. The valid req_id is from [0, queue_size - 1].

queue_N_rx_empty_rx_ring: N

The number of times the rx queue was empty for this queue.

queue_N_rx_csumUnchecked: N

The number of times the rx queue received a packet whose checksum wasn't checked for this queue.
queue_N_rx_xdp_aborted: N
   The number of times that an XDP packet was classified as XDP_ABORT.
queue_N_rx_xdp_drop: N
   The number of times that an XDP packet was classified as XDP_DROP.
queue_N_rx_xdp_pass: N
   The number of times that an XDP packet was classified as XDP_PASS.
queue_N_rx_xdp_tx: N
   The number of times that an XDP packet was classified as XDP_TX.
queue_N_rx_xdp_invalid: N
   The number of times that the XDP return code for the packet was not valid.
queue_N_rx_xdp_redirect: N
   The number of times that an XDP packet was classified as XDP_REDIRECT.
queue_N_xdp_tx_cnt: N
   The number of transmitted packets for this queue.
queue_N_xdp_tx_bytes: N
   The number of transmitted bytes for this queue.
queue_N_xdp_tx_queue_stop: N
   The number of times that this queue was full and stopped.
queue_N_xdp_tx_queue_wakeup: N
   The number of times that this queue resumed after being stopped.
queue_N_xdp_tx_dma_mapping_err: N
   Direct memory access error count. If this value is not 0, it indicates low system resources.
queue_N_xdp_tx_linearize: N
   The number of times XDP buffer linearization was attempted for this queue.
queue_N_xdp_tx_linearize_failed: N
   The number of times XDP buffer linearization failed for this queue.
queue_N_xdp_tx_napi_comp: N
   The number of times the napi handler called napi_complete for this queue.
queue_N_xdp_tx_tx_poll: N
   The number of times the napi handler was scheduled for this queue.
queue_N_xdp_tx_doorbells: N
   The number of transmission doorbells for this queue.
queue_N_xdp_tx_prepare_ctx_err: N
   The number of times ena_com_prepare_tx failed for this queue. This value should always be zero; if
   not, see the driver logs.
queue_N_xdp_tx_bad_req_id: N
   The req_id for this queue is not valid. The valid req_id is from [0, queue_size - 1 ].
queue_N_xdp_tx_llq_buffer_copy: N
   The number of packets that had their headers copied using llq buffer copy for this queue.
queue_N_xdp_tx_missed_tx: \(N\)

The number of times a tx queue entry missed a completion timeout for this queue.

queue_N_xdp_tx_unmask_interrupt: \(N\)

The number of times the tx interrupt was unmasked for this queue.

ena_admin_q_aborted_cmd: \(N\)

The number of admin commands that were aborted. This usually happens during the auto-recovery procedure.

ena_admin_q_submitted_cmd: \(N\)

The number of admin queue doorbells.

ena_admin_q_completed_cmd: \(N\)

The number of admin queue completions.

ena_admin_q_out_of_space: \(N\)

The number of times that the driver tried to submit new admin command, but the queue was full.

ena_admin_q_no_completion: \(N\)

The number of times that the driver did not get an admin completion for a command.

Driver error logs in syslog

The ENA driver writes log messages to syslog during system boot. You can examine these logs to look for errors if you are experiencing issues. Below is an example of information logged by the ENA driver in syslog during system boot, along with some annotations for select messages.

Which errors can I ignore?

The following warnings that may appear in your system's error logs can be ignored for the Elastic Network Adapter:
Set host attribute isn’t supported

Host attributes are not supported for this device.

failed to alloc buffer for rx queue

This is a recoverable error, and it indicates that there may have been a memory pressure issue when the error was thrown.

Feature X isn’t supported

The referenced feature is not supported by the Elastic Network Adapter. Possible values for X include:

- 10: RSS Hash function configuration is not supported for this device.
- 12: RSS Indirection table configuration is not supported for this device.
- 18: RSS Hash Input configuration is not supported for this device.
- 20: Interrupt moderation is not supported for this device.
- 27: The Elastic Network Adapter driver does not support polling the Ethernet capabilities from snmpd.

Failed to config AENQ

The Elastic Network Adapter does not support AENQ configuration.

Trying to set unsupported AENQ events

This error indicates an attempt to set an AENQ events group that is not supported by the Elastic Network Adapter.

Elastic Fabric Adapter

An Elastic Fabric Adapter (EFA) is a network device that you can attach to your Amazon EC2 instance to accelerate High Performance Computing (HPC) and machine learning applications. EFA enables you to achieve the application performance of an on-premises HPC cluster, with the scalability, flexibility, and elasticity provided by the AWS Cloud.

EFA provides lower and more consistent latency and higher throughput than the TCP transport traditionally used in cloud-based HPC systems. It enhances the performance of inter-instance communication that is critical for scaling HPC and machine learning applications. It is optimized to work on the existing AWS network infrastructure and it can scale depending on application requirements.

EFA integrates with Libfabric 1.11.1 and it supports Open MPI 4.0.5 and Intel MPI 2019 Update 7 for HPC applications, and Nvidia Collective Communications Library (NCCL) for machine learning applications.

**Note**

The OS-bypass capabilities of EFAs are not supported on Windows instances. If you attach an EFA to a Windows instance, the instance functions as an Elastic Network Adapter, without the added EFA capabilities.

**Contents**

- EFA basics (p. 981)
- Supported interfaces and libraries (p. 982)
- Supported instance types (p. 982)
- Supported AMIs (p. 983)
- EFA limitations (p. 983)
- Get started with EFA and MPI (p. 983)
EFA basics

An EFA is an Elastic Network Adapter (ENA) with added capabilities. It provides all of the functionality of an ENA, with an additional OS-bypass functionality. OS-bypass is an access model that allows HPC and machine learning applications to communicate directly with the network interface hardware to provide low-latency, reliable transport functionality.

Traditionally, HPC applications use the Message Passing Interface (MPI) to interface with the system’s network transport. In the AWS Cloud, this has meant that applications interface with MPI, which then uses the operating system’s TCP/IP stack and the ENA device driver to enable network communication between instances.

With an EFA, HPC applications use MPI or NCCL to interface with the Libfabric API. The Libfabric API bypasses the operating system kernel and communicates directly with the EFA device to put packets on the network. This reduces overhead and enables the HPC application to run more efficiently.
Note
Libfabric is a core component of the OpenFabrics Interfaces (OFI) framework, which defines and exports the user-space API of OFI. For more information, see the Libfabric OpenFabrics website.

Differences between EFAs and ENAs

Elastic Network Adapters (ENAs) provide traditional IP networking features that are required to support VPC networking. EFAs provide all of the same traditional IP networking features as ENAs, and they also support OS-bypass capabilities. OS-bypass enables HPC and machine learning applications to bypass the operating system kernel and to communicate directly with the EFA device.

Supported interfaces and libraries

EFA supports the following interfaces and libraries:

- Open MPI 4.0.5
- Intel MPI 2019 Update 7
- NVIDIA Collective Communications Library (NCCL) 2.4.2 and later

Supported instance types

The following instance types support EFAs:

- General purpose: m5dn.24xlarge | m5dn.metal | m5n.24xlarge | m5zn.12xlarge | m5zn.metal | m6i.32xlarge
- Compute optimized: c5n.18xlarge | c5n.metal | c6gn.16xlarge
- Memory optimized: r5dn.24xlarge | r5dn.metal | r5n.24xlarge | r5n.metal
- Storage optimized: i3en.24xlarge | i3en.metal
- Accelerated computing: g4dn.metal | inf1.24xlarge | p3dn.24xlarge | p4d.24xlarge

The available instance types vary by Region. To see the available instance types that support EFA in a Region, use the `describe-instance-types` command with the `--region` option and the appropriate Region code.

```
$ aws ec2 describe-instance-types \
  --region us-east-2 \
  --filters Name=network-info.efa-supported,Values=true \
  --query "InstanceTypes[*].[InstanceType]" \
  --output text
```

The following is example output.

```
g4dn.metal
i3en.24xlarge
r5n.24xlarge
c5n.18xlarge
m5n.24xlarge
inf1.24xlarge
m5dn.24xlarge
m5zn.24xlarge
c5n.metal
p3dn.24xlarge
i3en.metal
r5dn.24xlarge
```
Supported AMIs

The following AMIs support EFA with Intel x86-based instance types:

- Amazon Linux 2
- CentOS 7 and 8
- RHEL 7 and 8
- Ubuntu 18.04 and 20.04
- SUSE Linux Enterprise 15 SP2 and later
- openSUSE Leap 15.2 and later

The following AMIs support EFA with Arm-based (Graviton 2) instance types:

- Amazon Linux 2
- CentOS 8
- RHEL 8
- Ubuntu 18.04 and 20.04
- SUSE Linux Enterprise 15 SP2 and later

EFA limitations

EFA has the following limitations:

- p4d.24xlarge instances support up to four EFAs. All other supported instance types support only one EFA per instance.
- EFA OS-bypass traffic is limited to a single subnet. In other words, EFA traffic cannot be sent from one subnet to another. Normal IP traffic from the EFA can be sent from one subnet to another.
- EFA OS-bypass traffic is not routable. Normal IP traffic from the EFA remains routable.
- The EFA must be a member of a security group that allows all inbound and outbound traffic to and from the security group itself.
- EFA traffic between C6gn instances and other EFA-enabled instances is not supported.

Get started with EFA and MPI

This tutorial helps you to launch an EFA and MPI-enabled instance cluster for HPC workloads. In this tutorial, you will perform the following steps:

Contents

- Step 1: Prepare an EFA-enabled security group (p. 984)
- Step 2: Launch a temporary instance (p. 984)
- Step 3: Install the EFA software (p. 985)
- Step 4: Disable ptrace protection (p. 987)
- Step 5: (Optional) Install Intel MPI (p. 988)
- Step 6: Install your HPC application (p. 989)
- Step 7: Create an EFA-enabled AMI (p. 989)
- Step 8: Launch EFA-enabled instances into a cluster placement group (p. 989)
- Step 9: Terminate the temporary instance (p. 990)
Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure allows all inbound and outbound traffic for testing purposes only. For other scenarios, see Security group rules for different use cases (p. 1167).

To create an EFA-enabled security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups and then choose Create Security Group.
3. In the Create Security Group window, do the following:
   a. For Security group name, enter a descriptive name for the security group, such as EFA-enabled security group.
   b. (Optional) For Description, enter a brief description of the security group.
   c. For VPC, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose Create.
4. Select the security group that you created, and on the Description tab, copy the Group ID.
5. On the Inbound tab, do the following:
   a. Choose Edit.
   b. For Type, choose All traffic.
   c. For Source, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save.
6. On the Outbound tab, do the following:
   a. Choose Edit.
   b. For Type, choose All traffic.
   c. For Destination, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save.

Step 2: Launch a temporary instance

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose Select for one of the supported AMIs (p. 983).
4. On the Choose an Instance Type page, select one of the supported instance types (p. 982) and then choose Next: Configure Instance Details.
5. On the Configure Instance Details page, do the following:
   a. For Subnet, choose the subnet in which to launch the instance.
   b. For Elastic Fabric Adapter, choose Enable.
   c. In the Network Interfaces section, for device eth0, choose New network interface.
   d. Choose Next: Add Storage.
6. On the Add Storage page, specify the volumes to attach to the instances in addition to the volumes that are specified by the AMI (such as the root device volume). Then choose Next: Add Tags.

7. On the Add Tags page, specify a tag that you can use to identify the temporary instance, and then choose Next: Configure Security Group.

8. On the Configure Security Group page, for Assign a security group, select Select an existing security group, and then select the security group that you created in Step 1.

9. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instance.

Step 3: Install the EFA software

Install the EFA-enabled kernel, EFA drivers, Libfabric, and Open MPI stack that is required to support EFA on your temporary instance.

The steps differ depending on whether you intend to use EFA with Open MPI, with Intel MPI, or with Open MPI and Intel MPI.

To install the EFA software

1. Connect to the instance you launched. For more information, see Connect to your Linux instance (p. 499).

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes.

   • Amazon Linux 2, RHEL 7/8, and CentOS 7/8

     ```bash
     $ sudo yum update -y
     ```

   • Ubuntu 18.04 and 20.04

     ```bash
     $ sudo apt-get update
     $ sudo apt-get upgrade -y
     ```

   • SUSE Linux Enterprise

     ```bash
     $ sudo zypper update -y
     ```

3. Download the EFA software installation files. The software installation files are packaged into a compressed tarball (.tar.gz) file. To download the latest stable version, use the following command.

   ```bash
   $ curl -O https://efa-installer.amazonaws.com/aws-efa-installer-1.13.0.tar.gz
   ```

   You can also get the latest version by replacing the version number with latest in the preceding command.

4. (Optional) Verify the authenticity and integrity of the EFA tarball (.tar.gz) file. We recommend that you do this to verify the identity of the software publisher and to check that the file has not been altered or corrupted since it was published. If you do not want to verify the tarball file, skip this step.

   **Note**
   Alternatively, if you prefer to verify the tarball file by using an MD5 or SHA256 checksum instead, see Verify the EFA installer using a checksum (p. 1016).
a. Download the public GPG key and import it into your keyring.

```bash
$ wget https://efa-installer.amazonaws.com/aws-efa-installer.key && gpg --import aws-efa-installer.key
```

The command should return a key value. Make a note of the key value, because you need it in the next step.

b. Verify the GPG key's fingerprint. Run the following command and specify the key value from the previous step.

```bash
$ gpg --fingerprint key_value
```

The command should return a fingerprint that is identical to 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC. If the fingerprint does not match, don't run the EFA installation script, and contact AWS Support.

c. Download the signature file and verify the signature of the EFA tarball file.

```bash
$ wget https://efa-installer.amazonaws.com/aws-efa-installer-1.13.0.tar.gz.sig && gpg --verify ./aws-efa-installer-1.13.0.tar.gz.sig
```

The following shows example output.

```
gpg: Signature made Wed 29 Jul 2020 12:50:13 AM UTC using RSA key ID DD2D3CCC
gpg: Good signature from "Amazon EC2 EFA <ec2-efa-maintainers@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg: There is no indication that the signature belongs to the owner.
Primary key fingerprint: 4E90 91BC BB97 A96B 26B1  5E59 A054 80B1 DD2D 3CCC
```

If the result includes Good signature, and the fingerprint matches the fingerprint returned in the previous step, proceed to the next step. If not, don't run the EFA installation script, and contact AWS Support.

5. Extract the files from the compressed .tar.gz file and navigate into the extracted directory.

```bash
$ tar -xf aws-efa-installer-1.13.0.tar.gz && cd aws-efa-installer
```

6. Install the EFA software. Do one of the following depending on your use case.

   **Note**

   If you are using a SUSE Linux operating system, you must additionally specify the --skip-kmod option to prevent kmod installation. By default, SUSE Linux does not allow out-of-tree kernel modules. As a result, EFA and NVIDIA GPUDirect support is currently not supported with SUSE Linux.

- **Open MPI and Intel MPI**

  If you intend to use EFA with Open MPI and Intel MPI, you must install the EFA software with Libfabric and Open MPI, and you must complete Step 5: (Optional) Install Intel MPI. To install the EFA software with Libfabric and Open MPI, run the following command.

  ```bash
  $ sudo ./efa_installer.sh -y
  ```

  Libfabric is installed in the /opt/amazon/efa directory, while Open MPI is installed in the /opt/amazon/openmpi directory.

- **Open MPI only**
If you intend to use EFA with Open MPI only, you must install the EFA software with Libfabric and Open MPI, and you can skip Step 5: (Optional) Install Intel MPI. To install the EFA software with Libfabric and Open MPI, run the following command.

```bash
$ sudo ./efa_installer.sh -y
```

Libfabric is installed in the `/opt/amazon/efa` directory, while Open MPI is installed in the `/opt/amazon/openmpi` directory.

- **Intel MPI only**

If you intend to use EFA with Intel MPI only, you can install the EFA software without Libfabric and Open MPI. In this case, Intel MPI uses its embedded Libfabric. If you choose to do this, you must complete Step 5: (Optional) Install Intel MPI.

To install the EFA software without Libfabric and Open MPI, run the following command.

```bash
$ sudo ./efa_installer.sh -y --minimal
```

7. If the EFA installer prompts you to reboot the instance, do so and then reconnect to the instance. Otherwise, log out of the instance and then log back in to complete the installation.

8. Confirm that the EFA software components were successfully installed.

```bash
$ fi_info -p efa -t FI_EP_RDM
```

The command should return information about the Libfabric EFA interfaces. The following example shows the command output.

```
provider: efa
  fabric: EFA-fe80::94:3dff:fe89:1b70
  domain: efa_0-rdm
  version: 2.0
  type: FI_EP_RDM
  protocol: FI_PROTO_EFA
```

---

**Step 4: Disable ptrace protection**

To improve your HPC application's performance, Libfabric uses the instance's local memory for interprocess communications when the processes are running on the same instance.

The shared memory feature uses Cross Memory Attach (CMA), which is not supported with `ptrace protection`. If you are using a Linux distribution that has ptrace protection enabled by default, such as Ubuntu, you must disable it. If your Linux distribution does not have ptrace protection enabled by default, skip this step.

To disable ptrace protection

Do one of the following:

- To temporarily disable ptrace protection for testing purposes, run the following command.

  ```bash
  $ sudo sysctl -w kernel.yama.ptrace_scope=0
  ```

- To permanently disable ptrace protection, add `kernel.yama.ptrace_scope = 0` to `/etc/sysctl.d/10-ptrace.conf` and reboot the instance.
Step 5: (Optional) Install Intel MPI

**Important**
If you intend to only use Open MPI, skip this step. Perform this step only if you intend to use Intel MPI.

Intel MPI requires an additional installation and environment variable configuration.

**Prerequisites**
Ensure that the user performing the following steps has sudo permissions.

**To install Intel MPI**

1. To download the Intel MPI installation files, see the Intel Developer Zone website.

   You must register before you can download the installation files. After you have registered, do the following:
   a. For **Product**, choose Intel MPI Library for Linux.
   b. For **Version**, choose 2019 Update 7, and then choose Full Product.

2. The installation files are packaged into a compressed .tar.gz file. Extract the files from the compressed .tar.gz file and navigate into the extracted directory.

   ```
   $ tar -xf file_name.tar.gz
   $ cd directory_name
   ```

3. Open silent.cfg using your preferred text editor. In line 10, change ACCEPT_EULA=decline to ACCEPT_EULA=accept. Save the changes and close the file.

4. Run the installation script.

   ```
   $ sudo ./install.sh -s silent.cfg
   ```

   Intel MPI is installed in the /opt/intel/impi/ directory by default.

5. Add the Intel MPI environment variables to the corresponding shell startup scripts to ensure that they are set each time that the instance starts. Do one of the following depending on your shell.

   - For **bash**, add the following environment variable to /home/username/.bashrc and /home/username/.bash_profile.

     ```
     source /opt/intel/compilers_and_libraries/linux/mpi/intel64/bin/mpivars.sh
     ```

   - For **csh and tcsh**, add the following environment variable to /home/username/.cshrc.

     ```
     source /opt/intel/compilers_and_libraries/linux/mpi/intel64/bin/mpivars.csh
     ```

6. Log out of the instance and then log back in.

7. Run the following command to confirm that Intel MPI was successfully installed.

   ```
   $ which mpicc
   ```

   Ensure that the returned path includes the /opt/intel/ subdirectory.
Note
If you no longer want to use Intel MPI, remove the environment variables from the shell startup scripts.

Step 6: Install your HPC application

Install the HPC application on the temporary instance. The installation procedure varies depending on the specific HPC application. For more information, see Manage software on your Amazon Linux instance (p. 556).

Note
You might need to refer to your HPC application’s documentation for installation instructions.

Step 7: Create an EFA-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

To create an AMI from your temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and choose Actions, Image, Create image.
4. For Create image, do the following:
   a. For Image name, enter a descriptive name for the AMI.
   b. (Optional) For Image description, enter a brief description of the purpose of the AMI.
   c. Choose Create image.
5. In the navigation pane, choose AMIs.
6. Locate the AMI that you created in the list. Wait for the status to change from pending to available before continuing to the next step.

Step 8: Launch EFA-enabled instances into a cluster placement group

Launch your EFA-enabled instances into a cluster placement group using the EFA-enabled AMI that you created in Step 7, and the EFA-enabled security group that you created in Step 1.

Note
It is not an absolute requirement to launch your EFA-enabled instances into a cluster placement group. However, we do recommend running your EFA-enabled instances in a cluster placement group as it launches the instances into a low-latency group in a single Availability Zone.

To launch your EFA-enabled instances into a cluster placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose My AMIs, find the AMI that you created in Step 7, and then choose Select.
4. On the Choose an Instance Type page, select one of the supported instance types (p. 982) and then choose Next: Configure Instance Details.
5. On the Configure Instance Details page, do the following:
   a. For Number of instances, enter the number of EFA-enabled instances that you want to launch.
   b. For Network and Subnet, select the VPC and subnet into which to launch the instances.
c. For **Placement group**, select *Add instance to placement group*.

d. For **Placement group name**, select *Add to a new placement group*, enter a descriptive name for the placement group, and then for **Placement group strategy**, select *cluster*.

e. For EFA, choose *Enable*.

f. In the **Network Interfaces** section, for device *eth0*, choose *New network interface*. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you're launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.

g. Choose *Next: Add Storage*.

6. On the **Add Storage** page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume), and then choose **Next: Add Tags**.

7. On the **Add Tags** page, specify tags for the instances, such as a user-friendly name, and then choose **Next: Configure Security Group**.

8. On the **Configure Security Group** page, for **Assign a security group**, select *Select an existing security group*, and then select the security group that you created in **Step 1**.

9. Choose **Review and Launch**.

10. On the **Review Instance Launch** page, review the settings, and then choose **Launch** to choose a key pair and to launch your instances.

### Step 9: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.

**To terminate the temporary instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. In the navigation pane, choose **Instances**.

3. Select the temporary instance that you created and then choose **Actions, Instance state, Terminate instance**.

4. When prompted for confirmation, choose **Terminate**.

### Step 10: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

**To enable passwordless SSH between the instances in the cluster**

1. Select one instance in the cluster as the leader node, and connect to it.

2. Disable `strictHostKeyChecking` and enable `ForwardAgent` on the leader node. Open `~/.ssh/config` using your preferred text editor and add the following.

   ```
   Host *
   ForwardAgent yes
   Host *
   StrictHostKeyChecking no
   ```

3. Generate an RSA key pair.

   ```
   $ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
   ```
The key pair is created in the $HOME/.ssh/ directory.

4. Change the permissions of the private key on the leader node.

   $ chmod 600 ~/.ssh/id_rsa
   chmod 600 ~/.ssh/config

5. Open ~/.ssh/id_rsa.pub using your preferred text editor and copy the key.
6. For each member node in the cluster, do the following:
   a. Connect to the instance.
   b. Open ~/.ssh/authorized_keys using your preferred text editor and add the public key that you copied earlier.
7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

   $ ssh member_node_private_ip

You should connect to the member node without being prompted for a key or password.

Get started with EFA and NCCL

The NVIDIA Collective Communications Library (NCCL) is a library of standard collective communication routines for multiple GPUs across a single node or multiple nodes. NCCL can be used together with EFA, Libfabric, and MPI to support various machine learning workloads. For more information, see the NCCL website.

   Note

   • NCCL with EFA is supported with p3dn.24xlarge and p4d.24xlarge instances only.
   • Only NCCL 2.4.2 and later is supported with EFA.

The following tutorials help you to launch an EFA and NCCL-enabled instance cluster for machine learning workloads.

   • Use a base AMI (p. 991)
   • Use an AWS Deep Learning AMI (p. 1008)

Use a base AMI

The following steps help you to get started with Elastic Fabric Adapter using one of the supported base AMIs (p. 983).

   Note

   • Only the p3dn.24xlarge and p4d.24xlarge instance types are supported.
   • Only Amazon Linux 2, RHEL 7/8, CentOS 7/8, and Ubuntu 18.04 base AMIs are supported.

Contents

   • Step 1: Prepare an EFA-enabled security group (p. 992)
   • Step 2: Launch a temporary instance (p. 992)
   • Step 3: Install Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN (p. 993)
Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure allows all inbound and outbound traffic for testing purposes only. For other scenarios, see Security group rules for different use cases (p. 1167).

To create an EFA-enabled security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups and then choose Create Security Group.
3. In the Create Security Group window, do the following:
   a. For Security group name, enter a descriptive name for the security group, such as EFA-enabled security group.
   b. (Optional) For Description, enter a brief description of the security group.
   c. For VPC, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose Create.
4. Select the security group that you created, and on the Description tab, copy the Group ID.
5. On the Inbound tab, do the following:
   a. Choose Edit.
   b. For Type, choose All traffic.
   c. For Source, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save.
6. On the Outbound tab, do the following:
   a. Choose Edit.
   b. For Type, choose All traffic.
   c. For Destination, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save.

Step 2: Launch a temporary instance

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the **Choose an AMI** page, choose one of the supported AMIs.

4. On the **Choose an Instance Type** page, select `p3dn.24xlarge` or `p4d.24xlarge` and then choose **Next: Configure Instance Details**.

5. On the **Configure Instance Details** page, do the following:
   a. For **Subnet**, choose the subnet in which to launch the instance.
   b. For **Elastic Fabric Adapter**, choose **Enable**.
   c. In the **Network Interfaces** section, for device **eth0**, choose **New network interface**.
   d. Choose **Next: Add Storage**.

6. On the **Add Storage** page, specify the volumes to attach to the instances, in addition to the volumes specified by the AMI (such as the root device volume). Ensure that you provision enough storage for the Nvidia CUDA Toolkit. Then choose **Next: Add Tags**.

   **Note**
   You must provision an additional 10 to 20 GiB of storage for the Nvidia CUDA Toolkit. If you do not provision enough storage, you will receive an *insufficient disk space* error when attempting to install the Nvidia drivers and CUDA toolkit.

7. On the **Add Tags** page, specify a tag that you can use to identify the temporary instance, and then choose **Next: Configure Security Group**.

8. On the **Configure Security Group** page, for **Assign a security group**, select **Select an existing security group**. Then select the security group that you created in **Step 1**.

9. On the **Review Instance Launch** page, review the settings, and then choose **Launch** to choose a key pair and to launch your instance.

### Step 3: Install Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

**Amazon Linux 2**

**To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN**

1. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

   ```shell
   $ sudo yum groupinstall 'Development Tools' -y
   ```

2. To use the Nvidia GPU driver, you must first disable the `nouveau` open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   ```shell
   $ sudo yum install -y wget kernel-devel-$(*uname -r*) kernel-headers-$(*uname -r*)
   ```

   b. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` deny list file.

   ```shell
   $ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   blacklist vga16fb
   blacklist nouveau
   blacklist rivafb
   blacklist nvidiafb
   blacklist rivatv
   EOF
   ```

   c. Open `/etc/default/grub` using your preferred text editor and add the following.

   ```bash
   GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
   ```

   d. Rebuild the Grub configuration.

993
3. Reboot the instance and reconnect to it.

4. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.
   a. Install the EPEL repository for DKMS and enable any optional repos for your Linux
distribution.

   ```
   ```

   b. Install the CUDA repository public GPG key.

   ```
   $ distribution='rhel7'
   ```

   c. Set up the CUDA network repository and update the repository cache.

   ```
   $ ARCH=$( /bin/arch ) \\
   && sudo yum clean expire-cache
   ```

   d. Install the NVIDIA, CUDA drivers and cuDNN.

   ```
   $ sudo yum clean all \\
   && sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel
   ```

5. Reboot the instance and reconnect to it.

6. (p4d.24xlarge instances only) Start the Nvidia Fabric Manager service, and ensure that it
starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch
Management.

   ```
   $ sudo systemctl start nvidia-fabricmanager \\
   && sudo systemctl enable nvidia-fabricmanager
   ```

7. Ensure that the CUDA paths are set each time that the instance starts.

   - For bash shells, add the following statements to /home/username/.bashrc and /
home/username/.bash_profile.

   ```
   export PATH=/usr/local/cuda/bin:$PATH
   export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
   $LD_LIBRARY_PATH
   ```

   - For tcsh shells, add the following statements to /home/username/.cshrc.

   ```
   setenv PATH=/usr/local/cuda/bin:$PATH
   setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
   $LD_LIBRARY_PATH
   ```

8. To confirm that the Nvidia GPU drivers are functional, run the following command.

   ```
   $ nvidia-smi -q | head
   ```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia
CUDA toolkit.
To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

   ```
   $ sudo yum upgrade -y && sudo reboot
   ```

   After the instance has rebooted, reconnect to it.

2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

   ```
   $ sudo yum groupinstall 'Development Tools' -y \\
   && sudo yum install -y tar bzip2 make automake pciutils elfutils-libelf-devel 
   libglvnd-devel iptables firewalld vim bind-utils
   ```

3. To use the Nvidia GPU driver, you must first disable the nouveau open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   ```
   $ sudo yum install -y wget kernel-devel-$(uname -r) kernel-headers-$(uname -r)
   ```

   b. Add nouveau to the `/etc/modprobe.d/blacklist.conf` deny list file.

   ```
   $ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   blacklist vga16fb
   blacklist nouveau
   blacklist rivafb
   blacklist nvidiafb
   blacklist riva
   EOF
   ```

   c. Open `/etc/default/grub` using your preferred text editor and add the following.

   ```
   GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
   ```

   d. Rebuild the Grub configuration.

   ```
   $ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

4. Reboot the instance and reconnect to it.

5. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

   a. Install the EPEL repository for DKMS and enable any optional repos for your Linux distribution.

      • CentOS 7

      ```
      ```

      • CentOS 8

      ```
      $ sudo yum install -y epel-release
      ```

   b. Install the CUDA repository public GPG key.
• CentOS 7

$ distribution='rhel7'

c. Set up the CUDA network repository and update the repository cache.

$ ARCH=$( /bin/arch ) \
&& sudo yum clean expire-cache
d. (CentOS 8 only) Update the running kernel.

$ sudo yum install -y kernel kernel-core kernel-modules
e. Install the NVIDIA, CUDA drivers and cuDNN.

$ sudo yum clean all \
&& sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel

6. Reboot the instance and reconnect to it.

7. (p4d.24xlarge instances only) Start the Nvidia Fabric Manager service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

$ sudo systemctl start nvidia-fabricmanager \
&& sudo systemctl enable nvidia-fabricmanager

8. Ensure that the CUDA paths are set each time that the instance starts.

• For bash shells, add the following statements to /home/username/.bashrc and /home/username/.bash_profile.

    export PATH=/usr/local/cuda/bin:$PATH
    export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
    $LD_LIBRARY_PATH

• For tcsh shells, add the following statements to /home/username/.cshrc.

    setenv PATH=/usr/local/cuda/bin:$PATH
    setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
    $LD_LIBRARY_PATH

9. To confirm that the Nvidia GPU drivers are functional, run the following command.

$ nvidia-smi -q | head

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.
RHEL 7/8

To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

1. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

```bash
$ sudo yum groupinstall 'Development Tools' -y
```

2. To use the Nvidia GPU driver, you must first disable the `nouveau` open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

```bash
$ sudo yum install -y wget kernel-devel-$(uname -r) kernel-headers-$(uname -r)
```

   b. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` deny list file.

```bash
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

   c. Open `/etc/default/grub` using your preferred text editor and add the following.

```bash
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

   d. Rebuild the Grub configuration.

```bash
$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

3. Reboot the instance and reconnect to it.

4. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

   a. Install the EPEL repository for DKMS and enable any optional repos for your Linux distribution.

      * RHEL 7

```bash
```

      * RHEL 8

```bash
```

   b. Install the CUDA repository public GPG key.

```bash
$ distribution=$(./etc/os-release;echo $ID`rpm -E "%{?rhel}%{?fedora}"
$ distribution
```

   c. Set up the CUDA network repository and update the repository cache.

```bash
$ ARCH=($( /bin/arch ));
$ ARCH
```

997
Get started with EFA and NCCL

4. Install the NVIDIA, CUDA drivers and cuDNN.

```bash
$ sudo yum clean all
&& sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel
```

5. Reboot the instance and reconnect to it.

6. (p4d.24xlarge instances only) Start the Nvidia Fabric Manager service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```bash
$ sudo systemctl start nvidia-fabricmanager
&& sudo systemctl enable nvidia-fabricmanager
```

7. Ensure that the CUDA paths are set each time that the instance starts.

   - For **bash** shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

     ```bash
     export PATH=/usr/local/cuda/bin:$PATH
     export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:$LD_LIBRARY_PATH
     ```

   - For **tcsh** shells, add the following statements to `/home/username/.cshrc`.

     ```bash
     setenv PATH=/usr/local/cuda/bin:$PATH
     setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:$LD_LIBRARY_PATH
     ```

8. To confirm that the Nvidia GPU drivers are functional, run the following command.

   ```bash
   $ nvidia-smi -q | head
   ```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

**Ubuntu 18.04/20.04**

**To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN**

1. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

   ```bash
   $ sudo apt-get update
   && sudo apt-get install build-essential -y
   ```

2. To use the Nvidia GPU driver, you must first disable the **nouveau** open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   ```bash
   $ sudo apt-get install -y gcc make linux-headers-$(uname -r)
   ```

   b. Add **nouveau** to the `/etc/modprobe.d/blacklist.conf` deny list file.

   ```bash
   $ cat > EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   blacklist vgabfer
   ```
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF

c. Open `/etc/default/grub` using your preferred text editor and add the following.

```
GRUB_CMDLINE_LINUX="rd blacklist=nouveau"
```

d. Rebuild the Grub configuration.

```
$ sudo update-grub
```

3. Reboot the instance and reconnect to it.

4. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

a. Download and install the additional dependencies and add the CUDA repository.

   • Ubuntu 18.04

```
# sudo apt-key adv --fetch-keys http://developer.download.nvidia.com/compute/ 
  machine-learning/repos/ubuntu1804/x86_64/7fa2af80.pub 
  machine-learning/repos/ubuntu1804/x86_64/nvidia-machine-learning-repo-
  ubuntu1804_1.0.0-1_amd64.deb 
&& sudo dpkg -i /tmp/deeplearning.deb 
  repos/ubuntu1804/x86_64/cuda-ubuntu1804.pin 
&& sudo apt-key adv --fetch-keys https://developer.download.nvidia.com/ 
  compute/cuda/repos/ubuntu1804/x86_64/7fa2af80.pub 
&& sudo add-apt-repository 'deb http://developer.download.nvidia.com/compute/ 
  cuda/repos/ubuntu1804/x86_64/ /' 
&& sudo apt update
```

   • Ubuntu 20.04

```
$ sudo apt-key adv --fetch-keys http://developer.download.nvidia.com/compute/ 
  machine-learning/repos/ubuntu2004/x86_64/7fa2af80.pub 
  machine-learning/repos/ubuntu2004/x86_64/nvidia-machine-learning-repo-
  ubuntu2004_1.0.0-1_amd64.deb 
&& sudo dpkg -i /tmp/deeplearning.deb 
  repos/ubuntu2004/x86_64/cuda-ubuntu2004.pin 
&& sudo mv /tmp/cuda.pin /etc/apt/preferences.d/cuda-repository-pin-600 
&& sudo apt-key adv --fetch-keys https://developer.download.nvidia.com/ 
  compute/cuda/repos/ubuntu2004/x86_64/7fa2af80.pub 
&& sudo add-apt-repository 'deb http://developer.download.nvidia.com/compute/ 
  cuda/repos/ubuntu2004/x86_64/ /' 
&& sudo apt update
```

b. Install the NVIDIA, CUDA drivers and cuDNN.

```
$ sudo apt install -o Dpkg::Options::='--force-overwrite' cuda-drivers cuda-
  toolkit-11-0 libcudnn8 libcudnn8-dev -y
```

5. Reboot the instance and reconnect to it.

6. (p4d.24xlarge instances only) Install the Nvidia Fabric Manager.
a. You must install the version of the Nvidia Fabric Manager that matches the version of the Nvidia kernel module that you installed in the previous step.

Run the following command to determine the version of the Nvidia kernel module.

```
$ cat /proc/driver/nvidia/version | grep "Kernel Module"
```

The following is example output.

```
NVRM version: NVIDIA UNIX x86_64 Kernel Module 450.42.01 Tue Jun 15 21:26:37 UTC 2021
```

In the example above, major version 450 of the kernel module was installed. This means that you need to install Nvidia Fabric Manager version 450.

b. Install the Nvidia Fabric Manager. Run the following command and specify the major version identified in the previous step.

```
$ sudo apt install -o Dpkg::Options::='--force-overwrite' nvidia-fabricmanager-major_version_number
```

For example, if major version 450 of the kernel module was installed, use the following command to install the matching version of Nvidia Fabric Manager.

```
$ sudo apt install -o Dpkg::Options::='--force-overwrite' nvidia-fabricmanager-450
```

c. Start the service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```
$ sudo systemctl start nvidia-fabricmanager 
&& sudo systemctl enable nvidia-fabricmanager
```

7. Ensure that the CUDA paths are set each time that the instance starts.

- For `bash` shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

  ```
  export PATH=/usr/local/cuda/bin:$PATH
  export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
  $LD_LIBRARY_PATH
  ```

- For `tcsh` shells, add the following statements to `/home/username/.cshrc`.

  ```
  setenv PATH=/usr/local/cuda/bin:$PATH
  setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
  $LD_LIBRARY_PATH
  ```

8. To confirm that the Nvidia GPU drivers are functional, run the following command.

```
$ nvidia-smi -q | head
```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.
Step 4: Install the EFA software

Install the EFA-enabled kernel, EFA drivers, Libfabric, and Open MPI stack that is required to support EFA on your temporary instance.

To install the EFA software

1. Connect to the instance you launched. For more information, see Connect to your Linux instance (p. 499).

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes.
   - Amazon Linux 2, RHEL 7/8, and CentOS 7/8
     $ sudo yum update -y
   - Ubuntu 18.04
     $ sudo apt-get update && sudo apt-get upgrade -y

3. Download the EFA software installation files. The software installation files are packaged into a compressed tarball (.tar.gz) file. To download the latest stable version, use the following command.

   $ curl -O https://efa-installer.amazonaws.com/aws-efa-installer-1.13.0.tar.gz

   You can also get the latest version by replacing the version number with latest in the preceding command.

4. (Optional) Verify the authenticity and integrity of the EFA tarball (.tar.gz) file. We recommend that you do this to verify the identity of the software publisher and to check that the file has not been altered or corrupted since it was published. If you do not want to verify the tarball file, skip this step.

   Note
   Alternatively, if you prefer to verify the tarball file by using an MD5 or SHA256 checksum instead, see Verify the EFA installer using a checksum (p. 1016).
   a. Download the public GPG key and import it into your keyring.

      $ wget https://efa-installer.amazonaws.com/aws-efa-installer.key && gpg --import aws-efa-installer.key

      The command should return a key value. Make a note of the key value, because you need it in the next step.
   b. Verify the GPG key's fingerprint. Run the following command and specify the key value from the previous step.

      $ gpg --fingerprint key_value

      The command should return a fingerprint that is identical to 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC. If the fingerprint does not match, don't run the EFA installation script, and contact AWS Support.
   c. Download the signature file and verify the signature of the EFA tarball file.
$ wget https://efa-installer.amazonaws.com/aws-efa-installer-1.13.0.tar.gz.sig &&
  gpg --verify ./aws-efa-installer-1.13.0.tar.gz.sig

The following shows example output.

```
gpg: Signature made Wed 29 Jul 2020 12:50:13 AM UTC using RSA key ID DD2D3CCC
gpg: Good signature from "Amazon EC2 EFA <ec2-efa-maintainers@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg: Primary key fingerprint: 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC
```

If the result includes Good signature, and the fingerprint matches the fingerprint returned in the previous step, proceed to the next step. If not, don't run the EFA installation script, and contact AWS Support.

5. Extract the files from the compressed .tar.gz file and navigate into the extracted directory.

```
$ tar -xf aws-efa-installer-1.13.0.tar.gz && cd aws-efa-installer
```

6. Run the EFA software installation script.

```
$ sudo ./efa_installer.sh -y -g
```

Libfabric is installed in the /opt/amazon/efa directory, while Open MPI is installed in the /opt/amazon/openmpi directory.

7. If the EFA installer prompts you to reboot the instance, do so and then reconnect to the instance. Otherwise, log out of the instance and then log back in to complete the installation.

8. Confirm that the EFA software components were successfully installed.

```
$ fi_info -p efa -t FI_EP_RDM
```

The command should return information about the Libfabric EFA interfaces. The following example shows the command output.

- **p3dn.24xlarge with single network interface**

  ```
  provider: efa
  fabric: EFA-fe80::94:3dff:fe89:1b70
  domain: efa_0-rdm
  version: 2.0
  type: FI_EP_RDM
  protocol: FI_PROTO_EFA
  ```

- **p4d.24xlarge with multiple network interfaces**

  ```
  provider: efa
  fabric: EFA-fe80::c6e:8fff:fe6:e7ff
  domain: efa_0-rdm
  version: 111.0
  type: FI_EP_RDM
  protocol: FI_PROTO_EFA
  provider: efa
  fabric: EFA-fe80::c34:3eff:feb2:3c35
  domain: efa_1-rdm
  version: 111.0
  type: FI_EP_RDM
  ```
**Step 5: Install NCCL**

Install NCCL. For more information about NCCL, see the [NCCL repository](https://github.com/NVIDIA/nccl).

**To install NCCL**

1. Navigate to the `/opt` directory.

   `cd /opt`

2. Clone the official NCCL repository to the instance and navigate into the local cloned repository.

   `sudo git clone https://github.com/NVIDIA/nccl.git` & `cd nccl`

3. Build and install NCCL and specify the CUDA installation directory.

   `sudo make -j src.build CUDA_HOME=/usr/local/cuda`

**Step 6: Install the aws-ofi-nccl plugin**

The aws-ofi-nccl plugin maps NCCL's connection-oriented transport APIs to Libfabric's connection-less reliable interface. This enables you to use Libfabric as a network provider while running NCCL-based applications. For more information about the aws-ofi-nccl plugin, see the [aws-ofi-nccl repository](https://github.com/aws/aws-ofi-nccl).

**To install the aws-ofi-nccl plugin**

1. Navigate to your home directory.

   `cd ~HOME`

2. (Ubuntu only) Install the utilities that are required to install the `aws-ofi-nccl` plugin. To install the required utilities, run the following command.

   `sudo apt-get install libtool autoconf -y`

3. Clone the `aws` branch of the official AWS aws-ofi-nccl repository to the instance and navigate into the local cloned repository.

   `git clone https://github.com/aws/aws-ofi-nccl.git` & `cd aws-ofi-nccl`

4. To generate the configure script, run the `autogen.sh` script.
# ./autogen.sh

5. To generate the `make` files, run the `configure` script and specify the MPI, Libfabric, NCCL, and CUDA installation directories.

   ```bash
   ```

6. Add the Open MPI directory to the `PATH` variable.

   ```bash
   $ export PATH=/opt/amazon/openmpi/bin:$PATH
   ```

7. Install the aws-ofi-nccl plugin.

   ```bash
   $ make && sudo make install
   ```

**Step 7: Install the NCCL tests**

Install the NCCL tests. The NCCL tests enable you to confirm that NCCL is properly installed and that it is operating as expected. For more information about the NCCL tests, see the [nccl-tests repository](https://github.com/NVIDIA/nccl-tests).

**To install the NCCL tests**

1. Navigate to your home directory.

   ```bash
   $ cd $HOME
   ```

2. Clone the official nccl-tests repository to the instance and navigate into the local cloned repository.

   ```bash
   $ git clone https://github.com/NVIDIA/nccl-tests.git && cd nccl-tests
   ```

3. Add the Libfabric directory to the `LD_LIBRARY_PATH` variable.

   - Amazon Linux, Amazon Linux 2, RHEL, and CentOS

     ```bash
     $ export LD_LIBRARY_PATH=/opt/amazon/efa/lib64:$LD_LIBRARY_PATH
     ```

   - Ubuntu 18.04

     ```bash
     $ export LD_LIBRARY_PATH=/opt/amazon/efa/lib:$LD_LIBRARY_PATH
     ```

4. Install the NCCL tests and specify the MPI, NCCL, and CUDA installation directories.

   ```bash
   $ make MPI=1 MPI_HOME=/opt/amazon/openmpi NCCL_HOME=/opt/nccl/build CUDA_HOME=/usr/local/cuda
   ```

**Step 8: Test your EFA and NCCL configuration**

Run a test to ensure that your temporary instance is properly configured for EFA and NCCL.
To test your EFA and NCCL configuration

1. Create a host file that specifies the hosts on which to run the tests. The following command creates a host file named `my-hosts` that includes a reference to the instance itself.

   **IMDSv2**

   ```bash
   ```

   **IMDSv1**

   ```bash
   ```

2. Run the test and specify the host file (`--hostfile`) and the number of GPUs to use (`-n`). The following command runs the `all_reduce_perf` test on 8 GPUs on the instance itself, and specifies the following environment variables.

   - `FI_PROVIDER="efa"`—specifies the fabric interface provider. This must be set to "efa".
   - `FI_EFA_USE_DEVICE_RDMA=1`—uses the device's RDMA functionality for one-sided and two-sided transfer.
   - `NCCL_DEBUG=INFO`—enables detailed debugging output. You can also specify `VERSION` to print only the NCCL version at the start of the test, or `WARN` to receive only error messages.
   - `NCCL_ALGO=ring`—enables ring algorithm for collective operations.

   For more information about the NCCL test arguments, see the NCCL Tests README in the official nccl-tests repository.

   ```bash
   $ /opt/amazon/openmpi/bin/mpirun \
   -x FI_PROVIDER="efa" \
   -x FI_EFA_USE_DEVICE_RDMA=1 \
   -x RDMAV_FORK_SAFE=1 \
   -x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/lib64:/opt/amazon/openmpi/lib64:/opt/aws-ofi-nccl/lib:$LD_LIBRARY_PATH \
   -x NCCL_DEBUG=INFO \
   -x NCCL_ALGO=ring \
   --hostfile my-hosts -n 8 -N 8 \
   --mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to none \
   $HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
   ```

3. You can confirm that EFA is active as the underlying provider for NCCL when the `NCCL_DEBUG` log is printed.

   ```bash
   ip-192-168-2-54:14:14 [0] NCCL INFO NET/OFI Selected Provider is efa*
   ```

   The following additional information is displayed when using a `p4d.24xlarge` instance.

   ```bash
   ```
Step 9: Install your machine learning applications

Install the machine learning applications on the temporary instance. The installation procedure varies depending on the specific machine learning application. For more information about installing software on your Linux instance, see Managing Software on Your Linux Instance.

**Note**
You might need to refer to your machine learning application’s documentation for installation instructions.

Step 10: Create an EFA and NCCL-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

**To create an AMI from your temporary instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and choose **Actions, Image, Create image**.
4. For **Create image**, do the following:
   a. For **Image name**, enter a descriptive name for the AMI.
   b. (Optional) For **Image description**, enter a brief description of the purpose of the AMI.
   c. Choose **Create image**.
5. In the navigation pane, choose **AMIs**.
6. Locate the AMI that you created in the list. Wait for the status to change from **pending** to **available** before continuing to the next step.

Step 11: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.

**To terminate the temporary instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and then choose **Actions, Instance state, Terminate instance**.
4. When prompted for confirmation, choose **Terminate**.

Step 12: Launch EFA and NCCL-enabled instances into a cluster placement group

Launch your EFA and NCCL-enabled instances into a cluster placement group using the EFA-enabled AMI and the EFA-enabled security group that you created earlier.

**To launch your EFA and NCCL-enabled instances into a cluster placement group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance**.
3. On the **Choose an AMI** page, choose **My AMIs**, find the AMI that you created earlier, and then choose **Select**.
4. On the **Choose an Instance Type** page, select **p3dn.24xlarge** and then choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, do the following:
   
   a. For **Number of instances**, enter the number of EFA and NCCL-enabled instances that you want to launch.
   
   b. For **Network** and **Subnet**, select the VPC and subnet into which to launch the instances.
   
   c. For **Placement group**, select **Add instance to placement group**.
   
   d. For **Placement group name**, select **Add to a new placement group**, and then enter a descriptive name for the placement group. Then for **Placement group strategy**, select **cluster**.
   
   e. For **EFA**, choose **Enable**.
   
   f. In the **Network Interfaces** section, for device **eth0**, choose **New network interface**. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you are launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.
   
   g. Choose **Next: Add Storage**.

6. On the **Add Storage** page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume). Then choose **Next: Add Tags**.

7. On the **Add Tags** page, specify tags for the instances, such as a user-friendly name, and then choose **Next: Configure Security Group**.

8. On the **Configure Security Group** page, for **Assign a security group**, select **Select an existing security group**, and then select the security group that you created earlier.

9. Choose **Review and Launch**.

10. On the **Review Instance Launch** page, review the settings, and then choose **Launch** to choose a key pair and to launch your instances.

### Step 13: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

**To enable passwordless SSH between the instances in the cluster**

1. Select one instance in the cluster as the leader node, and connect to it.
2. Disable `strictHostKeyChecking` and enable `ForwardAgent` on the leader node. Open `~/.ssh/config` using your preferred text editor and add the following:

```bash
Host *
    ForwardAgent yes
Host *
    StrictHostKeyChecking no
```

3. Generate an RSA key pair.

   ```bash
   $ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
   
   The key pair is created in the $HOME/.ssh/ directory.
   
4. Change the permissions of the private key on the leader node.

   ```bash
   $ chmod 600 ~/.ssh/id_rsa
   chmod 600 ~/.ssh/config
   
5. Open `~/.ssh/id_rsa.pub` using your preferred text editor and copy the key.

6. For each member node in the cluster, do the following:
a. Connect to the instance.
b. Open ~/.ssh/authorized_keys using your preferred text editor and add the public key that you copied earlier.

7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

```
$ ssh member_node_private_ip
```

You should connect to the member node without being prompted for a key or password.

**Use an AWS Deep Learning AMI**

The following steps help you to get started with one of the following AWS Deep Learning AMIs:

- Deep Learning AMI (Amazon Linux 2) Version 25.0 and later
- Deep Learning AMI (Amazon Linux) Version 25.0 and later
- Deep Learning AMI (Ubuntu 18.04) Version 25.0 and later
- Deep Learning AMI (Ubuntu 16.04) Version 25.0 and later

For more information, see the [AWS Deep Learning AMI User Guide](#).

**Note**

Only the p3dn.24xlarge and p4d.24xlarge instance types are supported.

**Contents**

- Step 1: Prepare an EFA-enabled security group (p. 1008)
- Step 2: Launch a temporary instance (p. 1009)
- Step 3: Test your EFA and NCCL configuration (p. 1009)
- Step 4: Install your machine learning applications (p. 1011)
- Step 5: Create an EFA and NCCL-enabled AMI (p. 1011)
- Step 6: Terminate the temporary instance (p. 1011)
- Step 7: Launch EFA and NCCL-enabled instances into a cluster placement group (p. 1011)
- Step 8: Enable passwordless SSH (p. 1012)

**Step 1: Prepare an EFA-enabled security group**

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure allows all inbound and outbound traffic for testing purposes only. For other scenarios, see Security group rules for different use cases (p. 1167).

**To create an EFA-enabled security group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups and then choose Create Security Group.
3. In the Create Security Group window, do the following:
   a. For Security group name, enter a descriptive name for the security group, such as EFA-enabled security group.
   b. (Optional) For Description, enter a brief description of the security group.
c. For VPC, select the VPC into which you intend to launch your EFA-enabled instances.
d. Choose Create.
4. Select the security group that you created, and on the Description tab, copy the Group ID.
5. On the Inbound tab, do the following:
   a. Choose Edit.
   b. For Type, choose All traffic.
   c. For Source, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save.
6. On the Outbound tab, do the following:
   a. Choose Edit.
   b. For Type, choose All traffic.
   c. For Destination, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save.

Step 2: Launch a temporary instance

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose a supported AWS Deep Learning AMI Version 25.0 or later.
4. On the Choose an Instance Type page, select p3dn.24xlarge or p4d.24xlarge and then choose Next: Configure Instance Details.
5. On the Configure Instance Details page, do the following:
   a. For Subnet, choose the subnet in which to launch the instance.
   b. For Elastic Fabric Adapter, choose Enable.
   c. In the Network Interfaces section, for device eth0, choose New network interface.
   d. Choose Next: Add Storage.
6. On the Add Storage page, specify the volumes to attach to the instances, in addition to the volumes specified by the AMI (such as the root device volume). Then choose Next: Add Tags.
7. On the Add Tags page, specify a tag that you can use to identify the temporary instance, and then choose Next: Configure Security Group.
8. On the Configure Security Group page, for Assign a security group, select Select an existing security group. Then select the security group that you created in Step 1.
9. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instance.

Step 3: Test your EFA and NCCL configuration

Run a test to ensure that your temporary instance is properly configured for EFA and NCCL.

To test your EFA and NCCL configuration

1. Create a host file that specifies the hosts on which to run the tests. The following command creates a host file named my-hosts that includes a reference to the instance itself.
IMDSv2

```
```

IMDSv1

```
```

2. Run the test and specify the host file (--hostfile) and the number of GPUs to use (\(-n\)). The following command runs the all_reduce_perf test on 8 GPUs on the instance itself, and specifies the following environment variables.

   • `FI_PROVIDER="efa"`—specifies the fabric interface provider. This must be set to "efa".
   • `FI_EFA_USE_DEVICE_RDMA=1`—uses the device's RDMA functionality for one-sided and two-sided transfer.
   • `NCCL_DEBUG=INFO`—enables detailed debugging output. You can also specify VERSION to print only the NCCL version at the start of the test, or WARN to receive only error messages.
   • `NCCL_ALGO=ring`—enables ring algorithm for collective operations.

For more information about the NCCL test arguments, see the NCCL Tests README in the official nccl-tests repository.

```
$ /opt/amazon/openmpi/bin/mpirun \
-x FI_PROVIDER="efa" \
-x FI_EFA_USE_DEVICE_RDMA=1 \
-x RDMAV_FORK_SAFE=1 \
-x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/lib64:/opt/amazon/openmpi/lib64:/usr/local/cuda/efa/lib:$LD_LIBRARY_PATH \
-x NCCL_DEBUG=INFO \
-x NCCL_ALGO=ring \
--hostfile my-hosts -n 8 -N 8 \
--mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to none \
   $HOME/src/bin/efa-tests/efa-cuda-10.0/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
```

3. You can confirm that EFA is active as the underlying provider for NCCL when the NCCL_DEBUG log is printed.

```
ip-192-168-2-54:14:14 [0] NCCL INFO NET/OFI Selected Provider is efa*
```

The following additional information is displayed when using a p4d.24xlarge instance.

```
```
Step 4: Install your machine learning applications

Install the machine learning applications on the temporary instance. The installation procedure varies depending on the specific machine learning application. For more information about installing software on your Linux instance, see Managing Software on Your Linux Instance.

Note
You might need to refer to your machine learning application's documentation for installation instructions.

Step 5: Create an EFA and NCCL-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

To create an AMI from your temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and choose Actions, Image, Create image.
4. For Create image, do the following:
   a. For Image name, enter a descriptive name for the AMI.
   b. (Optional) For Image description, enter a brief description of the purpose of the AMI.
   c. Choose Create image.
5. In the navigation pane, choose AMIs.
6. Locate the AMI that you created in the list. Wait for the status to change from pending to available before continuing to the next step.

Step 6: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.

To terminate the temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and then choose Actions, Instance state, Terminate instance.
4. When prompted for confirmation, choose Terminate.

Step 7: Launch EFA and NCCL-enabled instances into a cluster placement group

Launch your EFA and NCCL-enabled instances into a cluster placement group using the EFA-enabled AMI and the EFA-enabled security group that you created earlier.

To launch your EFA and NCCL-enabled instances into a cluster placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose My AMIs, find the AMI that you created earlier, and then choose Select.
4. On the **Choose an Instance Type** page, select **p3dn.24xlarge** and then choose **Next: Configure Instance Details**.

5. On the **Configure Instance Details** page, do the following:
   
   a. For **Number of instances**, enter the number of EFA and NCCL-enabled instances that you want to launch.
   
   b. For **Network** and **Subnet**, select the VPC and subnet into which to launch the instances.
   
   c. For **Placement group**, select **Add instance to placement group**.
   
   d. For **Placement group name**, select **Add to a new placement group**, and then enter a descriptive name for the placement group. Then for **Placement group strategy**, select **cluster**.
   
   e. For **EFA**, choose **Enable**.
   
   f. In the **Network Interfaces** section, for device **eth0**, choose **New network interface**. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you are launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.
   
   g. Choose **Next: Add Storage**.

6. On the **Add Storage** page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume). Then choose **Next: Add Tags**.

7. On the **Add Tags** page, specify tags for the instances, such as a user-friendly name, and then choose **Next: Configure Security Group**.

8. On the **Configure Security Group** page, for **Assign a security group**, select **Select an existing security group**, and then select the security group that you created earlier.

9. Choose **Review and Launch**.

10. On the **Review Instance Launch** page, review the settings, and then choose **Launch** to choose a key pair and to launch your instances.

---

**Step 8: Enable passwordless SSH**

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

**To enable passwordless SSH between the instances in the cluster**

1. Select one instance in the cluster as the leader node, and connect to it.

2. Disable **strictHostKeyChecking** and enable **ForwardAgent** on the leader node. Open `-/.ssh/config` using your preferred text editor and add the following.

   ```
   Host *
   ForwardAgent yes
   Host *
   StrictHostKeyChecking no
   ```

3. Generate an RSA key pair.

   ```
   $ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
   ```

   The key pair is created in the `$HOME/.ssh/` directory.

4. Change the permissions of the private key on the leader node.

   ```
   $ chmod 600 ~/.ssh/id_rsa
cmd 600 ~/.ssh/config
   ```
5. Open ~/.ssh/id_rsa.pub using your preferred text editor and copy the key.
6. For each member node in the cluster, do the following:
   a. Connect to the instance.
   b. Open ~/.ssh/authorized_keys using your preferred text editor and add the public key that you copied earlier.
7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

```
$ ssh member_node_private_ip
```

You should connect to the member node without being prompted for a key or password.

**Work with EFA**

You can create, use, and manage an EFA much like any other elastic network interface in Amazon EC2. However, unlike elastic network interfaces, EFAs cannot be attached to or detached from an instance in a running state.

**EFA requirements**

To use an EFA, you must do the following:

- Choose one of the supported instance types (p. 982).
- Use one of the supported AMIs (p. 983).
- Install the EFA software components. For more information, see Step 3: Install the EFA software (p. 985) and Step 5: (Optional) Install Intel MPI (p. 988).
- Use a security group that allows all inbound and outbound traffic to and from the security group itself. For more information, see Step 1: Prepare an EFA-enabled security group (p. 984).

**Contents**

- Create an EFA (p. 1013)
- Attach an EFA to a stopped instance (p. 1014)
- Attach an EFA when launching an instance (p. 1014)
- Add an EFA to a launch template (p. 1014)
- Manage IP addresses for an EFA (p. 1015)
- Change the security group for an EFA (p. 1015)
- Detach an EFA (p. 1015)
- View EFAs (p. 1015)
- Delete an EFA (p. 1015)

**Create an EFA**

You can create an EFA in a subnet in a VPC. You can't move the EFA to another subnet after it's created, and you can only attach it to stopped instances in the same Availability Zone.

**To create a new EFA using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose **Create Network Interface**.
4. For **Description**, enter a descriptive name for the EFA.
5. For **Subnet**, select the subnet in which to create the EFA.
6. For **Private IP**, enter the primary private IPv4 address. If you don't specify an IPv4 address, we select an available private IPv4 address from the selected subnet.
7. (IPv6 only) If you selected a subnet that has an associated IPv6 CIDR block, you can optionally specify an IPv6 address in the **IPv6 IP** field.
8. For **Security groups**, select one or more security groups.
9. For **EFA**, choose **Enabled**.
10. Choose **Yes, Create**.

**To create a new EFA using the AWS CLI**

Use the `create-network-interface` command and for `interface-type`, specify `efa`, as shown in the following example.

```
aws ec2 create-network-interface --subnet-id subnet-01234567890 --description example_efa --interface-type efa
```

**Attach an EFA to a stopped instance**

You can attach an EFA to any supported instance that is in the **stopped** state. You cannot attach an EFA to an instance that is in the **running** state. For more information about the supported instance types, see [Supported instance types](p. 982).

You attach an EFA to an instance in the same way that you attach a network interface to an instance. For more information, see [Attach a network interface to an instance](p. 941).

**Attach an EFA when launching an instance**

**To attach an existing EFA when launching an instance (AWS CLI)**

Use the `run-instances` command and for `NetworkInterfaceId`, specify the ID of the EFA, as shown in the following example.

```
aws ec2 run-instances --image-id ami_id --count 1 --instance-type c5n.18xlarge --key-name my_key_pair --network-interfaces DeviceIndex=0,NetworkInterfaceId=efa_id,Groups=sg_id,SubnetId=subnet_id
```

**To attach a new EFA when launching an instance (AWS CLI)**

Use the `run-instances` command and for `InterfaceType`, specify `efa`, as shown in the following example.

```
aws ec2 run-instances --image-id ami_id --count 1 --instance-type c5n.18xlarge --key-name my_key_pair --network-interfaces DeviceIndex=0,InterfaceType=efa,Groups=sg_id,SubnetId=subnet_id
```

**Add an EFA to a launch template**

You can create a launch template that contains the configuration information needed to launch EFA-enabled instances. To create an EFA-enabled launch template, create a new launch template and specify a supported instance type, your EFA-enabled AMI, and an EFA-enabled security group. For more information, see [Get started with EFA and MPI](p. 983).
You can leverage launch templates to launch EFA-enabled instances with other AWS services, such as AWS Batch.

For more information about creating launch templates, see Create a launch template (p. 485).

Manage IP addresses for an EFA

You can change the IP addresses associated with an EFA. If you have an Elastic IP address, you can associate it with an EFA. If your EFA is provisioned in a subnet that has an associated IPv6 CIDR block, you can assign one or more IPv6 addresses to the EFA.

You assign an Elastic IP (IPv4) and IPv6 address to an EFA in the same way that you assign an IP address to an elastic network interface. For more information, see Managing IP addresses (p. 943).

Change the security group for an EFA

You can change the security group that is associated with an EFA. To enable OS-bypass functionality, the EFA must be a member of a security group that allows all inbound and outbound traffic to and from the security group itself.

You change the security group that is associated with an EFA in the same way that you change the security group that is associated with an elastic network interface. For more information, see Changing the security group (p. 944).

Detach an EFA

To detach an EFA from an instance, you must first stop the instance. You cannot detach an EFA from an instance that is in the running state.

You detach an EFA from an instance in the same way that you detach an elastic network interface from an instance. For more information, see Detach a network interface from an instance (p. 942).

View EFAs

You can view all of the EFAs in your account.

You view EFAs in the same way that you view elastic network interfaces. For more information, see View details about a network interface (p. 940).

Delete an EFA

To delete an EFA, you must first detach it from the instance. You cannot delete an EFA while it is attached to an instance.

You delete EFAs in the same way that you delete elastic network interfaces. For more information, see Delete a network interface (p. 946).

Monitor an EFA

You can use the following features to monitor the performance of your Elastic Fabric Adapters.

Amazon VPC flow logs

You can create an Amazon VPC Flow Log to capture information about the traffic going to and from an EFA. Flow log data can be published to Amazon CloudWatch Logs and Amazon S3. After you create a
flow log, you can retrieve and view its data in the chosen destination. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You create a flow log for an EFA in the same way that you create a flow log for an elastic network interface. For more information, see Creating a Flow Log in the Amazon VPC User Guide.

In the flow log entries, EFA traffic is identified by the srcAddress and destAddress, which are both formatted as MAC addresses, as shown in the following example.

<table>
<thead>
<tr>
<th>version</th>
<th>accountId</th>
<th>eniId</th>
<th>srcAddress</th>
<th>destAddress</th>
<th>sourcePort</th>
<th>destPort</th>
<th>action</th>
<th>log-status</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3794735123</td>
<td>eni-10000001</td>
<td>01:23:45:67:89:ab</td>
<td>05:23:45:67:89:ab</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>ACCEPT OK</td>
</tr>
<tr>
<td>9</td>
<td>5689</td>
<td>1521232534</td>
<td>1524512343</td>
<td></td>
<td>-</td>
<td>-</td>
<td>9</td>
<td>OK</td>
</tr>
</tbody>
</table>

Amazon CloudWatch

Amazon CloudWatch provides metrics that enable you to monitor your EFAs in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For more information, see Monitor your instances using CloudWatch (p. 818).

Verify the EFA installer using a checksum

You can optionally verify the EFA tarball (.tar.gz file) using an MD5 or SHA256 checksum. We recommend that you do this to verify the identity of the software publisher and to check that the application has not been altered or corrupted since it was published.

To verify the tarball

Use the `md5sum` utility for the MD5 checksum, or the `sha256sum` utility for the SHA256 checksum, and specify the tarball filename. You must run the command from the directory in which you saved the tarball file.

- **MD5**

  ```
  # md5sum tarball_filename.tar.gz
  ```

- **SHA256**

  ```
  # sha256sum tarball_filename.tar.gz
  ```

The commands should return a checksum value in the following format.

```
checksum_value tarball_filename.tar.gz
```

Compare the checksum value returned by the command with the checksum value provided in the table below. If the checksums match, then it is safe to run the installation script. If the checksums do not match, do not run the installation script, and contact AWS Support.

For example, the following command verifies the EFA 1.9.4 tarball using the SHA256 checksum.

```bash
# sha256sum aws-efa-installer-1.9.4.tar.gz
```

```
1009b5182693490d908ef0ed2c1dd4f813cc310a5d2062ce9619c4c12b5a7f14  aws-efa-installer-1.9.4.tar.gz
```
The following table lists the checksums for recent versions of EFA.

<table>
<thead>
<tr>
<th>Version</th>
<th>Download URL</th>
<th>Checksums</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFA 1.13.0</td>
<td><a href="https://efa-installer.amazonaws.com/aws-efa-installer-1.13.0.tar.gz">https://efa-installer.amazonaws.com/aws-efa-installer-1.13.0.tar.gz</a></td>
<td>MD5: c91d16556f4fd53becadb345828221e</td>
</tr>
<tr>

</table>
Placement groups

When you launch a new EC2 instance, the EC2 service attempts to place the instance in such a way that all of your instances are spread out across underlying hardware to minimize correlated failures. You can use placement groups to influence the placement of a group of interdependent instances to meet the needs of your workload. Depending on the type of workload, you can create a placement group using one of the following placement strategies:

- **Cluster** – packs instances close together inside an Availability Zone. This strategy enables workloads to achieve the low-latency network performance necessary for tightly-coupled node-to-node communication that is typical of HPC applications.
- **Partition** – spreads your instances across logical partitions such that groups of instances in one partition do not share the underlying hardware with groups of instances in different partitions. This strategy is typically used by large distributed and replicated workloads, such as Hadoop, Cassandra, and Kafka.
- **Spread** – strictly places a small group of instances across distinct underlying hardware to reduce correlated failures.

There is no charge for creating a placement group.

**Contents**
- Cluster placement groups (p. 1019)
- Partition placement groups (p. 1020)
- Spread placement groups (p. 1020)
- Placement group rules and limitations (p. 1021)
Cluster placement groups

A cluster placement group is a logical grouping of instances within a single Availability Zone. A cluster placement group can span peered VPCs in the same Region. Instances in the same cluster placement group enjoy a higher per-flow throughput limit for TCP/IP traffic and are placed in the same high-bisection bandwidth segment of the network.

The following image shows instances that are placed into a cluster placement group.

Cluster placement groups are recommended for applications that benefit from low network latency, high network throughput, or both. They are also recommended when the majority of the network traffic is between the instances in the group. To provide the lowest latency and the highest packet-per-second network performance for your placement group, choose an instance type that supports enhanced networking. For more information, see Enhanced Networking (p. 952).

We recommend that you launch your instances in the following way:

- Use a single launch request to launch the number of instances that you need in the placement group.
- Use the same instance type for all instances in the placement group.

If you try to add more instances to the placement group later, or if you try to launch more than one instance type in the placement group, you increase your chances of getting an insufficient capacity error.

If you stop an instance in a placement group and then start it again, it still runs in the placement group. However, the start fails if there isn't enough capacity for the instance.

If you receive a capacity error when launching an instance in a placement group that already has running instances, stop and start all of the instances in the placement group, and try the launch again. Starting the instances may migrate them to hardware that has capacity for all of the requested instances.
Partition placement groups

Partition placement groups help reduce the likelihood of correlated hardware failures for your application. When using partition placement groups, Amazon EC2 divides each group into logical segments called partitions. Amazon EC2 ensures that each partition within a placement group has its own set of racks. Each rack has its own network and power source. No two partitions within a placement group share the same racks, allowing you to isolate the impact of hardware failure within your application.

The following image is a simple visual representation of a partition placement group in a single Availability Zone. It shows instances that are placed into a partition placement group with three partitions—Partition 1, Partition 2, and Partition 3. Each partition comprises multiple instances. The instances in a partition do not share racks with the instances in the other partitions, allowing you to contain the impact of a single hardware failure to only the associated partition.

![Partition placement group diagram](image)

Partition placement groups can be used to deploy large distributed and replicated workloads, such as HDFS, HBase, and Cassandra, across distinct racks. When you launch instances into a partition placement group, Amazon EC2 tries to distribute the instances evenly across the number of partitions that you specify. You can also launch instances into a specific partition to have more control over where the instances are placed.

A partition placement group can have partitions in multiple Availability Zones in the same Region. A partition placement group can have a maximum of seven partitions per Availability Zone. The number of instances that can be launched into a partition placement group is limited only by the limits of your account.

In addition, partition placement groups offer visibility into the partitions—you can see which instances are in which partitions. You can share this information with topology-aware applications, such as HDFS, HBase, and Cassandra. These applications use this information to make intelligent data replication decisions for increasing data availability and durability.

If you start or launch an instance in a partition placement group and there is insufficient unique hardware to fulfill the request, the request fails. Amazon EC2 makes more distinct hardware available over time, so you can try your request again later.

Spread placement groups

A spread placement group is a group of instances that are each placed on distinct racks, with each rack having its own network and power source.

The following image shows seven instances in a single Availability Zone that are placed into a spread placement group. The seven instances are placed on seven different racks.

![Spread placement group diagram](image)
Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. Launching instances in a spread placement group reduces the risk of simultaneous failures that might occur when instances share the same racks. Spread placement groups provide access to distinct racks, and are therefore suitable for mixing instance types or launching instances over time.

A spread placement group can span multiple Availability Zones in the same Region. You can have a maximum of seven running instances per Availability Zone per group.

If you start or launch an instance in a spread placement group and there is insufficient unique hardware to fulfill the request, the request fails. Amazon EC2 makes more distinct hardware available over time, so you can try your request again later.

Placement group rules and limitations

General rules and limitations

Before you use placement groups, be aware of the following rules:

- The name that you specify for a placement group must be unique within your AWS account for the Region.
- You can't merge placement groups.
- An instance can be launched in one placement group at a time; it cannot span multiple placement groups.
- On-Demand Capacity Reservation (p. 453) and zonal Reserved Instances (p. 328) provide a capacity reservation for EC2 instances in a specific Availability Zone. The capacity reservation can be used by instances in a placement group. However, it is not possible to explicitly reserve capacity for a placement group.
- You cannot launch Dedicated Hosts in placement groups.

Cluster placement group rules and limitations

The following rules apply to cluster placement groups:

- The following instance types are supported:
  - Current generation (p. 194) instances, except for burstable performance (p. 216) instances (for example, T2) and Mac1 instances (p. 250).
  - The following previous generation (p. 197) instances: A1, C3, cc2.8xlarge, cr1.8xlarge, G2, hs1.8xlarge, I2, and R3.
- A cluster placement group can't span multiple Availability Zones.
- The maximum network throughput speed of traffic between two instances in a cluster placement group is limited by the slower of the two instances. For applications with high-throughput requirements, choose an instance type with network connectivity that meets your requirements.
- For instances that are enabled for enhanced networking, the following rules apply:
  - Instances within a cluster placement group can use up to 10 Gbps for single-flow traffic. Instances that are not within a cluster placement group can use up to 5 Gbps for single-flow traffic.
• Traffic to and from Amazon S3 buckets within the same Region over the public IP address space or through a VPC endpoint can use all available instance aggregate bandwidth.

• You can launch multiple instance types into a cluster placement group. However, this reduces the likelihood that the required capacity will be available for your launch to succeed. We recommend using the same instance type for all instances in a cluster placement group.

• Network traffic to the internet and over an AWS Direct Connect connection to on-premises resources is limited to 5 Gbps.

Partition placement group rules and limitations

The following rules apply to partition placement groups:

• A partition placement group supports a maximum of seven partitions per Availability Zone. The number of instances that you can launch in a partition placement group is limited only by your account limits.

• When instances are launched into a partition placement group, Amazon EC2 tries to evenly distribute the instances across all partitions. Amazon EC2 doesn’t guarantee an even distribution of instances across all partitions.

• A partition placement group with Dedicated Instances can have a maximum of two partitions.

Spread placement group rules and limitations

The following rules apply to spread placement groups:

• A spread placement group supports a maximum of seven running instances per Availability Zone. For example, in a Region with three Availability Zones, you can run a total of 21 instances in the group (seven per zone). If you try to start an eighth instance in the same Availability Zone and in the same spread placement group, the instance will not launch. If you need to have more than seven instances in an Availability Zone, then the recommendation is to use multiple spread placement groups. Using multiple spread placement groups does not provide guarantees about the spread of instances between groups, but it does ensure the spread for each group, thus limiting impact from certain classes of failures.

• Spread placement groups are not supported for Dedicated Instances.

Create a placement group

You can create a placement group using one of the following methods.

Note

You can tag a placement group on creation using the command line tools only.

New console

To create a placement group using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Placement Groups, Create placement group.
3. Specify a name for the group.
4. Choose the placement strategy for the group. If you choose Partition, choose the number of partitions within the group.
5. Choose Create group.
Old console

**To create a placement group using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups, Create Placement Group**.
3. Specify a name for the group.
4. Choose the placement strategy for the group. If you choose **Partition**, specify the number of partitions within the group.
5. Choose **Create**.

AWS CLI

**To create a placement group using the AWS CLI**

Use the `create-placement-group` command. The following example creates a placement group named `my-cluster` that uses the `cluster` placement strategy, and it applies a tag with a key of `purpose` and a value of `production`.

```
aws ec2 create-placement-group --group-name my-cluster --strategy cluster --tag-
specifications 'ResourceType=placement-group,Tags={Key=purpose,Value=production}'
```

**To create a partition placement group using the AWS CLI**

Use the `create-placement-group` command. Specify the `--strategy` parameter with the value `partition`, and specify the `--partition-count` parameter with the desired number of partitions. In this example, the partition placement group is named `HDFS-Group-A` and is created with five partitions.

```
aws ec2 create-placement-group --group-name HDFS-Group-A --strategy partition --
partition-count 5
```

PowerShell

**To create a placement group using the AWS Tools for Windows PowerShell**

Use the `New-EC2PlacementGroup` command.

Tag a placement group

To help categorize and manage your existing placement groups, you can tag them with custom metadata. For more information about how tags work, see Tag your Amazon EC2 resources (p. 1462).

When you tag a placement group, the instances that are launched into the placement group are not automatically tagged. You need to explicitly tag the instances that are launched into the placement group. For more information, see Add a tag when you launch an instance (p. 1470).

You can view, add, and delete tags using the new console and the command line tools.

New console

**To view, add, or delete a tag for an existing placement group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**.
3. Select a placement group, and then choose **Actions, Manage tags**.
4. The **Manage tags** section displays any tags that are assigned to the placement group. Do the following to add or remove tags:

   - To add a tag, choose **Add tag**, and then enter the tag key and value. You can add up to 50 tags per placement group. For more information, see Tag restrictions (p. 1466).
   - To delete a tag, choose **Remove** next to the tag that you want to delete.

5. Choose **Save changes**.

**AWS CLI**

**To view placement group tags**

Use the `describe-tags` command to view the tags for the specified resource. In the following example, you describe the tags for all of your placement groups.

```
aws ec2 describe-tags \\
   --filters Name=resource-type,Values=placement-group
```

```
{
   "Tags": [
      {
         "Key": "Environment",
         "ResourceId": "pg-0123456789EXAMPLE",
         "ResourceType": "placement-group",
         "Value": "Production"
      },
      {
         "Key": "Environment",
         "ResourceId": "pg-9876543210EXAMPLE",
         "ResourceType": "placement-group",
         "Value": "Production"
      }
   ]
}
```

You can also use the `describe-tags` command to view the tags for a placement group by specifying its ID. In the following example, you describe the tags for `pg-0123456789EXAMPLE`.

```
aws ec2 describe-tags \\
   --filters Name=resource-id,Values=pg-0123456789EXAMPLE
```

```
{
   "Tags": [
      {
         "Key": "Environment",
         "ResourceId": "pg-0123456789EXAMPLE",
         "ResourceType": "placement-group",
         "Value": "Production"
      }
   ]
}
```

You can also view the tags of a placement group by describing the placement group.

Use the `describe-placement-groups` command to view the configuration of the specified placement group, which includes any tags that were specified for the placement group.

```
aws ec2 describe-placement-groups \
```
To tag an existing placement group using the AWS CLI

You can use the create-tags command to tag existing resources. In the following example, the existing placement group is tagged with Key=Cost-Center and Value=CC-123.

```
aws ec2 create-tags
    --resources pg-0123456789EXAMPLE
    --tags Key=Cost-Center,Value=CC-123
```

To delete a tag from a placement group using the AWS CLI

You can use the delete-tags command to delete tags from existing resources. For examples, see Examples in the AWS CLI Command Reference.

PowerShell

To view placement group tags
Use the Get-EC2Tag command.

To describe the tags for a specific placement group
Use the Get-EC2PlacementGroup command.

To tag an existing placement group
Use the New-EC2Tag command.

To delete a tag from a placement group
Use the Remove-EC2Tag command.

Launch instances in a placement group

You can launch an instance into a placement group if the placement group rules and limitations are met (p. 1021) using one of the following methods.

Console

To launch instances into a placement group using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
Describe instances in a placement group

2. In the navigation pane, choose **Instances**.
3. Choose **Launch Instance**. Complete the wizard as directed, taking care to do the following:
   - On the **Choose an Instance Type** page, select an instance type that can be launched into a placement group.
   - On the **Configure Instance Details** page, the following fields are applicable to placement groups:
     - For **Number of instances**, enter the total number of instances that you need in this placement group, because you might not be able to add instances to the placement group later.
     - For **Placement group**, select the **Add instance to placement group** check box. If you do not see **Placement group** on this page, verify that you have selected an instance type that can be launched into a placement group. Otherwise, this option is not available.
     - For **Placement group name**, you can choose to add the instances to an existing placement group or to a new placement group that you create.
     - For **Placement group strategy**, choose the appropriate strategy. If you choose **partition**, for **Target partition**, choose **Auto distribution** to have Amazon EC2 do a best effort to distribute the instances evenly across all the partitions in the group. Alternatively, specify the partition in which to launch the instances.

AWS CLI

**To launch instances into a placement group using the AWS CLI**

Use the `run-instances` command and specify the placement group name using the `--placement "GroupName = my-cluster"` parameter. In this example, the placement group is named `my-cluster`.

```
aws ec2 run-instances --placement "GroupName = my-cluster"
```

**To launch instances into a specific partition of a partition placement group using the AWS CLI**

Use the `run-instances` command and specify the placement group name and partition using the `--placement "GroupName = HDFS-Group-A, PartitionNumber = 3"` parameter. In this example, the placement group is named `HDFS-Group-A` and the partition number is 3.

```
aws ec2 run-instances --placement "GroupName = HDFS-Group-A, PartitionNumber = 3"
```

PowerShell

**To launch instances into a placement group using AWS Tools for Windows PowerShell**

Use the `New-EC2Instance` command and specify the placement group name using the `Placement_GroupName` parameter.

**Describe instances in a placement group**

You can view the placement information of your instances using one of the following methods. You can also filter partition placement groups by the partition number using the AWS CLI.

New console

**To view the placement group and partition number of an instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Host and placement group**, find **Placement group**. If the instance is not in a placement group, the field is empty. Otherwise, it contains the name of the placement group name. If the placement group is a partition placement group, **Partition number** contains the partition number for the instance.

**Old console**

**To view the placement group and partition number of an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. In the **Description** tab, find **Placement group**. If the instance is not in a placement group, the field is empty. Otherwise, it contains the name of the placement group name. If the placement group is a partition placement group, **Partition number** contains the partition number for the instance.

**AWS CLI**

**To view the partition number for an instance in a partition placement group using the AWS CLI**

Use the `describe-instances` command and specify the `--instance-id` parameter.

```bash
aws ec2 describe-instances --instance-id i-0123a456700123456
```

The response contains the placement information, which includes the placement group name and the partition number for the instance.

```
"Placement": {
  "AvailabilityZone": "us-east-1c",
  "GroupName": "HDFS-Group-A",
  "PartitionNumber": 3,
  "Tenancy": "default"
}
```

**To filter instances for a specific partition placement group and partition number using the AWS CLI**

Use the `describe-instances` command and specify the `--filters` parameter with the `placement-group-name` and `placement-partition-number` filters. In this example, the placement group is named HDFS-Group-A and the partition number is 7.

```bash
aws ec2 describe-instances --filters "Name = placement-group-name, Values = HDFS-Group-A" "Name = placement-partition-number, Values = 7"
```

The response lists all the instances that are in the specified partition within the specified placement group. The following is example output showing only the instance ID, instance type, and placement information for the returned instances.

```
"Instances": [
  {
    "InstanceId": "i-0a1bc23d4567e8f90",
    "InstanceType": "r4.large",
  }
]
```
Change the placement group for an instance

You can change the placement group for an instance in any of the following ways:

- Move an existing instance to a placement group
- Move an instance from one placement group to another
- Remove an instance from a placement group

Before you move or remove the instance, the instance must be in the stopped state. You can move or remove an instance using the AWS CLI or an AWS SDK.

AWS CLI

**To move an instance to a placement group using the AWS CLI**

1. Stop the instance using the `stop-instances` command.
2. Use the `modify-instance-placement` command and specify the name of the placement group to which to move the instance.

   ```bash
   aws ec2 modify-instance-placement --instance-id i-0123a456700123456 --group-name MySpreadGroup
   ```
3. Start the instance using the `start-instances` command.

PowerShell

**To move an instance to a placement group using the AWS Tools for Windows PowerShell**

1. Stop the instance using the `Stop-EC2Instance` command.
2. Use the `Edit-EC2InstancePlacement` command and specify the name of the placement group to which to move the instance.
3. Start the instance using the `Start-EC2Instance` command.
AWS CLI

**To remove an instance from a placement group using the AWS CLI**

1. Stop the instance using the `stop-instances` command.
2. Use the `modify-instance-placement` command and specify an empty string for the placement group name.

```bash
aws ec2 modify-instance-placement --instance-id i-0123a456700123456 --group-name ""
```
3. Start the instance using the `start-instances` command.

PowerShell

**To remove an instance from a placement group using the AWS Tools for Windows PowerShell**

1. Stop the instance using the `Stop-EC2Instance` command.
2. Use the `Edit-EC2InstancePlacement` command and specify an empty string for the placement group name.
3. Start the instance using the `Start-EC2Instance` command.

---

**Delete a placement group**

If you need to replace a placement group or no longer need one, you can delete it. You can delete a placement group using one of the following methods.

**Requirement**

Before you can delete a placement group, it must contain no instances. You can terminate (p. 549) all instances that you launched into the placement group, move (p. 1028) them to another placement group, or remove (p. 1029) them from the placement group.

**New console**

**To delete a placement group using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**.
3. Select the placement group and choose **Actions**, **Delete**.
4. When prompted for confirmation, enter **Delete** and then choose **Delete**.

**Old console**

**To delete a placement group using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**.
3. Select the placement group and choose **Actions**, **Delete Placement Group**.
4. When prompted for confirmation, choose **Delete**.

**AWS CLI**

**To delete a placement group using the AWS CLI**

Use the `delete-placement-group` command and specify the placement group name to delete the placement group. In this example, the placement group name is `my-cluster`.

```bash
aws ec2 delete-placement-group --group-name my-cluster
```

**PowerShell**

To delete a placement group using the AWS Tools for Windows PowerShell

Use the `Remove-EC2PlacementGroup` command to delete the placement group.

---

**Network maximum transmission unit (MTU) for your EC2 instance**

The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed over the connection. The larger the MTU of a connection, the more data that can be passed in a single packet. Ethernet packets consist of the frame, or the actual data you are sending, and the network overhead information that surrounds it.

Ethernet frames can come in different formats, and the most common format is the standard Ethernet v2 frame format. It supports 1500 MTU, which is the largest Ethernet packet size supported over most of the internet. The maximum supported MTU for an instance depends on its instance type. All Amazon EC2 instance types support 1500 MTU, and many current instance sizes support 9001 MTU, or jumbo frames.

The following rules apply to instances that are in Wavelength Zones:

- Traffic that goes from one instance to another within a VPC in the same Wavelength Zone has an MTU of 1300.
- Traffic that goes from one instance to another that uses the carrier IP within a Wavelength Zone has an MTU of 1500.
- Traffic that goes from one instance to another between a Wavelength Zone and the Region that uses a public IP address has an MTU of 1500.
- Traffic that goes from one instance to another between a Wavelength Zone and the Region that uses a private IP address has an MTU of 1300.

To see Network MTU information for Windows instances, switch to this page in the Amazon EC2 User Guide for Windows Instances guide: Network maximum transmission unit (MTU) for your EC2 instance.

**Contents**

- Jumbo frames (9001 MTU) (p. 1030)
- Path MTU Discovery (p. 1031)
- Check the path MTU between two hosts (p. 1032)
- Check and set the MTU on your Linux instance (p. 1032)
- Troubleshoot (p. 1033)

**Jumbo frames (9001 MTU)**

Jumbo frames allow more than 1500 bytes of data by increasing the payload size per packet, and thus increasing the percentage of the packet that is not packet overhead. Fewer packets are needed to send
the same amount of usable data. However, traffic is limited to a maximum MTU of 1500 in the following cases:

- Traffic outside of a given AWS Region for EC2-Classic
- Traffic outside of a single VPC
- Traffic over an inter-region VPC peering connection
- Traffic over VPN connections
- Traffic over an internet gateway

If packets are over 1500 bytes, they are fragmented, or they are dropped if the Don't Fragment flag is set in the IP header.

Jumbo frames should be used with caution for internet-bound traffic or any traffic that leaves a VPC. Packets are fragmented by intermediate systems, which slows down this traffic. To use jumbo frames inside a VPC and not slow traffic that's bound for outside the VPC, you can configure the MTU size by route, or use multiple elastic network interfaces with different MTU sizes and different routes.

For instances that are collocated inside a cluster placement group, jumbo frames help to achieve the maximum network throughput possible, and they are recommended in this case. For more information, see Placement groups (p. 1018).

You can use jumbo frames for traffic between your VPCs and your on-premises networks over AWS Direct Connect. For more information, and for how to verify Jumbo Frame capability, see Setting Network MTU in the AWS Direct Connect User Guide.

All current generation instances (p. 200) support jumbo frames. The following previous generation instances support jumbo frames: A1, C3, G2, I2, M3, and R3.

For more information about supported MTU sizes for transit gateways, see MTU in Amazon VPC Transit Gateways.

Path MTU Discovery

Path MTU Discovery is used to determine the path MTU between two devices. The path MTU is the maximum packet size that's supported on the path between the originating host and the receiving host.

For IPv4, when a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: Destination Unreachable: Fragmentation Needed and Don't Fragment was Set (Type 3, Code 4). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

The IPv6 protocol does not support fragmentation in the network. When a host sends a packet that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: ICMPv6 Packet Too Big (PTB) (Type 2). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

By default, security groups do not allow any inbound ICMP traffic. However, security groups are stateful, therefore ICMP responses to outbound requests are allowed to flow in, regardless of security group rules. Therefore, you do not need to explicitly add an inbound ICMP rule to ensure that your instance can receive the ICMP message response. For more information about configuring ICMP rules in a network ACL, see Path MTU Discovery in the Amazon VPC User Guide.

Important
Path MTU Discovery does not guarantee that jumbo frames will not be dropped by some routers. An internet gateway in your VPC will forward packets up to 1500 bytes only. 1500 MTU packets are recommended for internet traffic.
Check the path MTU between two hosts

You can check the path MTU between two hosts using the `tracepath` command, which is part of the `iputils` package that is available by default on many Linux distributions, including Amazon Linux.

**To check path MTU using tracepath**

Use the following command to check the path MTU between your EC2 instance and another host. You can use a DNS name or an IP address as the destination. If the destination is another EC2 instance, verify that the security group allows inbound UDP traffic. This example checks the path MTU between an EC2 instance and `amazon.com`.

```
[ec2-user ~]$ tracepath amazon.com
```

```
1?: [LOCALHOST]     pmtu 9001
1:  ip-172-31-16-1.us-west-1.compute.internal (172.31.16.1)   0.187ms pmtu 1500
1:  no reply
2:  no reply
3:  no reply
4:  100.64.16.241 (100.64.16.241)                          0.574ms
5:  72.21.222.221 (72.21.222.221)                          84.447ms asymm 21
6:  205.251.229.97 (205.251.229.97)                        79.970ms asymm 19
7:  72.21.222.194 (72.21.222.194)                         96.546ms asymm 16
8:  72.21.222.239 (72.21.222.239)                         79.244ms asymm 15
9:  205.251.225.73 (205.251.225.73)                       91.867ms asymm 16
...
31:  no reply
    Too many hops: pmtu 1500
    Resume: pmtu 1500
```

In this example, the path MTU is 1500.

**Check and set the MTU on your Linux instance**

Some instances are configured to use jumbo frames, and others are configured to use standard frame sizes. You may want to use jumbo frames for network traffic within your VPC or you may want to use standard frames for internet traffic. Whatever your use case, we recommend verifying that your instance will behave the way you expect it to. You can use the procedures in this section to check your network interface's MTU setting and modify it if needed.

**To check the MTU setting on a Linux instance**

You can check the current MTU value using the following `ip` command. Note that in the example output, `mtu 9001` indicates that this instance uses jumbo frames.

```
[ec2-user ~]$ ip link show eth0
```

```
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9001 qdisc pfifo_fast state UP mode DEFAULT group default qlen 1000
   link/ether 02:90:c0:b7:9e:d1 brd ff:ff:ff:ff:ff:ff
```

**To set the MTU value on a Linux instance**

1. You can set the MTU value using the `ip` command. The following command sets the desired MTU value to 1500, but you could use 9001 instead.

   ```
   [ec2-user ~]$ sudo ip link set dev eth0 mtu 1500
   ```

2. (Optional) To persist your network MTU setting after a reboot, modify the following configuration files, based on your operating system type.
Troubleshoot

If you experience connectivity issues between your EC2 instance and an Amazon Redshift cluster when using jumbo frames, see Queries Appear to Hang in the Amazon Redshift Cluster Management Guide

Virtual private clouds

Amazon Virtual Private Cloud (Amazon VPC) enables you to define a virtual network in your own logically isolated area within the AWS cloud, known as a virtual private cloud (VPC). You can launch your Amazon EC2 resources, such as instances, into the subnets of your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using scalable infrastructure from AWS. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet or to your own data center.

When you create your AWS account, we create a default VPC for you in each Region. A default VPC is a VPC that is already configured and ready for you to use. You can launch instances into your default VPC immediately. Alternatively, you can create your own nondefault VPC and configure it as you need.

If you created your AWS account before 2013-12-04, you might have support for the EC2-Classic platform in some regions. If you created your AWS account after 2013-12-04, it does not support EC2-Classic, so you must launch your resources in a VPC. For more information, see EC2-Classic (p. 1034).

Amazon VPC documentation

For more information about Amazon VPC, see the following documentation.

<table>
<thead>
<tr>
<th>Guide</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon VPC User Guide</td>
<td>Describes key concepts and provides instructions for using the features of Amazon VPC.</td>
</tr>
<tr>
<td>Amazon VPC Peering Guide</td>
<td>Describes VPC peering connections and provides instructions for using them.</td>
</tr>
</tbody>
</table>
EC2-Classic

With EC2-Classic, your instances run in a single, flat network that you share with other customers. With Amazon VPC, your instances run in a virtual private cloud (VPC) that's logically isolated to your AWS account.

The EC2-Classic platform was introduced in the original release of Amazon EC2. If you created your AWS account after 2013-12-04, it does not support EC2-Classic, so you must launch your Amazon EC2 instances in a VPC.

If your account does not support EC2-Classic, we create a default VPC for you. By default, when you launch an instance, we launch it into your default VPC. Alternatively, you can create a nondefault VPC and specify it when you launch an instance.

Detect supported platforms

The Amazon EC2 console indicates which platforms you can launch instances into for the selected region, and whether you have a default VPC in that Region.

Verify that the Region you'll use is selected in the navigation bar. On the Amazon EC2 console dashboard, look for Supported Platforms under Account Attributes.

Accounts that support EC2-Classic

The dashboard displays the following under Account Attributes to indicate that the account supports both the EC2-Classic platform and VPCs in this Region, but the Region does not have a default VPC.

```
Supported Platforms
EC2
VPC
```

The output of the describe-account-attributes command includes both the EC2 and VPC values for the supported-platforms attribute.

```
aws ec2 describe-account-attributes --attribute-names supported-platforms
{
    "AccountAttributes": [
        {
            "AttributeName": "supported-platforms",
            "AttributeValues": [
                {
                    "AttributeValue": "EC2"
                },
                {
                    "AttributeValue": "VPC"
                }
            ]
        }
    ]
}
```
Accounts that require a VPC

The dashboard displays the following under **Account Attributes** to indicate that the account requires a VPC to launch instances in this Region, does not support the EC2-Classic platform in this Region, and the Region has a default VPC with the identifier `vpc-1a2b3c4d`.

**Supported Platforms**

- VPC

**Default VPC**

- `vpc-1a2b3c4d`

The output of the `describe-account-attributes` command for the specified Region includes only the VPC value for the `supported-platforms` attribute.

```
aws ec2 describe-account-attributes --attribute-names supported-platforms --region us-east-2
{
   "AccountAttributes": [
      {
         "AttributeValue": "VPC"
      }
   ],
   "AttributeName": "supported-platforms",
}
```

Instance types available in EC2-Classic

Most of the newer instance types require a VPC. The following are the only instance types supported in EC2-Classic:

- General purpose: M1, M3, and T1
- Compute optimized: C1, C3, and CC2
- Memory optimized: CR1, M2, and R3
- Storage optimized: D2, HS1, and I2
- Accelerated computing: G2

If your account supports EC2-Classic but you have not created a nondefault VPC, you can do one of the following to launch instances that require a VPC:

- Create a nondefault VPC and launch your VPC-only instance into it by specifying a subnet ID or a network interface ID in the request. Note that you must create a nondefault VPC if you do not have a default VPC and you are using the AWS CLI, Amazon EC2 API, or AWS SDK to launch a VPC-only instance.
• Launch your VPC-only instance using the Amazon EC2 console. The Amazon EC2 console creates a nondefault VPC in your account and launches the instance into the subnet in the first Availability Zone. The console creates the VPC with the following attributes:
  • One subnet in each Availability Zone, with the public IPv4 addressing attribute set to true so that instances receive a public IPv4 address. For more information, see IP Addressing in Your VPC in the Amazon VPC User Guide.
  • An Internet gateway, and a main route table that routes traffic in the VPC to the Internet gateway. This enables the instances you launch in the VPC to communicate over the Internet. For more information, see Internet Gateways in the Amazon VPC User Guide.
  • A default security group for the VPC and a default network ACL that is associated with each subnet. For more information, see Security Groups for Your VPC in the Amazon VPC User Guide.

If you have other resources in EC2-Classic, you can take steps to migrate them to a VPC. For more information, see Migrate from EC2-Classic to a VPC (p. 1053).

### Differences between instances in EC2-Classic and a VPC

The following table summarizes the differences between instances launched in EC2-Classic, instances launched in a default VPC, and instances launched in a nondefault VPC.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>EC2-Classic</th>
<th>Default VPC</th>
<th>Nondefault VPC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public IPv4 address (from</td>
<td>Your instance receives a public IPv4 address from the EC2-Classic public IPv4</td>

</tr>
</tbody>
</table>

Security groups for EC2-Classic

If you’re using EC2-Classic, you must use security groups created specifically for EC2-Classic. When you launch an instance in EC2-Classic, you must specify a security group in the same Region as the instance. You can’t specify a security group that you created for a VPC when you launch an instance in EC2-Classic.

After you launch an instance in EC2-Classic, you can’t change its security groups. However, you can add rules to or remove rules from a security group, and those changes are automatically applied to all instances that are associated with the security group after a short period.

Your AWS account automatically has a default security group per Region for EC2-Classic. If you try to delete the default security group, you’ll get the following error: Client.InvalidGroup.Reserved: The security group ‘default’ is reserved.

You can create custom security groups. The security group name must be unique within your account for the Region. To create a security group for use in EC2-Classic, choose No VPC for the VPC.

You can add inbound rules to your default and custom security groups. You can’t change the outbound rules for an EC2-Classic security group. When you create a security group rule, you can use a different security group for EC2-Classic in the same Region as the source or destination. To specify a security group for another AWS account, add the AWS account ID as a prefix; for example, 111122223333/sg-edcd9784.

In EC2-Classic, you can have up to 500 security groups in each Region for each account. You can add up to 100 rules to a security group. You can have up to 800 security group rules per instance. This is calculated as the multiple of rules per security group and security groups per instance. If you reference other security groups in your security group rules, we recommend that you use security group names that are 22 characters or less in length.

IP addressing and DNS

Amazon provides a DNS server that resolves Amazon-provided IPv4 DNS hostnames to IPv4 addresses. In EC2-Classic, the Amazon DNS server is located at 172.16.0.23.

If you create a custom firewall configuration in EC2-Classic, you must create a rule in your firewall that allows inbound traffic from port 53 (DNS)—with a destination port from the ephemeral range—from the address of the Amazon DNS server; otherwise, internal DNS resolution from your instances fails. If your firewall doesn’t automatically allow DNS query responses, then you need to allow traffic from the IP address of the Amazon DNS server. To get the IP address of the Amazon DNS server, use the following command from within your instance:

```
grep nameserver /etc/resolv.conf
```

Elastic IP addresses

If your account supports EC2-Classic, there’s one pool of Elastic IP addresses for use with the EC2-Classic platform and another for use with your VPCs. You can’t associate an Elastic IP address that you allocated
for use with a VPC with an instance in EC2-Classic, and vice-versa. However, you can migrate an Elastic IP address you've allocated for use in the EC2-Classic platform for use with a VPC. You cannot migrate an Elastic IP address to another Region.

**To allocate an Elastic IP address for use in EC2-Classic using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Choose Allocate new address.
4. Select Classic, and then choose Allocate. Close the confirmation screen.

**Migrate an Elastic IP Address from EC2-Classic**

If your account supports EC2-Classic, you can migrate Elastic IP addresses that you've allocated for use with EC2-Classic platform to be used with a VPC, within the same Region. This can assist you to migrate your resources from EC2-Classic to a VPC; for example, you can launch new web servers in your VPC, and then use the same Elastic IP addresses that you used for your web servers in EC2-Classic for your new VPC web servers.

After you've migrated an Elastic IP address to a VPC, you cannot use it with EC2-Classic. However, if required, you can restore it to EC2-Classic. You cannot migrate an Elastic IP address that was originally allocated for use with a VPC to EC2-Classic.

To migrate an Elastic IP address, it must not be associated with an instance. For more information about disassociating an Elastic IP address from an instance, see Disassociate an Elastic IP address (p. 919).

You can migrate as many EC2-Classic Elastic IP addresses as you can have in your account. However, when you migrate an Elastic IP address, it counts against your Elastic IP address limit for VPCs. You cannot migrate an Elastic IP address if it will result in your exceeding your limit. Similarly, when you restore an Elastic IP address to EC2-Classic, it counts against your Elastic IP address limit for EC2-Classic. For more information, see Elastic IP address limit (p. 922).

You cannot migrate an Elastic IP address that has been allocated to your account for less than 24 hours.

You can migrate an Elastic IP address from EC2-Classic using the Amazon EC2 console or the Amazon VPC console. This option is only available if your account supports EC2-Classic.

**To move an Elastic IP address using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address, and choose Actions, Move to VPC scope.
4. In the confirmation dialog box, choose Move Elastic IP.

You can restore an Elastic IP address to EC2-Classic using the Amazon EC2 console or the Amazon VPC console.

**To restore an Elastic IP address to EC2-Classic using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address, choose Actions, Restore to EC2 scope.
4. In the confirmation dialog box, choose Restore.
After you've performed the command to move or restore your Elastic IP address, the process of migrating the Elastic IP address can take a few minutes. Use the `describe-moving-addresses` command to check whether your Elastic IP address is still moving, or has completed moving.

After you've moved your Elastic IP address, you can view its allocation ID on the Elastic IPs page in the Allocation ID field.

If the Elastic IP address is in a moving state for longer than 5 minutes, contact Premium Support.

**To move an Elastic IP address using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `move-address-to-vpc` (AWS CLI)
- `Move-EC2AddressToVpc` (AWS Tools for Windows PowerShell)

**To restore an Elastic IP address to EC2-Classic using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `restore-address-to-classic` (AWS CLI)
- `Restore-EC2AddressToClassic` (AWS Tools for Windows PowerShell)

**To describe the status of your moving addresses using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `describe-moving-addresses` (AWS CLI)
- `Get-EC2Address` (AWS Tools for Windows PowerShell)

**Share and access resources between EC2-Classic and a VPC**

Some resources and features in your AWS account can be shared or accessed between EC2-Classic and a VPC, for example, through ClassicLink. For more information, see ClassicLink (p. 1041).

If your account supports EC2-Classic, you might have set up resources for use in EC2-Classic. If you want to migrate from EC2-Classic to a VPC, you must recreate those resources in your VPC. For more information about migrating from EC2-Classic to a VPC, see Migrate from EC2-Classic to a VPC (p. 1053).

The following resources can be shared or accessed between EC2-Classic and a VPC.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMI</td>
<td></td>
</tr>
<tr>
<td>Bundle task</td>
<td></td>
</tr>
<tr>
<td>EBS volume</td>
<td></td>
</tr>
<tr>
<td>Elastic IP address (IPv4)</td>
<td>You can migrate an Elastic IP address from EC2-Classic to a VPC. You can't migrate an Elastic</td>
</tr>
</tbody>
</table>
Resource | Notes
--- | ---
**IP address that was originally allocated for use in a VPC to EC2-Classic. For more information, see Migrate an Elastic IP Address from EC2-Classic (p. 1039).**

**Instance** | An EC2-Classic instance can communicate with instances in a VPC using public IPv4 addresses, or you can use ClassicLink to enable communication over private IPv4 addresses.

You can't migrate an instance from EC2-Classic to a VPC. However, you can migrate your application from an instance in EC2-Classic to an instance in a VPC. For more information, see Migrate from EC2-Classic to a VPC (p. 1053).

**Key pair**

**Load balancer** | If you're using ClassicLink, you can register a linked EC2-Classic instance with a load balancer in a VPC, provided that the VPC has a subnet in the same Availability Zone as the instance.

You can't migrate a load balancer from EC2-Classic to a VPC. You can't register an instance in a VPC with a load balancer in EC2-Classic.

**Placement group**

**Reserved Instance** | You can change the network platform for your Reserved Instances from EC2-Classic to a VPC. For more information, see Modify Reserved Instances (p. 354).

**Security group** | A linked EC2-Classic instance can use a VPC security groups through ClassicLink to control traffic to and from the VPC. VPC instances can't use EC2-Classic security groups.

You can't migrate a security group from EC2-Classic to a VPC. You can copy rules from a security group for EC2-Classic to a security group for a VPC. For more information, see Create a security group (p. 1158).

**Snapshot**

The following resources can't be shared or moved between EC2-Classic and a VPC:

- Spot Instances

**ClassicLink**

ClassicLink allows you to link EC2-Classic instances to a VPC in your account, within the same Region. If you associate the VPC security groups with a EC2-Classic instance, this enables communication between
your EC2-Classic instance and instances in your VPC using private IPv4 addresses. ClassicLink removes
the need to make use of public IPv4 addresses or Elastic IP addresses to enable communication between
instances in these platforms.

ClassicLink is available to all users with accounts that support the EC2-Classic platform, and can be
used with any EC2-Classic instance. For more information about migrating your resources to a VPC, see
Migrate from EC2-Classic to a VPC (p. 1053).

There is no additional charge for using ClassicLink. Standard charges for data transfer and instance usage
apply.

Contents

• ClassicLink basics (p. 1042)
• ClassicLink limitations (p. 1044)
• Work with ClassicLink (p. 1045)
• Example IAM policies for ClassicLink (p. 1048)
• Example: ClassicLink security group configuration for a three-tier web application (p. 1050)

ClassicLink basics

There are two steps to linking an EC2-Classic instance to a VPC using ClassicLink. First, you must enable
the VPC for ClassicLink. By default, all VPCs in your account are not enabled for ClassicLink, to maintain
their isolation. After you've enabled the VPC for ClassicLink, you can then link any running EC2-Classic
instance in the same Region in your account to that VPC. Linking your instance includes selecting security
groups from the VPC to associate with your EC2-Classic instance. After you've linked the instance, it
can communicate with instances in your VPC using their private IP addresses, provided the VPC security
groups allow it. Your EC2-Classic instance does not lose its private IP address when linked to the VPC.

Linking your instance to a VPC is sometimes referred to as attaching your instance.

A linked EC2-Classic instance can communicate with instances in a VPC, but it does not form part of the
VPC. If you list your instances and filter by VPC, for example, through the DescribeInstances API
request, or by using the Instances screen in the Amazon EC2 console, the results do not return any EC2-
Classic instances that are linked to the VPC. For more information about viewing your linked EC2-Classic
instances, see View your ClassicLink-enabled VPCs and linked instances (p. 1047).

By default, if you use a public DNS hostname to address an instance in a VPC from a linked EC2-Classic
instance, the hostname resolves to the instance's public IP address. The same occurs if you use a public
DNS hostname to address a linked EC2-Classic instance from an instance in the VPC. If you want the
public DNS hostname to resolve to the private IP address, you can enable ClassicLink DNS support for
the VPC. For more information, see Enable ClassicLink DNS support (p. 1047).

If you no longer require a ClassicLink connection between your instance and the VPC, you can unlink
the EC2-Classic instance from the VPC. This disassociates the VPC security groups from the EC2-Classic
instance. A linked EC2-Classic instance is automatically unlinked from a VPC when it's stopped. After
you've unlinked all linked EC2-Classic instances from the VPC, you can disable ClassicLink for the VPC.

Use other AWS services in your VPC with ClassicLink

Linked EC2-Classic instances can access the following AWS services in the VPC: Amazon Redshift,
Amazon ElastiCache, Elastic Load Balancing, and Amazon RDS. However, instances in the VPC cannot
access the AWS services provisioned by the EC2-Classic platform using ClassicLink.

If you use Elastic Load Balancing, you can register your linked EC2-Classic instances with the load
balancer. You must create your load balancer in the ClassicLink-enabled VPC and enable the Availability
Zone in which the instance runs. If you terminate the linked EC2-Classic instance, the load balancer
deregisters the instance.
If you use Amazon EC2 Auto Scaling, you can create an Amazon EC2 Auto Scaling group with instances that are automatically linked to a specified ClassicLink-enabled VPC at launch. For more information, see Linking EC2-Classic Instances to a VPC in the Amazon EC2 Auto Scaling User Guide.

If you use Amazon RDS instances or Amazon Redshift clusters in your VPC, and they are publicly accessible (accessible from the Internet), the endpoint you use to address those resources from a linked EC2-Classic instance by default resolves to a public IP address. If those resources are not publicly accessible, the endpoint resolves to a private IP address. To address a publicly accessible RDS instance or Redshift cluster over private IP using ClassicLink, you must use their private IP address or private DNS hostname, or you must enable ClassicLink DNS support for the VPC.

If you use a private DNS hostname or a private IP address to address an RDS instance, the linked EC2-Classic instance cannot use the failover support available for Multi-AZ deployments.

You can use the Amazon EC2 console to find the private IP addresses of your Amazon Redshift, Amazon ElastiCache, or Amazon RDS resources.

**To locate the private IP addresses of AWS resources in your VPC**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Check the descriptions of the network interfaces in the **Description** column. A network interface that's used by Amazon Redshift, Amazon ElastiCache, or Amazon RDS will have the name of the service in the description. For example, a network interface that's attached to an Amazon RDS instance will have the following description: RDSNetworkInterface.
4. Select the required network interface.
5. In the details pane, get the private IP address from the **Primary private IPv4 IP** field.

**Control the use of ClassicLink**

By default, IAM users do not have permission to work with ClassicLink. You can create an IAM policy that grants users permissions to enable or disable a VPC for ClassicLink, link or unlink an instance to a ClassicLink-enabled VPC, and to view ClassicLink-enabled VPCs and linked EC2-Classic instances. For more information about IAM policies for Amazon EC2, see IAM policies for Amazon EC2 (p. 1070).

For more information about policies for working with ClassicLink, see the following example: Example IAM policies for ClassicLink (p. 1048).

**Security groups in ClassicLink**

Linking your EC2-Classic instance to a VPC does not affect your EC2-Classic security groups. They continue to control all traffic to and from the instance. This excludes traffic to and from instances in the VPC, which is controlled by the VPC security groups that you associated with the EC2-Classic instance. EC2-Classic instances that are linked to the same VPC cannot communicate with each other through the VPC; regardless of whether they are associated with the same VPC security group. Communication between EC2-Classic instances is controlled by the EC2-Classic security groups associated with those instances. For an example of a security group configuration, see Example: ClassicLink security group configuration for a three-tier web application (p. 1050).

After you've linked your instance to a VPC, you cannot change which VPC security groups are associated with the instance. To associate different security groups with your instance, you must first unlink the instance, and then link it to the VPC again, choosing the required security groups.

**Routing for ClassicLink**

When you enable a VPC for ClassicLink, a static route is added to all of the VPC route tables with a destination of 10.0.0.0/8 and a target of local. This allows communication between instances in the VPC and any EC2-Classic instances that are then linked to the VPC. If you add a custom route table to a
ClassicLink-enabled VPC, a static route is automatically added with a destination of 10.0.0.0/8 and a target of local. When you disable ClassicLink for a VPC, this route is automatically deleted in all of the VPC route tables.

VPCs that are in the 10.0.0.0/16 and 10.1.0.0/16 IP address ranges can be enabled for ClassicLink only if they do not have any existing static routes in route tables in the 10.0.0.0/8 IP address range, excluding the local routes that were automatically added when the VPC was created. Similarly, if you've enabled a VPC for ClassicLink, you may not be able to add any more specific routes to your route tables within the 10.0.0.0/8 IP address range.

**Important**

If your VPC CIDR block is a publicly routable IP address range, consider the security implications before you link an EC2-Classic instance to your VPC. For example, if your linked EC2-Classic instance receives an incoming Denial of Service (DoS) request flood attack from a source IP address that falls within the VPC's IP address range, the response traffic is sent into your VPC. We strongly recommend that you create your VPC using a private IP address range as specified in RFC 1918.

For more information about route tables and routing in your VPC, see Route Tables in the Amazon VPC User Guide.

**Enable a VPC peering connection for ClassicLink**

If you have a VPC peering connection between two VPCs, and there are one or more EC2-Classic instances that are linked to one or both of the VPCs via ClassicLink, you can extend the VPC peering connection to enable communication between the EC2-Classic instances and the instances in the VPC on the other side of the VPC peering connection. This enables the EC2-Classic instances and the instances in the VPC to communicate using private IP addresses. To do this, you can enable a local VPC to communicate with a linked EC2-Classic instance in a peer VPC, or you can enable a local linked EC2-Classic instance to communicate with instances in a peer VPC.

If you enable a local VPC to communicate with a linked EC2-Classic instance in a peer VPC, a static route is automatically added to your route tables with a destination of 10.0.0.0/8 and a target of local.

For more information and examples, see Configurations With ClassicLink in the Amazon VPC Peering Guide.

**ClassicLink limitations**

To use the ClassicLink feature, you need to be aware of the following limitations:

- You can link an EC2-Classic instance to only one VPC at a time.
- If you stop your linked EC2-Classic instance, it's automatically unlinked from the VPC and the VPC security groups are no longer associated with the instance. You can link your instance to the VPC again after you've restarted it.
- You cannot link an EC2-Classic instance to a VPC that's in a different Region or a different AWS account.
- You cannot use ClassicLink to link a VPC instance to a different VPC, or to an EC2-Classic resource. To establish a private connection between VPCs, you can use a VPC peering connection. For more information, see the Amazon VPC Peering Guide.
- You cannot associate a VPC Elastic IP address with a linked EC2-Classic instance.
- You cannot enable EC2-Classic instances for IPv6 communication. You can associate an IPv6 CIDR block with your VPC and assign IPv6 address to resources in your VPC, however, communication between a ClassicLinked instance and resources in the VPC is over IPv4 only.
- VPCs with routes that conflict with the EC2-Classic private IP address range of 10/8 cannot be enabled for ClassicLink. This does not include VPCs with 10.0.0.0/16 and 10.1.0.0/16 IP address ranges that already have local routes in their route tables. For more information, see Routing for ClassicLink (p. 1043).
• VPCs configured for dedicated hardware tenancy cannot be enabled for ClassicLink. Contact Amazon Web Services Support to request that your dedicated tenancy VPC be allowed to be enabled for ClassicLink.

  **Important**
  EC2-Classic instances are run on shared hardware. If you've set the tenancy of your VPC to dedicated because of regulatory or security requirements, then linking an EC2-Classic instance to your VPC might not conform to those requirements, as this allows a shared tenancy resource to address your isolated resources directly using private IP addresses. If you need to enable your dedicated VPC for ClassicLink, provide a detailed reason in your request to Amazon Web Services Support.

• If you link your EC2-Classic instance to a VPC in the 172.16.0.0/16 range, and you have a DNS server running on the 172.16.0.23/32 IP address within the VPC, then your linked EC2-Classic instance can't access the VPC DNS server. To work around this issue, run your DNS server on a different IP address within the VPC.

• ClassicLink doesn't support transitive relationships out of the VPC. Your linked EC2-Classic instance doesn't have access to any VPN connection, VPC gateway endpoint, NAT gateway, or Internet gateway associated with the VPC. Similarly, resources on the other side of a VPN connection or an Internet gateway don't have access to a linked EC2-Classic instance.

**Work with ClassicLink**

You can use the Amazon EC2 and Amazon VPC consoles to work with the ClassicLink feature. You can enable or disable a VPC for ClassicLink, and link and unlink EC2-Classic instances to a VPC.

  **Note**
  The ClassicLink features are only visible in the consoles for accounts and Regions that support EC2-Classic.

**Tasks**

- Enable a VPC for ClassicLink (p. 1045)
- Create a VPC with ClassicLink enabled (p. 1046)
- Link an instance to a VPC (p. 1046)
- Link an instance to a VPC at launch (p. 1046)
- View your ClassicLink-enabled VPCs and linked instances (p. 1047)
- Enable ClassicLink DNS support (p. 1047)
- Disable ClassicLink DNS support (p. 1047)
- Unlink an instance from a VPC (p. 1048)
- Disable ClassicLink for a VPC (p. 1048)

**Enable a VPC for ClassicLink**

To link an EC2-Classic instance to a VPC, you must first enable the VPC for ClassicLink. You cannot enable a VPC for ClassicLink if the VPC has routing that conflicts with the EC2-Classic private IP address range. For more information, see *Routing for ClassicLink* (p. 1043).

To enable a VPC for ClassicLink

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose Your VPCs.
3. Select the VPC.
4. Choose Actions, Enable ClassicLink.
5. When prompted for confirmation, choose Enable ClassicLink.
6. (Optional) If you want the public DNS hostname to resolve to the private IP address, enable ClassicLink DNS support for the VPC before you link any instances. For more information, see Enable ClassicLink DNS support (p. 1047).

Create a VPC with ClassicLink enabled

You can create a new VPC and immediately enable it for ClassicLink by using the VPC wizard in the Amazon VPC console.

To create a VPC with ClassicLink enabled

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. From the Amazon VPC dashboard, choose Launch VPC Wizard.
3. Select one of the VPC configuration options and choose Select.
4. On the next page of the wizard, choose Yes for Enable ClassicLink. Complete the rest of the steps in the wizard to create your VPC. For more information about using the VPC wizard, see Scenarios for Amazon VPC in the Amazon VPC User Guide.
5. (Optional) If you want the public DNS hostname to resolve to the private IP address, enable ClassicLink DNS support for the VPC before you link any instances. For more information, see Enable ClassicLink DNS support (p. 1047).

Link an instance to a VPC

After you've enabled a VPC for ClassicLink, you can link an EC2-Classic instance to it. The instance must be in the running state.

If you want the public DNS hostname to resolve to the private IP address, enable ClassicLink DNS support for the VPC before you link the instance. For more information, see Enable ClassicLink DNS support (p. 1047).

To link an instance to a VPC

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select one or more running EC2-Classic instances.
4. Choose Actions, ClassicLink, Link to VPC.
5. Choose the VPC. The console displays only VPCs that are enabled for ClassicLink.
6. Select one or more security groups to associate with your instances. The console displays security groups only for VPCs enabled for ClassicLink.
7. Choose Link.

Link an instance to a VPC at launch

You can use the launch wizard in the Amazon EC2 console to launch an EC2-Classic instance and immediately link it to a ClassicLink-enabled VPC.

To link an instance to a VPC at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Amazon EC2 dashboard, choose Launch Instance.
3. Select an AMI, and then choose an instance type that is supported on EC2-Classic. For more information, see Instance types available in EC2-Classic (p. 1035).
4. On the Configure Instance Details page, do the following:
a. For **Network**, choose **Launch into EC2-Classic**. If this option is disabled, then the instance type is not supported on EC2-Classic.
b. Expand **Link to VPC (ClassicLink)** and choose a VPC from **Link to VPC**. The console displays only VPCs with ClassicLink enabled.

5. Complete the rest of the steps in the wizard to launch your instance. For more information, see Launch an instance using the Launch Instance Wizard (p. 477).

**View your ClassicLink-enabled VPCs and linked instances**

You can view all of your ClassicLink-enabled VPCs in the Amazon VPC console, and your linked EC2-Classic instances in the Amazon EC2 console.

**To view your ClassicLink-enabled VPCs**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select the VPC.
4. If the value of **ClassicLink** is **Enabled**, then the VPC is enabled for ClassicLink.

**Enable ClassicLink DNS support**

You can enable ClassicLink DNS support for your VPC so that DNS hostnames that are addressed between linked EC2-Classic instances and instances in the VPC resolve to private IP addresses and not public IP addresses. For this feature to work, your VPC must be enabled for DNS hostnames and DNS resolution.

**Note**

If you enable ClassicLink DNS support for your VPC, your linked EC2-Classic instance can access any private hosted zone associated with the VPC. For more information, see Working with Private Hosted Zones in the Amazon Route 53 Developer Guide.

**To enable ClassicLink DNS support**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select the VPC.
5. For **ClassicLink DNS support**, select **Enable**.
6. Choose **Save changes**.

**Disable ClassicLink DNS support**

You can disable ClassicLink DNS support for your VPC so that DNS hostnames that are addressed between linked EC2-Classic instances and instances in the VPC resolve to public IP addresses and not private IP addresses.

**To disable ClassicLink DNS support**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select the VPC.
5. For **ClassicLink DNS Support**, clear **Enable**.

6. Choose **Save changes**.

**Unlink an instance from a VPC**

If you no longer require a ClassicLink connection between your EC2-Classic instance and your VPC, you can unlink the instance from the VPC. Unlinking the instance disassociates the VPC security groups from the instance.

A stopped instance is automatically unlinked from a VPC.

**To unlink an instance from a VPC**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select one or more of your instances.
4. Choose **Actions**, **ClassicLink**, **Unlink from VPC**.
5. When prompted for confirmation, choose **Unlink**.

**Disable ClassicLink for a VPC**

If you no longer require a connection between EC2-Classic instances and your VPC, you can disable ClassicLink on the VPC. You must first unlink all linked EC2-Classic instances that are linked to the VPC.

**To disable ClassicLink for a VPC**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select your VPC.
4. Choose **Actions**, **Disable ClassicLink**.
5. When prompted for confirmation, choose **Disable ClassicLink**.

**Example IAM policies for ClassicLink**

You can enable a VPC for ClassicLink and then link an EC2-Classic instance to the VPC. You can also view your ClassicLink-enabled VPCs, and all of your EC2-Classic instances that are linked to a VPC. You can create policies with resource-level permission for the `ec2:EnableVpcClassicLink`, `ec2:DisableVpcClassicLink`, `ec2:AttachClassicLinkVpc`, and `ec2:DetachClassicLinkVpc` actions to control how users are able to use those actions. Resource-level permissions are not supported for `ec2:Describe*` actions.

**Examples**

- Full permissions to work with ClassicLink (p. 1048)
- Enable and disable a VPC for ClassicLink (p. 1049)
- Link instances (p. 1049)
- Unlink instances (p. 1050)

**Full permissions to work with ClassicLink**

The following policy grants users permissions to view ClassicLink-enabled VPCs and linked EC2-Classic instances, to enable and disable a VPC for ClassicLink, and to link and unlink instances from a ClassicLink-enabled VPC.
Enable and disable a VPC for ClassicLink

The following policy allows user to enable and disable VPCs for ClassicLink that have the specific tag 'purpose=classiclink'. Users cannot enable or disable any other VPCs for ClassicLink.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:*VpcClassicLink"],
            "Condition": {
                "StringEquals": {
                    "ec2:ResourceTag/purpose":"classiclink"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:AttachClassicLinkVpc"],
        }
    ]
}
```

Link instances

The following policy grants users permissions to link instances to a VPC only if the instance is an m3.large instance type. The second statement allows users to use the VPC and security group resources, which are required to link an instance to a VPC.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:AttachClassicLinkVpc"],
            "Condition": {
                "StringEquals": {
                    "ec2:InstanceType": "m3.large"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:AttachClassicLinkVpc"],
        }
    ]
}
```
The following policy grants users permissions to link instances to a specific VPC (vpc-1a2b3c4d) only, and to associate only specific security groups from the VPC to the instance (sg-1122aabb and sg-aabb2233). Users cannot link an instance to any other VPC, and they cannot specify any other of the VPC security groups to associate with the instance in the request.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:AttachClassicLinkVpc",
      "Resource": [
        "arn:aws:ec2:region:account:vpc/vpc-1a2b3c4d",
        "arn:aws:ec2:region:account:instance/*",
        "arn:aws:ec2:region:account:security-group/sg-aabb2233"
      ]
    }
  ]
}
```

**Unlink instances**

The following grants users permission to unlink any linked EC2-Classic instance from a VPC, but only if the instance has the tag "unlink=true". The second statement grants users permissions to use the VPC resource, which is required to unlink an instance from a VPC.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:DetachClassicLinkVpc",
      "Resource": [
        "arn:aws:ec2:region:account:instance/*"
      ],
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/unlink":"true"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DetachClassicLinkVpc",
      "Resource": [
        "arn:aws:ec2:region:account:vpc/*"
      ]
    }
  ]
}
```

**Example: ClassicLink security group configuration for a three-tier web application**

In this example, you have an application with three instances: a public-facing web server, an application server, and a database server. Your web server accepts HTTPS traffic from the Internet, and then
communicates with your application server over TCP port 6001. Your application server then communicates with your database server over TCP port 6004. You’re in the process of migrating your entire application to a VPC in your account. You’ve already migrated your application server and your database server to your VPC. Your web server is still in EC2-Classic and linked to your VPC via ClassicLink.

You want a security group configuration that allows traffic to flow only between these instances. You have four security groups: two for your web server (sg-1a1a1a1a and sg-2b2b2b2b), one for your application server (sg-3c3c3c3c), and one for your database server (sg-4d4d4d4d).

The following diagram displays the architecture of your instances, and their security group configuration.

Security groups for your web server (sg-1a1a1a1a and sg-2b2b2b2b)

You have one security group in EC2-Classic, and the other in your VPC. You associated the VPC security group with your web server instance when you linked the instance to your VPC via ClassicLink. The VPC security group enables you to control the outbound traffic from your web server to your application server.

The following are the security group rules for the EC2-Classic security group (sg-1a1a1a1a).

<table>
<thead>
<tr>
<th>Source</th>
<th>Type</th>
<th>Port Range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>HTTPS</td>
<td>443</td>
<td>Allows Internet traffic to reach your web server.</td>
</tr>
</tbody>
</table>

The following are the security group rules for the VPC security group (sg-2b2b2b2b).
### Outbound

<table>
<thead>
<tr>
<th>Destination</th>
<th>Type</th>
<th>Port Range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>sg-3c3c3c3c</td>
<td>TCP</td>
<td>6001</td>
<td>Allows outbound traffic from your web server to your application server in your VPC (or to any other instance associated with sg-3c3c3c3c).</td>
</tr>
</tbody>
</table>

### Security group for your application server (sg-3c3c3c3c)

The following are the security group rules for the VPC security group that's associated with your application server.

### Inbound

<table>
<thead>
<tr>
<th>Source</th>
<th>Type</th>
<th>Port Range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>sg-2b2b2b2b</td>
<td>TCP</td>
<td>6001</td>
<td>Allows the specified type of traffic from your web server (or any other instance associated with sg-2b2b2b2b) to reach your application server.</td>
</tr>
</tbody>
</table>

### Outbound

</tbody>
</table>
Migrate from EC2-Classic to a VPC

If you created your AWS account before December 4, 2013, you might have support for EC2-Classic in some AWS Regions. Some Amazon EC2 resources and features, such as enhanced networking and newer instance types, require a virtual private cloud (VPC). Some resources can be shared between EC2-Classic and a VPC, while some can’t. For more information, see Share and access resources between EC2-Classic and a VPC (p. 1040). We recommend that you migrate to a VPC to take advantage of VPC-only features.

To migrate from EC2-Classic to a VPC, you must migrate or recreate your EC2-Classic resources in a VPC. You can migrate and recreate your resources in full, or you can perform an incremental migration over time using ClassicLink.

Contents
- Options for getting a default VPC (p. 1053)
- Migrate your resources to a VPC (p. 1054)
- Use ClassicLink for an incremental migration (p. 1058)
- Example: Migrate a simple web application (p. 1059)

Options for getting a default VPC

A default VPC is a VPC that is configured and ready for you to use, and is only available in Regions that are VPC-only. For Regions that support EC2-Classic, you can create a nondefault VPC to set up your resources. However, you might want to use a default VPC if you prefer not to set up a VPC yourself, or if you do not have specific requirements for your VPC configuration. For more information about default VPCs, see Default VPC and Default Subnets in the Amazon VPC User Guide.

The following are options for using a default VPC when you have an AWS account that supports EC2-Classic.

Options
- Switch to a VPC-only Region (p. 1053)
- Create a new AWS account (p. 1053)
- Convert your existing AWS account to VPC-only (p. 1053)

Switch to a VPC-only Region

Use this option if you want to use your existing account to set up your resources in a default VPC and you do not need to use a specific Region. To find a Region that has a default VPC, see Detect supported platforms (p. 1034).

Create a new AWS account

New AWS accounts support VPC only. Use this option if you want an account that has a default VPC in every Region.

Convert your existing AWS account to VPC-only

Use this option if you want a default VPC in every Region in your existing account. Before you can convert your account, you must delete all of your EC2-Classic resources. You can also migrate some resources to a VPC. For more information, see Migrate your resources to a VPC (p. 1054).

To convert your EC2-Classic account

1. Delete or migrate (if applicable) the resources that you have created for use in EC2-Classic. These include the following:
Migrate from EC2-Classic to a VPC

- Amazon EC2 instances
- EC2-Classic security groups (excluding the default security group, which you cannot delete yourself)
- EC2-Classic Elastic IP addresses
- Classic Load Balancers
- Amazon RDS resources
- Amazon ElastiCache resources
- Amazon Redshift resources
- AWS Elastic Beanstalk resources
- AWS Data Pipeline resources
- Amazon EMR resources
- AWS OpsWorks resources

2. Go to the Amazon Web Services Support Center at console.aws.amazon.com/support.
3. Choose Create case.
4. Choose Account and billing support.
5. For Type, choose Account. For Category, choose Convert EC2 Classic to VPC.
6. Fill in the other details as required, and choose Submit. We will review your request and contact you to guide you through the next steps.

Migrate your resources to a VPC

You can migrate or move some of your resources to a VPC. Some resources can only be migrated from EC2-Classic to a VPC that's in the same Region and in the same AWS account. If the resource cannot be migrated, you must create a new resource for use in your VPC.

Prerequisites

Before you begin, you must have a VPC. If you don't have a default VPC, you can create a nondefault VPC using one of these methods:

- In the Amazon VPC console, use the VPC wizard to create a new VPC. For more information, see Amazon VPC Console Wizard Configurations. Use this option if you want to set up a VPC quickly, using one of the available configuration options.
- In the Amazon VPC console, set up the components of a VPC according to your requirements. For more information, see VPCs and Subnets. Use this option if you have specific requirements for your VPC, such as a particular number of subnets.

Topics

- Security groups (p. 1054)
- Elastic IP addresses (p. 1055)
- AMIs and instances (p. 1055)
- Amazon RDS DB instances (p. 1058)

Security groups

If you want your instances in your VPC to have the same security group rules as your EC2-Classic instances, you can use the Amazon EC2 console to copy your existing EC2-Classic security group rules to a new VPC security group.
You can only copy security group rules to a new security group in the same AWS account in the same Region. If you are using a different Region or a different AWS account, you must create a new security group and manually add the rules yourself. For more information, see Amazon EC2 security groups for Linux instances (p. 1152).

To copy your security group rules to a new security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group that's associated with your EC2-Classic instance, then choose Actions, and select Copy to new.
   
   **Note**
   
   To identify an EC2-Classic security group, check the VPC ID column. For each EC2-Classic security group, the value in the column is blank or a – symbol.

4. In the Create Security Group dialog box, specify a name and description for your new security group. Select your VPC from the VPC list.
5. The Inbound tab is populated with the rules from your EC2-Classic security group. You can modify the rules as required. In the Outbound tab, a rule that allows all outbound traffic has automatically been created for you. For more information about modifying security group rules, see Amazon EC2 security groups for Linux instances (p. 1152).
   
   **Note**
   
   If you've defined a rule in your EC2-Classic security group that references another security group, you cannot use the same rule in your VPC security group. Modify the rule to reference a security group in the same VPC.

6. Choose Create.

Elastic IP addresses

You can migrate an Elastic IP address that is allocated for use in EC2-Classic for use with a VPC. You cannot migrate an Elastic IP address to another Region or AWS account. For more information, see Migrate an Elastic IP Address from EC2-Classic (p. 1039).

To identify an Elastic IP address that is allocated for use in EC2-Classic

In the Amazon EC2 console, choose Elastic IPs in the navigation pane. In the Scope column, the value is standard.

Alternatively, use the following describe-addresses command.

```
aws ec2 describe-addresses --filters Name=domain,Values=standard
```

AMIs and instances

An AMI is a template for launching your Amazon EC2 instance. You can create your own AMI based on an existing EC2-Classic instance, then use that AMI to launch instances into your VPC.

Contents

- Identify EC2-Classic instances (p. 1056)
- Create an AMI (p. 1056)
- (Optional) Share or copy your AMI (p. 1057)
- (Optional) Store your data on Amazon EBS volumes (p. 1057)
- Launch an instance into your VPC (p. 1057)
**Identify EC2-Classic instances**

If you have instances running in both EC2-Classic and a VPC, you can identify your EC2-Classic instances.

**Amazon EC2 console**

Choose **Instances** in the navigation pane. In the **VPC ID** column, the value for each EC2-Classic instance is blank or a – symbol. If the **VPC ID** column is not present, choose the gear icon and make the column visible.

**AWS CLI**

Use the following `describe-instances` AWS CLI command. The `--query` parameter displays only instances where the value for `VpcId` is null.

```
aws ec2 describe-instances --query 'Reservations[*].Instances[?VpcId==`null`]'
```

**Create an AMI**

After you've identified your EC2-Classic instance, you can create an AMI from it.

**To create a Windows AMI**

For more information, see [Creating a custom Windows AMI](#).

**To create a Linux AMI**

The method that you use to create your Linux AMI depends on the root device type of your instance, and the operating system platform on which your instance runs. To find out the root device type of your instance, go to the **Instances** page, select your instance, and look at the information in the **Root device type** field in the **Description** tab. If the value is `ebs`, then your instance is EBS-backed. If the value is `instance-store`, then your instance is instance store-backed. You can also use the `describe-instances` AWS CLI command to find out the root device type.

The following table provides options for you to create your Linux AMI based on the root device type of your instance, and the software platform.

**Important**

Some instance types support both PV and HVM virtualization, while others support only one or the other. If you plan to use your AMI to launch a different instance type than your current instance type, verify that the instance type supports the type of virtualization that your AMI offers. If your AMI supports PV virtualization, and you want to use an instance type that supports HVM virtualization, you might have to reinstall your software on a base HVM AMI. For more information about PV and HVM virtualization, see [Linux AMI virtualization types](#).

<table>
<thead>
<tr>
<th>Instance root device type</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBS</td>
<td>Create an EBS-backed AMI from your instance. For more information, see <a href="#">Creating an Amazon EBS-backed Linux AMI</a>.</td>
</tr>
<tr>
<td>Instance store</td>
<td>Create an instance store-backed AMI from your instance using the AMI tools. For more information, see <a href="#">Creating an instance store-backed Linux AMI</a>.</td>
</tr>
<tr>
<td>Instance store</td>
<td>Convert your instance store-backed instance to an EBS-backed instance. For more information, see <a href="#">Converting your instance store-backed AMI to an Amazon EBS-backed AMI</a>.</td>
</tr>
</tbody>
</table>
(Optional) Share or copy your AMI

To use your AMI to launch an instance in a new AWS account, you must first share the AMI with your new account. For more information, see Share an AMI with specific AWS accounts (p. 92).

To use your AMI to launch an instance in a VPC in a different Region, you must first copy the AMI to that Region. For more information, see Copy an AMI (p. 138).

(Optional) Store your data on Amazon EBS volumes

You can create an Amazon EBS volume and use it to back up and store the data on your instance—like you would use a physical hard drive. Amazon EBS volumes can be attached and detached from any instance in the same Availability Zone. You can detach a volume from your instance in EC2-Classic, and attach it to a new instance that you launch into your VPC in the same Availability Zone.

For more information about Amazon EBS volumes, see the following topics:

- Amazon EBS volumes (p. 1177)
- Create an Amazon EBS volume (p. 1199)
- Attach an Amazon EBS volume to an instance (p. 1202)

To back up the data on your Amazon EBS volume, you can take periodic snapshots of your volume. For more information, see Create Amazon EBS snapshots (p. 1231). If you need to, you can create an Amazon EBS volume from your snapshot. For more information, see Create a volume from a snapshot (p. 1201).

Launch an instance into your VPC

After you've created an AMI, you can use the Amazon EC2 launch wizard to launch an instance into your VPC. The instance will have the same data and configurations as your existing EC2-Classic instance.

**Note**

You can use this opportunity to upgrade to a current generation instance type. However, verify that the instance type supports the type of virtualization that your AMI offers (PV or HVM). For more information about PV and HVM virtualization, see Linux AMI virtualization types (p. 75).

**To launch an instance into your VPC**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the dashboard, choose Launch instance.
3. On the Choose an Amazon Machine Image page, select the My AMIs category, and select the AMI you created. Alternatively, if you shared an AMI from another account, in the Ownership filter list, choose Shared with me. Select the AMI that you shared from your EC2-Classic account.
4. On the Choose an Instance Type page, select the type of instance, and choose Next: Configure Instance Details.
5. On the Configure Instance Details page, select your VPC from the Network list. Select the required subnet from the Subnet list. Configure any other details that you require, then go through the next pages of the wizard until you reach the Configure Security Group page.
6. Select Select an existing group, and select the security group that you created for your VPC. Choose Review and Launch.
7. Review your instance details, then choose Launch to specify a key pair and launch your instance.

For more information about the parameters that you can configure in each step of the wizard, see Launch an instance using the Launch Instance Wizard (p. 477).
### Amazon RDS DB instances

You can move your EC2-Classic DB instance to a VPC in the same Region, in the same account. For more information, see **Updating the VPC for a DB Instance** in the *Amazon RDS User Guide*.

### Use ClassicLink for an incremental migration

The ClassicLink feature makes it easier to manage an incremental migration to a VPC. ClassicLink enables you to link an EC2-Classic instance to a VPC in your account in the same Region, allowing your new VPC resources to communicate with the EC2-Classic instance using private IPv4 addresses. You can then migrate functionality one component at a time until your application is running fully in your VPC.

Use this option if you cannot afford downtime during the migration, for example, if you have a multi-tier application with processes that cannot be interrupted.

For more information about ClassicLink, see **ClassicLink** (p. 1041).

**Tasks**

- Step 1: Prepare your migration sequence (p. 1058)
- Step 2: Enable your VPC for ClassicLink (p. 1058)
- Step 3: Link your EC2-Classic instances to your VPC (p. 1058)
- Step 4: Complete the VPC migration (p. 1059)

**Step 1: Prepare your migration sequence**

To use ClassicLink effectively, you must first identify the components of your application that must be migrated to the VPC, and then confirm the order in which to migrate that functionality.

For example, you have an application that relies on a presentation web server, a backend database server, and authentication logic for transactions. You may decide to start the migration process with the authentication logic, then the database server, and finally, the web server.

Then, you can start migrating or recreating your resources. For more information, see **Migrate your resources to a VPC** (p. 1054).

**Step 2: Enable your VPC for ClassicLink**

After you've configured your new VPC instances and made the functionality of your application available in the VPC, you can use ClassicLink to enable private IP communication between your new VPC instances and your EC2-Classic instances. First, you must enable your VPC for ClassicLink.

**To enable a VPC for ClassicLink**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select a VPC.
4. Choose **Actions, Enable ClassicLink**.
5. When prompted for confirmation, choose **Enable ClassicLink**.

**Step 3: Link your EC2-Classic instances to your VPC**

After you've enabled ClassicLink in your VPC, you can link your EC2-Classic instances to the VPC. The instance must be in the **running** state.
To link an instance to a VPC

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select one or more running EC2-Classic instances.
4. Choose Actions, ClassicLink, Link to VPC.
5. Choose a VPC. The console displays only VPCs that are enabled for ClassicLink.
6. Select one or more security groups to associate with your instances. The console displays security groups only for VPCs enabled for ClassicLink.
7. Choose Link.

Step 4: Complete the VPC migration

Depending on the size of your application and the functionality that must be migrated, repeat the preceding steps until you've moved all of the components of your application from EC2-Classic into your VPC.

After you've enabled internal communication between the EC2-Classic and VPC instances, you must update your application to point to your migrated service in your VPC, instead of your service in the EC2-Classic platform. The exact steps for this depend on your application's design. Generally, this includes updating your destination IP addresses to point to the IP addresses of your VPC instances instead of your EC2-Classic instances.

After you've completed this step and you've tested that the application is functioning from your VPC, you can terminate your EC2-Classic instances, and disable ClassicLink for your VPC. You can also clean up any EC2-Classic resources that you no longer need to avoid incurring charges for them. For example, you can release Elastic IP addresses and delete the volumes that were associated with your EC2-Classic instances.

Example: Migrate a simple web application

In this example, you use AWS to host your gardening website. To manage your website, you have three running instances in EC2-Classic. Instances A and B host your public-facing web application, and you use Elastic Load Balancing to load balance the traffic between these instances. You've assigned Elastic IP addresses to instances A and B so that you have static IP addresses for configuration and administration tasks on those instances. Instance C holds your MySQL database for your website. You've registered the domain name www.garden.example.com, and you've used Route 53 to create a hosted zone with an alias record set that's associated with the DNS name of your load balancer.

The first part of migrating to a VPC is deciding what kind of VPC architecture suits your needs. In this case, you've decided on the following: one public subnet for your web servers, and one private subnet for
To migrate your web application to a VPC, you can follow these steps:

- **Create a VPC:** In this case, you can use the VPC wizard in the Amazon VPC console to create your VPC and subnets. The second wizard configuration creates a VPC with one private and one public subnet, and launches and configures a NAT device in your public subnet for you. For more information, see [VPC with public and private subnets (NAT)](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/) in the Amazon VPC User Guide.

- **Configure your security groups:** In your EC2-Classic environment, you have one security group for your web servers, and another security group for your database server. You can use the Amazon EC2 console to copy the rules from each security group into new security groups for your VPC. For more information, see [Security groups](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/) (p. 1054).

  **Tip**
  Create the security groups that are referenced by other security groups first.

- **Create AMIs and launch new instances:** Create an AMI from one of your web servers, and a second AMI from your database server. Then, launch replacement web servers into your public subnet, and launch your replacement database server into your private subnet. For more information, see [Create an AMI](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/) (p. 1056).

- **Configure your NAT device:** If you are using a NAT instance, you must create a security group for it that allows HTTP and HTTPS traffic from your private subnet. For more information, see [NAT instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/) (if you are using a NAT gateway, traffic from your private subnet is automatically allowed).

- **Configure your database:** When you created an AMI from your database server in EC2-Classic, all of the configuration information that was stored in that instance was copied to the AMI. You might have to connect to your new database server and update the configuration details. For example, if you configured your database to grant full read, write, and modification permissions to your web servers in
EC2-Classic, you need to update the configuration files to grant the same permissions to your new VPC web servers instead.

- **Configure your web servers**: Your web servers will have the same configuration settings as your instances in EC2-Classic. For example, if you configured your web servers to use the database in EC2-Classic, update your web servers’ configuration settings to point to your new database instance.

  **Note**
  By default, instances launched into a nondefault subnet are not assigned a public IP address, unless you specify otherwise at launch. Your new database server might not have a public IP address. In this case, you can update your web servers’ configuration file to use your new database server’s private DNS name. Instances in the same VPC can communicate with each other via private IP address.

- **Migrate your Elastic IP addresses**: Disassociate your Elastic IP addresses from your web servers in EC2-Classic, and then migrate them to a VPC. After you’ve migrated them, you can associate them with your new web servers in your VPC. For more information, see [Migrate an Elastic IP Address from EC2-Classic](p. 1039).

- **Create a new load balancer**: To continue using Elastic Load Balancing to load balance the traffic to your instances, make sure you understand the various ways to configure your load balancer in VPC. For more information, see the Elastic Load Balancing User Guide.

- **Update your DNS records**: After you’ve set up your load balancer in your public subnet, verify that your www.garden.example.com domain points to your new load balancer. To do this, update your DNS records and your alias record set in Route 53. For more information about using Route 53, see [Getting Started with Route 53](p. 1061).

- **Shut down your EC2-Classic resources**: After you’ve verified that your web application is working from within the VPC architecture, you can shut down your EC2-Classic resources to stop incurring charges for them.
Security in Amazon EC2

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Amazon EC2, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility includes the following areas:
  - Controlling network access to your instances, for example, through configuring your VPC and security groups. For more information, see Controlling network traffic (p. 1063).
  - Managing the credentials used to connect to your instances.
  - Managing the guest operating system and software deployed to the guest operating system, including updates and security patches. For more information, see Update management in Amazon EC2 (p. 1172).
  - Configuring the IAM roles that are attached to the instance and the permissions associated with those roles. For more information, see IAM roles for Amazon EC2 (p. 1125).

This documentation helps you understand how to apply the shared responsibility model when using Amazon EC2. It shows you how to configure Amazon EC2 to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EC2 resources.

**Contents**

- Update management in Amazon EC2 (p. 1172)
- Compliance validation for Amazon EC2 (p. 1173)

Infrastructure security in Amazon EC2

As a managed service, Amazon EC2 is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Amazon EC2 through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support
cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

**Network isolation**

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the AWS Cloud. Use separate VPCs to isolate infrastructure by workload or organizational entity.

A subnet is a range of IP addresses in a VPC. When you launch an instance, you launch it into a subnet in your VPC. Use subnets to isolate the tiers of your application (for example, web, application, and database) within a single VPC. Use private subnets for your instances if they should not be accessed directly from the internet.

To call the Amazon EC2 API from your VPC without sending traffic over the public internet, use AWS PrivateLink.

**Isolation on physical hosts**

Different EC2 instances on the same physical host are isolated from each other as though they are on separate physical hosts. The hypervisor isolates CPU and memory, and the instances are provided virtualized disks instead of access to the raw disk devices.

When you stop or terminate an instance, the memory allocated to it is scrubbed (set to zero) by the hypervisor before it is allocated to a new instance, and every block of storage is reset. This ensures that your data is not unintentionally exposed to another instance.

Network MAC addresses are dynamically assigned to instances by the AWS network infrastructure. IP addresses are either dynamically assigned to instances by the AWS network infrastructure, or assigned by an EC2 administrator through authenticated API requests. The AWS network allows instances to send traffic only from the MAC and IP addresses assigned to them. Otherwise, the traffic is dropped.

By default, an instance cannot receive traffic that is not specifically addressed to it. If you need to run network address translation (NAT), routing, or firewall services on your instance, you can disable source/destination checking for the network interface.

**Controlling network traffic**

Consider the following options for controlling network traffic to your EC2 instances:

- Restrict access to your instances using security groups (p. 1152). For example, you can allow traffic only from the address ranges for your corporate network.
- Use private subnets for your instances if they should not be accessed directly from the internet. Use a bastion host or NAT gateway for internet access from an instance in a private subnet.
- Use AWS Virtual Private Network or AWS Direct Connect to establish private connections from your remote networks to your VPCs. For more information, see Network-to-Amazon VPC Connectivity Options.
- Use VPC Flow Logs to monitor the traffic that reaches your instances.
- Use AWS Security Hub to check for unintended network accessibility from your instances.
- Use EC2 Instance Connect (p. 505) to connect to your instances using Secure Shell (SSH) without the need to share and manage SSH keys.
• Use **AWS Systems Manager Session Manager** to access your instances remotely instead of opening inbound SSH ports and managing SSH keys.

• Use **AWS Systems Manager Run Command** to automate common administrative tasks instead of opening inbound SSH ports and managing SSH keys.

In addition to restricting network access to each Amazon EC2 instance, Amazon VPC supports implementing additional network security controls like in-line gateways, proxy servers, and various network monitoring options.

For more information, see the [AWS Security Best Practices](https://aws.amazon.com/security) whitepaper.

### Amazon EC2 and interface VPC endpoints

You can improve the security posture of your VPC by configuring Amazon EC2 to use an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that enables you to privately access Amazon EC2 APIs by restricting all network traffic between your VPC and Amazon EC2 to the Amazon network. With interface endpoints, you also don’t need an internet gateway, a NAT device, or a virtual private gateway.

You are not required to configure AWS PrivateLink, but it’s recommended. For more information about AWS PrivateLink and VPC endpoints, see [Interface VPC Endpoints (AWS PrivateLink)](https://aws.amazon.com/privatelink).

#### Topics

- Create an interface VPC endpoint (p. 1064)
- Create an interface VPC endpoint policy (p. 1064)

### Create an interface VPC endpoint

Create an endpoint for Amazon EC2 using the following service name:

- `com.amazonaws.region.ec2` — Creates an endpoint for the Amazon EC2 API actions.

For more information, see Creating an Interface Endpoint in the [Amazon VPC User Guide](https://docs.aws.amazon.com/vpc/latest/userguide/).

### Create an interface VPC endpoint policy

You can attach a policy to your VPC endpoint to control access to the Amazon EC2 API. The policy specifies:

- The principal that can perform actions.
- The actions that can be performed.
- The resource on which the actions can be performed.

**Important**

When a non-default policy is applied to an interface VPC endpoint for Amazon EC2, certain failed API requests, such as those failing from `RequestLimitExceeded`, might not be logged to AWS CloudTrail or Amazon CloudWatch.

For more information, see Controlling Access to Services with VPC Endpoints in the [Amazon VPC User Guide](https://docs.aws.amazon.com/vpc/latest/userguide/).
The following example shows a VPC endpoint policy that denies permission to create unencrypted volumes or to launch instances with unencrypted volumes. The example policy also grants permission to perform all other Amazon EC2 actions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "ec2:*",
            "Effect": "Allow",
            "Resource": "*",
            "Principal": "*"
        },
        {
            "Action": [
                "ec2:CreateVolume"
            ],
            "Effect": "Deny",
            "Resource": "*",
            "Principal": "*",
            "Condition": {
                "Bool": {
                    "ec2:Encrypted": "false"
                }
            }
        },
        {
            "Action": [
                "ec2:RunInstances"
            ],
            "Effect": "Deny",
            "Resource": "*",
            "Principal": "*",
            "Condition": {
                "Bool": {
                    "ec2:Encrypted": "false"
                }
            }
        }
    ]
}
```

Resilience in Amazon EC2

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

If you need to replicate your data or applications over greater geographic distances, use AWS Local Zones. An AWS Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Like all AWS Regions, AWS Local Zones are completely isolated from other AWS Zones.

If you need to replicate your data or applications in an AWS Local Zone, AWS recommends that you use one of the following zones as the failover zone:

- Another Local Zone
Data protection in Amazon EC2

The AWS shared responsibility model applies to data protection in Amazon Elastic Compute Cloud. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon EC2 or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.
Amazon EBS encryption is an encryption solution for your EBS volumes and snapshots. It uses AWS KMS keys. For more information, see Amazon EBS encryption (p. 1335).

**Instance store volumes**

The data on NVMe instance store volumes is encrypted using an XTS-AES-256 cipher implemented on a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

The data on HDD instance store volumes on H1, D3, and D3en instances is encrypted using XTS-AES-256 and one-time keys.

**Memory**

Memory encryption is enabled on the following instances:

- Instances with AWS Graviton 2 processors, such as M6g instances. These processors support always-on memory encryption. The encryption keys are securely generated within the host system, do not leave the host system, and are destroyed when the host is rebooted or powered down.
- Instances with Intel Xeon Scalable processors (Ice Lake), such as M6i instances. These processors support always-on memory encryption using Intel Total Memory Encryption (TME).

**Encryption in transit**

**Encryption at the physical layer**

All data flowing across AWS Regions over the AWS global network is automatically encrypted at the physical layer before it leaves AWS secured facilities. All traffic between AZs is encrypted. Additional layers of encryption, including those listed in this section, may provide additional protections.

**Encryption provided by Amazon VPC and Transit Gateway cross-Region peering**

All cross-Region traffic that uses Amazon VPC and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all cross-Region traffic, as previously noted in this section.

**Encryption between instances**

AWS provides secure and private connectivity between EC2 instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances, using AEAD algorithms with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - General purpose: M5dn | M5n | M5zn | M6i
  - Compute optimized: C5a | C5ad | C5n | C6gn
  - Memory optimized: R5dn | R5n | high memory (u-*), virtualized only
  - Storage optimized: D3 | D3en | I3en
  - Accelerated computing: G4ad | G4dn | Inf1 | P3dn | P4d
- The instances are in the same Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.
An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves AWS secured facilities, as previously noted in this section.

**To view the instance types that encrypt in-transit traffic between instances using the AWS CLI**

Use the following `describe-instance-types` command.

```bash
aws ec2 describe-instance-types \
  --filters Name=network-info.encryption-in-transit-supported,Values=true \
  --query "InstanceTypes[*].[InstanceType]" --output text
```

**Encryption to and from AWS Outposts**

An Outpost creates special network connections called *service links* to its AWS home Region and, optionally, private connectivity to a VPC subnet that you specify. All traffic over those connection is fully encrypted. For more information, see *Connectivity through service links* and *Encryption in transit* in the *AWS Outposts User Guide*.

**Remote access encryption**

SSH provides a secure communications channel for remote access to your Linux instances, whether directly or through EC2 Instance Connect. Remote access to your instances using AWS Systems Manager Session Manager or the Run Command is encrypted using TLS 1.2, and requests to create a connection are signed using SigV4 and authenticated and authorized by *AWS Identity and Access Management*.

It is your responsibility to use an encryption protocol, such as Transport Layer Security (TLS), to encrypt sensitive data in transit between clients and your Amazon EC2 instances.

**Identity and access management for Amazon EC2**

Your security credentials identify you to services in AWS and grant you unlimited use of your AWS resources, such as your Amazon EC2 resources. You can use features of Amazon EC2 and AWS Identity and Access Management (IAM) to allow other users, services, and applications to use your Amazon EC2 resources without sharing your security credentials. You can use IAM to control how other users use resources in your AWS account, and you can use security groups to control access to your Amazon EC2 instances. You can choose to allow full use or limited use of your Amazon EC2 resources.

**Contents**

- Network access to your instance (p. 1068)
- Amazon EC2 permission attributes (p. 1069)
- IAM and Amazon EC2 (p. 1069)
- IAM policies for Amazon EC2 (p. 1070)
- AWS managed policies for Amazon Elastic Compute Cloud (p. 1124)
- IAM roles for Amazon EC2 (p. 1125)
- Authorize inbound traffic for your Linux instances (p. 1134)

**Network access to your instance**

A security group acts as a firewall that controls the traffic allowed to reach one or more instances. When you launch an instance, you assign it one or more security groups. You add rules to each security group that control traffic for the instance. You can modify the rules for a security group at any time; the new rules are automatically applied to all instances to which the security group is assigned.
Amazon EC2 permission attributes

Your organization might have multiple AWS accounts. Amazon EC2 enables you to specify additional AWS accounts that can use your Amazon Machine Images (AMIs) and Amazon EBS snapshots. These permissions work at the AWS account level only; you can’t restrict permissions for specific users within the specified AWS account. All users in the AWS account that you’ve specified can use the AMI or snapshot.

Each AMI has a LaunchPermission attribute that controls which AWS accounts can access the AMI. For more information, see Make an AMI public (p. 91).

Each Amazon EBS snapshot has a createVolumePermission attribute that controls which AWS accounts can use the snapshot. For more information, see Share an Amazon EBS snapshot (p. 1242).

IAM and Amazon EC2

IAM enables you to do the following:

- Create users and groups under your AWS account
- Assign unique security credentials to each user under your AWS account
- Control each user’s permissions to perform tasks using AWS resources
- Allow the users in another AWS account to share your AWS resources
- Create roles for your AWS account and define the users or services that can assume them
- Use existing identities for your enterprise to grant permissions to perform tasks using AWS resources

By using IAM with Amazon EC2, you can control whether users in your organization can perform a task using specific Amazon EC2 API actions and whether they can use specific AWS resources.

This topic helps you answer the following questions:

- How do I create groups and users in IAM?
- How do I create a policy?
- What IAM policies do I need to carry out tasks in Amazon EC2?
- How do I grant permissions to perform actions in Amazon EC2?
- How do I grant permissions to perform actions on specific resources in Amazon EC2?

Create an IAM group and users

To create an IAM group

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Groups and then choose Create New Group.
3. For Group Name, enter a name for your group, and then choose Next Step.
4. On the Attach Policy page, select an AWS managed policy and then choose Next Step. For example, for Amazon EC2, one of the following AWS managed policies might meet your needs:
   - PowerUserAccess
   - ReadOnlyAccess
   - AmazonEC2FullAccess
IAM policies

5. Choose Create Group.

Your new group is listed under Group Name.

To create an IAM user, add the user to your group, and create a password for the user

1. In the navigation pane, choose Users, Add user.
2. For User name, enter a user name.
3. For Access type, select both Programmatic access and AWS Management Console access.
4. For Console password, choose one of the following:
   - Autogenerated password. Each user gets a randomly generated password that meets the current password policy in effect (if any). You can view or download the passwords when you get to the Final page.
   - Custom password. Each user is assigned the password that you enter in the box.
5. Choose Next: Permissions.
6. On the Set permissions page, choose Add user to group. Select the check box next to the group that you created earlier and choose Next: Review.
7. Choose Create user.
8. To view the users' access keys (access key IDs and secret access keys), choose Show next to each password and secret access key to see. To save the access keys, choose Download .csv and then save the file to a safe location.
   Important
   You cannot retrieve the secret access key after you complete this step; if you misplace it you must create a new one.
9. Choose Close.
10. Give each user his or her credentials (access keys and password); this enables them to use services based on the permissions you specified for the IAM group.

IAM policies for Amazon EC2

By default, IAM users don't have permission to create or modify Amazon EC2 resources, or perform tasks using the Amazon EC2 API. (This means that they also can't do so using the Amazon EC2 console or CLI.) To allow IAM users to create or modify resources and perform tasks, you must create IAM policies that grant IAM users permission to use the specific resources and API actions they'll need, and then attach those policies to the IAM users or groups that require those permissions.

When you attach a policy to a user or group of users, it allows or denies the users permission to perform the specified tasks on the specified resources. For more general information about IAM policies, see
Permissions and Policies in the IAM User Guide. For more information about managing and creating custom IAM policies, see Managing IAM Policies.

Getting Started

An IAM policy must grant or deny permissions to use one or more Amazon EC2 actions. It must also specify the resources that can be used with the action, which can be all resources, or in some cases, specific resources. The policy can also include conditions that you apply to the resource.

Amazon EC2 partially supports resource-level permissions. This means that for some EC2 API actions, you cannot specify which resource a user is allowed to work with for that action. Instead, you have to allow users to work with all resources for that action.

Policy structure

The following topics explain the structure of an IAM policy.

Contents

- Policy syntax (p. 1071)
- Actions for Amazon EC2 (p. 1072)
- Supported resource-level permissions for Amazon EC2 API actions (p. 1073)
- Amazon Resource Names (ARNs) for Amazon EC2 (p. 1073)
- Condition keys for Amazon EC2 (p. 1074)
- Check that users have the required permissions (p. 1075)

Policy syntax

An IAM policy is a JSON document that consists of one or more statements. Each statement is structured as follows.
There are various elements that make up a statement:

- **Effect**: The *effect* can be *Allow* or *Deny*. By default, IAM users don't have permission to use resources and API actions, so all requests are denied. An explicit allow overrides the default. An explicit deny overrides any allows.

- **Action**: The *action* is the specific API action for which you are granting or denying permission. To learn about specifying *action*, see Actions for Amazon EC2 (p. 1072).

- **Resource**: The resource that's affected by the action. Some Amazon EC2 API actions allow you to include specific resources in your policy that can be created or modified by the action. You specify a resource using an Amazon Resource Name (ARN) or using the wildcard (*) to indicate that the statement applies to all resources. For more information, see Supported resource-level permissions for Amazon EC2 API actions (p. 1073).

- **Condition**: Conditions are optional. They can be used to control when your policy is in effect. For more information about specifying conditions for Amazon EC2, see Condition keys for Amazon EC2 (p. 1074).

For more information about example IAM policy statements for Amazon EC2, see Example policies for working with the AWS CLI or an AWS SDK (p. 1078).

**Actions for Amazon EC2**

In an IAM policy statement, you can specify any API action from any service that supports IAM. For Amazon EC2, use the following prefix with the name of the API action: `ec2:`. For example: `ec2:RunInstances` and `ec2:CreateImage`.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["ec2:action1", "ec2:action2"]
```

You can also specify multiple actions using wildcards. For example, you can specify all actions whose name begins with the word "Describe" as follows:

```
"Action": "ec2:Describe*"
```

To specify all Amazon EC2 API actions, use the * wildcard as follows:

```
"Action": "ec2:*"
```

For a list of Amazon EC2 actions, see Actions defined by Amazon EC2 in the Service Authorization Reference.
Supported resource-level permissions for Amazon EC2 API actions

Resource-level permissions refers to the ability to specify which resources users are allowed to perform actions on. Amazon EC2 has partial support for resource-level permissions. This means that for certain Amazon EC2 actions, you can control when users are allowed to use those actions based on conditions that have to be fulfilled, or specific resources that users are allowed to use. For example, you can grant users permissions to launch instances, but only of a specific type, and only using a specific AMI.

To specify a resource in an IAM policy statement, use its Amazon Resource Name (ARN). For more information about specifying the ARN value, see Amazon Resource Names (ARNs) for Amazon EC2 (p. 1073). If an API action does not support individual ARNs, you must use a wildcard (*) to specify that all resources can be affected by the action.

To see tables that identify which Amazon EC2 API actions support resource-level permissions, and the ARNs and condition keys that you can use in a policy, see Actions, resources, and condition keys for Amazon EC2.

Keep in mind that you can apply tag-based resource-level permissions in the IAM policies you use for Amazon EC2 API actions. This gives you better control over which resources a user can create, modify, or use. For more information, see Grant permission to tag resources during creation (p. 1075).

Amazon Resource Names (ARNs) for Amazon EC2

Each IAM policy statement applies to the resources that you specify using their ARNs.

An ARN has the following general syntax:

```
arn:aws:[service]:[region]:[account]:resourceType/resourcePath
```

- **service**: The service (for example, ec2).
- **region**: The Region for the resource (for example, us-east-1).
- **account**: The AWS account ID, with no hyphens (for example, 123456789012).
- **resourceType**: The type of resource (for example, instance).
- **resourcePath**: A path that identifies the resource. You can use the * wildcard in your paths.

For example, you can indicate a specific instance (i-1234567890abcdef0) in your statement using its ARN as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"
```

You can specify all instances that belong to a specific account by using the * wildcard as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*"
```

You can also specify all Amazon EC2 resources that belong to a specific account by using the * wildcard as follows.
IAM policies

"Resource": "arn:aws:ec2:us-east-1:123456789012:*"

To specify all resources, or if a specific API action does not support ARNs, use the * wildcard in the Resource element as follows.

"Resource": "*"

Many Amazon EC2 API actions involve multiple resources. For example, AttachVolume attaches an Amazon EBS volume to an instance, so an IAM user must have permissions to use the volume and the instance. To specify multiple resources in a single statement, separate their ARNs with commas, as follows.

"Resource": ["arn1", "arn2"]

For a list of ARNs for Amazon EC2 resources, see Resource types defined by Amazon EC2.

Condition keys for Amazon EC2

In a policy statement, you can optionally specify conditions that control when it is in effect. Each condition contains one or more key-value pairs. Condition keys are not case-sensitive. We've defined AWS-wide condition keys, plus additional service-specific condition keys.

For a list of service-specific condition keys for Amazon EC2, see Condition keys for Amazon EC2. Amazon EC2 also implements the AWS-wide condition keys. For more information, see Information available in all requests in the IAM User Guide.

To use a condition key in your IAM policy, use the Condition statement. For example, the following policy grants users permission to add and remove inbound and outbound rules for any security group. It uses the ec2:Vpc condition key to specify that these actions can only be performed on security groups in a specific VPC.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:AuthorizeSecurityGroupIngress",
      "ec2:AuthorizeSecurityGroupEgress",
      "ec2:RevokeSecurityGroupIngress",
      "ec2:RevokeSecurityGroupEgress"],
    "Condition": {
      "StringEquals": {
      }
    }
  }
}
```

If you specify multiple conditions, or multiple keys in a single condition, we evaluate them using a logical AND operation. If you specify a single condition with multiple values for one key, we evaluate the condition using a logical OR operation. For permissions to be granted, all conditions must be met.

You can also use placeholders when you specify conditions. For example, you can grant an IAM user permission to use resources with a tag that specifies his or her IAM user name. For more information, see IAM policy elements: Variables and tags in the IAM User Guide.
Important

Many condition keys are specific to a resource, and some API actions use multiple resources. If you write a policy with a condition key, use the `Resource` element of the statement to specify the resource to which the condition key applies. If not, the policy may prevent users from performing the action at all, because the condition check fails for the resources to which the condition key does not apply. If you do not want to specify a resource, or if you've written the `Action` element of your policy to include multiple API actions, then you must use the `...IfExists` condition type to ensure that the condition key is ignored for resources that do not use it. For more information, see `...IfExists Conditions` in the IAM User Guide.

All Amazon EC2 actions support the `aws:RequestedRegion` and `ec2:Region` condition keys. For more information, see Example: Restrict access to a specific Region (p. 1079).

The `ec2:SourceInstanceARN` key can be used for conditions that specify the ARN of the instance from which a request is made. This condition key is available AWS-wide and is not service-specific. For policy examples, see Amazon EC2: Attach or detach volumes to an EC2 instance and Example: Allow a specific instance to view resources in other AWS services (p. 1111). The `ec2:SourceInstanceARN` key cannot be used as a variable to populate the ARN for the `Resource` element in a statement.

For example policy statements for Amazon EC2, see Example policies for working with the AWS CLI or an AWS SDK (p. 1078).

Check that users have the required permissions

After you've created an IAM policy, we recommend that you check whether it grants users the permissions to use the particular API actions and resources they need before you put the policy into production.

First, create an IAM user for testing purposes, and then attach the IAM policy that you created to the test user. Then, make a request as the test user.

If the Amazon EC2 action that you are testing creates or modifies a resource, you should make the request using the `DryRun` parameter (or run the AWS CLI command with the `--dry-run` option). In this case, the call completes the authorization check, but does not complete the operation. For example, you can check whether the user can terminate a particular instance without actually terminating it. If the test user has the required permissions, the request returns `DryRunOperation`; otherwise, it returns `UnauthorizedOperation`.

If the policy doesn't grant the user the permissions that you expected, or is overly permissive, you can adjust the policy as needed and retest until you get the desired results.

Important

It can take several minutes for policy changes to propagate before they take effect. Therefore, we recommend that you allow five minutes to pass before you test your policy updates.

If an authorization check fails, the request returns an encoded message with diagnostic information. You can decode the message using the `DecodeAuthorizationMessage` action. For more information, see `DecodeAuthorizationMessage` in the AWS Security Token Service API Reference, and `decode-authorization-message` in the AWS CLI Command Reference.

Grant permission to tag resources during creation

Some resource-creating Amazon EC2 API actions enable you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see Tag your resources (p. 1463) and Control access to EC2 resources using resource tags (p. 1078).

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as `ec2:RunInstances` or `ec2:CreateVolume`. If tags are specified in the resource-
creating action, Amazon performs additional authorization on the `ec2:CreateTags` action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the `ec2:CreateTags` action.

In the IAM policy definition for the `ec2:CreateTags` action, use the `Condition` element with the `ec2:CreateAction` condition key to give tagging permissions to the action that creates the resource.

The following example demonstrates a policy that allows users to launch instances and apply any tags to instances and volumes during launch. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:RunInstances"],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Resource": "arn:aws:ec2:region:account:*/*",
            "Condition": {
                "StringEquals": {
                    "ec2:CreateAction": "RunInstances"
                }
            }
        }
    ]
}
```

Similarly, the following policy allows users to create volumes and apply any tags to the volumes during volume creation. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateVolume"],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Resource": "arn:aws:ec2:region:account:*/*",
            "Condition": {
                "StringEquals": {
                    "ec2:CreateAction": "CreateVolume"
                }
            }
        }
    ]
}
```
The `ec2:CreateTags` action is only evaluated if tags are applied during the resource-creating action. Therefore, a user that has permissions to create a resource (assuming there are no tagging conditions) does not require permissions to use the `ec2:CreateTags` action if no tags are specified in the request. However, if the user attempts to create a resource with tags, the request fails if the user does not have permissions to use the `ec2:CreateTags` action.

The `ec2:CreateTags` action is also evaluated if tags are provided in a launch template. For an example policy, see Tags in a launch template (p. 1099).

**Control access to specific tags**

You can use additional conditions in the `Condition` element of your IAM policies to control the tag keys and values that can be applied to resources.

The following condition keys can be used with the examples in the preceding section:

- `aws:RequestTag`: To indicate that a particular tag key or tag key and value must be present in a request. Other tags can also be specified in the request.
  - Use with the `StringEquals` condition operator to enforce a specific tag key and value combination, for example, to enforce the tag `cost-center=cc123`:
    ```json
    "StringEquals": { "aws:RequestTag/cost-center": "cc123" }
    ```
  - Use with the `StringLike` condition operator to enforce a specific tag key in the request; for example, to enforce the tag key `purpose`:
    ```json
    "StringLike": { "aws:RequestTag/purpose": "*" }
    ```

- `aws:TagKeys`: To enforce the tag keys that are used in the request.
  - Use with the `ForAllValues` modifier to enforce specific tag keys if they are provided in the request (if tags are specified in the request, only specific tag keys are allowed; no other tags are allowed). For example, the tag keys `environment` or `cost-center` are allowed:
    ```json
    "ForAllValues:StringEquals": { "aws:TagKeys": ["environment","cost-center"] }
    ```
  - Use with the `ForAnyValue` modifier to enforce the presence of at least one of the specified tag keys in the request. For example, at least one of the tag keys `environment` or `webserver` must be present in the request:
    ```json
    "ForAnyValue:StringEquals": { "aws:TagKeys": ["environment","webserver"] }
    ```

These condition keys can be applied to resource-creating actions that support tagging, as well as the `ec2:CreateTags` and `ec2:DeleteTags` actions. To learn whether an Amazon EC2 API action supports tagging, see Actions, resources, and condition keys for Amazon EC2.

To force users to specify tags when they create a resource, you must use the `aws:RequestTag` condition key or the `aws:TagKeys` condition key with the `ForAnyValue` modifier on the resource-creating action. The `ec2:CreateTags` action is not evaluated if a user does not specify tags for the resource-creating action.

For conditions, the condition key is not case-sensitive and the condition value is case-sensitive. Therefore, to enforce the case-sensitivity of a tag key, use the `aws:TagKeys` condition key, where the tag key is specified as a value in the condition.

For example IAM policies, see Example policies for working with the AWS CLI or an AWS SDK (p. 1078). For more information about multi-value conditions, see Creating a Condition That Tests Multiple Key Values in the IAM User Guide.
Control access to EC2 resources using resource tags

When you create an IAM policy that grants IAM users permission to use EC2 resources, you can include tag information in the Condition element of the policy to control access based on tags. This is known as attribute-based access control (ABAC). ABAC provides better control over which resources a user can modify, use, or delete. For more information, see What is ABAC for AWS?

For example, you can create a policy that allows users to terminate an instance, but denies the action if the instance has the tag environment=production. To do this, you use the ec2:ResourceTag condition key to allow or deny access to the resource based on the tags that are attached to the resource.

```
"StringEquals": { "ec2:ResourceTag/environment": "production" }
```

To learn whether an Amazon EC2 API action supports controlling access using the ec2:ResourceTag condition key, see Actions, resources, and condition keys for Amazon EC2. Note that the Describe actions do not support resource-level permissions, so you must specify them in a separate statement without conditions.

For example IAM policies, see Example policies for working with the AWS CLI or an AWS SDK (p. 1078).

If you allow or deny users access to resources based on tags, you must consider explicitly denying users the ability to add those tags to or remove them from the same resources. Otherwise, it’s possible for a user to circumvent your restrictions and gain access to a resource by modifying its tags.

Example policies for working with the AWS CLI or an AWS SDK

The following examples show policy statements that you could use to control the permissions that IAM users have to Amazon EC2. These policies are designed for requests that are made with the AWS CLI or an AWS SDK. For example policies for working in the Amazon EC2 console, see Example policies for working in the Amazon EC2 console (p. 1115). For examples of IAM policies specific to Amazon VPC, see Identity and Access Management for Amazon VPC.

Examples

- Example: Read-only access (p. 1078)
- Example: Restrict access to a specific Region (p. 1079)
- Work with instances (p. 1079)
- Work with volumes (p. 1081)
- Work with snapshots (p. 1083)
- Launch instances (RunInstances) (p. 1091)
- Work with Spot Instances (p. 1102)
- Example: Work with Reserved Instances (p. 1107)
- Example: Tag resources (p. 1108)
- Example: Work with IAM roles (p. 1109)
- Example: Work with route tables (p. 1111)
- Example: Allow a specific instance to view resources in other AWS services (p. 1111)
- Example: Work with launch templates (p. 1112)
- Work with instance metadata (p. 1112)

Example: Read-only access

The following policy grants users permissions to use all Amazon EC2 API actions whose names begin with Describe. The Resource element uses a wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support
resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

Users don’t have permission to perform any actions on the resources (unless another statement grants them permission to do so) because they’re denied permission to use API actions by default.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:*",
      "Resource": "*"
    }
  ]
}
```

**Example: Restrict access to a specific Region**

The following policy denies users permission to use all Amazon EC2 API actions unless the Region is Europe (Frankfurt). It uses the global condition key `aws:RequestedRegion`, which is supported by all Amazon EC2 API actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:RequestedRegion": "eu-central-1"
        }
      }
    }
  ]
}
```

Alternatively, you can use the condition key `ec2:Region`, which is specific to Amazon EC2 and is supported by all Amazon EC2 API actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "ec2:Region": "eu-central-1"
        }
      }
    }
  ]
}
```

**Work with instances**

**Examples**
Example: Describe, launch, stop, start, and terminate all instances (p. 1080)

Example: Describe all instances, and stop, start, and terminate only particular instances (p. 1080)

Example: Describe, launch, stop, start, and terminate all instances

The following policy grants users permissions to use the API actions specified in the Action element. The Resource element uses a * wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The users don't have permission to use any other API actions (unless another statement grants them permission to do so) because users are denied permission to use API actions by default.

```
{
   "Version": "2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "ec2:DescribeInstances",
               "ec2:DescribeImages",
               "ec2:DescribeKeyPairs",
               "ec2:DescribeSecurityGroups",
               "ec2:DescribeAvailabilityZones",
               "ec2:RunInstances",
               "ec2:TerminateInstances",
               "ec2:StopInstances",
               "ec2:StartInstances"
           ],
           "Resource": "*"
       }
   ]
}
```

Example: Describe all instances, and stop, start, and terminate only particular instances

The following policy allows users to describe all instances, to start and stop only instances i-1234567890abcdef0 and i-0598c7d356eba48d7, and to terminate only instances in the US East (N. Virginia) Region (us-east-1) with the resource tag "purpose=test".

The first statement uses a * wildcard for the Resource element to indicate that users can specify all resources with the action; in this case, they can list all instances. The * wildcard is also necessary in cases where the API action does not support resource-level permissions (in this case, ec2:DescribeInstances). For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The second statement uses resource-level permissions for the StopInstances and StartInstances actions. The specific instances are indicated by their ARNs in the Resource element.

The third statement allows users to terminate all instances in the US East (N. Virginia) Region (us-east-1) that belong to the specified AWS account, but only where the instance has the tag "purpose=test". The Condition element qualifies when the policy statement is in effect.

```
{
   "Version": "2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "ec2:StopInstances",
               "ec2:StartInstances",
               "ec2:TerminateInstances"
           ],
           "Resource": [
               "arn:aws:ec2:us-east-1:1234567890:instance/i-1234567890abcdef0",
               "arn:aws:ec2:us-east-1:1234567890:instance/i-0598c7d356eba48d7"
           ],
           "Condition": {
               "StringEquals": {
                   "ec2:ResourceTag/instance-type": "specific_instance_type"
               }
           }
       }
   ]
}
```
Work with volumes

Examples

- Example: Attach and detach volumes (p. 1081)
- Example: Create a volume (p. 1082)
- Example: Create a volume with tags (p. 1082)

Example: Attach and detach volumes

When an API action requires a caller to specify multiple resources, you must create a policy statement that allows users to access all required resources. If you need to use a `Condition` element with one or more of these resources, you must create multiple statements as shown in this example.

The following policy allows users to attach volumes with the tag "volume_user=iam-user-name" to instances with the tag "department=dev", and to detach those volumes from those instances. If you attach this policy to an IAM group, the `aws:username` policy variable gives each IAM user in the group permission to attach or detach volumes from the instances with a tag named `volume_user` that has his or her IAM user name as a value.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:AttachVolume", "ec2:DetachVolume"],
      "Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/department": "dev"
        }
      }
    }
  ]
}
```
Example: Create a volume

The following policy allows users to use the CreateVolume API action. The user is allowed to create a volume only if the volume is encrypted and only if the volume size is less than 20 GiB.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:CreateVolume"],
      "Condition": {
        "NumericLessThan": {
          "ec2:VolumeSize": "20"
        },
        "Bool":{
          "ec2:Encrypted": "true"
        }
      }
    }
  ]
}
```

Example: Create a volume with tags

The following policy includes the aws:RequestTag condition key that requires users to tag any volumes they create with the tags costcenter=115 and stack=prod. The aws:TagKeys condition key uses the ForAllValues modifier to indicate that only the keys costcenter and stack are allowed in the request (no other tags can be specified). If users don't pass these specific tags, or if they don't specify tags at all, the request fails.

For resource-creating actions that apply tags, users must also have permissions to use the CreateTags action. The second statement uses the ec2:CreateAction condition key to allow users to create tags only in the context of CreateVolume. Users cannot tag existing volumes or any other resources. For more information, see Grant permission to tag resources during creation (p. 1075).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateTaggedVolumes",
      "Effect": "Allow",
      "Action": ["ec2:AttachVolume", "ec2:DetachVolume"],
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/volume_user": "${aws:username}"
        }
      }
    }
  ]
}
```
The following policy allows users to create a volume without having to specify tags. The `CreateTags` action is only evaluated if tags are specified in the `CreateVolume` request. If users do specify tags, the tag must be `purpose=test`. No other tags are allowed in the request.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateVolume"],
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/purpose": "test",
                    "ec2:CreateAction": "CreateVolume"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/costcenter": "115",
                    "aws:RequestTag/stack": "prod"
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": ["costcenter","stack"]
                }
            }
        }
    ]
}
```

**Work with snapshots**

The following are example policies for both `CreateSnapshot` (point-in-time snapshot of an EBS volume) and `CreateSnapshots` (multi-volume snapshots).
Examples

- Example: Create a snapshot (p. 1084)
- Example: Create snapshots (p. 1084)
- Example: Create a snapshot with tags (p. 1085)
- Example: Create snapshots with tags (p. 1085)
- Example: Copying snapshots (p. 1090)
- Example: Modify permission settings for snapshots (p. 1090)

Example: Create a snapshot

The following policy allows customers to use the CreateSnapshot API action. The customer can create snapshots only if the volume is encrypted and only if the volume size is less than 20 GiB.

```json
{
"Version":"2012-10-17",
"Statement": [
{
"Effect":"Allow",
"Action":"ec2:CreateSnapshot",
"Resource":"arn:aws:ec2:us-east-1::snapshot/*"
},
{
"Effect":"Allow",
"Action":"ec2:CreateSnapshot",
"Resource":"arn:aws:ec2:us-east-1:123456789012:volume/*",
"Condition":{
"NumericLessThan":{
"ec2:VolumeSize":"20"
},
"Bool":{
"ec2:Encrypted":"true"
}
}
]
}
```

Example: Create snapshots

The following policy allows customers to use the CreateSnapshots API action. The customer can create snapshots only if all of the volumes on the instance are type GP2.

```json
{
"Version":"2012-10-17",
"Statement": [
{
"Effect":"Allow",
"Action":"ec2:CreateSnapshots",
"Resource":[
"arn:aws:ec2:us-east-1::snapshot/*",
"arn:aws:ec2:*:instance/*"
]
},
{
"Effect":"Allow",
"Action":"ec2:CreateSnapshots",
"Resource":"arn:aws:ec2:us-east-1:*:volume/*",
"Condition":{
"StringLikeIfExists":{
"ec2:VolumeType":"gp2"
}
}
]
}
```
Example: Create a snapshot with tags

The following policy includes the `aws:RequestTag` condition key that requires the customer to apply the tags `costcenter=115` and `stack=prod` to any new snapshot. The `aws:TagKeys` condition key uses the `ForAllValues` modifier to indicate that only the keys `costcenter` and `stack` can be specified in the request. The request fails if either of these conditions is not met.

For resource-creating actions that apply tags, customers must also have permissions to use the `CreateTags` action. The third statement uses the `ec2:CreateAction` condition key to allow customers to create tags only in the context of `CreateSnapshot`. Customers cannot tag existing volumes or any other resources. For more information, see Grant permission to tag resources during creation (p. 1075).

```json
{"Version":"2012-10-17","Statement": [
  {
    "Effect":"Allow",
    "Action":"ec2:CreateSnapshot",
    "Resource":"arn:aws:ec2:us-east-1:123456789012:volume/*"
  },
  {
    "Sid":"AllowCreateTaggedSnapshots",
    "Effect":"Allow",
    "Action":"ec2:CreateSnapshot",
    "Resource":"arn:aws:ec2:us-east-1::snapshot/*",
    "Condition":{
      "StringEquals":{
        "aws:RequestTag/costcenter":"115",
        "aws:RequestTag/stack":"prod"
      },
      "ForAllValues:StringEquals":{
        "aws:TagKeys":{
          "costcenter",
          "stack"
        }
      }
    }
  }
],
  {
    "Effect":"Allow",
    "Action":"ec2:CreateTags",
    "Resource":"arn:aws:ec2:us-east-1::snapshot/*",
    "Condition":{
      "StringEquals":{
        "ec2:CreateAction":"CreateSnapshot"
      }
    }
  }
}
```

Example: Create snapshots with tags

The following policy includes the `aws:RequestTag` condition key that requires the customer to apply the tags `costcenter=115` and `stack=prod` to any new snapshot. The `aws:TagKeys` condition
key uses the `ForAllValues` modifier to indicate that only the keys `costcenter` and `stack` can be specified in the request. The request fails if either of these conditions is not met.

```json
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
    },
    {
      "Sid":"AllowCreateTaggedSnapshots",
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
      "Resource": "arn:aws:ec2:us-east-1::snapshot/**",
      "Condition":{
        "StringEquals":{
          "aws:RequestTag/costcenter":"115",
          "aws:RequestTag/stack":"prod"
        },
        "ForAllValues:StringEquals":{
          "aws:TagKeys":{
            "costcenter",
            "stack"
          }
        }
      }
    },
    {
      "Effect":"Allow",
      "Action":"ec2:CreateTags",
      "Resource": "arn:aws:ec2:us-east-1::snapshot/**",
      "Condition":{
        "StringEquals":{
          "ec2:CreateAction":"CreateSnapshots"
        }
      }
    }
  ]
}
```

The following policy allows customers to create a snapshot without having to specify tags. The `CreateTags` action is evaluated only if tags are specified in the `CreateSnapshot` or `CreateSnapshots` request. If a tag is specified, the tag must be `purpose=test`. No other tags are allowed in the request.

```json
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshot",
      "Resource": "*"
    },
    {
      "Effect":"Allow",
      "Action":"ec2:CreateTags",
      "Resource": "arn:aws:ec2:us-east-1::snapshot/**",
      "Condition":{
        "StringEquals":{
          "ec2:CreateAction":"CreateSnapshots"
        }
      }
    }
  ]
}
```
The following policy allows snapshots to be created only if the source volume is tagged with
User:username for the customer, and the snapshot itself is tagged with Environment:Dev and
User:username. The customer can add additional tags to the snapshot.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        { 
            "Effect":"Allow",
            "Action":"ec2:CreateSnapshot",
            "Resource":"arn:aws:ec2:us-east-1:123456789012:volume/**",
            "Condition":{
                "StringEquals":{
                    "ec2:ResourceTag/User": "${aws:username}\n                }
            }
        },
        { 
            "Effect":"Allow",
            "Action":"ec2:CreateSnapshot",
            "Resource":"arn:aws:ec2:us-east-1::snapshot/**",
            "Condition":{
                "StringEquals":{
                    "aws:RequestTag/purpose": "test",
                    "ec2:CreateAction": "CreateSnapshot"
                },
                "ForAllValues:StringEquals":{
                    "aws:TagKeys": "purpose"
                }
            }
        }
    ]
}
```
The following policy for CreateSnapshots allows snapshots to be created only if the source volume is tagged with User:username for the customer, and the snapshot itself is tagged with Environment:Dev and User:username.

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
      "Resource":"arn:aws:ec2:us-east-1:*:instance/**",
    },
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
      "Resource":"arn:aws:ec2:us-east-1:123456789012:volume/**",
      "Condition":{
        "StringEquals":{
          "ec2:ResourceTag/User":"${aws:username}"}
      }
    },
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
      "Resource":"arn:aws:ec2:us-east-1::snapshot/**",
      "Condition":{
        "StringEquals":{
          "aws:RequestTag/Environment":"Dev",
          "aws:RequestTag/User":"${aws:username}"
        }
      }
    },
    {
      "Effect":"Allow",
      "Action":"ec2:CreateTags",
      "Resource":"arn:aws:ec2:us-east-1::snapshot/**"
    }
  ]
}
```

The following policy allows deletion of a snapshot only if the snapshot is tagged with User:username for the customer.

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect":"Allow",
      "Action":"ec2:DeleteSnapshot",
      "Resource":"arn:aws:ec2:us-east-1::snapshot/**",
    }
  ]
}
```
The following policy allows a customer to create a snapshot but denies the action if the snapshot being created has a tag key value=stack.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateSnapshots",
        "ec2:CreateTags"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": "ec2:CreateSnapshot",
      "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": "stack"
        }
      }
    }
  ]
}
```

The following policy allows a customer to create snapshots but denies the action if the snapshots being created have a tag key value=stack.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateSnapshots",
        "ec2:CreateTags"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": "ec2:CreateSnapshots",
      "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": "stack"
        }
      }
    }
  ]
}
```
The following policy allows you to combine multiple actions into a single policy. You can only create a snapshot (in the context of CreateSnapshots) when the snapshot is created in Region us-east-1. You can only create snapshots (in the context of CreateSnapshots) when the snapshots are being created in the Region us-east-1 and when the instance type is t2*.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:CreateSnapshots", "ec2:CreateSnapshot", "ec2:CreateTags"],
      "Condition": {
        "StringEqualsIgnoreCase": {"ec2:Region": "us-east-1"},
        "StringLikeIfExists": {"ec2:InstanceType": ["t2.*"]}
      }
    }
  ]
}
```

**Example: Copying snapshots**

Resource-level permissions specified for the CopySnapshot action apply to the new snapshot only. They cannot be specified for the source snapshot.

The following example policy allows principals to copy snapshots only if the new snapshot is created with tag key of `purpose` and a tag value of `production` (purpose=production).

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCopySnapshotWithTags",
      "Effect": "Allow",
      "Action": "ec2:CopySnapshot",
      "Resource": "arn:aws:ec2:*:123456789012:snapshot/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/purpose": "production"
        }
      }
    }
  ]
}
```

**Example: Modify permission settings for snapshots**

The following policy allows modification of a snapshot only if the snapshot is tagged with
User: `username`, where `username` is the customer's AWS account user name. The request fails if this condition is not met.
Launch instances (RunInstances)

The RunInstances API action launches one or more On-Demand Instances or one or more Spot Instances. RunInstances requires an AMI and creates an instance. Users can specify a key pair and security group in the request. Launching into a VPC requires a subnet, and creates a network interface. Launching from an Amazon EBS-backed AMI creates a volume. Therefore, the user must have permissions to use these Amazon EC2 resources. You can create a policy statement that requires users to specify an optional parameter on RunInstances, or restricts users to particular values for a parameter.

For more information about the resource-level permissions that are required to launch an instance, see Actions, resources, and condition keys for Amazon EC2.

By default, users don't have permissions to describe, start, stop, or terminate the resulting instances. One way to grant the users permission to manage the resulting instances is to create a specific tag for each instance, and then create a statement that enables them to manage instances with that tag. For more information, see Work with instances (p. 1079).

- Elastic GPUs (p. 1100)
- Launch templates (p. 1100)

AMIs

The following policy allows users to launch instances using only the specified AMIs, ami-9e1670f7 and ami-45cf5c3c. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region::image/ami-9e1670f7",
```
Alternatively, the following policy allows users to launch instances from all AMIs owned by Amazon. The Condition element of the first statement tests whether ec2:Owner is amazon. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

```
{
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [  
        "arn:aws:ec2:region::image/ami-*"
      ],
      "Condition": {  
        "StringEquals": {  
          "ec2:Owner": "amazon"
        }
      }
    },
    {  
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [  
        "arn:aws:ec2:region::account:instance/*",
        "arn:aws:ec2:region:account:subnet/*",
        "arn:aws:ec2:region:account:volume/*",
        "arn:aws:ec2:region:account:security-group/*",
        "arn:aws:ec2:region:account:key-pair/*"
      ]
    }
  ]
}
```

**Instance types**

The following policy allows users to launch instances using only the t2.micro or t2.small instance type, which you might do to control costs. The users can't launch larger instances because the Condition element of the first statement tests whether ec2:InstanceType is either t2.micro or t2.small.

```
{
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [  
        "arn:aws:ec2:region:account:instance/*"
      ],
      "Condition": {  
        "StringEquals": {  
          "ec2:InstanceType": [  
            "t2.micro",
            "t2.small"
          ]
        }
      }
    }
  ]
}
```
Alternatively, you can create a policy that denies users permissions to launch any instances except t2.micro and t2.small instance types.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2::instance/*",
      ],
      "Condition": {
        "StringNotEquals": {
          "ec2:InstanceType": ["t2.micro", "t2.small"]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2::image/ami-***",
        "arn:aws:ec2:region:account:instance/*",
        "arn:aws:ec2:region:account:subnet/*",
        "arn:aws:ec2:region:account:security-group/*",
        "arn:aws:ec2:region:account:volume/*",
      ]
    }
  ]
}
```

**Subnets**

The following policy allows users to launch instances using only the specified subnet, subnet-12345678. The group can't launch instances into any another subnet (unless another statement grants the users permission to do so).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:account:instance/*",
      ],
      "Condition": {
        "StringNotEquals": {
          "ec2:InstanceType": ["t2.micro", "t2.small"]
        }
      }
    }
  ]
}
```
IAM policies

Alternatively, you could create a policy that denies users permissions to launch an instance into any other subnet. The statement does this by denying permission to create a network interface, except where subnet subnet-12345678 is specified. This denial overrides any other policies that are created to allow launching instances into other subnets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
      ],
      "Condition": {
        "ArnNotEquals": {
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:image/ami-***",
        "arn:aws:ec2:region:account:instance/**",
        "arn:aws:ec2:region:account:instance/***",
        "arn:aws:ec2:region:account:subnet/**",
        "arn:aws:ec2:region:account:volume/**",
        "arn:aws:ec2:region:account:key-pair/**",
        "arn:aws:ec2:region:account:security-group/**
      ]
    }
  ]
}
```

EBS volumes

The following policy allows users to launch instances only if the EBS volumes for the instance are encrypted. The user must launch an instance from an AMI that was created with encrypted snapshots, to ensure that the root volume is encrypted. Any additional volume that the user attaches to the instance during launch must also be encrypted.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:image/ami-***",
        "arn:aws:ec2:region:account:instance/**",
        "arn:aws:ec2:region:account:instance/***",
        "arn:aws:ec2:region:account:subnet/**",
        "arn:aws:ec2:region:account:volume/**",
        "arn:aws:ec2:region:account:key-pair/**",
        "arn:aws:ec2:region:account:security-group/**
      ]
    }
  ]
}
```
Tags

Tag instances on creation

The following policy allows users to launch instances and tag the instances during creation. For resource-creating actions that apply tags, users must have permissions to use the CreateTags action. The second statement uses the ec2:CreateAction condition key to allow users to create tags only in the context of RunInstances, and only for instances. Users cannot tag existing resources, and users cannot tag volumes using the RunInstances request.

For more information, see Grant permission to tag resources during creation (p. 1075).

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:RunInstances"],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Resource": "arn:aws:ec2:us-east-1:123456789012:instance/**",
            "Condition": {
                "StringEquals": {
                    "ec2:CreateAction": "RunInstances"
                }
            }
        }
    ]
}
```
Tag instances and volumes on creation with specific tags

The following policy includes the `aws:RequestTag` condition key that requires users to tag any instances and volumes that are created by `RunInstances` with the tags `environment=production` and `purpose=webserver`. The `aws:TagKeys` condition key uses the `ForAllValues` modifier to indicate that only the keys `environment` and `purpose` are allowed in the request (no other tags can be specified). If no tags are specified in the request, the request fails.

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Action": [
"ec2:RunInstances"
],
"Resource": [
"arn:aws:ec2:region::image/*",
"arn:aws:ec2:region::account:subnet/*",
"arn:aws:ec2:region::account:network-interface/*",
"arn:aws:ec2:region::account:security-group/*",
"arn:aws:ec2:region::account:key-pair/*"
]
},
{
"Effect": "Allow",
"Action": [
"ec2:RunInstances"
],
"Resource": [
"arn:aws:ec2:region::account:volume/*",
"arn:aws:ec2:region::account:instance/*"
],
"Condition": {
"StringEquals": {
"aws:RequestTag/environment": "production",
"aws:RequestTag/purpose": "webserver"
},
"ForAllValues:StringEquals": {
"aws:TagKeys": ["environment","purpose"]
}
}
},
{
"Effect": "Allow",
"Action": [
"ec2:CreateTags"
],
"Resource": "arn:aws:ec2:region::account:*/*",
"Condition": {
"StringEquals": {
"ec2:CreateAction": "RunInstances"
}
}
}]
}
```

Tag instances and volumes on creation with at least one specific tag

The following policy uses the `ForAnyValue` modifier on the `aws:TagKeys` condition to indicate that at least one tag must be specified in the request, and it must contain the key `environment` or `webserver`. The tag must be applied to both instances and volumes. Any tag values can be specified in the request.
If instances are tagged on creation, they must be tagged with a specific tag

In the following policy, users do not have to specify tags in the request, but if they do, the tag must be purpose=test. No other tags are allowed. Users can apply the tags to any taggable resource in the RunInstances request.
IAM policies

To disallow anyone called tag on create for RunInstances

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": ["ec2:RunInstances"],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1::subnet/*",
                "arn:aws:ec2:us-east-1::network-interface/*",
                "arn:aws:ec2:us-east-1::security-group/*",
                "arn:aws:ec2:us-east-1::key-pair/*",
                "arn:aws:ec2:us-east-1::volume/*",
                "arn:aws:ec2:us-east-1::instance/*",
                "arn:aws:ec2:us-east-1::spot-instances-request/*"
            ]
        },
        {
            "Sid": "VisualEditor0",
            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "*
        }
    ]
}
```

Only allow specific tags for spot-instances-request. Surprise inconsistency number 2 comes into play here. Under normal circumstances, specifying no tags will result in Unauthenticated. In the case of spot-instances-request, this policy will not be evaluated if there are no spot-instances-request tags, so a non-tag Spot on Run request will succeed.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:region:account:*/**",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/purpose": "test",
                    "ec2:CreateAction": "RunInstances"
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": "purpose"
                }
            }
        }
    ]
}
```
"ec2:RunInstances"
],

"arn:aws:ec2:us-east-1:image/**",
"arn:aws:ec2:us-east-1:subnet/**",
"arn:aws:ec2:us-east-1:network-interface/**",
"arn:aws:ec2:us-east-1:security-group/**",
"arn:aws:ec2:us-east-1:key-pair/**",
"arn:aws:ec2:us-east-1:volume/**",
"arn:aws:ec2:us-east-1:instance/**",
]
},
{ "Sid": "VisualEditor0",
"Effect": "Allow",
"Action": "ec2:RunInstances",
"Resource": "arn:aws:ec2:us-east-1:spot-instances-request/**",
"Condition": {
"StringEquals": {
"aws:RequestTag/environment": "production"
}
}
}
]

Tags in a launch template

In the following example, users can launch instances, but only if they use a specific launch template (lt-09477bcd97b0d310e). The ec2:IsLaunchTemplateResource condition key prevents users from overriding any of the resources specified in the launch template. The second part of the statement allows users to tag instances on creation—this part of the statement is necessary if tags are specified for the instance in the launch template.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
        "ArnLike": {
          "ec2:LaunchTemplate": "arn:aws:ec2:region:account:launch-template/lt-09477bcd97b0d310e"
        },
        "Bool": {
          "ec2:IsLaunchTemplateResource": "true"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [ "ec2:CreateTags" ],
      "Condition": {
        "StringEquals": {
          "ec2:CreateAction": "RunInstances"
        }
      }
    }
  ]
}
```
Elastic GPUs

In the following policy, users can launch an instance and specify an elastic GPU to attach to the instance. Users can launch instances in any Region, but they can only attach an elastic GPU during a launch in the us-east-2 Region.

The ec2:ElasticGpuType condition key uses the ForAnyValue modifier to indicate that only the elastic GPU types eg1.medium and eg1.large are allowed in the request.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:RunInstances"],
            "Resource": ["arn:aws:ec2:*:account:elastic-gpu/*"],
            "Condition": {
                "StringEquals": {
                    "ec2:Region": "us-east-2"
                },
                "ForAnyValue:StringLike": {
                    "ec2:ElasticGpuType": [
                        "eg1.medium",
                        "eg1.large"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2::*:image/ami-*",
                "arn:aws:ec2::*:account:network-interface/*",
                "arn:aws:ec2::*:account:instance/*",
                "arn:aws:ec2::*:account:subnet/*",
                "arn:aws:ec2::*:account:volume/*",
                "arn:aws:ec2::*:account:key-pair/*",
                "arn:aws:ec2::*:account:security-group/*"
            ]
        }
    ]
}
```

Launch templates

In the following example, users can launch instances, but only if they use a specific launch template (lt-09477bcd97b0d310e). Users can override any parameters in the launch template by specifying the parameters in the RunInstances action.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2::*:image/ami-*",
                "arn:aws:ec2::*:account:network-interface/*",
                "arn:aws:ec2::*:account:instance/*",
                "arn:aws:ec2::*:account:subnet/*",
                "arn:aws:ec2::*:account:volume/*",
                "arn:aws:ec2::*:account:key-pair/*",
                "arn:aws:ec2::*:account:security-group/*"
            ]
        }
    ]
}
```
In this example, users can launch instances only if they use a launch template. The policy uses the `ec2:IsLaunchTemplateResource` condition key to prevent users from overriding any pre-existing ARNs in the launch template.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
        "ArnLike": {
          "ec2:LaunchTemplate": "arn:aws:ec2:region:account:launch-template/lt-09477bcd97b0d310e"
        }
      }
    }
  ]
}
```

The following example policy allows user to launch instances, but only if they use a launch template. Users cannot override the subnet and network interface parameters in the request; these parameters can only be specified in the launch template. The first part of the statement uses the `NotResource` element to allow all other resources except subnets and network interfaces. The second part of the statement allows the subnet and network interface resources, but only if they are sourced from the launch template.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "NotResource": [
        "arn:aws:ec2:region:account:subnet/**",
      ],
      "Condition": {
        "ArnLike": {
          "ec2:LaunchTemplate": "arn:aws:ec2:region:account:launch-template/**"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:account:subnet/**",
      ],
      "Condition": {
        "ArnLike": {
          "ec2:LaunchTemplate": "arn:aws:ec2:region:account:launch-template/**"
        }
      }
    }
  ]
}
```
The following example allows users to launch instances only if they use a launch template, and only if the launch template has the tag `Purpose=Webservers`. Users cannot override any of the launch template parameters in the `RunInstances` action.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Condition": {
        "ArnLike": {
        },
        "Bool": {
          "ec2:IsLaunchTemplateResource": "true"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/Purpose": "Webservers"
        }
      }
    }
  ]
}
```

**Work with Spot Instances**

You can use the `RunInstances` action to create Spot Instance requests, and tag the Spot Instance requests on create. The resource to specify for `RunInstances` is `spot-instances-request`.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the `RunInstances` statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the `RunInstances` statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use `RunInstances` to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the `spot-instances-request` resource; the call will succeed.
If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.

If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or * wildcard in the CreateTags allow statement, otherwise the call will fail.

You can request Spot Instances using RunInstances or RequestSpotInstances. The following example IAM policies apply only when requesting Spot Instances using RunInstances.

**Example: Request Spot Instances using RunInstances**

The following policy allows users to request Spot Instances by using the RunInstances action. The `spot-instances-request` resource, which is created by RunInstances, requests Spot Instances.

**Note**

To use RunInstances to create Spot Instance requests, you can omit `spot-instances-request` from the Resource list if you do not intend to tag the Spot Instance requests on create. This is because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": ["ec2:RunInstances"],
            "Resource": [
                "arn:aws:ec2:us-east-1:image/*",
                "arn:aws:ec2:us-east-1:subnet/*",
                "arn:aws:ec2:us-east-1:network-interface/*",
                "arn:aws:ec2:us-east-1:security-group/*",
                "arn:aws:ec2:us-east-1:key-pair/*",
                "arn:aws:ec2:us-east-1:volume/*",
                "arn:aws:ec2:us-east-1:instance/*",
                "arn:aws:ec2:us-east-1:spot-instances-request/*"
            ]
        }
    ]
}
```

**Warning**

**NOT SUPPORTED – Example: Deny users permission to request Spot Instances using RunInstances**

The following policy is not supported for the `spot-instances-request` resource.

The following policy is meant to give users the permission to launch On-Demand Instances, but deny users the permission to request Spot Instances. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement is meant to deny the RunInstances action for the `spot-instances-request` resource. However, this condition is not supported because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

```
{
    "Version": "2012-10-17",
    "Statement": [
```
Example: Tag Spot Instance requests on create

The following policy allows users to tag all resources that are created during instance launch. The first statement allows RunInstances to create the listed resources. The spot-instances-request resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement provides a * wildcard to allow all resources to be tagged when they are created at instance launch.

**Note**

If you tag a Spot Instance request on create, Amazon EC2 evaluates the spot-instances-request resource in the RunInstances statement. Therefore, you must explicitly allow the spot-instances-request resource for the RunInstances action, otherwise the call will fail.
Example: Deny tag on create for Spot Instance requests

The following policy denies users the permission to tag the resources that are created during instance launch.

The first statement allows RunInstances to create the listed resources. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement provides a * wildcard to deny all resources being tagged when they are created at instance launch. If `spot-instances-request` or any other resource is tagged on create, the RunInstances call will fail.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1::*:subnet/*",
                "arn:aws:ec2:us-east-1::*:network-interface/*",
                "arn:aws:ec2:us-east-1::*:security-group/*",
                "arn:aws:ec2:us-east-1::*:key-pair/*",
                "arn:aws:ec2:us-east-1::*:volume/*",
                "arn:aws:ec2:us-east-1::*:instance/*",
                "arn:aws:ec2:us-east-1::*:spot-instances-request/*"
            ]
        },
        {
            "Sid": "DenyTagResources",
            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Warning

**NOT SUPPORTED – Example: Allow creating a Spot Instance request only if it is assigned a specific tag**

The following policy is not supported for the `spot-instances-request` resource. The following policy is meant to grant RunInstances the permission to create a Spot Instance request only if the request is tagged with a specific tag.

The first statement allows RunInstances to create the listed resources.

The second statement is meant to grant users the permission to create a Spot Instance request only if the request has the tag `environment=production`. If this condition is applied to other resources created by RunInstances, specifying no tags results in an Unauthenticated error. However, if no tags are specified for the Spot Instance request, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement, which results in non-tagged Spot Instance requests being created by RunInstances. Note that specifying another tag other than `environment=production` results in an Unauthenticated error, because if a user tags a Spot Instance request, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

```json
{
    "Version": "2012-10-17",
```
"Statement": [
    {
        "Sid": "AllowRun",
        "Effect": "Allow",
        "Action": [
            "ec2:RunInstances"
        ],
        "Resource": [
            "arn:aws:ec2:us-east-1::image/*",
            "arn:aws:ec2:us-east-1::*:subnet/*",
            "arn:aws:ec2:us-east-1::*:security-group/*",
            "arn:aws:ec2:us-east-1::*:key-pair/*",
            "arn:aws:ec2:us-east-1::*:volume/*",
            "arn:aws:ec2:us-east-1::*:instance/*"
        ]
    },
    {
        "Sid": "RequestSpotInstancesOnlyIfTagIs_environment=production - NOT SUPPORTED - DO NOT USE!",
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": "arn:aws:ec2:us-east-1::*:spot-instances-request/**",
        "Condition": {
            "StringEquals": {
                "aws:RequestTag/environment": "production"
            }
        }
    },
    {
        "Sid": "TagResources",
        "Effect": "Allow",
        "Action": "ec2:CreateTags",
        "Resource": "*"
    }
]
}

Example: Deny creating a Spot Instance request if it is assigned a specific tag

The following policy denies RunInstances the permission to create a Spot Instance request if the request is tagged with environment=production.

The first statement allows RunInstances to create the listed resources.

The second statement denies users the permission to create a Spot Instance request if the request has the tag environment=production. Specifying environment=production as a tag results in an Unauthenticated error. Specifying other tags or specifying no tags will result in the creation of a Spot Instance request.

```json
{"Version": "2012-10-17",
 "Statement": [
     {
         "Sid": "AllowRun",
         "Effect": "Allow",
         "Action": ["ec2:RunInstances"
      ],
      "Resource": [
          "arn:aws:ec2:us-east-1::image/*",
          "arn:aws:ec2:us-east-1::*:subnet/*",
          "arn:aws:ec2:us-east-1::*:security-group/*",
          "arn:aws:ec2:us-east-1::*:key-pair/*",
          "arn:aws:ec2:us-east-1::*:volume/*",
          "arn:aws:ec2:us-east-1::*:instance/*"
      ]
  },
  {
      "Sid": "RequestSpotInstancesOnlyIfTagIs_environment=production - NOT SUPPORTED - DO NOT USE!",
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "arn:aws:ec2:us-east-1::*:spot-instances-request/**",
      "Condition": {
          "StringEquals": {
              "aws:RequestTag/environment": "production"
          }
      }
  },
  {
      "Sid": "TagResources",
      "Effect": "Allow",
      "Action": "ec2:CreateTags",
      "Resource": "*"
  }
]}
```
Example: Work with Reserved Instances

The following policy gives users permission to view, modify, and purchase Reserved Instances in your account.

It is not possible to set resource-level permissions for individual Reserved Instances. This policy means that users have access to all the Reserved Instances in the account.

The Resource element uses a * wildcard to indicate that users can specify all resources with the action; in this case, they can list and modify all Reserved Instances in the account. They can also purchase Reserved Instances using the account credentials. The * wildcard is also necessary in cases where the API action does not support resource-level permissions.

```json
{
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeReservedInstances",
      "ec2:ModifyReservedInstances",
      "ec2:PurchaseReservedInstancesOffering",
      "ec2:DescribeAvailabilityZones",
      "ec2:DescribeReservedInstancesOfferings"
    ],
    "Resource": "*"
  }
}
```

To allow users to view and modify the Reserved Instances in your account, but not purchase new Reserved Instances.

```json
{
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeReservedInstances",
      "ec2:ModifyReservedInstances",
      "ec2:PurchaseReservedInstancesOffering",
      "ec2:DescribeReservedInstancesOfferings"
    ],
    "Resource": "*"
  }
]
```
Example: Tag resources

The following policy allows users to use the CreateTags action to apply tags to an instance only if the tag contains the key environment and the value production. The ForAllValues modifier is used with the aws:TagKeys condition key to indicate that only the key environment is allowed in the request (no other tags are allowed). The user cannot tag any other resource types.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": [
                        "environment"
                    ]
                }
            }
        }
    ]
}
```

The following policy allows users to tag any taggable resource that already has a tag with a key of owner and a value of the IAM username. In addition, users must specify a tag with a key of anycompany:environment-type and a value of either test or prod in the request. Users can specify additional tags in the request.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/anycompany:environment-type": ["test","prod"],
                    "ec2:ResourceTag/owner": 
```

1108
You can create an IAM policy that allows users to delete specific tags for a resource. For example, the following policy allows users to delete tags for a volume if the tag keys specified in the request are `environment` or `cost-center`. Any value can be specified for the tag but the tag key must match either of the specified keys.

**Note**
If you delete a resource, all tags associated with the resource are also deleted. Users do not need permissions to use the `ec2:DeleteTags` action to delete a resource that has tags; they only need permissions to perform the deleting action.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "ec2:DeleteTags",
         "Condition": {
            "ForAllValues:StringEquals": {
               "aws:TagKeys": ["environment","cost-center"]
            }
         }
      }
   ]
}
```

This policy allows users to delete only the `environment=prod` tag on any resource, and only if the resource is already tagged with a key of `owner` and a value of the IAM username. Users cannot delete any other tags for a resource.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["ec2:DeleteTags"],
         "Resource": "arn:aws:ec2:region:account:*/*",
         "Condition": {
            "StringEquals": {
               "aws:RequestTag/environment": "prod",
               "ec2:ResourceTag/owner": "${aws:username}"},
            "ForAllValues:StringEquals": {
               "aws:TagKeys": ["environment"]
            }
         }
      }
   ]
}
```

**Example: Work with IAM roles**

The following policy allows users to attach, replace, and detach an IAM role to instances that have the tag `department=test`. Replacing or detaching an IAM role requires an association ID, therefore the
policy also grants users permission to use the `ec2:DescribeIamInstanceProfileAssociations` action.

IAM users must have permission to use the `iam:PassRole` action in order to pass the role to the instance.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation",
        "ec2:DisassociateIamInstanceProfile"
      ],
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/department":"test"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeIamInstanceProfileAssociations",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account:role/TestRole-*"
    }
  ]
}
```

The following policy allows users to attach or replace an IAM role for any instance. Users can only attach or replace IAM roles with names that begin with `TestRole-`. For the `iam:PassRole` action, ensure that you specify the name of the IAM role and not the instance profile (if the names are different). For more information, see Instance profiles (p. 1125).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeIamInstanceProfileAssociations",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account:role/TestRole-*"
    }
  ]
}
```
Example: Work with route tables

The following policy allows users to add, remove, and replace routes for route tables that are associated with VPC vpc-ec43eb89 only. To specify a VPC for the ec2:Vpc condition key, you must specify the full ARN of the VPC.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteRoute",
        "ec2:CreateRoute",
        "ec2:ReplaceRoute"
      ],
      "Condition": {
        "StringEquals": {
          "ec2:Vpc": "arn:aws:ec2:region:account:vpc/vpc-ec43eb89"
        }
      }
    }
  ]
}
```

Example: Allow a specific instance to view resources in other AWS services

The following is an example of a policy that you might attach to an IAM role. The policy allows an instance to view resources in various AWS services. It uses the ec2:SourceInstanceARN condition key to specify that the instance from which the request is made must be instance i-093452212644b0dd6. If the same IAM role is associated with another instance, the other instance cannot perform any of these actions.

The ec2:SourceInstanceARN key is an AWS-wide condition key, therefore it can be used for other service actions, not just Amazon EC2.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeVolumes",
        "s3:ListAllMyBuckets",
        "dynamodb:ListTables",
        "rds:DescribeDBInstances"
      ],
      "Resource": ["*"],
      "Condition": {
        "ArnEquals": {
          "ec2:SourceInstanceARN": "arn:aws:ec2:region:account:instance/i-093452212644b0dd6"
        }
      }
    }
  ]
}
```
Example: Work with launch templates

The following policy allows users to create a launch template version and modify a launch template, but only for a specific launch template (lt-09477bcd97b0d3abc). Users cannot work with other launch templates.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ec2:CreateLaunchTemplateVersion",
        "ec2:ModifyLaunchTemplate"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:ec2:region:account:launch-template/lt-09477bcd97b0d3abc"
    }
  ]
}
```

The following policy allows users to delete any launch template and launch template version, provided that the launch template has the tag Purpose=Testing.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ec2:DeleteLaunchTemplate",
        "ec2:DeleteLaunchTemplateVersions"
      ],
      "Effect": "Allow",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/Purpose": "Testing"
        }
      }
    }
  ]
}
```

Work with instance metadata

The following policies ensure that users can only retrieve instance metadata (p. 606) using Instance Metadata Service Version 2 (IMDSv2). You can combine the following four policies into one policy with four statements. When combined as one policy, you can use the policy as a service control policy (SCP). It can work equally well as a deny policy that you apply to an existing IAM policy (taking away and limiting existing permission), or as an SCP that is applied globally across an account, an organizational unit (OU), or an entire organization.

**Note**

The following RunInstances metadata options policies must be used in conjunction with a policy that gives the principal permissions to launch an instance with RunInstances. If the principal does not also have RunInstances permissions, it will not be able to launch an instance. For
more information, see the policies in Work with instances (p. 1079) and Launch instances (RunInstances) (p. 1091).

**Important**
If you use Auto Scaling groups and you need to require the use of IMDSv2 on all new instances, your Auto Scaling groups must use launch templates.

When an Auto Scaling group uses a launch template, the \texttt{ec2:RunInstances} permissions of the IAM principal are checked when a new Auto Scaling group is created. They are also checked when an existing Auto Scaling group is updated to use a new launch template or a new version of a launch template.

Restrictions on the use of IMDSv1 on IAM principals for \texttt{RunInstances} are only checked when an Auto Scaling group that is using a launch template, is created or updated. For an Auto Scaling group that is configured to use the \texttt{Latest} or \texttt{Default} launch template, the permissions are not checked when a new version of the launch template is created. For permissions to be checked, you must configure the Auto Scaling group to use a specific version of the launch template.

To enforce the use of IMDSv2 on instances launched by Auto Scaling groups, the following additional steps are required:

1. Disable the use of launch configurations for all accounts in your organization by using either service control policies (SCPs) or IAM permissions boundaries for new principals that are created. For existing IAM principals with Auto Scaling group permissions, update their associated policies with this condition key. To disable the use of launch configurations, create or modify the relevant SCP, permissions boundary, or IAM policy with the "autoscaling:LaunchConfigurationName" condition key with the value specified as null.

2. For new launch templates, configure the instance metadata options in the launch template. For existing launch templates, create a new version of the launch template and configure the instance metadata options in the new version.

3. In the policy that gives any principal the permission to use a launch template, restrict association of $latest$ and $default$ by specifying "autoscaling:LaunchTemplateVersionSpecified": "true". By restricting the use to a specific version of a launch template, you can ensure that new instances will be launched using the version in which the instance metadata options are configured. For more information, see LaunchTemplateSpecification in the Amazon EC2 Auto Scaling API Reference, specifically the Version parameter.

4. For an Auto Scaling group that uses a launch configuration, replace the launch configuration with a launch template. For more information, see Replacing a Launch Configuration with a Launch Template in the Amazon EC2 Auto Scaling User Guide.

5. For an Auto Scaling group that uses a launch template, make sure that it uses a new launch template with the instance metadata options configured, or uses a new version of the current launch template with the instance metadata options configured. For more information, see update-auto-scaling-group in the AWS CLI Command Reference.

**Examples**
- Require the use of IMDSv2 (p. 1113)
- Specify maximum hop limit (p. 1114)
- Limit who can modify the instance metadata options (p. 1114)
- Require role credentials to be retrieved from IMDSv2 (p. 1115)

**Require the use of IMDSv2**

The following policy specifies that you can’t call the \texttt{RunInstances} API unless the instance is also opted in to require the use of IMDSv2 (indicated by "\texttt{ec2:MetadataHttpTokens}": "required"). If you do not
specify that the instance requires IMDSv2, you get an UnauthorizedOperation error when you call the RunInstances API.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RequireImdsV2",
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": "arn:aws:ec2:*:*:instance/*",
      "Condition": {
        "StringNotEquals": {
          "ec2:MetadataHttpTokens": "required"
        }
      }
    }
  ]
}
```

Specify maximum hop limit

The following policy specifies that you can’t call the RunInstances API unless you also specify a hop limit, and the hop limit can’t be more than 3. If you fail to do that, you get an UnauthorizedOperation error when you call the RunInstances API.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "MaxImdsHopLimit",
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": "arn:aws:ec2:*:*:instance/*",
      "Condition": {
        "NumericGreaterThan": {
          "ec2:MetadataHttpPutResponseHopLimit": "3"
        }
      }
    }
  ]
}
```

Limit who can modify the instance metadata options

The following policy removes the ability for the general population of administrators to modify instance metadata options, and permits only users with the role `ec2-imds-admins` to make changes. If any principal other than the `ec2-imds-admins` role tries to call the ModifyInstanceMetadataOptions API, it will get an UnauthorizedOperation error. This statement could be used to control the use of the ModifyInstanceMetadataOptions API; there are currently no fine-grained access controls (conditions) for the ModifyInstanceMetadataOptions API.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowOnlyImdsAdminsToModifySettings",
      "Effect": "Deny",
      "Action": "ec2:ModifyInstanceMetadataOptions",
      "Resource": "*",
      "Condition": {
```
"StringNotLike": {
    "aws:PrincipalARN": "arn:aws:iam::*:role/ec2-imds-admins"
}
}
]
}

Require role credentials to be retrieved from IMDSv2

The following policy specifies that if this policy is applied to a role, and the role is assumed by the EC2 service and the resulting credentials are used to sign a request, then the request must be signed by EC2 role credentials retrieved from IMDSv2. Otherwise, all of its API calls will get an UnauthorizedOperation error. This statement/policy can be applied generally because, if the request is not signed by EC2 role credentials, it has no effect.

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RequireAllEc2RolesToUseV2",
            "Effect": "Deny",
            "Action": "*",
            "Resource": "*",
            "Condition": {
                "NumericLessThan": {
                    "ec2:RoleDelivery": "2.0"
                }
            }
        }
    ]
}

Example policies for working in the Amazon EC2 console

You can use IAM policies to grant users permissions to view and work with specific resources in the Amazon EC2 console. You can use the example policies in the previous section; however, they are designed for requests that are made with the AWS CLI or an AWS SDK. The console uses additional API actions for its features, so these policies may not work as expected. For example, a user that has permission to use only the DescribeVolumes API action will encounter errors when trying to view volumes in the console. This section demonstrates policies that enable users to work with specific parts of the console.

Tip
To help you work out which API actions are required to perform tasks in the console, you can use a service such as AWS CloudTrail. For more information, see the AWS CloudTrail User Guide. If your policy does not grant permission to create or modify a specific resource, the console displays an encoded message with diagnostic information. You can decode the message using the DecodeAuthorizationMessage API action for AWS STS, or the decode-authorization-message command in the AWS CLI.

Examples
- Example: Read-only access (p. 1116)
- Example: Use the EC2 launch wizard (p. 1117)
- Example: Work with volumes (p. 1120)
- Example: Work with security groups (p. 1120)
- Example: Work with Elastic IP addresses (p. 1122)
Example: Work with Reserved Instances (p. 1123)

For additional information about creating policies for the Amazon EC2 console, see the following AWS Security Blog post: Granting Users Permission to Work in the Amazon EC2 Console.

Example: Read-only access

To allow users to view all resources in the Amazon EC2 console, you can use the same policy as the following example: Example: Read-only access (p. 1078). Users cannot perform any actions on those resources or create new resources, unless another statement grants them permission to do so.

View instances, AMIs, and snapshots

Alternatively, you can provide read-only access to a subset of resources. To do this, replace the * wildcard in the ec2:Describe API action with specific ec2:Describe actions for each resource. The following policy allows users to view all instances, AMIs, and snapshots in the Amazon EC2 console. The ec2:DescribeTags action allows users to view public AMIs. The console requires the tagging information to display public AMIs; however, you can remove this action to allow users to view only private AMIs.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeInstances",
      "ec2:DescribeImages",
      "ec2:DescribeTags",
      "ec2:DescribeSnapshots"
    ],
    "Resource": "*
  }
]
```

Note

The Amazon EC2 ec2:Describe* API actions do not support resource-level permissions, so you cannot control which individual resources users can view in the console. Therefore, the * wildcard is necessary in the Resource element of the above statement. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

View instances and CloudWatch metrics

The following policy allows users to view instances in the Amazon EC2 console, as well as CloudWatch alarms and metrics in the Monitoring tab of the Instances page. The Amazon EC2 console uses the CloudWatch API to display the alarms and metrics, so you must grant users permission to use the cloudwatch:DescribeAlarms and cloudwatch:GetMetricStatistics actions.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeInstances",
      "cloudwatch:DescribeAlarms",
      "cloudwatch:GetMetricStatistics"
    ],
    "Resource": "*
  }
]
```
Example: Use the EC2 launch wizard

The Amazon EC2 launch wizard is a series of screens with options to configure and launch an instance. Your policy must include permission to use the API actions that allow users to work with the wizard's options. If your policy does not include permission to use those actions, some items in the wizard cannot load properly, and users cannot complete a launch.

Basic launch wizard access

To complete a launch successfully, users must be given permission to use the `ec2:RunInstances` API action, and at least the following API actions:

- `ec2:DescribeImages`: To view and select an AMI.
- `ec2:DescribeInstanceTypes`: To view and select an instance type.
- `ec2:DescribeVpcs`: To view the available network options.
- `ec2:DescribeSubnets`: To view all available subnets for the chosen VPC.
- `ec2:DescribeSecurityGroups` or `ec2:CreateSecurityGroup`: To view and select an existing security group, or to create a new one.
- `ec2:DescribeKeyPairs` or `ec2:CreateKeyPair`: To select an existing key pair, or to create a new one.
- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeImages",
            "ec2:DescribeInstanceTypes",
            "ec2:DescribeKeyPairs",
            "ec2:DescribeVpcs",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups",
            "ec2:CreateSecurityGroup",
            "ec2:AuthorizeSecurityGroupIngress",
            "ec2:CreateKeyPair"
         ],
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": "ec2:RunInstances",
         "Resource": "*"
      }
   ]
}
```

You can add API actions to your policy to provide more options for users, for example:

- `ec2:DescribeAvailabilityZones`: To view and select a specific Availability Zone.
- `ec2:DescribeNetworkInterfaces`: To view and select existing network interfaces for the selected subnet.
• To add outbound rules to VPC security groups, users must be granted permission to use the `ec2:AuthorizeSecurityGroupEgress` API action. To modify or delete existing rules, users must be granted permission to use the relevant `ec2:RevokeSecurityGroup*` API action.

• `ec2:CreateTags`: To tag the resources that are created by `RunInstances`. For more information, see *Grant permission to tag resources during creation (p. 1075)*. If users do not have permission to use this action and they attempt to apply tags on the tagging page of the launch wizard, the launch fails.

**Important**

Be careful about granting users permission to use the `ec2:CreateTags` action, because doing so limits your ability to use the `ec2:ResourceTag` condition key to restrict their use of other resources. If you grant users permission to use the `ec2:CreateTags` action, they can change a resource's tag in order to bypass those restrictions. For more information, see *Control access to EC2 resources using resource tags (p. 1078)*.

• To use Systems Manager parameters when selecting an AMI, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your policy. `ssm:DescribeParameters` grants your IAM users the permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your IAM users the permission to get the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see *Restrict access to specific Systems Manager parameters* later in this section.

Currently, the Amazon EC2 `Describe*` API actions do not support resource-level permissions, so you cannot restrict which individual resources users can view in the launch wizard. However, you can apply resource-level permissions on the `ec2:RunInstances` API action to restrict which resources users can use to launch an instance. The launch fails if users select options that they are not authorized to use.

**Restrict access to a specific instance type, subnet, and Region**

The following policy allows users to launch `t2.micro` instances using AMIs owned by Amazon, and only into a specific subnet (`subnet-1a2b3c4d`). Users can only launch in the `sa-east-1` Region. If users select a different Region, or select a different instance type, AMI, or subnet in the launch wizard, the launch fails.

The first statement grants users permission to view the options in the launch wizard or to create new ones, as explained in the example above. The second statement grants users permission to use the network interface, volume, key pair, security group, and subnet resources for the `ec2:RunInstances` action, which are required to launch an instance into a VPC. For more information about using the `ec2:RunInstances` action, see *Launch instances (RunInstances) (p. 1091)*. The third and fourth statements grant users permission to use the instance and AMI resources respectively, but only if the instance is a `t2.micro` instance, and only if the AMI is owned by Amazon.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeImages",
            "ec2:DescribeInstanceTypes",
            "ec2:DescribeKeyPairs",
            "ec2:CreateKeyPair",
            "ec2:DescribeVpcs",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups",
            "ec2:CreateSecurityGroup",
            "ec2:AuthorizeSecurityGroupIngress"
        ],
        "Resource": "*
    },
    "Resource": "*
}]
```
Restrict access to specific Systems Manager parameters

The following policy grants access to use Systems Manager parameters with a specific name.

The first statement grants users the permission to view Systems Manager parameters when selecting an AMI in the launch wizard. The second statement grants users the permission to only use parameters that are named `prod-*`.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ssm:DescribeParameters"
        ],
        "Resource": "*"
    }],
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ssm:GetParameters"
        ],
    }]
}
```
Example: Work with volumes

The following policy grants users permission to view and create volumes, and attach and detach volumes to specific instances.

Users can attach any volume to instances that have the tag "purpose=test", and also detach volumes from those instances. To attach a volume using the Amazon EC2 console, it is helpful for users to have permission to use the `ec2:DescribeInstances` action, as this allows them to select an instance from a pre-populated list in the Attach Volume dialog box. However, this also allows users to view all instances on the Instances page in the console, so you can omit this action.

In the first statement, the `ec2:DescribeAvailabilityZones` action is necessary to ensure that a user can select an Availability Zone when creating a volume.

Users cannot tag the volumes that they create (either during or after volume creation).

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeVolumes",
            "ec2:DescribeAvailabilityZones",
            "ec2:CreateVolume",
            "ec2:DescribeInstances"
        ],
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": [
            "ec2:AttachVolume",
            "ec2:DetachVolume"
        ],
        "Condition": {
            "StringEquals": {
                "ec2:ResourceTag/purpose": "test"
            }
        }
    },
    {
        "Effect": "Allow",
        "Action": [
            "ec2:AttachVolume",
            "ec2:DetachVolume"
        ],
    }
}
```

Example: Work with security groups

View security groups and add and remove rules

The following policy grants users permission to view security groups in the Amazon EC2 console, to add and remove inbound and outbound rules, and to list and modify rule descriptions for existing security groups that have the tag `Department=Test`.

In the first statement, the `ec2:DescribeTags` action allows users to view tags in the console, which makes it easier for users to identify the security groups that they are allowed to modify.
Work with the Create Security Group dialog box

You can create a policy that allows users to work with the Create Security Group dialog box in the Amazon EC2 console. To use this dialog box, users must be granted permission to use at least the following API actions:

- `ec2:CreateSecurityGroup`: To create a new security group.
- `ec2:DescribeVpcs`: To view a list of existing VPCs in the VPC list.

With these permissions, users can create a new security group successfully, but they cannot add any rules to it. To work with rules in the Create Security Group dialog box, you can add the following API actions to your policy:

- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.
- `ec2:AuthorizeSecurityGroupEgress`: To add outbound rules to VPC security groups.
- `ec2:RevokeSecurityGroupIngress`: To modify or delete existing inbound rules. This is useful to allow users to use the Copy to new feature in the console. This feature opens the Create Security Group dialog box and populates it with the same rules as the security group that was selected.
IAM policies

- **ec2:RevokeSecurityGroupEgress**: To modify or delete outbound rules for VPC security groups. This is useful to allow users to modify or delete the default outbound rule that allows all outbound traffic.

- **ec2:DeleteSecurityGroup**: To cater for when invalid rules cannot be saved. The console first creates the security group, and then adds the specified rules. If the rules are invalid, the action fails, and the console attempts to delete the security group. The user remains in the Create Security Group dialog box so that they can correct the invalid rule and try to create the security group again. This API action is not required, but if a user is not granted permission to use it and attempts to create a security group with invalid rules, the security group is created without any rules, and the user must add them afterward.

- **ec2:UpdateSecurityGroupRuleDescriptionsIngress**: To add or update descriptions of ingress (inbound) security group rules.

- **ec2:UpdateSecurityGroupRuleDescriptionsEgress**: To add or update descriptions of egress (outbound) security group rules.

- **ec2:ModifySecurityGroupRules**: To modify security group rules.

- **ec2:DescribeSecurityGroupRules**: To list security group rules.

The following policy grants users permission to use the Create Security Group dialog box, and to create inbound and outbound rules for security groups that are associated with a specific VPC (vpc-1a2b3c4d). Users can create security groups for EC2-Classic or another VPC, but they cannot add any rules to them. Similarly, users cannot add any rules to any existing security group that's not associated with VPC vpc-1a2b3c4d. Users are also granted permission to view all security groups in the console. This makes it easier for users to identify the security groups to which they can add inbound rules. This policy also grants users permission to delete security groups that are associated with VPC vpc-1a2b3c4d.

```json
{
   "Version": "2012-10-17",
   "Statement": [{
       "Effect": "Allow",
       "Action": [
           "ec2:DescribeSecurityGroups",
           "ec2:CreateSecurityGroup",
           "ec2:DescribeVpcs"
       ],
       "Resource": "*"
   },
   {"Effect": "Allow",
    "Action": [
       "ec2:DeleteSecurityGroup",
       "ec2:AuthorizeSecurityGroupIngress",
       "ec2:AuthorizeSecurityGroupEgress"
    ],
    "Condition":{
        "ArnEquals": {
            "ec2:Vpc": "arn:aws:ec2:region:111122223333:vpc/vpc-1a2b3c4d"
        }
    }
   }
}
```

### Example: Work with Elastic IP addresses

To allow users to view Elastic IP addresses in the Amazon EC2 console, you must grant users permission to use the ec2:DescribeAddresses action.
To allow users to work with Elastic IP addresses, you can add the following actions to your policy.

- `ec2:AllocateAddress`: To allocate an Elastic IP address.
- `ec2:ReleaseAddress`: To release an Elastic IP address.
- `ec2:AssociateAddress`: To associate an Elastic IP address with an instance or a network interface.
- `ec2:DescribeNetworkInterfaces` and `ec2:DescribeInstances`: To work with the `Associate address` screen. The screen displays the available instances or network interfaces to which you can associate an Elastic IP address.
- `ec2:DisassociateAddress`: To disassociate an Elastic IP address from an instance or a network interface.

The following policy allows users to view, allocate, and associate Elastic IP addresses with instances. Users cannot associate Elastic IP addresses with network interfaces, disassociate Elastic IP addresses, or release them.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeAddresses",
        "ec2:AllocateAddress",
        "ec2:DescribeInstances",
        "ec2:AssociateAddress"
      ],
      "Resource": "*"
    }
  ]
}
```

Example: Work with Reserved Instances

The following policy can be attached to an IAM user. It gives the user access to view and modify Reserved Instances in your account, as well as purchase new Reserved Instances in the AWS Management Console.

This policy allows users to view all the Reserved Instances, as well as On-Demand Instances, in the account. It's not possible to set resource-level permissions for individual Reserved Instances.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeReservedInstances",
      "ec2:ModifyReservedInstances",
      "ec2:PurchaseReservedInstancesOffering",
      "ec2:DescribeInstances",
      "ec2:DescribeInstanceTypes",
      "ec2:DescribeAvailabilityZones",
      "ec2:DescribeReservedInstancesOfferings"
    ],
    "Resource": "*"
  }]
}
```

The `ec2:DescribeAvailabilityZones` action is necessary to ensure that the Amazon EC2 console can display information about the Availability Zones in which you can purchase Reserved Instances. The
**AWS managed policies for Amazon Elastic Compute Cloud**

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

**AWS managed policy: AmazonEC2FullAccess**

You can attach the AmazonEC2FullAccess policy to your IAM identities. This policy grants permissions that allow full access to Amazon EC2.

To view the permissions for this policy, see AmazonEC2FullAccess in the AWS Management Console.

**AWS managed policy: AmazonEC2ReadOnlyAccess**

You can attach the AmazonEC2ReadOnlyAccess policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon EC2.

To view the permissions for this policy, see AmazonEC2ReadOnlyAccess in the AWS Management Console.

**AWS managed policy: AWSEC2FleetServiceRolePolicy**

This policy is attached to the service-linked role named AWSServiceRoleForEC2Fleet to allow EC2 Fleet to request, launch, terminate, and tag instances on your behalf. For more information, see Service-linked role for EC2 Fleet (p. 685).

**AWS managed policy: AWSEC2SpotFleetServiceRolePolicy**

This policy is attached to the service-linked role named AWSServiceRoleForEC2SpotFleet to allow Spot Fleet to launch and manage instances on your behalf. For more information, see Service-linked role for Spot Fleet (p. 715).
AWS managed policy: AWSEC2SpotServiceRolePolicy

This policy is attached to the service-linked role named AWSServiceRoleForEC2Spot to allow Amazon EC2 to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests (p. 379).

IAM roles for Amazon EC2

Applications must sign their API requests with AWS credentials. Therefore, if you are an application developer, you need a strategy for managing credentials for your applications that run on EC2 instances. For example, you can securely distribute your AWS credentials to the instances, enabling the applications on those instances to use your credentials to sign requests, while protecting your credentials from other users. However, it's challenging to securely distribute credentials to each instance, especially those that AWS creates on your behalf, such as Spot Instances or instances in Auto Scaling groups. You must also be able to update the credentials on each instance when you rotate your AWS credentials.

We designed IAM roles so that your applications can securely make API requests from your instances, without requiring you to manage the security credentials that the applications use. Instead of creating and distributing your AWS credentials, you can delegate permission to make API requests using IAM roles as follows:

1. Create an IAM role.
2. Define which accounts or AWS services can assume the role.
3. Define which API actions and resources the application can use after assuming the role.
4. Specify the role when you launch your instance, or attach the role to an existing instance.
5. Have the application retrieve a set of temporary credentials and use them.

For example, you can use IAM roles to grant permissions to applications running on your instances that need to use a bucket in Amazon S3. You can specify permissions for IAM roles by creating a policy in JSON format. These are similar to the policies that you create for IAM users. If you change a role, the change is propagated to all instances.

When creating IAM roles, associate least privilege IAM policies that restrict access to the specific API calls the application requires.

You can only attach one IAM role to an instance, but you can attach the same role to many instances. For more information about creating and using IAM roles, see Roles in the IAM User Guide.

You can apply resource-level permissions to your IAM policies to control the users' ability to attach, replace, or detach IAM roles for an instance. For more information, see Supported resource-level permissions for Amazon EC2 API actions (p. 1073) and the following example: Example: Work with IAM roles (p. 1109).

Contents

- Instance profiles (p. 1125)
- Retrieve security credentials from instance metadata (p. 1126)
- Grant an IAM user permission to pass an IAM role to an instance (p. 1127)
- Work with IAM roles (p. 1127)

Instance profiles

Amazon EC2 uses an instance profile as a container for an IAM role. When you create an IAM role using the IAM console, the console creates an instance profile automatically and gives it the same name as the
role to which it corresponds. If you use the Amazon EC2 console to launch an instance with an IAM role or to attach an IAM role to an instance, you choose the role based on a list of instance profile names.

If you use the AWS CLI, API, or an AWS SDK to create a role, you create the role and instance profile as separate actions, with potentially different names. If you then use the AWS CLI, API, or an AWS SDK to launch an instance with an IAM role or to attach an IAM role to an instance, specify the instance profile name.

An instance profile can contain only one IAM role. This limit cannot be increased.

For more information, see Instance Profiles in the IAM User Guide.

Retrieve security credentials from instance metadata

An application on the instance retrieves the security credentials provided by the role from the instance metadata item `iam/security-credentials/role-name`. The application is granted the permissions for the actions and resources that you've defined for the role through the security credentials associated with the role. These security credentials are temporary and we rotate them automatically. We make new credentials available at least five minutes before the expiration of the old credentials.

**Warning**

If you use services that use instance metadata with IAM roles, ensure that you don't expose your credentials when the services make HTTP calls on your behalf. The types of services that could expose your credentials include HTTP proxies, HTML/CSS validator services, and XML processors that support XML inclusion.

The following command retrieves the security credentials for an IAM role named `s3access`.

**IMDSv2**

```
```

**IMDSv1**

```
```

The following is example output.

```
{
   "Code" : "Success",
   "LastUpdated" : "2012-04-26T16:39:16Z",
   "Type" : "AWS-HMAC",
   "AccessKeyId" : "ASIAIOSFODNN7EXAMPLE",
   "SecretAccessKey" : "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
   "Token" : "token",
   "Expiration" : "2017-05-17T15:09:54Z"
}
```

For applications, AWS CLI, and Tools for Windows PowerShell commands that run on the instance, you do not have to explicitly get the temporary security credentials—the AWS SDKs, AWS CLI, and Tools for Windows PowerShell automatically get the credentials from the EC2 instance metadata service and use them. To make a call outside of the instance using temporary security credentials (for example, to test IAM policies), you must provide the access key, secret key, and the session token. For more information, see Using Temporary Security Credentials to Request Access to AWS Resources in the IAM User Guide.
Grant an IAM user permission to pass an IAM role to an instance

To enable an IAM user to launch an instance with an IAM role or to attach or replace an IAM role for an existing instance, you must grant the user permission to use the following API actions:

- `iam:PassRole`
- `ec2:AssociateIamInstanceProfile`
- `ec2:ReplaceIamInstanceProfileAssociation`

For example, the following IAM policy grants users permission to launch instances with an IAM role, or to attach or replace an IAM role for an existing instance using the AWS CLI.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances",
                "ec2:AssociateIamInstanceProfile",
                "ec2:ReplaceIamInstanceProfileAssociation"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "*"
        }
    ]
}
```

To grant users permission to launch instances with an IAM role, or to attach or replace an IAM role for an existing instance using the Amazon EC2 console, you must grant them permission to use `iam:ListInstanceProfiles`, `iam:PassRole`, `ec2:AssociateIamInstanceProfile`, and `ec2:ReplaceIamInstanceProfileAssociation` in addition to any other permissions they might need. For example policies, see Example policies for working in the Amazon EC2 console (p. 1115).

Work with IAM roles

You can create an IAM role and attach it to an instance during or after launch. You can also replace or detach an IAM role for an instance.

Contents

- Create an IAM role (p. 1128)
- Launch an instance with an IAM role (p. 1129)
- Attach an IAM role to an instance (p. 1130)
- Replace an IAM role (p. 1131)
- Detach an IAM role (p. 1133)
Create an IAM role

You must create an IAM role before you can launch an instance with that role or attach it to an instance.

To create an IAM role using the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles, Create role.
3. On the Select role type page, choose EC2 and the EC2 use case. Choose Next: Permissions.
4. On the Attach permissions policy page, select an AWS managed policy that grants your instances access to the resources that they need.
5. On the Review page, enter a name for the role and choose Create role.

Alternatively, you can use the AWS CLI to create an IAM role. The following example creates an IAM role with a policy that allows the role to use an Amazon S3 bucket.

To create an IAM role and instance profile (AWS CLI)

1. Create the following trust policy and save it in a text file named ec2-role-trust-policy.json.

   ```json
   { 
   "Version": "2012-10-17",
   "Statement": [ 
   { "Effect": "Allow",
   "Principal": { "Service": "ec2.amazonaws.com"},
   "Action": "sts:AssumeRole"
   } 
   ]
   }
   ```

2. Create the s3access role and specify the trust policy that you created using the create-role command.

   ```bash
   aws iam create-role --role-name s3access --assume-role-policy-document file://ec2-role-trust-policy.json
   ```

   ```json
curly-smaller
   { 
   "Role": {
   "AssumeRolePolicyDocument": { 
   "Version": "2012-10-17",
   "Statement": [ 
   { 
   "Action": "sts:AssumeRole",
   "Effect": "Allow",
   "Principal": { 
   "Service": "ec2.amazonaws.com"
   } 
   ]
   
   },
   "RoleId": "AROAIIKPSKS2LEXAMPLE",
   "CreateDate": "2013-12-12T23:46:37.247Z",
   "RoleName": "s3access",
   "Path": "/",
   "Arn": "arn:aws:iam::123456789012:role/s3access"
   }
   }
   ```
3. Create an access policy and save it in a text file named `ec2-role-access-policy.json`. For example, this policy grants administrative permissions for Amazon S3 to applications running on the instance.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": ["s3:*"],
         "Resource": ["*"]
       }
     ]
   }
   ```

4. Attach the access policy to the role using the `put-role-policy` command.

   ```bash
   aws iam put-role-policy --role-name s3access --policy-name S3-Permissions --policy-document file://ec2-role-access-policy.json
   ```

5. Create an instance profile named `s3access-profile` using the `create-instance-profile` command.

   ```bash
   aws iam create-instance-profile --instance-profile-name s3access-profile
   ```

   ```json
   {
     "InstanceProfile": {
       "InstanceProfileId": "AIPAJTLBPJLEGEXAMPLE",
       "Roles": [],
       "CreateDate": "2013-12-12T23:53:34.093Z",
       "InstanceProfileName": "s3access-profile",
       "Path": "/",
       "Arn": "arn:aws:iam::123456789012:instance-profile/s3access-profile"
     }
   }
   ```

6. Add the `s3access` role to the `s3access-profile` instance profile.

   ```bash
   aws iam add-role-to-instance-profile --instance-profile-name s3access-profile --role-name s3access
   ```

Alternatively, you can use the following AWS Tools for Windows PowerShell commands:

- `New-IAMRole`
- `Register-IAMRolePolicy`
- `New-IAMInstanceProfile`

**Launch an instance with an IAM role**

After you've created an IAM role, you can launch an instance, and associate that role with the instance during launch.

**Important**

After you create an IAM role, it might take several seconds for the permissions to propagate. If your first attempt to launch an instance with a role fails, wait a few seconds before trying again. For more information, see Troubleshooting Working with Roles in the IAM User Guide.

**To launch an instance with an IAM role (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the dashboard, choose **Launch instance**.
3. Select an AMI and instance type and then choose **Next: Configure Instance Details**.
4. On the **Configure Instance Details** page, for **IAM role**, select the IAM role that you created.

   **Note**
   The **IAM role** list displays the name of the instance profile that you created when you created your IAM role. If you created your IAM role using the console, the instance profile was created for you and given the same name as the role. If you created your IAM role using the AWS CLI, API, or an AWS SDK, you may have named your instance profile differently.

5. Configure any other details, then follow the instructions through the rest of the wizard, or choose **Review and Launch** to accept default settings and go directly to the **Review Instance Launch** page.
6. Review your settings, then choose **Launch** to choose a key pair and launch your instance.
7. If you are using the Amazon EC2 API actions in your application, retrieve the AWS security credentials made available on the instance and use them to sign the requests. The AWS SDK does this for you.

   **IMDSv2**

   ```bash
   ```

   **IMDSv1**

   ```bash
   ```

   Alternatively, you can use the AWS CLI to associate a role with an instance during launch. You must specify the instance profile in the command.

   **To launch an instance with an IAM role (AWS CLI)**

   1. Use the **run-instances** command to launch an instance using the instance profile. The following example shows how to launch an instance with the instance profile.

   ```bash
   AWS ec2 run-instances
   --image-id ami-11aa22bb
   --iam-instance-profile Name="s3access-profile"
   --key-name my-key-pair
   --security-groups my-security-group
   --subnet-id subnet-1a2b3c4d
   ```

   Alternatively, use the **New-EC2Instance** Tools for Windows PowerShell command.

   2. If you are using the Amazon EC2 API actions in your application, retrieve the AWS security credentials made available on the instance and use them to sign the requests. The AWS SDK does this for you.

   ```bash
   ```

   **Attach an IAM role to an instance**

   To attach an IAM role to an instance that has no role, the instance can be in the **stopped** or **running** state.
New console

To attach an IAM role to an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Security, Modify IAM role.
4. Select the IAM role to attach to your instance, and choose Save.

Old console

To attach an IAM role to an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Instance Settings, Attach/Replace IAM role.
4. Select the IAM role to attach to your instance, and choose Apply.

To attach an IAM role to an instance (AWS CLI)

1. If required, describe your instances to get the ID of the instance to which to attach the role.

   ```bash
   aws ec2 describe-instances
   ```

2. Use the `associate-iam-instance-profile` command to attach the IAM role to the instance by specifying the instance profile. You can use the Amazon Resource Name (ARN) of the instance profile, or you can use its name.

   ```bash
   aws ec2 associate-iam-instance-profile
   --instance-id i-1234567890abcdef0
   --iam-instance-profile Name="TestRole-1"
   ```

   ```json
   {     "IamInstanceProfileAssociation": {       "InstanceId": "i-1234567890abcdef0",       "State": "associating",       "AssociationId": "iip-assoc-0dbd8529a48294120",       "IamInstanceProfile": {         "Id": "AIPAJLNLDX3AMYZNWYYAY",         "Arn": "arn:aws:iam::123456789012:instance-profile/TestRole-1"       }     }   }
   ```

   Alternatively, use the following Tools for Windows PowerShell commands:
   - Get-EC2Instance
   - Register-EC2IamInstanceProfile

Replace an IAM role

To replace the IAM role on an instance that already has an attached IAM role, the instance must be in the running state. You can do this if you want to change the IAM role for an instance without detaching
the existing one first. For example, you can do this to ensure that API actions performed by applications running on the instance are not interrupted.

New console

To replace an IAM role for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Security, Modify IAM role.
4. Select the IAM role to attach to your instance, and choose Save.

Old console

To replace an IAM role for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Instance Settings, Attach/Replace IAM role.
4. Select the IAM role to attach to your instance, and choose Apply.

To replace an IAM role for an instance (AWS CLI)

1. If required, describe your IAM instance profile associations to get the association ID for the IAM instance profile to replace.

   ```
   aws ec2 describe-iam-instance-profile-associations
   ```

2. Use the replace-iam-instance-profile-association command to replace the IAM instance profile by specifying the association ID for the existing instance profile and the ARN or name of the instance profile that should replace it.

   ```
   aws ec2 replace-iam-instance-profile-association \
   --association-id iip-assoc-0044d817db6c0a4ba \
   --iam-instance-profile Name="TestRole-2"
   ```

   ```
   "IamInstanceProfileAssociation": {
     "InstanceId": "i-087711ddaf9f948f948f",
     "State": "associating",
     "AssociationId": "iip-assoc-09654be48e33b91e0",
     "IamInstanceProfile": {
       "Id": "AIPAJCJEDKX7QYHWYK7GS",
       "Arn": "arn:aws:iam::123456789012:instance-profile/TestRole-2"
     }
   }
   ```

   Alternatively, use the following Tools for Windows PowerShell commands:
   
   - Get-EC2IamInstanceProfileAssociation
   - Set-EC2IamInstanceProfileAssociation
Detach an IAM role

You can detach an IAM role from a running or stopped instance.

New console

To detach an IAM role from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Security, Modify IAM role.
4. For IAM role, choose No IAM Role. Choose Save.
5. In the confirmation dialog box, enter Detach, and then choose Detach.

Old console

To detach an IAM role from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Instance Settings, Attach/Replace IAM role.
4. For IAM role, choose No Role. Choose Apply.
5. In the confirmation dialog box, choose Yes, Detach.

To detach an IAM role from an instance (AWS CLI)

1. If required, use describe-iam-instance-profile-associations to describe your IAM instance profile associations and get the association ID for the IAM instance profile to detach.

   ```
   aws ec2 describe-iam-instance-profile-associations
   {
   "IamInstanceProfileAssociations": [
   {
   "InstanceId": "i-088ce778fbeb4361",
   "State": "associated",
   "AssociationId": "iip-assoc-0044d817db6c0a4ba",
   "IamInstanceProfile": {
   "Id": "AIPAJEDNCAA64SSD265D6",
   "Arn": "arn:aws:iam::123456789012:instance-profile/TestRole-2"
   }
   }
   ]
   }
   ```

2. Use the disassociate-iam-instance-profile command to detach the IAM instance profile using its association ID.

   ```
   aws ec2 disassociate-iam-instance-profile --association-id iip-assoc-0044d817db6c0a4ba
   {
   "IamInstanceProfileAssociation": {
   "InstanceId": "i-087711d9af98f9489",
   "State": "disassociating",
   "AssociationId": "iip-assoc-0044d817db6c0a4ba",
   "IamInstanceProfile": {
   ```
Alternatively, use the following Tools for Windows PowerShell commands:

- Get-EC2IamInstanceProfileAssociation
- Unregister-EC2IamInstanceProfile

Generate a policy for your IAM role based on access activity

When you first create an IAM role for your applications, you might sometimes grant permissions beyond what is required. Before launching your application in your production environment, you can generate an IAM policy that is based on the access activity for an IAM role. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the role in your specified date range. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM role. That way, you grant only the permissions that the role needs to interact with AWS resources for your specific use case. This helps you adhere to the best practice of granting least privilege. To learn more, see Generate policies based on access activity in the IAM User Guide.

Authorize inbound traffic for your Linux instances

Security groups enable you to control traffic to your instance, including the kind of traffic that can reach your instance. For example, you can allow computers from only your home network to access your instance using SSH. If your instance is a web server, you can allow all IP addresses to access your instance using HTTP or HTTPS, so that external users can browse the content on your web server.

Your default security groups and newly created security groups include default rules that do not enable you to access your instance from the internet. For more information, see Default security groups (p. 1156) and Custom security groups (p. 1157). To enable network access to your instance, you must allow inbound traffic to your instance. To open a port for inbound traffic, add a rule to a security group that you associated with your instance when you launched it.

To connect to your instance, you must set up a rule to authorize SSH traffic from your computer's public IPv4 address. To allow SSH traffic from additional IP address ranges, add another rule for each range you need to authorize.

If you've enabled your VPC for IPv6 and launched your instance with an IPv6 address, you can connect to your instance using its IPv6 address instead of a public IPv4 address. Your local computer must have an IPv6 address and must be configured to use IPv6.

If you need to enable network access to a Windows instance, see Authorizing inbound traffic for your Windows instances in the Amazon EC2 User Guide for Windows Instances.

Before you start

Decide who requires access to your instance; for example, a single host or a specific network that you trust such as your local computer's public IPv4 address. The security group editor in the Amazon EC2 console can automatically detect the public IPv4 address of your local computer for you. Alternatively, you can use the search phrase "what is my IP address" in an internet browser, or use the following service: Check IP. If you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.
Warning

If you use 0.0.0.0/0, you enable all IPv4 addresses to access your instance using SSH. If you use ::/0, you enable all IPv6 address to access your instance. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

Decide whether you'll support SSH access to your instances using EC2 Instance Connect. If you will not use EC2 Instance Connect, consider uninstalling it or denying the following action in your IAM policies: ec2-instance-connect:SendSSHPublicKey. For more information, see Uninstall EC2 Instance Connect (p. 514) and Configure IAM Permissions for EC2 Instance Connect (p. 509).

Add a rule for inbound SSH traffic to a Linux instance

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group to enable you to connect to your Linux instance from your IP address using SSH.

New console

To add a rule to a security group for inbound SSH traffic over IPv4 (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance and, in bottom half of the screen, choose the Security tab. Security groups lists the security groups that are associated with the instance. Inbound rules displays a list of the inbound rules that are in effect for the instance.
4. For the security group to which you'll add the new rule, choose the security group ID link to open the security group.
6. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose SSH.
   c. For Source, choose My IP to automatically populate the field with the public IPv4 address of your local computer.

   Alternatively, for Source, choose Custom and enter the public IPv4 address of your computer or network in CIDR notation. For example, if your IPv4 address is 203.0.113.25, enter 203.0.113.25/32 to list this single IPv4 address in CIDR notation. If your company allocates addresses from a range, enter the entire range, such as 203.0.113.0/24.

   For information about finding your IP address, see Before you start (p. 1134).
   d. Choose Save rules.

Old console

To add a rule to a security group for inbound SSH traffic over IPv4 (console)

1. In the navigation pane of the Amazon EC2 console, choose Instances. Select your instance and look at the Description tab; Security groups lists the security groups that are associated with the instance. Choose view inbound rules to display a list of the rules that are in effect for the instance.
2. In the navigation pane, choose Security Groups. Select one of the security groups associated with your instance.
3. In the details pane, on the **Inbound** tab, choose **Edit**. In the dialog, choose **Add Rule**, and then choose **SSH** from the **Type** list.

4. In the **Source** field, choose **My IP** to automatically populate the field with the public IPv4 address of your local computer. Alternatively, choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. For example, if your IPv4 address is `203.0.113.25`, specify `203.0.113.25/32` to list this single IPv4 address in CIDR notation. If your company allocates addresses from a range, specify the entire range, such as `203.0.113.0/24`.

For information about finding your IP address, see Before you start (p. 1134).

5. Choose **Save**.

If you launched an instance with an IPv6 address and want to connect to your instance using its IPv6 address, you must add rules that allow inbound IPv6 traffic over SSH.

**New console**

**To add a rule to a security group for inbound SSH traffic over IPv6 (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance and, in bottom half of the screen, choose the **Security** tab. **Security groups** lists the security groups that are associated with the instance. **Inbound rules** displays a list of the inbound rules that are in effect for the instance.
4. For the security group to which you'll add the new rule, choose the security group ID link to open the security group.
5. On the **Inbound rules** tab, choose **Edit inbound rules**.
6. On the **Edit inbound rules** page, do the following:
   a. Choose **Add rule**.
   b. For **Type**, choose **SSH**.
   c. For **Source**, choose **Custom** and enter the IPv6 address of your computer in CIDR notation. For example, if your IPv6 address is `2001:db8:1234:1a00:9691:9503:25ad:1761`, enter `2001:db8:1234:1a00:9691:9503:25ad:1761/128` to list the single IP address in CIDR notation. If your company allocates addresses from a range, enter the entire range, such as `2001:db8:1234:1a00::/64`.
   d. Choose **Save rules**.

**Old console**

**To add a rule to a security group for inbound SSH traffic over IPv6 (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**. Select the security group for your instance.
3. Choose **Inbound, Edit, Add Rule**.
4. For **Type**, choose **SSH**.
5. In the **Source** field, specify the IPv6 address of your computer in CIDR notation. For example, if your IPv6 address is `2001:db8:1234:1a00:9691:9503:25ad:1761`, specify `2001:db8:1234:1a00:9691:9503:25ad:1761/128` to list the single IP address in CIDR notation. If your company allocates addresses from a range, specify the entire range, such as `2001:db8:1234:1a00::/64`.
6. Choose **Save**.
Note
Be sure to run the following commands on your local system, not on the instance itself. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

To add a rule to a security group using the command line
1. Find the security group that is associated with your instance using one of the following commands:
   • describe-instance-attribute (AWS CLI)
     ```
     aws ec2 describe-instance-attribute --instance-id instance_id --attribute groupSet
     ```
   • Get-EC2InstanceAttribute (AWS Tools for Windows PowerShell)
     ```
     PS C:\> (Get-EC2InstanceAttribute -InstanceId instance_id -Attribute groupSet).Groups
     ```

   Both commands return a security group ID, which you use in the next step.
2. Add the rule to the security group using one of the following commands:
   • authorize-security-group-ingress (AWS CLI)
     ```
     aws ec2 authorize-security-group-ingress --group-id security_group_id --protocol tcp --port 22 --cidr cidr_ip_range
     ```
   • Grant-EC2SecurityGroupIngress (AWS Tools for Windows PowerShell)
     ```
     The Grant-EC2SecurityGroupIngress command needs an IpPermission parameter, which describes the protocol, port range, and IP address range to be used for the security group rule. The following command creates the IpPermission parameter:
     ```
     PS C:\> $ip1 = @{ IpProtocol="tcp"; FromPort="22"; ToPort="22"; IpRanges="cidr_ip_range" }
     ```
     ```
     PS C:\> Grant-EC2SecurityGroupIngress -GroupId security_group_id -IpPermission @($ip1)
     ```

Assign a security group to an instance
You can assign a security group to an instance when you launch the instance. When you add or remove rules, those changes are automatically applied to all instances to which you've assigned the security group.

After you launch an instance, you can change its security groups. For more information, see Changing an instance's security groups in the Amazon VPC User Guide.

Amazon EC2 key pairs and Linux instances
A key pair, consisting of a public key and a private key, is a set of security credentials that you use to prove your identity when connecting to an Amazon EC2 instance. Amazon EC2 stores the public key on your instance, and you store the private key. For Linux instances, the private key allows you to securely SSH into your instance. Anyone who possesses your private key can connect to your instances, so it's important that you store your private key in a secure place.
When you launch an instance, you are prompted for a key pair (p. 482). If you plan to connect to the instance using SSH, you must specify a key pair. You can choose an existing key pair or create a new one. When your instance boots for the first time, the public key that you specified at launch is placed on your Linux instance in an entry within ~/.ssh/authorized_keys. When you connect to your Linux instance using SSH, to log in you must specify the private key that corresponds to the public key. For more information about connecting to your instance, see Connect to your Linux instance (p. 499). For more information about key pairs and Windows instances, see Amazon EC2 key pairs and Windows instances in the Amazon EC2 User Guide for Windows Instances.

Because Amazon EC2 doesn't keep a copy of your private key, there is no way to recover a private key if you lose it. However, there can still be a way to connect to instances for which you've lost the private key. For more information, see Connect to your Linux instance if you lose your private key (p. 1148).

You can use Amazon EC2 to create your key pairs. You can also use a third-party tool to create your key pairs, and then import the public keys to Amazon EC2.

The keys that Amazon EC2 uses are ED25519 or 2048-bit SSH-2 RSA keys.

You can have up to 5,000 key pairs per Region.

Contents
- Create a key pair using Amazon EC2 (p. 1138)
- Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 1140)
- Tag a public key (p. 1142)
- Retrieve the public key from the private key (p. 1143)
- Retrieve the public key through instance metadata (p. 1144)
- Locate the public key on an instance (p. 1144)
- Identify the key pair that was specified at launch (p. 1145)
- Verify your key pair's fingerprint (p. 1145)
- Add or replace a key pair for your instance (p. 1146)
- Delete your key pair (p. 1147)
- Delete a public key from an instance (p. 1147)
- Connect to your Linux instance if you lose your private key (p. 1148)

Create a key pair using Amazon EC2

You can create a key pair using one of the following methods.

Console

To create your key pair

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under Network & Security, choose Key Pairs.
3. Choose Create key pair.
4. For Name, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can't include leading or trailing spaces.
5. For Key pair type, choose either RSA or ED25519. Note that ED25519 keys are not supported for Windows instances, EC2 Instance Connect, or EC2 Serial Console.
6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.

   If you chose **ED25519** in the previous step, the **Private key file format** options do not appear, and the private key format defaults to **pem**.

7. To add a tag to the public key, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

8. Choose **Create key pair**.

9. The private key file is automatically downloaded by your browser. The base file name is the name that you specified as the name of your key pair, and the file name extension is determined by the file format that you chose. Save the private key file in a safe place.

   **Important**
   This is the only chance for you to save the private key file.

10. If you will use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

    ```shell
    chmod 400 my-key-pair.pem
    ```

    If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file (p. 1487).

**AWS CLI**

**To create your key pair**

1. Use the `create-key-pair` command as follows to generate the key pair and to save the private key to a .pem file.

   ```shell
   aws ec2 create-key-pair --key-name my-key-pair --key-type rsa --query "KeyMaterial" --output text > my-key-pair.pem
   ```

   For **--key-name**, specify a name for the public key. The name can be up to 255 ASCII characters.

   For **--key-type**, specify either **rsa** or **ed25519**. If you do not include the **--key-type** parameter, an **rsa** key is created by default. Note that ED25519 keys are not supported for Windows instances, EC2 Instance Connect, and EC2 Serial Console.

   **--query "KeyMaterial"** prints the private key material to the output.

   **--output text > my-key-pair.pem** saves the private key material in a file with the .pem extension. The private key can have a name that's different from the public key name, but for ease of use, use the same name.

2. If you will use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

    ```shell
    chmod 400 my-key-pair.pem
    ```
Create a key pair using a third-party tool and import the public key to Amazon EC2

Instead of using Amazon EC2 to create your key pair, you can create an RSA or ED25519 key pair by using a third-party tool, and then import the public key to Amazon EC2.

Requirements for key pairs

- Supported types: RSA and ED25519. Amazon EC2 does not accept DSA keys.
- Note that ED25519 keys are not supported for Windows instances, EC2 Instance Connect, and EC2 Serial Console.
- Supported formats:
  - OpenSSH public key format (the format in ~/.ssh/authorized_keys). If you connect using SSH while using the EC2 Instance Connect API, the SSH2 format is also supported.
  - SSH private key file format must be PEM
  - (RSA only) Base64 encoded DER format
  - (RSA only) SSH public key file format as specified in RFC 4716
- Supported lengths: 1024, 2048, and 4096. If you connect using SSH while using the EC2 Instance Connect API, the supported lengths are 2048 and 4096.

To create a key pair using a third-party tool

1. Generate a key pair with a third-party tool of your choice. For example, you can use ssh-keygen (a tool provided with the standard OpenSSH installation). Alternatively, Java, Ruby, Python, and many other programming languages provide standard libraries that you can use to create an RSA or ED25519 key pair.
Create a key pair using a third-party tool and import the public key to Amazon EC2

Important
The private key must be in the PEM format. For example, use `ssh-keygen -m PEM` to generate the OpenSSH key in the PEM format.

2. Save the public key to a local file. For example, `~/.ssh/my-key-pair.pub`. The file name extension for this file is not important.

3. Save the private key to a local file that has the `.pem` extension. For example, `~/.ssh/my-key-pair.pem`.

Important
Save the private key file in a safe place. You'll need to provide the name of your public key when you launch an instance, and the corresponding private key each time you connect to the instance.

After you have created the key pair, use one of the following methods to import your public key to Amazon EC2.

Console

To import the public key

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Key Pairs.
3. Choose Import key pair.
4. For Name, enter a descriptive name for the public key. The name can include up to 255 ASCII characters. It can't include leading or trailing spaces.

   Note
   When you connect to your instance from the EC2 console, the console suggests this name for the name of your private key file.

5. Either choose Browse to navigate to and select your public key, or paste the contents of your public key into the Public key contents field.
6. Choose Import key pair.
7. Verify that the public key that you imported appears in the list of key pairs.

AWS CLI

To import the public key

Use the `import-key-pair` AWS CLI command.

To verify that the key pair was imported successfully

Use the `describe-key-pairs` AWS CLI command.

PowerShell

To import the public key

Use the `Import-EC2KeyPair` AWS Tools for Windows PowerShell command.

To verify that the key pair was imported successfully

Use the `Get-EC2KeyPair` AWS Tools for Windows PowerShell command.
Tag a public key

To help categorize and manage the public keys that you've either created using Amazon EC2 or imported to Amazon EC2, you can tag them with custom metadata. For more information about how tags work, see Tag your Amazon EC2 resources (p. 1462).

You can view, add, and delete tags using one of the following methods.

Console

To view, add, or delete a tag for an existing public key

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Key Pairs.
3. Select a public key, and then choose Actions, Manage tags.
4. The Manage tags page displays any tags that are assigned to the public key.
   - To add a tag, choose Add tag, and then enter the tag key and value. You can add up to 50 tags per key. For more information, see Tag restrictions (p. 1466).
   - To delete a tag, choose Remove next to the tag to delete.
5. Choose Save.

AWS CLI

To view public key tags

Use the describe-tags AWS CLI command. In the following example, you describe the tags for all of your public keys.

```bash
$ aws ec2 describe-tags --filters "Name=resource-type,Values=key-pair"
```

```json
{
   "Tags": [
      {
         "Key": "Environment",
         "ResourceId": "key-0123456789EXAMPLE",
         "ResourceType": "key-pair",
         "Value": "Production"
      },
      {
         "Key": "Environment",
         "ResourceId": "key-9876543210EXAMPLE",
         "ResourceType": "key-pair",
         "Value": "Production"
      }
   ]
}
```

To describe the tags for a specific public key

Use the describe-key-pairs AWS CLI command.

```bash
$ aws ec2 describe-key-pairs --key-pair-ids key-0123456789EXAMPLE
```

```json
{
   "KeyPairs": [
      {
         "KeyFamilies": ["小麦"]
      }
   ]
}
```
Retrieve the public key from the private key

To tag an existing public key

Use the create-tags AWS CLI command. In the following example, the existing key is tagged with Key=Cost-Center and Value=CC-123.

```bash
$ aws ec2 create-tags --resources key-0123456789EXAMPLE --tags Key=Cost-Center,Value=CC-123
```

To delete a tag from a public key

Use the delete-tags AWS CLI command. For examples, see Examples in the AWS CLI Command Reference.

PowerShell

To view public key tags

Use the Get-EC2Tag command.

To describe the tags for a specific public key

Use the Get-EC2KeyPair command.

To tag an existing public key

Use the New-EC2Tag command.

To delete a tag from a public key

Use the Remove-EC2Tag command.

Retrieve the public key from the private key

On your local Linux or macOS computer, you can use the ssh-keygen command to retrieve the public key for your key pair. Specify the path where you downloaded your private key (the .pem file).

```
ssh-keygen -y -f /path_to_key_pair/my-key-pair.pem
```

The command returns the public key, as shown in the following example.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADQABAAAAABAQCLKsKfKuSevGj3eYhCe53pcqgP3maAhDFcvBS706Vhz2ItxCih+PnDSUaw+WNQn/mZphTk/a/gU8jEzoOWbM4yxyb/wB96xbiFveSFJuOp/d6EJhJD01BXrlsLbITntckIj7Fbtx/JMKLtvwJryDUi1hMTJytwW+BhYKUMOZce5Pjz5/18SeJtnV31AoG/cQk+0FzZgaeJAAHco+C7/4wrUbfkXmHr6hCtXkVjDwHPkYQS3xgC0+FmUZofz221Cbt5IMucxXPKx4rWl+iZ7wB3RbBQoQzd8v7yeb7OslPnWoyN0gFU0XA246RA8QFYiCNYw13f05p6KLxEXAMPLE
```
If the command fails, run the following command to ensure that you've changed the permissions on your private key pair file so that only you can view it.

```
chmod 400 my-key-pair.pem
```

## Retrieve the public key through instance metadata

The public key that you specified when you launched an instance is also available through the instance metadata. To view the public key that you specified when launching the instance, use the following command from your instance.

**IMDSv2**

```
```

The following is an example output.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQDAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6Vh2ztxCh+PnDSUaw+WNQn/m2phtTk/a/gU8jEzoOWbxM4yxyyb/wB96xbiFveSFJuOp/d6RJhJ0I1iBxrlsLnBtntckl7FbtxJMXLvwwJryDUIIbMTjYtwB+QhYXUMO2ce5Pjz5/i8SeJtjnV3IA0G/cQk+0FzZqaeJAAHco+CY/5WrUBkrHmFj6CkwvJdWPkYQS3xqC0+FmUZofz211CBt5IMucxXPkX4rW1+z7wB3RbBqoQzd8v7yeb7OzlPnWOyN0qFU0XA246RA8QFYiCNYwI3f05p6KLiEXAMPLE my-key-pair
```

**IMDSv1**

```
```

The following is an example output.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQDAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6Vh2ztxCh+PnDSUaw+WNQn/m2phtTk/a/gU8jEzoOWbxM4yxyyb/wB96xbiFveSFJuOp/d6RJhJ0I1iBxrlsLnBtntckl7FbtxJMXLvwwJryDUIIbMTjYtwB+QhYXUMO2ce5Pjz5/i8SeJtjnV3IA0G/cQk+0FzZqaeJAAHco+CY/5WrUBkrHmFj6CkwvJdWPkYQS3xqC0+FmUZofz211CBt5IMucxXPkX4rW1+z7wB3RbBqoQzd8v7yeb7OzlPnWOyN0qFU0XA246RA8QFYiCNYwI3f05p6KLiEXAMPLE my-key-pair
```

If you change the key pair that you use to connect to the instance, we don't update the instance metadata to show the new public key. Instead, the instance metadata continues to show the public key for the key pair that you specified when you launched the instance. For more information, see [Retrieve instance metadata](p. 614).

## Locate the public key on an instance

When you launch an instance, you are prompted for a key pair (p. 482). If you plan to connect to the instance using SSH, you must specify a key pair. When your instance boots for the first time, the content of the public key that you specified at launch is placed on your Linux instance in an entry within `~/.ssh/authorized_keys`.

### To locate the public key on an instance

1. Connect to your instance. (p. 499)
2. In the terminal window, open the authorized_keys file using your favorite text editor (such as `vim` or `nano`).

```
[ec2-user ~]$ nano ~/.ssh/authorized_keys
```

The `authorized_keys` file opens, displaying the public key followed by the name of the key pair. The following is an example entry for the key pair named `my-key-pair`.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjgp3maAhDFcvBS706VhZ2tVcPnUSuAw+WNQn/mZphTk/a/gU8jEzoOWbkM4yxyyb/wB96xbF1FveSF7uOq/g/d6RJhJOI0iBXrlsLnBItncokiJ7PbtxJMXLVwvJryU11BMTjYtwB+QhYXMW0ze5Pja5/i8SeJtjnV31AoG/cQ+k+0FzZqaeJAHc+CY/5WrUBkrHmF2r6HcXKv5dWPkYQS3xqC0+PnUZofz221CBt51MucxXPkX4rW1+z7wB3RbBQoQzd8v7yeb70z1PmW0yW0qFU0XA246RA8gFY1CNYW1f85p6XLwEXAMPLE my-key-pair
```

### Identify the key pair that was specified at launch

When you launch an instance, you are prompted for a key pair (p. 482). If you plan to connect to the instance using SSH, you must specify a key pair.

#### To identify the key pair that was specified at launch

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Details** tab, under **Instance details**, the **Key pair name** field displays the name of the key pair that you specified when you launched the instance. The value of the **Key pair name** does not change even if you change the public key on the instance, or add key pairs.

### Verify your key pair's fingerprint

On the **Key Pairs** page in the Amazon EC2 console, the **Fingerprint** column displays the fingerprints generated from your key pairs. AWS calculates the fingerprint differently depending on whether the key pair was generated by AWS or a third-party tool. If you created the key pair using AWS, the fingerprint is calculated using an SHA-1 hash function. If you created the key pair with a third-party tool and uploaded the public key to AWS, or if you generated a new public key from an existing AWS-created private key and uploaded it to AWS, the fingerprint is calculated using an MDS hash function.

You can use the SSH2 fingerprint that's displayed on the **Key Pairs** page to verify that the private key you have on your local machine matches the public key stored in AWS. From the computer where you downloaded the private key file, generate an SSH2 fingerprint from the private key file. The output should match the fingerprint that's displayed in the console.

If you're using a Windows local machine, you can run the following commands using the Windows Subsystem for Linux (WSL). Install the WSL and a Linux distribution using the instructions in the [Windows 10 Installation Guide](https://docs.microsoft.com/en-us/windows/win32/containers). The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

If you created your key pair using AWS, you can use the OpenSSL tools to generate a fingerprint as shown in the following example.

```
$ openssl pkcs8 -in path_to_private_key -inform PEM -outform DER -topk8 -nocrypt | openssl sshal -c
```
Add or replace a key pair for your instance

If you created a key pair using a third-party tool and uploaded the public key to AWS, you can use the OpenSSL tools to generate the fingerprint as shown in the following example.

```
$ openssl rsa -in path_to_private_key -pubout -outform DER | openssl md5 -c
```

If you created an OpenSSH key pair using OpenSSH 7.8 or later and uploaded the public key to AWS, you can use `ssh-keygen` to generate the fingerprint as shown in the following examples.

For RSA key pairs:

```
$ ssh-keygen -ef path_to_private_key -m PEM | openssl rsa -RSAPublicKey_in -outform DER | openssl md5 -c
```

For ED25519 key pairs:

```
$ ssh-keygen -l -f path_to_private_key.pem
```

### Add or replace a key pair for your instance

You can change the key pair that is used to access the default system account of your instance by adding a new public key on the instance, or by replacing the public key (deleting the existing public key and adding a new one) on the instance. You might do this for the following reasons:

- If a user in your organization requires access to the system user account using a separate key pair, you can add the public key to your instance.
- If someone has a copy of the private key (`.pem` file) and you want to prevent them from connecting to your instance (for example, if they've left your organization), you can delete the public key on the instance and replace it with a new one.

The public keys are located in the `.ssh/authorized_keys` file on the instance.

To add or replace a key pair, you must be able to connect to your instance. If you've lost your existing private key or you launched your instance without a key pair, you won't be able to connect to your instance and therefore won't be able to add or replace a key pair. If you've lost your private key, you might be able to retrieve it. For more information, see Connect to your Linux instance if you lose your private key (p. 1148). If you launched your instance without a key pair, you won’t be able to connect to the instance unless you chose an AMI that is configured to allow users another way to log in.

**Note**

These procedures are for modifying the key pair for the default user account, such as `ec2-user`. For information about adding user accounts to your instance, see Manage user accounts on your Amazon Linux instance (p. 561).

### To add or replace a key pair

1. Create a new key pair using the Amazon EC2 console (p. 1138) or a third-party tool (p. 1140).
2. Retrieve the public key from your new key pair. For more information, see Retrieve the public key from the private key (p. 1143).
3. Connect to your instance (p. 499) using your existing private key.
4. Using a text editor of your choice, open the `.ssh/authorized_keys` file on the instance. Paste the public key information from your new key pair underneath the existing public key information. Save the file.
5. Disconnect from your instance, and test that you can connect to your instance using the new private key file.
Delete your key pair

When you delete a key pair using the following methods, you are only deleting the public key that you saved in Amazon EC2 when you created (p. 1138) or imported (p. 1140) the key pair. Deleting a key pair doesn't delete the public key from any instances that were previously launched using that key pair. It also doesn't delete the private key on your local computer. You can continue to connect to instances that you launched using a key pair that is subsequently deleted, as long as you still have the private key (.pem) file.

Note
To delete the public key from an instance, see Delete a public key from an instance (p. 1147).

If you're using an Auto Scaling group (for example, in an Elastic Beanstalk environment), ensure that the key pair you're deleting is not specified in an associated launch template or launch configuration. If Amazon EC2 Auto Scaling detects an unhealthy instance, it launches a replacement instance. However, the instance launch fails if the key pair cannot be found. For more information, see Launch templates in the Amazon EC2 Auto Scaling User Guide.

You can delete a key pair using one of the following methods.

Console

**To delete your key pair**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Key Pairs**.
3. Select the key pair to delete and choose **Delete**.
4. In the confirmation field, enter **Delete** and then choose **Delete**.

AWS CLI

**To delete your key pair**

Use the `delete-key-pair` AWS CLI command.

PowerShell

**To delete your key pair**

Use the `Remove-EC2KeyPair` AWS Tools for Windows PowerShell command.

Delete a public key from an instance

If you create a Linux AMI from an instance, the public key information is copied from the instance to the AMI. If you launch an instance from the AMI, the new instance includes the public key from the original
To delete a public key from an instance

1. Connect to your instance (p. 499).
2. Using a text editor of your choice, open the .ssh/authorized_keys file on the instance. Delete the public key information, and then save the file.

Warning
After you delete the public key from the instance and disconnect from the instance, you can't connect to it again unless the AMI provides another way of logging in.

Connect to your Linux instance if you lose your private key

If you lose the private key for an EBS-backed instance, you can regain access to your instance. You must stop the instance, detach its root volume and attach it to another instance as a data volume, modify the authorized_keys file with a new public key, move the volume back to the original instance, and restart the instance. For more information about launching, connecting to, and stopping instances, see Instance lifecycle (p. 471).

This procedure is only supported for instances with EBS root volumes. If the root device is an instance store volume, you cannot use this procedure to regain access to your instance; you must have the private key to connect to the instance. To determine the root device type of your instance, open the Amazon EC2 console, choose Instances, select the instance, and check the value of Root device type in the details pane. The value is either ebs or instance store.

In addition to the following steps, there are other ways to connect to your Linux instance if you lose your private key. For more information, see How can I connect to my Amazon EC2 instance if I lost my SSH key pair after its initial launch?

Steps for connecting to an EBS-backed instance with a different key pair

- Step 1: Create a new key pair (p. 1148)
- Step 2: Get information about the original instance and its root volume (p. 1149)
- Step 3: Stop the original instance (p. 1149)
- Step 4: Launch a temporary instance (p. 1149)
- Step 5: Detach the root volume from the original instance and attach it to the temporary instance (p. 1149)
- Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance (p. 1150)
- Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance (p. 1151)
- Step 8: Connect to the original instance using the new key pair (p. 1152)
- Step 9: Clean up (p. 1152)

Step 1: Create a new key pair

Create a new key pair using either the Amazon EC2 console or a third-party tool. If you want to name your new key pair exactly the same as the lost private key, you must first delete the existing key pair. For information about creating a new key pair, see Create a key pair using Amazon EC2 (p. 1138) or Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 1140).
Step 2: Get information about the original instance and its root volume

Make note of the following information because you'll need it to complete this procedure.

To get information about your original instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Instances in the navigation pane, and then select the instance that you'd like to connect to. (We'll refer to this as the original instance.)
3. On the Details tab, make note of the instance ID and AMI ID.
4. On the Networking tab, make note of the Availability Zone.
5. On the Storage tab, under Root device name, make note of the device name for the root volume (for example, /dev/xvda). Then, under Block devices, find this device name and make note of the volume ID (for example, vol-0a1234b5678c910de).

Step 3: Stop the original instance

Choose Instance state, Stop instance. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.

Warning
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

Step 4: Launch a temporary instance

Choose Launch instances, and then use the launch wizard to launch a temporary instance with the following options:

- On the Choose an AMI page, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see Create an Amazon EBS-backed Linux AMI (p. 102).
- On the Choose an Instance Type page, leave the default instance type that the wizard selects for you.
- On the Configure Instance Details page, specify the same Availability Zone as the original instance. If you're launching an instance in a VPC, select a subnet in this Availability Zone.
- On the Add Tags page, add the tag Name=Temporary to the instance to indicate that this is a temporary instance.
- On the Review page, choose Launch. Choose the key pair that you created in Step 1, then choose Launch Instances.

Step 5: Detach the root volume from the original instance and attach it to the temporary instance

1. In the navigation pane, choose Volumes and select the root device volume for the original instance (you made note of its volume ID in a previous step). Choose Actions, Detach Volume, and then select Yes, Detach. Wait for the state of the volume to become available. (You might need to choose the Refresh icon.)
2. With the volume still selected, choose Actions, and then select Attach Volume. Select the instance ID of the temporary instance, make note of the device name specified under Device (for example, /dev/sdf), and then choose Attach.
Note
If you launched your original instance from an AWS Marketplace AMI and your volume contains AWS Marketplace codes, you must first stop the temporary instance before you can attach the volume.

Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance

1. Connect to the temporary instance.
2. From the temporary instance, mount the volume that you attached to the instance so that you can access its file system. For example, if the device name is /dev/sdf, use the following commands to mount the volume as /mnt/tempvol.

   Note
   The device name might appear differently on your instance. For example, devices mounted as /dev/sdf might show up as /dev/xvdf on the instance. Some versions of Red Hat (or its variants, such as CentOS) might even increment the trailing letter by 4 characters, where /dev/sdf becomes /dev/xvdk.

   a. Use the lsblk command to determine if the volume is partitioned.

   ```
   [ec2-user ~]$ lsblk
   NAME   MAJ:MIN   RM  SIZE RO TYPE MOUNTPOINT
   xvda    202:0    0   8G  0 disk
   ##xvda1 202:1    0   8G  0 part /
   xvdf    202:80   0  101G  0 disk
   ##xvdf1 202:81   0  101G  0 part
   xvdg    202:96   0   30G  0 disk
   ```

   In the preceding example, /dev/xvda and /dev/xvdf are partitioned volumes, and /dev/xvdf is not. If your volume is partitioned, you mount the partition (/dev/xvdf1) instead of the raw device (/dev/xvdf) in the next steps.

   b. Create a temporary directory to mount the volume.

   ```
   [ec2-user ~]$ sudo mkdir /mnt/tempvol
   ```

c. Mount the volume (or partition) at the temporary mount point, using the volume name or device name that you identified earlier. The required command depends on your operating system's file system. Note that the device name might appear differently on your instance. See note in this section for more information.

   - Amazon Linux, Ubuntu, and Debian

   ```
   [ec2-user ~]$ sudo mount /dev/xvdf1 /mnt/tempvol
   ```

   - Amazon Linux 2, CentOS, SUSE Linux 12, and RHEL 7.x

   ```
   [ec2-user ~]$ sudo mount -o nouuid /dev/xvdf1 /mnt/tempvol
   ```

   Note
   If you get an error stating that the file system is corrupt, run the following command to use the fsck utility to check the file system and repair any issues:
3. From the temporary instance, use the following command to update authorized_keys on the mounted volume with the new public key from the authorized_keys for the temporary instance.

   **Important**
   The following examples use the Amazon Linux user name ec2-user. You might need to substitute a different user name, such as ubuntu for Ubuntu instances.

   ```
   [ec2-user ~]$
   cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   If this copy succeeded, you can go to the next step.

   (Optional) Otherwise, if you don't have permission to edit files in /mnt/tempvol, you must update the file using sudo and then check the permissions on the file to verify that you are able to log into the original instance. Use the following command to check the permissions on the file.

   ```
   [ec2-user ~]$
   ls -l /mnt/tempvol/home/ec2-user/.ssh
   ```

   In this example output, 222 is the user ID and 500 is the group ID. Next, use sudo to re-run the copy command that failed.

   ```
   [ec2-user ~]$
   cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   Run the following command again to determine whether the permissions changed.

   ```
   [ec2-user ~]$
   ls -l /mnt/tempvol/home/ec2-user/.ssh
   ```

   If the user ID and group ID have changed, use the following command to restore them.

   ```
   [ec2-user ~]$
   chown 222:500 /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   **Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance**

   1. From the temporary instance, unmount the volume that you attached so that you can reattach it to the original instance. For example, use the following command to unmount the volume at /mnt/tempvol.

   ```
   [ec2-user ~]$
   sudo umount /mnt/tempvol
   ```

   2. Detach the volume from the temporary instance (you unmounted it in the previous step): From the Amazon EC2 console, select the root device volume for the original instance (you made note of the volume ID in a previous step), choose Actions, Detach Volume, and then choose Yes, Detach. Wait for the state of the volume to become available. (You might need to choose the Refresh icon.)

   3. Reattach the volume to the original instance: With the volume still selected, choose Actions, Attach Volume. Select the instance ID of the original instance, specify the device name that you noted earlier in Step 2 (p. 1149) for the original root device attachment (/dev/sda1 or /dev/xvda), and then choose Attach.
Important
If you don't specify the same device name as the original attachment, you cannot start the original instance. Amazon EC2 expects the root device volume at sda1 or /dev/xvda.

Step 8: Connect to the original instance using the new key pair

Select the original instance, choose Instance state, Start instance. After the instance enters the running state, you can connect to it using the private key file for your new key pair.

Note
If the name of your new key pair and corresponding private key file is different from the name of the original key pair, ensure that you specify the name of the new private key file when you connect to your instance.

Step 9: Clean up

(Optional) You can terminate the temporary instance if you have no further use for it. Select the temporary instance, and choose Instance state, Terminate instance.

Amazon EC2 security groups for Linux instances

A security group acts as a virtual firewall for your EC2 instances to control incoming and outgoing traffic. Inbound rules control the incoming traffic to your instance, and outbound rules control the outgoing traffic from your instance. When you launch an instance, you can specify one or more security groups. If you don't specify a security group, Amazon EC2 uses the default security group. You can add rules to each security group that allow traffic to or from its associated instances. You can modify the rules for a security group at any time. New and modified rules are automatically applied to all instances that are associated with the security group. When Amazon EC2 decides whether to allow traffic to reach an instance, it evaluates all of the rules from all of the security groups that are associated with the instance.

When you launch an instance in a VPC, you must specify a security group that's created for that VPC. After you launch an instance, you can change its security groups. Security groups are associated with network interfaces. Changing an instance's security groups changes the security groups associated with the primary network interface (eth0). For more information, see Changing an instance's security groups in the Amazon VPC User Guide. You can also change the security groups associated with any other network interface. For more information, see Modify network interface attributes (p. 944).

Security is a shared responsibility between AWS and you. For more information, see Security in Amazon EC2 (p. 1062). AWS provides security groups as one of the tools for securing your instances, and you need to configure them to meet your security needs. If you have requirements that aren't fully met by security groups, you can maintain your own firewall on any of your instances in addition to using security groups.

To allow traffic to a Windows instance, see Amazon EC2 security groups for Windows instances in the Amazon EC2 User Guide for Windows Instances.

Contents

- Security group rules (p. 1153)
- Security group connection tracking (p. 1154)
  - Untracked connections (p. 1155)
  - Example (p. 1155)
  - Throttling (p. 1156)
- Default and custom security groups (p. 1156)
  - Default security groups (p. 1156)
Security group rules

The rules of a security group control the inbound traffic that's allowed to reach the instances that are associated with the security group. The rules also control the outbound traffic that's allowed to leave them.

The following are the characteristics of security group rules:

- By default, security groups allow all outbound traffic. Note that Amazon EC2 blocks traffic on port 25 by default. For more information, see Restriction on email sent using port 25 (p. 1476).
- Security group rules are always permissive; you can't create rules that deny access.
- Security group rules enable you to filter traffic based on protocols and port numbers.
- Security groups are stateful—if you send a request from your instance, the response traffic for that request is allowed to flow in regardless of inbound security group rules. For VPC security groups, this also means that responses to allowed inbound traffic are allowed to flow out, regardless of outbound rules. For more information, see Security group connection tracking (p. 1154).
- You can add and remove rules at any time. Your changes are automatically applied to the instances that are associated with the security group.

The effect of some rule changes can depend on how the traffic is tracked. For more information, see Security group connection tracking (p. 1154).

- When you associate multiple security groups with an instance, the rules from each security group are effectively aggregated to create one set of rules. Amazon EC2 uses this set of rules to determine whether to allow access.

You can assign multiple security groups to an instance. Therefore, an instance can have hundreds of rules that apply. This might cause problems when you access the instance. We recommend that you condense your rules as much as possible.
When you create a rule, you can specify the following:

- **Name**: The name for the security group (for example, `my-security-group`).
  
  A name can be up to 255 characters in length. Allowed characters are a-z, A-Z, 0-9, spaces, and _-/:@!$. When the name contains trailing spaces, we trim the spaces when we save the name. For example, if you enter "Test Security Group " for the name, we store it as "Test Security Group".

- **Protocol**: The protocol to allow. The most common protocols are 6 (TCP), 17 (UDP), and 1 (ICMP).

- **Port range**: For TCP, UDP, or a custom protocol, the range of ports to allow. You can specify a single port number (for example, `22`), or range of port numbers (for example, `7000-8000`).

- **ICMP type and code**: For ICMP, the ICMP type and code.

- **Source or destination**: The source (inbound rules) or destination (outbound rules) for the traffic. Specify one of these options:
  - An individual IPv4 address. You must use the /32 prefix length; for example, `203.0.113.1/32`.
  - An individual IPv6 address. You must use the /128 prefix length; for example, `2001:db8:1234:1a00::123/128`.
  - A range of IPv4 addresses, in CIDR block notation; for example, `203.0.113.0/24`.
  - A range of IPv6 addresses, in CIDR block notation; for example, `2001:db8:1234:1a00::/64`.
  - A prefix list ID, for example, `pl-1234abc1234abc123`. For more information, see Prefix lists in the Amazon VPC User Guide.
  - Another security group. This allows instances that are associated with the specified security group to access instances associated with this security group. Choosing this option does not add rules from the source security group to this security group. You can specify one of the following security groups:
    - The current security group
    - A different security group for the same VPC
    - A different security group for a peer VPC in a VPC peering connection

- **(Optional) Description**: You can add a description for the rule, which can help you identify it later. A description can be up to 255 characters in length. Allowed characters are a-z, A-Z, 0-9, spaces, and _-/:@!$.

When you create a security group rule, AWS assigns a unique ID to the rule. You can use the ID of a rule when you use the API or CLI to modify or delete the rule.

When you specify a security group as the source or destination for a rule, the rule affects all instances that are associated with the security group. Incoming traffic is allowed based on the private IP addresses of the instances that are associated with the source security group (and not the public IP or Elastic IP addresses). For more information about IP addresses, see Amazon EC2 instance IP addressing (p. 880). If your security group rule references a security group in a peer VPC, and the referenced security group or VPC peering connection is deleted, the rule is marked as stale. For more information, see Working with Stale Security Group Rules in the Amazon VPC Peering Guide.

If there is more than one rule for a specific port, Amazon EC2 applies the most permissive rule. For example, if you have a rule that allows access to TCP port 22 (SSH) from IP address `203.0.113.1`, and another rule that allows access to TCP port 22 from everyone, everyone has access to TCP port 22.

When you add, update, or remove rules, the changes are automatically applied to all instances associated with the security group.

**Security group connection tracking**

Your security groups use connection tracking to track information about traffic to and from the instance. Rules are applied based on the connection state of the traffic to determine if the traffic is allowed or
denied. With this approach, security groups are stateful. This means that responses to inbound traffic are allowed to flow out of the instance regardless of outbound security group rules, and vice versa.

As an example, suppose that you initiate an ICMP ping command to your instances from your home computer, and your inbound security group rules allow ICMP traffic. Information about the connection (including the port information) is tracked. Response traffic from the instance for the ping command is not tracked as a new request, but rather as an established connection, and is allowed to flow out of the instance, even if your outbound security group rules restrict outbound ICMP traffic.

For protocols other than TCP, UDP, or ICMP, only the IP address and protocol number is tracked. If your instance sends traffic to another host (host B), and host B initiates the same type of traffic to your instance in a separate request within 600 seconds of the original request or response, your instance accepts it regardless of inbound security group rules. Your instance accepts it because it's regarded as response traffic.

To ensure that traffic is immediately interrupted when you remove a security group rule, or to ensure that all inbound traffic is subject to firewall rules, you can use a network ACL for your subnet. Network ACLs are stateless and therefore do not automatically allow response traffic. For more information, see Network ACLs in the Amazon VPC User Guide.

Untracked connections

Not all flows of traffic are tracked. If a security group rule permits TCP or UDP flows for all traffic (0.0.0.0/0 or ::/0) and there is a corresponding rule in the other direction that permits all response traffic (0.0.0.0/0 or ::/0) for all ports (0-65535), then that flow of traffic is not tracked. The response traffic is therefore allowed to flow based on the inbound or outbound rule that permits the response traffic, and not on tracking information.

An untracked flow of traffic is immediately interrupted if the rule that enables the flow is removed or modified. For example, if you have an open (0.0.0.0/0) outbound rule, and you remove a rule that allows all (0.0.0.0/0) inbound SSH (TCP port 22) traffic to the instance (or modify it such that the connection would no longer be permitted), your existing SSH connections to the instance are immediately dropped. The connection was not previously being tracked, so the change will break the connection. On the other hand, if you have a narrower inbound rule that initially allows the SSH connection (meaning that the connection was tracked), but change that rule to no longer allow new connections from the address of the current SSH client, the existing connection will not be broken by changing the rule.

Example

In the following example, the security group has specific inbound rules for TCP and ICMP traffic, and outbound rules that allow all outbound IPv4 and IPv6 traffic.

<table>
<thead>
<tr>
<th>Inbound rules</th>
<th>Port number</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol type</td>
<td>Port number</td>
<td>Source IP</td>
</tr>
<tr>
<td>TCP</td>
<td>22 (SSH)</td>
<td>203.0.113.1/32</td>
</tr>
<tr>
<td>TCP</td>
<td>80 (HTTP)</td>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>TCP</td>
<td>80 (HTTP)</td>
<td>::/0</td>
</tr>
<tr>
<td>ICMP</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Outbound rules</th>
<th>Port number</th>
<th>Destination IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol type</td>
<td>Port number</td>
<td>Destination IP</td>
</tr>
<tr>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>
• TCP traffic on port 22 (SSH) to and from the instance is tracked, because the inbound rule allows traffic from 203.0.113.1/32 only, and not all IP addresses (0.0.0.0/0).
• TCP traffic on port 80 (HTTP) to and from the instance is not tracked, because both the inbound and outbound rules allow all traffic (0.0.0.0/0 or ::/0).
• ICMP traffic is always tracked, regardless of rules.
• If you remove the outbound rule from the security group, all traffic to and from the instance is tracked, including traffic on port 80 (HTTP).

**Throttling**

Amazon EC2 defines the maximum number of connections that can be tracked per instance. After the maximum is reached, any packets that are sent or received are dropped because a new connection cannot be established. When this happens, applications that send and receive packets cannot communicate properly.

To determine whether packets were dropped because the network traffic for your instance exceeded the maximum number of connections that can be tracked, use the `conntrack_allowance_exceeded` network performance metric. For more information, see Monitor network performance for your EC2 instance (p. 969).

Connections made through a Network Load Balancer are automatically tracked, even if the security group configuration does not require tracking. If you exceed the maximum number of connections that can be tracked per instance, we recommend that you scale either the number of instances registered with the load balancer or the size of the instances registered with the load balancer.

### Default and custom security groups

Your AWS account automatically has a default security group for the default VPC in each Region. If you don't specify a security group when you launch an instance, the instance is automatically associated with the default security group for the VPC. If you don't want your instances to use the default security group, you can create your own custom security groups and specify them when you launch your instances.

**Topics**
- Default security groups (p. 1156)
- Custom security groups (p. 1157)

### Default security groups

Your AWS account automatically has a default security group for the default VPC in each Region. If you don't specify a security group when you launch an instance, the instance is automatically associated with the default security group for the VPC.

A default security group is named `default`, and it has an ID assigned by AWS. The following table describes the default rules for a default security group.

<table>
<thead>
<tr>
<th>Inbound rule</th>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Description</th>
</tr>
</thead>
</table>

1156
The security group ID (its own resource ID) allows inbound traffic from network interfaces and instances that are assigned to the same security group.

<table>
<thead>
<tr>
<th>Outbound rules</th>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>All</td>
<td>All</td>
<td>All</td>
<td>Allows all outbound IPv4 traffic.</td>
</tr>
<tr>
<td>::/0</td>
<td>All</td>
<td>All</td>
<td>All</td>
<td>Allows all outbound IPv6 traffic. This rule is added only if your VPC has an associated IPv6 CIDR block.</td>
</tr>
</tbody>
</table>

You can add or remove inbound and outbound rules for any default security group.

You can't delete a default security group. If you try to delete a default security group, you see the following error: `Client.CannotDelete: the specified group: "sg-51530134" name: "default" cannot be deleted by a user.`

**Custom security groups**

If you don't want your instances to use the default security group, you can create your own security groups and specify them when you launch your instances. You can create multiple security groups to reflect the different roles that your instances play; for example, a web server or a database server.

When you create a security group, you must provide it with a name and a description. Security group names and descriptions can be up to 255 characters in length, and are limited to the following characters:

- a-z, A-Z, 0-9, spaces, and _-:/()#,@

A security group name cannot start with `sg-`. A security group name must be unique for the VPC.

The following are the default rules for a security group that you create:

- Allows no inbound traffic
- Allows all outbound traffic

After you've created a security group, you can change its inbound rules to reflect the type of inbound traffic that you want to reach the associated instances. You can also change its outbound rules.

For more information about the rules you can add to a security group, see Security group rules for different use cases (p. 1167).

**Work with security groups**

You can assign a security group to an instance when you launch the instance. When you add or remove rules, those changes are automatically applied to all instances to which you've assigned the security group. For more information, see Assign a security group to an instance (p. 1166).

After you launch an instance, you can change its security groups. For more information, see Change an instance's security group (p. 1166).
You can create, view, update, and delete security groups and security group rules using the Amazon EC2 console and the command line tools.

**Tasks**
- Create a security group (p. 1158)
- Copy a security group (p. 1159)
- View your security groups (p. 1159)
- Add rules to a security group (p. 1160)
- Update security group rules (p. 1163)
- Delete rules from a security group (p. 1164)
- Delete a security group (p. 1165)
- Assign a security group to an instance (p. 1166)
- Change an instance's security group (p. 1166)

**Create a security group**

Although you can use the default security group for your instances, you might want to create your own groups to reflect the different roles that instances play in your system.

By default, new security groups start with only an outbound rule that allows all traffic to leave the instances. You must add rules to enable any inbound traffic or to restrict the outbound traffic.

A security group can be used only in the VPC for which it is created.

**New console**

**To create a security group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create security group**.
4. In the **Basic details** section, do the following.
   a. Enter a descriptive name and brief description for the security group. They can’t be edited after the security group is created. The name and description can be up to 255 characters long. The valid characters are a-z, A-Z, 0-9, spaces, and ._-:/()#,@\[\]+=&;{}!: *.
   b. For **VPC**, choose the VPC.
5. You can add security group rules now, or you can add them later. For more information, see Add rules to a security group (p. 1160).
6. You can add tags now, or you can add them later. To add a tag, choose **Add new tag** and enter the tag key and value.
7. Choose **Create security group**.

**Old console**

**To create a security group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create Security Group**.
4. Specify a name and description for the security group.
5. For VPC, choose the ID of the VPC.
6. You can start adding rules, or you can choose Create to create the security group now (you can always add rules later). For more information about adding rules, see Add rules to a security group (p. 1160).

Command line

To create a security group

Use one of the following commands:

- create-security-group (AWS CLI)

Copy a security group

You can create a new security group by creating a copy of an existing one. When you copy a security group, the copy is created with the same inbound and outbound rules as the original security group. If the original security group is in a VPC, the copy is created in the same VPC unless you specify a different one.

The copy receives a new unique security group ID and you must give it a name. You can also add a description.

You can't copy a security group from one Region to another Region.

You can create a copy of a security group using one of the following methods.

New console

To copy a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group to copy and choose Actions, Copy to new security group.
4. Specify a name and optional description, and change the VPC and security group rules if needed.
5. Choose Create.

Old console

To copy a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group you want to copy, choose Actions, Copy to new.
4. The Create Security Group dialog opens, and is populated with the rules from the existing security group. Specify a name and description for your new security group. For VPC, choose the ID of the VPC. When you are done, choose Create.

View your security groups

You can view information about your security groups using one of the following methods.
New console

To view your security groups

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Your security groups are listed. To view the details for a specific security group, including its inbound and outbound rules, choose its ID in the Security group ID column.

Old console

To view your security groups

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. (Optional) Select VPC ID from the filter list, then choose the ID of the VPC.
4. Select a security group. General information is displayed on the Description tab, inbound rules on the Inbound tab, outbound rules on the Outbound tab, and tags on the Tags tab.

Command line

To view your security groups

Use one of the following commands.

- `describe-security-groups` (AWS CLI)
- `describe-security-group-rules` (AWS CLI)

Amazon EC2 Global View

You can use Amazon EC2 Global View to view your security groups across all Regions for which your AWS account is enabled. For more information, see List and filter resources across Regions using Amazon EC2 Global View (p. 1461).

Add rules to a security group

When you add a rule to a security group, the new rule is automatically applied to any instances that are associated with the security group. There might be a short delay before the rule is applied. For more information, see Security group rules for different use cases (p. 1167) and Security group rules (p. 1153).

New console

To add an inbound rule to a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group, and choose Actions, Edit inbound rules.
4. For each rule, choose Add rule and do the following.
   a. For Type, choose the type of protocol to allow.
• For TCP or UDP, you must enter the port range to allow.
• For custom ICMP, you must choose the ICMP type name from Protocol, and, if applicable, the code name from Port range.
• For any other type, the protocol and port range are configured automatically.

b. For **Source**, do one of the following to allow traffic.

- Choose Custom and then enter an IP address in CIDR notation, a CIDR block, another security group, or a prefix list.
- Choose Anywhere to allow all traffic for the specified protocol to reach your instance. This option automatically adds the 0.0.0.0/0 IPv4 CIDR block as the source. This is acceptable for a short time in a test environment, but it's unsafe in production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

  If your security group is in a VPC that's enabled for IPv6, this option automatically adds a rule for the ::/0 IPv6 CIDR block.
- Choose My IP to allow inbound traffic from only your local computer’s public IPv4 address.

c. For **Description**, optionally specify a brief description for the rule.

5. Choose **Preview changes**, **Save rules**.

---

**To add an outbound rule to a security group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Select the security group, and choose Actions, **Edit outbound rules**.
4. For each rule, choose **Add rule** and do the following.

a. For **Type**, choose the type of protocol to allow.

- For TCP or UDP, you must enter the port range to allow.
- For custom ICMP, you must choose the ICMP type name from Protocol, and, if applicable, the code name from Port range.
- For any other type, the protocol and port range are configured automatically.

b. For **Destination**, do one of the following.

- Choose Custom and then enter an IP address in CIDR notation, a CIDR block, another security group, or a prefix list for which to allow outbound traffic.
- Choose Anywhere to allow outbound traffic to all IP addresses. This option automatically adds the 0.0.0.0/0 IPv4 CIDR block as the destination.

  If your security group is in a VPC that's enabled for IPv6, this option automatically adds a rule for the ::/0 IPv6 CIDR block.
- Choose My IP to allow outbound traffic only to your local computer’s public IPv4 address.

c. (Optional) For **Description**, specify a brief description for the rule.

5. Choose **Preview changes**, **Confirm**.

---

Old console

To add rules to a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups** and select the security group.
3. On the **Inbound** tab, choose **Edit**.
4. In the dialog, choose **Add Rule** and do the following:
   - For **Type**, select the protocol.
   - If you select a custom TCP or UDP protocol, specify the port range in **Port Range**.
   - If you select a custom ICMP protocol, choose the ICMP type name from **Protocol**, and, if applicable, the code name from **Port Range**.
   - For **Source**, choose one of the following:
     - **Custom**: in the provided field, you must specify an IP address in CIDR notation, a CIDR block, or another security group.
     - **Anywhere**: automatically adds the 0.0.0.0/0 IPv4 CIDR block. This option enables all traffic of the specified type to reach your instance. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instance.
     - **My IP**: automatically adds the public IPv4 address of your local computer.
   - For **Description**, you can optionally specify a description for the rule.

For more information about the types of rules that you can add, see [Security group rules for different use cases](p. 1167).

5. Choose **Save**.
6. You can also specify outbound rules. On the **Outbound tab**, choose **Edit, Add Rule**, and do the following:
   - For **Type**, select the protocol.
   - If you select a custom TCP or UDP protocol, specify the port range in **Port Range**.
   - If you select a custom ICMP protocol, choose the ICMP type name from **Protocol**, and, if applicable, the code name from **Port Range**.
   - For **Destination**, choose one of the following:
     - **Custom**: in the provided field, you must specify an IP address in CIDR notation, a CIDR block, or another security group.
     - **Anywhere**: automatically adds the 0.0.0.0/0 IPv4 CIDR block. This option enables outbound traffic to all IP addresses.
     - **My IP**: automatically adds the IP address of your local computer.
   - For **Description**, you can optionally specify a description for the rule.

7. Choose **Save**.

**Command line**

**To add rules to a security group**

Use one of the following commands.

- `authorize-security-group-ingress` (AWS CLI)
- `Grant-EC2SecurityGroupIngress` (AWS Tools for Windows PowerShell)
To add one or more egress rules to a security group

Use one of the following commands.

- `authorize-security-group-egress` (AWS CLI)
- `Grant-EC2SecurityGroupEgress` (AWS Tools for Windows PowerShell)

Update security group rules

You can update a security group rule using one of the following methods. The updated rule is automatically applied to any instances that are associated with the security group.

New console

When you modify the protocol, port range, or source or destination of an existing security group rule using the console, the console deletes the existing rule and adds a new one for you.

To update a security group rule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. Choose Actions, Edit inbound rules to update a rule for inbound traffic or Actions, Edit outbound rules to update a rule for outbound traffic.
5. Update the rule as required.
6. Choose Preview changes, Confirm.

To tag a security group rule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. On the Inbound rules or Outbound rules tab, select the check box for the rule and then choose Manage tags.
5. The Manage tags page displays any tags that are assigned to the rule. To add a tag, choose Add tag and enter the tag key and value. To delete a tag, choose Remove next to the tag that you want to delete.
6. Choose Save changes.

Old console

When you modify the protocol, port range, or source or destination of an existing security group rule using the console, the console deletes the existing rule and adds a new one for you.

To update a security group rule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group to update, and choose the Inbound tab to update a rule for inbound traffic or the Outbound tab to update a rule for outbound traffic.
4. Choose **Edit**.
5. Modify the rule entry as required and choose **Save**.

**Command line**

You cannot modify the protocol, port range, or source or destination of an existing rule using the Amazon EC2 API or a command line tools. Instead, you must delete the existing rule and add a new rule. You can, however, update the description of an existing rule.

**To update a rule**

Use one the following command.

- **modify-security-group-rules** (AWS CLI)

**To update the description for an existing inbound rule**

Use one of the following commands.

- **update-security-group-rule-descriptions-ingress** (AWS CLI)
- **Update-EC2SecurityGroupRuleIngressDescription** (AWS Tools for Windows PowerShell)

**To update the description for an existing outbound rule**

Use one of the following commands.

- **update-security-group-rule-descriptions-egress** (AWS CLI)
- **Update-EC2SecurityGroupRuleEgressDescription** (AWS Tools for Windows PowerShell)

**To tag a security group rule**

Use one of the following commands.

- **create-tags** (AWS CLI)
- **New-EC2Tag** (AWS Tools for Windows PowerShell)

**Delete rules from a security group**

When you delete a rule from a security group, the change is automatically applied to any instances associated with the security group.

You can delete rules from a security group using one of the following methods.

**New console**

**To delete a security group rule**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Select the security group to update, choose **Actions**, and then choose **Edit inbound rules** to remove an inbound rule or **Edit outbound rules** to remove an outbound rule.
4. Choose the **Delete** button to the right of the rule to delete.
5. Choose **Preview changes**, **Confirm**.

Old console

**To delete a security group rule**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Select a security group.
4. On the **Inbound** tab (for inbound rules) or **Outbound** tab (for outbound rules), choose **Edit**. Choose **Delete** (a cross icon) next to each rule to delete.
5. Choose **Save**.

Command line

**To remove one or more ingress rules from a security group**

Use one of the following commands.

- `revoke-security-group-ingress` (AWS CLI)
- `Revoke-EC2SecurityGroupIngress` (AWS Tools for Windows PowerShell)

**To remove one or more egress rules from a security group**

Use one of the following commands.

- `revoke-security-group-egress` (AWS CLI)
- `Revoke-EC2SecurityGroupEgress` (AWS Tools for Windows PowerShell)

**Delete a security group**

You can't delete a security group that is associated with an instance. You can't delete the default security group. You can't delete a security group that is referenced by a rule in another security group in the same VPC. If your security group is referenced by one of its own rules, you must delete the rule before you can delete the security group.

New console

**To delete a security group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Select the security group to delete and choose **Actions**, **Delete security group**, **Delete**.

Old console

**To delete a security group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Select a security group and choose **Actions**, **Delete Security Group**.
4. Choose Yes, Delete.

Command line

To delete a security group

Use one of the following commands.

- delete-security-group (AWS CLI)
- Remove-EC2SecurityGroup (AWS Tools for Windows PowerShell)

Assign a security group to an instance

You can assign one or more security groups to an instance when you launch the instance. You can also specify one or more security groups in a launch template. The security groups will be assigned to all instances that are launched using the launch template.

- To assign a security group to an instance when you launch the instance, see Step 6: Configure Security Group (p. 482).
- To specify a security group in a launch template, see Step 6 of Create a new launch template using parameters you define (p. 485).

Change an instance's security group

After you launch an instance, you can change its security groups by adding or removing security groups. You can change the security groups when the instance is in the running or stopped state.

New console

To change the security groups for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, and then choose Actions, Security, Change security groups.
4. For Associated security groups, select a security group from the list and choose Add security group.
   To remove an already associated security group, choose Remove for that security group.
5. Choose Save.

Old console

To change the security groups for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, and then choose Actions, Networking, Change Security Groups.
4. To add one or more security groups, select its check box.
   To remove an already associated security group, clear its check box.
Command line

To change the security groups for an instance using the command line

Use one of the following commands.

- **modify-instance-attribute** (AWS CLI)
- **Edit-EC2InstanceAttribute** (AWS Tools for Windows PowerShell)

Security group rules for different use cases

You can create a security group and add rules that reflect the role of the instance that's associated with the security group. For example, an instance that's configured as a web server needs security group rules that allow inbound HTTP and HTTPS access. Likewise, a database instance needs rules that allow access for the type of database, such as access over port 3306 for MySQL.

The following are examples of the kinds of rules that you can add to security groups for specific kinds of access.

**Examples**
- Web server rules (p. 1167)
- Database server rules (p. 1168)
- Rules to connect to instances from your computer (p. 1169)
- Rules to connect to instances from an instance with the same security group (p. 1170)
- Rules for ping/ICMP (p. 1170)
- DNS server rules (p. 1170)
- Amazon EFS rules (p. 1171)
- Elastic Load Balancing rules (p. 1171)
- VPC peering rules (p. 1172)

**Web server rules**

The following inbound rules allow HTTP and HTTPS access from any IP address. If your VPC is enabled for IPv6, you can add rules to control inbound HTTP and HTTPS traffic from IPv6 addresses.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>0.0.0.0/0</td>
<td>Allows inbound HTTP access from any IPv4 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>0.0.0.0/0</td>
<td>Allows inbound HTTPS access from any IPv4 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>::/0</td>
<td>Allows inbound HTTP access from any IPv6 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>::/0</td>
<td>Allows inbound HTTPS access</td>
</tr>
</tbody>
</table>
Database server rules

The following inbound rules are examples of rules you might add for database access, depending on what type of database you're running on your instance. For more information about Amazon RDS instances, see the Amazon RDS User Guide.

For the source IP, specify one of the following:

- A specific IP address or range of IP addresses (in CIDR block notation) in your local network
- A security group ID for a group of instances that access the database

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>1433 (MS SQL)</td>
<td>from any IPv6 address</td>
<td></td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>3306 (MYSQL/Aurora)</td>
<td>The default port to access a MySQL or Aurora database, for example, on an Amazon RDS instance</td>
<td></td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>5439 (Redshift)</td>
<td>The default port to access an Amazon Redshift cluster database.</td>
<td></td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>5432 (PostgreSQL)</td>
<td>The default port to access a PostgreSQL database, for example, on an Amazon RDS instance</td>
<td></td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>1521 (Oracle)</td>
<td>The default port to access an Oracle database, for example, on an Amazon RDS instance</td>
<td></td>
</tr>
</tbody>
</table>

You can optionally restrict outbound traffic from your database servers. For example, you might want to allow access to the internet for software updates, but restrict all other kinds of traffic. You must first remove the default outbound rule that allows all outbound traffic.
Security group rules for different use cases

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Destination IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>0.0.0.0/0</td>
<td>Allows outbound HTTP access to any IPv4 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>0.0.0.0/0</td>
<td>Allows outbound HTTPS access to any IPv4 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>::/0</td>
<td>(IPv6-enabled VPC only) Allows outbound HTTP access to any IPv6 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>::/0</td>
<td>(IPv6-enabled VPC only) Allows outbound HTTPS access to any IPv6 address</td>
</tr>
</tbody>
</table>

Rules to connect to instances from your computer

To connect to your instance, your security group must have inbound rules that allow SSH access (for Linux instances) or RDP access (for Windows instances).

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>22 (SSH)</td>
<td>The public IPv4 address of your computer, or a range of IP addresses (in CIDR block notation) in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>3389 (RDP)</td>
<td>The public IPv4 address of your computer, or a range of IP addresses (in CIDR block notation) in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.</td>
</tr>
</tbody>
</table>
Rules to connect to instances from an instance with the same security group

To allow instances that are associated with the same security group to communicate with each other, you must explicitly add rules for this.

The following table describes the inbound rule for a security group that enables associated instances to communicate with each other. The rule allows all types of traffic.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Ports</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1 (All)</td>
<td>-1 (All)</td>
<td>-1 (All)</td>
<td>The ID of the security group</td>
</tr>
</tbody>
</table>

Rules for ping/ICMP

The ping command is a type of ICMP traffic. To ping your instance, you must add the following inbound ICMP rule.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>ICMP type</th>
<th>ICMP code</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>1</td>
<td>8 (Echo)</td>
<td>N/A</td>
<td>The public IPv4 address of your computer, or a range of IPv4 addresses (in CIDR block notation) in your local network</td>
</tr>
</tbody>
</table>

To use the ping6 command to ping the IPv6 address for your instance, you must add the following inbound ICMPv6 rule.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>ICMP type</th>
<th>ICMP code</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMPv6</td>
<td>58</td>
<td>128 (Echo)</td>
<td>0</td>
<td>The IPv6 address of your computer, or a range of IPv6 addresses (in CIDR block notation) in your local network</td>
</tr>
</tbody>
</table>

DNS server rules

If you’ve set up your EC2 instance as a DNS server, you must ensure that TCP and UDP traffic can reach your DNS server over port 53.

For the source IP, specify one of the following:

- An IP address or range of IP addresses (in CIDR block notation) in a network
Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
Security group rules for different use cases

- The ID of a security group for the set of instances in your network that require access to the DNS server

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>53</td>
</tr>
<tr>
<td>UDP</td>
<td>17</td>
<td>53</td>
</tr>
</tbody>
</table>

Amazon EFS rules

If you’re using an Amazon EFS file system with your Amazon EC2 instances, the security group that you associate with your Amazon EFS mount targets must allow traffic over the NFS protocol.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Ports</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>2049 (NFS)</td>
<td>The ID of the security group.</td>
<td>Allows inbound NFS access from resources (including the mount target) associated with this security group.</td>
</tr>
</tbody>
</table>

To mount an Amazon EFS file system on your Amazon EC2 instance, you must connect to your instance. Therefore, the security group associated with your instance must have rules that allow inbound SSH from your local computer or local network.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Ports</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>22 (SSH)</td>
<td>The IP address range of your local computer, or the range of IP addresses (in CIDR block notation) for your network.</td>
<td>Allows inbound SSH access from your local computer.</td>
</tr>
</tbody>
</table>

Elastic Load Balancing rules

If you’re using a load balancer, the security group associated with your load balancer must have rules that allow communication with your instances or targets.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>The listener port</td>
<td>For an Internet-facing load-</td>
<td>Allow inbound traffic on the load</td>
<td></td>
</tr>
</tbody>
</table>
Update management

For an internal load-balancer: the IPv4 CIDR block of the VPC balancer listener port.

<table>
<thead>
<tr>
<th>Outbound</th>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Destination IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>The instance listener port</td>
<td>The ID of the instance security group</td>
<td>Allow outbound traffic to instances on the instance listener port.</td>
<td></td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>The health check port</td>
<td>The ID of the instance security group</td>
<td>Allow outbound traffic to instances on the health check port.</td>
<td></td>
</tr>
</tbody>
</table>

The security group rules for your instances must allow the load balancer to communicate with your instances on both the listener port and the health check port.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>The instance listener port</td>
<td>The ID of the load balancer security group</td>
<td>Allow traffic from the load balancer on the instance listener port.</td>
<td></td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>The health check port</td>
<td>The ID of the load balancer security group</td>
<td>Allow traffic from the load balancer on the health check port.</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see Configure security groups for your Classic Load Balancer in the User Guide for Classic Load Balancers, and Security groups for your Application Load Balancer in the User Guide for Application Load Balancers.

VPC peering rules

You can update the inbound or outbound rules for your VPC security groups to reference security groups in the peered VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the peered VPC. For more information about how to configure security groups for VPC peering, see Updating your security groups to reference peer VPC groups.

Update management in Amazon EC2

We recommend that you regularly patch, update, and secure the operating system and applications on your EC2 instances. You can use AWS Systems Manager Patch Manager to automate the process of
installing security-related updates for both the operating system and applications. Alternatively, you can use any automatic update services or recommended processes for installing updates that are provided by the application vendor.

Compliance validation for Amazon EC2

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether Amazon Elastic Compute Cloud or other AWS services are in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
  
  **Note**
  Not all services are compliant with HIPAA.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **Evaluating Resources with Rules** in the **AWS Config Developer Guide** – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.
Amazon EC2 provides you with flexible, cost effective, and easy-to-use data storage options for your instances. Each option has a unique combination of performance and durability. These storage options can be used independently or in combination to suit your requirements.

After reading this section, you should have a good understanding about how you can use the data storage options supported by Amazon EC2 to meet your specific requirements. These storage options include the following:

- Amazon Elastic Block Store (p. 1175)
- Amazon EC2 instance store (p. 1408)
- Use Amazon EFS with Amazon EC2 (p. 1427)
- Use Amazon S3 with Amazon EC2 (p. 1426)

The following figure shows the relationship between these storage options and your instance.

Amazon EBS

Amazon EBS provides durable, block-level storage volumes that you can attach to a running instance. You can use Amazon EBS as a primary storage device for data that requires frequent and granular updates. For example, Amazon EBS is the recommended storage option when you run a database on an instance.

An EBS volume behaves like a raw, unformatted, external block device that you can attach to a single instance. The volume persists independently from the running life of an instance. After an EBS volume is attached to an instance, you can use it like any other physical hard drive. As illustrated in the previous
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Amazon EBS

figure, multiple volumes can be attached to an instance. You can also detach an EBS volume from one
instance and attach it to another instance. You can dynamically change the configuration of a volume
attached to an instance. EBS volumes can also be created as encrypted volumes using the Amazon EBS
encryption feature. For more information, see Amazon EBS encryption (p. 1335).

To keep a backup copy of your data, you can create a snapshot of an EBS volume, which is stored in
Amazon S3. You can create an EBS volume from a snapshot, and attach it to another instance. For more
information, see Amazon Elastic Block Store (p. 1175).

Amazon EC2 instance store

Many instances can access storage from disks that are physically attached to the host computer. This
disk storage is referred to as instance store. Instance store provides temporary block-level storage for
instances. The data on an instance store volume persists only during the life of the associated instance;
if you stop, hibernate, or terminate an instance, any data on instance store volumes is lost. For more
information, see Amazon EC2 instance store (p. 1408).

Amazon EFS file system

Amazon EFS provides scalable file storage for use with Amazon EC2. You can create an EFS file system
and configure your instances to mount the file system. You can use an EFS file system as a common data
source for workloads and applications running on multiple instances. For more information, see Use
Amazon EFS with Amazon EC2 (p. 1427).

Amazon S3

Amazon S3 provides access to reliable and inexpensive data storage infrastructure. It is designed to
make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time,
from within Amazon EC2 or anywhere on the web. For example, you can use Amazon S3 to store backup
copies of your data and applications. Amazon EC2 uses Amazon S3 to store EBS snapshots and instance
store-backed AMIs. For more information, see Use Amazon S3 with Amazon EC2 (p. 1426).

Adding storage

Every time you launch an instance from an AMI, a root storage device is created for that instance. The
root storage device contains all the information necessary to boot the instance. You can specify storage
volumes in addition to the root device volume when you create an AMI or launch an instance using block
device mapping. For more information, see Block device mappings (p. 1441).

You can also attach EBS volumes to a running instance. For more information, see Attach an Amazon EBS
volume to an instance (p. 1202).

Storage pricing

For information about storage pricing, open AWS Pricing, scroll down to Services Pricing, choose
Storage, and then choose the storage option to open that storage option's pricing page. For information
about estimating the cost of storage, see the AWS Pricing Calculator.

Amazon Elastic Block Store (Amazon EBS)

Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2
instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes
as devices on your instances. EBS volumes that are attached to an instance are exposed as storage
volumes that persist independently from the life of the instance. You can create a file system on top
of these volumes, or use them in any way you would use a block device (such as a hard drive). You can
dynamically change the configuration of a volume attached to an instance.
We recommend Amazon EBS for data that must be quickly accessible and requires long-term persistence. EBS volumes are particularly well-suited for use as the primary storage for file systems, databases, or for any applications that require fine granular updates and access to raw, unformatted, block-level storage. Amazon EBS is well suited to both database-style applications that rely on random reads and writes, and to throughput-intensive applications that perform long, continuous reads and writes.

With Amazon EBS, you pay only for what you use. For more information about Amazon EBS pricing, see the Projecting Costs section of the Amazon Elastic Block Store page.

Features of Amazon EBS

- You create an EBS volume in a specific Availability Zone, and then attach it to an instance in that same Availability Zone. To make a volume available outside of the Availability Zone, you can create a snapshot and restore that snapshot to a new volume anywhere in that Region. You can copy snapshots to other Regions and then restore them to new volumes there, making it easier to leverage multiple AWS Regions for geographical expansion, data center migration, and disaster recovery.

- Amazon EBS provides the following volume types: General Purpose SSD, Provisioned IOPS SSD, Throughput Optimized HDD, and Cold HDD. For more information, see EBS volume types (p. 1179).

The following is a summary of performance and use cases for each volume type.

- General Purpose SSD volumes (gp2 and gp3) balance price and performance for a wide variety of transactional workloads. These volumes are ideal for use cases such as boot volumes, medium-size single instance databases, and development and test environments.

- Provisioned IOPS SSD volumes (io1 and io2) are designed to meet the needs of I/O-intensive workloads that are sensitive to storage performance and consistency. They provide a consistent IOPS rate that you specify when you create the volume. This enables you to predictably scale to tens of thousands of IOPS per instance. Additionally, io2 volumes provide the highest levels of volume durability.

- Throughput Optimized HDD volumes (st1) provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. These volumes are ideal for large, sequential workloads such as Amazon EMR, ETL, data warehouses, and log processing.

- Cold HDD volumes (sc1) provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. These volumes are ideal for large, sequential, cold-data workloads. If you require infrequent access to your data and are looking to save costs, these volumes provide inexpensive block storage.

- You can create your EBS volumes as encrypted volumes, in order to meet a wide range of data-at-rest encryption requirements for regulated/audited data and applications. When you create an encrypted EBS volume and attach it to a supported instance type, data stored at rest on the volume, disk I/O, and snapshots created from the volume are all encrypted. The encryption occurs on the servers that host...
EC2 instances, providing encryption of data-in-transit from EC2 instances to EBS storage. For more information, see Amazon EBS encryption (p. 1335).

- You can create point-in-time snapshots of EBS volumes, which are persisted to Amazon S3. Snapshots protect data for long-term durability, and they can be used as the starting point for new EBS volumes. The same snapshot can be used to instantiate as many volumes as you wish. These snapshots can be copied across AWS Regions. For more information, see Amazon EBS snapshots (p. 1227).
- Performance metrics, such as bandwidth, throughput, latency, and average queue length, are available through the AWS Management Console. These metrics, provided by Amazon CloudWatch, allow you to monitor the performance of your volumes to make sure that you are providing enough performance for your applications without paying for resources you don't need. For more information, see Amazon EBS volume performance on Linux instances (p. 1376).

Amazon EBS volumes

An Amazon EBS volume is a durable, block-level storage device that you can attach to your instances. After you attach a volume to an instance, you can use it as you would use a physical hard drive. EBS volumes are flexible. For current-generation volumes attached to current-generation instance types, you can dynamically increase size, modify the provisioned IOPS capacity, and change volume type on live production volumes.

You can use EBS volumes as primary storage for data that requires frequent updates, such as the system drive for an instance or storage for a database application. You can also use them for throughput-intensive applications that perform continuous disk scans. EBS volumes persist independently from the running life of an EC2 instance.

You can attach multiple EBS volumes to a single instance. The volume and instance must be in the same Availability Zone. Depending on the volume and instance types, you can use Multi-Attach (p. 1203) to mount a volume to multiple instances at the same time.

Amazon EBS provides the following volume types: General Purpose SSD (gp2 and gp3), Provisioned IOPS SSD (io1 and io2), Throughput Optimized HDD (st1), Cold HDD (sc1), and Magnetic (standard). They differ in performance characteristics and price, allowing you to tailor your storage performance and cost to the needs of your applications. For more information, see Amazon EBS volume types (p. 1179).

Your account has a limit on the number of EBS volumes that you can use, and the total storage available to you. For more information about these limits, and how to request an increase in your limits, see Amazon EC2 service quotas (p. 1475).

For more information about pricing, see Amazon EBS Pricing.

Benefits of using EBS volumes

EBS volumes provide benefits that are not provided by instance store volumes.

**Data availability**

When you create an EBS volume, it is automatically replicated within its Availability Zone to prevent data loss due to failure of any single hardware component. You can attach an EBS volume to any EC2 instance in the same Availability Zone. After you attach a volume, it appears as a native block device similar to a hard drive or other physical device. At that point, the instance can interact with the volume just as it would with a local drive. You can connect to the instance and format the EBS volume with a file system, such as ext3, and then install applications.

If you attach multiple volumes to a device that you have named, you can stripe data across the volumes for increased I/O and throughput performance.

You can attach io1 and io2 EBS volumes to up to 16 Nitro-based instances. For more information, see Attach a volume to multiple instances with Amazon EBS Multi-Attach (p. 1203). Otherwise, you can attach an EBS volume to a single instance.

You can get monitoring data for your EBS volumes, including root device volumes for EBS-backed instances, at no additional charge. For more information about monitoring metrics, see Amazon CloudWatch metrics for Amazon EBS (p. 1391). For information about tracking the status of your volumes, see Amazon CloudWatch Events for Amazon EBS (p. 1397).

**Data persistence**

An EBS volume is off-instance storage that can persist independently from the life of an instance. You continue to pay for the volume usage as long as the data persists.

EBS volumes that are attached to a running instance can automatically detach from the instance with their data intact when the instance is terminated if you uncheck the **Delete on Termination** check box when you configure EBS volumes for your instance on the EC2 console. The volume can then be reattached to a new instance, enabling quick recovery. If the check box for **Delete on Termination** is checked, the volume(s) will delete upon termination of the EC2 instance. If you are using an EBS-backed instance, you can stop and restart that instance without affecting the data stored in the attached volume. The volume remains attached throughout the stop-start cycle. This enables you to process and store the data on your volume indefinitely, only using the processing and storage resources when required. The data persists on the volume until the volume is deleted explicitly. The physical block storage used by deleted EBS volumes is overwritten with zeroes before it is allocated to another account. If you are dealing with sensitive data, you should consider encrypting your data manually or storing the data on a volume protected by Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 1335).

By default, the root EBS volume that is created and attached to an instance at launch is deleted when that instance is terminated. You can modify this behavior by changing the value of the flag `DeleteOnTermination` to `false` when you launch the instance. This modified value causes the volume to persist even after the instance is terminated, and enables you to attach the volume to another instance.

By default, additional EBS volumes that are created and attached to an instance at launch are not deleted when that instance is terminated. You can modify this behavior by changing the value of the flag `DeleteOnTermination` to `true` when you launch the instance. This modified value causes the volumes to be deleted when the instance is terminated.

**Data encryption**

For simplified data encryption, you can create encrypted EBS volumes with the Amazon EBS encryption feature. All EBS volume types support encryption. You can use encrypted EBS volumes to meet a wide
range of data-at-rest encryption requirements for regulated/audited data and applications. Amazon EBS encryption uses 256-bit Advanced Encryption Standard algorithms (AES-256) and an Amazon-managed key infrastructure. The encryption occurs on the server that hosts the EC2 instance, providing encryption of data-in-transit from the EC2 instance to Amazon EBS storage. For more information, see Amazon EBS encryption (p. 1335).

Amazon EBS encryption uses AWS Key Management Service (AWS KMS) master keys when creating encrypted volumes and any snapshots created from your encrypted volumes. The first time you create an encrypted EBS volume in a region, a default master key is created for you automatically. This key is used for Amazon EBS encryption unless you select a custom master key (CMK) that you created separately using AWS KMS. Creating your own CMK gives you more flexibility, including the ability to create, rotate, disable, define access controls, and audit the encryption keys used to protect your data. For more information, see the AWS Key Management Service Developer Guide.

Snapshots

Amazon EBS provides the ability to create snapshots (backups) of any EBS volume and write a copy of the data in the volume to Amazon S3, where it is stored redundantly in multiple Availability Zones. The volume does not need to be attached to a running instance in order to take a snapshot. As you continue to write data to a volume, you can periodically create a snapshot of the volume to use as a baseline for new volumes. These snapshots can be used to create multiple new EBS volumes or move volumes across Availability Zones. Snapshots of encrypted EBS volumes are automatically encrypted.

When you create a new volume from a snapshot, it's an exact copy of the original volume at the time the snapshot was taken. EBS volumes that are created from encrypted snapshots are automatically encrypted. By optionally specifying a different Availability Zone, you can use this functionality to create a duplicate volume in that zone. The snapshots can be shared with specific AWS accounts or made public. When you create snapshots, you incur charges in Amazon S3 based on the volume's total size. For a successive snapshot of the volume, you are only charged for any additional data beyond the volume's original size.

Snapshots are incremental backups, meaning that only the blocks on the volume that have changed after your most recent snapshot are saved. If you have a volume with 100 GiB of data, but only 5 GiB of data have changed since your last snapshot, only the 5 GiB of modified data is written to Amazon S3. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot.

To help categorize and manage your volumes and snapshots, you can tag them with metadata of your choice. For more information, see Tag your Amazon EC2 resources (p. 1462).

To back up your volumes automatically, you can use Amazon Data Lifecycle Manager (p. 1280) or AWS Backup.

Flexibility

EBS volumes support live configuration changes while in production. You can modify volume type, volume size, and IOPS capacity without service interruptions. For more information, see Amazon EBS Elastic Volumes (p. 1323).

Amazon EBS volume types

Amazon EBS provides the following volume types, which differ in performance characteristics and price, so that you can tailor your storage performance and cost to the needs of your applications. The volumes types fall into these categories:

- **Solid state drives (SSD)** (p. 1180) — Optimized for transactional workloads involving frequent read/write operations with small I/O size, where the dominant performance attribute is IOPS.
- **Hard disk drives (HDD)** (p. 1181) — Optimized for large streaming workloads where the dominant performance attribute is throughput.
Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
EBS volumes

- **Previous generation (p. 1182)** — Hard disk drives that can be used for workloads with small datasets where data is accessed infrequently and performance is not of primary importance. We recommend that you consider a current generation volume type instead.

There are several factors that can affect the performance of EBS volumes, such as instance configuration, I/O characteristics, and workload demand. To fully use the IOPS provisioned on an EBS volume, use **EBS-optimized instances (p. 1354)**. For more information about getting the most out of your EBS volumes, see **Amazon EBS volume performance on Linux instances (p. 1376)**.

For more information about pricing, see **Amazon EBS Pricing**.

**Solid state drives (SSD)**

The SSD-backed volumes provided by Amazon EBS fall into these categories:

- **General Purpose SSD** — Provides a balance of price and performance. We recommend these volumes for most workloads.
- ** Provisioned IOPS SSD** — Provides high performance for mission-critical, low-latency, or high-throughput workloads.

The following is a summary of the use cases and characteristics of SSD-backed volumes. For information about the maximum IOPS and throughput per instance, see **Amazon EBS–optimized instances (p. 1354)**.

* The throughput limit is between 128 MiB/s and 250 MiB/s, depending on the volume size. Volumes smaller than or equal to 170 GiB deliver a maximum throughput of 128 MiB/s. Volumes larger than 170 GiB but smaller than 334 GiB deliver a maximum throughput of 250 MiB/s if burst credits are available. Volumes larger than or equal to 334 GiB deliver 250 MiB/s regardless of burst credits. gp2 volumes that were created before December 3, 2018 and that have not been modified since creation might not reach full performance unless you modify the volume (p. 1323).

† Maximum IOPS and throughput are guaranteed only on Instances built on the Nitro System (p. 199) provisioned with more than 32,000 IOPS. Other instances guarantee up to 32,000 IOPS and 500 MiB/s. io1 volumes that were created before December 6, 2017 and that have not been modified since creation might not reach full performance unless you modify the volume (p. 1323).

‡ io2 Block Express volumes are supported with R5b instances only. io2 volumes attached to an R5b instance during or after launch automatically run on Block Express. For more information, see io2 Block Express volumes (p. 1188).

Hard disk drives (HDD)

The HDD-backed volumes provided by Amazon EBS fall into these categories:

- Throughput Optimized HDD — A low-cost HDD designed for frequently accessed, throughput-intensive workloads.
- Cold HDD — The lowest-cost HDD design for less frequently accessed workloads.

The following is a summary of the use cases and characteristics of HDD-backed volumes. For information about the maximum IOPS and throughput per instance, see Amazon EBS–optimized instances (p. 1354).

**Previous generation volume types**

The following table describes previous-generation EBS volume types. If you need higher performance or performance consistency than previous-generation volumes can provide, we recommend that you consider using General Purpose SSD (gp2 and gp3) or other current volume types. For more information, see Previous Generation Volumes.

**General Purpose SSD volumes (gp3)**

General Purpose SSD (gp3) volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver a consistent baseline rate of 3,000 IOPS and 125 MiB/s, included with the price of storage. You can provision additional IOPS (up to 16,000) and throughput (up to 1,000 MiB/s) for an additional cost.

The maximum ratio of provisioned IOPS to provisioned volume size is 500 IOPS per GiB. The maximum ratio of provisioned throughput to provisioned IOPS is 0.25 MiB/s per IOPS. The following volume configurations support provisioning either maximum IOPS or maximum throughput:

- 32 GiB or larger: 500 IOPS/GiB x 32 GiB = 16,000 IOPS
- 8 GiB or larger and 4,000 IOPS or higher: 4,000 IOPS x 0.25 MiB/s/IOPS = 1,000 MiB/s

**General Purpose SSD volumes (gp2)**

General Purpose SSD (gp2) volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies and the ability to burst to 3,000 IOPS for extended periods of time. Between a minimum of 100 IOPS (at 33.33 GiB and below) and a maximum of 16,000 IOPS (at 5,334 GiB and above), baseline performance scales linearly at 3 IOPS per
GiB of volume size. AWS designs gp2 volumes to deliver their provisioned performance 99% of the time. A gp2 volume can range in size from 1 GiB to 16 TiB.

I/O Credits and burst performance

The performance of gp2 volumes is tied to volume size, which determines the baseline performance level of the volume and how quickly it accumulates I/O credits; larger volumes have higher baseline performance levels and accumulate I/O credits faster. I/O credits represent the available bandwidth that your gp2 volume can use to burst large amounts of I/O when more than the baseline performance is needed. The more credits your volume has for I/O, the more time it can burst beyond its baseline performance level and the better it performs when more performance is needed. The following diagram shows the burst-bucket behavior for gp2.

Each volume receives an initial I/O credit balance of 5.4 million I/O credits, which is enough to sustain the maximum burst performance of 3,000 IOPS for at least 30 minutes. This initial credit balance is designed to provide a fast initial boot cycle for boot volumes and to provide a good bootstrapping experience for other applications. Volumes earn I/O credits at the baseline performance rate of 3 IOPS per GiB of volume size. For example, a 100 GiB gp2 volume has a baseline performance of 300 IOPS.
When your volume requires more than the baseline performance I/O level, it draws on I/O credits in the credit balance to burst to the required performance level, up to a maximum of 3,000 IOPS. When your volume uses fewer I/O credits than it earns in a second, unused I/O credits are added to the I/O credit balance. The maximum I/O credit balance for a volume is equal to the initial credit balance (5.4 million I/O credits).

When the baseline performance of a volume is higher than maximum burst performance, I/O credits are never spent. If the volume is attached to an instance built on the Nitro System (p. 199), the burst balance is not reported. For other instances, the reported burst balance is 100%.

The burst duration of a volume is dependent on the size of the volume, the burst IOPS required, and the credit balance when the burst begins. This is shown in the following equation:

\[
\text{Burst duration} = \frac{\text{(Credit balance)}}{\text{(Burst IOPS)} - 3(\text{Volume size in GiB})}
\]

The following table lists several volume sizes and the associated baseline performance of the volume (which is also the rate at which it accumulates I/O credits), the burst duration at the 3,000 IOPS
maximum (when starting with a full credit balance), and the time in seconds that the volume would take to refill an empty credit balance.

<table>

</tr>
</tbody>
</table>

* The baseline performance of the volume exceeds the maximum burst performance.

**What happens if I empty my I/O credit balance?**

If your gp2 volume uses all of its I/O credit balance, the maximum IOPS performance of the volume remains at the baseline IOPS performance level (the rate at which your volume earns credits) and the volume’s maximum throughput is reduced to the baseline IOPS multiplied by the maximum I/O size. Throughput can never exceed 250 MiB/s. When I/O demand drops below the baseline level and unused credits are added to the I/O credit balance, the maximum IOPS performance of the volume again exceeds the baseline. For example, a 100 GiB gp2 volume with an empty credit balance has a baseline performance of 300 IOPS and a throughput limit of 75 MiB/s (300 I/O operations per second * 256 KiB per I/O operation = 75 MiB/s). The larger a volume is, the greater the baseline performance is and the faster it replenishes the credit balance. For more information about how IOPS are measured, see I/O characteristics and monitoring (p. 1378).

If you notice that your volume performance is frequently limited to the baseline level (due to an empty I/O credit balance), you should consider switching to a gp3 volume.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see Monitor the burst bucket balance for volumes (p. 1197).

**Throughput performance**

Throughput for a gp2 volume can be calculated using the following formula, up to the throughput limit of 250 MiB/s:

\[
\text{Throughput in MiB/s} = ((\text{Volume size in GiB}) \times (\text{IOPS per GiB}) \times (\text{I/O size in KiB}))
\]

Assuming \( V \) = volume size, \( I = \text{I/O size} \), \( R = \text{I/O rate} \), and \( T = \text{throughput} \), this can be simplified to:
The smallest volume size that achieves the maximum throughput is given by:

\[ T = \frac{V}{IR} \]

\[
\frac{250 \text{ MiB/s}}{256 \text{ KiB}(3 \text{ IOPS/GiB})} = \frac{[(250)(2^{20})(\text{Bytes})]/s}{(256)(2^{10})(\text{Bytes})([3 \text{ IOP/s}]/[(2^{30})(\text{Bytes})])}
\]

\[
\frac{(250)(2^{20})(2^{30})(\text{Bytes})}{(256)(2^{10})(3)} = 357,913,941,333 \text{ Bytes}
\]

\[ = 333 \text{ GiB} \text{ (334 GiB in practice because volumes are provisioned in whole gibibytes)} \]

** Provisioned IOPS SSD volumes **

Provisioned IOPS SSD (io1 and io2) volumes are designed to meet the needs of I/O-intensive workloads, particularly database workloads, that are sensitive to storage performance and consistency. Provisioned IOPS SSD volumes use a consistent IOPS rate, which you specify when you create the volume, and Amazon EBS delivers the provisioned performance 99.9 percent of the time.

io1 volumes are designed to provide 99.8 to 99.9 percent volume durability with an annual failure rate (AFR) no higher than 0.2 percent, which translates to a maximum of two volume failures per 1,000 running volumes over a one-year period. io2 volumes are designed to provide 99.999 percent volume durability with an AFR no higher than 0.001 percent, which translates to a single volume failure per 100,000 running volumes over a one-year period.

Provisioned IOPS SSD io1 and io2 volumes are available for all Amazon EC2 instance types. Provisioned IOPS SSD io2 volumes attached to R5b instances run on EBS Block Express. For more information, see io2 Block Express volumes.

** Considerations for io2 volumes **

- Keep the following in mind when launching instances with io2 volumes:
  - If you launch an R5b instance with an io2 volume, the volume automatically runs on Block Express (p. 1188), regardless of the volume's size and IOPS.
  - You can't launch an instance type that does not support Block Express (p. 1188) with an io2 volume that has a size greater than 16 TiB or IOPS greater than 64,000.
  - You can't launch an R5b instance with an encrypted io2 volume that has a size greater than 16 TiB or IOPS greater than 64,000 from an unencrypted AMI or a shared encrypted AMI. In this case, you must first create an encrypted AMI in your account and then use that AMI to launch the instance.
- Keep the following in mind when creating io2 volumes:
  - If you create an io2 volume with a size greater than 16 TiB or IOPS greater than 64,000 in a Region where Block Express (p. 1188) is supported, the volume automatically runs on Block Express.
• You can't create an io2 volume with a size greater than 16 TiB or IOPS greater than 64,000 in a Region where Block Express (p. 1188) is not supported.

• If you create an io2 volume with a size of 16 TiB or less and IOPS of 64,000 or less in a Region where Block Express (p. 1188) is supported, the volume does not run on Block Express.

• You can't create an encrypted io2 volume that has a size greater than 16 TiB or IOPS greater than 64,000 from an unencrypted snapshot or a shared encrypted snapshot. In this case, you must first create an encrypted snapshot in your account and then use that snapshot to create the volume.

• Keep the following in mind when attaching io2 volumes to instances:

  • If you attach an io2 volume to an R5b instance, the volume automatically runs on Block Express (p. 1188). It can take up to 48 hours to optimize the volume for Block Express. During this time, the volume provides io2 latency. After the volume has been optimized, it provides the sub-millisecond latency supported by Block Express.

  • You can't attach an io2 volume with a size greater than 16 TiB or IOPS greater than 64,000 to an instance type that does not support Block Express (p. 1188).

  • If you detach an io2 volume with a size of 16 TiB or less and IOPS of 64,000 or less from an R5b instance and attach it to an instance type that does not support Block Express (p. 1188), the volume no longer runs on Block Express and it provides io2 latency.

• Keep the following in mind when modifying io2 volumes:

  • You can't modify an io2 volume and increase its size beyond 16 TiB or its IOPS beyond 64,000 while it is attached to an instance type that does not support Block Express (p. 1188).

  • You can't modify the size or provisioned IOPS of an io2 volume that is attached to an R5b instance.

Performance

Provisioned IOPS SSD volumes can range in size from 4 GiB to 16 TiB and you can provision from 100 IOPS up to 64,000 IOPS per volume. You can achieve up to 64,000 IOPS only on Instances built on the Nitro System (p. 199). On other instance families you can achieve performance up to 32,000 IOPS. The maximum ratio of provisioned IOPS to requested volume size (in GiB) is 50:1 for io1 volumes, and 500:1 for io2 volumes. For example, a 100 GiB io1 volume can be provisioned with up to 5,000 IOPS, while a 100 GiB io2 volume can be provisioned with up to 50,000 IOPS. On a supported instance type, the following volume sizes allow provisioning up to the 64,000 IOPS maximum:

• io1 volume 1,280 GiB in size or greater (50 × 1,280 GiB = 64,000 IOPS)
• io2 volume 128 GiB in size or greater (500 × 128 GiB = 64,000 IOPS)

Provisioned IOPS SSD volumes provisioned with up to 32,000 IOPS support a maximum I/O size of 256 KiB and yield as much as 500 MiB/s of throughput. With the I/O size at the maximum, peak throughput is reached at 2,000 IOPS. Volumes provisioned with more than 32,000 IOPS (up to the maximum of 64,000 IOPS) yield a linear increase in throughput at a rate of 16 KiB per provisioned IOPS. For example, a volume provisioned with 48,000 IOPS can support up to 750 MiB/s of throughput (16 KiB per provisioned IOPS x 48,000 provisioned IOPS = 750 MiB/s). To achieve the maximum throughput of 1,000 MiB/s, a volume must be provisioned with 64,000 IOPS (16 KiB per provisioned IOPS x 64,000 provisioned IOPS = 1,000 MiB/s). The following graph illustrates these performance characteristics:
Your per-I/O latency experience depends on the provisioned IOPS and on your workload profile. For the best I/O latency experience, ensure that you provision IOPS to meet the I/O profile of your workload.

**io2 Block Express volumes**

*Note*

io2 Block Express volumes are supported with R5b instances only.

io2 Block Express volumes is the next generation of Amazon EBS storage server architecture. It has been built for the purpose of meeting the performance requirements of the most demanding I/O intensive applications that run on Nitro-based Amazon EC2 instances.

Block Express architecture increases performance and scale. Block Express servers communicate with Nitro-based instances using the Scalable Reliable Datagram (SRD) networking protocol. This interface is implemented in the Nitro Card dedicated for Amazon EBS I/O function on the host hardware of the instance. It minimizes I/O delay and latency variation (network jitter), which provides faster and more consistent performance for your applications. For more information, see io2 Block Express volumes.

io2 Block Express volumes are suited for workloads that benefit from a single volume that provides sub-millisecond latency, and supports higher IOPS, higher throughput, and larger capacity than io2 volumes.

io2 Block Express volumes support the same features as io2 volumes, including Multi-Attach, Elastic Volume operations, and encryption.

**Topics**
- Considerations (p. 1189)
- Performance (p. 1189)
Considerations

- io2 Block Express volumes are currently supported with R5b instances only.
- io2 Block Express volumes are currently available in all Regions where R5b instances are available, including us-east-1, us-east-2, us-west-2, ap-southeast-1, ap-northeast-1, and eu-central-1. R5b instance availability might vary by Availability Zone. For more information about R5b availability, see Find an Amazon EC2 instance type.
- io2 Block Express volumes do not support fast snapshot restore. We recommend that you initialize these volumes to ensure that they deliver full performance. For more information, see Initialize Amazon EBS volumes (p. 1381).

Performance

With io2 Block Express volumes, you can provision volumes with:

- Sub-millisecond average latency
- Storage capacity up to 64 TiB (65,536 GiB)
- Provisioned IOPS up to 256,000, with an IOPS:GiB ratio of 1,000:1. Maximum IOPS can be provisioned with volumes 256 GiB in size and larger (1,000 IOPS x 256 GiB = 256,000 IOPS).
- Volume throughput up to 4,000 MiB/s. Throughput scales proportionally up to 0.256 MiB/s per provisioned IOPS. Maximum throughput can be achieved at 16,000 IOPS or higher.

Quotas

io2 Block Express volumes adhere to the same service quotas as io2 volumes. For more information, see Amazon EBS quotas.
Pricing and billing

io2 volumes and io2 Block Express volumes are billed at the same rate. For more information, see Amazon EBS pricing.

Usage reports do not distinguish between io2 Block Express volumes and io2 volumes. We recommend that you use tags to help you identify costs associated with io2 Block Express volumes.

Throughput Optimized HDD volumes

Throughput Optimized HDD (st1) volumes provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. This volume type is a good fit for large, sequential workloads such as Amazon EMR, ETL, data warehouses, and log processing. Bootable st1 volumes are not supported.

Throughput Optimized HDD (st1) volumes, though similar to Cold HDD (sc1) volumes, are designed to support frequently accessed data.

This volume type is optimized for workloads involving large, sequential I/O, and we recommend that customers with workloads performing small, random I/O use gp2. For more information, see Inefficiency of small read/writes on HDD (p. 1196).

Throughput credits and burst performance

Like gp2, st1 uses a burst-bucket model for performance. Volume size determines the baseline throughput of your volume, which is the rate at which the volume accumulates throughput credits. Volume size also determines the burst throughput of your volume, which is the rate at which you can spend credits when they are available. Larger volumes have higher baseline and burst throughput. The more credits your volume has, the longer it can drive I/O at the burst level.

The following diagram shows the burst-bucket behavior for st1.

Subject to throughput and throughput-credit caps, the available throughput of an st1 volume is expressed by the following formula:

\[(\text{Volume size}) \times (\text{Credit accumulation rate per TiB}) = \text{Throughput}\]

For a 1-TiB st1 volume, burst throughput is limited to 250 MiB/s, the bucket fills with credits at 40 MiB/s, and it can hold up to 1 TiB-worth of credits.
Larger volumes scale these limits linearly, with throughput capped at a maximum of 500 MiB/s. After the bucket is depleted, throughput is limited to the baseline rate of 40 MiB/s per TiB.

On volume sizes ranging from 0.125 TiB to 16 TiB, baseline throughput varies from 5 MiB/s to a cap of 500 MiB/s, which is reached at 12.5 TiB as follows:

\[
\frac{40 \text{ MiB/s}}{12.5 \text{ TiB}} = \frac{500 \text{ MiB/s}}{1 \text{ TiB}}
\]

Burst throughput varies from 31 MiB/s to a cap of 500 MiB/s, which is reached at 2 TiB as follows:

\[
\frac{250 \text{ MiB/s}}{2 \text{ TiB}} = \frac{500 \text{ MiB/s}}{1 \text{ TiB}}
\]

The following table states the full range of base and burst throughput values for st1:

<table>
<thead>

The following diagram plots the table values:
Note
When you create a snapshot of a Throughput Optimized HDD (st1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see Monitor the burst bucket balance for volumes (p. 1197).

Cold HDD volumes

Cold HDD (sc1) volumes provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. With a lower throughput limit than st1, sc1 is a good fit for large, sequential cold-data workloads. If you require infrequent access to your data and are looking to save costs, sc1 provides inexpensive block storage. Bootable sc1 volumes are not supported.

Cold HDD (sc1) volumes, though similar to Throughput Optimized HDD (st1) volumes, are designed to support infrequently accessed data.

Note
This volume type is optimized for workloads involving large, sequential I/O, and we recommend that customers with workloads performing small, random I/O use gp2. For more information, see Inefficiency of small read/writes on HDD (p. 1196).

Throughput credits and burst performance

Like gp2, sc1 uses a burst-bucket model for performance. Volume size determines the baseline throughput of your volume, which is the rate at which the volume accumulates throughput credits. Volume size also determines the burst throughput of your volume, which is the rate at which you can spend credits when they are available. Larger volumes have higher baseline and burst throughput. The more credits your volume has, the longer it can drive I/O at the burst level.
Subject to throughput and throughput-credit caps, the available throughput of an sc1 volume is expressed by the following formula:

\[(\text{Volume size}) \times (\text{Credit accumulation rate per TiB}) = \text{Throughput}\]

For a 1-TiB sc1 volume, burst throughput is limited to 80 MiB/s, the bucket fills with credits at 12 MiB/s, and it can hold up to 1 TiB-worth of credits.

Larger volumes scale these limits linearly, with throughput capped at a maximum of 250 MiB/s. After the bucket is depleted, throughput is limited to the baseline rate of 12 MiB/s per TiB.

On volume sizes ranging from 0.125 TiB to 16 TiB, baseline throughput varies from 1.5 MiB/s to a maximum of 192 MiB/s, which is reached at 16 TiB as follows:

\[
\frac{12 \text{ MiB/s}}{16 \text{ TiB}} \times \frac{1 \text{ TiB}}{1 \text{ TiB}} = 192 \text{ MiB/s}
\]

Burst throughput varies from 10 MiB/s to a cap of 250 MiB/s, which is reached at 3.125 TiB as follows:

\[
\frac{80 \text{ MiB/s}}{3.125 \text{ TiB}} \times \frac{1 \text{ TiB}}{1 \text{ TiB}} = 250 \text{ MiB/s}
\]

The following table states the full range of base and burst throughput values for sc1:

The following diagram plots the table values:

![Diagram showing throughput vs. volume size]

**Note**

When you create a snapshot of a Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see [Monitor the burst bucket balance for volumes (p. 1197)](#).

**Magnetic volumes**

Magnetic volumes are backed by magnetic drives and are suited for workloads where data is accessed infrequently, and scenarios where low-cost storage for small volume sizes is important. These volumes deliver approximately 100 IOPS on average, with burst capability of up to hundreds of IOPS, and they can range in size from 1 GiB to 1 TiB.
Note
Magnetic is a previous generation volume type. For new applications, we recommend using one of the newer volume types. For more information, see Previous Generation Volumes.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see Monitor the burst bucket balance for volumes (p. 1197).

Performance considerations when using HDD volumes

For optimal throughput results using HDD volumes, plan your workloads with the following considerations in mind.

Comparing Throughput Optimized HDD and Cold HDD

The st1 and sc1 bucket sizes vary according to volume size, and a full bucket contains enough tokens for a full volume scan. However, larger st1 and sc1 volumes take longer for the volume scan to complete due to per-instance and per-volume throughput limits. Volumes attached to smaller instances are limited to the per-instance throughput rather than the st1 or sc1 throughput limits.

Both st1 and sc1 are designed for performance consistency of 90% of burst throughput 99% of the time. Non-compliant periods are approximately uniformly distributed, targeting 99% of expected total throughput each hour.

In general, scan times are expressed by this formula:

\[
\text{Scan time} = \frac{\text{Volume size}}{\text{Throughput}}
\]

For example, taking the performance consistency guarantees and other optimizations into account, an st1 customer with a 5-TiB volume can expect to complete a full volume scan in 2.91 to 3.27 hours.

- Optimal scan time

\[
\frac{5 \text{ TiB}}{500 \text{ MiB/s}} = \frac{5 \text{ TiB}}{0.00047684 \text{ TiB/s}} = 10,486 \text{ seconds} = 2.91 \text{ hours}
\]

- Maximum scan time

\[
\frac{2.91 \text{ hours}}{(0.90)(0.99)} = 3.27 \text{ hours}
\]

Similarly, an sc1 customer with a 5-TiB volume can expect to complete a full volume scan in 5.83 to 6.54 hours.

- Optimal scan time

\[
\frac{5 \text{ TiB}}{250 \text{ MiB/s}} = \frac{5 \text{ TiB}}{0.000238418 \text{ TiB/s}} = 20972 \text{ seconds} = 5.83 \text{ hours}
\]

- Maximum scan time

\[
\frac{5.83 \text{ hours}}{(0.90)(0.99)} = 6.54 \text{ hours}
\]
The following table shows ideal scan times for volumes of various size, assuming full buckets and sufficient instance throughput.

<table>
<thead>
<tr>
<th>Volume size (TiB)</th>

<td>9.32</td>
<td>18.64</td>
</tr>
</tbody>
</table>

* These scan times assume an average queue depth (rounded to the nearest whole number) of four or more when performing 1 MiB of sequential I/O.

Therefore if you have a throughput-oriented workload that needs to complete scans quickly (up to 500 MiB/s), or requires several full volume scans a day, use st1. If you are optimizing for cost, your data is relatively infrequently accessed, and you don't need more than 250 MiB/s of scanning performance, then use sc1.

**Inefficiency of small read/writes on HDD**

The performance model for st1 and sc1 volumes is optimized for sequential I/Os, favoring high-throughput workloads, offering acceptable performance on workloads with mixed IOPS and throughput, and discouraging workloads with small, random I/O.

For example, an I/O request of 1 MiB or less counts as a 1 MiB I/O credit. However, if the I/Os are sequential, they are merged into 1 MiB I/O blocks and count only as a 1 MiB I/O credit.

**Limitations on per-instance throughput**

Throughput for st1 and sc1 volumes is always determined by the smaller of the following:
• Throughput limits of the volume
• Throughput limits of the instance

As for all Amazon EBS volumes, we recommend that you select an appropriate EBS-optimized EC2 instance in order to avoid network bottlenecks. For more information, see Amazon EBS–optimized instances (p. 1354).

Monitor the burst bucket balance for volumes

You can monitor the burst-bucket level for gp2, st1, and sc1 volumes using the EBS BurstBalance metric available in Amazon CloudWatch. This metric shows the percentage of I/O credits (for gp2) or throughput credits (for st1 and sc1) remaining in the burst bucket. For more information about the BurstBalance metric and other metrics related to I/O, see I/O characteristics and monitoring (p. 1378). CloudWatch also allows you to set an alarm that notifies you when the BurstBalance value falls to a certain level. For more information, see Creating Amazon CloudWatch Alarms.

Constraints on the size and configuration of an EBS volume

The size of an Amazon EBS volume is constrained by the physics and arithmetic of block data storage, as well as by the implementation decisions of operating system (OS) and file system designers. AWS imposes additional limits on volume size to safeguard the reliability of its services.

The following sections describe the most important factors that limit the usable size of an EBS volume and offer recommendations for configuring your EBS volumes.

Contents
• Storage capacity (p. 1197)
• Service limitations (p. 1198)
• Partitioning schemes (p. 1198)
• Data block sizes (p. 1199)

Storage capacity

The following table summarizes the theoretical and implemented storage capacities for the most commonly used file systems on Amazon EBS, assuming a 4,096 byte block size.

<table>
<thead>

Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS volumes

† io2 Block Express volumes support up to 64 TiB for GPT partitions. For more information, see io2 Block Express volumes (p. 1188).

Service limitations

Amazon EBS abstracts the massively distributed storage of a data center into virtual hard disk drives. To an operating system installed on an EC2 instance, an attached EBS volume appears to be a physical hard disk drive containing 512-byte disk sectors. The OS manages the allocation of data blocks (or clusters) onto those virtual sectors through its storage management utilities. The allocation is in conformity with a volume partitioning scheme, such as master boot record (MBR) or GUID partition table (GPT), and within the capabilities of the installed file system (ext4, NTFS, and so on).

EBS is not aware of the data contained in its virtual disk sectors; it only ensures the integrity of the sectors. This means that AWS actions and OS actions are independent of each other. When you are selecting a volume size, be aware of the capabilities and limits of both, as in the following cases:

- EBS currently supports a maximum volume size of 64 TiB. This means that you can create an EBS volume as large as 64 TiB, but whether the OS recognizes all of that capacity depends on its own design characteristics and on how the volume is partitioned.
- Linux boot volumes may use either the MBR or GPT partitioning scheme. MBR supports boot volumes up to 2047 GiB (2 TiB - 1 GiB). GPT with GRUB 2 supports boot volumes 2 TiB or larger. If your Linux AMI uses MBR, your boot volume is limited to 2047 GiB, but your non-boot volumes do not have this limit. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1208).

Partitioning schemes

Among other impacts, the partitioning scheme determines how many logical data blocks can be uniquely addressed in a single volume. For more information, see Data block sizes (p. 1199). The common partitioning schemes in use are master boot record (MBR) and GUID partition table (GPT). The important differences between these schemes can be summarized as follows.

MBR

MBR uses a 32-bit data structure to store block addresses. This means that each data block is mapped with one of $2^{32}$ possible integers. The maximum addressable size of a volume is given by the following formula:

$$ (2^{32} - 1) \times \text{Block size} $$

The block size for MBR volumes is conventionally limited to 512 bytes. Therefore:

$$ (2^{32} - 1) \times 512 \text{ bytes} = 2 \text{ TiB} - 512 \text{ bytes} $$

Engineering workarounds to increase this 2-TiB limit for MBR volumes have not met with widespread industry adoption. Consequently, Linux and Windows never detect an MBR volume as being larger than 2 TiB even if AWS shows its size to be larger.

GPT

GPT uses a 64-bit data structure to store block addresses. This means that each data block is mapped with one of $2^{64}$ possible integers. The maximum addressable size of a volume is given by the following formula:

$$ (2^{64} - 1) \times \text{Block size} $$
The block size for GPT volumes is commonly 4,096 bytes. Therefore:

\[
(2^{64} - 1) \times 4,096 \text{ bytes} \\
= 2^{64} \times 4,096 \text{ bytes} - 1 \times 4,096 \text{ bytes} \\
= 2^{64} \times 2^{12} \text{ bytes} - 4,096 \text{ bytes} \\
= 64 \text{ ZiB} - 4,096 \text{ bytes}
\]

Real-world computer systems don't support anything close to this theoretical maximum. Implemented file-system size is currently limited to 50 TiB for ext4 and 256 TiB for NTFS—both of which exceed the 16-TiB limit imposed by AWS.

**Data block sizes**

Data storage on a modern hard drive is managed through *logical block addressing*, an abstraction layer that allows the operating system to read and write data in logical blocks without knowing much about the underlying hardware. The OS relies on the storage device to map the blocks to its physical sectors. EBS advertises 512-byte sectors to the operating system, which reads and writes data to disk using data blocks that are a multiple of the sector size.

The industry default size for logical data blocks is currently 4,096 bytes (4 KiB). Because certain workloads benefit from a smaller or larger block size, file systems support non-default block sizes that can be specified during formatting. Scenarios in which non-default block sizes should be used are outside the scope of this topic, but the choice of block size has consequences for the storage capacity of the volume. The following table shows storage capacity as a function of block size:

<table>
<thead>
<tr>
<th>Block size</th>
<th>Max volume size</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 KiB (default)</td>
<td>16 TiB</td>
</tr>
<tr>
<td>8 KiB</td>
<td>32 TiB</td>
</tr>
<tr>
<td>16 KiB</td>
<td>64 TiB</td>
</tr>
<tr>
<td>32 KiB</td>
<td>128 TiB</td>
</tr>
<tr>
<td>64 KiB (maximum)</td>
<td>256 TiB</td>
</tr>
</tbody>
</table>

The EBS-imposed limit on volume size (16 TiB) is currently equal to the maximum size enabled by 4-KiB data blocks.

**Create an Amazon EBS volume**

You can create an Amazon EBS volume and then attach it to any EC2 instance in the same Availability Zone. If you create an encrypted EBS volume, you can only attach it to supported instance types. For more information, see Supported instance types (p. 1337).

If you are creating a volume for a high-performance storage scenario, you should make sure to use a Provisioned IOPS SSD volume (io1 or io2) and attach it to an instance with enough bandwidth to support your application, such as an EBS-optimized instance. The same advice holds for Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes. For more information, see Amazon EBS-optimized instances (p. 1354).

Empty EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). However, storage blocks on volumes that were created from snapshots must be initialized (pulled down from Amazon S3 and written to the volume) before you can access the block. This preliminary action takes time and can cause a significant increase
in the latency of an I/O operation the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume. For most applications, amortizing this cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can force immediate initialization of the entire volume or enable fast snapshot restore. For more information, see Initialize Amazon EBS volumes (p. 1381).

Important
If you create an io2 volume with a size greater than 16 TiB or with IOPS greater than 64,000 in a Region where EBS Block Express is supported, the volume automatically runs on Block Express. io2 Block Express volumes can be attached to R5b instances only. For more information, see io2 Block Express volumes.

Methods of creating a volume

- Create and attach EBS volumes when you launch instances by specifying a block device mapping. For more information, see Launch an instance using the Launch Instance Wizard (p. 477) and Block device mappings (p. 1441).
- Create an empty EBS volume and attach it to a running instance. For more information, see Create an empty volume (p. 1200) below.
- Create an EBS volume from a previously created snapshot and attach it to a running instance. For more information, see Create a volume from a snapshot (p. 1201) below.

Create an empty volume

Empty volumes receive their maximum performance the moment that they are available and do not require initialization.

You can create an empty EBS volume using one of the following methods.

Console

To create an empty EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which you would like to create your volume. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see Resource locations (p. 1452).
3. In the navigation pane, choose ELASTIC BLOCK STORE, Volumes.
4. Choose Create Volume.
5. For Volume Type, choose a volume type. For more information, see Amazon EBS volume types (p. 1179).
6. For Size, enter the size of the volume, in GiB. For more information, see Constraints on the size and configuration of an EBS volume (p. 1197).
7. For IOPS, enter the maximum number of input/output operations per second (IOPS) that the volume should provide. You can specify IOPS only for gp3, io1, and io2 volumes.
8. For Throughput, enter the throughput that the volume should provide, in MiB/s. You can specify throughput only for gp3 volumes.
9. For Availability Zone, choose the Availability Zone in which to create the volume. An EBS volume must be attached to an EC2 instance that is in the same Availability Zone as the volume.
10. (Optional) If the instance type supports EBS encryption and you want to encrypt the volume, select Encrypt this volume and choose a CMK. If encryption by default is enabled in this Region, EBS encryption is enabled and the default CMK for EBS encryption is chosen. You can choose a different CMK from Master Key or paste the full ARN of any key that you can access. For more information, see Amazon EBS encryption (p. 1335).
11. (Optional) Choose **Create additional tags** to add tags to the volume. For each tag, provide a tag key and a tag value. For more information, see Tag your Amazon EC2 resources (p. 1462).

12. Choose **Create Volume**. The volume is ready for use when the volume status is **Available**.

13. To use your new volume, attach it to an instance, format it, and mount it. For more information, see Attach an Amazon EBS volume to an instance (p. 1202).

AWS CLI

**To create an empty EBS volume using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `create-volume` (AWS CLI)
- `New-EC2Volume` (AWS Tools for Windows PowerShell)

**Create a volume from a snapshot**

Volumes created from snapshots load lazily in the background. This means that there is no need to wait for all of the data to transfer from Amazon S3 to your EBS volume before the instance can start accessing an attached volume and all its data. If your instance accesses data that hasn't yet been loaded, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume data in the background. Volume performance is achieved after all blocks are downloaded and written to the volume. To avoid the initial performance hit in a production environment, see Initialize Amazon EBS volumes (p. 1381).

New EBS volumes that are created from encrypted snapshots are automatically encrypted. You can also encrypt a volume on-the-fly while restoring it from an unencrypted snapshot. Encrypted volumes can only be attached to instance types that support EBS encryption. For more information, see Supported instance types (p. 1337).

You can create a volume from a snapshot using one of the following methods.

**Console**

**To create an EBS volume from a snapshot using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region that your snapshot is located in.

   To use the snapshot to create a volume in a different region, copy your snapshot to the new Region and then use it to create a volume in that Region. For more information, see Copy an Amazon EBS snapshot (p. 1236).

3. In the navigation pane, choose **ELASTIC BLOCK STORE, Volumes**.
4. Choose **Create Volume**.
5. For **Volume Type**, choose a volume type. For more information, see Amazon EBS volume types (p. 1179).
6. For **Snapshot ID**, start typing the ID or description of the snapshot from which you are restoring the volume, and choose it from the list of suggested options.
7. (Optional) Select **Encrypt this volume** to change the encryption state of your volume. This is optional if encryption by default (p. 1338) is enabled. Select a CMK from **Master Key** to specify a CMK other than the default CMK for EBS encryption.
8. For **Size**, verify that the default size of the snapshot meets your needs or enter the size of the volume, in GiB.
If you specify both a volume size and a snapshot, the size must be equal to or greater than the snapshot size. When you select a volume type and a snapshot, the minimum and maximum sizes for the volume are shown next to **Size**. For more information, see *Constraints on the size and configuration of an EBS volume* (p. 1197).

9. For **IOPS**, enter the maximum number of input/output operations per second (IOPS) that the volume should provide. You can specify IOPS only for gp3, io1, and io2 volumes.

10. For **Throughput**, enter the throughput that the volume should provide, in MiB/s. You can specify throughput only for gp3 volumes.

11. For **Availability Zone**, choose the Availability Zone in which to create the volume. An EBS volume must be attached to an EC2 instance that is in the same Availability Zone as the volume.

12. (Optional) Choose **Create additional tags** to add tags to the volume. For each tag, provide a tag key and a tag value.

13. Choose **Create Volume**.

14. To use your new volume, attach it to an instance and mount it. For more information, see *Attach an Amazon EBS volume to an instance* (p. 1202).

15. If you created a volume that is larger than the snapshot, you must extend the file system on the volume to take advantage of the extra space. For more information, see *Amazon EBS Elastic Volumes* (p. 1323).

**AWS CLI**

**To create an EBS volume from a snapshot using the command line**

You can use one of the following commands. For more information about these command line interfaces, see *Access Amazon EC2* (p. 3).

- `create-volume` (AWS CLI)
- `New-EC2Volume` (AWS Tools for Windows PowerShell)

**Attach an Amazon EBS volume to an instance**

You can attach an available EBS volume to one or more of your instances that is in the same Availability Zone as the volume.

For information about adding EBS volumes to your instance at launch, see *Instance block device mapping* (p. 1447).

**Prerequisites**

- Determine how many volumes you can attach to your instance. For more information, see *Instance volume limits* (p. 1431).
- Determine whether you can attach your volume to multiple instances and enable Multi-Attach. For more information, see *Attach a volume to multiple instances with Amazon EBS Multi-Attach* (p. 1203).
- If a volume is encrypted, it can only be attached to an instance that supports Amazon EBS encryption. For more information, see *Supported instance types* (p. 1337).
- If a volume has an AWS Marketplace product code:
  - The volume can only be attached to a stopped instance.
  - You must be subscribed to the AWS Marketplace code that is on the volume.
  - The configuration (instance type, operating system) of the instance must support that specific AWS Marketplace code. For example, you cannot take a volume from a Windows instance and attach it to a Linux instance.
• AWS Marketplace product codes are copied from the volume to the instance.

**Important**

If you attach an io2 volume to an R5b instance, the volume always runs on EBS Block Express. Currently, only R5b instances support io2 Block Express volumes. For more information, see **io2 Block Express volumes**.

You can attach a volume to an instance using one of the following methods.

**Console**

**To attach an EBS volume to an instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Volumes.
3. Select an available volume and choose Actions, Attach Volume.
4. For Instance, start typing the name or ID of the instance. Select the instance from the list of options (only instances that are in the same Availability Zone as the volume are displayed).
5. For Device, you can keep the suggested device name, or type a different supported device name. For more information, see Device names on Linux instances (p. 1439).
6. Choose Attach.
7. Connect to your instance and mount the volume. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1208).

**AWS CLI**

**To attach an EBS volume to an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- attach-volume (AWS CLI)
- Add-EC2Volume (AWS Tools for Windows PowerShell)

**Note**

In some situations, you may find that a volume other than the volume attached to /dev/xvda or /dev/sda has become the root volume of your instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume. For more information, see Boot from the wrong volume.

**Attach a volume to multiple instances with Amazon EBS Multi-Attach**

Amazon EBS Multi-Attach enables you to attach a single Provisioned IOPS SSD (io1 or io2) volume to multiple instances that are in the same Availability Zone. You can attach multiple Multi-Attach enabled volumes to an instance or set of instances. Each instance to which the volume is attached has full read and write permission to the shared volume. Multi-Attach makes it easier for you to achieve higher application availability in clustered Linux applications that manage concurrent write operations.

**Contents**

- Considerations and limitations (p. 319)
Considerations and limitations

- Multi-Attach enabled volumes can be attached to up to 16 Linux instances built on the Nitro System (p. 199) that are in the same Availability Zone. You can attach a volume that is Multi-Attach enabled to Windows instances, but the operating system does not recognize the data on the volume that is shared between the instances, which can result in data inconsistency.
- Multi-Attach is supported exclusively on Provisioned IOPS SSD volumes (p. 1186).
- Multi-Attach for io1 volumes is available in the following Regions only: us-east-1, us-west-2, eu-west-1, and ap-northeast-2.

Multi-Attach for io2 and io2 Block Express volumes is available in all Regions that support those volumes types volumes.

- Standard file systems, such as XFS and EXT4, are not designed to be accessed simultaneously by multiple servers, such as EC2 instances. Using Multi-Attach with a standard file system can result in data corruption or loss, so this is not safe for production workloads. You can use a clustered file system to ensure data resiliency and reliability for production workloads.
- Multi-Attach enabled volumes do not support I/O fencing. I/O fencing protocols control write access in a shared storage environment to maintain data consistency. Your applications must provide write ordering for the attached instances to maintain data consistency.
- Multi-Attach enabled volumes can't be created as boot volumes.
- Multi-Attach enabled volumes can be attached to one block device mapping per instance.
- Multi-Attach can't be enabled during instance launch using either the Amazon EC2 console or RunInstances API.
- Multi-Attach enabled volumes that have an issue at the Amazon EBS infrastructure layer are unavailable to all attached instances. Issues at the Amazon EC2 or networking layer might impact only some attached instances.
- The following table shows volume modification support for Multi-Attach enabled io1 and io2 volumes after creation.

<table>
<thead>
<tr>
<th>io2 volumes</th>
<th>io1 volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify volume type</td>
<td>✗</td>
</tr>
<tr>
<td>Modify volume size</td>
<td>✓</td>

<tr>
<td>Enable Multi-Attach</td>
<td>✓ *</td>
</tr>
<tr>
<td>Disable Multi-Attach</td>
<td>✓ *</td>
</tr>
</tbody>
</table>

* You can't enable or disable Multi-Attach while the volume is attached to an instance.
Performance

Each attached instance is able to drive its maximum IOPS performance up to the volume's maximum provisioned performance. However, the aggregate performance of all of the attached instances can't exceed the volume's maximum provisioned performance. If the attached instances' demand for IOPS is higher than the volume's Provisioned IOPS, the volume will not exceed its provisioned performance.

For example, say you create an io2 Multi-Attach enabled volume with 50,000 Provisioned IOPS and you attach it to an m5.8xlarge instance and a c5.12xlarge instance. The m5.8xlarge and c5.12xlarge instances support a maximum of 30,000 and 40,000 IOPS respectively. Each instance can drive its maximum IOPS as it is less than the volume's Provisioned IOPS of 50,000. However, if both instances drive I/O to the volume simultaneously, their combined IOPS can't exceed the volume's provisioned performance of 50,000 IOPS. The volume will not exceed 50,000 IOPS.

To achieve consistent performance, it is best practice to balance I/O driven from attached instances across the sectors of a Multi-Attach enabled volume.

Work with Multi-Attach

Multi-Attach enabled volumes can be managed in much the same way that you would manage any other Amazon EBS volume. However, in order to use the Multi-Attach functionality, you must enable it for the volume. When you create a new volume, Multi-Attach is disabled by default.

Contents

- Enable Multi-Attach (p. 1205)
- Disable Multi-Attach (p. 1206)
- Attach a volume to instances (p. 1207)
- Delete on termination (p. 1207)

Enable Multi-Attach

You can enable Multi-Attach for io1 and io2 volumes during creation.

Use one of the following methods to enable Multi-Attach for an io1 or io2 volume during creation.

Console

To enable Multi-Attach during volume creation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Choose Create Volume.
4. For Volume Type, choose Provisioned IOPS SSD (io1) or Provisioned IOPS SSD (io2).
5. For Size and IOPS, choose the required volume size and the number of IOPS to provision.
6. For Availability Zone, choose the same Availability Zone that the instances are in.
7. For Multi-Attach, choose Enable.
8. Choose Create Volume.

Command line

To enable Multi-Attach during volume creation

Use the create-volume command and specify the --multi-attach-enabled parameter.
You can also enable Multi-Attach for io2 volumes after they have been created.

**Note**
You can't enable Multi-Attach for io1 volumes after creation.

Use one of the following methods to enable Multi-Attach for an Amazon EBS volume after it has been created.

**Console**

To enable Multi-Attach after creation

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Volumes*.
3. Select the volume and choose *Actions*, *Modify Volume*.
4. For *Multi-Attach*, choose *Enable*.
5. Choose *Modify*.

**Command line**

To enable Multi-Attach after creation

Use the `modify-volume` command and specify the `--multi-attach-enabled` parameter.

```
# aws ec2 modify-volume --volume-id vol-1234567890abcdef0 --multi-attach-enabled
```

**Disable Multi-Attach**

You can disable Multi-Attach for an io2 volume only if it is attached to no more than one instance.

**Note**
You can't disable Multi-Attach for io1 volumes after creation.

Use one of the following methods to disable Multi-Attach for an io2 volume.

**Console**

To disable Multi-Attach

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Volumes*.
3. Select the volume and choose *Actions*, *Modify Volume*.
4. For *Multi-Attach*, clear *Enable*.
5. Choose *Modify*.

**Command line**

To disable Multi-Attach after creation

Use the `modify-volume` command and specify the `--no-multi-attach-enabled` parameter.

```
# aws ec2 modify-volume --volume-id vol-1234567890abcdef0 --no-multi-attach-enabled
```
Attach a volume to instances

You attach a Multi-Attach enabled volume to an instance in the same way that you attach any other EBS volume. For more information, see Attach an Amazon EBS volume to an instance (p. 1202).

Delete on termination

Multi-Attach enabled volumes are deleted on instance termination if the last attached instance is terminated and if that instance is configured to delete the volume on termination. If the volume is attached to multiple instances that have different delete on termination settings in their volume block device mappings, the last attached instance's block device mapping setting determines the delete on termination behavior.

To ensure predictable delete on termination behavior, enable or disable delete on termination for all of the instances to which the volume is attached.

By default, when a volume is attached to an instance, the delete on termination setting for the block device mapping is set to false. If you want to turn on delete on termination for a Multi-Attach enabled volume, modify the block device mapping.

If you want the volume to be deleted when the attached instances are terminated, enable delete on termination in the block device mapping for all of the attached instances. If you want to retain the volume after the attached instances have been terminated, disable delete on termination in the block device mapping for all of the attached instances. For more information, see Preserve Amazon EBS volumes on instance termination (p. 552).

You can modify an instance's delete on termination setting at launch or after it has launched. If you enable or disable delete on termination during instance launch, the settings apply only to volumes that are attached at launch. If you attach a volume to an instance after launch, you must explicitly set the delete on termination behavior for that volume.

You can modify an instance's delete on termination setting using the command line tools only.

To modify the delete on termination setting for an existing instance

Use the modify-instance-attribute command and specify the DeleteOnTermination attribute in the --block-device-mappings option.

aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json

Specify the following in mapping.json.

```
[
  {
    "DeviceName": "/dev/sdf",
    "Ebs": {
      "DeleteOnTermination": true|false
    }
  }
]
```

Monitor a Multi-Attach enabled volume

You can monitor a Multi-Attach enabled volume using the CloudWatch Metrics for Amazon EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 1391).
Data is aggregated across all of the attached instances. You can't monitor metrics for individual attached instances.

**Pricing and billing**

There are no additional charges for using Amazon EBS Multi-Attach. You are billed the standard charges that apply to Provisioned IOPS SSD (io1 and io2) volumes. For more information, see Amazon EBS pricing.

**Make an Amazon EBS volume available for use on Linux**

After you attach an Amazon EBS volume to your instance, it is exposed as a block device. You can format the volume with any file system and then mount it. After you make the EBS volume available for use, you can access it in the same ways that you access any other volume. Any data written to this file system is written to the EBS volume and is transparent to applications using the device.

You can take snapshots of your EBS volume for backup purposes or to use as a baseline when you create another volume. For more information, see Amazon EBS snapshots (p. 1227).

You can get directions for volumes on a Windows instance from Make a volume available for use on Windows in the *Amazon EC2 User Guide for Windows Instances*.

**Format and mount an attached volume**

Suppose that you have an EC2 instance with an EBS volume for the root device, /dev/xvda, and that you have just attached an empty EBS volume to the instance using /dev/sdf. Use the following procedure to make the newly attached volume available for use.

**To format and mount an EBS volume on Linux**

1. Connect to your instance using SSH. For more information, see Connect to your Linux instance (p. 499).
2. The device could be attached to the instance with a different device name than you specified in the block device mapping. For more information, see Device names on Linux instances (p. 1439). Use the `lsblk` command to view your available disk devices and their mount points (if applicable) to help you determine the correct device name to use. The output of `lsblk` removes the /dev/ prefix from full device paths.

The following is example output for an instance built on the Nitro System (p. 199), which exposes EBS volumes as NVMe block devices. The root device is /dev/nvme0n1, which has two partitions named nvme0n1p1 and nvme0n1p128. The attached volume is /dev/nvme1n1, which has no partitions and is not yet mounted.

```bash
[ec2-user ~]$ lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme1n1 259:0  0   10G  0 disk
nvme0n1 259:1  0   8G  0 disk
  nvme0n1p1 259:2  0   8G  0 part /
  nvme0n1p128 259:3  0   1M  0 part
```

The following is example output for a T2 instance. The root device is /dev/xvda, which has one partition named xvda1. The attached volume is /dev/xvdf, which has no partitions and is not yet mounted.

```bash
[ec2-user ~]$ lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda   202:0  0   8G  0 disk
```

1208
3. Determine whether there is a file system on the volume. New volumes are raw block devices, and you must create a file system on them before you can mount and use them. Volumes that were created from snapshots likely have a file system on them already; if you create a new file system on top of an existing file system, the operation overwrites your data.

Use one or both of the following methods to determine whether there is a file system on the volume:

- Use the `file -s` command to get information about a specific device, such as its file system type. If the output shows simply `data`, as in the following example output, there is no file system on the device.

  ```bash
e2-user ~]$ sudo file -s /dev/xvdf
/dev/xvdf: data
  ```

  If the device has a file system, the command shows information about the file system type. For example, the following output shows a root device with the XFS file system.

  ```bash
e2-user ~]$ sudo file -s /dev/xvda1
/dev/xvda1: SGI XFS filesystem data (blksz 4096, inosz 512, v2 dirs)
  ```

- Use the `lsblk -f` command to get information about all of the devices attached to the instance.

  ```bash
e2-user ~]$ sudo lsblk -f
  ```

  For example, the following output shows that there are three devices attached to the instances —nvme1n1, nvme0n1, and nvme2n1. The first column lists the devices and their partitions. The `FSTYPE` column shows the file system type for each device. If the column is empty for a specific device, it means that the device does not have a file system. In this case, device nvme1n1 and partition nvme0n1p1 on device nvme0n1 are both formatted using the XFS file system, while device nvme2n1 and partition nvme0n1p128 on device nvme0n1 do not have file systems.

  ```
  NAME  FSTYPE LABEL UUID      MOUNTPOINT
  nvme1n1         xfs  7f939f28-6dcc-4315-8c42-6806080b94dd
  nvme0n1          xfs     / 90e29211-2de8-4967-b0fb-16f51a6e6464
  #/nvme0n1p1 xfs /90e29211-2de8-4967-b0fb-16f51a6e6464
  #/nvme0n1p128
  nvme2n1
  ```

  If the output from these commands show that there is no file system on the device, you must create one.

4. (Conditional) If you discovered that there is a file system on the device in the previous step, skip this step. If you have an empty volume, use the `mkfs -t` command to create a file system on the volume.

  **Warning**
  Do not use this command if you’re mounting a volume that already has data on it (for example, a volume that was created from a snapshot). Otherwise, you’ll format the volume and delete the existing data.

  ```bash
e2-user ~]$ sudo mkfs -t xfs /dev/xvdf
  ```

  If you get an error that `mkfs.xfs` is not found, use the following command to install the XFS tools and then repeat the previous command:
5. Use the `mkdir` command to create a mount point directory for the volume. The mount point is
where the volume is located in the file system tree and where you read and write files to after you
mount the volume. The following example creates a directory named `/data`.

```
[ec2-user ~]$ sudo mkdir /data
```

6. Use the following command to mount the volume at the directory you created in the previous step.

```
[ec2-user ~]$ sudo mount /dev/xvdf /data
```

7. Review the file permissions of your new volume mount to make sure that your users and
applications can write to the volume. For more information about file permissions, see File security
at *The Linux Documentation Project*.

8. The mount point is not automatically preserved after rebooting your instance. To automatically
mount this EBS volume after reboot, see Automatically mount an attached volume after
reboot (p. 1210).

### Automatically mount an attached volume after reboot

To mount an attached EBS volume on every system reboot, add an entry for the device to the `/etc/
fstab` file.

You can use the device name, such as `/dev/xvdf`, in `/etc/fstab`, but we recommend using the
device's 128-bit universally unique identifier (UUID) instead. Device names can change, but the UUID
persists throughout the life of the partition. By using the UUID, you reduce the chances that the system
becomes unbootable after a hardware reconfiguration. For more information, see Identify the EBS
device (p. 1351).

To mount an attached volume automatically after reboot

1. (Optional) Create a backup of your `/etc/fstab` file that you can use if you accidentally destroy or
delete this file while editing it.

```
[ec2-user ~]$ sudo cp /etc/fstab /etc/fstab.orig
```

2. Use the `blkid` command to find the UUID of the device. Make a note of the UUID of the device that
you want to mount after reboot. You'll need it in the following step.

   For example, the following command shows that there are two devices mounted to the instance, and
   it shows the UUIDs for both devices.

   ```
   [ec2-user ~]$ sudo blkid
   /dev/xvda1: LABEL="/" UUID="ca774df7-756d-4261-a3f1-76038323e572" TYPE="xfs"
   PARTLABEL="Linux" PARTUUID="02dcd367-e87c-4f2e-9a72-a3cf8f299c10"
   /dev/xvdf: UUID="aebf131c-6957-451e-8d34-ec978d9581ae" TYPE="xfs"
   ```

   For Ubuntu 18.04 use the `lsblk` command.

   ```
   [ec2-user ~]$ sudo lsblk -o +UUID
   ```

3. Open the `/etc/fstab` file using any text editor, such as `nano` or `vim`.

```
[ec2-user ~]$ sudo vim /etc/fstab
```
4. Add the following entry to /etc/fstab to mount the device at the specified mount point. The fields are the UUID value returned by `blkid` (or `lsblk` for Ubuntu 18.04), the mount point, the file system, and the recommended file system mount options. For more information about the required fields, run `man fstab` to open the `fstab` manual.

In the following example, we mount the device with UUID `aebf131c-6957-451e-8d34-ec978d9581ae` to mount point `/data` and we use the `xfs` file system. We also use the `defaults` and `nofail` flags. We specify 0 to prevent the file system from being dumped, and we specify 2 to indicate that it is a non-root device.

```
UUID=aebf131c-6957-451e-8d34-ec978d9581ae /data xfs defaults,nofail 0 2
```

**Note**
If you ever boot your instance without this volume attached (for example, after moving the volume to another instance), the `nofail` mount option enables the instance to boot even if there are errors mounting the volume. Debian derivatives, including Ubuntu versions earlier than 16.04, must also add the `nobootwait` mount option.

5. To verify that your entry works, run the following commands to unmount the device and then mount all file systems in /etc/fstab. If there are no errors, the /etc/fstab file is OK and your file system will mount automatically after it is rebooted.

```
[ec2-user ~]$ sudo umount /data
[ec2-user ~]$ sudo mount -a
```

If you receive an error message, address the errors in the file.

**Warning**
Errors in the /etc/fstab file can render a system unbootable. Do not shut down a system that has errors in the /etc/fstab file.

If you are unsure how to correct errors in /etc/fstab and you created a backup file in the first step of this procedure, you can restore from your backup file using the following command.

```
[ec2-user ~]$ sudo mv /etc/fstab.orig /etc/fstab
```

### View information about an Amazon EBS volume

You can view descriptive information about your EBS volumes. For example, you can view information about all volumes in a specific Region or view detailed information about a single volume, including its size, volume type, whether the volume is encrypted, which master key was used to encrypt the volume, and the specific instance to which the volume is attached.

You can get additional information about your EBS volumes, such as how much disk space is available, from the operating system on the instance.

#### View volume information

You can view information about a volume using one of the following methods.

**Console**

**To view information about an EBS volume using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Volumes**.
3. (Optional) Use the filter options in the search field to display only the volumes that interest you. For example, if you know the instance ID, choose **Instance ID** from the search field menu, and then choose the instance ID from the list provided. To remove a filter, choose it again.

4. Select the volume.

5. In the details pane, you can inspect the information provided about the volume. **Attachment information** shows the instance ID this volume is attached to and the device name under which it is attached.

6. (Optional) Choose the **Attachment information** link to view additional details about the instance.

**To view the EBS volumes that are attached to an instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. In the **Storage** tab, view the information provided about root and block devices.
5. (Optional) Choose a link in the **Volume ID** column to view additional details for the volume.

**AWS CLI**

**To view information about an EBS volume using the command line**

You can use one of the following commands to view volume attributes. For more information, see **Access Amazon EC2** (p. 3).

- `describe-volumes` (AWS CLI)
- `Get-EC2Volume` (AWS Tools for Windows PowerShell)

**Amazon EC2 Global View**

You can use Amazon EC2 Global View to view your volumes across all Regions for which your AWS account is enabled. For more information, see **List and filter resources across Regions using Amazon EC2 Global View** (p. 1461).

**Volume state**

Volume state describes the availability of an Amazon EBS volume. You can view the volume state in the **State** column on the **Volumes** page in the console, or by using the `describe-volumes` AWS CLI command.

The possible volume states are:

- **creating**
  
  The volume is being created.

- **available**
  
  The volume is not attached to an instance.

- **in-use**
  
  The volume is attached to an instance.

- **deleting**
  
  The volume is being deleted.
deleted

The volume is deleted.

error

The underlying hardware related to your EBS volume has failed, and the data associated with the volume is unrecoverable. For information about how to restore the volume or recover the data on the volume, see My EBS volume has a status of “error”.

View volume metrics

You can get additional information about your EBS volumes from Amazon CloudWatch. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 1391).

View free disk space

You can get additional information about your EBS volumes, such as how much disk space is available, from the Linux operating system on the instance. For example, use the following command:

```
[ec2-user ~]$ df -hT /dev/xvda1
Filesystem     Type      Size  Used Avail Use% Mounted on
/dev/xvda1     xfs       8.0G  1.2G  6.9G  15% /
```

For information about viewing free disk space on a Windows instance, see View free disk space in the Amazon EC2 User Guide for Windows Instances.

Replace an Amazon EBS volume

Amazon EBS snapshots are the preferred backup tool on Amazon EC2 because of their speed, convenience, and cost. When creating a volume from a snapshot, you recreate its state at a specific point in the past with all data intact. By attaching a volume created from a snapshot to an instance, you can duplicate data across Regions, create test environments, replace a damaged or corrupted production volume in its entirety, or retrieve specific files and directories and transfer them to another attached volume. For more information, see Amazon EBS snapshots (p. 1227).

The procedure for replacing a volume differs depending on whether the volume is the root volume or a data volume.

Topics

- Replace a root volume (p. 1213)
- Replace a data volume (p. 1216)

Replace a root volume

Amazon EC2 enables you to replace the root EBS volume for an instance without stopping the instance. You can restore the root volume for an instance to its launch state, or to a specific snapshot. This allows you to fix issues, such as root volume corruption or guest operating system network configuration errors, while retaining the following:

- Data stored on instance store volumes — Instance store volumes remain attached to the instance after the root volume has been replaced.
- Network configuration — All network interfaces remain attached to the instance and they retain their IP addresses, identifiers, and attachment IDs. When the instance becomes available, all pending
network traffic is flushed. Additionally, the instance remains on the same physical host, so it retains its public and private IP addresses and DNS name.

- IAM policies — IAM profiles and policies (such as tag-based policies) that are associated with the instance are retained and enforced.

When you replace the root volume for an instance, a new volume is restored to the original volume's launch state, or using a specific snapshot. The original volume is detached from the instance, and the new volume is attached to the instance in its place. The original volume is not automatically deleted. If you no longer need it, you can delete it manually after the root volume replacement task completes. For more information about root volume replacement task states, see View root volume replacement tasks (p. 1215).

Topics

- Considerations (p. 319)
- Replace a root volume (p. 1214)
- View root volume replacement tasks (p. 1215)

Considerations

- The instance is automatically rebooted when the root volume is replaced. The contents of the memory (RAM) is erased during the reboot.
- You can't replace the root volume if it is an instance store volume.
- You can't replace the root volume for metal instances.
- You can only use snapshots that belong to the same lineage as the instance's current root volume. You can't use snapshot copies created from snapshots that were taken from the root volume. Additionally, after successfully completing a root volume replacement task, snapshots taken from the previous root volume can't be used to create a root volume replacement task for the new volume.

Replace a root volume

When you replace the root volume for an instance, you can choose to restore the volume to its initial launch state, or you can choose to restore the volume to a specific snapshot. If you choose to restore the volume to a specific snapshot, then you must select a snapshot that was taken of that root volume. If you choose to restore the root volume to its initial launch state, the root volume is restored from the snapshot that was used to create the volume.

You can replace the root volume for an instance using one of the following methods. If you use the Amazon EC2 console, note that replacing the root volume is only available in the new console.

Amazon EC2 console

To replace the root volume

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance for which to replace the root volume and choose Actions, Monitor and troubleshoot, Replace root volume.
4. In the Replace root volume screen, do one of the following:
   - To restore the instance's root volume to its initial launch state, choose Create replacement task without selecting a snapshot.
   - To restore the instance's root volume to a specific snapshot, for Snapshot, select the snapshot to use, and then choose Create replacement task.
AWS CLI

To restore the root volume to the initial launch state

Use the `create-replace-root-volume-task` command. Specify the ID of the instance for which to replace the root volume and omit the `--snapshot-id` parameter.

```
# aws ec2 create-replace-root-volume-task --instance-id instance_id
```

For example:

```
# aws ec2 create-replace-root-volume-task --instance-id i-1234567890abcdef0
```

To restore the root volume to a specific snapshot

Use the `create-replace-root-volume-task` command. Specify the ID of the instance for which to replace the root volume and the ID of the snapshot to use.

```
# aws ec2 create-replace-root-volume-task --instance-id instance_id --snapshot-id snapshot_id
```

For example:

```
# aws ec2 create-replace-root-volume-task --instance-id i-1234567890abcdef0 --snapshot-id snap-9876543210abcdef0
```

View root volume replacement tasks

After you start a root volume replacement task, the task enters the following states:

- `pending` — the replacement volume is being created.
- `in-progress` — the original volume is being detached and the replacement volume is being attached.
- `succeeded` — the replacement volume has been successfully attached to the instance and the instance is available.
- `failing` — the replacement task is in the process of failing.
- `failed` — the replacement task has failed but the original root volume is still attached.
- `failing-detached` — the replacement task is in the process of failing. The instance might have no root volume attached.
- `failed-detached` — the replacement task has failed and the instance has no root volume attached.

You can view the root volume replacement tasks for an instance using one of the following methods.

Amazon EC2 console

To view the root volume replacement tasks

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance for which to view the root volume replacement tasks, and then choose the Storage tab.
4. In the **Storage** tab, expand **Recent root volume replacement tasks**.

**AWS CLI**

**To view the status of a root volume replacement task**

Use the `describe-replace-root-volume-tasks` command and specify the IDs of the root volume replacement tasks to view.

```bash
$ aws ec2 describe-replace-root-volume-tasks --replace-root-volume-task-ids task_id_1 task_id_2
```

For example:

```bash
$ aws ec2 describe-replace-root-volume-tasks --replace-root-volume-task-ids replacevol-1234567890abcdef0
```

```json
{
  "ReplaceRootVolumeTasks": [
    {
      "ReplaceRootVolumeTaskId": "replacevol-1234567890abcdef0",
      "InstanceId": "i-1234567890abcdef0",
      "TaskState": "succeeded",
      "StartTime": "2020-11-06 13:09:54.0",
      "CompleteTime": "2020-11-06 13:10:14.0"
    }
  ]
}
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```bash
$ aws ec2 describe-replace-root-volume-tasks --filters Name=instance-id,Values=instance_id
```

For example:

```bash
$ aws ec2 describe-replace-root-volume-tasks --filters Name=instance-id,Values=i-1234567890abcdef0
```

**Replace a data volume**

You can use the following procedure to replace a (non-root) data volume with another volume created from a previous snapshot of that volume. You must detach the current volume and then attach the new volume.

Note that EBS volumes can only be attached to EC2 instances in the same Availability Zone.

Use the following method.

**Console**

**To replace a data volume**

1. Create a volume from the snapshot and write down the ID of the new volume. For more information, see Create a volume from a snapshot (p. 1201).
Monitor the status of your volumes

Amazon Web Services (AWS) automatically provides data that you can use to monitor your Amazon Elastic Block Store (Amazon EBS) volumes.

Contents

- EBS volume status checks (p. 1217)
- EBS volume events (p. 1219)
- Work with an impaired volume (p. 1221)
- Work with the Auto-Enabled IO volume attribute (p. 1223)

For additional monitoring information, see Amazon CloudWatch metrics for Amazon EBS (p. 1391) and Amazon CloudWatch Events for Amazon EBS (p. 1397).

**EBS volume status checks**

Volume status checks enable you to better understand, track, and manage potential inconsistencies in the data on an Amazon EBS volume. They are designed to provide you with the information that you need to determine whether your Amazon EBS volumes are impaired, and to help you control how a potentially inconsistent volume is handled.

Volume status checks are automated tests that run every 5 minutes and return a pass or fail status. If all checks pass, the status of the volume is `ok`. If a check fails, the status of the volume is `impaired`. If the status is `insufficient-data`, the checks may still be in progress on the volume. You can view the results of volume status checks to identify any impaired volumes and take any necessary actions.

When Amazon EBS determines that a volume's data is potentially inconsistent, the default is that it disables I/O to the volume from any attached EC2 instances, which helps to prevent data corruption. After I/O is disabled, the next volume status check fails, and the volume status is `impaired`. In addition, you'll see an event that lets you know that I/O is disabled, and that you can resolve the impaired status of the volume by enabling I/O to the volume. We wait until you enable I/O to give you the opportunity to decide whether to continue to let your instances use the volume, or to run a consistency check using a command, such as `fsck`, before doing so.

**Note**
Volume status is based on the volume status checks, and does not reflect the volume state. Therefore, volume status does not indicate volumes in the `error` state (for example, when a volume is incapable of accepting I/O.) For information about volume states, see Volume state (p. 1212).

If the consistency of a particular volume is not a concern, and you'd prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume
to automatically enable I/O. If you enable the Auto-Enable IO volume attribute (autoEnableIO in the API), the volume status check continues to pass. In addition, you'll see an event that lets you know that the volume was determined to be potentially inconsistent, but that its I/O was automatically enabled. This enables you to check the volume's consistency or replace it at a later time.

The I/O performance status check compares actual volume performance to the expected performance of a volume. It alerts you if the volume is performing below expectations. This status check is available only for Provisioned IOPS SSD (io1 and io2) volumes that are attached to an instance. The status check is not valid for General Purpose SSD (gp2 and gp3), Throughput Optimized HDD (st1), Cold HDD (sc1), or Magnetic (standard) volumes. The I/O performance status check is performed once every minute, and CloudWatch collects this data every 5 minutes. It might take up to 5 minutes from the moment that you attach an io1 or io2 volume to an instance for the status check to report the I/O performance status.

**Important**

While initializing Provisioned IOPS SSD volumes that were restored from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the I/O Performance status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see Initialize Amazon EBS volumes (p. 1381).

The following table lists statuses for Amazon EBS volumes.

<table>
<thead>
<tr>
<th>Volume status</th>
<th>I/O enabled status</th>
<th>I/O performance status (io1 and io2 volumes only)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Normal (Volume performance is as expected)</td>
</tr>
<tr>
<td>warning</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Degraded (Volume performance is below expectations)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Severely Degraded (Volume performance is well below expectations)</td>
</tr>
<tr>
<td>impaired</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Stalled (Volume performance is severely impacted)</td>
</tr>
<tr>
<td></td>
<td>Disabled (Volume is offline and pending recovery, or is waiting for the user to enable I/O)</td>
<td>Not Available (Unable to determine I/O performance because I/O is disabled)</td>
</tr>
<tr>
<td>insufficient-data</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Insufficient Data</td>
</tr>
<tr>
<td></td>
<td>Insufficient Data</td>
<td></td>
</tr>
</tbody>
</table>

You can view and work with status checks using the following methods.

**Console**

**To view status checks**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Volumes**. The **Volume Status** column displays the operational status of each volume.
3. To view the status details of a volume, select the volume and choose **Status Checks**.
4. If you have a volume with a failed status check (status is **impaired**), see Work with an impaired volume (p. 1221).

Alternatively, you can choose **Events** in the navigator to view all the events for your instances and volumes. For more information, see EBS volume events (p. 1219).

**AWS CLI**

**To view volume status information**

Use one of the following commands.

- `describe-volume-status` (AWS CLI)
- `Get-EC2VolumeStatus` (AWS Tools for Windows PowerShell)

For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

**EBS volume events**

When Amazon EBS determines that a volume's data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure.

To automatically enable I/O on a volume with potential data inconsistencies, change the setting of the **Auto-Enabled IO** volume attribute (`autoEnableIO` in the API). For more information about changing this attribute, see Work with an impaired volume (p. 1221).

Each event includes a start time that indicates the time at which the event occurred, and a duration that indicates how long I/O for the volume was disabled. The end time is added to the event when I/O for the volume is enabled.

Volume status events include one of the following descriptions:

**Awaiting Action: Enable IO**

- Volume data is potentially inconsistent. I/O is disabled for the volume until you explicitly enable it. The event description changes to **IO Enabled** after you explicitly enable I/O.

**IO Enabled**

- I/O operations were explicitly enabled for this volume.

**IO Auto-Enabled**

- I/O operations were automatically enabled on this volume after an event occurred. We recommend that you check for data inconsistencies before continuing to use the data.

**Normal**

- For **io1**, **io2**, and **gp3** volumes only. Volume performance is as expected.
Degraded

For io1, io2, and gp3 volumes only. Volume performance is below expectations.

Severely Degraded

For io1, io2, and gp3 volumes only. Volume performance is well below expectations.

Stalled

For io1, io2, and gp3 volumes only. Volume performance is severely impacted.

You can view events for your volumes using the following methods.

Console

**To view events for your volumes**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events. All instances and volumes that have events are listed.
3. You can filter by volume to view only volume status. You can also filter on specific status types.
4. Select a volume to view its specific event.

AWS CLI

**To view events for your volumes**

Use one of the following commands.

- `describe-volume-status` (AWS CLI)
- `Get-EC2VolumeStatus` (AWS Tools for Windows PowerShell)

For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

If you have a volume where I/O is disabled, see Work with an impaired volume (p. 1221). If you have a volume where I/O performance is below normal, this might be a temporary condition due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on an instance that cannot support the I/O bandwidth required, accessing data on the volume for the first time, etc.).
Work with an impaired volume

Use the following options if a volume is impaired because the volume's data is potentially inconsistent.

Options

- Option 1: Perform a consistency check on the volume attached to its instance (p. 1221)
- Option 2: Perform a consistency check on the volume using another instance (p. 1221)
- Option 3: Delete the volume if you no longer need it (p. 1222)

Option 1: Perform a consistency check on the volume attached to its instance

The simplest option is to enable I/O and then perform a data consistency check on the volume while the volume is still attached to its Amazon EC2 instance.

To perform a consistency check on an attached volume

1. Stop any applications from using the volume.
2. Enable I/O on the volume. Use one of the following methods.
   
   **Console**
   
   1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   2. In the navigation pane, choose Volumes.
   3. Select the volume on which to enable I/O operations.
   4. In the details pane, choose Enable Volume IO, and then choose Yes, Enable.

   ![Enable Volume IO](image)

   AWS CLI

   **To enable I/O for a volume with the command line**

   You can use one of the following commands to view event information for your Amazon EBS volumes. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

   - enable-volume-io (AWS CLI)
   - Enable-EC2VolumeIO (AWS Tools for Windows PowerShell)

3. Check the data on the volume.

   a. Run the fsck command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact the AWS Support Center. Choose Troubleshoot, and then in the Troubleshoot Status Checks dialog box, choose Contact Support to submit a support case.

Option 2: Perform a consistency check on the volume using another instance

Use the following procedure to check the volume outside your production environment.
Important
This procedure may cause the loss of write I/Os that were suspended when volume I/O was
disabled.

To perform a consistency check on a volume in isolation

1. Stop any applications from using the volume.
2. Detach the volume from the instance. For more information, see Detach an Amazon EBS volume
from a Linux instance (p. 1224).
3. Enable I/O on the volume. Use one of the following methods.

   Console
   1. In the navigation pane, choose Volumes.
   2. Select the volume that you detached in the previous step.
   3. In the details pane, choose Enable Volume IO, and then choose Yes, Enable.

   AWS CLI

   To enable I/O for a volume with the command line

   You can use one of the following commands to view event information for your Amazon EBS
volumes. For more information about these command line interfaces, see Access Amazon
EC2 (p. 3).

   - enable-volume-io (AWS CLI)
   - Enable-EC2VolumeIO (AWS Tools for Windows PowerShell)
4. Attach the volume to another instance. For more information, see Launch your instance (p. 475) and
Attach an Amazon EBS volume to an instance (p. 1202).
5. Check the data on the volume.
   a. Run the fsck command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact the AWS Support
   Center. Choose Troubleshoot, and then in the troubleshooting dialog box, choose Contact
   Support to submit a support case.

Option 3: Delete the volume if you no longer need it

If you want to remove the volume from your environment, simply delete it. For information about
deleting a volume, see Delete an Amazon EBS volume (p. 1226).

If you have a recent snapshot that backs up the data on the volume, you can create a new volume from
the snapshot. For more information, see Create a volume from a snapshot (p. 1201).
Work with the Auto-Enabled IO volume attribute

When Amazon EBS determines that a volume's data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure. If the consistency of a particular volume is not a concern, and you prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the Auto-Enabled IO volume attribute (autoEnableIO in the API), I/O between the volume and the instance is automatically re-enabled and the volume's status check will pass. In addition, you'll see an event that lets you know that the volume was in a potentially inconsistent state, but that its I/O was automatically enabled. When this event occurs, you should check the volume's consistency and replace it if necessary. For more information, see EBS volume events (p. 1219).

You can view and modify the Auto-Enabled IO attribute of a volume using the following methods.

Console

To view the Auto-Enabled IO attribute of a volume

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume and choose Status Checks. Auto-Enabled IO displays the current setting (Enabled or Disabled) for your volume.

To modify the Auto-Enabled IO attribute of a volume

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume and choose Actions, Change Auto-Enable IO Setting. Alternatively, choose the Status Checks tab, and for Auto-Enabled IO, choose Edit.
4. Select the Auto-Enable Volume IO check box to automatically enable I/O for an impaired volume. To disable the feature, clear the check box.
5. Choose Save.

AWS CLI

To view the autoEnableIO attribute of a volume

Use one of the following commands.

- `describe-volume-attribute` (AWS CLI)
- `Get-EC2VolumeAttribute` (AWS Tools for Windows PowerShell)

To modify the autoEnableIO attribute of a volume

Use one of the following commands.

- `modify-volume-attribute` (AWS CLI)
- `Edit-EC2VolumeAttribute` (AWS Tools for Windows PowerShell)

For more information about these command line interfaces, see Access Amazon EC2 (p. 3)

Detach an Amazon EBS volume from a Linux instance

You need to detach an Amazon Elastic Block Store (Amazon EBS) volume from an instance before you can attach it to a different instance or delete it. Detaching a volume does not affect the data on the volume.

For information about detaching volumes from a Windows instance, see Detach a volume from a Windows instance in the Amazon EC2 User Guide for Windows Instances.

Topics

- Considerations (p. 319)
- Unmount and detach a volume (p. 1225)
- Troubleshoot (p. 1225)

Considerations

- You can detach an Amazon EBS volume from an instance explicitly or by terminating the instance. However, if the instance is running, you must first unmount the volume from the instance.
- If an EBS volume is the root device of an instance, you must stop the instance before you can detach the volume.
• You can reattach a volume that you detached (without unmounting it), but it might not get the same mount point. If there were writes to the volume in progress when it was detached, the data on the volume might be out of sync.

• After you detach a volume, you are still charged for volume storage as long as the storage amount exceeds the limit of the AWS Free Tier. You must delete a volume to avoid incurring further charges. For more information, see Delete an Amazon EBS volume (p. 1226).

Unmount and detach a volume

Use the following procedures to unmount and detach a volume from an instance. This can be useful when you need to attach the volume to a different instance or when you need to delete the volume.

Steps
• Step 1: Unmount the volume (p. 1225)
• Step 2: Detach the volume from the instance (p. 1225)

Step 1: Unmount the volume

From your Linux instance, use the following command to unmount the /dev/sdh device.

```
[ec2-user ~]# umount -d /dev/sdh
```

Step 2: Detach the volume from the instance

To detach the volume from the instance, use one of the following methods:

Console

To detach an EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select a volume and choose Actions, Detach Volume.
4. When prompted for confirmation, choose Yes, Detach.

Command line

To detach an EBS volume from an instance using the command line

After unmounting the volume, you can use one of the following commands to detach it. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- detach-volume (AWS CLI)
- Dismount-EC2Volume (AWS Tools for Windows PowerShell)

Troubleshoot

The following are common problems encountered when detaching volumes, and how to resolve them.

Note

To guard against the possibility of data loss, take a snapshot of your volume before attempting to unmount it. Forced detachment of a stuck volume can cause damage to the file system or the
data it contains or an inability to attach a new volume using the same device name, unless you reboot the instance.

- If you encounter problems while detaching a volume through the Amazon EC2 console, it can be helpful to use the `describe-volumes` CLI command to diagnose the issue. For more information, see `describe-volumes`.

- If your volume stays in the `detaching` state, you can force the detachment by choosing `Force Detach`. Use this option only as a last resort to detach a volume from a failed instance, or if you are detaching a volume with the intention of deleting it. The instance doesn't get an opportunity to flush file system caches or file system metadata. If you use this option, you must perform the file system check and repair procedures.

- If you've tried to force the volume to detach multiple times over several minutes and it stays in the `detaching` state, you can post a request for help to the Amazon EC2 forum. To help expedite a resolution, include the volume ID and describe the steps that you've already taken.

- When you attempt to detach a volume that is still mounted, the volume can become stuck in the `busy` state while it is trying to detach. The following output from `describe-volumes` shows an example of this condition:

```json
"Volumes": [
  {

When you encounter this state, detachment can be delayed indefinitely until you unmount the volume, force detachment, reboot the instance, or all three.

## Delete an Amazon EBS volume

After you no longer need an Amazon EBS volume, you can delete it. After deletion, its data is gone and the volume can’t be attached to any instance. However, before deletion, you can store a snapshot of the volume, which you can use to re-create the volume later.

**Note**

You can’t delete a volume if it’s attached to an instance. To delete a volume, you must first detach it. For more information, see Detach an Amazon EBS volume from a Linux instance (p. 1224).

You can check if a volume is attached to an instance. In the console, on the Volumes page, you can view the state of your volumes.

- If a volume is attached to an instance, it’s in the `in-use` state.
- If a volume is detached from an instance, it’s in the `available` state. You can delete this volume.

You can delete an EBS volume using one of the following methods.
To delete an EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select a volume and choose Actions, Delete Volume. If Delete Volume is greyed out, the volume is attached to an instance.
4. In the confirmation dialog box, choose Yes, Delete.

To delete an EBS volume using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- delete-volume (AWS CLI)
- Remove-EC2Volume (AWS Tools for Windows PowerShell)

Amazon EBS snapshots

You can back up the data on your Amazon EBS volumes to Amazon S3 by taking point-in-time snapshots. Snapshots are incremental backups, which means that only the blocks on the device that have changed after your most recent snapshot are saved. This minimizes the time required to create the snapshot and saves on storage costs by not duplicating data. Each snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume.

When you create an EBS volume based on a snapshot, the new volume begins as an exact replica of the original volume that was used to create the snapshot. The replicated volume loads data in the background so that you can begin using it immediately. If you access data that hasn't been loaded yet, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume's data in the background. For more information, see Create Amazon EBS snapshots (p. 1231).

When you delete a snapshot, only the data unique to that snapshot is removed. For more information, see Delete an Amazon EBS snapshot (p. 1234).

Snapshot events

You can track the status of your EBS snapshots through CloudWatch Events. For more information, see EBS snapshot events (p. 1401).

Multi-volume snapshots

Snapshots can be used to create a backup of critical workloads, such as a large database or a file system that spans across multiple EBS volumes. Multi-volume snapshots allow you to take exact point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You are no longer required to stop your instance or to coordinate between volumes to ensure crash consistency, because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating a multi-volume EBS snapshot under Create Amazon EBS snapshots (p. 1231).

Snapshot pricing
Charges for your snapshots are based on the amount of data stored. Because snapshots are incremental, deleting a snapshot might not reduce your data storage costs. Data referenced exclusively by a snapshot is removed when that snapshot is deleted, but data referenced by other snapshots is preserved. For more information, see Amazon Elastic Block Store Volumes and Snapshots in the AWS Billing and Cost Management User Guide.

How incremental snapshots work

This section shows how an EBS snapshot captures the state of a volume at a point in time, and how successive snapshots of a changing volume create a history of those changes.

Relations among multiple snapshots of the same volume

The diagram in this section shows Volume 1 at three points in time. A snapshot is taken of each of these three volume states. The diagram specifically shows the following:

- In State 1, the volume has 10 GiB of data. Because Snap A is the first snapshot taken of the volume, the entire 10 GiB of data must be copied.
- In State 2, the volume still contains 10 GiB of data, but 4 GiB have changed. Snap B needs to copy and store only the 4 GiB that changed after Snap A was taken. The other 6 GiB of unchanged data, which are already copied and stored in Snap A, are referenced by Snap B rather than being copied again. This is indicated by the dashed arrow.
- In State 3, 2 GiB of data have been added to the volume, for a total of 12 GiB. Snap C needs to copy the 2 GiB that were added after Snap B was taken. As shown by the dashed arrows, Snap C also references 4 GiB of data stored in Snap B, and 6 GiB of data stored in Snap A.
- The total storage required for the three snapshots is 16 GiB.
Relations among incremental snapshots of different volumes

The diagram in this section shows how incremental snapshots can be taken from different volumes.

**Important**

The diagram assumes that you own Vol 1 and that you have created Snap A. If Vol 1 was owned by another AWS account and that account took Snap A and shared it with you, then Snap B would be a full snapshot.
1. **Vol 1** has 10 GiB of data. Because **Snap A** is the first snapshot taken of the volume, the entire 10 GiB of data is copied and stored.

2. **Vol 2** is created from **Snap A**, so it is an exact replica of **Vol 1** at the time the snapshot was taken.

3. Over time, 4 GiB of data is added to **Vol 2** and its total size becomes 14 GiB.

4. **Snap B** is taken from **Vol 2**. For **Snap B**, only the 4 GiB of data that was added after the volume was created from **Snap A** is copied and stored. The other 10 GiB of unchanged data, which is already stored in **Snap A**, is referenced by **Snap B** instead of being copied and stored again.

   **Snap B** is an incremental snapshot of **Snap A**, even though it was created from a different volume.

For more information about how data is managed when you delete a snapshot, see Delete an Amazon EBS snapshot (p. 1234).

**Copy and share snapshots**

You can share a snapshot across AWS accounts by modifying its access permissions. You can make copies of your own snapshots as well as snapshots that have been shared with you. For more information, see Share an Amazon EBS snapshot (p. 1242).
A snapshot is constrained to the AWS Region where it was created. After you create a snapshot of an EBS volume, you can use it to create new volumes in the same Region. For more information, see Create a volume from a snapshot (p. 1201). You can also copy snapshots across Regions, making it possible to use multiple Regions for geographical expansion, data center migration, and disaster recovery. You can copy any accessible snapshot that has a completed status. For more information, see Copy an Amazon EBS snapshot (p. 1236).

**Encryption support for snapshots**

EBS snapshots fully support EBS encryption.

- Snapshots of encrypted volumes are automatically encrypted.
- Volumes that you create from encrypted snapshots are automatically encrypted.
- Volumes that you create from an unencrypted snapshot that you own or have access to can be encrypted on-the-fly.
- When you copy an unencrypted snapshot that you own, you can encrypt it during the copy process.
- When you copy an encrypted snapshot that you own or have access to, you can reencrypt it with a different key during the copy process.
- The first snapshot you take of an encrypted volume that has been created from an unencrypted snapshot is always a full snapshot.
- The first snapshot you take of a reencrypted volume, which has a different CMK compared to the source snapshot, is always a full snapshot.

Complete documentation of possible snapshot encryption scenarios is provided in Create Amazon EBS snapshots (p. 1231) and in Copy an Amazon EBS snapshot (p. 1236).

For more information, see Amazon EBS encryption (p. 1335).

**Create Amazon EBS snapshots**

You can create a point-in-time snapshot of an EBS volume and use it as a baseline for new volumes or for data backup. If you make periodic snapshots of a volume, the snapshots are incremental—the new snapshot saves only the blocks that have changed since your last snapshot.

Snapshots occur asynchronously; the point-in-time snapshot is created immediately, but the status of the snapshot is pending until the snapshot is complete (when all of the modified blocks have been transferred to Amazon S3), which can take several hours for large initial snapshots or subsequent snapshots where many blocks have changed. While it is completing, an in-progress snapshot is not affected by ongoing reads and writes to the volume.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your Amazon EBS volume at the time the snapshot command is issued. This might exclude any data that has been cached by any applications or the operating system. If you can pause any file writes to the volume long enough to take a snapshot, your snapshot should be complete. However, if you can't pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You can remount and use your volume while the snapshot status is pending.

To make snapshot management easier, you can tag your snapshots during creation or add tags afterward. For example, you can apply tags describing the original volume from which the snapshot was created, or the device name that was used to attach the original volume to an instance. For more information, see Tag your Amazon EC2 resources (p. 1462).

**Snapshot encryption**

Snapshots that are taken from encrypted volumes are automatically encrypted. Volumes that are created from encrypted snapshots are also automatically encrypted. The data in your encrypted volumes and
any associated snapshots is protected both at rest and in motion. For more information, see Amazon EBS encryption (p. 1335).

By default, only you can create volumes from snapshots that you own. However, you can share your unencrypted snapshots with specific AWS accounts, or you can share them with the entire AWS community by making them public. For more information, see Share an Amazon EBS snapshot (p. 1242).

You can share an encrypted snapshot only with specific AWS accounts. For others to use your shared, encrypted snapshot, you must also share the CMK key that was used to encrypt it. Users with access to your encrypted snapshot must create their own personal copy of it and then use that copy. Your copy of a shared, encrypted snapshot can also be re-encrypted using a different key. For more information, see Share an Amazon EBS snapshot (p. 1242).

**Multi-volume snapshots**

You can create multi-volume snapshots, which are point-in-time snapshots for all EBS volumes attached to an EC2 instance. You can also create lifecycle policies to automate the creation and retention of multi-volume snapshots. For more information, see Amazon Data Lifecycle Manager (p. 1280).

After the snapshots are created, each snapshot is treated as an individual snapshot. You can perform all snapshot operations, such as restore, delete, and copy across Regions or accounts, just as you would with a single volume snapshot. You can also tag your multi-volume snapshots as you would a single volume snapshot. We recommend you tag your multiple volume snapshots to manage them collectively during restore, copy, or retention.

Multi-volume, crash-consistent snapshots are typically restored as a set. It is helpful to identify the snapshots that are in a crash-consistent set by tagging your set with the instance ID, name, or other relevant details. You can also choose to automatically copy tags from the source volume to the corresponding snapshots. This helps you to set the snapshot metadata, such as access policies, attachment information, and cost allocation, to match the source volume.

After creating your snapshots, they appear in your EC2 console created at the exact point-in-time.

If any one snapshot for the multi-volume snapshot set fails, all of the other snapshots display an error status and a createSnapshots CloudWatch event with a result of failed is sent to your AWS account. For more information, see Create snapshots (createSnapshots) (p. 1401).

**Amazon Data Lifecycle Manager**

You can create, retain, and delete snapshots manually, or you can use Amazon Data Lifecycle Manager to manage your snapshots for you. For more information, see Amazon Data Lifecycle Manager (p. 1280).

**Considerations**

The following considerations apply to creating snapshots:

- When you create a snapshot for an EBS volume that serves as a root device, you should stop the instance before taking the snapshot.
- You cannot create snapshots from instances for which hibernation is enabled.
- You cannot create snapshots from hibernated instances.
- Although you can take a snapshot of a volume while a previous snapshot of that volume is in the pending status, having multiple pending snapshots of a volume can result in reduced volume performance until the snapshots complete.
- There is a limit of one pending snapshot for a single st1 or sc1 volume, or five pending snapshots for a single volume of the other volume types. If you receive a ConcurrentSnapshotLimitExceeded error while trying to create multiple concurrent snapshots of the same volume, wait for one or more of the pending snapshots to complete before creating another snapshot of that volume.
• When a snapshot is created from a volume with an AWS Marketplace product code, the product code is propagated to the snapshot.

Create a snapshot

To create a snapshot from the specified volume, use one of the following methods.

Console

To create a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Snapshots under Elastic Block Store in the navigation pane.
3. Choose Create Snapshot.
4. For Select resource type, choose Volume.
5. For Volume, select the volume.
6. (Optional) Enter a description for the snapshot.
7. (Optional) Choose Add Tag to add tags to your snapshot. For each tag, provide a tag key and a tag value.
8. Choose Create Snapshot.

AWS CLI

To create a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

• create-snapshot (AWS CLI)
• New-EC2Snapshot (AWS Tools for Windows PowerShell)

Create a multi-volume snapshot

To create a snapshot from the volumes of an instance, use one of the following methods.

Console

To create multi-volume snapshots using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Snapshots under Elastic Block Store in the navigation pane.
3. Choose Create Snapshot.
4. For Select resource type, choose Instance.
5. Select the instance ID for which you want to create simultaneous backups for all of the attached EBS volumes. Multi-volume snapshots support up to 40 EBS volumes per instance.
6. (Optional) Set Exclude root volume.
7. (Optional) Set Copy tags from volume flag to automatically copy tags from the source volume to the corresponding snapshots. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.
8. (Optional) Choose Add Tag to add tags to your snapshot. For each tag, provide a tag key and a tag value.
9. Choose Create Snapshot.
AWS CLI

To create multi-volume snapshots using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- create-snapshots (AWS CLI)
- New-EC2SnapshotBatch (AWS Tools for Windows PowerShell)

If all of the snapshots complete successfully, a createSnapshots CloudWatch event with a result of succeed is sent to your AWS account. If any one snapshot for the multi-volume snapshot set fails, all of the other snapshots display an error status and a createSnapshots CloudWatch event with a result of failed is sent to your AWS account. For more information, see Create snapshots (createSnapshots) (p. 1401).

Work with EBS snapshots

You can copy snapshots, share snapshots, and create volumes from snapshots. For more information, see the following:

- Copy an Amazon EBS snapshot (p. 1236)
- Share an Amazon EBS snapshot (p. 1242)
- Create a volume from a snapshot (p. 1201)

Delete an Amazon EBS snapshot

After you no longer need an Amazon EBS snapshot of a volume, you can delete it. Deleting a snapshot has no effect on the volume. Deleting a volume has no effect on the snapshots made from it.

Incremental snapshot deletion

If you make periodic snapshots of a volume, the snapshots are incremental. This means that only the blocks on the device that have changed after your most recent snapshot are saved in the new snapshot. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to create volumes.

If data was present on a volume held in an earlier snapshot or series of snapshots, and that data is subsequently deleted from the volume later on, the data is still considered to be unique data of the earlier snapshots. Unique data is only deleted from the sequence of snapshots if all snapshots that reference the unique data are deleted.

When you delete a snapshot, only the data that is referenced exclusively by that snapshot is removed. Unique data is only deleted if all of the snapshots that reference it are deleted. Deleting previous snapshots of a volume does not affect your ability to create volumes from later snapshots of that volume.

Deleting a snapshot might not reduce your organization's data storage costs. Other snapshots might reference that snapshot's data, and referenced data is always preserved. If you delete a snapshot containing data being used by a later snapshot, costs associated with the referenced data are allocated to the later snapshot. For more information about how snapshots store data, see How incremental snapshots work (p. 1228) and the following example.

In the following diagram, Volume 1 is shown at three points in time. A snapshot has captured each of the first two states, and in the third, a snapshot has been deleted.
• In State 1, the volume has 10 GiB of data. Because Snap A is the first snapshot taken of the volume, the entire 10 GiB of data must be copied.

• In State 2, the volume still contains 10 GiB of data, but 4 GiB have changed. Snap B needs to copy and store only the 4 GiB that changed after Snap A was taken. The other 6 GiB of unchanged data, which are already copied and stored in Snap A, are referenced by Snap B rather than (again) copied. This is indicated by the dashed arrow.

• In state 3, the volume has not changed since State 2, but Snapshot A has been deleted. The 6 GiB of data stored in Snapshot A that were referenced by Snapshot B have now been moved to Snapshot B, as shown by the heavy arrow. As a result, you are still charged for storing 10 GiB of data; 6 GiB of unchanged data preserved from Snap A and 4 GiB of changed data from Snap B.

Deleting a snapshot with some of its data referenced by another snapshot

![Diagram showing the deletion of a snapshot with some of its data referenced by another snapshot.]

Considerations

The following considerations apply to deleting snapshots:

• You can't delete a snapshot of the root device of an EBS volume used by a registered AMI. You must first deregister the AMI before you can delete the snapshot. For more information, see Deregister your Linux AMI (p. 151).

• You can't delete a snapshot that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault.

• You can create, retain, and delete snapshots manually, or you can use Amazon Data Lifecycle Manager to manage your snapshots for you. For more information, see Amazon Data Lifecycle Manager (p. 1280).
Delete a snapshot

To delete a snapshot, use one of the following methods.

Console

To delete a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Snapshots in the navigation pane.
3. Select a snapshot and then choose Delete from the Actions list.
4. Choose Yes, Delete.

AWS CLI

To delete a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- delete-snapshot (AWS CLI)
- Remove-EC2Snapshot (AWS Tools for Windows PowerShell)

Delete a multi-volume snapshot

To delete multi-volume snapshots, retrieve all of the snapshots for your multi-volume snapshot set using the tag you applied to the set when you created the snapshots. Then, delete the snapshots individually.

You will not be prevented from deleting individual snapshots in the multi-volume snapshot set. If you delete a snapshot while it is in the pending state, only that snapshot is deleted. The other snapshots in the multi-volume snapshot set still complete successfully.

Copy an Amazon EBS snapshot

With Amazon EBS, you can create point-in-time snapshots of volumes, which we store for you in Amazon S3. After you create a snapshot and it has finished copying to Amazon S3 (when the snapshot status is completed), you can copy it from one AWS Region to another, or within the same Region. Amazon S3 server-side encryption (256-bit AES) protects a snapshot's data in transit during a copy operation. The snapshot copy receives an ID that is different from the ID of the original snapshot.

To copy multi-volume snapshots to another AWS Region, retrieve the snapshots using the tag you applied to the multi-volume snapshot set when you created it. Then individually copy the snapshots to another Region.

If you would like another account to be able to copy your snapshot, you must either modify the snapshot permissions to allow access to that account or make the snapshot public so that all AWS accounts can copy it. For more information, see Share an Amazon EBS snapshot (p. 1242).

For information about copying an Amazon RDS snapshot, see Copying a DB Snapshot in the Amazon RDS User Guide.
Use cases

- Geographic expansion: Launch your applications in a new AWS Region.
- Migration: Move an application to a new Region, to enable better availability and to minimize cost.
- Disaster recovery: Back up your data and logs across different geographical locations at regular intervals. In case of disaster, you can restore your applications using point-in-time backups stored in the secondary Region. This minimizes data loss and recovery time.
- Encryption: Encrypt a previously unencrypted snapshot, change the key with which the snapshot is encrypted, or create a copy that you own in order to create a volume from it (for encrypted snapshots that have been shared with you).
- Data retention and auditing requirements: Copy your encrypted EBS snapshots from one AWS account to another to preserve data logs or other files for auditing or data retention. Using a different account helps prevent accidental snapshot deletions, and protects you if your main AWS account is compromised.

Prerequisites

- You can copy any accessible snapshots that have a completed status, including shared snapshots and snapshots that you have created.
- You can copy AWS Marketplace, VM Import/Export, and Storage Gateway snapshots, but you must verify that the snapshot is supported in the destination Region.

Considerations

- Each account can have up to twenty concurrent snapshot copy requests to a single destination Region.
- User-defined tags are not copied from the source snapshot to the new snapshot. You can add user-defined tags during or after the copy operation. For more information, see Tag your Amazon EC2 resources (p. 1462).
- Snapshots created by a snapshot copy operation have an arbitrary volume ID that should not be used for any purpose.
- Resource-level permissions specified for the snapshot copy operation apply only to the new snapshot. You cannot specify resource-level permissions for the source snapshot. For an example, see Example: Copying snapshots (p. 1090).

Pricing

- For pricing information about copying snapshots across AWS Regions and accounts, see Amazon EBS Pricing.
- Snapshot copy operations within a single account and Region do not copy any actual data and therefore are cost-free as long as the encryption status of the snapshot copy does not change.
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- If you copy a snapshot to a new Region, a complete (non-incremental) copy is created. This results in additional storage costs. Subsequent copies of the same snapshot are incremental.

Incremental snapshot copying

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. When you copy a snapshot across Regions or accounts, the copy is an incremental copy if the following conditions are met:

- The snapshot was copied to the destination Region or account previously.
• The most recent snapshot copy still exists in the destination Region or account.
• All copies of the snapshot in the destination Region or account are either unencrypted or were encrypted using the same KMS key.

If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy. If a copy is still pending when you start another copy, the second copy starts only after the first copy finishes.

We recommend that you tag your snapshots with the volume ID and creation time so that you can keep track of the most recent snapshot copy of a volume in the destination Region or account.

To see whether your snapshot copies are incremental, check the `copySnapshot` CloudWatch event.

**Encryption and snapshot copying**

When you copy a snapshot, you can encrypt the copy or you can specify a KMS key that is different than the original, and the resulting copied snapshot uses the new KMS key. However, changing the encryption status of a snapshot during a copy operation results in a full (not incremental) copy, which might incur greater data transfer and storage charges.

To copy an encrypted snapshot shared from another AWS account, you must have permissions to use the snapshot and the customer master key (CMK) that was used to encrypt the snapshot. When using an encrypted snapshot that was shared with you, we recommend that you re-encrypt the snapshot by copying it using a KMS key that you own. This protects you if the original KMS key is compromised, or if the owner revokes it, which could cause you to lose access to any encrypted volumes that you created using the snapshot. For more information, see Share an Amazon EBS snapshot (p. 1242).

You apply encryption to EBS snapshot copies by setting the `Encrypted` parameter to `true`. (The `Encrypted` parameter is optional if `encryption by default` (p. 1338) is enabled).

Optionally, you can use `KmsKeyId` to specify a custom key to use to encrypt the snapshot copy. (The `Encrypted` parameter must also be set to `true`, even if encryption by default is enabled.) If `KmsKeyId` is not specified, the key that is used for encryption depends on the encryption state of the source snapshot and its ownership.

The following tables describe the encryption outcome for each possible combination of settings.

**Topics**

- Encryption outcomes: Copying snapshots that you own (p. 1238)
- Encryption outcomes: Copying snapshots that are shared with you (p. 1239)

### Copy a snapshot

To copy a snapshot, use one of the following methods.
Console

To copy a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to copy, and then choose Copy from the Actions list.
4. In the Copy Snapshot dialog box, update the following as necessary:
   - **Destination region**: Select the Region where you want to write the copy of the snapshot.
   - **Description**: By default, the description includes information about the source snapshot so that you can identify a copy from the original. You can change this description as necessary.
   - **Encryption**: If the source snapshot is not encrypted, you can choose to encrypt the copy. If you have enabled encryption by default (p. 1338), the Encryption option is set and cannot be unset from the snapshot console. If the Encryption option is set, you can choose to encrypt it to a customer managed CMK by selecting one in the field, described below. You cannot strip encryption from an encrypted snapshot.
   - **Master Key**: The customer master key (CMK) to be used to encrypt this snapshot. The default key for your account is displayed initially, but you can optionally select from the master keys in your account or type/paste the ARN of a key from a different account. You can create new master encryption keys in the AWS KMS console.
5. Choose Copy.
6. In the Copy Snapshot confirmation dialog box, choose Snapshots to go to the Snapshots page in the Region specified, or choose Close.

To view the progress of the copy process, switch to the destination Region, and then refresh the Snapshots page. Copies in progress are listed at the top of the page.

AWS CLI

To copy a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).
- copy-snapshot (AWS CLI)
- Copy-EC2Snapshot (AWS Tools for Windows PowerShell)

To check for failure

If you attempt to copy an encrypted snapshot without having permissions to use the encryption key, the operation fails silently. The error state is not displayed in the console until you refresh the page. You can also check the state of the snapshot from the command line, as in the following example.

```
aws ec2 describe-snapshots --snapshot-id snap-0123abcd
```

If the copy failed because of insufficient key permissions, you see the following message:
"StateMessage": "Given key ID is not accessible".

When copying an encrypted snapshot, you must have DescribeKey permissions on the default CMK. Explicitly denying these permissions results in copy failure. For information about managing CMK keys, see Controlling Access to Customer Master Keys.
View Amazon EBS snapshot information

You can view detailed information about your snapshots using one of the following methods.

Console

To view snapshot information using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Snapshots in the navigation pane.
3. To reduce the list, choose an option from the Filter list. For example, to view only your snapshots, choose Owned By Me. You can also filter your snapshots using tags and snapshot attributes. Choose the search bar to view the available tags and attributes.
4. To view more information about a snapshot, select it.

AWS CLI

To view snapshot information using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- describe-snapshots (AWS CLI)
- Get-EC2Snapshot (AWS Tools for Windows PowerShell)

Example Example 1: Filter based on tags

The following command describes the snapshots with the tag Stack=production.

```
aws ec2 describe-snapshots --filters Name=tag:Stack,Values=production
```

Example Example 2: Filter based on volume

The following command describes the snapshots created from the specified volume.

```
aws ec2 describe-snapshots --filters Name=volume-id,Values=vol-049df61146c4d7901
```

Example Example 3: Filter based on snapshot age

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following command displays the IDs of all snapshots created by your AWS account (represented by 123456789012) before the specified date (represented by 2020-03-31). If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime<="2020-03-31")].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime>="2019-01-01") && (StartTime<="2019-12-31")].[SnapshotId]" --output text
```
Share an Amazon EBS snapshot

You can modify the permissions of a snapshot if you want to share it with other AWS accounts. You can share snapshots publicly with all other AWS accounts, or you can share them privately with individual AWS accounts that you specify. Users that you have authorized can use the snapshots that you share to create their own EBS volumes, while your original snapshot remains unaffected.

**Important**
When you share a snapshot, you are giving others access to all of the data on the snapshot. Share snapshots only with people that you trust with *all* of your snapshot data.

Topics

- Before you share a snapshot (p. 1242)
- Share a snapshot (p. 1242)
- Share a KMS key (p. 1243)
- View snapshots that are shared with you (p. 1245)
- Use snapshots that are shared with you (p. 1245)
- Determine the use of snapshots that you share (p. 1245)

Before you share a snapshot

The following considerations apply to sharing snapshots:

- Snapshots are constrained to the Region in which they were created. To share a snapshot with another Region, copy the snapshot to that Region and then share the copy. For more information, see Copy an Amazon EBS snapshot (p. 1236).
- You can’t share snapshots that are encrypted with the default AWS managed key. You can only share snapshots that are encrypted with a customer managed key. For more information, see Creating Keys in the *AWS Key Management Service Developer Guide*.
- You can share only unencrypted snapshots publicly.
- When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. For more information, see Share a KMS key (p. 1243).

Share a snapshot

You can share a snapshot using one of the methods described in the section.

Console

**To share a snapshot**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Snapshots in the navigation pane.
3. Select the snapshot and then choose Actions, Modify Permissions.
4. Make the snapshot public or share it with specific AWS accounts as follows:
   - To make the snapshot public, choose Public.
   - To share the snapshot with one or more AWS accounts, choose Private, enter the AWS account ID (without hyphens) in AWS Account Number, and choose Add Permission. Repeat for any additional AWS accounts.
5. Choose Save.
AWS CLI

The permissions for a snapshot are specified using the `createVolumePermission` attribute of the snapshot. To make a snapshot public, set the group to `all`. To share a snapshot with a specific AWS account, set the user to the ID of the AWS account.

**To share a snapshot publicly**

Use one of the following commands.

- **modify-snapshot-attribute** *(AWS CLI)*
  
  For `--attribute`, specify `createVolumePermission`. For `--operation-type`, specify `add`. For `--group-names`, specify `all`.

  $$
  \text{AWS CLI}\n  
  \text{$\ast$ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --group-names all}
  $$

  - **Edit-EC2SnapshotAttribute** *(AWS Tools for Windows PowerShell)*

    For `-Attribute`, specify `CreateVolumePermission`. For `-OperationType`, specify `Add`. For `-GroupName`, specify `all`.

    $$
    \text{PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -GroupName all}
    $$

**To share a snapshot privately**

Use one of the following commands.

- **modify-snapshot-attribute** *(AWS CLI)*
  
  For `--attribute`, specify `createVolumePermission`. For `--operation-type`, specify `add`. For `--user-ids`, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

  $$
  \text{AWS CLI}\n  
  \text{$\ast$ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --user-ids 123456789012}
  $$

  - **Edit-EC2SnapshotAttribute** *(AWS Tools for Windows PowerShell)*

    For `-Attribute`, specify `CreateVolumePermission`. For `-OperationType`, specify `Add`. For `-UserId`, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

    $$
    \text{PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -UserId 123456789012}
    $$

**Share a KMS key**

When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. You can apply cross-account permissions to a customer managed key either when it is created or at a later time.

Users of your shared customer managed key who are accessing encrypted snapshots must be granted permissions to perform the following actions on the key:

- **kms:DescribeKey**
• kms:CreateGrant
• kms:GenerateDataKey
• kms:ReEncrypt
• kms:Decrypt

For more information about controlling access to a customer managed key, see Using key policies in AWS KMS in the AWS Key Management Service Developer Guide.

To share customer managed key using the AWS KMS console

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. Choose Customer managed keys in the navigation pane.
4. In the Alias column, choose the alias (text link) of the customer managed key that you used to encrypt the snapshot. The key details open in a new page.
5. In the Key policy section, you see either the policy view or the default view. The policy view displays the key policy document. The default view displays sections for Key administrators, Key deletion, Key Use, and Other AWS accounts. The default view displays if you created the policy in the console and have not customized it. If the default view is not available, you'll need to manually edit the policy in the policy view. For more information, see Viewing a Key Policy (Console) in the AWS Key Management Service Developer Guide.

Use either the policy view or the default view, depending on which view you can access, to add one or more AWS account IDs to the policy, as follows:

• (Policy view) Choose Edit. Add one or more AWS account IDs to the following statements:
  "Allow use of the key" and "Allow attachment of persistent resources". Choose Save changes. In the following example, the AWS account ID 444455556666 is added to the policy.

```json
```

1244
View snapshots that are shared with you

You can view snapshots that are shared with you using one of the following methods.

Console

To view shared snapshots using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Filter the listed snapshots. In the top-left corner of the screen, choose one of the following options:
   - Private snapshots — To view only snapshots that are shared with you privately.
   - Public snapshots — To view only snapshots that are shared with you publicly.

AWS CLI

To view snapshot permissions using the command line

Use one of the following commands:

- describe-snapshot-attribute (AWS CLI)
- Get-EC2SnapshotAttribute (AWS Tools for Windows PowerShell)

Use snapshots that are shared with you

To use a shared unencrypted snapshot

Locate the shared snapshot by ID or description. For more information, see View snapshots that are shared with you (p. 1245). You can use this snapshot as you would any other snapshot that you own in your account. For example, you can create a volume from the snapshot or copy it to a different Region.

To use a shared encrypted snapshot

Locate the shared snapshot by ID or description. For more information, see View snapshots that are shared with you (p. 1245). Create a copy of the shared snapshot in your account, and encrypt the copy with a KMS key that you own. You can then use the copy to create volumes or you can copy it to different Regions.

Determine the use of snapshots that you share

You can use AWS CloudTrail to monitor whether a snapshot that you have shared with others is copied or used to create a volume. The following events are logged in CloudTrail:

- SharedSnapshotCopyInitiated — A shared snapshot is being copied.
- SharedSnapshotVolumeCreated — A shared snapshot is being used to create a volume.
Amazon EBS local snapshots on Outposts

Amazon EBS snapshots are a point-in-time copy of your EBS volumes.

By default, snapshots of EBS volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. You can also use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally on Amazon S3 on the Outpost itself. This ensures that the snapshot data resides on the Outpost, and on your premises. In addition, you can use AWS Identity and Access Management (IAM) policies and permissions to set up data residency enforcement policies to ensure that snapshot data does not leave the Outpost. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has data residency requirements.

This topic provides information about working with Amazon EBS local snapshots on Outposts. For more information about Amazon EBS snapshots and about working with snapshots in an AWS Region, see Amazon EBS snapshots (p. 1227).

For more information about AWS Outposts, see AWS Outposts Features and the AWS Outposts User Guide. For pricing information, see AWS Outposts pricing.

Topics

- Frequently asked questions (p. 1246)
- Prerequisites (p. 1247)
- Considerations (p. 319)
- Controlling access with IAM (p. 1248)
- Working with local snapshots (p. 1249)

Frequently asked questions

1. What are local snapshots?

By default, Amazon EBS snapshots of volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. If the Outpost is provisioned with Amazon S3 on Outposts, you can choose to store the snapshots locally on the Outpost itself. Local snapshots are incremental, which means that only the blocks of the volume that have changed after your most recent snapshot are saved. You can use these snapshots to restore a volume on the same Outpost as the snapshot at any time. For more information about Amazon EBS snapshots, see Amazon EBS snapshots (p. 1227).

2. Why should I use local snapshots?

Snapshots are a convenient way of backing up your data. With local snapshots, all of your snapshot data is stored locally on the Outpost. This means that it does not leave your premises. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has residency requirements.

Additionally, using local snapshots can help to reduce the bandwidth used for communication between the Region and the Outpost in bandwidth constrained environments.

3. How do I enforce snapshot data residency on Outposts?

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots and to enforce data residency. You can create a policy that prevents principals from creating snapshots from Outpost volumes and instances and storing the snapshots in an AWS Region. Currently, copying snapshots and images from an Outpost to a Region is not supported. For more information, see Controlling access with IAM (p. 1248).
4. Are multi-volume, crash-consistent local snapshots supported?

Yes, you can create multi-volume, crash-consistent local snapshots from instances on an Outpost.

5. How do I create local snapshots?

You can create snapshots manually using the AWS Command Line Interface (AWS CLI) or the Amazon EC2 console. For more information see, Working with local snapshots (p. 1249). You can also automate the lifecycle of local snapshots using Amazon Data Lifecycle Manager. For more information see, Automate snapshots on an Outpost (p. 1254).

6. Can I create, use, or delete local snapshots if my Outpost loses connectivity to its Region?

No. The Outpost must have connectivity with its Region as the Region provides the access, authorization, logging, and monitoring services that are critical for your snapshots' health. If there is no connectivity, you can't create new local snapshots, create volumes or launch instances from existing local snapshots, or delete local snapshots.

7. How quickly is Amazon S3 storage capacity made available after deleting local snapshots?

Amazon S3 storage capacity becomes available within 72 hours after deleting local snapshots and the volumes that reference them.

8. How can I ensure that I do not run out of Amazon S3 capacity on my Outpost?

We recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity, and delete snapshots and volumes that you no longer need to avoid running out of storage capacity. If you are using Amazon Data Lifecycle Manager to automate the lifecycle of local snapshots, ensure that your snapshot retention policies do not retain snapshots for longer than is needed.

9. Can I use local snapshots and AMIs backed by local snapshots with Spot Instances and Spot Fleet?

No, you can't use local snapshots or AMIs backed by local snapshots to launch Spot Instances or a Spot Fleet.

10. Can I use local snapshots and AMIs backed by local snapshots with Amazon EC2 Auto Scaling?

Yes, you can use local snapshots and AMIs backed by local snapshots to launch Auto Scaling groups in a subnet that is on the same Outpost as the snapshots. The Amazon EC2 Auto Scaling group service-linked role must have permission to use the KMS key used to encrypt the snapshots.

You can't use local snapshots or AMIs backed by local snapshots to launch Auto Scaling groups in an AWS Region.

Prerequisites

To store snapshots on an Outpost, you must have an Outpost that is provisioned with Amazon S3 on Outposts. For more information about Amazon S3 on Outposts, see Using Amazon S3 on Outposts in the Amazon Simple Storage Service Developer Guide.

Considerations

Keep the following in mind when working with local snapshots.

- Outposts must have connectivity to their AWS Region to use local snapshots.
- Snapshot metadata is stored in the AWS Region associated with the Outpost. This does not include any snapshot data.
- Snapshots stored on Outposts are encrypted by default. Unencrypted snapshots are not supported. Snapshots that are created on an Outpost and snapshots that are copied to an Outpost are encrypted...
using the default KMS key for the Region or a different KMS key that you specify at the time of the request.

- When you create a volume on an Outpost from a local snapshot, you cannot re-encrypt the volume using a different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.
- After you delete local snapshots from an Outpost, the Amazon S3 storage capacity used by the deleted snapshots becomes available within 72 hours. For more information, see Delete local snapshots (p. 1254).
- You can't export local snapshots from an Outpost.
- You can't enable fast snapshot restore for local snapshots.
- EBS direct APIs are not supported with local snapshots.
- You can't copy local snapshots or AMIs from an Outpost to an AWS Region, from one Outpost to another, or within an Outpost. However, you can copy snapshots from an AWS Region to an Outpost. For more information, see Copy snapshots from an AWS Region to an Outpost (p. 1253).
- When copying a snapshot from an AWS region to an Outpost, the data is transferred over the service link. Copying multiple snapshots simultaneously could impact other services running on the Outpost.
- You can't share local snapshots.
- You must use IAM policies to ensure that your data residency requirements are met. For more information, see Controlling access with IAM (p. 1248).
- Local snapshots are incremental backups. Only the blocks in the volume that have changed after your most recent snapshot are saved. Each local snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume. For more information, see How incremental snapshots work (p. 1228).
- You can't use IAM policies to enforce data residency for CopySnapshot and CopyImage actions.

Controlling access with IAM

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots. The following are example policies that you can use to grant or deny permission to perform specific actions with local snapshots.

**Important**

Copying snapshots and images from an Outpost to a Region is currently not supported. As a result, you currently can't use IAM policies to enforce data residency for CopySnapshot and CopyImage actions.

**Topics**
- Enforce data residency for snapshots (p. 1248)
- Prevent principals from deleting local snapshots (p. 1249)

**Enforce data residency for snapshots**

The following example policy prevents all principals from creating snapshots from volumes and instances on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef and storing the snapshot data in an AWS Region. Principals can still create local snapshots. This policy ensures that all snapshots remain on the Outpost.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
```
Prevent principals from deleting local snapshots

The following example policy prevents all principals from deleting local snapshots that are stored on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ec2:DeleteSnapshot"
      ],
      "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
      "Condition": {
        "StringEquals": {
          "ec2:OutpostArn": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteSnapshot"
      ],
      "Resource": "*"
    }
  ]
}
```

Working with local snapshots

The following sections explain how to use local snapshots.

Topics
- Rules for storing snapshots (p. 1250)
Rules for storing snapshots

The following rules apply to snapshot storage:

- If the most recent snapshot of a volume is stored on an Outpost, then all successive snapshots must be stored on the same Outpost.
- If the most recent snapshot of a volume is stored in an AWS Region, then all successive snapshots must be stored in the same Region. To start creating local snapshots from that volume, do the following:
  1. Create a snapshot of the volume in the AWS Region.
  2. Copy the snapshot to the Outpost from the AWS Region.
  3. Create a new volume from the local snapshot.
  4. Attach the volume to an instance on the Outpost.

For the new volume on the Outpost, the next snapshot can be stored on the Outpost or in the AWS Region. All successive snapshots must then be stored in that same location.

- Local snapshots, including snapshots created on an Outpost and snapshots copied to an Outpost from an AWS Region, can be used only to create volumes on the same Outpost.
- If you create a volume on an Outpost from a snapshot in a Region, then all successive snapshots of that new volume must be in the same Region.
- If you create a volume on an Outpost from a local snapshot, then all successive snapshots of that new volume must be on the same Outpost.

Create local snapshots from volumes on an Outpost

You can create local snapshots from volumes on your Outpost. You can choose to store the snapshots on the same Outpost as the source volume, or in the Region for the Outpost.

Local snapshots can be used to create volumes on the same Outpost only.

You can create local snapshots from volumes on an Outpost using one of the following methods.

Console

To create local snapshots from volumes on an Outpost

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Volumes.
2. Select the volume on the Outpost, and choose Actions, Create Snapshot.
3. (Optional) For Description, enter a brief description for the snapshot.
4. For **Snapshot destination**, choose **AWS Outpost**. The snapshot will be created on the same Outpost as the source volume. The **Outpost ARN** field shows the Amazon Resource Name (ARN) of the destination Outpost.

5. (Optional) Choose **Add Tag** to add tags to your snapshot. For each tag, provide a tag key and a tag value.

6. Choose **Create Snapshot**.

**Command line**

**To create local snapshots from volumes on an Outpost**

Use the `create-snapshot` command. Specify the ID of the volume from which to create the snapshot, and the ARN of the destination Outpost on which to store the snapshot. If you omit the Outpost ARN, the snapshot is stored in the AWS Region for the Outpost.

For example, the following command creates a local snapshot of volume `vol-1234567890abcdef0`, and stores the snapshot on Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 create-snapshot --volume-id vol-1234567890abcdef0 --outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "single volume local snapshot"
```

**Create multi-volume local snapshots from instances on an Outpost**

You can create crash-consistent multi-volume local snapshots from instances on your Outpost. You can choose to store the snapshots on the same Outpost as the source instance, or in the Region for the Outpost.

Multi-volume local snapshots can be used to create volumes on the same Outpost only.

You can create multi-volume local snapshots from instances on an Outpost using one of the following methods.

**Console**

**To create multi-volume local snapshots from instances on an Outpost**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. Choose **Create Snapshot**.
3. For **Select resource type**, choose **Instance**.
4. For **Instance ID**, select the instance on the Outpost from which to create the snapshots.
5. (Optional) For **Description**, enter a brief description for the snapshots.
6. For **Snapshot destination**, choose **AWS Outpost**. The snapshots will be created on the same Outpost as the source instance. The **Outpost ARN** shows the ARN of the destination Outpost.
7. (Optional) To exclude the root volume from being snapshotted, select **Exclude root volume**.
8. (Optional) To automatically copy tags from the source volume to the snapshots, select **Copy tags from volume**. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.
9. (Optional) Choose **Add Tag** to add tags to your snapshot. For each tag, provide a tag key and a tag value.
10. Choose **Create Snapshot**.
During snapshot creation, the snapshots are managed together. If one of the snapshots in the volume set fails, the other snapshots in the volume set are moved to error status.

Command line

**To create multi-volume local snapshots from instances on an Outpost**

Use the `create-snapshots` command. Specify the ID of the instance from which to create the snapshots, and the ARN of the destination Outpost on which to store the snapshots. If you omit the Outpost ARN, the snapshots are stored in the AWS Region for the Outpost.

For example, the following command creates snapshots of the volumes attached to instance `i-1234567890abcdef0` and stores the snapshots on Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 create-snapshots --instance-specification InstanceId=i-1234567890abcdef0 --outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "multi-volume local snapshots"
```

**Create AMIs from local snapshots**

You can create Amazon Machine Images (AMIs) using a combination of local snapshots and snapshots that are stored in the Region of the Outpost. For example, if you have an Outpost in `us-east-1`, you can create an AMI with data volumes that are backed by local snapshots on that Outpost, and a root volume that is backed by a snapshot in the `us-east-1` Region.

**Note**

- You can’t create AMIs that include backing snapshots stored across multiple Outposts.
- You can’t currently create AMIs directly from instances on an Outposts using `CreateImage` API or the Amazon EC2 console for Outposts that are enabled with Amazon S3 on Outposts.
- AMIs that are backed by local snapshots can be used to launch instances on the same Outpost only.

**To create an AMI on an Outpost from snapshots in a Region**

1. Copy the snapshots from the Region to the Outpost. For more information, see Copy snapshots from an AWS Region to an Outpost (p. 1253).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the snapshot copies on the Outpost. For more information, see Creating an AMI from a snapshot.

**To create an AMI on an Outpost from an instance on an Outpost**

1. Create snapshots from the instance on the Outpost and store the snapshots on the Outpost. For more information, see Create multi-volume local snapshots from instances on an Outpost (p. 1251).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the local snapshots. For more information, see Creating an AMI from a snapshot.

**To create an AMI in a Region from an instance on an Outpost**

1. Create snapshots from the instance on the Outpost and store the snapshots in the Region. For more information, see Create local snapshots from volumes on an Outpost (p. 1250) or Create multi-volume local snapshots from instances on an Outpost (p. 1251).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the snapshot copies in the Region. For more information, see Creating an AMI from a snapshot.

Copy snapshots from an AWS Region to an Outpost

You can copy snapshots from an AWS Region to an Outpost. You can do this only if the snapshots are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the snapshot to the Region for the Outpost, and then copy it from that Region to the Outpost.

**Note**
You can't copy local snapshots from an Outpost to a Region, from one Outpost to another, or within the same Outpost.

You can copy snapshots from a Region to an Outpost using one of the following methods.

**Console**

**To copy a snapshot from an AWS Region to an Outpost**

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Snapshots.
2. Select the snapshot in the Region, and choose Actions, Copy.
3. For Destination Region, choose the Region for the destination Outpost.
4. For Snapshot Destination, choose AWS Outpost.

The Snapshot Destination field only appears if you have Outposts in the selected destination Region. If the field does not appear, you do not have any Outposts in the selected destination Region.

5. For Destination Outpost ARN, enter the ARN of the Outpost to which to copy the snapshot.
6. (Optional) For Description, enter a brief description of the copied snapshot.
7. Encryption is enabled by default for the snapshot copy. Encryption cannot be disabled. For KMS key, choose the KMS key to use.
8. Choose Copy.

**Command line**

**To copy a snapshot from a Region to an Outpost**

Use the `copy-snapshot` command. Specify the ID of the snapshot to copy, the Region from which to copy the snapshot, and the ARN of the destination Outpost.

For example, the following command copies snapshot snap-1234567890abcdef0 from the us-east-1 Region to Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
$ aws ec2 copy-snapshot --source-region us-east-1 --source-snapshot- id snap-1234567890abcdef0 --destination-outpost-arn arn:aws:outposts:us-

Copy AMIs from an AWS Region to an Outpost

You can copy AMIs from an AWS Region to an Outpost. When you copy an AMI from a Region to an Outpost, all of the snapshots associated with the AMI are copied from the Region to the Outpost.
You can copy an AMI from a Region to an Outpost only if the snapshots associated with the AMI are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the AMI to the Region for the Outpost, and then copy it from that Region to the Outpost.

**Note**
You can't copy an AMI from an Outpost to a Region, from one Outpost to another, or within an Outpost.

You can copy AMIs from a Region to an Outpost using the AWS CLI only.

**Command line**

**To copy an AMI from a Region to an Outpost**

Use the `copy-image` command. Specify the ID of the AMI to copy, the source Region, and the ARN of the destination Outpost.

For example, the following command copies AMI `ami-1234567890abcdef0` from the `us-east-1` Region to Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 copy-image --source-region us-east-1 --source-image-id ami-1234567890abcdef0 --name "Local AMI copy" --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0
```

**Create volumes from local snapshots**

You can create volumes on Outposts from local snapshots. Volumes must be created on the same Outpost as the source snapshots. You cannot use local snapshots to create volumes in the Region for the Outpost.

When you create a volume from a local snapshot, you cannot re-encrypt the volume using different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.

For more information, see [Create a volume from a snapshot](p. 1201).

**Launch instances from AMIs backed by local snapshots**

You can launch instances from AMIs that are backed by local snapshots. You must launch Instances on the same Outpost as the source AMI. For more information, see [Launch an instance on your Outpost](p. 1213) in the **AWS Outposts User Guide**.

**Delete local snapshots**

You can delete local snapshots from an Outpost. After you delete a snapshot from an Outpost, the Amazon S3 storage capacity used by the deleted snapshot becomes available within 72 hours after deleting the snapshot and the volumes that reference that snapshot.

Because Amazon S3 storage capacity does not become available immediately, we recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity. Delete snapshots and volumes that you no longer need to avoid running out of storage capacity.

For more information about deleting snapshots, see [Delete a snapshot](p. 1236).

**Automate snapshots on an Outpost**

You can create Amazon Data Lifecycle Manager snapshot lifecycle policies that automatically create, copy, retain, and delete snapshots of your volumes and instances on an Outpost. You can choose
whether to store the snapshots in a Region or whether to store them locally on an Outpost. Additionally, you can automatically copy snapshots that are created and stored in an AWS Region to an Outpost.

The following table shows provides an Overview of the supported features.

<table>
<thead>
<tr>
<th>Resource location</th>
<th>Snapshot destination</th>
<th>Cross-region copy</th>
<th>Fast snapshot restore</th>
<th>Cross-account sharing</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>Region</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Outpost</td>
<td>Region</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Outpost</td>
<td>Outpost</td>
<td>✗</td>
<td>✗</td>
<td>✗</td>
</tr>
</tbody>
</table>

**Considerations**

- Only Amazon EBS snapshot lifecycle policies are currently supported. EBS-backed AMI policies and Cross-account sharing event policies are not supported.
- If a policy manages snapshots for volumes or instances in a Region, then snapshots are created in the same Region as the source resource.
- If a policy manages snapshots for volumes or instances on an Outpost, then snapshots can be created on the source Outpost, or in the Region for that Outpost.
- A single policy can't manage both snapshots in a Region and snapshots on an Outpost. If you need to automate snapshots in a Region and on an Outpost, you must create separate policies.
- Fast snapshot restore is not supported for snapshots created on an Outpost, or for snapshots copied to an Outpost.
- Cross-account sharing is not supported for snapshots created on an Outpost.

For more information about creating a snapshot lifecycle that manages local snapshots, see Automating snapshot lifecycles (p. 1285).

**Use EBS direct APIs to access the contents of an EBS snapshot**

You can use the Amazon Elastic Block Store (Amazon EBS) direct APIs to create EBS snapshots, write data directly to your snapshots, read data on your snapshots, and identify the differences or changes between two snapshots. If you’re an independent software vendor (ISV) who offers backup services for Amazon EBS, the EBS direct APIs make it more efficient and cost-effective to track incremental changes on your EBS volumes through snapshots. This can be done without having to create new volumes from snapshots, and then use Amazon Elastic Compute Cloud (Amazon EC2) instances to compare the differences.

You can create incremental snapshots directly from data on-premises into EBS volumes and the cloud to use for quick disaster recovery. With the ability to write and read snapshots, you can write your on-premises data to an EBS snapshot during a disaster. Then after recovery, you can restore it back to AWS or on-premises from the snapshot. You no longer need to build and maintain complex mechanisms to copy data to and from Amazon EBS.

This user guide provides an overview of the elements that make up the EBS direct APIs, and examples of how to use them effectively. For more information about the actions, data types, parameters, and errors of the APIs, see the EBS direct APIs reference. For more information about the supported AWS Regions, endpoints, and service quotas for the EBS direct APIs, see Amazon EBS Endpoints and Quotas in the AWS General Reference.
Understand the EBS direct APIs

The following are the key elements that you should understand before getting started with the EBS direct APIs.

Pricing

The price that you pay to use the EBS direct APIs depends on the requests you make. For more information, see Amazon EBS pricing.

Snapshots

Snapshots are the primary means to back up data from your EBS volumes. With the EBS direct APIs, you can also back up data from your on-premises disks to snapshots. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. For more information, see Amazon EBS snapshots (p. 1227).

Note

Public snapshots are not supported by the EBS direct APIs.

Blocks

A block is a fragment of data within a snapshot. Each snapshot can contain thousands of blocks. All blocks in a snapshot are of a fixed size.

Block indexes

A block index is the offset position of a block within a snapshot, and it is used to identify the block. Multiply the BlockIndex value with the BlockSize value (BlockIndex * BlockSize) to identify the logical offset of the data in the logical volume.

Block tokens

A block token is the identifying hash of a block within a snapshot, and it is used to locate the block data. Block tokens returned by EBS direct APIs are temporary. They change on the expiry timestamp specified for them, or if you run another ListSnapshotBlocks or ListChangedBlocks request for the same snapshot.

Checksum

A checksum is a small-sized datum derived from a block of data for the purpose of detecting errors that were introduced during its transmission or storage. The EBS direct APIs use checksums to validate data integrity. When you read data from an EBS snapshot, the service provides Base64-encoded SHA256
checksums for each block of data transmitted, which you can use for validation. When you write data to an EBS snapshot, you must provide a Base64 encoded SHA256 checksum for each block of data transmitted. The service validates the data received using the checksum provided. For more information, see Use checksums (p. 1263) later in this guide.

Encryption

Encryption protects your data by converting it into unreadable code that can be deciphered only by people who have access to the KMS key used to encrypt it. You can use the EBS direct APIs to read and write encrypted snapshots, but there are some limitations. For more information, see Use encryption (p. 1263) later in this guide.

API actions

The EBS direct APIs consists of six actions. There are three read actions and three write actions. The read actions are ListSnapshotBlocks, ListChangedBlocks, and GetSnapshotBlock. The write actions are StartSnapshot, PutSnapshotBlock, and CompleteSnapshot. These actions are described in the following sections.

List snapshot blocks

The ListSnapshotBlocks action returns the block indexes and block tokens of blocks in the specified snapshot.

List changed blocks

The ListChangedBlocks action returns the block indexes and block tokens of blocks that are different between two specified snapshots of the same volume and snapshot lineage.

Get snapshot block

The GetSnapshotBlock action returns the data in a block for the specified snapshot ID, block index, and block token.

Start snapshot

The StartSnapshot action starts a snapshot, either as an incremental snapshot of an existing one or as a new snapshot. The started snapshot remains in a pending state until it is completed using the CompleteSnapshot action.

Put snapshot block

The PutSnapshotBlock action adds data to a started snapshot in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service validates the checksum after the transmission is completed. The request fails if the checksum computed by the service doesn’t match what you specified.

Complete snapshot

The CompleteSnapshot action completes a started snapshot that is in a pending state. The snapshot is then changed to a completed state.

Use the EBS direct APIs to read snapshots

The following steps describe how to use the EBS direct APIs to read snapshots:

1. Use the ListSnapshotBlocks action to view all block indexes and block tokens of blocks in a snapshot. Or use the ListChangedBlocks action to view only the block indexes and block tokens of blocks that are different between two snapshots of the same volume and snapshot lineage. These actions help you identify the block tokens and block indexes of blocks for which you might want to get data.
2. Use the GetSnapshotBlock action, and specify the block index and block token of the block for which you want to get data.

For examples of how to run these actions, see the Work with the EBS direct APIs using the API or AWS SDKs (p. 1264) and Work with the EBS direct APIs using the command line (p. 1268) sections later in this guide.

Use the EBS direct APIs to write incremental snapshots

The following steps describe how to use the EBS direct APIs to write incremental snapshots:

1. Use the StartSnapshot action and specify a parent snapshot ID to start a snapshot as an incremental snapshot of an existing one, or omit the parent snapshot ID to start a new snapshot. This action returns the new snapshot ID, which is in a pending state.

2. Use the PutSnapshotBlock action and specify the ID of the pending snapshot to add data to it in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service computes the checksum of the data received and validates it with the checksum that you specified. The action fails if the checksums don't match.

3. When you're done adding data to the pending snapshot, use the CompleteSnapshot action to start an asynchronous workflow that seals the snapshot and moves it to a completed state.

Repeat these steps to create a new, incremental snapshot using the previously created snapshot as the parent.

For example, in the following diagram, snapshot A is the first new snapshot started. Snapshot A is used as the parent snapshot to start snapshot B. Snapshot B is used as the parent snapshot to start and create snapshot C. Snapshots A, B, and C are incremental snapshots. Snapshot A is used to create EBS volume 1. Snapshot D is created from EBS volume 1. Snapshot D is an incremental snapshot of A; it is not an incremental snapshot of B or C.

For examples of how to run these actions, see the Work with the EBS direct APIs using the API or AWS SDKs (p. 1264) and Work with the EBS direct APIs using the command line (p. 1268) sections later in this guide.

Permissions for IAM users

An AWS Identity and Access Management (IAM) user must have the following policies to use the EBS direct APIs. For more information, see Changing Permissions for an IAM User.
Be cautious when assigning the following policies to IAM users. By assigning these policies, you might give access to a user who is denied access to the same resource through the Amazon EC2 APIs, such as the CopySnapshot or CreateVolume actions.

Permissions to read snapshots

The following policy allows the read EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace `<Region>` with the Region of the snapshot.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:ListSnapshotBlocks",
            "ebs:ListChangedBlocks",
            "ebs:GetSnapshotBlock"
         ],
         "Resource": "arn:aws:ec2:<Region>::snapshot/*"
      }
   ]
}
```

The following policy allows the read EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:ListSnapshotBlocks",
            "ebs:ListChangedBlocks",
            "ebs:GetSnapshotBlock"
         ],
         "Resource": "arn:aws:ec2:*::snapshot/*",
         "Condition": {
            "StringEqualsIgnoreCase": {
               "aws:ResourceTag/<Key>": "<Value>"
            }
         }
      }
   ]
}
```

The following policy allows all of the read EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the `aws:CurrentTime` global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:ListSnapshotBlocks",
            "ebs:ListChangedBlocks",
            "ebs:GetSnapshotBlock"
         ]
      }
   ]
}
```
The following policy grants access to decrypt an encrypted snapshot using a specific KMS key. It grants access to encrypt new snapshots using the default KMS key ID for EBS snapshots. It also provides the ability to determine if encrypt by default is enabled on the account. In the policy, replace <Region> with the Region of the KMS key, <AccountId> with the ID of the AWS account of the KMS key, and <KeyId> with the ID of the KMS key used to encrypt the snapshot that you want to read with the EBS direct APIs.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:GenerateDataKey",
            "kms:GenerateDataKeyWithoutPlaintext",
            "kms:ReEncrypt*",
            "kms:CreateGrant",
            "ec2:CreateTags",
            "kms:DescribeKey",
            "ec2:GetEbsDefaultKmsKeyId",
            "ec2:GetEbsEncryptionByDefault"
         ],
         "Resource": "arn:aws:kms:<Region>:<AccountId>:key/<KeyId>"
      }
   ]
}
```

For more information, see Changing Permissions for an IAM User in the IAM User Guide.

**Permissions to write snapshots**

The following policy allows the write EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace <Region> with the Region of the snapshot.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:StartSnapshot",
            "ebs:PutSnapshotBlock",
            "ebs:CompleteSnapshot"
         ],
         "Resource": "arn:aws:ec2:<Region>:snapshot/**"
      }
   ]
}
```
The following policy allows the write EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ebs:StartSnapshot",
                "ebs:PutSnapshotBlock",
                "ebs:CompleteSnapshot"
            ],
            "Resource": "arn:aws:ec2:*::snapshot/*",
            "Condition": {
                "StringEqualsIgnoreCase": {
                    "aws:ResourceTag/<Key>": "<Value>"
                }
            }
        }
    ]
}
```

The following policy allows all of the EBS direct APIs to be used. It also allows the `StartSnapshot` action only if a parent snapshot ID is specified. Therefore, this policy blocks the ability to start new snapshots without using a parent snapshot.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "ebs:ParentSnapshot": "arn:aws:ec2:*::snapshot/*"
                }
            }
        }
    ]
}
```

The following policy allows all of the EBS direct APIs to be used. It also allows only the `user` tag key to be created for a new snapshot. This policy also ensures that the user has access to create tags. The `StartSnapshot` action is the only action that can specify tags.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": "user"
                }
            }
        }
    ]
}
```
The following policy allows all of the write EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the `aws:CurrentTime` global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ebs:StartSnapshot",
                "ebs:PutSnapshotBlock",
                "ebs:CompleteSnapshot"
            ],
            "Resource": "arn:aws:ec2:*::snapshot/*",
            "Condition": {
                "DateGreaterThan": {
                    "aws:CurrentTime": "2018-05-29T00:00:00Z"
                },
                "DateLessThan": {
                    "aws:CurrentTime": "2020-05-29T23:59:59Z"
                }
            }
        }
    ]
}
```

The following policy grants access to decrypt an encrypted snapshot using a specific KMS key. It grants access to encrypt new snapshots using the default KMS key ID for EBS snapshots. It also provides the ability to determine if encrypt by default is enabled on the account. In the policy, replace `<Region>` with the Region of the KMS key, `<AccountId>` with the ID of the AWS account of the KMS key, and `<KeyId>` with the ID of the KMS key used to encrypt the snapshot that you want to read with the EBS direct APIs.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:GenerateDataKey",
                "kms:GenerateDataKeyWithoutPlaintext",
                "kms:ReEncrypt*",
                "kms:CreateGrant",
                "ec2:CreateTags",
                "kms:DescribeKey",
                "ec2:GetEbsDefaultKmsKeyId",
                "ec2:GetEbsEncryptionByDefault"
            ],
            "Resource": 
```
For more information, see Changing Permissions for an IAM User in the IAM User Guide.

Use encryption

If Amazon EBS encryption by default is enabled on your AWS account, you cannot start a new snapshot using an un-encrypted parent snapshot. You must first encrypt the parent snapshot by copying it. For more information, see Copy an Amazon EBS snapshot (p. 1236) and Encryption by default (p. 1338).

To start an encrypted snapshot, specify the Amazon Resource Name (ARN) of an KMS key, or specify an encrypted parent snapshot in your StartSnapshot request. If neither are specified, and Amazon EBS encryption by default is enabled on the account, then the default KMS key for the account is used. If no default KMS key has been specified for the account, then the AWS managed key is used.

Important
By default, all principals in the account have access to the default AWS managed key, and they can use it for EBS encryption and decryption operations. For more information, see Default KMS key for EBS encryption (p. 1337).

You might need additional IAM permissions to use the EBS direct APIs with encryption. For more information, see the Permissions for IAM users (p. 1258) section earlier in this guide.

Use Signature Version 4 signing

Signature Version 4 is the process to add authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For information about how to obtain credentials for your account, see Understanding and getting your credentials.

If you intend to manually create HTTP requests, you must learn how to sign them. When you use the AWS Command Line Interface (AWS CLI) or one of the AWS SDKs to make requests to AWS, these tools automatically sign the requests for you with the access key that you specify when you configure the tools. When you use these tools, you don't need to learn how to sign requests yourself.

For more information, see Signing AWS requests with Signature Version 4 in the AWS General Reference.

Use checksums

The GetSnapshotBlock action returns data that is in a block of a snapshot, and the PutSnapshotBlock action adds data to a block in a snapshot. The block data that is transmitted is not signed as part of the Signature Version 4 signing process. As a result, checksums are used to validate the integrity of the data as follows:

- When you use the GetSnapshotBlock action, the response provides a Base64-encoded SHA256 checksum for the block data using the x-amz-Checksum header, and the checksum algorithm using the x-amz-Checksum-Algorithm header. Use the returned checksum to validate the integrity of the data. If the checksum that you generate doesn't match what Amazon EBS provided, you should consider the data not valid and retry your request.

- When you use the PutSnapshotBlock action, your request must provide a Base64-encoded SHA256 checksum for the block data using the x-amz-Checksum header, and the checksum algorithm using the x-amz-Checksum-Algorithm header. The checksum that you provide is validated against a checksum generated by Amazon EBS to validate the integrity of the data. If the checksums do not correspond, the request fails.
When you use the CompleteSnapshot action, your request can optionally provide an aggregate Base64-encoded SHA256 checksum for the complete set of data added to the snapshot. Provide the checksum using the `x-amz-Checksum` header, the checksum algorithm using the `x-amz-Checksum-Algorithm` header, and the checksum aggregation method using the `x-amz-Checksum-Aggregation-Method` header. To generate the aggregated checksum using the linear aggregation method, arrange the checksums for each written block in ascending order of their block index, concatenate them to form a single string, and then generate the checksum on the entire string using the SHA256 algorithm.

The checksums in these actions are part of the Signature Version 4 signing process.

**Work with the EBS direct APIs using the API or AWS SDKs**

The [EBS direct APIs Reference](https://docs.aws.amazon.com/elasticblockstore/latest/directory/) provides descriptions and syntax for each of the service's actions and data types. You can also use one of the AWS SDKs to access an API that's tailored to the programming language or platform that you're using. For more information, see [AWS SDKs](https://docs.aws.amazon.com/efs/latest/ug/using-efs-sdk.html).

The EBS direct APIs require an AWS Signature Version 4 signature. For more information, see [Use Signature Version 4 signing](https://docs.aws.amazon.com/efs/latest/ug/using-efs-sdk.html#use-signature-version-4-signing).

**Use the API to read snapshots**

**List blocks in a snapshot**

The following `ListChangedBlocks` example request returns the block indexes and block tokens of blocks that are in snapshot `snap-0acEXAMPLEcf41648`. The `startingBlockIndex` parameter limits the results to block indexes greater than 1000, and the `maxResults` parameter limits the results to the first 100 blocks.

```
GET /snapshots/snap-0acEXAMPLEcf41648/blocks?maxResults=100&startingBlockIndex=1000
```

The following example response for the previous request lists the block indexes and block tokens in the snapshot. Use the `GetSnapshotBlock` action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
HTTP/1.1 200 OK

List blocks that are different between two snapshots

The following ListChangedBlocks example request returns the block indexes and block tokens of blocks that are different between snapshots snap-0acEXAMPLEcf41648 and snap-0c9EXAMPLE1b30e2f. The startingBlockIndex parameter limits the results to block indexes greater than 0, and the maxResults parameter limits the results to the first 500 blocks.

```
GET /snapshots/snap-0c9EXAMPLE1b30e2f/changedblocks?
firstSnapshotId=snap-0acEXAMPLEcf41648&maxResults=500&startingBlockIndex=0
```

The following example response for the previous request shows that block indexes 0, 3072, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the GetSnapshotBlock action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```

```
Get block data from a snapshot

The following GetSnapshotBlock example request returns the data in the block index 3072 with block 
token AAUBARGCaufCqBRZC8tEikPYGGkSV3vqvoJj2xKD13jDFiytUxBLXYgTmkid, in snapshot 
snap-0c9EXAMPLE130e2f.

```
GET /snapshots/snap-0c9EXAMPLE130e2f/blocks/3072?
blockToken=AAUBARGCaufCqBRZC8tEikPYGGkSV3vqvoJj2xKD13jDFiytUxBLXYgTmkid HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200617T232838Z
Authorization: <Authentication parameter>
```

The following example response for the previous request shows the size of the data returned, the 
checksum to validate the data, and the algorithm used to generate the checksum. The binary data is 
transmitted in the body of the response and is represented as BlockData in the following example.

```
HTTP/1.1 200 OK
x-amzn-RequestId: 2d0db2fb-bd88-474a-81c4e57d7b9f

Connection: keep-alive

BlockData
```

Use the API to write incremental snapshots

Start a snapshot

The following StartSnapshot example request starts an 8 GiB snapshot, using snapshot 
snap-123EXAMPLE1234567 as the parent snapshot. The new snapshot will be an incremental snapshot 
of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests 
made for the snapshot within the specified 60 minute timeout period. The 550e8400-e29b-41d4- 
a716-446655440000 client token ensures idempotency for the request. If the client token is omitted, 
the AWS SDK automatically generates one for you. For more information about idempotency, see 
Idempotency for StartSnapshot API (p. 1279).

```
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
```
The following example response for the previous request shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in a subsequent PutSnapshotBlocks request to write data to the snapshot.

```
HTTP/1.1 201 Created
x-amzn-RequestId: 929e6eb9-7183-405a-9502-5b7da37c1b18
Content-Type: application/json
Content-Length: 181
Date: Thu, 18 Jun 2020 04:07:29 GMT

  "VolumeSize": 8
}
```

Put data into a snapshot

The following PutSnapshot example request writes 524288 Bytes of data to block index 1000 on snapshot snap-052EXAMPLEc85d8dd. The Base64 encoded QOD3gmEQOXATfJx2Aa34W4FU2nZGYXfQtsUuktOw8DM= checksum was generated using the SHA256 algorithm. The data is transmitted in the body of the request and is represented as BlockData in the following example.

```
PUT /snapshots/snap-052EXAMPLEc85d8dd/blocks/1000 HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-Data-Length: 524288
x-amz-Checksum: QOD3gmEQOXATfJx2Aa34W4FU2nZGYXfQtsUuktOw8DM=
x-amz-Checksum-Algorithm: SHA256
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T042215Z
X-Amz-Content-SHA256: UNSIGNED-PAYLOAD
Authorization: <Authentication parameter>

BlockData
```

The following is example response for the previous request confirms the data length, checksum, and checksum algorithm for the data received by the service.

```
HTTP/1.1 201 Created
x-amzn-RequestId: 643ac797-7e0c-4ad0-8417-97b77b43c57b
x-amz-Checksum: QOD3gmEQOXATfJx2Aa34W4FU2nZGYXfQtsUuktOw8DM=
```
**Complete a snapshot**

The following [CompleteSnapshot] example request completes snapshot snap-052EXAMPLEc85d8dd. The command specifies that 5 blocks were written to the snapshot. The 6D3nmwi5f2F0wlh7xX8qprrJBFzDX8aadOcA3KCM3c= checksum represents the checksum for the complete set of data written to a snapshot.

```plaintext
POST /snapshots/completion/snap-052EXAMPLEc85d8dd HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-ChangedBlocksCount: 5
x-amz-Checksum: 6D3nmwi5f2F0wlh7xX8qprrJBFzDX8aadOcA3KCM3c=
x-amz-Checksum-Algorithm: SHA256
x-amz-Checksum-Aggregation-Method: LINEAR
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T043158Z
Authorization: <Authentication parameter>
```

The following is an example response for the previous request.

```plaintext
HTTP/1.1 202 Accepted
x-amzn-RequestId: 06cba5b5-b731-49de-af40-80333ac3a117
Content-Type: application/json
Content-Length: 20
Date: Thu, 18 Jun 2020 04:31:50 GMT
Connection: keep-alive
{"Status":"pending"}
```

**Work with the EBS direct APIs using the command line**

The following examples show how to use the EBS direct APIs using the AWS Command Line Interface (AWS CLI). For more information about installing and configuring the AWS CLI, see [Installing the AWS CLI] and [Quickly Configuring the AWS CLI].

**Use the AWS CLI to read snapshots**

**List blocks in a snapshot**

The following [list-snapshot-blocks] example command returns the block indexes and block tokens of blocks that are in snapshot snap-0987654321. The --starting-block-index parameter limits the results to block indexes greater than 1000, and the --max-results parameter limits the results to the first 100 blocks.

```plaintext
aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --max-results 100
```

The following example response for the previous command lists the block indexes and block tokens in the snapshot. Use the [get-snapshot-block] command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.
List blocks that are different between two snapshots

The following list-changed-blocks example command returns the block indexes and block tokens of blocks that are different between snapshots snap-1234567890 and snap-0987654321. The --starting-block-index parameter limits the results to block indexes greater than 0, and the --max-results parameter limits the results to the first 500 blocks.

```
aws ebs list-changed-blocks --first-snapshot-id snap-1234567890 --second-snapshot-id snap-0987654321 --starting-block-index 0 --max-results 500
```

The following example response for the previous command shows that block indexes 0, 6000, 6001, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6001, 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the get-snapshot-block command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
{  
  "ChangedBlocks": [  
    {  
      "BlockIndex": 0,  
      "FirstBlockToken": "AAABAVahm9SO60Dyi100RySzn2ZjGjW/KN3uygGlS0QOYwesbBbnX2dGpmc",  
      "SecondBlockToken": "AAABAf80o6UFl1rDbSZGIUraCEdDyBu9T1vtCQxxoKV8qrUFP7vcM6iWGSr"
    },  
    {  
      "BlockIndex": 6000,  
      "FirstBlockToken": "AAABATGQIgwra0wJwqIMjCA/Sy7e/YoGFZsHejzGNvjKauzNggeil3YHBFQB"
    },  
    {  
      "BlockIndex": 6001,  
      "FirstBlockToken": "AAABAATZ9CuTqpUvp/dXqRWw4d07e0gTZ3jvn6hiW3Ou9duM8MiMw6yQayzF2c"
    },  
    {  
      "BlockIndex": 6002,  
      "FirstBlockToken": "AAABAQdx5w0rvVv6Pmso/YR1xon9JFR85XsF1LjgOHe6pygYr6laElp0"
    },  
    {  
      "BlockIndex": 6003,  
      "FirstBlockToken": "AAABATgWZ6CoXcFWUKv7JbUXMiSp59KVxJGL/BWBClkw6spzCJvDVaTsJ"  
    },  
    ...  
  ]  
}
**Get block data from a snapshot**

The following `get-snapshot-block` example command returns the data in the block index 6001 with block token `AAABASBpSJ2UAD3PLxFnJnCt6zun4/T4sU25Bnb8jB5q6F0XHfQyAQ04hJoR` in snapshot `snap-1234567890`. The binary data is output to the `data` file in the C:\Temp directory on a Windows computer. If you run the command on a Linux or Unix computer, replace the output path with `/tmp/data` to output the data to the `data` file in the /tmp directory.

```
aws ebs get-snapshot-block --snapshot-id snap-1234567890 --block-index 6001 --block-token AAABASBpSJ2UAD3PLxFnJnCt6zun4/T4sU25Bnb8jB5q6F0XHfQyAQ04hJoR C:/Temp/data
```

The following example response for the previous command shows the size of the data returned, the checksum to validate the data, and the algorithm of the checksum. The binary data is automatically saved to the directory and file you specified in the request command.

```
{
  "DataLength": "524288",
  "Checksum": "cf0Y6/Fn0oFa4VyjQPoA/I0zhTfIPTKzvxGv20KowXc=",
  "ChecksumAlgorithm": "SHA256"
}
```

**Use the AWS CLI to write incremental snapshots**

**Start a snapshot**

The following `start-snapshot` example command starts an 8 GiB snapshot, using snapshot `snap-123EXAMPLE1234567` as the parent snapshot. The new snapshot will be an incremental snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The 550e8400-e29b-41d4-a716-446655440000 client token ensures idempotency for the request. If the client token is omitted,
the AWS SDK automatically generates one for you. For more information about idempotency, see Idempotency for StartSnapshot API (p. 1279).

```
aws ebs start-snapshot --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

The following example response for the previous command shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in subsequent put-snapshot-block commands to write data to the snapshot, then use the complete-snapshot command to complete the snapshot and change its status to completed.

```
{
    "SnapshotId": "snap-0aaEXAMPLEe306d62",
    "OwnerId": "111122223333",
    "Status": "pending",
    "VolumeSize": 8,
    "BlockSize": 524288
}
```

### Put data into a snapshot

The following put-snapshot example command writes 524288 Bytes of data to block index 1000 on snapshot snap-0aaEXAMPLEe306d62. The Base64 encoded QOD3gmEQOXATfJx2AaA34W4FU2nZGYXfqtsUuktOW8DM= checksum was generated using the SHA256 algorithm. The data that is transmitted is in the /tmp/data file.

```
aws ebs put-snapshot-block --snapshot-id snap-0aaEXAMPLEe306d62 --block-index 1000 --data-length 524288 --block-data /tmp/data --checksum QOD3gmEQOXATfJx2AaA34W4FU2nZGYXfqtsUuktOW8DM= --checksum-algorithm SHA256
```

The following example response for the previous command confirms the data length, checksum, and checksum algorithm for the data received by the service.

```
{
    "DataLength": "524288",
    "Checksum": "QOD3gmEQOXATfJx2AaA34W4FU2nZGYXfqtsUuktOW8DM=",
    "ChecksumAlgorithm": "SHA256"
}
```

### Complete a snapshot

The following complete-snapshot example command completes snapshot snap-0aaEXAMPLEe306d62. The command specifies that 5 blocks were written to the snapshot. The 6D3nmwi15f2PWolh7xX8QprrJBFzDX8aad0cA3KCM3c= checksum represents the checksum for the complete set of data written to a snapshot. For more information about checksums, see Use checksums (p. 1263) earlier in this guide.

```
aws ebs complete-snapshot --snapshot-id snap-0aaEXAMPLEe306d62 --changed-blocks-count 5 --checksum 6D3nmwi15f2PWolh7xX8QprrJBFzDX8aad0cA3KCM3c= --checksum-algorithm SHA256 --checksum-aggregation-method LINEAR
```

The following is an example response for the previous command.

```
{
}
```
Optimize performance

You can run API requests concurrently. Assuming PutSnapshotBlock latency is 100ms, then a thread can process 10 requests in one second. Furthermore, assuming your client application creates multiple threads and connections (for example, 100 connections), it can make 1000 (10 * 100) requests per second in total. This will correspond to a throughput of around 500 MB per second.

The following list contains few things to look for in your application:

- Is each thread using a separate connection? If the connections are limited on the application then multiple threads will wait for the connection to be available and you will notice lower throughput.
- Is there any wait time in the application between two put requests? This will reduce the effective throughput of a thread.
- The bandwidth limit on the instance – If bandwidth on the instance is shared by other applications, it could limit the available throughput for PutSnapshotBlock requests.

Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability.

Review the EBS direct APIs service quotas to determine the maximum API requests that you can run per second. For more information, see Amazon Elastic Block Store Endpoints and Quotas in the AWS General Reference.

Frequently asked questions

Can a snapshot be accessed using the EBS direct APIs if it has a pending status?

No. The snapshot can be accessed only if it has a completed status.

Are the block indexes returned by the EBS direct APIs in numerical order?

Yes. The block indexes returned are unique, and in numerical order.

Can I submit a request with a MaxResults parameter value of under 100?

No. The minimum MaxResult parameter value you can use is 100. If you submit a request with a MaxResult parameter value of under 100, and there are more than 100 blocks in the snapshot, then the API will return at least 100 results.

Can I run API requests concurrently?

You can run API requests concurrently. Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability. For more information, see Optimize performance (p. 1272).

Review the EBS direct APIs service quotas to determine the API requests that you can run per second. For more information, see Amazon Elastic Block Store Endpoints and Quotas in the AWS General Reference.

When running the ListChangedBlocks action, is it possible to get an empty response even though there are blocks in the snapshot?

Yes. If the changed blocks are scarce in the snapshot, the response may be empty but the API will return a next page token value. Use the next page token value to continue to the next page of
results. You can confirm that you have reached the last page of results when the API returns a next page token value of null.

If the NextToken parameter is specified together with a StartingBlockIndex parameter, which of the two is used?

The NextToken is used, and the StartingBlockIndex is ignored.

How long are the block tokens and next tokens valid?

Block tokens are valid for seven days, and next tokens are valid for 60 minutes.

Are encrypted snapshots supported?

Yes. Encrypted snapshots can be accessed using the EBS direct APIs.

To access an encrypted snapshot, the user must have access to the KMS key used to encrypt the snapshot, and the AWS KMS decrypt action. See the Permissions for IAM users (p. 1258) section earlier in this guide for the AWS KMS policy to assign to a user.

Are public snapshots supported?

Public snapshots are not supported.

Does list snapshot block return all block indexes and block tokens in a snapshot, or only those that have data written to them?

It returns only block indexes and tokens that have data written to them.

Can I get a history of the API calls made by the EBS direct APIs on my account for security analysis and operational troubleshooting purposes?

Yes. To receive a history of EBS direct APIs API calls made on your account, turn on AWS CloudTrail in the AWS Management Console. For more information, see Log API Calls for EBS direct APIs with AWS CloudTrail (p. 1273).

Log API Calls for EBS direct APIs with AWS CloudTrail

The EBS direct APIs service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in EBS direct APIs as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in Event history. Data events are not captured in Event history. You can use the information collected by CloudTrail to determine the request that was made to EBS direct APIs, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information about CloudTrail, see the AWS CloudTrail User Guide.

EBS direct APIs Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in EBS direct APIs, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for EBS direct APIs, create a trail. A trail enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:
Supported API actions

For EBS direct APIs, you can use CloudTrail to log two types of events:

- **Management events** — Management events provide visibility into management operations that are performed on snapshots in your AWS account. The following API actions are logged by default as management events in trails:
  - `StartSnapshot`
  - `CompleteSnapshot`

  For more information about logging management events, see Logging management events for trails in the CloudTrail User Guide.

- **Data events** — These events provide visibility into the snapshot operations performed on or within a snapshot. The following API actions can optionally be logged as data events in trails:
  - `ListSnapshotBlocks`
  - `ListChangedBlocks`
  - `GetSnapshotBlock`
  - `PutSnapshotBlock`

  Data events are not logged by default when you create a trail. You can use only advanced event selectors to record data events on EBS direct API calls. For more information, see Logging data events for trails in the CloudTrail User Guide.

  **Note**
  If you perform an action on a snapshot that is shared with you, data events are not sent to the AWS account that owns the snapshot.

Identity information

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail `userIdentityElement`.

Understand EBS direct APIs Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.
**StartSnapshot**

```json
{
    "eventVersion": "1.05",

EBS direct APIs and interface VPC endpoints

You can establish a private connection between your VPC and EBS direct APIs by creating an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that enables you to privately access EBS direct APIs without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don’t need public IP addresses to communicate with EBS direct APIs. Traffic between your VPC and EBS direct APIs does not leave the Amazon network.

Each interface endpoint is represented by one or more Elastic Network Interfaces in your subnets.

For more information, see Interface VPC endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

Considerations for EBS direct APIs VPC endpoints

Before you set up an interface VPC endpoint for EBS direct APIs, ensure that you review Interface endpoint properties and limitations in the Amazon VPC User Guide.

VPC endpoint policies are not supported for EBS direct APIs. By default, full access to EBS direct APIs is allowed through the endpoint. However, you can control access to the interface endpoint using security groups. For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Create an interface VPC endpoint for EBS direct APIs

You can create a VPC endpoint for EBS direct APIs using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for EBS direct APIs using the following service name:

• com.amazonaws.region.ebs

If you enable private DNS for the endpoint, you can make API requests to EBS direct APIs using its default DNS name for the Region, for example, ebs.us-east-1.amazonaws.com. For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Idempotency for StartSnapshot API

Idempotency ensures that an API request completes only once. With an idempotent request, if the original request completes successful, the subsequent retries return the result from the original successful request and they have no additional effect.

The StartSnapshot API supports idempotency using a client token. A client token is a unique string that you specify when you make an API request. If you retry an API request with the same client token and the same request parameters after it has completed successfully, the result of the original request is returned. If you retry a request with the same client token, but change one or more of the request parameters, the ConflictException error is returned.

If you do not specify your own client token, the AWS SDKs automatically generates a client token for the request to ensure that it is idempotent.

A client token can be any string that includes up to up to 64 ASCII characters. You should not reuse the same client tokens for different requests.

To make an idempotent StartSnapshot request with your own client token using the API

Specify the ClientToken request parameter.
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T040724Z
Authorization: <Authentication parameter>
{
  "VolumeSize": 8,
  "ParentSnapshot": snap-123EXAMPLE1234567,
  "ClientToken": "550e8400-e29b-41d4-a716-446655440000",
  "Timeout": 60
}

To make an idempotent StartSnapshot request with your own client token using the AWS CLI

Specify the client-token request parameter.

```bash
$ aws ebs start-snapshot --region us-east-2 --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

Automate the snapshot lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of snapshots that you use to back up your Amazon EBS volumes.

For more information, see Amazon Data Lifecycle Manager (p. 1280).

Amazon Data Lifecycle Manager

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of EBS snapshots and EBS-backed AMIs. When you automate snapshot and AMI management, it helps you to:

- Protect valuable data by enforcing a regular backup schedule.
- Create standardized AMIs that can be refreshed at regular intervals.
- Retain backups as required by auditors or internal compliance.
- Reduce storage costs by deleting outdated backups.
- Create disaster recovery backup policies that back up data to isolated accounts.

When combined with the monitoring features of Amazon CloudWatch Events and AWS CloudTrail, Amazon Data Lifecycle Manager provides a complete backup solution for Amazon EC2 instances and individual EBS volumes at no additional cost.

**Important**

Amazon Data Lifecycle Manager cannot be used to manage snapshots or AMIs that are created by any other means.

Amazon Data Lifecycle Manager cannot be used to automate the creation, retention, and deletion of instance store-backed AMIs.

Contents

- How Amazon Data Lifecycle Manager works (p. 1281)
- Considerations for Amazon Data Lifecycle Manager (p. 1283)
- Automate snapshot lifecycles (p. 1285)
- Automate AMI lifecycles (p. 1292)
- Automate cross-account snapshot copies (p. 1298)
How Amazon Data Lifecycle Manager works

The following are the key elements of Amazon Data Lifecycle Manager.

Elements

- Snapshots (p. 1281)
- EBS-backed AMIs (p. 1281)
- Target resource tags (p. 1281)
- Amazon Data Lifecycle Manager tags (p. 1281)
- Lifecycle policies (p. 1282)
- Policy schedules (p. 1282)

Snapshots

Snapshots are the primary means to back up data from your EBS volumes. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. When you delete one snapshot in a series of snapshots for a volume, only the data that's unique to that snapshot is removed. The rest of the captured history of the volume is preserved.

For more information, see Amazon EBS snapshots (p. 1227).

EBS-backed AMIs

An Amazon Machine Image (AMI) provides the information that's required to launch an instance. You can launch multiple instances from a single AMI when you need multiple instances with the same configuration. Amazon Data Lifecycle Manager supports EBS-backed AMIs only. EBS-backed AMIs include a snapshot for each EBS volume that's attached to the source instance.

For more information, see Amazon Machine Images (AMI) (p. 70).

Target resource tags

Amazon Data Lifecycle Manager uses resource tags to identify the resources to back up. Tags are customizable metadata that you can assign to your AWS resources (including Amazon EC2 instances, EBS volumes and snapshots). An Amazon Data Lifecycle Manager policy (described later) targets an instance or volume for backup using a single tag. Multiple tags can be assigned to an instance or volume if you want to run multiple policies on it.

You can't use a \\ or '=' character in a tag key.

For more information, see Tag your Amazon EC2 resources (p. 1462).

Amazon Data Lifecycle Manager tags

Amazon Data Lifecycle Manager applies the following tags to all snapshots and AMIs created by a policy, to distinguish them from snapshots and AMIs created by any other means:

- aws:dlm:lifecycle-policy-id
- aws:dlm:lifecycle-schedule-name
- aws:dlm:expirationTime
- dlm:managed
You can also specify custom tags to be applied to snapshots and AMIs on creation. You can't use a '\' or '=' character in a tag key.

The target tags that Amazon Data Lifecycle Manager uses to associate volumes with a snapshot policy can optionally be applied to snapshots created by the policy. Similarly, the target tags that are used to associate instances with an AMI policy can optionally be applied to AMIs created by the policy.

**Lifecycle policies**

A lifecycle policy consists of these core settings:

- **Policy type**—Defines the type of resources that the policy can manage. Amazon Data Lifecycle Manager supports the following types of lifecycle policies:
  - Snapshot lifecycle policy—Used to automate the lifecycle of EBS snapshots. These policies can target individual EBS volumes or all EBS volumes attached to an instance.
  - EBS-backed AMI lifecycle policy—Used to automate the lifecycle of EBS-backed AMIs and their backing snapshots. These policies can target instances only.
  - Cross-account copy event policy—Used to automate snapshot copies across accounts. Use this policy type in conjunction with an EBS snapshot policy that shares snapshots across accounts.

- **Resource type**—Defines the type of resources that are targeted by the policy. Snapshot lifecycle policies can target instances or volumes. Use **VOLUME** to create snapshots of individual volumes, or use **INSTANCE** to create multi-volume snapshots of all of the volumes that are attached to an instance. For more information, see Multi-volume snapshots (p. 1232). AMI lifecycle policies can target instances only. One AMI is created that includes snapshots of all of the volumes that are attached to the target instance.

- **Target tags**—Specifies the tags that must be assigned to an EBS volume or an Amazon EC2 instance for it to be targeted by the policy.

- **Schedules**—The start times and intervals for creating snapshots or AMIs. The first snapshot or AMI creation operation starts within one hour after the specified start time. Subsequent snapshot or AMI creation operations start within one hour of their scheduled time. A policy can have up to four schedules: one mandatory schedule, and up to three optional schedules. For more information, see Policy schedules (p. 1282).

- **Retention**—Specifies how snapshots or AMIs are to be retained. You can retain snapshots or AMIs based either on their total count (count-based), or their age (age-based). For snapshot policies, when the retention threshold is reached, the oldest snapshot is deleted. For AMI policies, when the retention threshold is reached, the oldest AMI is deregistered and its backing snapshots are deleted.

For example, you could create a policy with settings similar to the following:

- Manages all EBS volumes that have a tag with a key of **account** and a value of **finance**.
- Creates snapshots every 24 hours at **0900 UTC**.
- Retains only the five most recent snapshots.
- Starts snapshot creation no later than **0959 UTC** each day.

**Policy schedules**

Policy schedules define when snapshots or AMIs are created by the policy. Policies can have up to four schedules—one mandatory schedule, and up to three optional schedules.

Adding multiple schedules to a single policy lets you create snapshots or AMIs at different frequencies using the same policy. For example, you can create a single policy that creates daily, weekly, monthly, and yearly snapshots. This eliminates the need to manage multiple policies.

For each schedule, you can define the frequency, fast snapshot restore settings (snapshot lifecycle policies only), cross-Region copy rules, and tags. The tags that are assigned to a schedule are
automatically assigned to the snapshots or AMIs that are created when the schedule is initiated. In addition, Amazon Data Lifecycle Manager automatically assigns a system-generated tag based on the schedule’s frequency to each snapshot or AMI.

Each schedule is initiated individually based on its frequency. If multiple schedules are initiated at the same time, Amazon Data Lifecycle Manager creates only one snapshot or AMI and applies the retention settings of the schedule that has the highest retention period. The tags of all of the initiated schedules are applied to the snapshot or AMI.

- (Snapshot lifecycle policies only) If more than one of the initiated schedules is enabled for fast snapshot restore, then the snapshot is enabled for fast snapshot restore in all of the Availability Zones specified across all of the initiated schedules. The highest retention settings of the initiated schedules is used for each Availability Zone.
- If more than one of the initiated schedules is enabled for cross-Region copy, the snapshot or AMI is copied to all Regions specified across all of the initiated schedules. The highest retention period of the initiated schedules is applied.

**Considerations for Amazon Data Lifecycle Manager**

Your AWS account has the following quotas related to Amazon Data Lifecycle Manager:

- You can create up to 100 lifecycle policies per Region.
- You can add up to 45 tags per resource.

The following considerations apply to lifecycle policies:

- A policy does not begin creating snapshots or AMIs until you set its activation status to *enabled*. You can configure a policy to be enabled upon creation.
- The first snapshot or AMI creation operation starts within one hour after the specified start time. Subsequent snapshot or AMI creation operations start within one hour of their scheduled time.
- If you modify a policy by removing or changing its target tags, the EBS volumes or instances with those tags are no longer managed by the policy.
- If you modify a schedule name for a policy, the snapshots or AMIs created under the old schedule name are no longer affected by the policy.
- If you modify a time-based retention schedule to use a new time interval, the new interval is used only for new snapshots or AMIs created after the change. The new schedule does not affect the retention schedule of snapshots or AMIs created before the change.
- You cannot change the retention schedule of a policy from count-based to time-based after creation. To make this change, you must create a new policy.
- If you disable a policy with an age-based retention schedule, the snapshots or AMIs that are set to expire while the policy is disabled are retained indefinitely. You must delete the snapshots or deregister the AMIs manually. When you enable the policy again, Amazon Data Lifecycle Manager resumes deleting snapshots or deregistering AMIs as their retention periods expire.
- If you delete the resource to which a policy with count-based retention applies, the policy no longer manages the previously created snapshots or AMIs. You must manually delete the snapshots or deregister the AMIs if they are no longer needed.
- If you delete the resource to which a policy with age-based retention applies, the policy continues to delete snapshots or deregister AMIs on the defined schedule, up to, but not including, the last snapshot or AMI. You must manually delete the last snapshot or deregister the last AMI if it is no longer needed.
- You can create multiple policies to back up an EBS volume or an Amazon EC2 instance. For example, if an EBS volume has two tags, where tag A is the target for policy A to create a snapshot every 12
hours, and tag B is the target for policy B to create a snapshot every 24 hours, Amazon Data Lifecycle Manager creates snapshots according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag A, and specify two schedules—one for every 12 hours and one for every 24 hours.

- If you create a policy that targets instances, and new volumes are attached to the instance after the policy has been created, the newly-added volumes are included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.
- For AMI lifecycle policies, when the AMI retention threshold is reached, the oldest AMI is deregistered and its backing snapshots are deleted.
- If a policy with a custom cron-based schedule and age-based or count-based retention rule is configured to create only one snapshot or AMI, the policy will not automatically delete that snapshot or AMI when the retention threshold is reached. You must manually delete the snapshot or deregister the AMI if it is no longer needed.

The following considerations apply to snapshot lifecycle policies and fast snapshot restore (p. 1346):

- A snapshot that is enabled for fast snapshot restore remains enabled even if you delete or disable the lifecycle policy, disable fast snapshot restore for the lifecycle policy, or disable fast snapshot restore for the Availability Zone. You can disable fast snapshot restore for these snapshots manually.
- If you enable fast snapshot restore and you exceed the maximum number of snapshots that can be enabled for fast snapshot restore, Amazon Data Lifecycle Manager creates snapshots as scheduled but does not enable them for fast snapshot restore. After a snapshot that is enabled for fast snapshot restore is deleted, the next snapshot that Amazon Data Lifecycle Manager creates is enabled for fast snapshot restore.
- When you enable fast snapshot restore for a snapshot, it takes 60 minutes per TiB to optimize the snapshot. We recommend that you create a schedule that ensures that each snapshot is fully optimized before Amazon Data Lifecycle Manager creates the next snapshot.
- You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour. For more information, see Pricing and Billing (p. 1350).

  **Note**
  Depending on the configuration of your lifecycle policies, you could have multiple snapshots enabled for fast snapshot restore simultaneously.

The following considerations apply to snapshot lifecycle policies and Multi-Attach (p. 1203) enabled volumes:

- When creating a lifecycle policy based on instance tags for Multi-Volume snapshots, Amazon Data Lifecycle Manager initiates a snapshot of the volume for each attached instance. Use the `timestamp` tag to identify the set of time-consistent snapshots that are created from the attached instances.

The following considerations apply to sharing snapshots across accounts:

- You can only share snapshots that are unencrypted or that are encrypted using a customer managed key.
- You can't share snapshots that are encrypted with the default EBS encryption KMS key.
- If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

The following considerations apply to cross-account copy event policies:
• You can only copy snapshots that are unencrypted or that are encrypted using a customer managed key.
• You can create a cross-account copy event policy that copies snapshots that are shared outside of Amazon Data Lifecycle Manager.
• If you want to encrypt snapshots in the target account, then the IAM role selected for the cross-account copy event policy must have permission to use the required KMS key.

The following considerations apply to EBS-backed AMI policies and AMI deprecation:

• If you increase the AMI deprecation count for a schedule with count-based retention, the change is applied to all AMIs (existing and new) created by the schedule.
• If you increase the AMI deprecation period for a schedule with age-based retention, the change is applied to new AMIs only. Existing AMIs are not affected.
• If you remove the AMI deprecation rule from a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.
• If you decrease the AMI deprecation count or period for a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.
• If you manually deprecate an AMI that was created by an AMI policy, Amazon Data Lifecycle Manager will not override the deprecation.
• If you manually cancel deprecation for an AMI that was previously deprecated by an AMI policy, Amazon Data Lifecycle Manager will not override the cancellation.
• If an AMI is created by multiple conflicting schedules, and one or more of those schedules do not have an AMI deprecation rule, Amazon Data Lifecycle Manager will not deprecate that AMI.
• If an AMI is created by multiple conflicting schedules, and all of those schedules have an AMI deprecation rule, Amazon Data Lifecycle Manager will use the deprecation rule with the latest deprecation date.

Automate snapshot lifecycles

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate Amazon EBS snapshot lifecycles.

Use one of the following procedures to create a snapshot lifecycle policy.

New console

To create a snapshot policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS snapshot policy and then choose Next.
4. In the Target resources section, do the following:
   a. For Target resource types, choose the type of resource to back up. Choose Volume to create snapshots of individual volumes, or choose Instance to create multi-volume snapshots from the volumes attached to an instance.
   b. (For AWS Outpost customers only) For Target resource location, specify where the source resources are located.
      • If the source resources are located in an AWS Region, choose AWS Region. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target
tags in the current Region only. If the resource is located in a Region, snapshots created by the policy will be stored in the same Region.

- If the source resources are located on an Outpost in your account, choose **AWS Outpost**. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target tags across all of the Outposts in your account. If the resource is located on an Outpost, snapshots created by the policy can be stored in the same Region or on the same Outpost as the resource.

- If you do not have any Outposts in your account, this option is hidden and **AWS Region** is selected for you.

c. For **Target resource tags**, choose the resource tags that identify the volumes or instances to back up. Only resources that have the specified tag key and value pairs are backed up by the policy.

5. For **Description**, enter a brief description for the policy.

6. For **IAM role**, choose the IAM role that has permissions to manage snapshots and to describe volumes and instances. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.

7. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.

8. For **Policy status after creation**, choose **Enable policy** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start creating snapshots until you manually enable it after creation.

9. Choose **Next**.

10. On the **Configure schedule** screen, configure the policy schedules. A policy can have up to 4 schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:

    a. In the **Schedule details** section do the following:

        i. For **Schedule name**, specify a descriptive name for the schedule.

        ii. For **Frequency** and the related fields, configure the interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see **Cron expressions** in the *Amazon CloudWatch Events User Guide*.

        iii. For **Starting at**, specify the time at which the policy runs are scheduled to start. The first policy run starts within an hour after the scheduled time. The time must be entered in the `hh:mm` UTC format.

        iv. For **Retention type**, specify the retention policy for snapshots created by the schedule. You can retain snapshots based on either their total count or their age.

           For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest snapshot is deleted when a new one is created.

           For age-based retention, the range is 1 day to 100 years. After the retention period of each snapshot expires, it is deleted.

           **Note**

           All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

        v. (For AWS Outposts customers only) For **Snapshot destination**, specify the destination for snapshots created by the policy.

           - If the policy targets resources in a Region, snapshots must be created in the same Region. **AWS Region** is selected for you.
• If the policy targets resources on an Outpost, you can choose to create snapshots on the same Outpost as the source resource, or in the Region that is associated with the Outpost.

• If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.

b. In the Tagging section, do the following:

i. To copy all of the user-defined tags from the source volume to the snapshots created by the schedule, select **Copy tags from source**.

ii. To specify additional tags to assign to snapshots created by this schedule, choose **Add tags**.

c. To enable fast snapshot restore for snapshots created by the schedule, in the **Fast snapshot restore** section, select **Enable fast snapshot restore**. If you enable fast snapshot restore, you must choose the Availability Zones in which to enable it. If the schedule uses an age-based retention schedule, you must specify the period for which to enable fast snapshot restore for each snapshot. If the schedule uses count-based retention, you must specify the maximum number of snapshots to enable for fast snapshot restore.

If the schedule creates snapshots on an Outpost, you can't enable fast snapshot restore. Fast snapshot restore is not supported with local snapshots that are stored on an Outpost.

**Note**
You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

d. To copy snapshots created by the schedule to an Outpost or to a different Region, in the **Cross-Region copy** section, select **Enable cross-Region copy**.

If the schedule creates snapshots in a Region, you can copy the snapshots to up to three additional Regions or Outposts in your account. You must specify a separate cross-Region copy rule for each destination Region or Outpost.

For each Region or Outpost, you can choose different retention policies and you can choose whether to copy all tags or no tags. If the source snapshot is encrypted, or if encryption by default is enabled, the copied snapshots are encrypted. If the source snapshot is unencrypted, you can enable encryption. If you do not specify a KMS key, the snapshots are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

**Note**
You must ensure that you do not exceed the number of concurrent snapshot copies per Region.

If the policy creates snapshots on an Outpost, then you can't copy the snapshots to a Region or to another Outpost and the cross-Region copy settings are not available.

e. In the **Cross-account sharing**, configure the policy to automatically share the snapshots created by the schedule with other AWS accounts. Do the following:

i. To enable sharing with other AWS accounts, select **Enable cross-account sharing**.

ii. To add the accounts with which to share the snapshots, choose **Add account**, enter the 12-digit AWS account ID, and choose **Add**.

iii. To automatically unshare shared snapshots after a specific period, select **Unshare automatically**. If you choose to automatically unshare shared snapshots, the period after which to automatically unshare the snapshots cannot be longer than the period
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Amazon Data Lifecycle Manager

for which the policy retains its snapshots. For example, if the policy's retention configuration retains snapshots for a period of 5 days, you can configure the policy to automatically unshare shared snapshots after periods up to 4 days. This applies to policies with age-based and count-based snapshot retention configurations.

If you do not enable automatic unsharing, the snapshot is shared until it is deleted.

To add additional schedules, choose Add another schedule, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.

After you have added the required schedules, choose Review policy.

11. Review the policy summary, and then choose Create policy.

Old console

To create a snapshot policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. Provide the following information for your policy as needed:
   - Description—A description of the policy.
   - Policy type—The type of policy to create. Choose EBS snapshot policy.
   - Resource type—The type of resource to back up. Choose Volume to create snapshots of individual volumes, or choose Instance to create multi-volume snapshots from the volumes attached to an instance.
   - Resource location—The location of the resources to backup. If the source resources are located in an AWS Region, choose AWS Region. If the source resources are located on an Outpost in your account, choose AWS Outpost. If you choose AWS Outpost, Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target tags across all of the Outposts in your account.
     If you do not have any Outposts in your account, then AWS Region is selected by default.

   Note
   If the resource is located in a Region, snapshots created by the policy will be stored in the same Region. If the resource is located on an Outpost, snapshots created by the policy can be stored in the same Region or on the same Outpost as the resource.
   - Target with these tags—The resource tags that identify the volumes or instances to back up. Only resources that have the specified tag key and value pairs are backed up by the policy.
   - Policy tags—The tags to apply to the lifecycle policy.
4. For IAM role, choose the IAM role that has permissions to create, delete, and describe snapshots and to describe volumes and instances. AWS provides a default role, or you can create a custom IAM role.
5. Add the policy schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, specify the following information:
   - Schedule name—A name for the schedule.
   - Frequency—The interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose Custom cron expression to specify an interval of up to one year. For more information, see Cron expressions in the Amazon CloudWatch Events User Guide.
   - Starting at hh:mm UTC—The time at which the policy runs are scheduled to start. The first policy run starts within an hour after the scheduled time.
- **Retention type**—You can retain snapshots based on either their total count or their age. For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest snapshot is deleted when a new one is created. For age-based retention, the range is 1 day to 100 years. After the retention period of each snapshot expires, it is deleted. The retention period should be greater than or equal to the interval.

  **Note**
  All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

- **Snapshot destination**—Specifies the destination for snapshots created by the policy. To create snapshots in the same AWS Region as the source resource, choose **AWS Region**. To create snapshots on an Outpost, choose **AWS Outpost**.

  If the policy targets resources in a Region, snapshots are created in the same Region, and cannot be created on an Outpost.

  If the policy targets resources on an Outpost, snapshots can be created on the same Outpost as the source resource, or in the Region that is associated with the Outpost.

- **Copy tags from source**—Choose whether to copy all of the user-defined tags from the source volume to the snapshots created by the schedule.

- **Variable tags**—If the source resource is an instance, you can choose to automatically tag your snapshots with the following variable tags:
  - `instance-id`—The ID of the source instance.
  - `timestamp`—The date and time of the policy run.

- **Additional tags**—Specify any additional tags to assign to the snapshots created by this schedule.

- **Fast snapshot restore**—Choose whether to enable fast snapshot restore for all snapshots that are created by the schedule. If you enable fast snapshot restore, you must choose the Availability Zones in which to enable it. You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour. You can also specify the maximum number of snapshots that can be enabled for fast snapshot restore.

  If the policy creates snapshots on an Outpost, you can't enable fast snapshot restore. Fast snapshot restore is not supported with local snapshots that are stored on an Outpost.

- **Cross region copy**—If the policy creates snapshots in a Region, then you can copy the snapshots to up to three additional Regions or Outposts in your account. You must specify a separate cross-Region copy rule for each destination Region or Outpost.

  For each Region or Outpost, you can choose different retention policies and you can choose whether to copy all tags or no tags. If the source snapshot is encrypted, or if encryption by default is enabled, the copied snapshots are encrypted. If the source snapshot is unencrypted, you can enable encryption. If you do not specify a KMS key, the snapshots are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

  You must ensure that you do not exceed the number of concurrent snapshot copies per Region.

  If the policy creates snapshots on an Outpost, then you can't copy the snapshots to a Region or to another Outpost and the cross-Region copy settings are not available.

6. For **Policy status after creation**, choose **Enable policy** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running.

7. Choose **Create Policy**.
**Command line**

Use the `create-lifecycle-policy` command to create a snapshot lifecycle policy. For `PolicyType`, specify `EBS_SNAPSHOT_MANAGEMENT`.

**Note**
To simplify the syntax, the following examples use a JSON file, `policyDetails.json`, that includes the policy details.

**Example 1—Snapshot lifecycle policy**

This example creates a snapshot lifecycle policy that creates snapshots of all volumes that have a tag key of `costcenter` with a value of `115`. The policy includes two schedules. The first schedule creates a snapshot every day at 03:00 UTC. The second schedule creates a weekly snapshot every Friday at 17:00 UTC.

```bash
aws dlm create-lifecycle-policy \
--description "My volume policy" \
--state ENABLED --execution-role-arn \
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
--policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```json
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": [
    "VOLUME"
  ],
  "TargetTags": [{
    "Key": "costcenter",
    "Value": "115"
  }],
  "Schedules": [{
    "Name": "DailySnapshots",
    "TagsToAdd": [{
      "Key": "type",
      "Value": "myDailySnapshot"
    }],
    "CreateRule": {
      "Interval": 24,
      "IntervalUnit": "HOURS",
      "Times": [
        "03:00"
      ]
    },
    "RetainRule": {
      "Count": 5
    },
    "CopyTags": false
  },
  {"Name": "WeeklySnapshots",
   "TagsToAdd": [{
     "Key": "type",
     "Value": "myWeeklySnapshot"
   }],
   "CreateRule": {
     "CronExpression": "cron(0 17 ? * FRI *)"
   },
   "RetainRule": {
     "Count": 5
   }
  }
}
```
Upon success, the command returns the ID of the newly created policy. The following is example output.

```
{
  "PolicyId": "policy-0123456789abcdef0"
}
```

**Example 2—Snapshot lifecycle policy that automates local snapshots of Outpost resources**

This example creates a snapshot lifecycle policy that creates snapshots of volumes tagged with `team=dev` across all of your Outposts. The policy creates the snapshots on the same Outposts as the source volumes. The policy creates snapshots every 12 hours starting at 00:00 UTC.

```
aws dlm create-lifecycle-policy
  --description "My local snapshot policy"
  --state ENABLED --execution-role-arn
  arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole
  --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": "VOLUME",
  "ResourceLocations": "OUTPOST",
  "TargetTags": [{
    "Key": "team",
    "Value": "dev"
  }],
  "Schedules": [{
    "Name": "on-site backup",
    "CreateRule": {
      "Interval": 12,
      "IntervalUnit": "HOURS",
      "Times": [
        "00:00"
      ],
      "Location": [
        "OUTPOST_LOCAL"
      ]
    },
    "RetainRule": {
      "Count": 1
    },
    "CopyTags": false
  }]
}
```

**Example 3—Snapshot lifecycle policy that creates snapshots in a Region and copies them to an Outpost**

The following example policy creates snapshots of volumes that are tagged with `team=dev`. Snapshots are created in the same Region as the source volume. Snapshots are created every 12 hours starting at 00:00 UTC, and retains a maximum of 1 snapshot. The policy also copies the snapshots to Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/`
op-1234567890abcdef0, encrypts the copied snapshots using the default encryption KMS key, and retains the copies for 1 month.

```
aws dlm create-lifecycle-policy \
  --description "Copy snapshots to Outpost" \
  --state ENABLED --execution-role-arn \
  arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```json
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": "VOLUME",
  "ResourceLocations": "CLOUD",
  "TargetTags": [{
    "Key": "team",
    "Value": "dev"
  }],
  "Schedules": [{
    "Name": "on-site backup",
    "CopyTags": false,
    "CreateRule": {
      "Interval": 12,
      "IntervalUnit": "HOURS",
      "Times": [
        "00:00"
      ],
      "Location": "CLOUD"
    },
    "RetainRule": {
      "Count": 1
    },
    "CrossRegionCopyRules" : [
    {
      "Target": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0",
      "Encrypted": true,
      "CopyTags": true,
      "RetainRule": {
        "Interval": 1,
        "IntervalUnit": "MONTHS"
      }
    }]
  }
}
```

## Automate AMI lifecycles

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate EBS-backed AMI lifecycles.

Use one of the following procedures to create an AMI lifecycle policy.

### New console

**To create an AMI policy**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**, and then choose **Create lifecycle policy**.
3. On the Select policy type screen, choose EBS-backed AMI policy, and then choose Next.

4. In the Target resources section, for Target resource tags, choose the resource tags that identify the volumes or instances to back up. The policy backs up only the resources that have the specified tag key and value pairs.

5. For Description, enter a brief description for the policy.

6. For IAM role, choose the IAM role that has permissions to manage AMIs and snapshot and to describe instances. To use the default role provided by Amazon Data Lifecycle Manager, choose Default role. Alternatively, to use a custom IAM role that you previously created, choose Choose another role, and then select the role to use.

7. For Policy tags, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.

8. For Policy status after creation, choose Enable policy to start running the policy at the next scheduled time, or Disable policy to prevent the policy from running. If you do not enable the policy now, it will not start creating AMIs until you manually enable it after creation.

9. In the Instance reboot section, indicate whether instances should be rebooted before AMI creation. To prevent the targeted instances from being rebooted, choose No. Choosing No could cause data consistency issues. To reboot instances before AMI creation, choose Yes. Choosing this ensures data consistency, but could result in multiple targeted instances rebooting simultaneously.

10. Choose Next.

11. On the Configure schedule screen, configure the policy schedules. A policy can have up to four schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:

   a. In the Schedule details section do the following:

      i. For Schedule name, specify a descriptive name for the schedule.

      ii. For Frequency and the related fields, configure the interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose Custom cron expression to specify an interval of up to one year. For more information, see Cron expressions in the Amazon CloudWatch Events User Guide.

      iii. For Starting at, specify the time to start the policy runs. The first policy run starts within an hour after the time that you schedule. You must enter the time in the hh:mm UTC format.

      iv. For Retention type, specify the retention policy for AMIs created by the schedule. You can retain AMIs based on either their total count or their age.

         For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest AMI is deregistered when a new one is created.

         For age-based retention, the range is 1 day to 100 years. After the retention period of each AMI expires, it is deregistered.

         Note
         All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

   b. In the Tagging section, do the following:

      i. To copy all of the user-defined tags from the source instance to the AMIs created by the schedule, select Copy tags from source.

      ii. By default, AMIs created by the schedule are automatically tagged with the ID of the source instance. To prevent this automatic tagging from happening, for Variable tags, remove the instance-id:$(instance-id) tile.

      iii. To specify additional tags to assign to AMIs created by this schedule, choose Add tags.
c. To deprecate AMIs when they should no longer be used, in the **AMI deprecation** section, select **Enable AMI deprecation for this schedule** and then specify the AMI deprecation rule. The AMI deprecation rule specifies when AMIs are to be deprecated.

If the schedule uses count-based AMI retention, you must specify the number of oldest AMIs to deprecate. The deprecation count must be less than or equal to the schedule's AMI retention count, and it can't be greater than 1000. For example, if the schedule is configured to retain a maximum of 5 AMIs, then you can configure the scheduled to deprecate up to 5 oldest AMIs.

If the schedule uses age-based AMI retention, you must specify the period after which AMIs are to be deprecated. The deprecation count must be less than or equal to the schedule's AMI retention period, and it can't be greater than 10 years (120 months, 520 weeks, or 3650 days). For example, if the schedule is configured to retain AMIs for 10 days, then you can configure the schedule to deprecate AMIs after periods up to 10 days after creation.

d. To copy AMIs created by the schedule to different Regions, in the **Cross-Region copy** section, select **Enable cross-Region copy**. You can copy AMIs to up to three additional Regions in your account. You must specify a separate cross-Region copy rule for each destination Region.

For each destination Region, you can specify the following:

- A retention policy for the AMI copy. When the retention period expires, the copy in the destination Region is automatically deregistered.
- Encryption status for the AMI copy. If the source AMI is encrypted, or if encryption by default is enabled, the copied AMIs are always encrypted. If the source AMI is unencrypted and encryption by default is disabled, you can optionally enable encryption. If you do not specify a KMS key, the AMIs are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.
- A deprecation rule for the AMI copy. When the deprecation period expires, the AMI copy is automatically deprecated. The deprecation period must be less than or equal to the copy retention period, and it can't be greater than 10 years.
- Whether to copy all tags or no tags from the source AMI.

**Note**
Do not exceed the number of concurrent AMI copies per Region.

e. To add additional schedules, choose **Add another schedule**, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.

f. After you have added the required schedules, choose **Review policy**.

12. Review the policy summary, and then choose **Create policy**.

**Console**

**To create an AMI lifecycle policy**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**, and then choose **Create lifecycle policy**.
3. Provide the following information for your policy as needed:

- **Description**—A description of the policy.
- **Policy type**—The type of policy to create. Choose **EBS-backed AMI policy**.
• **Target with these tags**—The resource tags that identify the instances to back up. Only instances that have the specified tag key and value pairs are backed up by the policy.

• **Policy tags**—The tags to apply to the lifecycle policy.

4. For **IAM role**, choose the IAM role that has permissions to manage images. AWS provides a default roles, or you can create a custom IAM role.

5. Add the policy schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, specify the following information:

   • **Schedule name**—A name for the schedule.
   
   • **Frequency**—The interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose Custom cron expression to specify an interval of up to one year. For more information, see Cron expressions in the Amazon CloudWatch Events User Guide.
   
   • **Starting at hh:mm UTC**—The time at which the policy runs are scheduled to start. The first policy run starts within an hour after the scheduled time.
   
   • **Retention type**—You can retain AMIs based on either their total count or their age. For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest AMI is deleted when a new one is created. For age-based retention, the range is 1 day to 100 years. After the retention period of each AMI expires, it is deleted. The retention period should be greater than or equal to the interval.

   **Note**
   
   All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

   • **Copy tags from source**—Choose whether to copy all of the user-defined tags from the source instance to the AMIs created by the schedule.
   
   • **Dynamic tags**—You can choose to automatically tag your AMIs with the ID of the source instance.
   
   • **Additional tags**—Specify any additional tags to assign to the AMIs created by this schedule.
   
   • **Enable cross Region copy**—You can copy AMIs to up to three additional Regions.

   For each Region, you can choose different retention policies and you can choose whether to copy all tags or no tags. If the source AMI is encrypted, or if encryption by default is enabled, the copied AMIs are encrypted. If the AMI is unencrypted, you can enable encryption. If you do not specify a KMS key, the AMIs are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

   Do not exceed the number of concurrent AMI copies per Region.

6. Indicate whether instances should be rebooted before AMI creation. To prevent the targeted instances from being rebooted, for Reboot Instance at policy run, choose No. Choosing this option could cause data consistency issues. To reboot instances before AMI creation, for Reboot Instance at policy run, choose Yes. Choosing this ensures data consistency but could result in multiple targeted instances rebooting simultaneously.

7. For **Policy status after creation**, choose Enable policy to start the policy runs at the next scheduled time, or Disable policy to prevent the policy from running.

8. Choose Create Policy.

**Command line**

Use the create-lifecycle-policy command to create an AMI lifecycle policy. For PolicyType, specify IMAGE_MANAGEMENT.
Note
To simplify the syntax, the following examples use a JSON file, policyDetails.json, that includes the policy details.

Example 1: Age-based retention and AMI deprecation

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production without rebooting the targeted instances. The policy includes one schedule that creates an AMI every day at 01:00 UTC. The policy retains AMIs for 2 days and deprecates them after 1 day. It also copies the tags from the source instance to the AMIs that it creates.

```
aws dlm create-lifecycle-policy \\
--description "My AMI policy" \\
--state ENABLED --execution-role-arn \\
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement \\
--policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
    "PolicyType": "IMAGE_MANAGEMENT",
    "ResourceTypes": [
        "INSTANCE"
    ],
    "TargetTags": [
    {
        "Key": "purpose",
        "Value": "production"
    }],
    "Schedules": [
    {
        "Name": "DailyAMIs",
        "TagsToAdd": [
            {
                "Key": "type",
                "Value": "myDailyAMI"
            }
        ],
        "CreateRule": {
            "Interval": 24,
            "IntervalUnit": "HOURS",
            "Times": [
                "01:00"
            ]
        },
        "RetainRule": {
            "Interval": 2,
            "IntervalUnit": "DAYS"
        },
        "DeprecateRule": {
            "Interval": 1,
            "IntervalUnit": "DAYS"
        },
        "CopyTags": true
    }],
    "Parameters": {
        "NoReboot": true
    }
}
```

Upon success, the command returns the ID of the newly created policy. The following is example output.

```
{
}
```
Example 2: Count-based retention and AMI deprecation with cross-Region copy

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production and reboots the target instances. The policy includes one schedule that creates an AMI every 6 hours starting at 17:30 UTC. The policy retains 3 AMIs and automatically deprecates the 2 oldest AMIs. It also has a cross-Region copy rule that copies AMIs to us-east-1, retains 2 AMI copies, and automatically deprecates the oldest AMI.

```
aws dlm create-lifecycle-policy \
  --description "My AMI policy" \
  --state ENABLED \
  --execution-role-arn \
  arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement \
  --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
  "PolicyType": "IMAGE_MANAGEMENT",
  "ResourceTypes" : [
    "INSTANCE"
  ],
  "TargetTags": [{
    "Key":"purpose",
    "Value":"production"
  }],
  "Parameters" : {
    "NoReboot": true
  },
  "Schedules" : [{
    "Name" : "Schedule1",
    "CopyTags": true,
    "CreateRule" : {
      "Interval": 6,
      "IntervalUnit": "HOURS",
      "Times" : ["17:30"]
    },
    "RetainRule":{
      "Count" : 3
    },
    "DeprecateRule":{
      "Count" : 2
    },
    "CrossRegionCopyRules": [{
      "TargetRegion": "us-east-1",
      "Encrypted": true,
      "RetainRule":{
        "IntervalUnit": "DAYS",
        "Interval": 2
      },
      "DeprecateRule":{
        "IntervalUnit": "DAYS",
        "Interval": 1
      },
      "CopyTags": true
    }]
  }]
}
```
Automate cross-account snapshot copies

Automating cross-account snapshot copies enables you to copy your Amazon EBS snapshots to specific Regions in an isolated account and encrypt those snapshots with an encryption key. This enables you to protect yourself against data loss in the event of your account being compromised.

Automating cross-account snapshot copies involves two accounts:

- **Source account**—The source account is the account that creates and shares the snapshots with the target account. In this account, you must create an EBS snapshot policy that creates snapshots at set intervals and then shares them with other AWS accounts.

- **Target account**—The target account is the account with destination account with which the snapshots are shared, and it is the account that creates copies of the shared snapshots. In this account, you must create a cross-account copy event policy that automatically copies snapshots that are shared with it by one or more specified source accounts.

**Topics**

- Create cross-account snapshot copy policies (p. 1298)
- Specify snapshot description filters (p. 1305)

Create cross-account snapshot copy policies

To prepare the source and target accounts for cross-account snapshot copying, you need to perform the following steps:

**Topics**

- Step 1: Create the EBS snapshot policy (Source account) (p. 1298)
- Step 2: Share the customer managed key (Source account) (p. 1298)
- Step 3: Create cross-account copy event policy (Target account) (p. 1300)
- Step 4: Allow IAM role to use the required KMS keys (Target account) (p. 1303)

**Step 1: Create the EBS snapshot policy (Source account)**

In the source account, create an EBS snapshot policy that will create the snapshots and share them with the required target accounts.

When you create the policy, ensure that you enable cross-account sharing and that you specify the target AWS accounts with which to share the snapshots. These are the accounts with which the snapshots are to be shared. If you are sharing encrypted snapshots, then you must give the selected target accounts permission to use the KMS key used to encrypt the source volume. For more information, see Step 2: Share the customer managed key (Source account) (p. 1298).

For more information about creating an EBS snapshot policy, see Automate snapshot lifecycles (p. 1285).

Use one of the following methods to create the EBS snapshot policy.

**Step 2: Share the customer managed key (Source account)**

If you are sharing encrypted snapshots, you must grant the IAM role and the target AWS accounts (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

**Note**

Perform this step only if you are sharing encrypted snapshots. If you are sharing unencrypted snapshots, skip this step.
Console

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose Customer managed key and then select the KMS key that you need to share with the target accounts.

   Make note of the KMS key ARN, you’ll need this later.
4. On the Key policy tab, scroll down to the Key users section. Choose Add, enter the name of the IAM role that you selected in the previous step, and then choose Add.
5. On the Key policy tab, scroll down to the Other AWS accounts section. Choose Add other AWS accounts, and then add all of the target AWS accounts that you chose to share the snapshots with in the previous step.
6. Choose Save changes.

Command line

Use the get-key-policy command to retrieve the key policy that is currently attached to the KMS key.

For example, the following command retrieves the key policy for a KMS key with an ID of 9d5e2b3d-e410-4a27-a958-19e220d83a1e and writes it to a file named snapshotKey.json.

```
$ aws kms get-key-policy --policy-name default --key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e --query Policy --output text > snapshotKey.json
```

Open the key policy using your preferred text editor. Add the ARN of the IAM role that you specified when you created the snapshot policy and the ARNs of the target accounts with which to share the KMS key.

For example, in the following policy, we added the ARN of the default IAM role, and the ARN of the root account for target account 222222222222.

```
{
  "Sid" : "Allow use of the key",
  "Effect" : "Allow",
  "Principal" : {
    "AWS" : [
      "arn:aws:iam::111111111111:role/service-role/AWSDataLifecycleManagerDefaultRole",
      "arn:aws:iam::222222222222:root"
    ]
  },
  "Action" : [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt***",
    "kms:GenerateDataKey***",
    "kms:DescribeKey"
  ],
  "Resource" : "*"
},
{
  "Sid" : "Allow attachment of persistent resources",
  "Effect" : "Allow",
  "Principal" : {
    "AWS" : [n}
```
Save and close the file. Then use the `put-key-policy` command to attach the updated key policy to the KMS key.

```
$ aws kms put-key-policy
   --policy-name default --key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e
   --policy file://snapshotKey.json
```

**Step 3: Create cross-account copy event policy (Target account)**

In the target account, you must create a cross-account copy event policy that will automatically copy snapshots that are shared by the required source accounts.

This policy runs in the target account only when one of the specified source accounts shares snapshot with the account.

Use one of the following methods to create the cross-account copy event policy.

**New console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose Cross-account copy event policy, and then choose Next.
4. For Policy description, enter a brief description for the policy.
5. For Policy tags, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
6. In the Event settings section, define the snapshot sharing event that will cause the policy to run. Do the following:
   a. For Sharing accounts, specify the source AWS accounts from which you want to copy the shared snapshots. Choose Add account, enter the 12-digit AWS account ID, and then choose Add.
   b. For Filter by description, enter the required snapshot description using a regular expression. Only snapshots that are shared by the specified source accounts and that have descriptions that match the specified filter are copied by the policy. For more information, see Specify snapshot description filters (p. 1305).
7. For IAM role, choose the IAM role that has permissions to perform snapshot copy actions. To use the default role provided by Amazon Data Lifecycle Manager, choose Default role. Alternatively,
to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.

If you are copying encrypted snapshots, you must grant the selected IAM role permissions to use the encryption KMS key used to encrypt the source volume. Similarly, if you are encrypting the snapshot in the destination Region using a different KMS key, you must grant the IAM role permission to use the destination KMS key. For more information, see **Step 4: Allow IAM role to use the required KMS keys (Target account)** (p. 1303).

8. In the **Copy action** section, define the snapshot copy actions that the policy should perform when it is activated. The policy can copy snapshots to up to three Regions. You must specify a separate copy rule for each destination Region. For each rule that you add, do the following:

   a. For **Name**, enter a descriptive name for the copy action.
   b. For **Target Region**, select the Region to which to copy the snapshots.
   c. For **Expire**, specify how long to retain the snapshot copies in the target Region after creation.
   d. To encrypt the snapshot copy, for **Encryption**, select **Enable encryption**. If the source snapshot is encrypted, or if encryption by default is enabled for your account, the snapshot copy is always encrypted, even if you do not enable encryption here. If the source snapshot is unencrypted and encryption by default is not enabled for your account, you can choose to enable or disable encryption. If you enable encryption, but do not specify a KMS key, the snapshots are encrypted using the default encryption KMS key in each destination Region. If you specify a KMS key for the destination Region, you must have access to the KMS key.

   9. To add additional snapshot copy actions, choose **Add new Regions**.

10. For **Policy status after creation**, choose **Enable policy** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start copying snapshots until you manually enable it after creation.

11. Choose **Create policy**.

### Old console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Lifecycle Manager** and then choose **Create Lifecycle Policy**.
3. For **Policy Type**, choose **Cross-account copy event policy**. For **Description**, enter a brief description for the policy.
4. In the **Cross-account copy event settings** section, for **Copy snapshots shared by**, enter the source AWS accounts from which you want to copy the shared snapshots.
5. For **Snapshot description filter**, enter the required snapshot description using a regular expression. Only snapshots that are shared by the specified sources accounts and that have descriptions that match the specified filter are copied by the policy. For more information, see **Specify snapshot description filters** (p. 1305).
6. For **IAM role**, choose the IAM role that has permissions to perform the snapshot copy action. AWS provides a default role, or you can create a custom IAM role.

   If you are copying encrypted snapshots, you must grant the selected IAM role permissions to use the encryption KMS key used to encrypt the source volume. Similarly, if you are encrypting the snapshot in the destination Region using a different KMS key, you must grant the IAM role permission to use the destination KMS key. For more information, see **Step 4: Allow IAM role to use the required KMS keys (Target account)** (p. 1303).

7. In the **Copy settings** section, you can configure the policy to copy snapshots to up to three Regions in the target account. Do the following:

   a. For **Name**, enter a descriptive name for the copy action.
   b. For **Target Region**, select the Region to which to copy the snapshots.
c. For **Retain copy for**, specify how long to retain the snapshot copies in the target Region after creation.

d. For **Encryption**, select **Enable** to encrypt the snapshot copy in the target Region. If the source snapshot is encrypted, or if encryption by default is enabled for your account, the snapshot copy is always encrypted, even if you do not enable encryption here. If the source snapshot is unencrypted and encryption by default is not enabled for your account, you can choose to enable or disable encryption. If you enable encryption, but do not specify a KMS key, the snapshots are encrypted using the default encryption KMS key in each destination Region. If you specify a KMS key for the destination Region, you must have access to the KMS key.

e. (Optional) To copy the snapshot to additional Regions, choose **Add additional region**, and then complete the required fields.

8. For **Policy status after creation**, choose **Enable** policy to start the policy runs at the next scheduled time.

9. Choose **Create Policy**.

**Command line**

Use the `create-lifecycle-policy` command to create a policy. To create a cross-account copy event policy, for `PolicyType`, specify `EVENT_BASED_POLICY`.

For example, the following command creates a cross-account copy event policy in target account 222222222222. The policy copies snapshots that are shared by source account 111111111111. The policy copies snapshots to `sa-east-1` and `eu-west-2`. Snapshots copied to `sa-east-1` are unencrypted and they are retained for 3 days. Snapshots copied to `eu-west-2` are encrypted using KMS key `8af79514-350d-4c52-bac8-8985e84171c7` and they are retained for 1 month. The policy uses the default IAM role.

```
$ aws dlm create-lifecycle-policy \
--description "Copy policy" \
--state ENABLED --execution-role-arn arn:aws:iam::222222222222:role/service-role/AWSDataLifecycleManagerDefaultRole \
--policy-details file://policyDetails.json
```

The following shows the contents of the `policyDetails.json` file.

```
{
  "PolicyType" : "EVENT_BASED_POLICY",
  "EventSource" : {
    "Type" : "MANAGED_CWE",
    "Parameters": {
      "EventType" : "shareSnapshot",
      "SnapshotOwner": ["111111111111"]
    }
  },
  "Actions" : [{
    "Name":"Copy Snapshot to Sao Paulo and London",
    "CrossRegionCopy" : [{
      "Target" : "sa-east-1",
      "EncryptionConfiguration" : {
        "Encrypted" : false
      },
      "RetainRule" : {
        "Interval" : 3,
        "IntervalUnit" : "DAYS"
      }
    }]
  }]
}
```
Step 4: Allow IAM role to use the required KMS keys (Target account)

If you are copying encrypted snapshots, you must grant the IAM role (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

**Note**

Only perform this step if you are copying encrypted snapshots. If you are copying unencrypted snapshots, skip this step.

Use one of the following methods to add the required policies to the IAM role.

**Console**

2. In the navigation pane, select **Roles**. Search for and select the IAM role that you selected when you created the cross-account copy event policy in the previous step. If you chose to use the default role, the role is named **AWSDataLifecycleManagerDefaultRole**.
3. Choose **Add inline policy** and then select the **JSON** tab.
4. Replace the existing policy with the following, and specify the ARNs of the KMS keys.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:RevokeGrant",
                "kms:CreateGrant",
                "kms:ListGrants"
            ],
            "Resource": [
                "arn:aws:kms:region:source_account_id:key/shared_cmk_id"
            ],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": "true"
                }
            }
        }
    ]
}
```
5. Choose Review policy
6. For Name, enter a descriptive name for the policy, and then choose Create policy.

Command line

Using your preferred text editor, create a new JSON file named policyDetails.json. Add the following policy and specify the ARNs of the KMS keys that the role needs permissions to use. In the following example, the policy grants the IAM role permission to use KMS key 1234abcd-12ab-34cd-56ef-1234567890ab, which was shared by source account 111111111111, and KMS key 4567dcba-23ab-34cd-56ef-0987654321yz, which exists in target account 222222222222.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:RevokeGrant",
                "kms:CreateGrant",
                "kms:ListGrants"
            ],
            "Resource": [
                "arn:aws:kms:sa-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:eu-west-2:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": [
                "arn:aws:kms:region:source_account_id:key/shared_cmk_id"
            ]
        }
    ]
}
```
"Resource": [
  "arn:aws:kms:sa-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
  "arn:aws:kms:eu-west-2:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
]
}
}
}

Save and close the file. Then use the `put-role-policy` command to add the policy to the IAM role.

For example

```latex
# aws iam put-role-policy \
--role-name AWSDataLifecycleManagerDefaultRole \
--policy-name CopyPolicy \
--policy-document file://AdminPolicy.json
```

Specify snapshot description filters

When you create the snapshot copy policy in the target account, you must specify a snapshot description filter. The snapshot description filter enables you to specify an additional level of filtering that lets you control which snapshots are copied by the policy. This means that a snapshot is only copied by the policy if it is shared by one of the specified source accounts, and it has a snapshot description that matches the specified filter. In other words, if a snapshot is shared by one of the specified source accounts, but it does not have a description that matches the specified filter, it is not copied by the policy.

The snapshot filter description must be specified using a regular expression. It is a mandatory field when creating cross-account copy event policies using the console and the command line. The following are example regular expressions that can be used:

- `.*` — This filter matches all snapshot descriptions. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts.
- `Created for policy: policy-0123456789abcdef0.*` — This filter matches only snapshots that are created by a policy with an ID of `policy-0123456789abcdef0`. If you use an expression like this, only snapshots that are shared with your account by one of the specified source accounts, and that have been created by a policy with the specified ID are copied by the policy.
- `.*production.*` — This filter matches any snapshot that has the word `production` anywhere in its description. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts and that have the specified text in their description.

View, modify, and delete lifecycle policies

Use the following procedures to view, modify and delete existing lifecycle policies.

Topics
- View lifecycle policies (p. 1305)
- Modify lifecycle policies (p. 1307)
- Delete lifecycle policies (p. 1207)

View lifecycle policies

Use one of the following procedures to view a lifecycle policy.
Console

To view a lifecycle policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager.
3. Select a lifecycle policy from the list. The Details tab displays information about the policy.

Command line

Use the get-lifecycle-policy command to display information about a lifecycle policy.

```
aws dlm get-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The following is example output. It includes the information that you specified, plus metadata inserted by AWS.

```
{
  "Policy": {
    "Description": "My first policy",
    "DateCreated": "2018-05-15T00:16:21+0000",
    "State": "ENABLED",
    "ExecutionRoleArn": "arn:aws:iam::210774411744:role/AWSDataLifecycleManagerDefaultRole",
    "PolicyId": "policy-0123456789abcdef0",
    "DateModified": "2018-05-15T00:16:22+0000",
    "PolicyDetails": {
      "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
      "ResourceTypes": ["VOLUME"],
      "TargetTags": [
        {
          "Value": "115",
          "Key": "costcenter"
        }
      ],
      "Schedules": ["TagsToAdd": [
        {
          "Value": "myDailySnapshot",
          "Key": "type"
        }
      ],
      "RetainRule": {
        "Count": 5
      },
      "CopyTags": false,
      "CreateRule": {
        "Interval": 24,
        "IntervalUnit": "HOURS",
        "Times": [
          "03:00"
        ]
      },
      "Name": "DailySnapshots"
    }
  }
}
```
Modify lifecycle policies

Use one of the following procedures to modify a lifecycle policy.

Console

To modify a lifecycle policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager.
3. Select a lifecycle policy from the list.
4. Choose Actions, Modify Lifecycle Policy.
5. Modify the policy settings as needed. For example, you can modify the schedule, add or remove tags, or enable or disable the policy.
6. Choose Update policy.

Command line

Use the update-lifecycle-policy command to modify the information in a lifecycle policy. To simplify the syntax, this example references a JSON file, policyDetailsUpdated.json, that includes the policy details.

```
aws dlm update-lifecycle-policy --state DISABLED --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole --policy-details file://policyDetailsUpdated.json
```

The following is an example of the policyDetailsUpdated.json file.

```json
{
"ResourceTypes": [
  "VOLUME"
],
"TargetTags": [
  {
    "Key": "costcenter",
    "Value": "120"
  }
],
"Schedules": [
  {
    "Name": "DailySnapshots",
    "TagsToAdd": [
      {
        "Key": "type",
        "Value": "myDailySnapshot"
      }
    ],
    "CreateRule": {
      "Interval": 12,
      "IntervalUnit": "HOURS",
      "Times": [
        "15:00"
      ]
    }
  }
}
```
"RetainRule": {
    "Count": 5
},
"CopyTags": false
}
]

To view the updated policy, use the `get-lifecycle-policy` command. You can see that the state, the value of the tag, the snapshot interval, and the snapshot start time were changed.

**Delete lifecycle policies**

Use one of the following procedures to delete a lifecycle policy.

**Note**
When you delete a lifecycle policy, the snapshots or AMIs created by that policy are not automatically deleted. If you no longer need the snapshots or AMIs, you must delete them manually.

**Old console**

**To delete a lifecycle policy**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic Block Store**, **Lifecycle Manager**.
3. Select a lifecycle policy from the list.
4. Choose **Actions**, **Delete Lifecycle Policy**.
5. When prompted for confirmation, choose **Delete Lifecycle Policy**.

**Command line**

Use the `delete-lifecycle-policy` command to delete a lifecycle policy and free up the target tags specified in the policy for reuse.

**Note**
You can delete snapshots created only by Amazon Data Lifecycle Manager.

```
aws dlm delete-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The Amazon Data Lifecycle Manager API Reference provides descriptions and syntax for each of the actions and data types for the Amazon Data Lifecycle Manager Query API.

Alternatively, you can use one of the AWS SDKs to access the API in a way that's tailored to the programming language or platform that you're using. For more information, see AWS SDKs.

**AWS Identity and Access Management**

Access to Amazon Data Lifecycle Manager requires credentials. Those credentials must have permissions to access AWS resources, such as instances, volumes, snapshots, and AMIs. The following sections provide details about how you can use AWS Identity and Access Management (IAM), and help secure access to your resources.

**Topics**
AWS managed policies

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases. AWS managed policies make it more efficient for you to assign appropriate permissions to users, groups, and roles, than if you had to write the policies yourself.

However, you can't change the permissions defined in AWS managed policies. AWS occasionally updates the permissions defined in an AWS managed policy. When this occurs, the update affects all principal entities (users, groups, and roles) that the policy is attached to.

Amazon Data Lifecycle Manager provides two AWS managed policies for common use cases. These policies make it more efficient to define the appropriate permissions and control access to your resources. The AWS managed policies provided by Amazon Data Lifecycle Manager are designed to be attached to roles that you pass to Amazon Data Lifecycle Manager.

The following are the AWS managed policies that Amazon Data Lifecycle Manager provides. You can also find these AWS managed policies in the Policies section of the IAM console.

AWSDataLifecycleManagerServiceRole

The AWSDataLifecycleManagerServiceRole policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS snapshot policies and cross-account copy event policies.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateSnapshot",
                "ec2:CreateSnapshots",
                "ec2:DeleteSnapshot",
                "ec2:DescribeInstances",
                "ec2:DescribeVolumes",
                "ec2:DescribeSnapshots",
                "ec2:EnableFastSnapshotRestores",
                "ec2:DescribeFastSnapshotRestores",
                "ec2:DisableFastSnapshotRestores",
                "ec2:CopySnapshot",
                "ec2:ModifySnapshotAttribute",
                "ec2:DescribeSnapshotAttribute"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:*::snapshot/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:*::volume/*"
        }
    ]
}```
"Action": [
  "events:PutRule",
  "events:DeleteRule",
  "events:DescribeRule",
  "events:EnableRule",
  "events:DisableRule",
  "events:ListTargetsByRule",
  "events:PutTargets",
  "events:RemoveTargets"
],
"Resource": "arn:aws:events:*::*:rule/AwsDataLifecycleRule.managed-cwe.*"}
}

AWSDataLifecycleManagerServiceRoleForAMIManagement

The **AWSDataLifecycleManagerServiceRoleForAMIManagement** policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS-backed AMI policies.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CreateTags",
      "Resource": [
        "arn:aws:ec2:*::snapshot/*",
        "arn:aws:ec2:*::image/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeImages",
        "ec2:DescribeInstances",
        "ec2:DescribeImageAttribute",
        "ec2:DescribeVolumes",
        "ec2:DescribeSnapshots",
        "ec2:EnableImageDeprecation",
        "ec2:DisableImageDeprecation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DeleteSnapshot",
      "Resource": "arn:aws:ec2:*::*:snapshot/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:ResetImageAttribute",
        "ec2:DeregisterImage",
        "ec2:CreateImage",
        "ec2:CopyImage",
        "ec2:ModifyImageAttribute"
      ],
      "Resource": "*"
    }
  ]
}
```
AWS managed policy updates

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

The following table provides details about updates to AWS managed policies for Amazon Data Lifecycle Manager since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Document history (p. 1549).

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWSDataLifecycleManagerServiceRoleForAMIMangement</td>
<td>— Added permissions to support AMI deprecation.</td>
<td>August 23, 2021</td>
</tr>
<tr>
<td>Amazon Data Lifecycle Manager started tracking changes</td>
<td>Amazon Data Lifecycle Manager started tracking changes for its AWS managed policies.</td>

</tr>
</tbody>
</table>

IAM service roles

An AWS Identity and Access Management (IAM) role is similar to a user, in that it is an AWS identity with permissions policies that determine what the identity can and can't do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. A service role is a role that an AWS service assumes to perform actions on your behalf. As a service that performs backup operations on your behalf, Amazon Data Lifecycle Manager requires that you pass it a role to assume when performing policy operations on your behalf. For more information about IAM roles, see IAM Roles in the IAM User Guide.

The role that you pass to Amazon Data Lifecycle Manager must have an IAM policy with the permissions that enable Amazon Data Lifecycle Manager to perform actions associated with policy operations, such as creating snapshots and AMIs, copying snapshots and AMIs, deleting snapshots, and deregistering AMIs. Different permissions are required for each of the Amazon Data Lifecycle Manager policy types. The role must also have Amazon Data Lifecycle Manager listed as a trusted entity, which enables Amazon Data Lifecycle Manager to assume the role.

Topics
- Default service roles for Amazon Data Lifecycle Manager (p. 1312)
- Custom service roles for Amazon Data Lifecycle Manager (p. 1312)
Default service roles for Amazon Data Lifecycle Manager

Amazon Data Lifecycle Manager uses the following default service roles:

- **AWSDataLifecycleManagerDefaultRole**—default role for managing snapshots. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by snapshot and cross-account snapshot copy policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRole AWS managed policy.

- **AWSDataLifecycleManagerDefaultRoleForAMIManagement**—default role for managing AMIs. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by EBS-backed AMI policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRoleForAMIManagement AWS managed policy.

If you are using the Amazon Data Lifecycle Manager console, Amazon Data Lifecycle Manager automatically creates the AWSDataLifecycleManagerDefaultRole service role the first time you create a snapshot or cross-account snapshot copy policy, and it automatically creates the AWSDataLifecycleManagerDefaultRoleForAMIManagement service role the first time you create an EBS-backed AMI policy.

If you are not using the console, you can manually create the service roles using the create-default-role command. For --resource-type, specify snapshot to create AWSDataLifecycleManagerDefaultRole, or image to create AWSDataLifecycleManagerDefaultRoleForAMIManagement.

```
$ aws dlm create-default-role --resource-type snapshot|image
```

If you delete the default service roles, and then need to create them again, you can use the same process to recreate them in your account.

Custom service roles for Amazon Data Lifecycle Manager

As an alternative to using the default service roles, you can create custom IAM roles with the required permissions and then select them when you create a lifecycle policy.

To create a custom IAM role

1. Create roles with the following permissions.

   Permissions required for managing snapshot lifecycle policies

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "ec2:CreateSnapshot",
           "ec2:CreateSnapshots",
           "ec2:DeleteSnapshot",
           "ec2:DescribeInstances",
           "ec2:DescribeVolumes",
           "ec2:DescribeSnapshots",
           "ec2:EnableFastSnapshotRestores",
           "ec2:DescribeFastSnapshotRestores",
           "ec2:DisableFastSnapshotRestores",
           "ec2:CopySnapshot",
           "ec2:ModifySnapshotAttribute",
           "ec2:DescribeSnapshotAttribute"
         ],
         "Resource": "*"
       }
     ]
   }
   ```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Amazon Data Lifecycle Manager

```json
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateTags"
    ],
    "Resource": "arn:aws:ec2::*::snapshot/*"
},
{
    "Effect": "Allow",
    "Action": [
        "events:PutRule",
        "events:DeleteRule",
        "events:DescribeRule",
        "events:EnableRule",
        "events:DisableRule",
        "events:ListTargetsByRule",
        "events:PutTargets",
        "events:RemoveTargets"
    ],
    "Resource": "arn:aws:events::*:rule/AwsDataLifecycleRule.managed-cwe.*"
}
```  

- Permissions required for managing AMI lifecycle policies

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": [
                "arn:aws:ec2::*::snapshot/*",
                "arn:aws:ec2::*:image/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeImages",
                "ec2:DescribeInstances",
                "ec2:DescribeImageAttribute",
                "ec2:DescribeVolumes",
                "ec2:DescribeSnapshots"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DeleteSnapshot",
            "Resource": "arn:aws:ec2::*:snapshot/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:ResetImageAttribute",
                "ec2:DeregisterImage",
                "ec2:CreateImage",
                "ec2:CopyImage",
                "ec2:ModifyImageAttribute"
            ],
            "Resource": "*"
        }
    ]
}
```
For more information, see Creating a Role in the IAM User Guide.

2. Add a trust relationship to the roles.
   a. In the IAM console, choose Roles.
   b. Select the roles that you created, and then choose Trust relationships.
   c. Choose Edit Trust Relationship, add the following policy, and then choose Update Trust Policy.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "dlm.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

Permissions for IAM users

An IAM user must have the following permissions to use Amazon Data Lifecycle Manager.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iam:PassRole", "iam:ListRoles"],
      "Resource": "arn:aws:iam::123456789012:role/AWSDataLifecycleManagerDefaultRole"
    },
    {
      "Effect": "Allow",
      "Action": ["dlm:*"],
      "Resource": "*"
    }
  ]
}
```

For more information, see Changing Permissions for an IAM User in the IAM User Guide.

Permissions for encryption

If the source volume is encrypted, ensure that the Amazon Data Lifecycle Manager default roles (AWSDataLifecycleManagerDefaultRole and AWSDataLifecycleManagerDefaultRoleForAMIManagement) have permission to use the KMS keys used to encrypt the volume.

If you enable Cross Region copy for unencrypted snapshots or AMIs backed by unencrypted snapshots, and choose to enable encryption in the destination Region, ensure that the default roles have permission to use the KMS key needed to perform the encryption in the destination Region.

If you enable Cross Region copy for encrypted snapshots or AMIs backed by encrypted snapshots, ensure that the default roles have permission to use both the source and destination KMS keys.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.
Monitor the lifecycle of snapshots and AMIs

You can use the following features to monitor the lifecycle of your snapshots and AMIs.

Features

- Console and AWS CLI (p. 1315)
- AWS CloudTrail (p. 1315)
- Monitor your policies using CloudWatch Events (p. 1315)
- Monitor your policies using Amazon CloudWatch (p. 1316)

Console and AWS CLI

You can view your lifecycle policies using the Amazon EC2 console or the AWS CLI. Each snapshot and AMI created by a policy has a timestamp and policy-related tags. You can filter snapshots and AMIs using these tags to verify that your backups are being created as you intend. For information about viewing lifecycle policies using the console, see View lifecycle policies (p. 1305).

AWS CloudTrail

With AWS CloudTrail, you can track user activity and API usage to demonstrate compliance with internal policies and regulatory standards. For more information, see the AWS CloudTrail User Guide.

Monitor your policies using CloudWatch Events

Amazon EBS and Amazon Data Lifecycle Manager emit events related to lifecycle policy actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the Amazon CloudWatch Events User Guide.

The following events are available:

**Note**

No events are emitted for AMI lifecycle policy actions.

- createSnapshot—An Amazon EBS event emitted when a CreateSnapshot action succeeds or fails. For more information, see Amazon CloudWatch Events for Amazon EBS (p. 1397).
- DLM Policy State Change—An Amazon Data Lifecycle Manager event emitted when a lifecycle policy enters an error state. The event contains a description of what caused the error. The following is an example of an event when the permissions granted by the IAM role are insufficient.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "DLM Policy State Change",
    "source": "aws.dlm",
    "account": "123456789012",
    "time": "2018-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    ],
    "detail": {
        "state": "ERROR",
        "cause": "Role provided does not have sufficient permissions",
        "policy_id": "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    }
}
```
The following is an example of an event when a limit is exceeded.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "DLM Policy State Change",
    "source": "aws.dlm",
    "account": "123456789012",
    "time": "2018-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    ],
    "detail": {
        "state": "ERROR",
        "cause": "Maximum allowed active snapshot limit exceeded",
        "policy_id": "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    }
}
```

**Monitor your policies using Amazon CloudWatch**

You can monitor your Amazon Data Lifecycle Manager lifecycle policies using CloudWatch, which collects raw data and processes it into readable, near-real-time metrics. You can use these metrics to see exactly how many Amazon EBS snapshots and EBS-backed AMIs are created, deleted, and copied by your policies over time. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met.

Metrics are kept for a period of 15 months, so that you can access historical information and gain a better understanding of how your lifecycle policies perform over an extended period.

For more information about Amazon CloudWatch, see the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/).

**Topics**

- Supported metrics (p. 1316)
- View CloudWatch metrics for your policies (p. 1319)
- Graph metrics for your policies (p. 1320)
- Create a CloudWatch alarm for a policy (p. 1321)
- Example use cases (p. 143)
- Managing policies that report failed actions (p. 1323)

**Supported metrics**

The Data Lifecycle Manager namespace includes the following metrics for Amazon Data Lifecycle Manager lifecycle policies. The supported metrics differ by policy type.

All metrics can be measured on the **DLMPolicyId** dimension. The most useful statistics are **sum** and **average**, and the unit of measure is **count**.

Choose a tab to view the metrics supported by that policy type.
### EBS snapshot policies

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourcesTargeted</td>
<td>The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.</td>
</tr>
<tr>
<td>SnapshotsCreateStarted</td>
<td>The number of snapshot create actions initiated by a snapshot policy. Each action is recorded only once, even if there are multiple subsequent retries.</td>
</tr>
<tr>
<td></td>
<td>If a snapshot create action fails, Amazon Data Lifecycle Manager sends a SnapshotsCreateFailed metric.</td>
</tr>
<tr>
<td>SnapshotsCreateCompleted</td>
<td>The number of snapshots created by a snapshot policy. This includes successful retries within 60 minutes of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCreateFailed</td>
<td>The number of snapshots that could not be created by a snapshot policy. This includes unsuccessful retries within 60 minutes from the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsSharedCompleted</td>
<td>The number of snapshots shared across accounts by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsDeleteCompleted</td>
<td>The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsDeleteFailed</td>
<td>The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionStarted</td>
<td>The number of cross-Region snapshot copy actions initiated by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionCompleted</td>
<td>The number of cross-Region snapshot copies created by a snapshot policy. This includes successful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionFailed</td>
<td>The number of cross-Region snapshot copies that could not be created by a snapshot policy. This includes unsuccessful retries within 24 hours from the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteCompleted</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
</tbody>
</table>

### EBS-backed AMI policies

The following metrics can be used with EBS-backed AMI policies:
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourcesTargeted</td>
<td>The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.</td>
</tr>
<tr>
<td>SnapshotsDeleteCompleted</td>
<td>The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsDeleteFailed</td>
<td>The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegion</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>ImagesCreateStarted</td>
<td>The number of <code>CreateImage</code> actions initiated by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCreateCompleted</td>
<td>The number of AMIs created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCreateFailed</td>
<td>The number of AMIs that could not be created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesDeregisterCompleted</td>
<td>The number of AMIs deregistered by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesDeregisterFailed</td>
<td>The number of AMIs that could not be deregistered by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegion</td>
<td>The number of cross-Region copy actions initiated by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegionCompleted</td>
<td>The number of cross-Region AMI copies created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegionFailed</td>
<td>The number of cross-Region AMI copies that could not be created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegionDeregisterCompleted</td>
<td>The number of cross-Region AMI copies deregistered, as designated by the retention rule, by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegionDeregisterFailed</td>
<td>The number of cross-Region AMI copies that could not be deregistered, as designated by the retention rule, by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>EnableImageDeprecation</td>
<td>The number of AMIs that were marked for deprecation by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>EnableImageDeprecationFailed</td>
<td>The number of AMIs that could not be marked for deprecation by an EBS-backed AMI policy.</td>
</tr>
</tbody>
</table>
### Cross-account copy event policies

The following metrics can be used with cross-account copy event policies:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SnapshotsCopiedAccountStarted</td>
<td>The number of cross-account snapshot copy actions initiated by a cross-account copy event policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountCompleted</td>
<td>The number of snapshots copied from another account by a cross-account copy event policy. This includes successful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountFailed</td>
<td>The number of snapshots that could not be copied from another account by a cross-account copy event policy. This includes unsuccessful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountDeleteCompleted</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a cross-account copy event policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a cross-account copy event policy.</td>
</tr>
</tbody>
</table>

### View CloudWatch metrics for your policies

You can use the AWS Management Console or the command line tools to list the metrics that Amazon Data Lifecycle Manager sends to Amazon CloudWatch.

**Amazon EC2 console**

**To view metrics using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Lifecycle Manager*.
3. Select a policy in the grid and then choose the *Monitoring* tab.

**CloudWatch console**

**To view metrics using the Amazon CloudWatch console**

2. In the navigation pane, choose *Metrics*.
3. Select the *EBS* namespace and then select *Data Lifecycle Manager metrics*.

**AWS CLI**

**To list all the available metrics for Amazon Data Lifecycle Manager**
Use the `list-metrics` command.

```bash
# aws cloudwatch list-metrics --namespace AWS/EBS
```

**To list all the metrics for a specific policy**

Use the `list-metrics` command and specify the `DLMPolicyId` dimension.

```bash
# aws cloudwatch list-metrics --namespace AWS/EBS --dimensions
   Name=DLMPolicyId,Value=policy-abcdef01234567890
```

**To list a single metric across all policies**

Use the `list-metrics` command and specify the `--metric-name` option.

```bash
# aws cloudwatch list-metrics --namespace AWS/EBS --metric-name
   SnapshotsCreateCompleted
```

**Graph metrics for your policies**

After you create a policy, you can open the Amazon EC2 console and view the monitoring graphs for the policy on the **Monitoring** tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs metrics are available:

- Resources targeted (based on `ResourcesTargeted`)
- Snapshot creation started (based on `SnapshotsCreateStarted`)
- Snapshot creation completed (based on `SnapshotsCreateCompleted`)
- Snapshot creation failed (based on `SnapshotsCreateFailed`)
- Snapshot sharing completed (based on `SnapshotsSharedCompleted`)
- Snapshot deletion completed (based on `SnapshotsDeleteCompleted`)
- Snapshot deletion failed (based on `SnapshotsDeleteFailed`)
- Snapshot cross-Region copy started (based on `SnapshotsCopiedRegionStarted`)
- Snapshot cross-Region copy completed (based on `SnapshotsCopiedRegionCompleted`)
- Snapshot cross-Region copy failed (based on `SnapshotsCopiedRegionFailed`)
- Snapshot cross-Region copy deletion completed (based on `SnapshotsCopiedRegionDeleteCompleted`)
- Snapshot cross-Region copy deletion failed (based on `SnapshotsCopiedRegionDeleteFailed`)
- Snapshot cross-account copy started (based on `SnapshotsCopiedAccountStarted`)
- Snapshot cross-account copy completed (based on `SnapshotsCopiedAccountCompleted`)
- Snapshot cross-account copy failed (based on `SnapshotsCopiedAccountFailed`)
- Snapshot cross-account copy deletion completed (based on `SnapshotsCopiedAccountDeleteCompleted`)
- Snapshot cross-account copy deletion failed (based on `SnapshotsCopiedAccountDeleteFailed`)
- AMI creation started (based on `ImagesCreateStarted`)
- AMI creation completed (based on `ImagesCreateCompleted`)
- AMI creation failed (based on `ImagesCreateFailed`)
• AMI deregistration completed (based on ImagesDeregisterCompleted)
• AMI deregistration failed (based on ImagesDeregisterFailed)
• AMI cross-Region copy started (based on ImagesCopiedRegionStarted)
• AMI cross-Region copy completed (based on ImagesCopiedRegionCompleted)
• AMI cross-Region copy failed (based on ImagesCopiedRegionFailed)
• AMI cross-Region copy deregistration completed (based on ImagesCopiedRegionDeregisterCompleted)
• AMI cross-Region copy deregister failed (based on ImagesCopiedRegionDeregisterFailed)
• AMI enable deprecation completed (based on EnableImageDeprecationCompleted)
• AMI enable deprecation failed (based on EnableImageDeprecationFailed)
• AMI cross-Region copy enable deprecation completed (based on EnableCopiedImageDeprecationCompleted)
• AMI cross-Region copy enable deprecation failed (based on EnableCopiedImageDeprecationFailed)

Create a CloudWatch alarm for a policy

You can create a CloudWatch alarm that monitors CloudWatch metrics for your policies. CloudWatch will automatically send you a notification when the metric reaches a threshold that you specify. You can create a CloudWatch alarm using the CloudWatch console.

For more information about creating alarms using the CloudWatch console, see the following topic in the Amazon CloudWatch User Guide.

• Create a CloudWatch Alarm Based on a Static Threshold
• Create a CloudWatch Alarm Based on Anomaly Detection

Example use cases

The following are example use cases.

Topics

• Example 1: ResourcesTargeted metric (p. 1321)
• Example 2: SnapshotDeleteFailed metric (p. 1322)
• Example 3: SnapshotsCopiedRegionFailed metric (p. 1322)

Example 1: ResourcesTargeted metric

You can use the ResourcesTargeted metric to monitor the total number of resources that are targeted by a specific policy each time it is run. This enables you to trigger an alarm when the number of targeted resources is below or above an expected threshold.

For example, if you expect your daily policy to create backups of no more than 50 volumes, you can create an alarm that sends an email notification when the sum for ResourcesTargeted is greater than 50 over a 1 hour period. In this way, you can ensure that no snapshots have been unexpectedly created from volumes that have been incorrectly tagged.

You can use the following command to create this alarm:

```
$ aws cloudwatch put-metric-alarm \ 
   --alarm-name resource-targeted-monitor \ 
```
Example 2: SnapshotDeleteFailed metric

You can use the SnapshotDeleteFailed metric to monitor for failures to delete snapshots as per the policy's snapshot retention rule.

For example, if you've created a policy that should automatically delete snapshots every twelve hours, you can create an alarm that notifies your engineering team when the sum of SnapshotDeleteFailed is greater than 0 over a 1 hour period. This could help to investigate improper snapshot retention and to ensure that your storage costs are not increased by unnecessary snapshots.

You can use the following command to create this alarm:

```
$ aws cloudwatch put-metric-alarm
--alarm-name snapshot-deletion-failed-monitor
--alarm-description "Alarm when snapshot deletions fail"
--metric-name SnapshotsDeleteFailed
--namespace AWS/EBS
--statistic Sum
--period 3600
--threshold 0
--comparison-operator GreaterThanThreshold
--dimensions "Name=DLMPolicyId,Value=policy_id"
--evaluation-periods 1
--alarm-actions sns_topic_arn
```

Example 3: SnapshotsCopiedRegionFailed metric

Use the SnapshotsCopiedRegionFailed metric to identify when your policies fail to copy snapshots to other Regions.

For example, if your policy copies snapshots across Regions daily, you can create an alarm that sends an SMS to your engineering team when the sum of SnapshotCrossRegionCopyFailed is greater than 0 over a 1 hour period. This can useful for verifying whether subsequent snapshots in the lineage were successfully copied by the policy.

You can use the following command to create this alarm:

```
$ aws cloudwatch put-metric-alarm
--alarm-name snapshot-copy-region-failed-monitor
--alarm-description "Alarm when snapshot copy fails"
--metric-name SnapshotsCopiedRegionFailed
--namespace AWS/EBS
--statistic Sum
--period 3600
--threshold 0
--comparison-operator GreaterThanThreshold
--dimensions "Name=DLMPolicyId,Value=policy_id"
--evaluation-periods 1
--alarm-actions sns_topic_arn
```
Managing policies that report failed actions

For more information about what to do when one of your policies reports an unexpected non-zero value for a failed action metric, see the What should I do if Amazon Data Lifecycle Manager reports failed actions in CloudWatch metrics? AWS Knowledge Center article.

Amazon EBS data services

Amazon EBS provides the following data services.

Data services

- Amazon EBS Elastic Volumes (p. 1323)
- Amazon EBS encryption (p. 1335)
- Amazon EBS fast snapshot restore (p. 1346)

Amazon EBS Elastic Volumes

With Amazon EBS Elastic Volumes, you can increase the volume size, change the volume type, or adjust the performance of your EBS volumes. If your instance supports Elastic Volumes, you can do so without detaching the volume or restarting the instance. This enables you to continue using your application while the changes take effect.

There is no charge to modify the configuration of a volume. You are charged for the new volume configuration after volume modification starts. For more information, see the Amazon EBS Pricing page.

Contents

- Requirements when modifying volumes (p. 1323)
- Request modifications to your EBS volumes (p. 1325)
- Monitor the progress of volume modifications (p. 1328)
- Extend a Linux file system after resizing a volume (p. 1331)

Requirements when modifying volumes

The following requirements and limitations apply when you modify an Amazon EBS volume. To learn more about the general requirements for EBS volumes, see Constraints on the size and configuration of an EBS volume (p. 1197).

Topics

- Supported instance types (p. 1323)
- Requirements for Linux volumes (p. 1324)
- Limitations (p. 1324)

Supported instance types

Elastic Volumes are supported on the following instances:

- All current-generation instances (p. 194)
- The following previous-generation instances: C1, C3, CC2, CR1, G2, I2, M1, M3, and R3
If your instance type does not support Elastic Volumes, see Modify an EBS volume if Elastic Volumes is not supported (p. 1328).

Requirements for Linux volumes

Linux AMIs require a GUID partition table (GPT) and GRUB 2 for boot volumes that are 2 TiB (2,048 GiB) or larger. Many Linux AMIs today still use the MBR partitioning scheme, which only supports boot volume sizes up to 2 TiB. If your instance does not boot with a boot volume larger than 2 TiB, the AMI you are using may be limited to a boot volume size of less than 2 TiB. Non-boot volumes do not have this limitation on Linux instances. For requirements affecting Windows volumes, see Requirements for Windows volumes in the Amazon EC2 User Guide for Windows Instances.

Before attempting to resize a boot volume beyond 2 TiB, you can determine whether the volume is using MBR or GPT partitioning by running the following command on your instance:

```bash
[ec2-user ~]$ sudo gdisk -l /dev/xvda
```

An Amazon Linux instance with GPT partitioning returns the following information:

```
GPT fdisk (gdisk) version 0.8.10
Partition table scan:
  MBR: protective
  BSD: not present
  APM: not present
  GPT: present

Found valid GPT with protective MBR; using GPT.
```

A SUSE instance with MBR partitioning returns the following information:

```
GPT fdisk (gdisk) version 0.8.8
Partition table scan:
  MBR: MBR only
  BSD: not present
  APM: not present
  GPT: not present
```

Limitations

- There are limits to the maximum aggregated storage that can be requested across volume modifications. For more information, see Amazon EBS service quotas in the Amazon Web Services General Reference.
- After modifying a volume, you must wait at least six hours and ensure that the volume is in the in-use or available state before you can modify the same volume. This is sometimes referred to as a cooldown period.
- If the volume was attached before November 3, 2016 23:40 UTC, you must initialize Elastic Volumes support. For more information, see Initializing Elastic Volumes Support (p. 1326).
- If you encounter an error message while attempting to modify an EBS volume, or if you are modifying an EBS volume attached to a previous-generation instance type, take one of the following steps:
  - For a non-root volume, detach the volume from the instance, apply the modifications, and then re-attach the volume.
  - For a root volume, stop the instance, apply the modifications, and then restart the instance.
- Modification time is increased for volumes that are not fully initialized. For more information see Initialize Amazon EBS volumes (p. 1381).
• The new volume size can't exceed the supported capacity of its file system and partitioning scheme. For more information, see Constraints on the size and configuration of an EBS volume (p. 1197).

• If you modify the volume type of a volume, the size and performance must be within the limits of the target volume type. For more information, see Amazon EBS volume types (p. 1179).

• You can't decrease the size of an EBS volume. However, you can create a smaller volume and then migrate your data to it using an application-level tool such as rsync.

• After provisioning over 32,000 IOPS on an existing io1 or io2 volume, you might need to detach and re-attach the volume, or restart the instance to see the full performance improvements.

• For io2 volumes, you can't increase the size beyond 16 TiB or the IOPS beyond 64,000 while the volume is attached to an instance type that does not support io2 Block Express volumes. Currently, only R5b instances support io2 Block Express volumes. For more information, see io2 Block Express volumes (p. 1188).

• You can't modify the size or provisioned IOPS of an io2 volume that is attached to an R5b instance.

• You can't modify the volume type of Multi-Attach enabled io2 volumes.

• You can't modify the volume type, size, or Provisioned IOPS of Multi-Attach enabled io1 volumes.

• A gp2 volume that is attached to an instance as a root volume can't be modified to an st1 or sc1 volume. If detached and modified to st1 or sc1, it can't be re-attached to an instance as the root volume.

• While m3.medium instances fully support volume modification, m3.large, m3.xlarge, and m3.2xlarge instances might not support all volume modification features.

Request modifications to your EBS volumes

With Elastic Volumes, you can dynamically increase the size, increase or decrease the performance, and change the volume type of your Amazon EBS volumes without detaching them.

Use the following process when modifying a volume:

1. (Optional) Before modifying a volume that contains valuable data, it is a best practice to create a snapshot of the volume in case you need to roll back your changes. For more information, see Create Amazon EBS snapshots (p. 1231).

2. Request the volume modification.

3. Monitor the progress of the volume modification. For more information, see Monitor the progress of volume modifications (p. 1328).

4. If the size of the volume was modified, extend the volume's file system to take advantage of the increased storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 1331).

Contents

• Modify an EBS volume using Elastic Volumes (p. 1325)

• Initialize Elastic Volumes support (if needed) (p. 1326)

• Modify an EBS volume if Elastic Volumes is not supported (p. 1328)

Modify an EBS volume using Elastic Volumes

You can only increase volume size. You can increase or decrease volume performance. If you are not changing the volume type, then volume size and performance modifications must be within the limits of the current volume type. If you are changing the volume type, then volume size and performance modifications must be within the limits of the target volume type.

To modify an EBS volume, use one of the following methods.
Console

To modify an EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Volumes, select the volume to modify, and then choose Actions, Modify Volume.
3. The Modify Volume window displays the volume ID and the volume's current configuration, including type, size, IOPS, and throughput. Set new configuration values as follows:
   - To modify the type, choose a value for Volume Type.
   - To modify the size, enter a new value for Size.
   - To modify the IOPS, if the volume type is gp3, io1, or io2, enter a new value for IOPS.
   - To modify the throughput, if the volume type is gp3, enter a new value for Throughput.
4. After you have finished changing the volume settings, choose Modify. When prompted for confirmation, choose Yes.
5. Modifying volume size has no practical effect until you also extend the volume's file system to make use of the new storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 1331).

AWS CLI

To modify an EBS volume using the AWS CLI

Use the modify-volume command to modify one or more configuration settings for a volume. For example, if you have a volume of type gp2 with a size of 100 GiB, the following command changes its configuration to a volume of type io1 with 10,000 IOPS and a size of 200 GiB.

```
aws ec2 modify-volume --volume-type io1 --iops 10000 --size 200 --volume-id vol-11111111111111111
```

The following is example output:

```
{
   "VolumeModification": {
       "TargetSize": 200,
       "TargetVolumeType": "io1",
       "ModificationState": "modifying",
       "VolumeId": "vol-11111111111111111",
       "TargetIops": 10000,
       "StartTime": "2017-01-19T22:21:02.959Z",
       "Progress": 0,
       "OriginalVolumeType": "gp2",
       "OriginalIops": 300,
       "OriginalSize": 100
   }
}
```

Modifying volume size has no practical effect until you also extend the volume's file system to make use of the new storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 1331).

Initialize Elastic Volumes support (if needed)

Before you can modify a volume that was attached to an instance before November 3, 2016 23:40 UTC, you must initialize volume modification support using one of the following actions:
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS data services

- Detach and attach the volume
- Stop and start the instance

Use one of the following procedures to determine whether your instances are ready for volume modification.

New console

To determine whether your instances are ready using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose Instances.
3. Choose the Show/Hide Columns icon (the gear). Select the Launch time attribute column and then choose Confirm.
4. Sort the list of instances by the Launch Time column. For each instance that was started before the cutoff date, choose the Storage tab and check the Attachment time column to see when its volumes were attached.

Old console

To determine whether your instances are ready using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose Instances.
3. Choose the Show/Hide Columns icon (the gear). Select the Launch Time and Block Devices attributes and then choose Close.
4. Sort the list of instances by the Launch Time column. For instances that were started before the cutoff date, check when the devices were attached. In the following example, you must initialize volume modification for the first instance because it was started before the cutoff date and its root volume was attached before the cutoff date. The other instances are ready because they were started after the cutoff date.

AWS CLI

To determine whether your instances are ready using the CLI

Use the following describe-instances command to determine whether the volume was attached before November 3, 2016 23:40 UTC.

```
aws ec2 describe-instances --query "Reservations[*].Instances[*].[InstanceId,LaunchTime<='2016-11-01',BlockDeviceMappings[*][Ebs.AttachTime<='2016-11-01']]" --output text
```

The first line of the output for each instance shows its ID and whether it was started before the cutoff date (True or False). The first line is followed by one or more lines that show whether each EBS volume was attached before the cutoff date (True or False). In the following example output, you must initialize volume modification for the first instance because it was started before the cutoff date and its root volume was attached before the cutoff date. The other instances are ready because they were started after the cutoff date.
Modify an EBS volume if Elastic Volumes is not supported

If you are using a supported instance type, you can use Elastic Volumes to dynamically modify the size, performance, and volume type of your Amazon EBS volumes without detaching them.

If you cannot use Elastic Volumes but you need to modify the root (boot) volume, you must stop the instance, modify the volume, and then restart the instance.

After the instance has started, you can check the file system size to see if your instance recognizes the larger volume space. On Linux, use the `df -h` command to check the file system size.

```bash
[ec2-user ~]$ df -h
Filesystem      Size  Used Avail Use% Mounted on
/dev/xvda1      7.9G  943M  6.9G  12% /
/tmpfs           1.9G     0  1.9G   0% /dev/shm
```

If the size does not reflect your newly expanded volume, you must extend the file system of your device so that your instance can use the new space. For more information, see Extend a Linux file system after resizing a volume (p. 1331).

Monitor the progress of volume modifications

When you modify an EBS volume, it goes through a sequence of states. The volume enters the modifying state, the optimizing state, and finally the completed state. At this point, the volume is ready to be further modified.

**Note**

Rarely, a transient AWS fault can result in a failed state. This is not an indication of volume health; it merely indicates that the modification to the volume failed. If this occurs, retry the volume modification.

While the volume is in the optimizing state, your volume performance is in between the source and target configuration specifications. Transitional volume performance will be no less than the source volume performance. If you are downgrading IOPS, transitional volume performance is no less than the target volume performance.

Volume modification changes take effect as follows:

- Size changes usually take a few seconds to complete and take effect after the volume has transitioned to the Optimizing state.
- Performance (IOPS) changes can take from a few minutes to a few hours to complete and are dependent on the configuration change being made.
- It might take up to 24 hours for a new configuration to take effect, and in some cases more, such as when the volume has not been fully initialized. Typically, a fully used 1-TiB volume takes about 6 hours to migrate to a new performance configuration.

To monitor the progress of a volume modification, use one of the following methods.
To monitor progress of a modification using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume.
4. The State column and the State field in the details pane contain information in the following format: volume-state - modification-state (progress%). The possible volume states are creating, available, in-use, deleting, deleted, and error. The possible modification states are modifying, optimizing, and completed. Shortly after the volume modification is completed, we remove the modification state and progress, leaving only the volume state.

In this example, the modification state of the selected volume is optimizing. The modification state of the next volume is modifying.

5. Choose the text in the State field in the details pane to display information about the most recent modification action, as shown in the previous step.

To monitor progress of a modification using the AWS CLI

Use the describe-volumes-modifications command to view the progress of one or more volume modifications. The following example describes the volume modifications for two volumes.

aws ec2 describe-volumes-modifications --volume-ids vol-11111111111111111 vol-22222222222222222

In the following example output, the volume modifications are still in the modifying state. Progress is reported as a percentage.

```json
{
   "VolumesModifications": [
      {
         "TargetSize": 200,
         "TargetVolumeType": "io1",
         "ModificationState": "modifying",
         "VolumeId": "vol-11111111111111111"
      }
   ]
}
```
The next example describes all volumes with a modification state of either optimizing or completed, and then filters and formats the results to show only modifications that were initiated on or after February 1, 2017:

```bash
aws ec2 describe-volumes-modifications --filters Name=modification-state,Values="optimizing","completed" --query "VolumesModifications[?StartTime>='2017-02-01'].{ID:VolumeId,STATE:ModificationState}"
```

The following is example output with information about two volumes:

```
[
  {
    "STATE": "optimizing",
    "ID": "vol-06397e7a0eEXAMPLE"
  },
  {
    "STATE": "completed",
    "ID": "vol-ba74e18c2aEXAMPLE"
  }
]
```

CloudWatch Events console

With CloudWatch Events, you can create a notification rule for volume modification events. You can use your rule to generate a notification message using Amazon SNS or to invoke a Lambda function in response to matching events. Events are emitted on a best effort basis.

**To monitor progress of a modification using CloudWatch Events**

2. Choose Events, Create rule.
3. For Build event pattern to match events by service, choose Custom event pattern.
4. For Build custom event pattern, replace the contents with the following and choose Save.

```json
{
  "source": [
    "aws.ec2"
  ],
```
Extend a Linux file system after resizing a volume

After you increase the size of an EBS volume (p. 1325), you must use file system–specific commands to extend the file system to the larger size. You can resize the file system as soon as the volume enters the optimizing state.

Important
Before extending a file system that contains valuable data, it is best practice to create a snapshot of the volume, in case you need to roll back your changes. For more information, see Create Amazon EBS snapshots (p. 1231). If your Linux AMI uses the MBR partitioning scheme, you are limited to a boot volume size of up to 2 TiB. For more information, see Requirements for Linux volumes (p. 1324) and Constraints on the size and configuration of an EBS volume (p. 1197).

The process for extending a file system on Linux is as follows:

1. Your EBS volume might have a partition that contains the file system and data. Increasing the size of a volume does not increase the size of the partition. Before you extend the file system on a resized volume, check whether the volume has a partition that must be extended to the new size of the volume.
2. Use a file system-specific command to resize each file system to the new volume capacity.

For information about extending a Windows file system, see Extend a Windows file system after resizing a volume in the Amazon EC2 User Guide for Windows Instances.

The following examples walk you through the process of extending a Linux file system. For file systems and partitioning schemes other than the ones shown here, refer to the documentation for those file systems and partitioning schemes for instructions.
Note

If you are using logical volumes on the Amazon EBS volume, you must use Logical Volume Manager (LVM) to extend the logical volume. For instructions on how to do this, see the Extend the logical volume section in the How do I create an LVM logical volume on an entire EBS volume? AWS Knowledge Center article.

Examples

- Example: Extend the file system of NVMe EBS volumes (p. 1332)
- Example: Extend the file system of EBS volumes (p. 1333)

Example: Extend the file system of NVMe EBS volumes

For this example, suppose that you have an instance built on the Nitro System (p. 199), such as an M5 instance. You resized the boot volume from 8 GB to 16 GB and an additional volume from 8 GB to 30 GB. Use the following procedure to extend the file system of the resized volumes.

To extend the file system of NVMe EBS volumes

1. Connect to your instance (p. 499).
2. To verify the file system for each volume, use the `df -hT` command.

```
[ec2-user ~]# df -hT
```

The following is example output for an instance that has a boot volume with an XFS file system and an additional volume with an XFS file system. The naming convention `/dev/nvme[0-26]n1` indicates that the volumes are exposed as NVMe block devices.

```
[ec2-user ~]# df -hT
Filesystem  Type  Size  Used  Avail  Use%  Mounted on
/dev/nvme0n1p1  xfs   8.0G  1.6G  6.5G   20%  /
/dev/nvme1n1  xfs   8.0G   33M  8.0G    1%  /data
...
```

3. To check whether the volume has a partition that must be extended, use the `lsblk` command to display information about the NVMe block devices attached to your instance.

```
[ec2-user ~]# lsblk
NAME       MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme1n1    259:0   0  30G  0 disk /data
nvme0n1    259:1   0  16G  0 disk
##nvme0n1p1  259:2   0   8G  0 part /
##nvme0n1p128 259:3   0   1M  0 part
```

This example output shows the following:

- The root volume, `/dev/nvme0n1`, has a partition, `/dev/nvme0n1p1`. While the size of the root volume reflects the new size, 16 GB, the size of the partition reflects the original size, 8 GB, and must be extended before you can extend the file system.
- The volume `/dev/nvme1n1` has no partitions. The size of the volume reflects the new size, 30 GB.

4. For volumes that have a partition, such as the root volume shown in the previous step, use the `growpart` command to extend the partition. Notice that there is a space between the device name and the partition number.

```
[ec2-user ~]# sudo growpart /dev/nvme0n1 1
```
5. (Optional) To verify that the partition reflects the increased volume size, use the `lsblk` command again.

```
[ec2-user ~]# lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme1n1       259:0    0  30G  0 disk /data
nvme0n1       259:1    0  16G  0 disk
##nvme0n1p1   259:2    0  16G  0 part /
##nvme0n1p128 259:3    0   1M  0 part
```

6. To verify the size of the file system for each volume, use the `df -h` command. In this example output, both file systems reflect the original volume size, 8 GB.

```
[ec2-user ~]# df -h
Filesystem       Size  Used Avail Use% Mounted on
/dev/nvme0n1p1   8.0G  1.6G  6.5G  20% /
/dev/nvme1n1     8.0G   33M  8.0G   1% /data
...```

7. To extend the file system on each volume, use the correct command for your file system, as follows:

- [XFS file system] To extend the file system on each volume, use the `xfs_growfs` command. In this example, `/` and `/data` are the volume mount points shown in the output for `df -h`.

```
[ec2-user ~]# sudo xfs_growfs -d /
[ec2-user ~]# sudo xfs_growfs -d /data
```

If the XFS tools are not already installed, you can install them as follows.

```
[ec2-user ~]# sudo yum install xfsprogs
```

- [ext4 file system] To extend the file system on each volume, use the `resize2fs` command.

```
[ec2-user ~]# sudo resize2fs /dev/nvme0n1p1
[ec2-user ~]# sudo resize2fs /dev/nvme1n1
```

- [Other file system] To extend the file system on each volume, refer to the documentation for your file system for instructions.

8. (Optional) To verify that each file system reflects the increased volume size, use the `df -h` command again.

```
[ec2-user ~]# df -h
Filesystem       Size  Used Avail Use% Mounted on
/dev/nvme0n1p1    16G  1.6G  15G  10% /
/dev/nvme1n1      30G   33M  30G   1% /data
...```

**Example: Extend the file system of EBS volumes**

For this example, suppose that you have resized the boot volume of an instance, such as a T2 instance, from 8 GB to 16 GB and an additional volume from 8 GB to 30 GB. Use the following procedure to extend the file system of the resized volumes.

**To extend the file system of EBS volumes**

1. Connect to your instance (p. 499).
2. To verify the file system in use for each volume, use the `df -hT` command.
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS data services

```
[ec2-user ~]$ df -hT
```

The following is example output for an instance that has a boot volume with an ext4 file system and an additional volume with an XFS file system.

```
[ec2-user ~]$ df -hT
Filesystem        Type  Size  Used  Avail Use% Mounted on  
/dev/xvda1        ext4   8.0G   1.9G   6.2G  24% /  
/dev/xvdf1        xfs    8.0G   45M   8.0G   1% /data  
...
```

3. To check whether the volume has a partition that must be extended, use the `lsblk` command to display information about the block devices attached to your instance.

```
[ec2-user ~]$ lsblk
NAME       MAJ:MIN  RM  SIZE RO  TYPE MOUNTPOINT
xvda        202:0   0 16G  0  disk  
    #xvda1 202:1   0  8G  0  part  /  
    #xvdf   202:80  0 30G  0  disk  
    #xvdf1 202:81  0  8G  0  part  /data  
```

This example output shows the following:

- The root volume, `/dev/xvda`, has a partition, `/dev/xvda1`. While the size of the volume is 16 GB, the size of the partition is still 8 GB and must be extended.
- The volume `/dev/xvdf` has a partition, `/dev/xvdf1`. While the size of the volume is 30G, the size of the partition is still 8 GB and must be extended.

4. For volumes that have a partition, such as the volumes shown in the previous step, use the `growpart` command to extend the partition. Notice that there is a space between the device name and the partition number.

```
[ec2-user ~]$ sudo growpart /dev/xvda 1
[ec2-user ~]$ sudo growpart /dev/xvdf 1
```

5. (Optional) To verify that the partitions reflect the increased volume size, use the `lsblk` command again.

```
[ec2-user ~]$ lsblk
NAME       MAJ:MIN  RM  SIZE RO  TYPE MOUNTPOINT
xvda        202:0   0 16G  0  disk  
    #xvda1 202:1   0  8G  0  part  /  
    #xvdf   202:80  0 30G  0  disk  
    #xvdf1 202:81  0  8G  0  part  /data  
```

6. To verify the size of the file system for each volume, use the `df -h` command. In this example output, both file systems reflect the original volume size, 8 GB.

```
[ec2-user ~]$ df -h
Filesystem   Size  Used  Avail Use% Mounted on  
/dev/xvda1    8.0G  1.9G  6.2G  24% /  
/dev/xvdf1    8.0G   45M  8.0G   1% /data  
...
```

7. To extend the file system on each volume, use the correct command for your file system, as follows:

- [XFS volumes] To extend the file system on each volume, use the `xfs_growfs` command. In this example, `/` and `/data` are the volume mount points shown in the output for `df -h`. 

If the XFS tools are not already installed, you can install them as follows.

```
[ec2-user ~]$ sudo xfs_growfs -d /
[ec2-user ~]$ sudo xfs_growfs -d /data
```

- [ext4 volumes] To extend the file system on each volume, use the `resize2fs` command.

```
[ec2-user ~]$ sudo resize2fs /dev/xvda1
[ec2-user ~]$ sudo resize2fs /dev/xvdf1
```

- [Other file system] To extend the file system on each volume, refer to the documentation for your file system for instructions.

8. (Optional) To verify that each file system reflects the increased volume size, use the `df -h` command again.

```
[ec2-user ~]$ df -h
Filesystem  Size  Used  Avail  Use%  Mounted on
/dev/xvda1  16G  1.9G   14G   12%  /
/dev/xvdf1  30G  45M   30G    1%  /data
...       
```

## Amazon EBS encryption

Use Amazon EBS encryption as a straightforward encryption solution for your EBS resources associated with your EC2 instances. With Amazon EBS encryption, you aren't required to build, maintain, and secure your own key management infrastructure. Amazon EBS encryption uses AWS KMS keys when creating encrypted volumes and snapshots.

Encryption operations occur on the servers that host EC2 instances, ensuring the security of both data-at-rest and data-in-transit between an instance and its attached EBS storage.

You can attach both encrypted and unencrypted volumes to an instance simultaneously.

### Contents

- How EBS encryption works (p. 1335)
- Requirements (p. 1337)
- Default KMS key for EBS encryption (p. 1337)
- Encryption by default (p. 1338)
- Encrypt EBS resources (p. 1339)
- Encryption scenarios (p. 1340)
- Set encryption defaults using the API and CLI (p. 1345)

### How EBS encryption works

You can encrypt both the boot and data volumes of an EC2 instance.

When you create an encrypted EBS volume and attach it to a supported instance type, the following types of data are encrypted:

- Data at rest inside the volume
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS data services

- All data moving between the volume and the instance
- All snapshots created from the volume
- All volumes created from those snapshots

EBS encrypts your volume with a data key using the industry-standard AES-256 algorithm. Your data key is stored on disk with your encrypted data, but not before EBS encrypts it with your KMS key. Your data key never appears on disk in plaintext. The same data key is shared by snapshots of the volume and any subsequent volumes created from those snapshots. For more information, see Data keys in the AWS Key Management Service Developer Guide.

Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes in slightly different ways depending on whether the snapshot from which you create an encrypted volume is encrypted or unencrypted.

**How EBS encryption works when the snapshot is encrypted**

When you create an encrypted volume from an encrypted snapshot that you own, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a GenerateDataKeyWithoutPlaintext request to AWS KMS, specifying the KMS key that you chose for volume encryption.
2. AWS KMS generates a new data key, encrypts it under the KMS key that you chose for volume encryption, and sends the encrypted data key to Amazon EBS to be stored with the volume metadata.
3. When you attach the encrypted volume to an instance, Amazon EC2 sends a CreateGrant request to AWS KMS so that it can decrypt the data key.
4. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
5. Amazon EC2 uses the plaintext data key in hypervisor memory to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

**How EBS encryption works when the snapshot is unencrypted**

When you create an encrypted volume from unencrypted snapshot, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a CreateGrant request to AWS KMS, so that it can encrypt the volume that is created from the snapshot.
2. Amazon EC2 sends a GenerateDataKeyWithoutPlaintext request to AWS KMS, specifying the KMS key that you chose for volume encryption.
3. AWS KMS generates a new data key, encrypts it under the KMS key that you chose for volume encryption, and sends the encrypted data key to Amazon EBS to be stored with the volume metadata.
4. Amazon EC2 sends a Decrypt request to AWS KMS to get the encryption key to encrypt the volume data.
5. When you attach the encrypted volume to an instance, Amazon EC2 sends a CreateGrant request to AWS KMS, so that it can decrypt the data key.
6. When you attach the encrypted volume to an instance, Amazon EC2 sends a Decrypt request to AWS KMS, specifying the encrypted data key.
7. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
8. Amazon EC2 uses the plaintext data key in hypervisor memory to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

For more information, see How Amazon Elastic Block Store (Amazon EBS) uses AWS KMS and Amazon EC2 example two in the AWS Key Management Service Developer Guide.
Requirements

Before you begin, verify that the following requirements are met.

Supported volume types

Encryption is supported by all EBS volume types. You can expect the same IOPS performance on encrypted volumes as on unencrypted volumes, with a minimal effect on latency. You can access encrypted volumes the same way that you access unencrypted volumes. Encryption and decryption are handled transparently, and they require no additional action from you or your applications.

Supported instance types

Amazon EBS encryption is available on all current generation (p. 194) instance types and the following previous generation (p. 197) instance types: A1, C3, cr1.8xlarge, G2, I2, M3, and R3.

Permissions for IAM users

When you configure a KMS key as the default key for EBS encryption, the default KMS key policy allows any IAM user with access to the required KMS actions to use this KMS key to encrypt or decrypt EBS resources. You must grant IAM users permission to call the following actions in order to use EBS encryption:

- kms:CreateGrant
- kms:Decrypt
- kms:DescribeKey
- kms:GenerateDataKeyWithoutPlainText
- kms:ReEncrypt

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "kms:CreateGrant",
      "Resource": [
        "arn:aws:kms:us-east-2:123456789012:key/abcd1234-a123-456d-a12b-a123b4cd56ef"
      ],
      "Condition": {
        "Bool": {
          "kms:GrantIsForAWSResource": true
        }
      }
    }
  ]
}
```

For more information, see Allows access to the AWS account and enables IAM policies in the Default key policy section in the AWS Key Management Service Developer Guide.

Default KMS key for EBS encryption

Amazon EBS automatically creates a unique AWS managed key in each Region where you store AWS resources. This KMS key has the alias `alias/aws/ebs`. By default, Amazon EBS uses this KMS key for
encryption. Alternatively, you can specify a symmetric customer managed key that you created as the default KMS key for EBS encryption. Using your own KMS key gives you more flexibility, including the ability to create, rotate, and disable KMS keys.

**Important**
Amazon EBS does not support asymmetric KMS keys. For more information, see Using symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

**New console**

**To configure the default KMS key for EBS encryption for a Region**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, EBS encryption**.
5. Choose **Manage**.
6. For **Default encryption key**, choose a symmetric customer managed key.
7. Choose **Update EBS encryption**.

**Old console**

**To configure the default KMS key for EBS encryption for a Region**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, Settings**.
5. Choose **Change the default key** and then choose an available KMS key.
6. Choose **Save settings**.

**Encryption by default**

You can configure your AWS account to enforce the encryption of the new EBS volumes and snapshot copies that you create. For example, Amazon EBS encrypts the EBS volumes created when you launch an instance and the snapshots that you copy from an unencrypted snapshot. For examples of transitioning from unencrypted to encrypted EBS resources, see Encrypt unencrypted resources (p. 1340).

Encryption by default has no effect on existing EBS volumes or snapshots.

**Considerations**

- Encryption by default is a Region-specific setting. If you enable it for a Region, you cannot disable it for individual volumes or snapshots in that Region.
- When you enable encryption by default, you can launch an instance only if the instance type supports EBS encryption. For more information, see Supported instance types (p. 1337).
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- When migrating servers using AWS Server Migration Service (SMS), do not turn on encryption by default. If encryption by default is already on and you are experiencing delta replication failures, turn off encryption by default. Instead, enable AMI encryption when you create the replication job.
New console

**To enable encryption by default for a Region**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, EBS encryption**.
5. Choose **Manage**.
6. Select **Enable**. You keep the AWS managed key with the alias alias/aws/ebs created on your behalf as the default encryption key, or choose a symmetric customer managed key.
7. Choose **Update EBS encryption**.

Old console

**To enable encryption by default for a Region**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, Settings**.
5. Under **EBS Storage**, select **Always encrypt new EBS volumes**.
6. Choose **Save settings**.

You cannot change the KMS key that is associated with an existing snapshot or encrypted volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

**Encrypt EBS resources**

You encrypt EBS volumes by enabling encryption, either using encryption by default (p. 1338) or by enabling encryption when you create a volume that you want to encrypt.

When you encrypt a volume, you can specify the symmetric KMS key to use to encrypt the volume. If you do not specify a KMS key, the KMS key that is used for encryption depends on the encryption state of the source snapshot and its ownership. For more information, see the encryption outcomes table (p. 1344).

**Note**

If you are using the API or AWS CLI to specify a KMS key, be aware that AWS authenticates the KMS key asynchronously. If you specify a KMS key ID, an alias, or an ARN that is not valid, the action can appear to complete, but it eventually fails.

You cannot change the KMS key that is associated with an existing snapshot or volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

**Encrypt an empty volume on creation**

When you create a new, empty EBS volume, you can encrypt it by enabling encryption for the specific volume creation operation. If you enabled EBS encryption by default, the volume is automatically encrypted using your default KMS key for EBS encryption. Alternatively, you can specify a different symmetric KMS key for the specific volume creation operation. The volume is encrypted by the time it is first available, so your data is always secured. For detailed procedures, see Create an Amazon EBS volume (p. 1199).
By default, the KMS key that you selected when creating a volume encrypts the snapshots that you make from the volume and the volumes that you restore from those encrypted snapshots. You cannot remove encryption from an encrypted volume or snapshot, which means that a volume restored from an encrypted snapshot, or a copy of an encrypted snapshot, is always encrypted.

Public snapshots of encrypted volumes are not supported, but you can share an encrypted snapshot with specific accounts. For detailed directions, see Share an Amazon EBS snapshot (p. 1242).

**Encrypt unencrypted resources**

Although there is no direct way to encrypt an existing unencrypted volume or snapshot, you can encrypt them by creating either a volume or a snapshot. If you enabled encryption by default, Amazon EBS encrypts the resulting new volume or snapshot using your default KMS key for EBS encryption. Even if you have not enabled encryption by default, you can enable encryption when you create an individual volume or snapshot. Whether you enable encryption by default or in individual creation operations, you can override the default KMS key for EBS encryption and select a symmetric customer managed key. For more information, see Create an Amazon EBS volume (p. 1199) and Copy an Amazon EBS snapshot (p. 1236).

To encrypt the snapshot copy to a customer managed key, you must both enable encryption and specify the KMS key, as shown in Copy an unencrypted snapshot (encryption by default not enabled) (p. 1342).

**Important**

Amazon EBS does not support asymmetric KMS keys. For more information, see Using Symmetric and Asymmetric KMS keys in the AWS Key Management Service Developer Guide.

You can also apply new encryption states when launching an instance from an EBS-backed AMI. This is because EBS-backed AMIs include snapshots of EBS volumes that can be encrypted as described. For more information, see Use encryption with EBS-backed AMIs (p. 156).

**Encryption scenarios**

When you create an encrypted EBS resource, it is encrypted by your account's default KMS key for EBS encryption unless you specify a different customer managed key in the volume creation parameters or the block device mapping for the AMI or instance. For more information, see Default KMS key for EBS encryption (p. 1337).

The following examples illustrate how you can manage the encryption state of your volumes and snapshots. For a full list of encryption cases, see the encryption outcomes table (p. 1344).

**Examples**

- Restore an unencrypted volume (encryption by default not enabled) (p. 1340)
- Restore an unencrypted volume (encryption by default enabled) (p. 1341)
- Copy an unencrypted snapshot (encryption by default not enabled) (p. 1342)
- Copy an unencrypted snapshot (encryption by default enabled) (p. 1342)
- Re-encrypt an encrypted volume (p. 1343)
- Re-encrypt an encrypted snapshot (p. 1343)
- Migrate data between encrypted and unencrypted volumes (p. 1344)
- Encryption outcomes (p. 1344)

**Restore an unencrypted volume (encryption by default not enabled)**

Without encryption by default enabled, a volume restored from an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting volume by setting the `Encrypted` parameter and, optionally, the `KmsKeyId` parameter. The following diagram illustrates the process.
If you leave out the `KmsKeyId` parameter, the resulting volume is encrypted using your default KMS key for EBS encryption. You must specify a KMS key ID to encrypt the volume to a different KMS key.

For more information, see Create a volume from a snapshot (p. 1201).

**Restore an unencrypted volume (encryption by default enabled)**

When you have enabled encryption by default, encryption is mandatory for volumes restored from unencrypted snapshots, and no encryption parameters are required for your default KMS key to be used. The following diagram shows this simple default case:

If you want to encrypt the restored volume to a symmetric customer managed key, you must supply both the `Encrypted` and `KmsKeyId` parameters as shown in Restore an unencrypted volume (encryption by default not enabled) (p. 1340).
Copy an unencrypted snapshot (encryption by default not enabled)

Without encryption by default enabled, a copy of an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting snapshot by setting the `Encrypted` parameter and, optionally, the `KmsKeyId` parameter. If you omit `KmsKeyId`, the resulting snapshot is encrypted by your default KMS key. You must specify a KMS key ID to encrypt the volume to a different symmetric KMS key.

The following diagram illustrates the process.

![Diagram](image)

You can encrypt an EBS volume by copying an unencrypted snapshot to an encrypted snapshot and then creating a volume from the encrypted snapshot. For more information, see Copy an Amazon EBS snapshot (p. 1236).

Copy an unencrypted snapshot (encryption by default enabled)

When you have enabled encryption by default, encryption is mandatory for copies of unencrypted snapshots, and no encryption parameters are required if your default KMS key is used. The following diagram illustrates this default case:

![Diagram](image)
Re-encrypt an encrypted volume

When the CreateVolume action operates on an encrypted snapshot, you have the option of re-encrypting it with a different KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During volume creation, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically decrypted, then re-encrypted by KMS key B.

For more information, see Create a volume from a snapshot (p. 1201).

Re-encrypt an encrypted snapshot

The ability to encrypt a snapshot during copying allows you to apply a new symmetric KMS key to an already-encrypted snapshot that you own. Volumes restored from the resulting copy are only accessible using the new KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During copy, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically re-encrypted by KMS key B.
In a related scenario, you can choose to apply new encryption parameters to a copy of a snapshot that has been shared with you. By default, the copy is encrypted with a KMS key shared by the snapshot's owner. However, we recommend that you create a copy of the shared snapshot using a different KMS key that you control. This protects your access to the volume if the original KMS key is compromised, or if the owner revokes the KMS key for any reason. For more information, see Encryption and snapshot copying (p. 1238).

**Migrate data between encrypted and unencrypted volumes**

When you have access to both an encrypted and unencrypted volume, you can freely transfer data between them. EC2 carries out the encryption and decryption operations transparently.

For example, use the `rsync` command to copy the data. In the following command, the source data is located in `/mnt/source` and the destination volume is mounted at `/mnt/destination`.

```
[ec2-user ~]$ sudo rsync -avh --progress /mnt/source/ /mnt/destination/
```

**Encryption outcomes**

The following table describes the encryption outcome for each possible combination of settings.

<table>
<thead>
<tr>
<th>Is encryption enabled?</th>
<th>Is encryption by default enabled?</th>
<th>Source of volume</th>
<th>Default (no customer managed key specified)</th>
<th>Custom (customer managed key specified)</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>

</table>
### Is encryption enabled?  |  Is encryption by default enabled?  |  Source of volume  |  Default (no customer managed key specified)  |  Custom (customer managed key specified)
--- | --- | --- | --- | ---
No | Yes | New (empty) volume | Encrypted by default customer managed key | N/A
No | Yes | Unencrypted snapshot that you own | Encrypted by default customer managed key | 
No | Yes | Encrypted snapshot that you own | Encrypted by same key | 
No | Yes | Unencrypted snapshot that is shared with you | Encrypted by default customer managed key | 
Yes | Yes | New volume | Encrypted by default customer managed key | Encrypted by a specified customer managed key
Yes | Yes | Unencrypted snapshot that you own | Encrypted by default customer managed key | 
Yes | Yes | Encrypted snapshot that you own | Encrypted by same key | 
Yes | Yes | Unencrypted snapshot that is shared with you | Encrypted by default customer managed key | 
Yes | Yes | Encrypted snapshot that is shared with you | Encrypted by default customer managed key | 

* This is the default customer managed key used for EBS encryption for the AWS account and Region. By default this is a unique AWS managed key for EBS, or you can specify a customer managed key. For more information, see Default KMS key for EBS encryption (p. 1337).

** This is a customer managed key specified for the volume at launch time. This customer managed key is used instead of the default customer managed key for the AWS account and Region.

** Set encryption defaults using the API and CLI

You can manage encryption by default and the default KMS key using the following API actions and CLI commands.

<table>
<thead>
<tr>
<th>API action</th>
<th>CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DisableEbsEncryptionByDefault</td>
<td>disable-ebs-encryption-by-default</td>
<td>Disables encryption by default.</td>

Amazon EBS fast snapshot restore

Amazon EBS fast snapshot restore enables you to create a volume from a snapshot that is fully initialized at creation. This eliminates the latency of I/O operations on a block when it is accessed for the first time. Volumes that are created using fast snapshot restore instantly deliver all of their provisioned performance.

To get started, enable fast snapshot restore for specific snapshots in specific Availability Zones. Each snapshot and Availability Zone pair refers to one fast snapshot restore. When you create a volume from one of these snapshots in one of its enabled Availability Zones, the volume is restored using fast snapshot restore.

Fast snapshot restore must be explicitly enabled on a per-snapshot basis. If you create a new snapshot from a volume that was restored from a fast snapshot restore-enabled snapshot, the new snapshot is not automatically enabled for fast snapshot restore. You must explicitly enable it for the new snapshot.

You can enable fast snapshot restore for snapshots that you own and for public and private snapshots that are shared with you.

Contents
- Fast snapshot restore quotas (p. 1346)
- Fast snapshot restore states (p. 1347)
- Volume creation credits (p. 1347)
- Manage fast snapshot restore (p. 1347)
- View snapshots with fast snapshot restore enabled (p. 1348)
- View volumes restored using fast snapshot restore (p. 1349)
- Monitor fast snapshot restore (p. 1350)
- Pricing and Billing (p. 1350)

Fast snapshot restore quotas

You can enable up to 50 snapshots for fast snapshot restore per Region. The quota applies to snapshots that you own and snapshots that are shared with you. If you enable fast snapshot restore for a snapshot
that is shared with you, it counts towards your fast snapshot restore quota. It does not count towards the snapshot owner's fast snapshot restore quota.

**Fast snapshot restore states**

After you enable fast snapshot restore for a snapshot, it can be in one of the following states.

- **enabling** — A request was made to enable fast snapshot restore.
- **optimizing** — Fast snapshot restore is being enabled. It takes 60 minutes per TiB to optimize a snapshot. Snapshots in this state offer some performance benefit when restoring volumes.
- **enabled** — Fast snapshot restore is enabled. Snapshots in this state offer the full performance benefit when restoring volumes.
- **disabling** — A request was made to disable fast snapshot restore, or a request to enable fast snapshot restore failed.
- **disabled** — Fast snapshot restore is disabled. You can enable fast snapshot restore again as needed.

**Volume creation credits**

The number of volumes that receive the full performance benefit of fast snapshot restore is determined by the volume creation credits for the snapshot. There is one credit bucket per snapshot per Availability Zone. Each volume that you create from a snapshot with fast snapshot restore enabled consumes one credit from the credit bucket. If you create a volume but there is less than one credit in the bucket, the volume is created without benefit of fast snapshot restore.

When you enable fast snapshot restore for a snapshot that is shared with you, you get a separate credit bucket for the shared snapshot in your account. If you create volumes from the shared snapshot, the credits are consumed from your credit bucket; they are not consumed from the snapshot owner's credit bucket.

The size of a credit bucket depends on the size of the snapshot, not the size of the volumes created from the snapshot. The size of the credit bucket for each snapshot is calculated as follows:

\[
\text{MAX} (1, \text{MIN} (10, \text{FLOOR}(1024/\text{snapshot\_size\_gib})))
\]

As you consume credits, the credit bucket is refilled over time. The refill rate for each credit bucket is calculated as follows:

\[
\text{MIN} (10, 1024/\text{snapshot\_size\_gib})
\]

For example, if you enable fast snapshot restore for a snapshot with a size of 100 GiB, the maximum size of its credit bucket is 10 credits and the refill rate is 10 credits per hour. When the credit bucket is full, you can create 10 initialized volumes from this snapshot simultaneously.

You can use Cloudwatch metrics to monitor the size of your credit buckets and the number of credits available in each bucket. For more information, see Fast snapshot restore metrics (p. 1396).

After you create a volume from a snapshot with fast snapshot restore enabled, you can describe the volume using `describe-volumes` and check the `fastRestored` field in the output to determine whether the volume was created as an initialized volume using fast snapshot restore.

**Manage fast snapshot restore**

Fast snapshot restore is disabled for a snapshot by default. You can enable or disable fast snapshot restore for snapshots that you own and for snapshots that are shared with you. When you enable or disable fast snapshot restore for a snapshot, the changes apply to your account only.
**Note**
When you enable fast snapshot restore for a snapshot, your account is billed for each minute that fast snapshot restore is enabled in a particular Availability Zone. Charges are pro-rated and have a minimum of one hour.

When you delete a snapshot that you own, fast snapshot restore is automatically disabled for that snapshot in your account. If you enabled fast snapshot restore for a snapshot that is shared with you, and the snapshot owner deletes or unshares it, fast snapshot restore is automatically disabled for the shared snapshot in your account.

If you enabled fast snapshot restore for a snapshot that is shared with you, and it's encrypted using a custom CMK, fast snapshot restore is not automatically disabled for the snapshot when the snapshot owner revokes your access to the custom CMK. You must manually disable fast snapshot restore for that snapshot.

Use the following procedure to enable or disable fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

**To enable or disable fast snapshot restore**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Snapshots.
3. Select the snapshot.
5. Select or deselect Availability Zones, and then choose Save.
6. To track the state of fast snapshot restore as it is enabled, see Fast Snapshot Restore on the Description tab.

**Note**
After you enable fast snapshot restore for a snapshot, it enters the optimizing state. Snapshots that are in the optimizing state provide some performance benefits when using them to restore volumes. They start to provide the full performance benefits of fast snapshot restore only after they enter the enabled state.

**To manage fast snapshot restore using the AWS CLI**

- `enable-fast-snapshot-restores`
- `disable-fast-snapshot-restores`
- `describe-fast-snapshot-restores`

**View snapshots with fast snapshot restore enabled**

Use the following procedure to view the state of fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

**To view the state of fast snapshot restore using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Snapshots.
3. Select the snapshot.
4. On the Description tab, see Fast Snapshot Restore, which indicates the state of fast snapshot restore. For example, it might show a state of "2 Availability Zones optimizing" or "2 Availability Zones enabled".
To view snapshots with fast snapshot restore enabled using the AWS CLI

Use the `describe-fast-snapshot-restores` command to describe the snapshots that are enabled for fast snapshot restore.

```
aws ec2 describe-fast-snapshot-restores --filters Name=state,Values=enabled
```

The following is example output.

```
{
    "FastSnapshotRestores": [
        {
            "SnapshotId": "snap-0e946653493cb0447",
            "AvailabilityZone": "us-east-2a",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",
            "OwnerId": "123456789012",
            "EnablingTime": "2020-01-25T23:57:49.596Z",
            "OptimizingTime": "2020-01-25T23:58:25.573Z",
            "EnabledTime": "2020-01-25T23:59:29.852Z"
        },
        {
            "SnapshotId": "snap-0e946653493cb0447",
            "AvailabilityZone": "us-east-2b",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",
            "OwnerId": "123456789012",
            "EnablingTime": "2020-01-25T23:57:49.596Z",
            "OptimizingTime": "2020-01-25T23:58:25.573Z",
            "EnabledTime": "2020-01-25T23:59:29.852Z"
        }
    ]
}
```

View volumes restored using fast snapshot restore

When you create a volume from a snapshot that is enabled for fast snapshot restore in the Availability Zone for the volume, it is restored using fast snapshot restore.

Use the `describe-volumes` command to view volumes that were created from a snapshot that is enabled for fast snapshot restore.

```
aws ec2 describe-volumes --filters Name=fast-restored,Values=true
```

The following is example output.

```
{
    "Volumes": [
        {
            "Attachments": [],
            "AvailabilityZone": "us-east-2a",
            "CreateTime": "2020-01-26T00:34:11.093Z",
            "Encrypted": true,
            "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/8c5b2c63-b9bc-45a3-a87a-5513e232e843",
            "Size": 20,
            "SnapshotId": "snap-0e946653493cb0447",
            "State": "available",
            "VolumeId": "vol-0d371921d4ca797b0",
            "Iops": 100,
```
Monitor fast snapshot restore

Amazon EBS emits Amazon CloudWatch events when the fast snapshot restore state for a snapshot changes. For more information, see EBS fast snapshot restore events (p. 1405).

Pricing and Billing

You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

For example, if you enable fast snapshot restore for one snapshot in us-east-1a for one month (30 days), you are billed $540 (1 snapshot x 1 AZ x 720 hours x $0.75 per hour). If you enable fast snapshot restore for two snapshots in us-east-1a, us-east-1b, and us-east-1c for the same period, you are billed $3240 (2 snapshots x 3 AZs x 720 hours x $0.75 per hour).

If you enable fast snapshot restore for a public or private snapshot that is shared with you, your account is billed; the snapshot owner is not billed. When a snapshot that is shared with you is deleted or unshared by the snapshot owner, fast snapshot restore is disabled for the snapshot in your account and billing is stopped.

For more information, see Amazon EBS pricing.

Amazon EBS and NVMe on Linux instances

EBS volumes are exposed as NVMe block devices on instances built on the Nitro System (p. 199). The device names are /dev/nvme0n1, /dev/nvme1n1, and so on. The device names that you specify in a block device mapping are renamed using NVMe device names (/dev/nvme[0-26]n1). The block device driver can assign NVMe device names in a different order than you specified for the volumes in the block device mapping.

The EBS performance guarantees stated in Amazon EBS Product Details are valid regardless of the block-device interface.

Contents

- Install or upgrade the NVMe driver (p. 1350)
- Identify the EBS device (p. 1351)
- Work with NVMe EBS volumes (p. 1353)
- I/O operation timeout (p. 1354)

Install or upgrade the NVMe driver

To access NVMe volumes, the NVMe drivers must be installed. Instances can support NVMe EBS volumes, NVMe instance store volumes, both types of NVMe volumes, or no NVMe volumes. For more information, see Summary of networking and storage features (p. 200).

The following AMIs include the required NVMe drivers:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with linux-aws kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

For more information about NVMe drivers on Windows instances, see Amazon EBS and NVMe on Windows Instances in the Amazon EC2 User Guide for Windows Instances.

**To confirm that your instance has the NVMe driver**

You can confirm that your instance has the NVMe driver and check the driver version using the following command. If the instance has the NVMe driver, the command returns information about the driver.

```
$ modinfo nvme
```

**To update the NVMe driver**

If your instance has the NVMe driver, you can update the driver to the latest version using the following procedure.

1. Connect to your instance.
2. Update your package cache to get necessary package updates as follows.
   - For Amazon Linux 2, Amazon Linux, CentOS, and Red Hat Enterprise Linux:
     ```bash
     [ec2-user ~]# sudo yum update -y
     ```
   - For Ubuntu and Debian:
     ```bash
     [ec2-user ~]# sudo apt-get update -y
     ```
3. Ubuntu 16.04 and later include the `linux-aws` package, which contains the NVMe and ENA drivers required by Nitro-based instances. Upgrade the `linux-aws` package to receive the latest version as follows:
   ```bash
   [ec2-user ~]# sudo apt-get install --only-upgrade -y linux-aws
   ```
   For Ubuntu 14.04, you can install the latest `linux-aws` package as follows:
   ```bash
   [ec2-user ~]# sudo apt-get install linux-aws
   ```
4. Reboot your instance to load the latest kernel version.
   ```bash
   sudo reboot
   ```
5. Reconnect to your instance after it has rebooted.

**Identify the EBS device**

EBS uses single-root I/O virtualization (SR-IOV) to provide volume attachments on Nitro-based instances using the NVMe specification. These devices rely on standard NVMe drivers on the operating system. These drivers typically discover attached devices by scanning the PCI bus during instance boot,
and create device nodes based on the order in which the devices respond, not on how the devices are specified in the block device mapping. In Linux, NVMe device names follow the pattern `/dev/nvme<x>n<y>`, where `<x>` is the enumeration order, and, for EBS, `<y>` is 1. Occasionally, devices can respond to discovery in a different order in subsequent instance starts, which causes the device name to change. Additionally, the device name assigned by the block device driver can be different from the name specified in the block device mapping.

We recommend that you use stable identifiers for your EBS volumes within your instance, such as one of the following:

- For Nitro-based instances, the block device mappings that are specified in the Amazon EC2 console when you are attaching an EBS volume or during `AttachVolume` or `RunInstances` API calls are captured in the vendor-specific data field of the NVMe controller identification. With Amazon Linux AMIs later than version 2017.09.01, we provide a `udev` rule that reads this data and creates a symbolic link to the block-device mapping.

- The EBS volume ID and the mount point are stable between instance state changes. The NVMe device name can change depending on the order in which the devices respond during instance boot. We recommend using the EBS volume ID and the mount point for consistent device identification.

- NVMe EBS volumes have the EBS volume ID set as the serial number in the device identification. Use the `lsblk -o +SERIAL` command to list the serial number.

- The NVMe device name format can vary depending on whether the EBS volume was attached during or after the instance launch. NVMe device names for volumes attached after instance launch include the `/dev/` prefix, while NVMe device names for volumes attached during instance launch do not include the `/dev/` prefix. If you are using an Amazon Linux or FreeBSD AMI, use the `sudo ebsnvme-id /dev/nvme<device> -u` command for a consistent NVMe device name. For other distributions, use the `sudo ebsnvme-id /dev/nvme<device> -u` command to determine the NVMe device name.

- When a device is formatted, a UUID is generated that persists for the life of the filesystem. A device label can be specified at the same time. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1208) and Boot from the wrong volume (p. 1518).

### Amazon Linux AMIs

With Amazon Linux AMI 2017.09.01 or later (including Amazon Linux 2), you can run the `ebsnvme-id` command as follows to map the NVMe device name to a volume ID and device name:

The following example shows the command and output for a volume attached during instance launch. Note that the NVMe device name does not include the `/dev/` prefix.

```
[ec2-user ~]$ sudo /sbin/ebsnvme-id /dev/nvme0n1
Volume ID: vol-01324f611e2463981
sda
```

The following example shows the command and output for a volume attached after instance launch. Note that the NVMe device name includes the `/dev/` prefix.

```
[ec2-user ~]$ sudo /sbin/ebsnvme-id /dev/nvme1n1
Volume ID: vol-064784f1011136656
/dev/sdf
```

Amazon Linux also creates a symbolic link from the device name in the block device mapping (for example, `/dev/sdf`), to the NVMe device name.

### FreeBSD AMIs

Starting with FreeBSD 12.2-RELEASE, you can run the `ebsnvme-id` command as shown above. Pass either the name of the NVMe device (for example, `nvme0`) or the disk device (for example, `nvd0`
or nda0). FreeBSD also creates symbolic links to the disk devices (for example, /dev/aws/disk/ ebs/volume_id).

### Other Linux AMIs

With a kernel version of 4.2 or later, you can run the `nvme id-ctrl` command as follows to map an NVMe device to a volume ID. First, install the NVMe command line package, `nvme-cli`, using the package management tools for your Linux distribution. For download and installation instructions for other distributions, refer to the documentation specific to your distribution.

The following example gets the volume ID and NVMe device name for a volume that was attached during instance launch. Note that the NVMe device name does not include the `/dev/` prefix. The device name is available through the NVMe controller vendor-specific extension (bytes 384:4095 of the controller identification):

```
[ec2-user ~]$ sudo nvme id-ctrl -v /dev/nvme0n1
NVME Identify Controller:
  vid     : 0x1d0f
  ssvid   : 0x1d0f
  sn      : vol01234567890abcdef
  mn      : Amazon Elastic Block Store
  ...
0000: 2f 64 65 76 2f 73 64 6a 20 20 20 20 20 20 20 20 "sda..."
```

The following example gets the volume ID and NVMe device name for a volume that was attached after instance launch. Note that the NVMe device name includes the `/dev/` prefix.

```
[ec2-user ~]$ sudo nvme id-ctrl -v /dev/nvme1n1
NVME Identify Controller:
  vid     : 0x1d0f
  ssvid   : 0x1d0f
  sn      : volabcdef01234567890
  mn      : Amazon Elastic Block Store
  ...
0000: 2f 64 65 76 2f 73 64 6a 20 20 20 20 20 20 20 20 "/dev/sdf..."
```

The `lsblk` command lists available devices and their mount points (if applicable). This helps you determine the correct device name to use. In this example, `/dev/nvme0n1p1` is mounted as the root device and `/dev/nvme1n1` is attached but not mounted.

```
[ec2-user ~]$ lsblk
NAME          MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
nvme1n1       259:3   0  100G  0 disk
nvme0n1       259:0   0   8G  0 disk
nvme0n1p1    259:1   0   8G  0 part  /
nvme0n1p128  259:2   0   1M  0 part
```

### Work with NVMe EBS volumes

To format and mount an NVMe EBS volume, see Make an Amazon EBS volume available for use on Linux (p. 1208).

If you are using Linux kernel 4.2 or later, any change you make to the volume size of an NVMe EBS volume is automatically reflected in the instance. For older Linux kernels, you might need to detach and attach the EBS volume or reboot the instance for the size change to be reflected. With Linux kernel 3.19 or later, you can use the `hdparm` command as follows to force a rescan of the NVMe device:

```
[ec2-user ~]$ sudo hdparm -z /dev/nvme1n1
```
When you detach an NVMe EBS volume, the instance does not have an opportunity to flush the file system caches or metadata before detaching the volume. Therefore, before you detach an NVMe EBS volume, you should first sync and unmount it. If the volume fails to detach, you can attempt a force-detach command as described in Detach an Amazon EBS volume from a Linux instance (p. 1224).

I/O operation timeout

EBS volumes attached to Nitro-based instances use the default NVMe driver provided by the operating system. Most operating systems specify a timeout for I/O operations submitted to NVMe devices. The default timeout is 30 seconds and can be changed using the `nvme_core.io_timeout` boot parameter. For most Linux kernels earlier than version 4.6, this parameter is `nvme.io_timeout`.

If I/O latency exceeds the value of this timeout parameter, the Linux NVMe driver fails the I/O and returns an error to the filesystem or application. Depending on the I/O operation, your filesystem or application can retry the error. In some cases, your filesystem might be remounted as read-only.

For an experience similar to EBS volumes attached to Xen instances, we recommend setting `nvme_core.io_timeout` to the highest value possible. For current kernels, the maximum is 4294967295, while for earlier kernels the maximum is 255. Depending on the version of Linux, the timeout might already be set to the supported maximum value. For example, the timeout is set to 4294967295 by default for Amazon Linux AMI 2017.09.01 and later.

You can verify the maximum value for your Linux distribution by writing a value higher than the suggested maximum to `/sys/module/nvme_core/parameters/io_timeout` and checking for the Numerical result out of range error when attempting to save the file.

Amazon EBS–optimized instances

An Amazon EBS–optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

EBS–optimized instances deliver dedicated bandwidth to Amazon EBS. When attached to an EBS–optimized instance, General Purpose SSD (`gp2` and `gp3`) volumes are designed to deliver their baseline and burst performance 99% of the time, and Provisioned IOPS SSD (`io1` and `io2`) volumes are designed to deliver their provisioned performance 99.9% of the time. Both Throughput Optimized HDD (`st1`) and Cold HDD (`sc1`) guarantee performance consistency of 90% of burst throughput 99% of the time. Non-compliant periods are approximately uniformly distributed, targeting 99% of expected total throughput each hour. For more information, see Amazon EBS volume types (p. 1179).

Contents

- Supported instance types (p. 1354)
- Get maximum performance (p. 1373)
- View instances types that support EBS optimization (p. 1373)
- Enable EBS optimization at launch (p. 1374)
- Enable EBS optimization for an existing instance (p. 1375)

Supported instance types

The following tables show which instance types support EBS optimization. They include the dedicated bandwidth to Amazon EBS, the typical maximum aggregate throughput that can be achieved on that connection with a streaming read workload and 128 KiB I/O size, and the maximum IOPS the instance can support if you are using a 16 KiB I/O size. Choose an EBS–optimized instance that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.
EBS optimized by default

The following table lists the instance types that support EBS optimization and EBS optimization is enabled by default. There is no need to enable EBS optimization and no effect if you disable EBS optimization.

**Note**
You can also view this information programatically using the AWS CLI. For more information, see View instances types that support EBS optimization (p. 1373).

### EBS optimization supported

The following table lists the instance types that support EBS optimization but EBS optimization is not enabled by default. You can enable EBS optimization when you launch these instances or after they are running. Instances must have EBS optimization enabled to achieve the level of performance described. When you enable EBS optimization for an instance that is not EBS-optimized by default, you pay an additional low, hourly fee for the dedicated capacity. For pricing information, see EBS-Optimized Instances on the Amazon EC2 Pricing, On-Demand Pricing page.

#### Note

You can also view this information programmatically using the AWS CLI. For more information, see View instances types that support EBS optimization (p. 1373).

The i2.8xlarge, c3.8xlarge, and r3.8xlarge instances do not have dedicated EBS bandwidth and therefore do not offer EBS optimization. On these instances, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

**Get maximum performance**

You can use the EBSI0Balance% and EBSByteBalance% metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see Monitor your instances using CloudWatch (p. 818).

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of io1 or io2 volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four io1 or io2 volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads, use six io1 or io2 volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see Storage Configuration for SAP HANA.

**Considerations**

- G4dn, i3en, Inf1, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.
- C5, C5d, C5n, M5, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.
- u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide the performance in the table above. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

**View instances types that support EBS optimization**

You can use the AWS CLI to view the instances types in the current Region that support EBS optimization.

**To view the instance types that support EBS optimization and that have it enabled by default**

Use the following describe-instance-types command.
$ aws ec2 describe-instance-types \
--filters Name=ebs-info.ebs-optimized-support,Values=default --output=table

Example output for eu-west-1:

```
<table>
<thead>
<tr>
<th>EBSOptimized</th>
<th>InstanceType</th>
<th>MaxBandwidth(Mb/s)</th>
<th>MaxIOPS</th>
<th>MaxThroughput(MB/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>m5dn.8xlarge</td>
<td>6800</td>
<td>30000</td>
<td>850.0</td>
</tr>
<tr>
<td>default</td>
<td>m6gd.xlarge</td>
<td>4750</td>
<td>20000</td>
<td>593.75</td>
</tr>
<tr>
<td>default</td>
<td>c4.4xlarge</td>
<td>2000</td>
<td>16000</td>
<td>250.0</td>
</tr>
<tr>
<td>default</td>
<td>r4.16xlarge</td>
<td>14000</td>
<td>75000</td>
<td>1750.0</td>
</tr>
<tr>
<td>default</td>
<td>m5ad.large</td>
<td>2880</td>
<td>16000</td>
<td>360.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

To view the instance types that support EBS optimization but do not have it enabled by default

Use the following `describe-instance-types` command.

$ aws ec2 describe-instance-types \
--filters Name=ebs-info.ebs-optimized-support,Values=supported --output=table

Example output for eu-west-1:

```
<table>
<thead>
<tr>
<th>EBSOptimized</th>
<th>InstanceType</th>
<th>MaxBandwidth(Mb/s)</th>
<th>MaxIOPS</th>
<th>MaxThroughput(MB/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>supported</td>
<td>m2.4xlarge</td>
<td>1000</td>
<td>8000</td>
<td>125.0</td>
</tr>
<tr>
<td>supported</td>
<td>i2.2xlarge</td>
<td>1000</td>
<td>8000</td>
<td>125.0</td>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Enable EBS optimization at launch**

You can enable optimization for an instance by setting its attribute for EBS optimization.

**To enable Amazon EBS optimization when launching an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Launch Instance**.
3. In **Step 1: Choose an Amazon Machine Image (AMI)**, select an AMI.
4. In **Step 2: Choose an Instance Type**, select an instance type that is listed as supporting Amazon EBS optimization.
5. In **Step 3: Configure Instance Details**, complete the fields that you need and choose **Launch as EBS-optimized instance**. If the instance type that you selected in the previous step doesn't support Amazon EBS optimization, this option is not present. If the instance type that you selected is Amazon EBS–optimized by default, this option is selected and you can't deselect it.
6. Follow the directions to complete the wizard and launch your instance.

**To enable EBS optimization when launching an instance using the command line**

You can use one of the following commands with the corresponding option. For more information about these command line interfaces, see [Access Amazon EC2](p. 3).

- **run-instances** with **--ebs-optimized** (AWS CLI)
- **New-EC2Instance** with **-EbsOptimized** (AWS Tools for Windows PowerShell)

**Enable EBS optimization for an existing instance**

You can enable or disable optimization for an existing instance by modifying its Amazon EBS–optimized instance attribute. If the instance is running, you must stop it first.

**Warning**
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

**To enable EBS optimization for an existing instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and select the instance.
3. To stop the instance, choose **Actions, Instance state, Stop instance**. It can take a few minutes for the instance to stop.
4. With the instance still selected, choose **Actions, Instance settings, Change instance type**.
5. For **Change Instance Type**, do one of the following:
   - If the instance type of your instance is Amazon EBS–optimized by default, **EBS-optimized** is selected and you can't change it. You can choose **Cancel**, because Amazon EBS optimization is already enabled for the instance.
   - If the instance type of your instance supports Amazon EBS optimization, choose **EBS-optimized** and then choose **Apply**.
   - If the instance type of your instance does not support Amazon EBS optimization, you can't choose **EBS-optimized**. You can select an instance type from **Instance type** that supports Amazon EBS optimization, choose **EBS-optimized**, and then choose **Apply**.
6. Choose **Instance state, Start instance**.

**To enable EBS optimization for an existing instance using the command line**

1. If the instance is running, use one of the following commands to stop it:
   - **stop-instances** (AWS CLI)
   - **Stop-EC2Instance** (AWS Tools for Windows PowerShell)
2. To enable EBS optimization, use one of the following commands with the corresponding option:
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS performance

- modify-instance-attribute with --ebs-optimized (AWS CLI)
- Edit-EC2InstanceAttribute with -EbsOptimized (AWS Tools for Windows PowerShell)

Amazon EBS volume performance on Linux instances

Several factors, including I/O characteristics and the configuration of your instances and volumes, can affect the performance of Amazon EBS. Customers who follow the guidance on our Amazon EBS and Amazon EC2 product detail pages typically achieve good performance out of the box. However, there are some cases where you may need to do some tuning in order to achieve peak performance on the platform. This topic discusses general best practices as well as performance tuning that is specific to certain use cases. We recommend that you tune performance with information from your actual workload, in addition to benchmarking, to determine your optimal configuration. After you learn the basics of working with EBS volumes, it’s a good idea to look at the I/O performance you require and at your options for increasing Amazon EBS performance to meet those requirements.

AWS updates to the performance of EBS volume types might not immediately take effect on your existing volumes. To see full performance on an older volume, you might first need to perform a ModifyVolume action on it. For more information, see Modifying the Size, IOPS, or Type of an EBS Volume on Linux.

Contents
- Amazon EBS performance tips (p. 1376)
- I/O characteristics and monitoring (p. 1378)
- Initialize Amazon EBS volumes (p. 1381)
- RAID configuration on Linux (p. 1383)
- Benchmark EBS volumes (p. 1387)

Amazon EBS performance tips

These tips represent best practices for getting optimal performance from your EBS volumes in a variety of user scenarios.

Use EBS-optimized instances

On instances without support for EBS-optimized throughput, network traffic can contend with traffic between your instance and your EBS volumes; on EBS-optimized instances, the two types of traffic are kept separate. Some EBS-optimized instance configurations incur an extra cost (such as C3, R3, and M3), while others are always EBS-optimized at no extra cost (such as M4, C4, C5, and D2). For more information, see Amazon EBS-optimized instances (p. 1354).

Understand how performance is calculated

When you measure the performance of your EBS volumes, it is important to understand the units of measure involved and how performance is calculated. For more information, see I/O characteristics and monitoring (p. 1378).

Understand your workload

There is a relationship between the maximum performance of your EBS volumes, the size and number of I/O operations, and the time it takes for each action to complete. Each of these factors (performance, I/O, and latency) affects the others, and different applications are more sensitive to one factor or another. For more information, see Benchmark EBS volumes (p. 1387).
Be aware of the performance penalty when initializing volumes from snapshots

There is a significant increase in latency when you first access each block of data on a new EBS volume that was created from a snapshot. You can avoid this performance hit using one of the following options:

- Access each block prior to putting the volume into production. This process is called initialization (formerly known as pre-warming). For more information, see Initialize Amazon EBS volumes (p. 1381).
- Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see Amazon EBS fast snapshot restore (p. 1346).

Factors that can degrade HDD performance

When you create a snapshot of a Throughput Optimized HDD (st1) or Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress. This behavior is specific to these volume types. Other factors that can limit performance include driving more throughput than the instance can support, the performance penalty encountered while initializing volumes created from a snapshot, and excessive amounts of small, random I/O on the volume. For more information about calculating throughput for HDD volumes, see Amazon EBS volume types (p. 1179).

Your performance can also be impacted if your application isn't sending enough I/O requests. This can be monitored by looking at your volume's queue length and I/O size. The queue length is the number of pending I/O requests from your application to your volume. For maximum consistency, HDD-backed volumes must maintain a queue length (rounded to the nearest whole number) of 4 or more when performing 1 MiB sequential I/O. For more information about ensuring consistent performance of your volumes, see I/O characteristics and monitoring (p. 1378).

Increase read-ahead for high-throughput, read-heavy workloads on st1 and sc1

Some workloads are read-heavy and access the block device through the operating system page cache (for example, from a file system). In this case, to achieve the maximum throughput, we recommend that you configure the read-ahead setting to 1 MiB. This is a per-block-device setting that should only be applied to your HDD volumes.

To examine the current value of read-ahead for your block devices, use the following command:

```
[ec2-user ~]# sudo blockdev --report /dev/<device>
```

Block device information is returned in the following format:

```
RO RA SSZ BSZ StartSec Size Device
rw 256 512 4096 4096 8587820544 /dev/<device>
```

The device shown reports a read-ahead value of 256 (the default). Multiply this number by the sector size (512 bytes) to obtain the size of the read-ahead buffer, which in this case is 128 KiB. To set the buffer value to 1 MiB, use the following command:

```
[ec2-user ~]# sudo blockdev --setra 2048 /dev/<device>
```

Verify that the read-ahead setting now displays 2,048 by running the first command again.

Only use this setting when your workload consists of large, sequential I/Os. If it consists mostly of small, random I/Os, this setting will actually degrade your performance. In general, if your workload consists mostly of small or random I/Os, you should consider using a General Purpose SSD (gp2 and gp3) volume rather than an st1 or sc1 volume.
Use a modern Linux kernel

Use a modern Linux kernel with support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation EC2 instance. If your average I/O size is at or near 44 KiB, you may be using an instance or kernel without support for indirect descriptors. For information about deriving the average I/O size from Amazon CloudWatch metrics, see I/O characteristics and monitoring (p. 1378).

To achieve maximum throughput on st1 or sc1 volumes, we recommend applying a value of 256 to the xen_blkfront.max parameter (for Linux kernel versions below 4.6) or the xen_blkfront.max间接_segments parameter (for Linux kernel version 4.6 and above). The appropriate parameter can be set in your OS boot command line.

For example, in an Amazon Linux AMI with an earlier kernel, you can add it to the end of the kernel line in the GRUB configuration found in /boot/grub/menu.lst:

```
kernelpassword::vmlinuz-4.4.5-15.26.amzn1.x86_64 root=LABEL=/ console=ttyS0
xen_blkfront.max=256
```

For a later kernel, the command would be similar to the following:

```
kernelpassword::vmlinuz-4.9.20-11.31.amzn1.x86_64 root=LABEL=/ console=tty1 console=ttyS0
xen_blkfront.max间接_segments=256
```

Reboot your instance for this setting to take effect.

For more information, see Configuring GRUB (p. 184). Other Linux distributions, especially those that do not use the GRUB boot loader, may require a different approach to adjusting the kernel parameters.

For more information about EBS I/O characteristics, see the Amazon EBS: Designing for Performance re:Invent presentation on this topic.

Use RAID 0 to maximize utilization of instance resources

Some instance types can drive more I/O throughput than what you can provision for a single EBS volume. You can join multiple volumes together in a RAID 0 configuration to use the available bandwidth for these instances. For more information, see RAID configuration on Linux (p. 1383).

Track performance using Amazon CloudWatch

Amazon Web Services provides performance metrics for Amazon EBS that you can analyze and view with Amazon CloudWatch and status checks that you can use to monitor the health of your volumes. For more information, see Monitor the status of your volumes (p. 1217).

I/O characteristics and monitoring

On a given volume configuration, certain I/O characteristics drive the performance behavior for your EBS volumes. SSD-backed volumes—General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2)—deliver consistent performance whether an I/O operation is random or sequential. HDD-backed volumes—Throughput Optimized HDD (st1) and Cold HDD (sc1)—deliver optimal performance only when I/O operations are large and sequential. To understand how SSD and HDD volumes will perform in your application, it is important to know the connection between demand on the volume, the quantity of IOPS available to it, the time it takes for an I/O operation to complete, and the volume's throughput limits.

Topics
IOPS

IOPS are a unit of measure representing input/output operations per second. The operations are measured in KiB, and the underlying drive technology determines the maximum amount of data that a volume type counts as a single I/O. I/O size is capped at 256 KiB for SSD volumes and 1,024 KiB for HDD volumes because SSD volumes handle small or random I/O much more efficiently than HDD volumes.

When small I/O operations are physically sequential, Amazon EBS attempts to merge them into a single I/O operation up to the maximum I/O size. Similarly, when I/O operations are larger than the maximum I/O size, Amazon EBS attempts to split them into smaller I/O operations. The following table shows some examples.

<table>
<thead>
<tr>
<th>Volume type</th>
<th>Maximum I/O size</th>
<th>I/O operations from your application</th>
<th>Number of IOPS</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSD</td>
<td>256 KiB</td>
<td>1 x 1024 KiB I/O operation</td>
<td>4 (1,024÷256=4)</td>
<td>Amazon EBS splits the 1,024 I/O operation into four smaller 256 KiB operations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 x sequential 32 KiB I/O operations</td>
<td>1 (8x32=256)</td>
<td>Amazon EBS merges the eight sequential 32 KiB I/O operations into a single 256 KiB operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 random 32 KiB I/O operations</td>
<td>8</td>
<td>Amazon EBS counts random I/O operations separately.</td>
</tr>
<tr>
<td>HDD</td>
<td>1,024 KiB</td>
<td>1 x 1024 KiB I/O operation</td>
<td>1</td>
<td>The I/O operation is already equal to the maximum I/O size. It is not merged or split.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 x sequential 128 KiB I/O operations</td>
<td>1 (8x128=1,024)</td>
<td>Amazon EBS merges the eight sequential 128 KiB I/O operations into a single 1,024 KiB I/O operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 random 32 KiB I/O operations</td>
<td>8</td>
<td>Amazon EBS counts random I/O operations separately.</td>
</tr>
</tbody>
</table>
Consequently, when you create an SSD-backed volume supporting 3,000 IOPS (either by provisioning a Provisioned IOPS SSD volume at 3,000 IOPS or by sizing a General Purpose SSD volume at 1,000 GiB), and you attach it to an EBS-optimized instance that can provide sufficient bandwidth, you can transfer up to 3,000 I/Os of data per second, with throughput determined by I/O size.

Volume queue length and latency

The volume queue length is the number of pending I/O requests for a device. Latency is the true end-to-end client time of an I/O operation, in other words, the time elapsed between sending an I/O to EBS and receiving an acknowledgement from EBS that the I/O read or write is complete. Queue length must be correctly calibrated with I/O size and latency to avoid creating bottlenecks either on the guest operating system or on the network link to EBS.

Optimal queue length varies for each workload, depending on your particular application’s sensitivity to IOPS and latency. If your workload is not delivering enough I/O requests to fully use the performance available to your EBS volume, then your volume might not deliver the IOPS or throughput that you have provisioned.

Transaction-intensive applications are sensitive to increased I/O latency and are well-suited for SSD-backed volumes. You can maintain high IOPS while keeping latency down by maintaining a low queue length and a high number of IOPS available to the volume. Consistently driving more IOPS to a volume than it has available can cause increased I/O latency.

Throughput-intensive applications are less sensitive to increased I/O latency, and are well-suited for HDD-backed volumes. You can maintain high throughput to HDD-backed volumes by maintaining a high queue length when performing large, sequential I/O.

I/O size and volume throughput limits

For SSD-backed volumes, if your I/O size is very large, you may experience a smaller number of IOPS than you provisioned because you are hitting the throughput limit of the volume. For example, a gp2 volume under 1,000 GiB with burst credits available has an IOPS limit of 3,000 and a volume throughput limit of 250 MiB/s. If you are using a 256 KiB I/O size, your volume reaches its throughput limit at 1000 IOPS (1000 x 256 KiB = 250 MiB). For smaller I/O sizes (such as 16 KiB), this same volume can sustain 3,000 IOPS because the throughput is well below 250 MiB/s. (These examples assume that your volume's I/O is not hitting the throughput limits of the instance.) For more information about the throughput limits for each EBS volume type, see Amazon EBS volume types (p. 1179).

For smaller I/O operations, you may see a higher-than-provisioned IOPS value as measured from inside your instance. This happens when the instance operating system merges small I/O operations into a larger operation before passing them to Amazon EBS.

If your workload uses sequential I/Os on HDD-backed st1 and sc1 volumes, you may experience a higher than expected number of IOPS as measured from inside your instance. This happens when the instance operating system merges sequential I/Os and counts them in 1,024 KiB-sized units. If your workload uses small or random I/Os, you may experience a lower throughput than you expect. This is because we count each random, non-sequential I/O toward the total IOPS count, which can cause you to hit the volume's IOPS limit sooner than expected.

Whatever your EBS volume type, if you are not experiencing the IOPS or throughput you expect in your configuration, ensure that your EC2 instance bandwidth is not the limiting factor. You should always use a current-generation, EBS-optimized instance (or one that includes 10 Gb/s network connectivity) for optimal performance. For more information, see Amazon EBS-optimized instances (p. 1354). Another possible cause for not experiencing the expected IOPS is that you are not driving enough I/O to the EBS volumes.

Monitor I/O characteristics using CloudWatch

You can monitor these I/O characteristics with each volume's CloudWatch volume metrics (p. 1392). Important metrics to consider include the following:
• BurstBalance
• VolumeReadBytes
• VolumeWriteBytes
• VolumeReadOps
• VolumeWriteOps
• VolumeQueueLength

BurstBalance displays the burst bucket balance for gp2, st1, and sc1 volumes as a percentage of the remaining balance. When your burst bucket is depleted, volume I/O (for gp2 volumes) or volume throughput (for st1 and sc1 volumes) is throttled to the baseline. Check the BurstBalance value to determine whether your volume is being throttled for this reason. For a complete list of the available Amazon EBS metrics, see Amazon EBS metrics (p. 1391) and Amazon EBS metrics for Nitro-based instances (p. 825).

HDD-backed st1 and sc1 volumes are designed to perform best with workloads that take advantage of the 1,024 KiB maximum I/O size. To determine your volume's average I/O size, divide VolumeWriteBytes by VolumeWriteOps. The same calculation applies to read operations. If average I/O size is below 64 KiB, increasing the size of the I/O operations sent to an st1 or sc1 volume should improve performance.

**Note**

If average I/O size is at or near 44 KiB, you might be using an instance or kernel without support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation instance.

If your I/O latency is higher than you require, check VolumeQueueLength to make sure your application is not trying to drive more IOPS than you have provisioned. If your application requires a greater number of IOPS than your volume can provide, you should consider using a larger gp2 volume with a higher base performance level or an io1 or io2 volume with more provisioned IOPS to achieve faster latencies.

**Related resources**

For more information about Amazon EBS I/O characteristics, see the following re:Invent presentation: Amazon EBS: Designing for Performance.

**Initialize Amazon EBS volumes**

Empty EBS volumes receive their maximum performance the moment that they are created and do not require initialization (formerly known as pre-warming).

For volumes that were created from snapshots, the storage blocks must be pulled down from Amazon S3 and written to the volume before you can access them. This preliminary action takes time and can cause a significant increase in the latency of I/O operations the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume.

**Important**

While initializing Provisioned IOPS SSD volumes that were created from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the I/O Performance status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see EBS volume status checks (p. 1217).

For most applications, amortizing the initialization cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can use one of the following options:

• Force the immediate initialization of the entire volume. For more information, see Initialize Amazon EBS volumes on Linux (p. 1382).
• Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fullyinitialized at creation and instantly deliver all of their provisioned performance. For more information, see Amazon EBS fast snapshot restore (p. 1346).

Initialize Amazon EBS volumes on Linux

Empty EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). For volumes that have been created from snapshots, use the dd or fio utilities to read from all of the blocks on a volume. All existing data on the volume will be preserved.

For information about initializing Amazon EBS volumes on Windows, see Initializing Amazon EBS volumes on Windows.

To initialize a volume created from a snapshot on Linux

1. Attach the newly-restored volume to your Linux instance.
2. Use the lsblk command to list the block devices on your instance.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
xvdf   202:80   0   30G  0 disk
xvda1  202:1    0   8G  0 disk /
```

Here you can see that the new volume, /dev/xvdf, is attached, but not mounted (because there is no path listed under the MOUNTPOINT column).
3. Use the dd or fio utilities to read all of the blocks on the device. The dd command is installed by default on Linux systems, but fio is considerably faster because it allows multi-threaded reads.

**Note**
This step may take several minutes up to several hours, depending on your EC2 instance bandwidth, the IOPS provisioned for the volume, and the size of the volume.

[dd] The if (input file) parameter should be set to the drive you wish to initialize. The of (output file) parameter should be set to the Linux null virtual device, /dev/null. The bs parameter sets the block size of the read operation; for optimal performance, this should be set to 1 MB.

**Important**
Incorrect use of dd can easily destroy a volume's data. Be sure to follow precisely the example command below. Only the if=/dev/xvdf parameter will vary depending on the name of the device you are reading.

```
[ec2-user ~]$ sudo dd if=/dev/xvdf of=/dev/null bs=1M
```

[fio] If you have fio installed on your system, use the following command to initialize your volume. The --filename (input file) parameter should be set to the drive you wish to initialize.

```
[ec2-user ~]$ sudo fio --filename=/dev/xvdf --rw=read --bs=128k --iodepth=32 --ioengine=libaio --direct=1 --name=volume-initialize
```

To install fio on Amazon Linux, use the following command:

```
sudo yum install -y fio
```

To install fio on Ubuntu, use the following command:
When the operation is finished, you will see a report of the read operation. Your volume is now ready for use. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1208).

**RAID configuration on Linux**

With Amazon EBS, you can use any of the standard RAID configurations that you can use with a traditional bare metal server, as long as that particular RAID configuration is supported by the operating system for your instance. This is because all RAID is accomplished at the software level.

Amazon EBS volume data is replicated across multiple servers in an Availability Zone to prevent the loss of data from the failure of any single component. This replication makes Amazon EBS volumes ten times more reliable than typical commodity disk drives. For more information, see Amazon EBS Availability and Durability in the Amazon EBS product detail pages.

**Note**
You should avoid booting from a RAID volume. Grub is typically installed on only one device in a RAID array, and if one of the mirrored devices fails, you may be unable to boot the operating system.

If you need to create a RAID array on a Windows instance, see RAID configuration on Windows in the Amazon EC2 User Guide for Windows Instances.

**Contents**
- RAID configuration options (p. 1383)
- Create a RAID 0 array on Linux (p. 1384)
- Create snapshots of volumes in a RAID array (p. 1386)

**RAID configuration options**

Creating a RAID 0 array allows you to achieve a higher level of performance for a file system than you can provision on a single Amazon EBS volume. Use RAID 0 when I/O performance is of the utmost importance. With RAID 0, I/O is distributed across the volumes in a stripe. If you add a volume, you get the straight addition of throughput and IOPS. However, keep in mind that performance of the stripe is limited to the worst performing volume in the set, and that the loss of a single volume in the set results in a complete data loss for the array.

The resulting size of a RAID 0 array is the sum of the sizes of the volumes within it, and the bandwidth is the sum of the available bandwidth of the volumes within it. For example, two 500 GiB io1 volumes with 4,000 provisioned IOPS each create a 1000 GiB RAID 0 array with an available bandwidth of 8,000 IOPS and 1,000 MiB/s of throughput.

**Important**
RAID 5 and RAID 6 are not recommended for Amazon EBS because the parity write operations of these RAID modes consume some of the IOPS available to your volumes. Depending on the configuration of your RAID array, these RAID modes provide 20-30% fewer usable IOPS than a RAID 0 configuration. Increased cost is a factor with these RAID modes as well; when using identical volume sizes and speeds, a 2-volume RAID 0 array can outperform a 4-volume RAID 6 array that costs twice as much.

RAID 1 is also not recommended for use with Amazon EBS. RAID 1 requires more Amazon EC2 to Amazon EBS bandwidth than non-RAID configurations because the data is written to multiple volumes simultaneously. In addition, RAID 1 does not provide any write performance improvement.
Create a RAID 0 array on Linux

This documentation provides a basic RAID 0 setup example.

Before you perform this procedure, you need to decide how large your RAID 0 array should be and how many IOPS you want to provision.

Use the following procedure to create a RAID 0 array. Note that you can get directions for Windows instances from Create a RAID 0 array on Windows in the Amazon EC2 User Guide for Windows Instances.

To create a RAID 0 array on Linux

1. Create the Amazon EBS volumes for your array. For more information, see Create an Amazon EBS volume (p. 1199).

   **Important**
   Create volumes with identical size and IOPS performance values for your array. Make sure you do not create an array that exceeds the available bandwidth of your EC2 instance. For more information, see Amazon EBS–optimized instances (p. 1354).

2. Attach the Amazon EBS volumes to the instance that you want to host the array. For more information, see Attach an Amazon EBS volume to an instance (p. 1202).

3. Use the `mdadm` command to create a logical RAID device from the newly attached Amazon EBS volumes. Substitute the number of volumes in your array for `number_of_volumes` and the device names for each volume in the array (such as `/dev/xvdf`) for `device_name`. You can also substitute `MY_RAID` with your own unique name for the array.

   **Note**
   You can list the devices on your instance with the `lsblk` command to find the device names.

   To create a RAID 0 array, run the following command (note the `--level=0` option to stripe the array):

   ```
   [ec2-user ~]$ sudo mdadm --create --verbose /dev/md0 --level=0 --name=MY_RAID --raid-devices=number_of_volumes device_name1 device_name2
   ```

4. Allow time for the RAID array to initialize and synchronize. You can track the progress of these operations with the following command:

   ```
   [ec2-user ~]$ sudo cat /proc/mdstat
   ```

   The following is example output:

   ```
   Personalities : [raid0]
   md0 : active raid0 xvdc[1] xvdb[0]
       41910272 blocks super 1.2 512k chunks
   unused devices: <none>
   ```

   In general, you can display detailed information about your RAID array with the following command:

   ```
   [ec2-user ~]$ sudo mdadm --detail /dev/md0
   ```

   The following is example output:

   ```
   /dev/md0:
       Version : 1.2
       Creation Time : Wed May 19 11:12:56 2021
   ```
Raid Level : raid0
Array Size : 41910272 (39.97GiB 42.92GB)
Raid Devices : 2
Total Devices : 2
Persistence : Superblock is persistent

Update Time : Wed May 19 11:12:56 2021
State : clean
Active Devices : 2
Working Devices : 2
Failed Devices : 0
Spare Devices : 0
Chunk Size : 512K
Consistency Policy : none

Name : MY_RAID
UUID : 646aa723:db31bbcc7:13c43d3e:d5c51e0c
Events : 0

<table>
<thead>
<tr>
<th>Number</th>
<th>Major</th>
<th>Minor</th>
<th>RaidDevice</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>202</td>
<td>16</td>
<td>0</td>
<td>active sync /dev/sdb</td>
</tr>
<tr>
<td>1</td>
<td>202</td>
<td>32</td>
<td>1</td>
<td>active sync /dev/sdc</td>
</tr>
</tbody>
</table>

5. Create a file system on your RAID array, and give that file system a label to use when you mount it later. For example, to create an ext4 file system with the label MY_RAID, run the following command:

```bash
[ec2-user ~]$ sudo mkfs.ext4 -L MY_RAID /dev/md0
```

Depending on the requirements of your application or the limitations of your operating system, you can use a different file system type, such as ext3 or XFS (consult your file system documentation for the corresponding file system creation command).

6. To ensure that the RAID array is reassembled automatically on boot, create a configuration file to contain the RAID information:

```bash
[ec2-user ~]$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf
```

**Note**
If you are using a Linux distribution other than Amazon Linux, you might need to modify this command. For example, you might need to place the file in a different location, or you might need to add the `--examine` parameter. For more information, run `man mdadm.conf` on your Linux instance.

7. Create a new ramdisk image to properly preload the block device modules for your new RAID configuration:

```bash
[ec2-user ~]$ sudo dracut -H -f /boot/initramfs-$(uname -r).img $(uname -r)
```

8. Create a mount point for your RAID array.

```bash
[ec2-user ~]$ sudo mkdir -p /mnt/raid
```

9. Finally, mount the RAID device on the mount point that you created:

```bash
[ec2-user ~]$ sudo mount LABEL=MY_RAID /mnt/raid
```

Your RAID device is now ready for use.
10. (Optional) To mount this Amazon EBS volume on every system reboot, add an entry for the device to the /etc/fstab file.

   a. Create a backup of your /etc/fstab file that you can use if you accidentally destroy or delete this file while you are editing it.
      
      ```bash
      [ec2-user ~]$ sudo cp /etc/fstab /etc/fstab.orig
      ```
   
   b. Open the /etc/fstab file using your favorite text editor, such as nano or vim.
   
   c. Comment out any lines starting with "UUID=" and, at the end of the file, add a new line for your RAID volume using the following format:
      
      ```
      device_label mount_point file_system_type fs_mntops fs_freq fs_passno
      ```
      
      The last three fields on this line are the file system mount options, the dump frequency of the file system, and the order of file system checks done at boot time. If you don't know what these values should be, then use the values in the example below for them (defaults,nofail 0 2). For more information about /etc/fstab entries, see the `fstab` manual page (by entering `man fstab` on the command line). For example, to mount the ext4 file system on the device with the label MY_RAID at the mount point /mnt/raid, add the following entry to /etc/fstab:
      
      ```
      LABEL=MY_RAID   /mnt/raid   ext4    defaults,nofail        0       2
      ```
      
      **Note**
      If you ever intend to boot your instance without this volume attached (for example, so this volume could move back and forth between different instances), you should add the nofail mount option that allows the instance to boot even if there are errors in mounting the volume. Debian derivatives, such as Ubuntu, must also add the nobootwait mount option.
      
      ```
      LABEL=MY_RAID   /mnt/raid   ext4    defaults,nofail        0       2
      ```
      
   d. After you've added the new entry to /etc/fstab, you need to check that your entry works. Run the `sudo mount -a` command to mount all file systems in /etc/fstab.
      
      ```bash
      [ec2-user ~]$ sudo mount -a
      ```
      
   e. (Optional) If you are unsure how to correct /etc/fstab errors, you can always restore your backup /etc/fstab file with the following command.
      
      ```bash
      [ec2-user ~]$ sudo mv /etc/fstab.orig /etc/fstab
      ```

**Create snapshots of volumes in a RAID array**

If you want to back up the data on the EBS volumes in a RAID array using snapshots, you must ensure that the snapshots are consistent. This is because the snapshots of these volumes are created independently. To restore EBS volumes in a RAID array from snapshots that are out of sync would degrade the integrity of the array.
To create a consistent set of snapshots for your RAID array, use EBS multi-volume snapshots. Multi-volume snapshots allow you to take point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You do not have to stop your instance to coordinate between volumes to ensure consistency because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating multi-volume snapshots under Creating Amazon EBS snapshots.

**Benchmark EBS volumes**

You can test the performance of Amazon EBS volumes by simulating I/O workloads. The process is as follows:

1. Launch an EBS-optimized instance.
2. Create new EBS volumes.
3. Attach the volumes to your EBS-optimized instance.
4. Configure and mount the block device.
5. Install a tool to benchmark I/O performance.
7. Delete your volumes and terminate your instance so that you don’t continue to incur charges.

**Important**

Some of the procedures result in the destruction of existing data on the EBS volumes you benchmark. The benchmarking procedures are intended for use on volumes specially created for testing purposes, not production volumes.

**Set up your instance**

To get optimal performance from EBS volumes, we recommend that you use an EBS-optimized instance. EBS-optimized instances deliver dedicated throughput between Amazon EC2 and Amazon EBS, with instance. EBS-optimized instances deliver dedicated bandwidth between Amazon EC2 and Amazon EBS, with specifications depending on the instance type. For more information, see Amazon EBS–optimized instances (p. 1354).

To create an EBS-optimized instance, choose **Launch as an EBS-Optimized instance** when launching the instance using the Amazon EC2 console, or specify *--ebs-optimized* when using the command line. Be sure that you launch a current-generation instance that supports this option. For more information, see Amazon EBS–optimized instances (p. 1354).

**Set up Provisioned IOPS SSD or General Purpose SSD volumes**

To create Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp2 and gp3) volumes using the Amazon EC2 console, for **Volume type**, choose **Provisioned IOPS SSD (io1)**, **Provisioned IOPS SSD (io2)**, **General Purpose SSD (gp2)**, or **General Purpose SSD (gp3)**. At the command line, specify *io1*, *io2*, *gp2*, or *gp3* for the **--volume-type** parameter. For *io1*, *io2*, and *gp3* volumes, specify the number of I/O operations per second (IOPS) for the **--iops** parameter. For more information, see Amazon EBS volume types (p. 1179) and Create an Amazon EBS volume (p. 1199).

For the example tests, we recommend that you create a RAID 0 array with 6 volumes, which offers a high level of performance. Because you are charged by gigabytes provisioned (and the number of provisioned IOPS for io1, io2, and gp3 volumes), not the number of volumes, there is no additional cost for creating multiple, smaller volumes and using them to create a stripe set. If you're using Oracle Orion to benchmark your volumes, it can simulate striping the same way that Oracle ASM does, so we recommend that you let Orion do the striping. If you are using a different benchmarking tool, you need to stripe the volumes yourself.
For instructions on how to create a RAID 0 array with 6 volumes, see Create a RAID 0 array on Linux (p. 1384).

Set up Throughput Optimized HDD (st1) or Cold HDD (sc1) volumes

To create an st1 volume, choose Throughput Optimized HDD when creating the volume using the Amazon EC2 console, or specify --type st1 when using the command line. To create an sc1 volume, choose Cold HDD when creating the volume using the Amazon EC2 console, or specify --type sc1 when using the command line. For information about creating EBS volumes, see Create an Amazon EBS volume (p. 1199). For information about attaching these volumes to your instance, see Attach an Amazon EBS volume to an instance (p. 1202).

AWS provides a JSON template for use with AWS CloudFormation that simplifies this setup procedure. Access the template and save it as a JSON file. AWS CloudFormation allows you to configure your own SSH keys and offers an easier way to set up a performance test environment to evaluate st1 volumes. The template creates a current-generation instance and a 2 TiB st1 volume, and attaches the volume to the instance at /dev/xvdf.

To create an HDD volume using the template

2. Choose Create Stack.
3. Choose Upload a Template to Amazon S3 and select the JSON template you previously obtained.
4. Give your stack a name like "ebs-perf-testing", and select an instance type (the default is r3.8xlarge) and SSH key.
5. Choose Next twice, and then choose Create Stack.
6. After the status for your new stack moves from CREATE_IN_PROGRESS to COMPLETE, choose Outputs to get the public DNS entry for your new instance, which will have a 2 TiB st1 volume attached to it.
7. Connect using SSH to your new stack as user ec2-user, with the hostname obtained from the DNS entry in the previous step.
8. Proceed to Install benchmark tools (p. 1388).

Install benchmark tools

The following table lists some of the possible tools you can use to benchmark the performance of EBS volumes.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fio</td>
<td>For benchmarking I/O performance. (Note that fio has a dependency on libaio-devel.)</td>
</tr>
<tr>
<td></td>
<td>To install fio on Amazon Linux, run the following command:</td>
</tr>
<tr>
<td></td>
<td>[ec2-user ~]# sudo yum install -y fio</td>
</tr>
<tr>
<td></td>
<td>To install fio on Ubuntu, run the following command:</td>
</tr>
<tr>
<td></td>
<td>sudo apt-get install -y fio</td>
</tr>
<tr>
<td>Oracle Orion Calibration Tool</td>
<td>For calibrating the I/O performance of storage systems to be used with Oracle databases.</td>
</tr>
</tbody>
</table>
These benchmarking tools support a wide variety of test parameters. You should use commands that approximate the workloads your volumes will support. These commands provided below are intended as examples to help you get started.

Choose the volume queue length
Choosing the best volume queue length based on your workload and volume type.

Queue length on SSD-backed volumes
To determine the optimal queue length for your workload on SSD-backed volumes, we recommend that you target a queue length of 1 for every 1000 IOPS available (baseline for General Purpose SSD volumes and the provisioned amount for Provisioned IOPS SSD volumes). Then you can monitor your application performance and tune that value based on your application requirements.

Increasing the queue length is beneficial until you achieve the provisioned IOPS, throughput or optimal system queue length value, which is currently set to 32. For example, a volume with 3,000 provisioned IOPS should target a queue length of 3. You should experiment with tuning these values up or down to see what performs best for your application.

Queue length on HDD-backed volumes
To determine the optimal queue length for your workload on HDD-backed volumes, we recommend that you target a queue length of at least 4 while performing 1MiB sequential I/Os. Then you can monitor your application performance and tune that value based on your application requirements. For example, a 2 TiB st1 volume with burst throughput of 500 MiB/s and IOPS of 500 should target a queue length of 4, 8, or 16 while performing 1,024 KiB, 512 KiB, or 256 KiB sequential I/Os respectively. You should experiment with tuning these values up or down to see what performs best for your application.

Disable C-states
Before you run benchmarking, you should disable processor C-states. Temporarily idle cores in a supported CPU can enter a C-state to save power. When the core is called on to resume processing, a certain amount of time passes until the core is again fully operational. This latency can interfere with processor benchmarking routines. For more information about C-states and which EC2 instance types support them, see Processor state control for your EC2 instance.

Disable C-states on Linux
You can disable C-states on Amazon Linux, RHEL, and CentOS as follows:

1. Get the number of C-states.

```
$ cpupower idle-info | grep "Number of idle states:"  
```

2. Disable the C-states from c1 to cN. Ideally, the cores should be in state c0.

```
$ for i in `seq 1 $((N-1))`; do cpupower idle-set -d $i; done
```

Perform benchmarking
The following procedures describe benchmarking commands for various EBS volume types.

Run the following commands on an EBS-optimized instance with attached EBS volumes. If the EBS volumes were created from snapshots, be sure to initialize them before benchmarking. For more information, see Initialize Amazon EBS volumes (p. 1381).

When you are finished testing your volumes, see the following topics for help cleaning up: Delete an Amazon EBS volume (p. 1226) and Terminate your instance (p. 547).
Benchmark Provisioned IOPS SSD and General Purpose SSD volumes

Run **fio** on the RAID 0 array that you created.

The following command performs 16 KB random write operations.

```
[ec2-user ~]$ sudo fio --directory=/mnt/p_iops_vol0 --ioengine=psync --name fio_test_file --direct=1 --rw=randwrite --bs=16k --size=1G --numjobs=16 --time_based --runtime=180 --group_reporting --norandommap
```

The following command performs 16 KB random read operations.

```
[ec2-user ~]$ sudo fio --directory=/mnt/p_iops_vol0 --name fio_test_file --direct=1 --rw=randread --bs=16k --size=1G --numjobs=16 --time_based --runtime=180 --group_reporting --norandommap
```

For more information about interpreting the results, see this tutorial: Inspecting disk IO performance with **fio**.

**Benchmark st1 and sc1 volumes**

Run **fio** on your st1 or sc1 volume.

**Note**

Prior to running these tests, set buffered I/O on your instance as described in Increase read-ahead for high-throughput, read-heavy workloads on st1 and sc1 (p. 1377).

The following command performs 1 MiB sequential read operations against an attached st1 block device (e.g., `/dev/xvdf`):

```
[ec2-user ~]$ sudo fio --filename=/dev/<device> --direct=1 --rw=read --randrepeat=0 --ioengine=libaio --bs=1024k --iodepth=8 --time_based=1 --runtime=180 --name=fio_direct_read_test
```

The following command performs 1 MiB sequential write operations against an attached st1 block device:

```
[ec2-user ~]$ sudo fio --filename=/dev/<device> --direct=1 --rw=write --randrepeat=0 --ioengine=libaio --bs=1024k --iodepth=8 --time_based=1 --runtime=180 --name=fio_direct_write_test
```

Some workloads perform a mix of sequential reads and sequential writes to different parts of the block device. To benchmark such a workload, we recommend that you use separate, simultaneous **fio** jobs for reads and writes, and use the **fio** offset_increment option to target different block device locations for each job.

Running this workload is a bit more complicated than a sequential-write or sequential-read workload. Use a text editor to create a fio job file, called **fio_rw_mix.cfg** in this example, that contains the following:

```
[globals]
clocksource=clock_gettime
randrepeat=0
runtime=180

[sequential-write]
bs=1M
ioengine=libaio
direct=1
iodepth=8
filename=/dev/<device>
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS CloudWatch metrics

```
do_verify=0
rw=write
rwmixread=0
rwmixwrite=100

[sequential-read]
bs=1M
ioengine=libaio
direct=1
iodepth=8
filename=/dev/<device>
do_verify=0
rw=read
rwmixread=100
rwmixwrite=0
offset=100g
```

Then run the following command:

```
[ec2-user ~]$ sudo fio fio_rw_mix.cfg
```

For more information about interpreting the results, see this tutorial: Inspecting disk I/O performance with fio.

Multiple fio jobs for direct I/O, even though using sequential read or write operations, can result in lower than expected throughput for st1 and sc1 volumes. We recommend that you use one direct I/O job and use the iodepth parameter to control the number of concurrent I/O operations.

**Amazon CloudWatch metrics for Amazon EBS**

Amazon CloudWatch metrics are statistical data that you can use to view, analyze, and set alarms on the operational behavior of your volumes.

Data is available automatically in 1-minute periods at no charge.

When you get data from CloudWatch, you can include a Period request parameter to specify the granularity of the returned data. This is different than the period that we use when we collect the data (1-minute periods). We recommend that you specify a period in your request that is equal to or greater than the collection period to ensure that the returned data is valid.

You can get the data using either the CloudWatch API or the Amazon EC2 console. The console takes the raw data from the CloudWatch API and displays a series of graphs based on the data. Depending on your needs, you might prefer to use either the data from the API or the graphs in the console.

**Topics**
- Amazon EBS metrics (p. 1391)
- Dimensions for Amazon EBS metrics (p. 1396)
- Graphs in the Amazon EC2 console (p. 1396)

**Amazon EBS metrics**

Amazon Elastic Block Store (Amazon EBS) sends data points to CloudWatch for several metrics. All Amazon EBS volume types automatically send 1-minute metrics to CloudWatch, but only when the volume is attached to an instance.

**Metrics**
- Volume metrics for volumes attached to all instance types (p. 1392)
- Volume metrics for volumes attached to Nitro-based instance types (p. 1395)
Volume metrics for volumes attached to all instance types

The AWS/EBS namespace includes the following metrics for EBS volumes that are attached to all instance types. To get information about the available disk space from the operating system on an instance, see View free disk space (p. 1213).

**Note**

- Some metrics have differences on instances that are built on the Nitro System. For a list of these instance types, see Instances built on the Nitro System (p. 199).
- The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances. For more information about these metrics see, Amazon EBS metrics for Nitro-based instances (p. 825).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| VolumeThroughputPercentage     | **Note**  
This metric is not supported with Multi-Attach enabled volumes.  
Used with Provisioned IOPS SSD volumes only. The percentage of I/O operations per second (IOPS) delivered of the total IOPS provisioned for an Amazon EBS volume. Provisioned IOPS SSD volumes deliver their provisioned performance 99.9 percent of the time.  
During a write, if there are no other pending I/O requests in a minute, the metric value will be 100 percent. Also, a volume's I/O performance may become degraded temporarily due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on a non-EBS-optimized instance, or accessing data on the volume for the first time).  
Units: Percent                                                                                                                                                                                                                     |
| VolumeConsumedReadWriteOps     | Used with Provisioned IOPS SSD volumes only. The total amount of read and write operations (normalized to 256K capacity units) consumed in a specified period of time.  
I/O operations that are smaller than 256K each count as 1 consumed IOPS. I/O operations that are larger than 256K are counted in 256K capacity units. For example, a 1024K I/O would count as 4 consumed IOPS.  
Units: Count                                                                                                                                                                                                                     |
| BurstBalance                   | Used with General Purpose SSD (gp2), Throughput Optimized HDD (st1), and Cold HDD (sc1) volumes only. Provides information about the percentage of I/O credits (for gp2) or throughput credits (for st1 and sc1) remaining in the burst bucket. Data is reported to CloudWatch only when the volume is active. If the volume is not attached, no data is reported.  
The `Sum` statistic on this metric is not relevant for volumes attached to instances built on the Nitro System.  
If the baseline performance of the volume exceeds the maximum burst performance, credits are never spent. If the volume is attached to an instance built on the Nitro System, the burst balance is not reported. For other instances, the reported burst balance is 100%. For more information, see **I/O Credits and burst performance** (p. 1183).  
Units: Percent                                                                                                                                                                                                                     |

**Volume metrics for volumes attached to Nitro-based instance types**

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances. For more information about these metrics see, `Amazon EBS metrics for Nitro-based instances` (p. 825).
Fast snapshot restore metrics

AWS/EBS namespace includes the following metrics for fast snapshot restore (p. 1346).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FastSnapshotRestoreCreditsBucketSize</td>
<td>The maximum number of volume create credits that can be accumulated. This metric is reported per snapshot per Availability Zone. The most meaningful statistic is <strong>Average</strong>. The results for the <strong>Minimum</strong> and <strong>Maximum</strong> statistics are the same as for <strong>Average</strong> and could be used instead.</td>
</tr>
<tr>
<td>FastSnapshotRestoreCreditsBalance</td>
<td>The number of volume create credits available. This metric is reported per snapshot per Availability Zone. The most meaningful statistic is <strong>Average</strong>. The results for the <strong>Minimum</strong> and <strong>Maximum</strong> statistics are the same as for <strong>Average</strong> and could be used instead.</td>
</tr>
</tbody>
</table>

Dimensions for Amazon EBS metrics

The supported dimension is the volume ID (**VolumeId**). All available statistics are filtered by volume ID.

For the volume metrics (p. 1392), the supported dimension is the volume ID (**VolumeId**). All available statistics are filtered by volume ID.

For the fast snapshot restore metrics (p. 1396), the supported dimensions are the snapshot ID (**SnapshotId**) and the Availability Zone (**AvailabilityZone**).

Graphs in the Amazon EC2 console

After you create a volume, you can view the volume’s monitoring graphs in the Amazon EC2 console. Select a volume on the **Volumes** page in the console and choose **Monitoring**. The following table lists the graphs that are displayed. The column on the right describes how the raw data metrics from the CloudWatch API are used to produce each graph. The period for all the graphs is 5 minutes.

<table>
<thead>
<tr>
<th>Graph</th>
<th>Description using raw metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read Bandwidth (KiB/s)</td>
<td>Sum(VolumeReadBytes) / Period / 1024</td>
</tr>
<tr>
<td>Write Bandwidth (KiB/s)</td>
<td>Sum(VolumeWriteBytes) / Period / 1024</td>
</tr>
<tr>
<td>Read Throughput (IOPS)</td>
<td>Sum(VolumeReadOps) / Period</td>
</tr>
<tr>
<td>Write Throughput (IOPS)</td>
<td>Sum(VolumeWriteOps) / Period</td>
</tr>
<tr>
<td>Avg Queue Length (Operations)</td>
<td>Avg(VolumeQueueLength)</td>
</tr>
<tr>
<td>% Time Spent Idle</td>
<td>Sum(VolumeIdleTime) / Period × 100</td>
</tr>
<tr>
<td>Avg Read Size (KiB/Operation)</td>
<td>Avg(VolumeReadBytes) / 1024</td>
</tr>
</tbody>
</table>

For Nitro-based instances, the following formula derives Average Read Size using **CloudWatch Metric Math**.
Graph | Description using raw metrics
--- | ---
| \((\text{Sum(VolumeReadBytes)} / \text{Sum(VolumeReadOps)}) / 1024\) | The VolumeReadBytes and VolumeReadOps metrics are available in the EBS CloudWatch console.

### Avg Write Size (KiB/Operation)

| Avg(VolumeWriteBytes) / 1024 | For Nitro-based instances, the following formula derives Average Write Size using CloudWatch Metric Math: \((\text{Sum(VolumeWriteBytes)} / \text{Sum(VolumeWriteOps)}) / 1024\) The VolumeWriteBytes and VolumeWriteOps metrics are available in the EBS CloudWatch console.

### Avg Read Latency (ms/Operation)

| Avg(VolumeTotalReadTime) × 1000 | For Nitro-based instances, the following formula derives Average Read Latency using CloudWatch Metric Math: \((\text{Sum(VolumeTotalReadTime)} / \text{Sum(VolumeReadOps)}) × 1000\) The VolumeTotalReadTime and VolumeReadOps metrics are available in the EBS CloudWatch console.

### Avg Write Latency (ms/Operation)

| Avg(VolumeTotalWriteTime) × 1000 | For Nitro-based instances, the following formula derives Average Write Latency using CloudWatch Metric Math: \((\text{Sum(VolumeTotalWriteTime)} / \text{Sum(VolumeWriteOps)}) × 1000\) The VolumeTotalWriteTime and VolumeWriteOps metrics are available in the EBS CloudWatch console.

For the average latency graphs and average size graphs, the average is calculated over the total number of operations (read or write, whichever is applicable to the graph) that completed during the period.

### Amazon CloudWatch Events for Amazon EBS

Amazon EBS emits notifications based on Amazon CloudWatch Events for a variety of volume, snapshot, and encryption status changes. With CloudWatch Events, you can establish rules that trigger programmatic actions in response to a change in volume, snapshot, or encryption key state. For example, when a snapshot is created, you can trigger an AWS Lambda function to share the completed snapshot with another account or copy it to another Region for disaster-recovery purposes.

Events in CloudWatch are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see Event Patterns in CloudWatch Events in the Amazon CloudWatch Events User Guide.

For more information, see Using Events in the Amazon CloudWatch User Guide.
EBS volume events

Amazon EBS sends events to CloudWatch Events when the following volume events occur.

Events

- Create volume (createVolume) (p. 1398)
- Delete volume (deleteVolume) (p. 1399)
- Volume attach or reattach (attachVolume, reattachVolume) (p. 1400)

Create volume (createVolume)

The createVolume event is sent to your AWS account when an action to create a volume completes. However it is not saved, logged, or archived. This event can have a result of either available or failed. Creation will fail if an invalid AWS KMS key was provided, as shown in the examples below.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createVolume event.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
    ],
    "detail": {
        "result": "available",
        "cause": "",
        "event": "createVolume",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
    }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed createVolume event. The cause for the failure was a disabled KMS key.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"
    ],
    "detail": {
        "result": "failed",
        "cause": "CloudWatch Event Delivery Failure",
        "event": "createVolume",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
    }
}
```
The following is an example of a JSON object that is emitted by EBS after a failed createVolume event. The cause for the failure was a KMS key pending import.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Volume Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "sa-east-1",
  "resources": [
  ],
  "detail": {
     "event": "createVolume",
     "result": "failed",
     "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab is pending import.",
     "request-id": "01234567-0123-0123-0123456789ab",
  }
}
```

Delete volume (deleteVolume)

The deleteVolume event is sent to your AWS account when an action to delete a volume completes. However it is not saved, logged, or archived. This event has the result deleted. If the deletion does not complete, the event is never sent.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful deleteVolume event.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Volume Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
     "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"
  ],
  "detail": {
     "result": "deleted",
     "cause": "",
     "event": "deleteVolume",
  }
}
```
Volume attach or reattach (attachVolume, reattachVolume)

The attachVolume or reattachVolume event is sent to your AWS account if a volume fails to attach or reattach to an instance. However it is not saved, logged, or archived. If you use a KMS key to encrypt an EBS volume and the KMS key becomes invalid, EBS will emit an event if that KMS key is later used to attach or reattach to an instance, as shown in the examples below.

Event data

The listing below is an example of a JSON object emitted by EBS after a failed attachVolume event. The cause for the failure was a KMS key pending deletion.

```json
}
```

The listing below is an example of a JSON object emitted by EBS after a failed reattachVolume event. The cause for the failure was a KMS key pending deletion.

```json
}
```
EBS snapshot events

Amazon EBS sends events to CloudWatch Events when the following volume events occur.

**Events**

- Create snapshot (createSnapshot) (p. 1401)
- Create snapshots (createSnapshots) (p. 1401)
- Copy snapshot (copySnapshot) (p. 1403)
- Share snapshot (shareSnapshot) (p. 1404)

**Create snapshot (createSnapshot)**

The `createSnapshot` event is sent to your AWS account when an action to create a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either `succeeded` or `failed`.

**Event data**

The listing below is an example of a JSON object emitted by EBS for a successful `createSnapshot` event. In the `detail` section, the `source` field contains the ARN of the source volume. The `startTime` and `endTime` fields indicate when creation of the snapshot started and completed.

```json
{
   "version": "0",
   "id": "01234567-0123-0123-0123-012345678901",
   "detail-type": "EBS Snapshot Notification",
   "source": "aws.ec2",
   "account": "012345678901",
   "time": "yyyy-mm-ddTh:mm:ssZ",
   "region": "us-east-1",
   "resources": [
      "arn:aws:ec2:us-west-2::volume/vol-01234567",
      "arn:aws:ec2:us-west-2::snapshot/snap-01234567"
   ],
   "detail": {
      "event": "createSnapshot",
      "result": "succeeded",
      "cause": "",
      "request-id": "",
      "snapshot_id": "arn:aws:ec2:us-west-2::snapshot/snap-01234567",
      "source": "arn:aws:ec2:us-west-2::volume/vol-01234567",
      "startTime": "yyyy-mm-ddTh:mm:ssZ",
      "endTime": "yyyy-mm-ddTh:mm:ssZ"
   }
}
```

**Create snapshots (createSnapshots)**

The `createSnapshots` event is sent to your AWS account when an action to create a multi-volume snapshot completes. This event can have a result of either `succeeded` or `failed`.

**Event data**

The listing below is an example of a JSON object emitted by EBS for a successful `createSnapshots` event. In the `detail` section, the `source` field contains the ARNs of the source volumes of the multi-
volume snapshot set. The **startTime** and **endTime** fields indicate when creation of the snapshot started and completed.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Multi-Volume Snapshots Completion Status",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
    "arn:aws:ec2::us-east-1:snapshot/snap-012345678"
  ],
  "detail": {
    "event": "createSnapshots",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ",
    "snapshots": [
      {
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
        "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "status": "completed"
      },
      {
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678",
        "source": "arn:aws:ec2::us-east-1:volume/vol-012345678",
        "status": "completed"
      }
    ]
  }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed **createSnapshots** event. The cause for the failure was one or more snapshots for the multi-volume snapshot set failed to complete. The values of **snapshot_id** are the ARNs of the failed snapshots. **startTime** and **endTime** represent when the create-snapshots action started and ended.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Multi-Volume Snapshots Completion Status",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
    "arn:aws:ec2::us-east-1:snapshot/snap-012345678"
  ],
  "detail": {
    "event": "createSnapshots",
    "result": "failed",
    "cause": "Snapshot snap-01234567 is in status error",
    "request-id": "",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ",
    "snapshots": [
      {
      }
    ]
  }
}
```
Copy snapshot (copySnapshot)

The copySnapshot event is sent to your AWS account when an action to copy a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS after a successful copySnapshot event. The value of snapshot_id is the ARN of the newly created snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2::snapshot/snap-01234567",
        "arn:aws:ec2::us-west-2::snapshot/snap-01234567",
        "arn:aws:ec2::eu-west-1::snapshot/snap-76543210",
        "arn:aws:ec2::eu-west-1::snapshot/snap-76543210",
        "arn:aws:ec2::eu-west-1::snapshot/snap-76543210"
    ],
    "detail": {
        "event": "copySnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-west-2::snapshot/snap-01234567",
        "source": "arn:aws:ec2::us-west-2::snapshot/snap-01234567",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ",
        "Incremental": "True"
    }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed copySnapshot event. The cause for the failure was an invalid source snapshot ID. The value of snapshot_id is the ARN of the failed snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "arn:aws:ec2::us-east-1:volume/vol-01234567"
    ],
    "detail": {
        "event": "copySnapshot",
        "result": "failed",
        "cause": "",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ"
    }
}
```
EBS CloudWatch events

Share snapshot (shareSnapshot)

The `shareSnapshot` event is sent to your AWS account when another account shares a snapshot with it. However it is not saved, logged, or archived. The result is always `succeeded`.

**Event data**

The following is an example of a JSON object emitted by EBS after a completed `shareSnapshot` event. In the `detail` section, the value of `source` is the AWS account number of the user that shared the snapshot with you. `startTime` and `endTime` represent when the share-snapshot action started and ended. The `shareSnapshot` event is emitted only when a private snapshot is shared with another user. Sharing a public snapshot does not trigger the event.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyyMMdd-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-west-2::snapshot/snap-01234567"
  ],
  "detail": {
    "event": "shareSnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2:us-west-2::snapshot/snap-01234567",
    "source": "arn:aws:ec2:us-west-2::snapshot/snap-01234567",
    "startTime": "yyyyMMdd-ddThh:mm:ssZ",
    "endTime": "yyyyMMdd-ddThh:mm:ssZ"
  }
}
```

EBS volume modification events

Amazon EBS sends `modifyVolume` events to CloudWatch Events when a volume is modified. However it is not saved, logged, or archived.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Volume Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyyMMdd-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-west-2::snapshot/snap-01234567"
  ],
  "detail": {
    "event": "modifyVolume",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2:us-west-2::snapshot/snap-01234567",
    "source": "arn:aws:ec2:us-west-2::snapshot/snap-01234567",
    "startTime": "yyyyMMdd-ddThh:mm:ssZ",
    "endTime": "yyyyMMdd-ddThh:mm:ssZ"
  }
}
```
EBS CloudWatch events

Amazon EBS sends events to CloudWatch Events when the state of fast snapshot restore for a snapshot changes. Events are emitted on a best effort basis.

The following is example data for this event.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Fast Snapshot Restore State-change Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1::snapshot/snap-03a55cf6513fa1b6"
  ],
  "detail": {
    "snapshot-id": "snap-123456789abcdef0",
    "state": "optimizing",
    "zone": "us-east-1a",
    "message": "Client.UserInitiated - Lifecycle state transition",
  }
}
```

The possible values for state are enabling, optimizing, enabled, disabling, and disabled.

The possible values for message are as follows:

Client.InvalidSnapshot.InvalidState - The requested snapshot transitioned to an invalid state (Error)

A request to enable fast snapshot restore failed and the state transitioned to disabling or disabled. Fast snapshot restore cannot be enabled for this snapshot.

Client.UserInitiated

The state successfully transitioned to enabling or disabling.

Client.UserInitiated - Lifecycle state transition

The state successfully transitioned to optimizing, enabled, or disabled.

Server.InsufficientCapacity - There was insufficient capacity available to satisfy the request

A request to enable fast snapshot restore failed due to insufficient capacity, and the state transitioned to disabling or disabled. Wait and then try again.
Server.InternalError – An internal error caused the operation to fail

A request to enable fast snapshot restore failed due to an internal error, and the state transitioned to disabling or disabled. Wait and then try again.

Client.InvalidSnapshot.InvalidState – The requested snapshot was deleted or access permissions were revoked

The fast snapshot restore state for the snapshot has transitioned to disabling or disabled because the snapshot was deleted or unshared by the snapshot owner. Fast snapshot restore cannot be enabled for a snapshot that has been deleted or is no longer shared with you.

Using AWS Lambda to handle CloudWatch events

You can use Amazon EBS and CloudWatch Events to automate your data-backup workflow. This requires you to create an IAM policy, a AWS Lambda function to handle the event, and an Amazon CloudWatch Events rule that matches incoming events and routes them to the Lambda function.

The following procedure uses the createSnapshot event to automatically copy a completed snapshot to another Region for disaster recovery.

To copy a completed snapshot to another Region

1. Create an IAM policy, such as the one shown in the following example, to provide permissions to use the CopySnapshot action and write to the CloudWatch Events log. Assign the policy to the IAM user that will handle the CloudWatch event.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs:*:*:*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CopySnapshot"
            ],
            "Resource": "*
        }
    ]
}
```

2. Define a function in Lambda that will be available from the CloudWatch console. The sample Lambda function below, written in Node.js, is invoked by CloudWatch when a matching createSnapshot event is emitted by Amazon EBS (signifying that a snapshot was completed). When invoked, the function copies the snapshot from us-east-2 to us-east-1.

```javascript
// Sample Lambda function to copy an EBS snapshot to a different Region
var AWS = require('aws-sdk');
var ec2 = new AWS.EC2();

// define variables
var destinationRegion = 'us-east-1';
```
var sourceRegion = 'us-east-2';

console.log('Loading function');

//main function
exports.handler = (event, context, callback) => {

    // Get the EBS snapshot ID from the CloudWatch event details
    var snapshotArn = event.detail.snapshot_id.split('/');
    const snapshotId = snapshotArn[1];
    const description = `Snapshot copy from ${snapshotId} in ${sourceRegion}.`;
    console.log(`snapshotId: ${snapshotId}`);

    // Load EC2 class and update the configuration to use destination Region to
    // initiate the snapshot.
    AWS.config.update({region: destinationRegion});
    var ec2 = new AWS.EC2();

    // Prepare variables for ec2.modifySnapshotAttribute call
    const copySnapshotParams = {
        Description: description,
        DestinationRegion: destinationRegion,
        SourceRegion: sourceRegion,
        SourceSnapshotId: snapshotId
    };

    // Execute the copy snapshot and log any errors
    ec2.copySnapshot(copySnapshotParams, (err, data) => {
        if (err) {
            const errorMessage = `Error copying snapshot ${snapshotId} to Region
${destinationRegion}.`;
            console.log(errorMessage);
            console.log(err);
            callback(errorMessage);
        } else {
            const successMessage = `Successfully started copy of snapshot ${snapshotId}
to Region ${destinationRegion}.`;
            console.log(successMessage);
            console.log(data);
            callback(null, successMessage);
        }
    });
};

To ensure that your Lambda function is available from the CloudWatch console, create it in the
Region where the CloudWatch event will occur. For more information, see the AWS Lambda
Developer Guide.

4. Choose Events, Create rule, Select event source, and Amazon EBS Snapshots.
5. For Specific Event(s), choose createSnapshot and for Specific Result(s), choose succeeded.
6. For Rule target, find and choose the sample function that you previously created.
7. Choose Target, Add Target.
8. For Lambda function, select the Lambda function that you previously created and choose Configure
details.
9. On the Configure rule details page, type values for Name and Description. Select the State check
box to activate the function (setting it to Enabled).
10. Choose Create rule.

Your rule should now appear on the Rules tab. In the example shown, the event that you configured
should be emitted by EBS the next time you copy a snapshot.
### Amazon EBS quotas

To view the quotas for your Amazon EBS resources, open the Service Quotas console at [https://console.aws.amazon.com/servicequotas/](https://console.aws.amazon.com/servicequotas/). In the navigation pane, choose **AWS services**, and select **Amazon Elastic Block Store (Amazon EBS)**.

For a list of Amazon EBS service quotas, see [Amazon Elastic Block Store endpoints and quotas](https://docs.aws.amazon.com/elasticloadbalancing/latest/application/admin/ElasticLoadBalancing-EBS-quotas.html) in the **AWS General Reference**.

### Amazon EC2 instance store

An **instance store** provides temporary block-level storage for your instance. This storage is located on disks that are physically attached to the host computer. Instance store is ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content, or for data that is replicated across a fleet of instances, such as a load-balanced pool of web servers.

An instance store consists of one or more instance store volumes exposed as block devices. The size of an instance store as well as the number of devices available varies by instance type.

The virtual devices for instance store volumes are `ephemeral[0-23]`. Instance types that support one instance store volume have `ephemeral0`. Instance types that support two instance store volumes have `ephemeral0` and `ephemeral1`, and so on.

---

**Contents**

- Instance store lifetime (p. 1409)
- Instance store volumes (p. 1409)
- Add instance store volumes to your EC2 instance (p. 1417)
- SSD instance store volumes (p. 1421)
- Instance store swap volumes (p. 1422)
- Optimize disk performance for instance store volumes (p. 1425)
Instance store lifetime

You can specify instance store volumes for an instance only when you launch it. You can't detach an instance store volume from one instance and attach it to a different instance.

The data in an instance store persists only during the lifetime of its associated instance. If an instance reboots (intentionally or unintentionally), data in the instance store persists. However, data in the instance store is lost under any of the following circumstances:

- The underlying disk drive fails
- The instance stops
- The instance hibernates
- The instance terminates

Therefore, do not rely on instance store for valuable, long-term data. Instead, use more durable data storage, such as Amazon S3, Amazon EBS, or Amazon EFS.

When you stop, hibernate, or terminate an instance, every block of storage in the instance store is reset. Therefore, your data cannot be accessed through the instance store of another instance.

If you create an AMI from an instance, the data on its instance store volumes isn't preserved and isn't present on the instance store volumes of the instances that you launch from the AMI.

If you change the instance type, an instance store will not be attached to the new instance type. For more information, see Change the instance type (p. 310).

Instance store volumes

The instance type determines the size of the instance store available and the type of hardware used for the instance store volumes. Instance store volumes are included as part of the instance's usage cost. You must specify the instance store volumes that you'd like to use when you launch the instance (except for NVMe instance store volumes, which are available by default). Then format and mount the instance store volumes before using them. You can't make an instance store volume available after you launch the instance. For more information, see Add instance store volumes to your EC2 instance (p. 1417).

Some instance types use NVMe or SATA-based solid state drives (SSD) to deliver high random I/O performance. This is a good option when you need storage with very low latency, but you don't need the data to persist when the instance terminates or you can take advantage of fault-tolerant architectures. For more information, see SSD instance store volumes (p. 1421).

The data on NVMe instance store volumes and some HDD instance store volumes is encrypted at rest. For more information, see Data protection in Amazon EC2 (p. 1066).

The following table provides the quantity, size, type, and performance optimizations of instance store volumes available on each supported instance type. For a complete list of instance types, including EBS-only types, see Amazon EC2 Instance Types.

* Volumes attached to certain instances suffer a first-write penalty unless initialized. For more information, see Optimize disk performance for instance store volumes (p. 1425).

** For more information, see Instance store volume TRIM support (p. 1422).

† The c1.medium and m1.small instance types also include a 900 MB instance store swap volume, which may not be automatically enabled at boot time. For more information, see Instance store swap volumes (p. 1422).

**To query instance store volume information using the AWS CLI**

You can use the describe-instance-types AWS CLI command to display information about an instance type, such as its instance store volumes. The following example displays the total size of instance storage for all R5 instances with instance store volumes.

```bash
describe-instance-types --filters "Name=instance-type,Values=r5*" "Name=instance-storage-supported,Values=true" --query "InstanceTypes[].[InstanceType, InstanceStorageInfo.TotalSizeInGB]" --output table
```

* | DescribeInstanceTypes |
The following example displays the complete instance storage details for the specified instance type.

```
aws ec2 describe-instance-types --filters "Name=instance-type,Values=r5d.4xlarge" --query "InstanceTypes[].InstanceStorageInfo"
```

The example output shows that this instance type has two 300 GB NVMe SSD volumes, for a total of 600 GB of instance storage.

```
[
  {
    "TotalSizeInGB": 600,
    "Disks": [
      {
        "SizeInGB": 300,
        "Count": 2,
        "Type": "ssd"
      }
    ],
    "NvmeSupport": "required"
  }
]
```

## Add instance store volumes to your EC2 instance

You specify the EBS volumes and instance store volumes for your instance using a block device mapping. Each entry in a block device mapping includes a device name and the volume that it maps to. The default block device mapping is specified by the AMI you use. Alternatively, you can specify a block device mapping for the instance when you launch it.

All the NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in the block device mapping for the AMI or the instance has no effect. For more information, see Block device mappings (p. 1441).

A block device mapping always specifies the root volume for the instance. The root volume is either an Amazon EBS volume or an instance store volume. For more information, see Storage for the root device (p. 73). The root volume is mounted automatically. For instances with an instance store volume for the root volume, the size of this volume varies by AMI, but the maximum size is 10 GB.

You can use a block device mapping to specify additional EBS volumes when you launch your instance, or you can attach additional EBS volumes after your instance is running. For more information, see Amazon EBS volumes (p. 1177).

You can specify the instance store volumes for your instance only when you launch it. You can't attach instance store volumes to an instance after you've launched it.

If you change the instance type, an instance store will not be attached to the new instance type. For more information, see Change the instance type (p. 310).
The number and size of available instance store volumes for your instance varies by instance type. Some instance types do not support instance store volumes. If the number of instance store volumes in a block device mapping exceeds the number of instance store volumes available to an instance, the additional volumes are ignored. For more information about the instance store volumes supported by each instance type, see Instance store volumes (p. 1409).

If the instance type you choose for your instance supports non-NVMe instance store volumes, you must add them to the block device mapping for the instance when you launch it. NVMe instance store volumes are available by default. After you launch an instance, you must ensure that the instance store volumes for your instance are formatted and mounted before you can use them. The root volume of an instance store-backed instance is mounted automatically.

Contents
- Add instance store volumes to an AMI (p. 1418)
- Add instance store volumes to an instance (p. 1419)
- Make instance store volumes available on your instance (p. 1420)

Add instance store volumes to an AMI

You can create an AMI with a block device mapping that includes instance store volumes. If you launch an instance with an instance type that supports instance store volumes and an AMI that specifies instance store volumes in its block device mapping, the instance includes these instance store volumes. If the number of instance store volumes in the block device mapping exceeds the number of instance store volumes available to the instance, the additional instance store volumes are ignored.

Considerations
- For M3 instances, specify instance store volumes in the block device mapping of the instance, not the AMI. Amazon EC2 might ignore instance store volumes that are specified only in the block device mapping of the AMI.
- When you launch an instance, you can omit non-NVMe instance store volumes specified in the AMI block device mapping or add instance store volumes.

New console

To add instance store volumes to an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the instance.
3. Choose Actions, Image and templates, Create image.
4. On the Create image page, enter a meaningful name and description for your image.
5. For each instance store volume to add, choose Add volume, from Volume type select an instance store volume, and from Device select a device name. (For more information, see Device names on Linux instances (p. 1439).) The number of available instance store volumes depends on the instance type. For instances with NVMe instance store volumes, the device mapping of these volumes depends on the order in which the operating system enumerates the volumes.
6. Choose Create image.

Old console

To add instance store volumes to an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the instance.
3. Choose **Actions, Image, Create Image**.

4. In the **Create Image** dialog box, type a meaningful name and description for your image.

5. For each instance store volume to add, choose **Add New Volume**, from **Volume Type** select an instance store volume, and from **Device** select a device name. (For more information, see Device names on Linux instances (p. 1439).) The number of available instance store volumes depends on the instance type. For instances with NVMe instance store volumes, the device mapping of these volumes depends on the order in which the operating system enumerates the volumes.

6. Choose **Create Image**.

**To add instance store volumes to an AMI using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `create-image` or `register-image` (AWS CLI)
- `New-EC2Image` and `Register-EC2Image` (AWS Tools for Windows PowerShell)

**Add instance store volumes to an instance**

When you launch an instance, the default block device mapping is provided by the specified AMI. If you need additional instance store volumes, you must add them to the instance as you launch it. You can also omit devices specified in the AMI block device mapping.

**Considerations**

- For M3 instances, you might receive instance store volumes even if you do not specify them in the block device mapping for the instance.
- For HS1 instances, no matter how many instance store volumes you specify in the block device mapping of an AMI, the block device mapping for an instance launched from the AMI automatically includes the maximum number of supported instance store volumes. You must explicitly remove the instance store volumes that you don't want from the block device mapping for the instance before you launch it.

**To update the block device mapping for an instance using the console**

1. Open the Amazon EC2 console.

2. From the dashboard, choose **Launch instance**.

3. In **Step 1: Choose an Amazon Machine Image (AMI)**, select the AMI to use and choose **Select**.

4. Follow the wizard to complete **Step 1: Choose an Amazon Machine Image (AMI), Step 2: Choose an Instance Type**, and **Step 3: Configure Instance Details**.

5. In **Step 4: Add Storage**, modify the existing entries as needed. For each instance store volume to add, choose **Add New Volume**, from **Volume Type** select an instance store volume, and from **Device** select a device name. The number of available instance store volumes depends on the instance type.

6. Complete the wizard and launch the instance.

7. (Optional) To view the instance store volumes available on your instance, run the `lsblk` command.

**To update the block device mapping for an instance using the command line**

You can use one of the following options commands with the corresponding command. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `--block-device-mappings` with `run-instances` (AWS CLI)
• -BlockDeviceMapping with New-EC2Instance (AWS Tools for Windows PowerShell)

Make instance store volumes available on your instance

After you launch an instance, the instance store volumes are available to the instance, but you can't access them until they are mounted. For Linux instances, the instance type determines which instance store volumes are mounted for you and which are available for you to mount yourself. For Windows instances, the EC2Config service mounts the instance store volumes for an instance. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different than the name that Amazon EC2 recommends.

Many instance store volumes are pre-formatted with the ext3 file system. SSD-based instance store volumes that support TRIM instruction are not pre-formatted with any file system. However, you can format volumes with the file system of your choice after you launch your instance. For more information, see Instance store volume TRIM support (p. 1422). For Windows instances, the EC2Config service reformats the instance store volumes with the NTFS file system.

You can confirm that the instance store devices are available from within the instance itself using instance metadata. For more information, see View the instance block device mapping for instance store volumes (p. 1450).

For Windows instances, you can also view the instance store volumes using Windows Disk Management. For more information, see List disks using Windows Disk Management.

For Linux instances, you can view and mount the instance store volumes as described in the following procedure.

To make an instance store volume available on Linux

1. Connect to the instance using an SSH client. For more information, see Connect to your Linux instance (p. 499).
2. Use the df -h command to view the volumes that are formatted and mounted.

```
[ec2-user ~]$ df -h
Filesystem      Size  Used Avail Use% Mounted on
devtmpfs        3.8G   72K  3.8G   1% /dev
tmpfs           3.8G     0  3.8G   0% /dev/shm
/dev/nvme0n1p1  7.9G  1.2G  6.6G  15% /
```

3. Use the lsblk command to view any volumes that were mapped at launch but not formatted and mounted.

```
[ec2-user ~]$ lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme0n1       259:1    0     8G  0 disk
##nvme0n1p1   259:2    0     8G  0 part /
##nvme0n1p128 259:3    0    1M  0 part
nvme1n1       259:0    0  69.9G  0 disk
```

4. To format and mount an instance store volume that was mapped only, do the following:
   a. Create a file system on the device using the mkfs command.

```
[ec2-user ~]$ sudo mkfs -t xfs /dev/nvme1n1
```

   b. Create a directory on which to mount the device using the mkdir command.

```
[ec2-user ~]$ sudo mkdir /data
```
c. Mount the device on the newly created directory using the `mount` command.

```
[ec2-user ~]$ sudo mount /dev/nvme1n1 /data
```

For instructions on how to mount an attached volume automatically after reboot, see Automatically mount an attached volume after reboot (p. 1210).

## SSD instance store volumes

To ensure the best IOPS performance from your SSD instance store volumes on Linux, we recommend that you use the most recent version of Amazon Linux, or another Linux AMI with a kernel version of 3.8 or later. If you do not use a Linux AMI with a kernel version of 3.8 or later, your instance won’t achieve the maximum IOPS performance available for these instance types.

Like other instance store volumes, you must map the SSD instance store volumes for your instance when you launch it. The data on an SSD instance volume persists only for the life of its associated instance. For more information, see Add instance store volumes to your EC2 instance (p. 1417).

### NVMe SSD volumes

Some instances offer non-volatile memory express (NVMe) solid state drives (SSD) instance store volumes. For more information about the type of instance store volume supported by each instance type, see Instance store volumes (p. 1409).

To access NVMe volumes, the NVMe drivers (p. 1350) must be installed. The following AMIs meet this requirement:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

After you connect to your instance, you can list the NVMe devices using the `lspci` command. The following is example output for an `i3.8xlarge` instance, which supports four NVMe devices.

```
[ec2-user ~]$ lspci
00:00.0 Host bridge: Intel Corporation 440FX - 82441FX PMC [Natoma] (rev 02)
00:01.0 ISA bridge: Intel Corporation 82371SB PIIX3 ISA [Natoma/Triton II]
00:01.1 IDE interface: Intel Corporation 82371SB PIIX3 IDE [Natoma/Triton II]
00:01.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 01)
00:02.0 VGA compatible controller: Cirrus Logic GD 5446
00:03.0 Ethernet controller: Device 1d0f:ec20
00:17.0 Non-Volatile memory controller: Device 1d0f:cd01
00:18.0 Non-Volatile memory controller: Device 1d0f:cd01
00:19.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1a.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1f.0 Unassigned class [ff80]: XenSource, Inc. Xen Platform Device (rev 01)
```

If you are using a supported operating system but you do not see the NVMe devices, verify that the NVMe module is loaded using the following command.
• Amazon Linux, Amazon Linux 2, Ubuntu 14/16, Red Hat Enterprise Linux, SUSE Linux Enterprise Server, CentOS 7

```bash
$ lsmod | grep nvme
nvme          48813  0
```

• Ubuntu 18

```bash
$ cat /lib/modules/$(uname -r)/modules.builtin | grep nvme
s/nvme/host/nvme-core.ko
kernel/drivers/nvme/host/nvme.ko
kernel/drivers/nvmem/nvmem_core.ko
```

The NVMe volumes are compliant with the NVMe 1.0e specification. You can use the NVMe commands with your NVMe volumes. With Amazon Linux, you can install the `nvme-cli` package from the repo using the `yum install` command. With other supported versions of Linux, you can download the `nvme-cli` package if it's not available in the image.

The data on NVMe instance storage is encrypted using an XTS-AES-256 block cipher implemented in a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

### Non-NVMe SSD volumes

The following instances support instance store volumes that use non-NVMe SSDs to deliver high random I/O performance: C3, G2, I2, M3, R3, and X1. For more information about the instance store volumes supported by each instance type, see Instance store volumes (p. 1409).

### Instance store volume TRIM support

Some instance types support SSD volumes with TRIM. For more information, see Instance store volumes (p. 1409).

Instance store volumes that support TRIM are fully trimmed before they are allocated to your instance. These volumes are not formatted with a file system when an instance launches, so you must format them before they can be mounted and used. For faster access to these volumes, you should skip the TRIM operation when you format them.

With instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller when you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. On Linux, use the `fstrim` command to enable periodic TRIM.

### Instance store swap volumes

Swap space in Linux can be used when a system requires more memory than it has been physically allocated. When swap space is enabled, Linux systems can swap infrequently used memory pages from physical memory to swap space (either a dedicated partition or a swap file in an existing file system) and free up that space for memory pages that require high-speed access.

**Note**

Using swap space for memory paging is not as fast or efficient as using RAM. If your workload is regularly paging memory into swap space, you should consider migrating to a larger instance type with more RAM. For more information, see Change the instance type (p. 310).
The c1.medium and m1.small instance types have a limited amount of physical memory to work with, and they are given a 900 MiB swap volume at launch time to act as virtual memory for Linux AMIs. Although the Linux kernel sees this swap space as a partition on the root device, it is actually a separate instance store volume, regardless of your root device type.

Amazon Linux automatically enables and uses this swap space, but your AMI may require some additional steps to recognize and use this swap space. To see if your instance is using swap space, you can use the `swapon -s` command.

```
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

The above instance has a 900 MiB swap volume attached and enabled. If you don’t see a swap volume listed with this command, you may need to enable swap space for the device. Check your available disks using the `lsblk` command.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk
```

Here, the swap volume `xvda3` is available to the instance, but it is not enabled (notice that the `MOUNTPOINT` field is empty). You can enable the swap volume with the `swapon` command.

```
Note
You must prepend `/dev/` to the device name listed by `lsblk`. Your device may be named differently, such as `sda3`, `sde3`, or `xvde3`. Use the device name for your system in the command below.
```

```
[ec2-user ~]$ sudo swapon /dev/xvda3
```

Now the swap space should show up in `lsblk` and `swapon -s` output.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk [SWAP]
```

```
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

You also need to edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

Append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvda3 none swap sw 0 0
```

**To use an instance store volume as swap space**

Any instance store volume can be used as swap space. For example, the m3.medium instance type includes a 4 GB SSD instance store volume that is appropriate for swap space. If your instance store
volume is much larger (for example, 350 GB), you may consider partitioning the volume with a smaller swap partition of 4-8 GB and the rest for a data volume.

**Note**
This procedure applies only to instance types that support instance storage. For a list of supported instance types, see [Instance store volumes](#).

1. List the block devices attached to your instance to get the device name for your instance store volume.

```
[ec2-user ~]# lsblk -p
NAME   MAJ:MIN RM  SIZE   RO Type MOUNTPOINT
/dev/xvdbe 202:16   0   4G  0 disk /media/ephemeral0
/dev/xvda1 202:1    0   8G  0 disk /
```

In this example, the instance store volume is `/dev/xvdbe`. Because this is an Amazon Linux instance, the instance store volume is formatted and mounted at `/media/ephemeral0`; not all Linux operating systems do this automatically.

2. (Optional) If your instance store volume is mounted (it lists a `MOUNTPOINT` in the `lsblk` command output), unmount it with the following command.

```
[ec2-user ~]# sudo umount /dev/xvdb
```

3. Set up a Linux swap area on the device with the `mkswap` command.

```
[ec2-user ~]# sudo mkswap /dev/xvdb
mkswap: /dev/xvdbe: warning: wiping old ext3 signature.
Setting up swapspace version 1, size = 4188668 KiB
no label, UUID=b4f63d28-67ed-46f0-b5e5-6928319e620b
```

4. Enable the new swap space.

```
[ec2-user ~]# sudo swapon /dev/xvdb
```

5. Verify that the new swap space is being used.

```
[ec2-user ~]# swapon -s
Filename   Type    Size Used Priority
/dev/xvdb          partition 4188668 0 -1
```

6. Edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]# sudo vim /etc/fstab
```

If your `/etc/fstab` file has an entry for `/dev/xvdb` (or `/dev/sdb`) change it to match the line below; if it does not have an entry for this device, append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvdb none       swap    sw 0  0
```

**Important**
Instance store volume data is lost when an instance is stopped or hibernated; this includes the instance store swap space formatting created in Step 3 (p. 1424). If you stop and restart an instance that has been configured to use instance store swap space, you must repeat Step 1 (p. 1424) through Step 5 (p. 1424) on the new instance store volume.

---

1424
Optimize disk performance for instance store volumes

Because of the way that Amazon EC2 virtualizes disks, the first write to any location on some instance store volumes performs more slowly than subsequent writes. For most applications, amortizing this cost over the lifetime of the instance is acceptable. However, if you require high disk performance, we recommend that you initialize your drives by writing once to every drive location before production use.

**Note**
Some instance types with direct-attached solid state drives (SSD) and TRIM support provide maximum performance at launch time, without initialization. For information about the instance store for each instance type, see Instance store volumes (p. 1409).

If you require greater flexibility in latency or throughput, we recommend using Amazon EBS.

To initialize the instance store volumes, use the following `dd` commands, depending on the store to initialize (for example, `/dev/sdb` or `/dev/nvme1n1`).

**Note**
Make sure to unmount the drive before performing this command.
Initialization can take a long time (about 8 hours for an extra large instance).

To initialize the instance store volumes, use the following commands on the m1.large, m1.xlarge, c1.xlarge, m2.xlarge, m2.2xlarge, and m2.4xlarge instance types:

```
dd if=/dev/zero of=/dev/sdb bs=1M
dd if=/dev/zero of=/dev/sdc bs=1M
dd if=/dev/zero of=/dev/sdd bs=1M
dd if=/dev/zero of=/dev/sde bs=1M
```

To perform initialization on all instance store volumes at the same time, use the following command:

```
dd if=/dev/zero bs=1M | tee /dev/sdb | tee /dev/sdc | tee /dev/sde > /dev/sdd
```

Configuring drives for RAID initializes them by writing to every drive location. When configuring software-based RAID, make sure to change the minimum reconstruction speed:

```
echo $((30*1024)) > /proc/sys/dev/raid/speed_limit_min
```

File storage

Cloud file storage is a method for storing data in the cloud that provides servers and applications access to data through shared file systems. This compatibility makes cloud file storage ideal for workloads that rely on shared file systems and provides simple integration without code changes.

There are many file storage solutions that exist, ranging from a single node file server on a compute instance using block storage as the underpinnings with no scalability or few redundancies to protect the data, to a do-it-yourself clustered solution, to a fully-managed solution. The following content introduces some of the storage services provided by AWS for use with Linux.

**Contents**
- Use Amazon S3 with Amazon EC2 (p. 1426)
- Use Amazon EFS with Amazon EC2 (p. 1427)
Use Amazon S3 with Amazon EC2

Amazon S3 is a repository for internet data. Amazon S3 provides access to reliable, fast, and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. Amazon S3 stores data objects redundantly on multiple devices across multiple facilities and allows concurrent read or write access to these data objects by many separate clients or application threads. You can use the redundant data stored in Amazon S3 to recover quickly and reliably from instance or application failures.

Amazon EC2 uses Amazon S3 for storing Amazon Machine Images (AMIs). You use AMIs for launching EC2 instances. In case of instance failure, you can use the stored AMI to immediately launch another instance, thereby allowing for fast recovery and business continuity.

Amazon EC2 also uses Amazon S3 to store snapshots (backup copies) of the data volumes. You can use snapshots for recovering data quickly and reliably in case of application or system failures. You can also use snapshots as a baseline to create multiple new data volumes, expand the size of an existing data volume, or move data volumes across multiple Availability Zones, thereby making your data usage highly scalable. For more information about using data volumes and snapshots, see Amazon Elastic Block Store (p. 1175).

Objects are the fundamental entities stored in Amazon S3. Every object stored in Amazon S3 is contained in a bucket. Buckets organize the Amazon S3 namespace at the highest level and identify the account responsible for that storage. Amazon S3 buckets are similar to internet domain names. Objects stored in the buckets have a unique key value and are retrieved using a URL. For example, if an object with a key value /photos/mygarden.jpg is stored in the DOC-EXAMPLE-BUCKET1 bucket, then it is addressable using the URL https://DOC-EXAMPLE-BUCKET1.s3.amazonaws.com/photos/mygarden.jpg.

For more information about the features of Amazon S3, see the Amazon S3 product page.

Usage examples

Given the benefits of Amazon S3 for storage, you might decide to use this service to store files and data sets for use with EC2 instances. There are several ways to move data to and from Amazon S3 to your instances. In addition to the examples discussed below, there are a variety of tools that people have written that you can use to access your data in Amazon S3 from your computer or your instance. Some of the common ones are discussed in the AWS forums.

If you have permission, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

GET or wget

The wget utility is an HTTP and FTP client that allows you to download public objects from Amazon S3. It is installed by default in Amazon Linux and most other distributions, and available for download on Windows. To download an Amazon S3 object, use the following command, substituting the URL of the object to download.

```
[ec2-user ~]$ wget https://my_bucket.s3.amazonaws.com/path-to-file
```

This method requires that the object you request is public; if the object is not public, you receive an "ERROR 403: Forbidden" message. If you receive this error, open the Amazon S3 console and change the permissions of the object to public. For more information, see the Amazon Simple Storage Service Developer Guide.

AWS Command Line Interface
The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. The AWS CLI enables users to authenticate themselves and download restricted items from Amazon S3 and also to upload items. For more information, such as how to install and configure the tools, see the AWS Command Line Interface detail page.

The `aws s3 cp` command is similar to the Unix `cp` command. You can copy files from Amazon S3 to your instance, copy files from your instance to Amazon S3, and copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance.

```
[ec2-user ~]$ aws s3 cp s3://my_bucket/my_folder/my_file.ext my_copied_file.ext
```

Use the following command to copy an object from your instance back into Amazon S3.

```
[ec2-user ~]$ aws s3 cp my_copied_file.ext s3://my_bucket/my_folder/my_file.ext
```

The `aws s3 sync` command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance.

```
[ec2-user ~]$ aws s3 sync s3://remote_S3_bucket local_directory
```

Amazon S3 API

If you are a developer, you can use an API to access data in Amazon S3. For more information, see the Amazon Simple Storage Service Developer Guide. You can use this API and its examples to help develop your application and integrate it with other APIs and SDKs, such as the boto Python interface.

**Use Amazon EFS with Amazon EC2**

Amazon EFS provides scalable file storage for use with Amazon EC2. You can use an EFS file system as a common data source for workloads and applications running on multiple instances. For more information, see the Amazon Elastic File System product page.

**Important**

Amazon EFS is not supported on Windows instances.

You can mount an EFS file system to your instance in the following ways:

**Topics**

- Create an EFS file system using Amazon EFS Quick Create (p. 1427)
- Create an EFS file system and mount it to your instance (p. 1428)

**Create an EFS file system using Amazon EFS Quick Create**

You can create an EFS file system and mount it to your instance at the time of launch using the Amazon EFS Quick Create feature of the Instance Launch Wizard.

When you create an EFS file system using EFS Quick Create, the file system is created with the following service recommended settings:
• Automatic backups turned on. For more information, see Using AWS Backup with Amazon EFS in the Amazon Elastic File System User Guide.

• Mount targets in each default subnet in the selected VPC, using the VPC’s default security group. For more information, see Managing file system network accessibility in the Amazon Elastic File System User Guide.

• General Purpose performance mode. For more information, see Performance Modes in the Amazon Elastic File System User Guide.

• Bursting throughput mode. For more information, see Throughput Modes in the Amazon Elastic File System User Guide.

• Encryption of data at rest enabled using your default key for Amazon EFS (aws/elasticfilesystem). For more information, see Encrypting Data at Rest in the Amazon Elastic File System User Guide.

• Amazon EFS lifecycle management enabled with a 30-day policy. For more information, see EFS lifecycle management in the Amazon Elastic File System User Guide.

To create an EFS file system using Amazon EFS Quick Create

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Choose Launch Instance.

3. On the Choose an AMI page, choose a Linux AMI.

4. On the Choose an Instance Type page, select an instance type and then choose Next: Configure Instance Details.

5. On the Configure Instance Details page, for File systems, choose Create new file system, enter a name for the new file system, and then choose Create.

To enable access to the file system, the following security groups are automatically created and attached to the instance and the mount targets of the file system.

• Instance security group—Includes no inbound rules and an outbound rule that allows traffic over the NFS 2049 port.

• File system mount targets security group—Includes an inbound rule that allows traffic over the NFS 2049 port from the instance security group (described above), and an outbound rule that allows traffic over the NFS 2049 port.

You can also choose to manually create and attach the security groups. To do this, clear Automatically create and attach the required security groups.

Configure the remaining settings as needed and choose Next: Add Storage.

6. On the Add Storage page, specify the volumes to attach to the instances, in addition to the volumes specified by the AMI (such as the root device volume). Ensure that you provision enough storage for the Nvidia CUDA Toolkit. Then choose Next: Add Tags.

7. On the Add Tags page, specify a tag that you can use to identify the temporary instance, and then choose Next: Configure Security Group.

8. On the Configure Security Group page, review the security groups and then choose Review and Launch.

9. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instance.

Create an EFS file system and mount it to your instance

In this tutorial, you create an EFS file system and two Linux instances that can share data using the file system.
Tasks
- Prerequisites (p. 1429)
- Step 1: Create an EFS file system (p. 1429)
- Step 2: Mount the file system (p. 1429)
- Step 3: Test the file system (p. 1430)
- Step 4: Clean up (p. 1431)

Prerequisites
- Create a security group (for example, efs-sg) to associate with the EC2 instances and EFS mount target, and add the following rules:
  - Allow inbound SSH connections to the EC2 instances from your computer (the source is the CIDR block for your network).
  - Allow inbound NFS connections to the file system via the EFS mount target from the EC2 instances that are associated with this security group (the source is the security group itself). For more information, see Amazon EFS rules (p. 1171), and Creating security Groups in the Amazon Elastic File System User Guide.
- Create a key pair. You must specify a key pair when you configure your instances or you can't connect to them. For more information, see Create a key pair (p. 5).

Step 1: Create an EFS file system

Amazon EFS enables you to create a file system that multiple instances can mount and access at the same time. For more information, see Creating Resources for Amazon EFS in the Amazon Elastic File System User Guide.

To create a file system
2. Choose Create file system.
3. (Optional) For Name, enter a name for the file system. This creates a tag with Name as the key and the name of the file system as the value.
4. For Virtual Private Cloud (VPC), select the VPC to use for your instances.
5. Choose Create.
6. After the file system is created, note the file system ID. It is used later in this tutorial.
7. Choose the file system ID.
8. On the file systems page, choose Network, Manage. View the mount targets that Amazon EFS creates in each Availability Zone in the Region in which your VPC resides. For each Availability Zone for your instances, ensure that the value for Security groups is the security group that you created in Prerequisites (p. 1429).
9. Choose Save.

Step 2: Mount the file system

Use the following procedure to launch two t2.micro instances. Note that T2 instances must be launched in a subnet. You can use a default VPC or a nondefault VPC.

Note
There are other ways that you can mount the volume (for example, on an already running instance). For more information, see Mounting File Systems in the Amazon Elastic File System User Guide.
To launch two instances and mount an EFS file system

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. For Step 1: Choose an Amazon Machine Image (AMI), select an Amazon Linux AMI.
4. For Step 2: Choose an Instance Type, keep the default instance type, t2.micro, and choose Next: Configure Instance Details.
5. For Step 3: Configure Instance Details, do the following:
   a. For Number of instances, enter 2.
   b. [Default VPC] If you have a default VPC, it is the default value for Network. Keep the default VPC and the default value for Subnet to use the default subnet in the Availability Zone that Amazon EC2 chooses for your instances.
   [Nondefault VPC] Select your VPC for Network, and a public subnet from Subnet.
   c. [Nondefault VPC] For Auto-assign Public IP, choose Enable. Otherwise, your instances do not get public IP addresses or public DNS names.
   d. For File systems, choose Add file system. Ensure that the value matches the file system ID that you created in Step 1: Create an EFS file system (p. 1429). The path shown next to the file system ID is the mount point that the instance will use, which you can change. Under Advanced Details, the User data is automatically generated, and includes the commands needed to mount the file system.
   e. Advance to Step 6 of the wizard.
6. On the Configure Security Group page, choose Select an existing security group and select the security group that you created in Prerequisites (p. 1429). Then choose Review and Launch.
8. In the Select an existing key pair or create a new key pair dialog box, select Choose an existing key pair and choose your key pair. Select the acknowledgment check box, and choose Launch Instances.
9. In the navigation pane, choose Instances to see the status of your instances. Initially, their status is pending. After the status changes to running, your instances are ready for use.

Your instance is now configured to mount the Amazon EFS file system at launch and whenever it's rebooted.

Step 3: Test the file system

You can connect to your instances and verify that the file system is mounted to the directory that you specified (for example, /mnt/efs).

To verify that the file system is mounted

1. Connect to your instances. For more information, see Connect to your Linux instance (p. 499).
2. From the terminal window for each instance, run the df -T command to verify that the EFS file system is mounted.

```bash
$ df -T
Filesystem  Type         1K-blocks  Used      Available  Use% Mounted on
/dev/xvda1  ext4        8123812  1949800  6073764   25% /
devtmpfs    devtmpfs     4078468   56000  4077912    1% /dev
tmpfs       tmpfs        4089312     0      4089312   0% /dev/shm
efs-dns     nfs4         9007199254740992 0  9007199254740992 0% /mnt/efs
```
Note that the name of the file system, shown in the example output as `efs-dns`, has the following form.

```
file-system-id.efs.aws-region.amazonaws.com:/
```

3. (Optional) Create a file in the file system from one instance, and then verify that you can view the file from the other instance.
   a. From the first instance, run the following command to create the file.

```
$ sudo touch /mnt/efs/test-file.txt
```

b. From the second instance, run the following command to view the file.

```
$ ls /mnt/efs
  test-file.txt
```

**Step 4: Clean up**

When you are finished with this tutorial, you can terminate the instances and delete the file system.

**To terminate the instances**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instances to terminate.
4. Choose **Instance state**, **Terminate instance**.
5. Choose **Terminate** when prompted for confirmation.

**To delete the file system**

2. Select the file system to delete.
3. Choose **Actions**, **Delete file system**.
4. When prompted for confirmation, enter the file system ID and choose **Delete file system**.

**Instance volume limits**

The maximum number of volumes that your instance can have depends on the operating system and instance type. When considering how many volumes to add to your instance, you should consider whether you need increased I/O bandwidth or increased storage capacity.

**Contents**

- Nitro System volume limits (p. 1432)
- Linux-specific volume limits (p. 1432)
- Bandwidth versus capacity (p. 1432)
Nitro System volume limits

Instances built on the Nitro System (p. 199) support a maximum number of attachments, which are shared between network interfaces, EBS volumes, and NVMe instance store volumes. Every instance has at least one network interface attachment. NVMe instance store volumes are automatically attached. For more information, see Elastic network interfaces (p. 922) and Instance store volumes (p. 1409).

Most of these instances support a maximum of 28 attachments. For example, if you have no additional network interface attachments on an EBS-only instance, you can attach up to 27 EBS volumes to it. If you have one additional network interface on an instance with 2 NVMe instance store volumes, you can attach 24 EBS volumes to it.

For other instances, the following limits apply:

- d3.8xlarge and d3en.12xlarge instances support a maximum of 3 EBS volumes.
- inf1.xlarge and inf1.2xlarge instances support a maximum of 26 EBS volumes.
- inf1.6xlarge instances support a maximum of 23 EBS volumes.
- inf1.24xlarge instances support a maximum of 11 EBS volumes.
- Most bare metal instances support a maximum of 31 EBS volumes.
- mac1.metal instances support a maximum of 16 EBS volumes.
- High memory virtualized instances support a maximum of 27 EBS volumes.
- High memory bare metal instances support a maximum of 19 EBS volumes.

If you launched a u-6tb1.metal, u-9tb1.metal, or u-12tb1.metal high memory bare metal instance before March 12, 2020, it supports a maximum of 14 EBS volumes. To attach up to 19 EBS volumes to these instances, contact your account team to upgrade the instance at no additional cost.

Linux-specific volume limits

Attaching more than 40 volumes can cause boot failures. This number includes the root volume, plus any attached instance store volumes and EBS volumes. If you experience boot problems on an instance with a large number of volumes, stop the instance, detach any volumes that are not essential to the boot process, and then reattach the volumes after the instance is running.

Important
Attaching more than 40 volumes to a Linux instance is supported on a best effort basis only and is not guaranteed.

Bandwidth versus capacity

For consistent and predictable bandwidth use cases, use EBS-optimized or 10 Gigabit network connectivity instances and General Purpose SSD or Provisioned IOPS SSD volumes. Follow the guidance in Amazon EBS–optimized instances (p. 1354) to match the IOPS you have provisioned for your volumes to the bandwidth available from your instances for maximum performance. For RAID configurations, many administrators find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead. Test your individual application performance and tune it as required.

Amazon EC2 instance root device volume

When you launch an instance, the root device volume contains the image used to boot the instance. When we introduced Amazon EC2, all AMIs were backed by Amazon EC2 instance store, which means the root device for an instance launched from the AMI is an instance store volume created from a template stored
Root device storage concepts

You can launch an instance from either an instance store-backed AMI or an Amazon EBS-backed AMI. The description of an AMI includes which type of AMI it is; you'll see the root device referred to in some places as either ebs (for Amazon EBS-backed) or instance store (for instance store-backed). This is important because there are significant differences between what you can do with each type of AMI. For more information about these differences, see Storage for the root device (p. 73).

Instance store-backed instances

Instances that use instance stores for the root device automatically have one or more instance store volumes available, with one volume serving as the root device volume. When an instance is launched, the image that is used to boot the instance is copied to the root volume. Note that you can optionally use additional instance store volumes, depending on the instance type.

Any data on the instance store volumes persists as long as the instance is running, but this data is deleted when the instance is terminated (instance store-backed instances do not support the Stop action) or if it fails (such as if an underlying drive has issues).
After an instance store-backed instance fails or terminates, it cannot be restored. If you plan to use Amazon EC2 instance store-backed instances, we highly recommend that you distribute the data on your instance stores across multiple Availability Zones. You should also back up critical data from your instance store volumes to persistent storage on a regular basis.

For more information, see [Amazon EC2 instance store](p. 1408).

**Amazon EBS-backed instances**

Instances that use Amazon EBS for the root device automatically have an Amazon EBS volume attached. When you launch an Amazon EBS-backed instance, we create an Amazon EBS volume for each Amazon EBS snapshot referenced by the AMI you use. You can optionally use other Amazon EBS volumes or instance store volumes, depending on the instance type.

An Amazon EBS-backed instance can be stopped and later restarted without affecting data stored in the attached volumes. There are various instance- and volume-related tasks you can do when an Amazon EBS-backed instance is in a stopped state. For example, you can modify the properties of the instance, change its size, or update the kernel it is using, or you can attach your root volume to a different running instance for debugging or any other purpose.

If an Amazon EBS-backed instance fails, you can restore your session by following one of these methods:

- Stop and then start again (try this method first).
- Automatically snapshot all relevant volumes and create a new AMI. For more information, see [Create an Amazon EBS-backed Linux AMI](p. 102).
- Attach the volume to the new instance by following these steps:
  1. Create a snapshot of the root volume.
  2. Register a new AMI using the snapshot.
  3. Launch a new instance from the new AMI.
  4. Detach the remaining Amazon EBS volumes from the old instance.
  5. Reattach the Amazon EBS volumes to the new instance.

For more information, see [Amazon EBS volumes](p. 1177).

**Choose an AMI by root device type**

The AMI that you specify when you launch your instance determines the type of root device volume that your instance has. You can view AMIs by root device type using one of the following methods.
Console

To choose an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. From the filter lists, select the image type (such as Public images). In the search bar choose Platform to select the operating system (such as Amazon Linux), and Root Device Type to select EBS images.
4. (Optional) To get additional information to help you make your choice, choose the Show/Hide Columns icon, update the columns to display, and choose Close.
5. Choose an AMI and write down its AMI ID.

To choose an instance store-backed AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. From the filter lists, select the image type (such as Public images). In the search bar, choose Platform to select the operating system (such as Amazon Linux), and Root Device Type to select Instance store.
4. (Optional) To get additional information to help you make your choice, choose the Show/Hide Columns icon, update the columns to display, and choose Close.
5. Choose an AMI and write down its AMI ID.

AWS CLI

To verify the type of the root device volume of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- describe-images (AWS CLI)
- Get-EC2Image (AWS Tools for Windows PowerShell)

Determine the root device type of your instance

New console

To determine the root device type of an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the instance.
3. On the Storage tab, under Root device details, check the value of Root device type as follows:
   - If the value is EBS, this is an Amazon EBS-backed instance.
   - If the value is INSTANCE-STORE, this is an instance store-backed instance.

Old console

To determine the root device type of an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and select the instance.
3. On the **Description** tab, check the value of **Root device type** as follows:
   - If the value is `ebs`, this is an Amazon EBS-backed instance.
   - If the value is `instance store`, this is an instance store-backed instance.

**AWS CLI**

To determine the root device type of an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2** (p. 3).

- `describe-instances` (AWS CLI)
- `Get-EC2Instance` (AWS Tools for Windows PowerShell)

**Change the root volume to persist**

By default, the root volume for an AMI backed by Amazon EBS is deleted when the instance terminates. You can change the default behavior to ensure that the volume persists after the instance terminates. To change the default behavior, set the `DeleteOnTermination` attribute to `false` using a block device mapping.

**Tasks**

- Configure the root volume to persist during instance launch (p. 1436)
- Configure the root volume to persist for an existing instance (p. 1437)
- Confirm that a root volume is configured to persist (p. 1438)

**Configure the root volume to persist during instance launch**

You can configure the root volume to persist when you launch an instance using the Amazon EC2 console or the command line tools.

**Console**

To configure the root volume to persist when you launch an instance using the console

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Instances** and then choose **Launch instances**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select the AMI to use and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, deselect **Delete On Termination** for the root volume.
6. Complete the remaining wizard pages, and then choose **Launch**.

**AWS CLI**

To configure the root volume to persist when you launch an instance using the AWS CLI

Use the `run-instances` command and include a block device mapping that sets the `DeleteOnTermination` attribute to `false`. 1436
Change the root volume to persist

```bash
$ aws ec2 run-instances --block-device-mappings file://mapping.json ...other parameters...
```

Specify the following in mapping.json.

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

Tools for Windows PowerShell

To configure the root volume to persist when you launch an instance using the Tools for Windows PowerShell

Use the `New-EC2Instance` command and include a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```powershell
C:\> $ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.BlockDeviceMapping
C:\> $bdm.DeviceName = "dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> New-EC2Instance -ImageId ami-0abcdef1234567890 -BlockDeviceMapping $bdm ...other parameters...
```

Configure the root volume to persist for an existing instance

You can configure the root volume to persist for a running instance using the command line tools only.

AWS CLI

To configure the root volume to persist for an existing instance using the AWS CLI

Use the `modify-instance-attribute` command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in mapping.json.

```json
[
  {
    "DeviceName": "/dev/xvda",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

Tools for Windows PowerShell

To configure the root volume to persist for an existing instance using the AWS Tools for Windows PowerShell
Use the `Edit-EC2InstanceAttribute` command with a block device mapping that sets the `DeleteOnTermination` attribute to false.

```powershell
C:\> $ebs = New-Object Amazon.EC2.Model.EbsInstanceBlockDeviceSpecification
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.InstanceBlockDeviceMappingSpecification
C:\> $bdm.DeviceName = "/dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -BlockDeviceMapping $bdm
```

Confirm that a root volume is configured to persist

You can confirm that a root volume is configured to persist using the Amazon EC2 console or the command line tools.

**New console**

To confirm that a root volume is configured to persist using the Amazon EC2 console

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Storage** tab, under **Block devices**, locate the entry for the root volume. If **Delete on termination** is **No**, the volume is configured to persist.

**Old console**

To confirm that a root volume is configured to persist using the Amazon EC2 console

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Description** tab, choose the entry for **Root device**. If **Delete on termination** is **False**, the volume is configured to persist.

**AWS CLI**

To confirm that a root volume is configured to persist using the AWS CLI

Use the `describe-instances` command and verify that the `DeleteOnTermination` attribute in the `BlockDeviceMappings` response element is set to **false**.

```
$ aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

```
  "BlockDeviceMappings": [
    {
      "DeviceName": "/dev/sdal",
      "Ebs": {
        "Status": "attached",
        "DeleteOnTermination": false,
        "VolumeId": "vol-1234567890abcdef0",
        "AttachTime": "2013-07-19T02:42:39.000Z"
      }
    }
  ]
```

---

1438
Tools for Windows PowerShell

To confirm that a root volume is configured to persist using the AWS Tools for Windows PowerShell

Use the `Get-EC2Instance` and verify that the `DeleteOnTermination` attribute in the `BlockDeviceMappings` response element is set to false.

```
C:\> (Get-EC2Instance -InstanceId i-i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

Change the initial size of the root volume

By default, the size of the root volume is determined by the size of the snapshot. You can increase the initial size of the root volume using the block device mapping of the instance as follows.

1. Determine the device name of the root volume specified in the AMI, as described in View the EBS volumes in an AMI block device mapping (p. 1446).
2. Confirm the size of the snapshot specified in the AMI block device mapping, as described in View Amazon EBS snapshot information (p. 1241).
3. Override the size of the root volume using the instance block device mapping, as described in Update the block device mapping when launching an instance (p. 1447), specifying a volume size that is larger than the snapshot size.

For example, the following entry for the instance block device mapping increases the size of the root volume, `/dev/xvda`, to 100 GiB. You can omit the snapshot ID in the instance block device mapping because the snapshot ID is already specified in the AMI block device mapping.

```json
{
    "DeviceName": "/dev/xvda",
    "Ebs": {
      "VolumeSize": 100
    }
}
```

For more information, see Block device mappings (p. 1441).

Device names on Linux instances

When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The number of volumes that your instance can support is determined by the operating system. For more information, see Instance volume limits (p. 1431).

Contents

- Available device names (p. 1440)
- Device name considerations (p. 1440)

For information about device names on Windows instances, see Device naming on Windows instances in the Amazon EC2 User Guide for Windows Instances.
Available device names

There are two types of virtualization available for Linux instances: paravirtual (PV) and hardware virtual machine (HVM). The virtualization type of an instance is determined by the AMI used to launch the instance. All instance types support HVM AMIs. Some previous generation instance types support PV AMIs. Be sure to note the virtualization type of your AMI because the recommended and available device names that you can use depend on the virtualization type of your instance. For more information, see Linux AMI virtualization types (p. 75).

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume.

<table>
<thead>
<tr>
<th>Virtualization type</th>
<th>Available</th>
<th>Reserved for root</th>
<th>Recommended for EBS volumes</th>
<th>Instance store volumes</th>
</tr>
</thead>
<tbody>

</table>

* The device names that you specify for NVMe EBS volumes in a block device mapping are renamed using NVMe device names (/dev/nvme[0-26]n1). The block device driver can assign NVMe device names in a different order than you specified for the volumes in the block device mapping.

** NVMe instance store volumes are automatically enumerated and assigned an NVMe device name.

For more information about instance store volumes, see Amazon EC2 instance store (p. 1408). For more information about NVMe EBS volumes (Nitro-based instances), including how to identify the EBS device, see Amazon EBS and NVMe on Linux instances (p. 1350).

Device name considerations

Keep the following in mind when selecting a device name:

- Although you can attach your EBS volumes using the device names used to attach instance store volumes, we strongly recommend that you don't because the behavior can be unpredictable.
- The number of NVMe instance store volumes for an instance depends on the size of the instance. NVMe instance store volumes are automatically enumerated and assigned an NVMe device name (/dev/nvme[0-26]n1).
• Depending on the block device driver of the kernel, the device could be attached with a different name than you specified. For example, if you specify a device name of /dev/sdh, your device could be renamed /dev/xvdh or /dev/hdh. In most cases, the trailing letter remains the same. In some versions of Red Hat Enterprise Linux (and its variants, such as CentOS), the trailing letter could change (/dev/sda could become /dev/xvde). In these cases, the trailing letter of each device name is incremented the same number of times. For example, if /dev/sdb is renamed /dev/xvdf, then /dev/sdc is renamed /dev/xvdg. Amazon Linux creates a symbolic link for the name you specified to the renamed device. Other operating systems could behave differently.

• HVM AMIs do not support the use of trailing numbers on device names, except for /dev/sda1, which is reserved for the root device, and /dev/sda2. While using /dev/sda2 is possible, we do not recommend using this device mapping with HVM instances.

• When using PV AMIs, you cannot attach volumes that share the same device letters both with and without trailing digits. For example, if you attach a volume as /dev/sdc and another volume as /dev/sdc1, only /dev/sdc is visible to the instance. To use trailing digits in device names, you must use trailing digits on all device names that share the same base letters (such as /dev/sdc1, /dev/sdc2, /dev/sdc3).

• Some custom kernels might have restrictions that limit use to /dev/sd[f-p] or /dev/sd[f-p][1-6]. If you’re having trouble using /dev/sd[q-z] or /dev/sd[q-z][1-6], try switching to /dev/sd[f-p] or /dev/sd[f-p][1-6].

Block device mappings

Each instance that you launch has an associated root device volume, which is either an Amazon EBS volume or an instance store volume. You can use block device mapping to specify additional EBS volumes or instance store volumes to attach to an instance when it’s launched. You can also attach additional EBS volumes to a running instance; see Attach an Amazon EBS volume to an instance (p. 1202). However, the only way to attach instance store volumes to an instance is to use block device mapping to attach the volumes as the instance is launched.

For more information about root device volumes, see Change the root volume to persist (p. 1436).

Contents

• Block device mapping concepts (p. 1441)
• AMI block device mapping (p. 1445)
• Instance block device mapping (p. 1447)

Block device mapping concepts

A block device is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer.

Amazon EC2 supports two types of block devices:

• Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
• EBS volumes (remote storage devices)

A block device mapping defines the block devices (instance store volumes and EBS volumes) to attach to an instance. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you
launched the instance. Note that all NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in your block device mapping has no effect.

Contents

• Block device mapping entries (p. 1442)
• Block device mapping instance store caveats (p. 1442)
• Example block device mapping (p. 1443)
• How devices are made available in the operating system (p. 1444)

Block device mapping entries

When you create a block device mapping, you specify the following information for each block device that you need to attach to the instance:

• The device name used within Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume. The name assigned can be different from the name that Amazon EC2 recommends. For more information, see Device names on Linux instances (p. 1439).

For Instance store volumes, you also specify the following information:

• The virtual device: ephemeral[0–23]. Note that the number and size of available instance store volumes for your instance varies by instance type.

For NVMe instance store volumes, the following information also applies:

• These volumes are automatically enumerated and assigned a device name; including them in your block device mapping has no effect.

For EBS volumes, you also specify the following information:

• The ID of the snapshot to use to create the block device (snap-xxxxxxxx). This value is optional as long as you specify a volume size.
• The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
• Whether to delete the volume on instance termination (true or false). The default value is true for the root device volume and false for attached volumes. When you create an AMI, its block device mapping inherits this setting from the instance. When you launch an instance, it inherits this setting from the AMI.
• The volume type, which can be gp2 and gp3 for General Purpose SSD, io1 and io2 for Provisioned IOPS SSD, st1 for Throughput Optimized HDD, sc1 for Cold HDD, or standard for Magnetic. The default value is gp2.
• The number of input/output operations per second (IOPS) that the volume supports. (Used only with io1 and io2 volumes.)

Block device mapping instance store caveats

There are several caveats to consider when launching instances with AMIs that have instance store volumes in their block device mappings:

• Some instance types include more instance store volumes than others, and some instance types contain no instance store volumes at all. If your instance type supports one instance store volume, and
Your AMI has mappings for two instance store volumes, then the instance launches with one instance store volume.

- Instance store volumes can only be mapped at launch time. You cannot stop an instance without instance store volumes (such as the t2.micro), change the instance to a type that supports instance store volumes, and then restart the instance with instance store volumes. However, you can create an AMI from the instance and launch it on an instance type that supports instance store volumes, and map those instance store volumes to the instance.

- If you launch an instance with instance store volumes mapped, and then stop the instance and change it to an instance type with fewer instance store volumes and restart it, the instance store volume mappings from the initial launch still show up in the instance metadata. However, only the maximum number of supported instance store volumes for that instance type are available to the instance.

  **Note**
  When an instance is stopped, all data on the instance store volumes is lost.

- Depending on instance store capacity at launch time, M3 instances may ignore AMI instance store block device mappings at launch unless they are specified at launch. You should specify instance store block device mappings at launch time, even if the AMI you are launching has the instance store volumes mapped in the AMI, to ensure that the instance store volumes are available when the instance launches.

**Example block device mapping**

This figure shows an example block device mapping for an EBS-backed instance. It maps /dev/sdb to ephemeral0 and maps two EBS volumes, one to /dev/sdh and the other to /dev/sdj. It also shows the EBS volume that is the root device volume, /dev/sda1.
Note that this example block device mapping is used in the example commands and APIs in this topic. You can find example commands and APIs that create block device mappings in Specify a block device mapping for an AMI (p. 1445) and Update the block device mapping when launching an instance (p. 1447).

**How devices are made available in the operating system**

Device names like `/dev/sdh` and `xvdh` are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an EC2 instance. After a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

With a Linux instance, the device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots. The instance type determines which instance store volumes are formatted and mounted by default. You can mount additional instance store volumes at launch, as long as you don't exceed the number of instance store volumes available for your instance type. For more information, see Amazon EC2 instance store (p. 1408). The block device driver for the instance determines which devices are used when the volumes are formatted and mounted. For more information, see Attach an Amazon EBS volume to an instance (p. 1202).
AMI block device mapping

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. An AMI that Amazon provides includes a root device only. To add more block devices to an AMI, you must create your own AMI.

Contents
- Specify a block device mapping for an AMI (p. 1445)
- View the EBS volumes in an AMI block device mapping (p. 1446)

Specify a block device mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an instance store-backed AMI, you can add instance store volumes only by modifying the block device mapping entries in the image manifest file when registering the image.

Note
For M3 instances, you must specify instance store volumes in the block device mapping for the instance when you launch it. When you launch an M3 instance, instance store volumes specified in the block device mapping for the AMI may be ignored if they are not specified as part of the instance block device mapping.

To add volumes to an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose Instances.
3. Select an instance and choose Actions, Image and templates, Create image.
4. Enter a name and a description for the image.
5. The instance volumes appear under Instance volumes. To add another volume, choose Add volume.
6. For Volume type, choose the volume type. For Device choose the device name. For an EBS volume, you can specify additional details, such as a snapshot, volume size, volume type, IOPS, and encryption state.
7. Choose Create image.

To add volumes to an AMI using the command line

Use the create-image AWS CLI command to specify a block device mapping for an EBS-backed AMI. Use the register-image AWS CLI command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the --block-device-mappings parameter. Arguments encoded in JSON can be supplied either directly on the command line or by reference to a file:

```
--block-device-mappings [mapping, ...]
--block-device-mappings [file://mapping.json]
```

To add an instance store volume, use the following mapping.
To add an empty 100 GiB gp2 volume, use the following mapping.

```json
{
    "DeviceName": "/dev/sdg",
    "Ebs": {
        "VolumeSize": 100
    }
}
```

To add an EBS volume based on a snapshot, use the following mapping.

```json
{
    "DeviceName": "/dev/sdh",
    "Ebs": {
        "SnapshotId": "snap-xxxxxxxx"
    }
}
```

To omit a mapping for a device, use the following mapping.

```json
{
    "DeviceName": "/dev/sdj",
    "NoDevice": ""
}
```

Alternatively, you can use the -BlockDeviceMapping parameter with the following commands (AWS Tools for Windows PowerShell):

- `New-EC2Image`
- `Register-EC2Image`

### View the EBS volumes in an AMI block device mapping

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

**To view the EBS volumes for an AMI using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. Choose EBS images from the Filter list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the Details tab. At a minimum, the following information is available for the root device:
   - **Root Device Type** (ebs)
   - **Root Device Name** (for example, /dev/sda1)
   - **Block Devices** (for example, /dev/sda1=snap-1234567890abcdef0:8:true)

If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional volumes as well. (This screen doesn't display instance store volumes.)
To view the EBS volumes for an AMI using the command line

Use the `describe-images` (AWS CLI) command or `Get-EC2Image` (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an AMI.

**Instance block device mapping**

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI.

**Limitations**

- For the root volume, you can only modify the following: volume size, volume type, and the *Delete on Termination* flag.
- When you modify an EBS volume, you can’t decrease its size. Therefore, you must specify a snapshot whose size is equal to or greater than the size of the snapshot specified in the block device mapping of the AMI.

**Contents**

- Update the block device mapping when launching an instance (p. 1447)
- Update the block device mapping of a running instance (p. 1449)
- View the EBS volumes in an instance block device mapping (p. 1449)
- View the instance block device mapping for instance store volumes (p. 1450)

**Update the block device mapping when launching an instance**

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn’t make a permanent change to the block device mapping of the AMI from which it was launched.

**To add volumes to an instance using the console**

1. Open the Amazon EC2 console.
2. From the dashboard, choose *Launch Instance*.
3. On the *Choose an Amazon Machine Image (AMI)* page, select the AMI to use and choose *Select*.
4. Follow the wizard to complete the *Choose an Instance Type* and *Configure Instance Details* pages.
5. On the *Add Storage* page, you can modify the root volume, EBS volumes, and instance store volumes as follows:
   - To change the size of the root volume, locate the *Root* volume under the *Type* column, and change its *Size* field.
   - To suppress an EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the volume and click its *Delete* icon.
   - To add an EBS volume, choose *Add New Volume*, choose *EBS* from the *Type* list, and fill in the fields (*Device*, *Snapshot*, and so on).
   - To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume, and choose its *Delete* icon.
   - To add an instance store volume, choose *Add New Volume*, select *Instance Store* from the *Type* list, and select a device name from *Device*. 
6. Complete the remaining wizard pages, and choose **Launch**.

**To add volumes to an instance using the AWS CLI**

Use the `run-instances` AWS CLI command with the `--block-device-mappings` option to specify a block device mapping for an instance at launch.

For example, suppose that an EBS-backed AMI specifies the following block device mapping:

- `/dev/sdb=ephemeral0`
- `/dev/sdh=snap-1234567890abcdef0`
- `/dev/sdj=:100`

To prevent `/dev/sdj` from attaching to an instance launched from this AMI, use the following mapping.

```json
{
  "DeviceName": "/dev/sdj",
  "NoDevice": ""
}
```

To increase the size of `/dev/sdh` to 300 GiB, specify the following mapping. Notice that you don’t need to specify the snapshot ID for `/dev/sdh`, because specifying the device name is enough to identify the volume.

```json
{
  "DeviceName": "/dev/sdh",
  "Ebs": {
    "VolumeSize": 300
  }
}
```

To increase the size of the root volume at instance launch, first call `describe-images` with the ID of the AMI to verify the device name of the root volume. For example, "RootDeviceName": "/dev/xvda". To override the size of the root volume, specify the device name of the root device used by the AMI and the new volume size.

```json
{
  "DeviceName": "/dev/xvda",
  "Ebs": {
    "VolumeSize": 100
  }
}
```

To attach an additional instance store volume, `/dev/sdc`, specify the following mapping. If the instance type doesn’t support multiple instance store volumes, this mapping has no effect. If the instance supports NVMe instance store volumes, they are automatically enumerated and assigned an NVMe device name.

```json
{
  "DeviceName": "/dev/sdc",
  "VirtualName": "ephemeral1"
}
```

**To add volumes to an instance using the AWS Tools for Windows PowerShell**

Use the `-BlockDeviceMapping` parameter with the `New-EC2Instance` command (AWS Tools for Windows PowerShell).
Update the block device mapping of a running instance

You can use the `modify-instance-attribute` AWS CLI command to update the block device mapping of a running instance. You do not need to stop the instance before changing this attribute.

```
aws ec2 modify-instance-attribute --instance-id i-1a2b3c4d --block-device-mappings file://mapping.json
```

For example, to preserve the root volume at instance termination, specify the following in `mapping.json`.

```
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

Alternatively, you can use the `-BlockDeviceMapping` parameter with the `Edit-EC2InstanceAttribute` command (AWS Tools for Windows PowerShell).

View the EBS volumes in an instance block device mapping

You can easily enumerate the EBS volumes mapped to an instance.

**Note**
For instances launched before the release of the 2009-10-31 API, AWS can’t display the block device mapping. You must detach and reattach the volumes so that AWS can display the block device mapping.

**To view the EBS volumes for an instance using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, choose Instances.
3. In the search box, enter Root device type, and then choose EBS. This displays a list of EBS-backed instances.
4. Select the desired instance and look at the details displayed in the Storage tab. At a minimum, the following information is available for the root device:
   - **Root device type** (for example, EBS)
   - **Root device name** (for example, /dev/xvda)
   - **Block devices** (for example, /dev/xvda, /dev/sdf, and /dev/sdj)

   If the instance was launched with additional EBS volumes using a block device mapping, they appear under Block devices. Any instance store volumes do not appear on this tab.
5. To display additional information about an EBS volume, choose its volume ID to go to the volume page. For more information, see View information about an Amazon EBS volume (p. 1211).

**To view the EBS volumes for an instance using the command line**

Use the `describe-instances` (AWS CLI) command or `Get-EC2Instance` (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an instance.
View the instance block device mapping for instance store volumes

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. The method you use to view the instance store volumes for your instance depends on the volume type.

**NVMe instance store volumes**

You can use the NVMe command line package, `nvme-cli`, to query the NVMe instance store volumes in the block device mapping. Download and install the package on your instance, and then run the following command.

```
[ec2-user ~]$ sudo nvme list
```

The following is example output for an instance. The text in the Model column indicates whether the volume is an EBS volume or an instance store volume. In this example, both `/dev/nvme1n1` and `/dev/nvme2n1` are instance store volumes.

<table>
<thead>
<tr>
<th>Node</th>
<th>SN</th>
<th>Model</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/dev/nvme0n1</code></td>
<td>vol06a4c3f8715b7a597</td>
<td>Amazon Elastic Block Store</td>
<td>1</td>
</tr>
<tr>
<td><code>/dev/nvme1n1</code></td>
<td>AWS2C1436F5159EB6614</td>
<td>Amazon EC2 NVMe Instance Storage</td>
<td>1</td>
</tr>
<tr>
<td><code>/dev/nvme2n1</code></td>
<td>AWSB1F4F0C0A6C281EA</td>
<td>Amazon EC2 NVMe Instance Storage</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**HDD or SSD instance store volumes**

You can use instance metadata to query the HDD or SSD instance store volumes in the block device mapping. NVMe instance store volumes are not included.

The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`. For more information, see Instance metadata and user data (p. 606).

First, connect to your running instance. From the instance, use this query to get its block device mapping.

**IMDSv2**

```
```

**IMDSv1**

```
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed `m1.small` instance looks like this.

```
ami
ephemeral0
root
swap
```
The `ami` device is the root device as seen by the instance. The instance store volumes are named `ephemeral[0-23]`. The `swap` device is for the page file. If you've also mapped EBS volumes, they appear as `ebs1`, `ebs2`, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

**IMDSv2**

```
```

**IMDSv1**

```
```

The instance type determines the number of instance store volumes that are available to the instance. If the number of instance store volumes in a block device mapping exceeds the number of instance store volumes available to an instance, the additional volumes are ignored. To view the instance store volumes for your instance, run the `lsblk` command. To learn how many instance store volumes are supported by each instance type, see Instance store volumes (p. 1409).
Resources and tags

Amazon EC2 provides different resources that you can create and use. Some of these resources include images, instances, volumes, and snapshots. When you create a resource, we assign the resource a unique resource ID.

Some resources can be tagged with values that you define, to help you organize and identify them.

The following topics describe resources and tags, and how you can work with them.

Contents
- Resource locations (p. 1452)
- Resource IDs (p. 1453)
- List and filter your resources (p. 1454)
- Tag your Amazon EC2 resources (p. 1462)
- Amazon EC2 service quotas (p. 1475)
- Amazon EC2 usage reports (p. 1476)

Resource locations

Amazon EC2 resources are specific to the AWS Region or Availability Zone in which they reside.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EC2 resource identifiers</td>
<td>Regional</td>
<td>Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.</td>
</tr>
<tr>
<td>User-supplied resource names</td>
<td>Regional</td>
<td>Each resource name, such as a security group name or key pair name, is tied to its Region and can be used only in the Region where you created the resource. Although you can create resources with the same name in multiple Regions, they aren’t related to each other.</td>
</tr>
<tr>
<td>AMIs</td>
<td>Regional</td>
<td>An AMI is tied to the Region where its files are located within Amazon S3. You can copy an AMI from one Region to another. For more information, see Copy an AMI (p. 138).</td>
</tr>
<tr>
<td>EBS snapshots</td>
<td>Regional</td>
<td>An EBS snapshot is tied to its Region and can only be used to create volumes in the same Region. You can copy a snapshot from one Region to another. For more information, see Copy an Amazon EBS snapshot (p. 1236).</td>
</tr>
<tr>
<td>EBS volumes</td>
<td>Availability Zone</td>
<td>An Amazon EBS volume is tied to its Availability Zone and can be attached only to instances in the same Availability Zone.</td>
</tr>
<tr>
<td>Elastic IP addresses</td>
<td>Regional</td>
<td>An Elastic IP address is tied to a Region and can be associated only with an instance in the same Region.</td>
</tr>
<tr>
<td>Resource</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Instances</td>
<td>Availability Zone</td>
<td>An instance is tied to the Availability Zones in which you launched it. However, its instance ID is tied to the Region.</td>
</tr>
<tr>
<td>Key pairs</td>
<td>Global or Regional</td>
<td>The key pairs that you create using Amazon EC2 are tied to the Region where you created them. You can create your own RSA key pair and upload it to the Region in which you want to use it; therefore, you can make your key pair globally available by uploading it to each Region. For more information, see Amazon EC2 key pairs and Linux instances (p. 1137).</td>
</tr>
<tr>
<td>Security groups</td>
<td>Regional</td>
<td>A security group is tied to a Region and can be assigned only to instances in the same Region. You can't enable an instance to communicate with an instance outside its Region using security group rules. Traffic from an instance in another Region is seen as WAN bandwidth.</td>
</tr>
</tbody>
</table>

**Resource IDs**

When resources are created, we assign each resource a unique resource ID. A resource ID takes the form of a resource identifier (such as `snap` for a snapshot) followed by a hyphen and a unique combination of letters and numbers.

Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.

You can use resource IDs to find your resources in the Amazon EC2 console. If you are using a command line tool or the Amazon EC2 API to work with Amazon EC2, resource IDs are required for certain commands. For example, if you are using the `stop-instances` AWS CLI command to stop an instance, you must specify the instance ID in the command.

**Resource ID length**

Prior to January 2016, the IDs assigned to newly created resources of certain resource types used 8 characters after the hyphen (for example, `i-1a2b3c4d`). From January 2016 to June 2018, we changed the IDs of these resource types to use 17 characters after the hyphen (for example, `i-1234567890abcdef0`). Depending on when your account was created, you might have resources of the following resource types with short IDs, though any new resources of these types receive the longer IDs:

- bundle
- conversion-task
- customer-gateway
- dhcp-options
- elastic-ip-allocation
- elastic-ip-association
- export-task
- flow-log
List and filter your resources

You can get a list of some types of resources using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include, or exclude, only the resources that match certain criteria.

Contents
- List and filter resources using the console (p. 1454)
- List and filter using the CLI and API (p. 1459)
- List and filter resources across Regions using Amazon EC2 Global View (p. 1461)

List and filter resources using the console

Contents
- List resources using the console (p. 1454)
- Filter resources using the console (p. 1455)

List resources using the console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.
To list EC2 resources using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose the option that corresponds to the resource type. For example, to list your instances, choose **Instances**.

   The page displays all resources of the selected resource type.

Filter resources using the console

To filter a list of resources

1. In the navigation pane, select a resource type (for example, **Instances**).
2. Choose the search field.
3. Choose the filter from the list.
4. Choose a filter value.
5. When you are finished, remove the filter.

The search and filter functionality differs slightly between the old and new Amazon EC2 console.

New console

The new console supports two types of filtering.

- **API filtering** happens on the server side. The filtering is applied on the API call, which reduces the number of resources returned by the server. It allows for quick filtering across large sets of resources, and it can reduce data transfer time and cost between the server and the browser.
- **Client filtering** happens on the client side. It enables you to filter down on data that is already available in the browser (in other words, data that has already been returned by the API). Client filtering works well in conjunction with an API filter to filter down to smaller data sets in the browser.

The new Amazon EC2 console supports the following types of searches:

Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources’ attributes, without specifying an attribute to search.

**Note**

All keyword searches use **client filtering**.

To search by keyword, enter or paste what you’re looking for in the search field, and then choose **Enter**. For example, searching for `123` matches all instances that have `123` in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID. If your free text search returns unexpected matches, apply additional filters.

Search by attributes

Searching by an attribute lets you search a specific attribute across all of your resources.

**Note**

Attribute searches use either **API filtering** or **client filtering**, depending on the selected attribute. When performing an attribute search, the attributes are grouped accordingly.

For example, you can search the **Instance state** attribute for all of your instances to return only instances that are in the **stopped** state. To do this:
1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state: API filters** and **Client filters**.

2. To search on the server side, choose **Instance state** under **API filters**. To search on the client side, choose **Instance state (client)** under **Client filters**.

   A list of possible values for the selected attribute appears.

3. Choose **stopped** from the list.

You can use the following techniques to enhance or refine your searches:

**Inverse search**

Inverse searches let you search for resources that do **not** match a specified value. Inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character.

**Note**

Inverse search is supported with keyword searches and attribute searches on **client filters** only. It is not supported with attribute searches on API filters.

For example, you can search the **Instance state** attribute for all of your instances to exclude all instances that are in the **terminated** state. To do this:

1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state: API filters** and **Client filters**.

2. Choose **Instance state (client)**. Inverse search is only supported on **client filters**.

   A list of possible values for the selected attribute appears.

3. Enter ! (exclamation mark) to display the inverse filters.

4. Choose **!terminated** from the list.
To filter instances based on an instance state attribute, you can also use the search icons ( ) in the Instance state column. The search icon with a plus sign (+) displays all the instances that match that attribute. The search icon with a minus sign (-) excludes all instances that match that attribute.

Here is another example of using the inverse search: To list all instances that are not assigned the security group named launch-wizard-1, search by the Security group name attribute, and for the keyword, enter !launch-wizard-1.

**Partial search**

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword that you want to search for. For example, to search for all t2.micro, t2.small, and t2.medium instances, search by the Instance Type attribute, and for the keyword, enter t2.

**Note**

Partial search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

**Regular expression search**

To use regular expression searches, you must enable Use regular expression matching in the Preferences.

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for a value that starts with s, search for ^s. To search for a value that ends with xyz, search for xyz$. Or to search for a value that starts with a number that is followed by one or more characters, search for [0-9]+.*. Regular expression searches are not case-sensitive.
Note
Regular expression search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

Wildcard search

Use the * wildcard to match zero or more characters. Use the ? wildcard to match zero or one character. For example, if you have a data set with the following values: prod, prods, and production; "prod*" matches all values, whereas "prod?" matches only prod and prods. To use the literals values, escape them with a backslash (\). For example, "prod\*" would match prod*.

Note
Wildcard search is supported with attribute searches on API filters only. It is not supported with keyword searches and attribute searches on client filters only.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for Instance State : Running and Instance State : Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for Instance State : Running and Instance Type : c4.large returns only instances that are of type c4.large AND that are in the stopped state.

Old console

The old Amazon EC2 console supports the following types of searches:

Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes. To search by keyword, enter or paste what you're looking for in the search field, and then choose Enter. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID. If your free text search returns unexpected matches, apply additional filters.

Search by attributes

Searching by an attribute lets you search a specific attribute across all of your resources. For example, you can search the State attribute for all of your instances to return only instances that are in the stopped state. To do this:

1. In the search field on the Instances screen, start entering Instance State. As you enter characters, a list of matching attributes appears.
2. Select Instance State from the list. A list of possible values for the selected attribute appears.
3. Select Stopped from the list.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do not match a specified value. Inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character. For example, to list all instances that are not terminated, search by the Instance State attribute, and for the keyword, enter !Terminated.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword you want to search for. For example, to search for all t2.micro, t2.small, and t2.medium instances, search by the Instance Type attribute, and for the keyword, enter t2.
Regular expression search

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for all instances that have an attribute value that starts with s, search for ^s. Or to search for all instances that have an attribute value that ends with xyz, search for xyz$.

Regular expression searches are not case-sensitive.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for Instance State: Running and Instance State: Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for Instance State: Running and Instance Type: c4.large returns only instances that are of type c4.large AND that are in the stopped state.

List and filter using the CLI and API

Each resource type has a corresponding CLI command and API action that you use to list resources of that type. The resulting lists of resources can be long, so it can be faster and more useful to filter the results to include only the resources that match specific criteria.

Filtering considerations

• You can specify multiple filters and multiple filter values in a single request.
• You can use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches zero or one character.
• Filter values are case sensitive.
• Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of *amazon?\ searches for the literal string *amazon?\.

Supported filters

To see the supported filters for each Amazon EC2 resource, see the following documentation:

• AWS CLI: The describe commands in the AWS CLI Command Reference-Amazon EC2.
• Query API: The Describe API actions in the Amazon EC2 API Reference.

Example Example: Specify a single filter

You can list your Amazon EC2 instances using describe-instances. Without filters, the response contains information for all of your resources. You can use the following command to include only the running instances in your output.

```
aws ec2 describe-instances --filters Name=instance-state-name,Values=running
```

To list only the instance IDs for your running instances, add the --query parameter as follows.

```
aws ec2 describe-instances --filters Name=instance-state-name,Values=running --query "Reservations[*].Instances[*].InstanceId" --output text
```
The following is example output.

```
i-0ef1f57f78d4775a4
i-0626d4edd54f1286d
i-04a636d18e83cfacb
```

**Example Example: Specify multiple filters or filter values**

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the results.

You can use the following command to list all instances whose type is either `m5.large` or `m5d.large`.

```
aws ec2 describe-instances --filters Name=instance-type,Values=m5.large,m5d.large
```

You can use the following command to list all stopped instances whose type is `t2.micro`.

```
aws ec2 describe-instances --filters Name=instance-state-name,Values=stopped Name=instance-type,Values=t2.micro
```

**Example Example: Use wildcards in a filter value**

If you specify `database` as the filter value for the `description` filter when describing EBS snapshots using `describe-snapshots`, the command returns only the snapshots whose description is "database".

```
aws ec2 describe-snapshots --filters Name=description,Values=database
```

The * wildcard matches zero or more characters. If you specify `*database*` as the filter value, the command returns only snapshots whose description includes the word database.

```
aws ec2 describe-snapshots --filters Name=description,Values=*database*
```

The ? wildcard matches exactly 1 character. If you specify `database?` as the filter value, the command returns only snapshots whose description is "database" or "database" followed by one character.

```
aws ec2 describe-snapshots --filters Name=description,Values=database?
```

If you specify `database????`, the command returns only snapshots whose description is "database" followed by up to four characters. It excludes descriptions with "database" followed by five or more characters.

```
aws ec2 describe-snapshots --filters Name=description,Values=database????
```

**Example Example: Filter based on date**

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following `describe-snapshots` command displays the IDs of all snapshots created by your AWS account (represented by `123456789012`) before the specified date (represented by `2020-03-31`). If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[? (StartTime<='2020-03-31')].[SnapshotId]" --output text
```
The following command displays the IDs of all snapshots created in the specified date range.

```bash
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

Filter based on tags

For examples of how to filter a list of resources according to their tags, see Work with tags using the command line (p. 1471).

List and filter resources across Regions using Amazon EC2 Global View

Amazon EC2 Global View enables you to view some of your Amazon EC2 and Amazon VPC resources across a single AWS Region, or across multiple Regions in a single console. Using Amazon EC2 Global View, you can view a summary of all of your VPCs, subnets, instances, security groups, and volumes across all of the Regions for which your AWS account is enabled. Amazon EC2 Global View also provides global search functionality that lets you search for specific resources or specific resource types across multiple Regions simultaneously.

Amazon EC2 Global View does not let you modify resources in any way.

Required permissions

An IAM user must have the following permissions to use Amazon EC2 Global View.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeVpcs",
        "ec2:DescribeRegions",
        "ec2:DescribeVolumes",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
      ],
      "Resource": "*"
    }
  ]
}
```

To use Amazon EC2 Global View

Open the Amazon EC2 Global View console at https://console.aws.amazon.com/ec2globalview/home.

The console consists of two tabs:

- **Region explorer**—This tab includes the following sections:
  - **Resource summary**—Provides a high-level overview of your resources across all Regions.

  **Enabled Regions** indicates the number of Regions for which your AWS account is enabled. The remaining fields indicate the number of resources that you currently have in those Regions. Choose any of the links to view the resources of that type across all Regions. For example, if the link below the **Instances** label is **29 in 10 Regions**, it indicates that you currently have 29 instances across 10 Regions. Choose the link to view a list of all 29 instances.
Tag your resources

- **Resource counts per Region**—Lists all of the AWS Regions (including those for which your account is not enabled) and provides totals for each resource type for each Region.

Choose a Region name to view all resources of all types for that specific Region. For example, choose *Africa (Cape Town) af-south-1* to view all VPCs, subnets, instances, security groups, and volumes in that Region. Alternatively, select a Region and choose **View resources for selected Region**.

Choose the value for a specific resource type in a specific Region to view only resources of that type in that Region. For example, choose the value for Instances for *Africa (Cape Town) af-south-1* to view only the instances in that Region.

- **Global search**—This tab enables you to search for specific resources or specific resource types across a single Region or across multiple Regions. It also enables you to view details for a specific resource.

To search for resources, enter the search criteria in the field preceding the grid. You can search by Region, by resource type, and by the tags assigned to resources.

To view the details for a specific resource, select it in the grid. You can also choose the resource ID of a resource to open it in its respective console. For example, choose an instance ID to open the instance in the Amazon EC2 console, or choose a subnet ID to open the subnet in the Amazon VPC console.

---

Tag your Amazon EC2 resources

To help you manage your instances, images, and other Amazon EC2 resources, you can assign your own metadata to each resource in the form of *tags*. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. This topic describes tags and shows you how to create them.

**Warning**

Tag keys and their values are returned by many different API calls. Denying access to **DescribeTags** doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

Contents

- Tag basics (p. 1462)
- Tag your resources (p. 1463)
- Tag restrictions (p. 1466)
- Tags and access management (p. 1467)
- Tag your resources for billing (p. 1467)
- Work with tags using the console (p. 1467)
- Work with tags using the command line (p. 1471)
- Add tags to a resource using CloudFormation (p. 1474)

**Tag basics**

A tag is a label that you assign to an AWS resource. Each tag consists of a *key* and an optional *value*, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account's Amazon EC2 instances that helps you track each instance's owner and stack level.
The following diagram illustrates how tagging works. In this example, you've assigned two tags to each of your instances—one tag with the key `Owner` and another with the key `Stack`. Each tag also has an associated value.

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the AWS whitepaper Tagging Best Practices.

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

**Note**

After you delete a resource, its tags might remain visible in the console, API, and CLI output for a short period. These tags will be gradually disassociated from the resource and be permanently deleted.

**Tag your resources**

You can tag most Amazon EC2 resources that already exist in your account. The table (p. 1464) below lists the resources that support tagging.

If you're using the Amazon EC2 console, you can apply tags to resources by using the **Tags** tab on the relevant resource screen, or you can use the **Tags** screen. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of `Name` and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather
than during resource creation). The console may organize resources according to the Name tag, but this tag doesn't have any semantic meaning to the Amazon EC2 service.

If you're using the Amazon EC2 API, the AWS CLI, or an AWS SDK, you can use the CreateTags EC2 API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation. For more information about enabling users to tag resources on creation, see Grant permission to tag resources during creation (p. 1075).

The following table describes the Amazon EC2 resources that can be tagged, and the resources that can be tagged on creation using the Amazon EC2 API, the AWS CLI, or an AWS SDK.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Although EC2 allows for any character in its tags, other services are more restrictive. The allowed characters across services are: letters, numbers, and spaces representable in UTF-8, and the following characters: + - = . _ : / @.
- Tag keys and values are case-sensitive.
- The aws: prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the aws: prefix do not count against your tags per resource limit.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called DeleteMe, you must use the DeleteSnapshots action with the resource identifiers of the snapshots, such as snap-1234567890abcdef0.
When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

You can't tag all resources. For more information, see Tagging support for Amazon EC2 resources (p. 1464).

**Tags and access management**

If you're using AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to create, edit, or delete tags. For more information, see Grant permission to tag resources during creation (p. 1075).

You can also use resource tags to implement attribute-based control (ABAC). You can create IAM policies that allow operations based on the tags for the resource. For more information, see Control access to EC2 resources using resource tags (p. 1078).

**Tag your resources for billing**

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. For more information about setting up a cost allocation report with tags, see Monthly cost allocation report in the AWS Billing and Cost Management User Guide. To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using cost allocation tags in the AWS Billing and Cost Management User Guide.

**Note**

If you've just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost allocation tags can indicate which resources are contributing to costs, but deleting or deactivating resources doesn't always reduce costs. For example, snapshot data that is referenced by another snapshot is preserved, even if the snapshot that contains the original data is deleted. For more information, see Amazon Elastic Block Store volumes and snapshots in the AWS Billing and Cost Management User Guide.

**Note**

Elastic IP addresses that are tagged do not appear on your cost allocation report.

**Work with tags using the console**

Using the Amazon EC2 console, you can see which tags are in use across all of your Amazon EC2 resources in the same Region. You can view tags by resource and by resource type, and you can also view how many items of each resource type are associated with a specified tag. You can also use the Amazon EC2 console to apply or remove tags from one or more resources at a time.

For more information about using filters when listing your resources, see List and filter your resources (p. 1454).

For ease of use and best results, use Tag Editor in the AWS Management Console, which provides a central, unified way to create and manage your tags. For more information, see Tag Editor in Getting Started with the AWS Management Console.

**Tasks**
• Display tags (p. 1468)
• Add and delete tags on an individual resource (p. 1469)
• Add and delete tags to a group of resources (p. 1470)
• Add a tag when you launch an instance (p. 1470)
• Filter a list of resources by tag (p. 1471)

Display tags

You can display tags in two different ways in the Amazon EC2 console. You can display the tags for an individual resource or for all resources.

Display tags for individual resources

When you select a resource-specific page in the Amazon EC2 console, it displays a list of those resources. For example, if you select Instances from the navigation pane, the console displays your Amazon EC2 instances. When you select a resource from one of these lists (for example, an instance), if the resource supports tags, you can view and manage its tags. On most resource pages, you can view the tags by choosing the Tags tab.

You can add a column to the resource list that displays all values for tags with the same key. You can use this column sort and filter the resource list by the tag.

New console

• Choose the Preferences gear-shaped icon in the top right corner of the screen. In the Preferences dialog box, under Tag columns, select one of more tag keys, and then choose Confirm.

Old console

There are two ways to add a new column to the resource list to display your tags:

• On the Tags tab, select Show Column. A new column is added to the console.
• Choose the Show/Hide Columns gear-shaped icon, and in the Show/Hide Columns dialog box, select the tag key under Your Tag Keys.

Display tags for all resources

You can display tags across all resources by selecting Tags from the navigation pane in the Amazon EC2 console. The following image shows the Tags pane, which lists all tags in use by resource type.
Add and delete tags on an individual resource

You can manage tags for an individual resource directly from the resource's page.

**To add a tag to an individual resource**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see Resource locations (p. 1452).
3. In the navigation pane, select a resource type (for example, Instances).
4. Select the resource from the resource list and choose the Tags tab.
5. Choose Manage tags, Add tag. Enter the key and value for the tag. When you are finished adding tags, choose Save.

**To delete a tag from an individual resource**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see Resource locations (p. 1452).
3. In the navigation pane, select a resource type (for example, Instances).
4. Select the resource from the resource list and choose the Tags tab.
5. Choose Manage tags. For each tag, choose Remove. When you are finished removing tags, choose Save.
Add and delete tags to a group of resources

To add a tag to a group of resources

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can’t. For more information, see Resource locations (p. 1452).
3. In the navigation pane, choose Tags.
4. At the top of the content pane, choose Manage Tags.
5. For Filter, select the type of resource (for example, instances).
6. In the resources list, select the check box next to each resource.
7. Under Add Tag, enter the tag key and value and choose Add Tag.

Note
If you add a new tag with the same tag key as an existing tag, the new tag overwrites the existing tag.

To remove a tag from a group of resources

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can’t. For more information, see Resource locations (p. 1452).
3. In the navigation pane, choose Tags, Manage Tags.
4. To view the tags in use, select the Show/Hide Columns gear-shaped icon, and in the Show/Hide Columns dialog box, select the tag keys to view and choose Close.
5. For Filter, select the type of resource (for example, instances).
6. In the resource list, select the check box next to each resource.
7. Under Remove Tag, enter the tag key and choose Remove Tag.

Add a tag when you launch an instance

To add a tag using the Launch Wizard

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can’t. Select the Region that meets your needs. For more information, see Resource locations (p. 1452).
2. Choose Launch Instance.
3. The Choose an Amazon Machine Image (AMI) page displays a list of basic configurations called Amazon Machine Images (AMIs). Select the AMI to use and choose Select. For more information, see Find a Linux AMI (p. 84).
4. On the Configure Instance Details page, configure the instance settings as necessary, and then choose Next: Add Storage.
5. On the Add Storage page, you can specify additional storage volumes for your instance. Choose Next: Add Tags when done.
6. On the Add Tags page, specify tags for the instance, the volumes, or both. Choose Add another tag to add more than one tag to your instance. Choose Next: Configure Security Group when you are done.
7. On the **Configure Security Group** page, you can choose from an existing security group that you own, or let the wizard create a new security group for you. Choose **Review and Launch** when you are done.

8. Review your settings. When you're satisfied with your selections, choose **Launch**. Select an existing key pair or create a new one, select the acknowledgment check box, and then choose **Launch Instances**.

**Filter a list of resources by tag**

You can filter your list of resources based on one or more tag keys and tag values.

**To filter a list of resources by tag**

1. In the navigation pane, select a resource type (for example, **Instances**).
2. Choose the search field.
3. Choose the tag key from in the list.
4. Choose the corresponding tag value from the list.
5. When you are finished, remove the filter.

For more information about filters, see [List and filter your resources (p. 1454)].

**Work with tags using the command line**

You can add tags to many EC2 resource when you create them, using the tag specifications parameter for the create command. You can view the tags for a resource using the describe command for the resource. You can also add, update, or delete tags for your existing resources using the following commands.

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags</td>
<td>create-tags</td>
<td>New-EC2Tag</td>
</tr>
<tr>
<td>Delete one or more tags</td>
<td>delete-tags</td>
<td>Remove-EC2Tag</td>
</tr>
<tr>
<td>Describe one or more tags</td>
<td>describe-tags</td>
<td>Get-EC2Tag</td>
</tr>
</tbody>
</table>

**Tasks**

- Add tags on resource creation (p. 1471)
- Add tags to an existing resource (p. 1472)
- Describe tagged resources (p. 1473)

**Add tags on resource creation**

The following examples demonstrate how to apply tags when you create resources.

The way you enter JSON-formatted parameters on the command line differs depending on your operating system. Linux, macOS, or Unix and Windows PowerShell use single quotes (') to enclose the JSON data structure. Omit the single quotes when using the commands with the Windows command line. For more information, see [Specifying parameter values for the AWS CLI].
Example Example: Launch an instance and apply tags to the instance and volume

The following `run-instances` command launches an instance and applies a tag with the key `webserver` and the value `production` to the instance. The command also applies a tag with the key `cost-center` and the value `cc123` to any EBS volume that’s created (in this case, the root volume).

```bash
aws ec2 run-instances \\
--image-id ami-abc12345 \\
--count 1 \\
--instance-type t2.micro \\
--key-name MyKeyPair \\
--subnet-id subnet-6e7f829e \\
--tag-specifications 'ResourceType=instance,Tags=[{Key=webserver,Value=production}]'
'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

You can apply the same tag keys and values to both instances and volumes during launch. The following command launches an instance and applies a tag with a key of `cost-center` and a value of `cc123` to both the instance and any EBS volume that’s created.

```bash
aws ec2 run-instances \\
--image-id ami-abc12345 \\
--count 1 \\
--instance-type t2.micro \\
--key-name MyKeyPair \\
--subnet-id subnet-6e7f829e \\
--tag-specifications 'ResourceType=instance,Tags=[{Key=cost-center,Value=cc123}]'
'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

Example Example: Create a volume and apply a tag

The following `create-volume` command creates a volume and applies two tags: `purpose=production` and `cost-center=cc123`.

```bash
aws ec2 create-volume \\
--availability-zone us-east-1a \\
--volume-type gp2 \\
--size 80 \\
--tag-specifications 'ResourceType=volume,Tags=[{Key=purpose,Value=production},
{Key=cost-center,Value=cc123}]'
```

Add tags to an existing resource

The following examples demonstrate how to add tags to an existing resource using the `create-tags` command.

Example Example: Add a tag to a resource

The following command adds the tag `Stack=production` to the specified image, or overwrites an existing tag for the AMI where the tag key is `Stack`. If the command succeeds, no output is returned.

```bash
aws ec2 create-tags \\
--resources ami-78a54011 \\
--tags Key=Stack,Value=production
```

Example Example: Add tags to multiple resources

This example adds (or overwrites) two tags for an AMI and an instance. One of the tags contains just a key (`webserver`), with no value (we set the value to an empty string). The other tag consists of a key (`stack`) and value (`Production`). If the command succeeds, no output is returned.

```bash
aws ec2 create-tags \\
--resources ami-78a54011,ami-abc12345 \\
--tags Key=webserver,Value=
Key=stack,Value=Production
```
Work with tags using the command line

```
aws ec2 create-tags \
  --resources ami-1a2b3c4d i-1234567890abcdef0 \
  --tags Key=webserver,Value=  Key=stack,Value=Production
```

**Example: Add tags with special characters**

This example adds the tag `[Group]=test` to an instance. The square brackets ([ and ]) are special characters, which must be escaped.

If you are using Linux or OS X, to escape the special characters, enclose the element with the special character with double quotes ("), and then enclose the entire key and value structure with single quotes (').

```
aws ec2 create-tags \
  --resources i-1234567890abcdef0 \
  --tags 'Key=\"[Group]\",Value=test'
```

If you are using Windows, to escape the special characters, enclose the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (\) as follows:

```
aws ec2 create-tags \n  --resources i-1234567890abcdef0 \n  --tags Key=\"[Group]\",Value=test
```

If you are using Windows PowerShell, to escape the special characters, enclose the value that has special characters with double quotes ("), precede each double quote character with a backslash (\), and then enclose the entire key and value structure with single quotes (') as follows:

```
aws ec2 create-tags `\n  --resources i-1234567890abcdef0 `\n  --tags 'Key=\"[Group]\",Value=test'
```

**Describe tagged resources**

The following examples show you how to use filters with the `describe-instances` to view instances with specific tags. All EC2 describe commands use this syntax to filter by tag across a single resource type. Alternatively, you can use the `describe-tags` command to filter by tag across EC2 resource types.

**Example: Describe instances with the specified tag key**

The following command describes the instances with a `Stack` tag, regardless of the value of the tag.

```
aws ec2 describe-instances \
  --filters Name=tag-key,Values=Stack
```

**Example: Describe instances with the specified tag**

The following command describes the instances with the tag `Stack=production`.

```
aws ec2 describe-instances \
  --filters Name=tag:Stack,Values=production
```

**Example: Describe instances with the specified tag value**

The following command describes the instances with a tag with the value `production`, regardless of the tag key.
aws ec2 describe-instances \
   --filters Name=tag-value,Values=production

Example Example: Describe all EC2 resources with the specified tag

The following command describes all EC2 resources with the tag `Stack=Test`.

aws ec2 describe-tags \
   --filters Name=key,Values=Stack Name=value,Values=Test

Add tags to a resource using CloudFormation

With Amazon EC2 resource types, you specify tags using either a `Tags` or `TagSpecifications` property.

The following examples add the tag `Stack=Production` to `AWS::EC2::Instance` using its `Tags` property.

Example Example: Tags in YAML

```
Tags:
  - Key: "Stack"
    Value: "Production"
```

Example Example: Tags in JSON

```
"Tags": [
  {
    "Key": "Stack",
    "Value": "Production"
  }
]
```

The following examples add the tag `Stack=Production` to `AWS::EC2::LaunchTemplate LaunchTemplateData` using its `TagSpecifications` property.

Example Example: TagSpecifications in YAML

```
TagSpecifications:
  - ResourceType: "instance"
    Tags:
      - Key: "Stack"
        Value: "Production"
```

Example Example: TagSpecifications in JSON

```
"TagSpecifications": [
  {
    "ResourceType": "instance",
    "Tags": [
      {
        "Key": "Stack",
        "Value": "Production"
      }
    ]
  }
]"
Amazon EC2 service quotas

Amazon EC2 provides different resources that you can use. These resources include images, instances, volumes, and snapshots. When you create your AWS account, we set default quotas (also referred to as limits) on these resources on a per-Region basis. For example, there is a maximum number of instances that you can launch in a Region. So if you were to launch an instance in the US West (Oregon) Region, for example, the request must not cause your usage to exceed your maximum number of instances in that Region.

The Amazon EC2 console provides limit information for the resources managed by the Amazon EC2 and Amazon VPC consoles. You can request an increase for many of these limits. Use the limit information that we provide to manage your AWS infrastructure. Plan to request any limit increases in advance of the time that you'll need them.

For more information, see Amazon EC2 endpoints and quotas in the Amazon Web Services General Reference. For information about Amazon EBS quotas, see Amazon EBS quotas (p. 1408).

View your current limits

Use the Limits page in the Amazon EC2 console to view the current limits for resources provided by Amazon EC2 and Amazon VPC, on a per-Region basis.

To view your current limits

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select a Region.
3. From the navigation pane, choose Limits.
4. Locate the resource in the list. You can use the search fields to filter the list by resource name or resource group. The Current limit column displays the current maximum for the resource for your account.

Request an increase

Use the Limits page in the Amazon EC2 console to request an increase in your Amazon EC2 or Amazon VPC resources, on a per-Region basis.

Alternatively, request an increase using Service Quotas. For more information, see Requesting a quota increase in the Service Quotas User Guide.

To request an increase using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select a Region.
3. From the navigation pane, choose Limits.
4. Select the resource in the list, and choose Request limit increase.
5. Complete the required fields on the limit increase form and choose Submit. We'll respond to you using the contact method that you specified.

Restriction on email sent using port 25

On all instances, Amazon EC2 restricts traffic on port 25 by default. You can request that this restriction be removed. For more information, see How do I remove the restriction on port 25 from my EC2 instance? in the AWS Knowledge Center.

Amazon EC2 usage reports

AWS provides a free reporting tool called AWS Cost Explorer that enables you to analyze the cost and usage of your EC2 instances and the usage of your Reserved Instances. You can view data up to the last 13 months, and forecast how much you are likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time, identify areas that need further inquiry, and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

Here’s an example of some of the questions that you can answer when using Cost Explorer:

- How much am I spending on instances of each instance type?
- How many instance hours are being used by a particular department?
- How is my instance usage distributed across Availability Zones?
- How is my instance usage distributed across AWS accounts?
- How well am I using my Reserved Instances?
- Are my Reserved Instances helping me save money?

For more information about working with reports in Cost Explorer, including saving reports, see Analyzing your costs with Cost Explorer.
Troubleshoot EC2 instances

The following documentation can help you troubleshoot problems that you might have with your instance.

Contents

• Troubleshoot instance launch issues (p. 1477)
• Troubleshoot connecting to your instance (p. 1480)
• Troubleshoot stopping your instance (p. 1491)
• Troubleshoot instance termination (shutting down) (p. 1493)
• Troubleshoot instances with failed status checks (p. 1494)
• Troubleshoot an unreachable instance (p. 1515)
• Boot from the wrong volume (p. 1518)
• Use EC2Rescue for Linux (p. 1519)
• EC2 Serial Console for Linux instances (p. 1529)
• Send a diagnostic interrupt (for advanced users) (p. 1545)

For additional help with Windows instances, see Troubleshoot Windows instances in the Amazon EC2 User Guide for Windows Instances.

Troubleshoot instance launch issues

The following issues prevent you from launching an instance.

Launch Issues

• Instance limit exceeded (p. 1477)
• Insufficient instance capacity (p. 1478)
• The requested configuration is currently not supported. Please check the documentation for supported configurations. (p. 1478)
• Instance terminates immediately (p. 1479)

Instance limit exceeded

Description

You get the InstanceLimitExceeded error when you try to launch a new instance or restart a stopped instance.

Cause

If you get an InstanceLimitExceeded error when you try to launch a new instance or restart a stopped instance, you have reached the limit on the number of instances that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run on a per-Region basis.
Solution

You can request an instance limit increase on a per-region basis. For more information, see Amazon EC2 service quotas (p. 1475).

Insufficient instance capacity

Description

You get the InsufficientInstanceCapacity error when you try to launch a new instance or restart a stopped instance.

Cause

If you get this error when you try to launch an instance or restart a stopped instance, AWS does not currently have enough available On-Demand capacity to fulfill your request.

Solution

To resolve the issue, try the following:

• Wait a few minutes and then submit your request again; capacity can shift frequently.
• Submit a new request with a reduced number of instances. For example, if you're making a single request to launch 15 instances, try making 3 requests for 5 instances, or 15 requests for 1 instance instead.
• If you’re launching an instance, submit a new request without specifying an Availability Zone.
• If you’re launching an instance, submit a new request using a different instance type (which you can resize at a later stage). For more information, see Change the instance type (p. 310).
• If you are launching instances into a cluster placement group, you can get an insufficient capacity error. For more information, see Placement group rules and limitations (p. 1021).

The requested configuration is currently not supported. Please check the documentation for supported configurations.

Description

You get the Unsupported error when you try to launch a new instance because the instance configuration is not supported.

Cause

The error message provides additional details. For example, an instance type or instance purchasing option might not be supported in the specified Region or Availability Zone.

Solution

Try a different instance configuration. To search for an instance type that meets your requirements, see Find an Amazon EC2 instance type (p. 309).
Instance terminates immediately

Description

Your instance goes from the pending state to the terminated state.

Cause

The following are a few reasons why an instance might immediately terminate:

- You've exceeded your EBS volume limits. For more information, see Instance volume limits (p. 1431).
- An EBS snapshot is corrupted.
- The root EBS volume is encrypted and you do not have permissions to access the KMS key for decryption.
- A snapshot specified in the block device mapping for the AMI is encrypted and you do not have permissions to access the KMS key for decryption or you do not have access to the KMS key to encrypt the restored volumes.
- The instance store-backed AMI that you used to launch the instance is missing a required part (an image.part.xx file).

For more information, get the termination reason using one of the following methods.

To get the termination reason using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the instance.
3. On the first tab, find the reason next to State transition reason.

To get the termination reason using the AWS Command Line Interface

1. Use the describe-instances command and specify the instance ID.

   ```sh
   aws ec2 describe-instances --instance-id instance_id
   ```

2. Review the JSON response returned by the command and note the values in the StateReason response element.

   The following code block shows an example of a StateReason response element.

   ```json
   "StateReason": {
     "Code": "Server.InternalError"
   },
   ```

   To get the termination reason using AWS CloudTrail

   For more information, see Viewing events with CloudTrail event history in the AWS CloudTrail User Guide.

Solution

Depending on the termination reason, take one of the following actions:
Troubleshoot connecting to your instance

The following information can help you troubleshoot issues with connecting to your instance. For additional help with Windows instances, see Troubleshoot Windows instances in the Amazon EC2 User Guide for Windows Instances.

Connection problems and errors

- Common causes for connection issues (p. 1480)
- Error connecting to your instance: Connection timed out (p. 1481)
- Error: unable to load key ... Expecting: ANY PRIVATE KEY (p. 1484)
- Error: User key not recognized by server (p. 1484)
- Error: Permission denied or connection closed by [instance] port 22 (p. 1485)
- Error: Unprotected private key file (p. 1487)
- Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----" (p. 1488)
- Error: Server refused our key or No supported authentication methods available (p. 1488)
- Cannot ping instance (p. 1489)
- Error: Server unexpectedly closed network connection (p. 1489)
- Error: Host key validation failed for EC2 Instance Connect (p. 1489)

Common causes for connection issues

We recommend that you begin troubleshooting by checking some common causes for issues connecting to your instance.

Verify the user name for your instance

You can connect to your instance using the user name for your user account or the default user name for the AMI that you used to launch your instance.

- Get the user name for your user account.
  - For more information about how to create a user account, see Manage user accounts on your Amazon Linux instance (p. 561).
- Get the default user name for the AMI that you used to launch your instance:
  - For Amazon Linux 2 or the Amazon Linux AMI, the user name is ec2-user.
  - For a CentOS AMI, the user name is centos or ec2-user.
  - For a Debian AMI, the user name is admin.
  - For a Fedora AMI, the user name is fedora or ec2-user.
  - For a RHEL AMI, the user name is ec2-user or root.
  - For a SUSE AMI, the user name is ec2-user or root.
  - For an Ubuntu AMI, the user name is ubuntu.
• Otherwise, check with the AMI provider.

Verify that your security group rules allow traffic

Make sure your security group rules allow inbound traffic from your public IPv4 address on the proper port. For steps to verify, see Error connecting to your instance: Connection timed out (p. 1481)

Verify that your instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check your instance to make sure it is running and has passed its status checks.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. Verify the following:
   a. In the Instance state column, verify that your instance is in the running state.
   b. In the Status check column, verify that your instance has passed the two status checks.

Verify the general prerequisites for connecting to your instance

For more information, see General prerequisites for connecting to your instance (p. 499).

Error connecting to your instance: Connection timed out

If you try to connect to your instance and get an error message Network error: Connection timed out or Error connecting to [instance], reason: -> Connection timed out: connect, try the following:

Check your security group rules.

You need a security group rule that allows inbound traffic from your public IPv4 address on the proper port.

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. On the Security tab at the bottom of the console page, under Inbound rules, check the list of rules that are in effect for the selected instance.
   • For Linux instances: Verify that there is a rule that allows traffic from your computer to port 22 (SSH).
   • For Windows instances: Verify that there is a rule that allows traffic from your computer to port 3389 (RDP).
4. Each time you restart your instance, a new IP address (and host name) will be assigned. If your security group has a rule that allows inbound traffic from a single IP address, this address might not be static if your computer is on a corporate network or if you are connecting through an internet service provider (ISP). Instead, specify the range of IP addresses used by client computers. If your security group does not have a rule that allows inbound traffic as described in the previous step, add a rule to your security group. For more information, see Authorize inbound traffic for your Linux instances (p. 1134).
For more information about security group rules, see Security group rules in the Amazon VPC User Guide.

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the Description tab at the bottom of the console page, next to Security groups, select view inbound rules to display the list of rules that are in effect for the selected instance.
4. For Linux instances: When you select view inbound rules, a window will appear that displays the port(s) to which traffic is allowed. Verify that there is a rule that allows traffic from your computer to port 22 (SSH).
   
   For Windows instances: When you select view inbound rules, a window will appear that displays the port(s) to which traffic is allowed. Verify that there is a rule that allows traffic from your computer to port 3389 (RDP).

   Each time you restart your instance, a new IP address (and host name) will be assigned. If your security group has a rule that allows inbound traffic from a single IP address, this address may not be static if your computer is on a corporate network or if you are connecting through an internet service provider (ISP). Instead, specify the range of IP addresses used by client computers. If your security group does not have a rule that allows inbound traffic as described in the previous step, add a rule to your security group. For more information, see Authorize inbound traffic for your Linux instances (p. 1134).

   For more information about security group rules, see Security group rules in the Amazon VPC User Guide.

Check the route table for the subnet.

You need a route that sends all traffic destined outside the VPC to the internet gateway for the VPC.

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. On the Networking tab, make note of the values for VPC ID and Subnet ID.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create internet gateway, enter a name for the internet gateway, and choose Create internet gateway. Then, for the internet gateway you created, choose Actions, Attach to VPC, select your VPC, and then choose Attach internet gateway to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:
   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target. For IPv6, choose Add route, use ::/0 as the destination and the internet gateway as the target.
Error connecting to your instance: Connection timed out

c. Choose Save routes.

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the Description tab, write down the values of VPC ID and Subnet ID.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create Internet Gateway to create an internet gateway. Select the internet gateway, and then choose Attach to VPC and follow the directions to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route Table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (:/0) that points to the internet gateway. Otherwise, do the following:
   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target. For IPv6, choose Add route, use ::/0 as the destination and the internet gateway as the target.
   c. Choose Save routes.

Check the network access control list (ACL) for the subnet.

The network ACLs must allow inbound traffic from your local IP address on port 22 (for Linux instances) or port 3389 (for Windows instances). It must also allow outbound traffic to the ephemeral ports (1024-65535).

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet.
4. On the Network ACL tab, for Inbound rules, verify that the rules allow inbound traffic from your computer on the required port. Otherwise, delete or modify the rule that is blocking the traffic.
5. For Outbound rules, verify that the rules allow outbound traffic to your computer on the ephemeral ports. Otherwise, delete or modify the rule that is blocking the traffic.

If your computer is on a corporate network

Ask your network administrator whether the internal firewall allows inbound and outbound traffic from your computer on port 22 (for Linux instances) or port 3389 (for Windows instances).

If you have a firewall on your computer, verify that it allows inbound and outbound traffic from your computer on port 22 (for Linux instances) or port 3389 (for Windows instances).

Check that your instance has a public IPv4 address.

If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses (p. 914).

Check the CPU load on your instance; the server may be overloaded.
AWS automatically provides data such as Amazon CloudWatch metrics and instance status, which you can use to see how much CPU load is on your instance and, if necessary, adjust how your loads are handled. For more information, see Monitor your instances using CloudWatch (p. 818).

- If your load is variable, you can automatically scale your instances up or down using Auto Scaling and Elastic Load Balancing.
- If your load is steadily growing, you can move to a larger instance type. For more information, see Change the instance type (p. 310).

To connect to your instance using an IPv6 address, check the following:

- Your subnet must be associated with a route table that has a route for IPv6 traffic (: /0) to an internet gateway.
- Your security group rules must allow inbound traffic from your local IPv6 address on the proper port (22 for Linux and 3389 for Windows).
- Your network ACL rules must allow inbound and outbound IPv6 traffic.
- If you launched your instance from an older AMI, it might not be configured for DHCPv6 (IPv6 addresses are not automatically recognized on the network interface). For more information, see Configure IPv6 on Your Instances in the Amazon VPC User Guide.
- Your local computer must have an IPv6 address, and must be configured to use IPv6.

Error: unable to load key ... Expecting: ANY PRIVATE KEY

If you try to connect to your instance and get the error message, unable to load key ... Expecting: ANY PRIVATE KEY, the file in which the private key is stored is incorrectly configured. If the private key file ends in .pem, it might still be incorrectly configured. A possible cause for an incorrectly configured private key file is a missing certificate.

If the private key file is incorrectly configured, follow these steps to resolve the error

1. Create a new key pair. For more information, see Create a key pair using Amazon EC2 (p. 1138).
2. Add the new key pair to your instance. For more information, see Connect to your Linux instance if you lose your private key (p. 1148).
3. Connect to your instance using the new key pair.

Error: User key not recognized by server

If you use SSH to connect to your instance

- Use ssh -vvv to get triple verbose debugging information while connecting:

  ssh -vvv -i path/my-key-pair.pem my-instance-user-name@ec2-203-0-113-25.compute-1.amazonaws.com

The following sample output demonstrates what you might see if you were trying to connect to your instance with a key that was not recognized by the server:

  open/ANT/myusername/.ssh/known_hosts).
  debug2: bits set: 504/1024

1484
If you use PuTTY to connect to your instance

- Verify that your private key (.pem) file has been converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance from Windows using PuTTY (p. 515).

  Note
  In PuTTYgen, load your private key file and select Save Private Key rather than Generate.

- Verify that you are connecting with the appropriate user name for your AMI. Enter the user name in the Host name box in the PuTTY Configuration window.
  - For Amazon Linux 2 or the Amazon Linux AMI, the user name is ec2-user.
  - For a CentOS AMI, the user name is centos or ec2-user.
  - For a Debian AMI, the user name is admin.
  - For a Fedora AMI, the user name is fedora or ec2-user.
  - For a RHEL AMI, the user name is ec2-user or root.
  - For a SUSE AMI, the user name is ec2-user or root.
  - For an Ubuntu AMI, the user name is ubuntu.
  - Otherwise, check with the AMI provider.

- Verify that you have an inbound security group rule to allow inbound traffic to the appropriate port. For more information, see Authorizing Network Access to Your Instances (p. 1134).

Error: Permission denied or connection closed by [instance] port 22

If you connect to your instance using SSH and get any of the following errors, Host key not found in [directory], Permission denied (publickey), Authentication failed, permission denied, or Connection closed by [instance] port 22, verify that you are connecting with the
appropriate user name for your AMI and that you have specified the proper private key (.pem) file for your instance.

The appropriate user names are as follows:

- For Amazon Linux 2 or the Amazon Linux AMI, the user name is ec2-user.
- For a CentOS AMI, the user name is centos or ec2-user.
- For a Debian AMI, the user name is admin.
- For a Fedora AMI, the user name is fedora or ec2-user.
- For a RHEL AMI, the user name is ec2-user or root.
- For a SUSE AMI, the user name is ec2-user or root.
- For an Ubuntu AMI, the user name is ubuntu.
- Otherwise, check with the AMI provider.

For example, to use an SSH client to connect to an Amazon Linux instance, use the following command:

```bash
ssh -i /path/my-key-pair.pem my-instance-user-name@ec2-203-0-113-25.compute-1.amazonaws.com
```

Confirm that you are using the private key file that corresponds to the key pair that you selected when you launched the instance.

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and then select your instance.
3. On the Details tab, under Instance details, verify the value of Key pair name.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the .pem file for your key pair, you can replace the key pair with a new one. For more information, see Connect to your Linux instance if you lose your private key (p. 1148).

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and then select your instance.
3. In the Description tab, verify the value of Key pair name.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the .pem file for your key pair, you can replace the key pair with a new one. For more information, see Connect to your Linux instance if you lose your private key (p. 1148).

If you generated your own key pair, ensure that your key generator is set up to create RSA keys. DSA keys are not accepted.

If you get a Permission denied (publickey) error and none of the above applies (for example, you were able to connect previously), the permissions on the home directory of your instance may have been changed. Permissions for /home/my-instance-user-name/.ssh/authorized_keys must be limited to the owner only.
To verify the permissions on your instance

1. Stop your instance and detach the root volume. For more information, see Stop and start your instance (p. 524) and Detach an Amazon EBS volume from a Linux instance (p. 1224).
2. Launch a temporary instance in the same Availability Zone as your current instance (use a similar or the same AMI as you used for your current instance), and attach the root volume to the temporary instance. For more information, see Attach an Amazon EBS volume to an instance (p. 1202).
3. Connect to the temporary instance, create a mount point, and mount the volume that you attached. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1208).
4. From the temporary instance, check the permissions of the /home/my-instance-user-name/ directory of the attached volume. If necessary, adjust the permissions as follows:

   ```
   [ec2-user ~]# chmod 600 mount_point/home/my-instance-user-name/.ssh/authorized_keys
   [ec2-user ~]# chmod 700 mount_point/home/my-instance-user-name/.ssh
   [ec2-user ~]# chmod 700 mount_point/home/my-instance-user-name
   ```

5. Unmount the volume, detach it from the temporary instance, and re-attach it to the original instance. Ensure that you specify the correct device name for the root volume; for example, /dev/xvda.
6. Start your instance. If you no longer require the temporary instance, you can terminate it.

Error: Unprotected private key file

Your private key file must be protected from read and write operations from any other users. If your private key can be read or written to by anyone but you, then SSH ignores your key and you see the following warning message below.

```
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@

If you see a similar message when you try to log in to your instance, examine the first line of the error message to verify that you are using the correct public key for your instance. The above example uses the private key .ssh/my_private_key.pem with file permissions of 0777, which allow anyone to read or write to this file. This permission level is very insecure, and so SSH ignores this key.

If you are connecting from MacOS or Linux, run the following command to fix this error, substituting the path for your private key file.

```
[ec2-user ~]# chmod 0400 .ssh/my_private_key.pem
```

If you are connecting from Windows, perform the following steps on your local computer.

1. Navigate to your .pem file.
2. Right-click on the .pem file and select Properties.
3. Choose the Security tab.
4. Select Advanced.
5. Verify that you are the owner of the file. If not, change the owner to your username.
6. Select Disable inheritance and Remove all inherited permissions from this object.
7. Select Add, Select a principal, enter your username, and select OK.
8. From the Permission Entry window, grant Read permissions and select OK.
9. Select OK to close the Advanced Security Settings window.
10. Select OK to close the Properties window.
11. You should be able to connect to your Linux instance from Windows via SSH.

From a Windows command prompt, run the following commands.

1. From the command prompt, navigate to the file path location of your .pem file.
2. Run the following command to reset and remove explicit permissions:

   ```cmd
   icacls.exe $path /reset
   ```

3. Run the following command to grant Read permissions to the current user:

   ```cmd
   icacls.exe $path /GRANT:R "$($env:USERNAME):(R)"
   ```

4. Run the following command to disable inheritance and remove inherited permissions.

   ```cmd
   icacls.exe $path /inheritance:r
   ```

5. You should be able to connect to your Linux instance from Windows via SSH.

Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"

If you use a third-party tool, such as `ssh-keygen`, to create an RSA key pair, it generates the private key in the OpenSSH key format. When you connect to your instance, if you use the private key in the OpenSSH format to decrypt the password, you’ll get the error Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----".

To resolve the error, the private key must be in the PEM format. Use the following command to create the private key in the PEM format:

```bash
ssh-keygen -m PEM
```

**Error: Server refused our key or No supported authentication methods available**

If you use PuTTY to connect to your instance and get either of the following errors, Error: Server refused our key or Error: No supported authentication methods available, verify that you are connecting with the appropriate user name for your AMI. Type the user name in User name in the PuTTY Configuration window.

The appropriate user names are as follows:
Cannot ping instance

- For Amazon Linux 2 or the Amazon Linux AMI, the user name is `ec2-user`.
- For a CentOS AMI, the user name is `centos` or `ec2-user`.
- For a Debian AMI, the user name is `admin`.
- For a Fedora AMI, the user name is `fedora` or `ec2-user`.
- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.
- Otherwise, check with the AMI provider.

You should also verify that your private key (.pem) file has been correctly converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance from Windows using PuTTY (p. 515).

Cannot ping instance

The `ping` command is a type of ICMP traffic — if you are unable to ping your instance, ensure that your inbound security group rules allow ICMP traffic for the `Echo Request` message from all sources, or from the computer or instance from which you are issuing the command.

If you are unable to issue a `ping` command from your instance, ensure that your outbound security group rules allow ICMP traffic for the `Echo Request` message to all destinations, or to the host that you are attempting to ping.

`Ping` commands can also be blocked by a firewall or time out due to network latency or hardware issues. You should consult your local network or system administrator for help with further troubleshooting.

Error: Server unexpectedly closed network connection

If you are connecting to your instance with PuTTY and you receive the error "Server unexpectedly closed network connection," verify that you have enabled keepalives on the Connection page of the PuTTY Configuration to avoid being disconnected. Some servers disconnect clients when they do not receive any data within a specified period of time. Set the Seconds between keepalives to 59 seconds.

If you still experience issues after enabling keepalives, try to disable Nagle's algorithm on the Connection page of the PuTTY Configuration.

Error: Host key validation failed for EC2 Instance Connect

If you rotate your instance host keys, the new host keys are not automatically uploaded to the AWS trusted host keys database. This causes host key validation to fail when you try to connect to your instance using the EC2 Instance Connect browser-based client, and you're unable to connect to your instance.

To resolve the error, you must run the `eic_harvest_hostkeys` script on your instance, which uploads your new host key to EC2 Instance Connect. The script is located at `/opt/aws/bin/` on Amazon Linux 2 instances, and at `/usr/share/ec2-instance-connect/` on Ubuntu instances.

Amazon Linux 2

To resolve the host key validation failed error on an Amazon Linux 2 instance

1. Connect to your instance using SSH.
You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Amazon Linux 2, the default user name is `ec2-user`.

For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using SSH (p. 502).

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /opt/aws/bin/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

Ubuntu

**To resolve the host key validation failed error on an Ubuntu instance**

1. Connect to your instance using SSH.

You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Ubuntu, the default user name is `ubuntu`.

For example, if your instance was launched using Ubuntu, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using SSH (p. 502).

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /usr/share/ec2-instance-connect/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.
Troubleshoot stopping your instance

If you have stopped your Amazon EBS-backed instance and it appears stuck in the stopping state, there may be an issue with the underlying host computer.

There is no cost for instance usage while an instance is in the stopping state or in any other state except running. You are only charged for instance usage when an instance is in the running state.

Force stop the instance

Force the instance to stop using either the console or the AWS CLI.

New console

To force stop the instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the stuck instance.
3. Choose Instance state, Force stop instance, Stop.

Old console

To force stop the instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the stuck instance.
3. Choose Instance State, Stop, Yes, Forcefully Stop.

AWS CLI

To force stop the instance using the AWS CLI

Use the stop-instances command and the --force option as follows:

```bash
aws ec2 stop-instances --instance-ids i-0123ab456c789d01e --force
```

If, after 10 minutes, the instance has not stopped, post a request for help in the Amazon EC2 forum. To help expedite a resolution, include the instance ID, and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the Support Center.

Create a replacement instance

To attempt to resolve the problem while you are waiting for assistance from the Amazon EC2 forum or the Support Center, create a replacement instance. Create an AMI of the stuck instance, and launch a new instance using the new AMI.

New console

To create a replacement instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the stuck instance.
3. Choose Actions, Image and templates, Create image.
4. On the **Create image** page, do the following:
   a. Enter a name and description for the AMI.
   b. Choose **No reboot**.
   c. Choose **Create image**.

   For more information, see Create a Linux AMI from an instance (p. 103).

5. Launch a new instance from the AMI and verify that the new instance is working.

6. Select the stuck instance, and choose **Actions, Instance state, Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

---

Old console

**To create a replacement instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions, Image, Create Image**.
4. In the **Create Image** dialog box, fill in the following fields, and then choose **Create Image**:
   a. Specify a name and description for the AMI.
   b. Choose **No reboot**.

   For more information, see Create a Linux AMI from an instance (p. 103).

5. Launch a new instance from the AMI and verify that the new instance is working.

6. Select the stuck instance, and choose **Actions, Instance State, Terminate**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

---

AWS CLI

**To create a replacement instance using the CLI**

1. Create an AMI from the stuck instance using the `create-image` (AWS CLI) command and the `--no-reboot` option as follows:

   ```
   aws ec2 create-image --instance-id i-0123ab456c789d01e --name "AMI" --description "AMI for replacement instance" --no-reboot
   ```

2. Launch a new instance from the AMI using the `run-instances` (AWS CLI) command as follows:

   ```
   aws ec2 run-instances --image-id ami-1a2b3c4d --count 1 --instance-type c3.large --key-name MyKeyPair --security-groups MySecurityGroup
   ```

3. Verify that the new instance is working.
4. Terminate the stuck instance using the `terminate-instances` (AWS CLI) command as follows:

   ```
   aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
   ```

---

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:
(Alternate) To create a replacement instance using the console

1. Select the instance and choose **Description**, **Block devices**. Select each volume and make note of its volume ID. Be sure to note which volume is the root volume.

2. In the navigation pane, choose **Volumes**. Select each volume for the instance, and choose **Actions**, **Create Snapshot**.

3. In the navigation pane, choose **Snapshots**. Select the snapshot that you just created, and choose **Actions**, **Create Volume**.

4. Launch an instance with the same operating system as the stuck instance. Note the volume ID and device name of its root volume.

5. In the navigation pane, choose **Instances**, select the instance that you just launched, and choose **Instance state**, **Stop instance**.

6. In the navigation pane, choose **Volumes**, select the root volume of the stopped instance, and choose **Actions**, **Detach Volume**.

7. Select the root volume that you created from the stuck instance, choose **Actions**, **Attach Volume**, and attach it to the new instance as its root volume (using the device name that you made note of). Attach any additional non-root volumes to the instance.

8. In the navigation pane, choose **Instances** and select the replacement instance. Choose **Instance state**, **Start instance**. Verify that the instance is working.

9. Select the stuck instance, choose **Instance state**, **Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

---

**Troubleshoot instance termination (shutting down)**

You are not billed for any instance usage while an instance is not in the *running* state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to *shutting-down*.

**Instance terminates immediately**

Several issues can cause your instance to terminate immediately on start-up. See [Instance terminates immediately](p. 1479) for more information.

**Delayed instance termination**

If your instance remains in the *shutting-down* state longer than a few minutes, it might be delayed due to shutdown scripts being run by the instance.

Another possible cause is a problem with the underlying host computer. If your instance remains in the *shutting-down* state for several hours, Amazon EC2 treats it as a stuck instance and forcibly terminates it.

If it appears that your instance is stuck terminating and it has been longer than several hours, post a request for help to the [Amazon EC2 forum](URL). To help expedite a resolution, include the instance ID and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the [Support Center](URL).

**Terminated instance still displayed**

After you terminate an instance, it remains visible for a short while before being deleted. The state shows as *terminated*. If the entry is not deleted after several hours, contact Support.
Instances automatically launched or terminated

Generally, the following behaviors mean that you’ve used Amazon EC2 Auto Scaling, EC2 Fleet, or Spot Fleet to scale your computing resources automatically based on criteria that you’ve defined:

- You terminate an instance and a new instance launches automatically.
- You launch an instance and one of your instances terminates automatically.
- You stop an instance and it terminates and a new instance launches automatically.

To stop automatic scaling, see the Amazon EC2 Auto Scaling User Guide, EC2 Fleet (p. 656), or Create a Spot Fleet request (p. 717).

Troubleshoot instances with failed status checks

The following information can help you troubleshoot issues if your instance fails a status check. First determine whether your applications are exhibiting any problems. If you verify that the instance is not running your applications as expected, review the status check information and the system logs.

For examples of problems that can cause status checks to fail, see Status checks for your instances (p. 788).

Contents
- Review status check information (p. 1495)
- Retrieve the system logs (p. 1495)
- Troubleshoot system log errors for Linux-based instances (p. 1496)

- ERROR: mmu_update failed (Memory management update failed) (p. 1497)
- I/O error (block device failure) (p. 1498)
- I/O ERROR: neither local nor remote disk (Broken distributed block device) (p. 1499)
- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions) (p. 1500)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch) (p. 1500)
- "FATAL: Could not load /lib/modules" or "BusyBox (Missing kernel modules) (p. 1501)
- ERROR Invalid kernel (EC2 incompatible kernel) (p. 1502)
- fsck: No such file or directory while trying to open... (File system not found) (p. 1503)
- General error mounting filesystems (failed mount) (p. 1505)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch) (p. 1506)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch) (p. 1507)
- XENBUS: Device with no driver... (p. 1508)
- ... days without being checked, check forced (File system check required) (p. 1509)
- fsck died with exit status... (Missing device) (p. 1510)
- GRUB prompt (grubdom>) (p. 1510)
- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address) (p. 1512)
• Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration) (p. 1513)
• XENBUS: Timeout connecting to devices (Xenbus timeout) (p. 1514)

Review status check information

To investigate impaired instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the details pane, choose Status Checks to see the individual results for all System Status Checks and Instance Status Checks.

If a system status check has failed, you can try one of the following options:

• Create an instance recovery alarm. For more information, see Create alarms that stop, terminate, reboot, or recover an instance (p. 842).
• If you changed the instance type to an instance built on the Nitro System (p. 199), status checks fail if you migrated from an instance that does not have the required ENA and NVMe drivers. For more information, see Compatibility for changing the instance type (p. 311).
• For an instance using an Amazon EBS-backed AMI, stop and restart the instance.
• For an instance using an instance-store backed AMI, terminate the instance and launch a replacement.
• Wait for Amazon EC2 to resolve the issue.
• Post your issue to the Amazon EC2 forum.
• If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service automatically launches a replacement instance. For more information, see Health Checks for Auto Scaling Instances in the Amazon EC2 Auto Scaling User Guide.
• Retrieve the system log and look for errors.

Retrieve the system logs

If an instance status check fails, you can reboot the instance and retrieve the system logs. The logs may reveal an error that can help you troubleshoot the issue. Rebooting clears unnecessary information from the logs.

To reboot an instance and retrieve the system log

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select your instance.
3. Choose Instance state, Reboot instance. It might take a few minutes for your instance to reboot.
4. Verify that the problem still exists; in some cases, rebooting may resolve the problem.
5. When the instance is in the running state, choose Actions, Monitor and troubleshoot, Get system log.
6. Review the log that appears on the screen, and use the list of known system log error statements below to troubleshoot your issue.
7. If your experience differs from our check results, or if you are having an issue with your instance that our checks did not detect, choose Submit feedback on the Status Checks tab to help us improve our detection tests.
8. If your issue is not resolved, you can post your issue to the Amazon EC2 forum.
Troubleshoot system log errors for Linux-based instances

For Linux-based instances that have failed an instance status check, such as the instance reachability check, verify that you followed the steps above to retrieve the system log. The following list contains some common system log errors and suggested actions you can take to resolve the issue for each error.

Memory Errors

- Out of memory: kill process (p. 1496)
- ERROR: mmu_update failed (Memory management update failed) (p. 1497)

Device Errors

- I/O error (block device failure) (p. 1498)
- I/O ERROR: neither local nor remote disk (Broken distributed block device) (p. 1499)

Kernel Errors

- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions) (p. 1500)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch) (p. 1500)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules) (p. 1501)
- ERROR Invalid kernel (EC2 incompatible kernel) (p. 1502)

File System Errors

- fsck: No such file or directory while trying to open... (File system not found) (p. 1503)
- General error mounting filesystems (failed mount) (p. 1505)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch) (p. 1506)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch) (p. 1507)
- XENBUS: Device with no driver... (p. 1508)
- ... days without being checked, check forced (File system check required) (p. 1509)
- fsck died with exit status... (Missing device) (p. 1510)

Operating System Errors

- GRUB prompt (grubdom>) (p. 1510)
- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address) (p. 1512)
- Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration) (p. 1513)
- XENBUS: Timeout connecting to devices (Xenbus timeout) (p. 1514)

Out of memory: kill process

An out-of-memory error is indicated by a system log entry similar to the one shown below.
ERROR: mmu_update failed (Memory management update failed)

Memory management update failures are indicated by a system log entry similar to the following:

```
... Press `ESC' to enter the menu... 0   [H] Booting 'Amazon Linux 2011.09
(2.6.35.14-95.38.amzn1.i686)'

root (hd0)
Filesystem type is ext2fs, using whole disk
kernel /boot/vmlinux-2.6.35.14-95.38.amzn1.i686 root=LABEL=/ console=hvc0 LANG=
en_US.UTF-8 KEYTABLE=us
```
I/O error (block device failure)

An input/output error is indicated by a system log entry similar to the following example:

```
[9943662.053217] end_request: I/O error, dev sde, sector 52428288
[9943664.191262] end_request: I/O error, dev sde, sector 52428168
[9943664.191285] Buffer I/O error on device md0, logical block 209713024
[9943664.191304] Buffer I/O error on device md0, logical block 209713025
[9943664.191310] Buffer I/O error on device md0, logical block 209713026
[9943664.191317] Buffer I/O error on device md0, logical block 209713027
[9943664.191324] Buffer I/O error on device md0, logical block 209713028
[9943664.191332] Buffer I/O error on device md0, logical block 209713029
[9943664.191339] Buffer I/O error on device md0, logical block 209713030
[9943664.191339] Buffer I/O error on device md0, logical block 209713031
[9943664.191581] end_request: I/O error, dev sde, sector 52428280
[9943664.191590] Buffer I/O error on device md0, logical block 209713136
[9943664.191597] Buffer I/O error on device md0, logical block 209713137
[9943664.191767] end_request: I/O error, dev sde, sector 52428288
[9943664.191970] end_request: I/O error, dev sde, sector 52428288
[9943664.192143] end_request: I/O error, dev sde, sector 52428288
[9943664.192949] end_request: I/O error, dev sde, sector 52428288
[9943664.193112] end_request: I/O error, dev sde, sector 52428288
[9943664.193266] end_request: I/O error, dev sde, sector 52428288
...```

Potential causes

<table>
<thead>
<tr>
<th>Instance type</th>

</tr>
</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>A failed Amazon EBS volume</td>
</tr>
<tr>
<td>Instance store-backed</td>
<td>A failed physical drive</td>
</tr>
</tbody>
</table>

Suggested actions

**For this instance type**  
Amazon EBS-backed

**Do this**

1. Stop the instance.
2. Detach the volume.
3. Attempt to recover the volume.
An input/output error on the device is indicated by a system log entry similar to the following example:

```plaintext
...  
block drbd1: Local IO failed in request_timer_fn. Detaching...  
Aborting journal on device drbd1-8.  
block drbd1: IO ERROR: neither local nor remote disk  
Buffer I/O error on device drbd1, logical block 557056  
lost page write due to I/O error on drbd1  
JBD2: I/O error detected when updating journal superblock for drbd1-8.
```

### Potential causes

<table>

</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>A failed Amazon EBS volume</td>
</tr>
<tr>
<td>Instance store-backed</td>
<td>A failed physical drive</td>
</tr>
</tbody>
</table>

### Suggested action

Terminate the instance and launch a new instance.

For an Amazon EBS-backed instance you can recover data from a recent snapshot by creating an image from it. Any data added after the snapshot cannot be recovered.
This condition is indicated by a system log similar to the one shown below. Using an unstable or old Linux kernel (for example, 2.6.16-xenU) can cause an interminable loop condition at startup.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1 20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007

BIOS-provided physical RAM map:
    Xen: 0000000000000000 - 0000000026700000 (usable)

0MB HIGHMEM available.

Begin: Waiting for root file system... ...
Done.
Gave up waiting for root device. Common problems:
- Boot args (cat /proc/cmdline)
  - Check rootdelay= (did the system wait long enough?)
  - Check root= (did the system wait for the right device?)
- Missing modules (cat /proc/modules; ls /dev)
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or directory
```
Potential causes

One or more of the following conditions can cause this problem:

- Missing ramdisk
- Missing correct modules from ramdisk
- Amazon EBS root volume not correctly attached as /dev/sda1

ERROR Invalid kernel (EC2 incompatible kernel)

This condition is indicated by a system log similar to the one shown below.

```bash
...  
root (hd0)  
Filesystem type is ext2fs, using whole disk
kernel /vmlinuz root=/dev/sda1 ro
initrd /initrd.img
ERROR Invalid kernel: elf_xen_note_check: ERROR: Will only load images built for the generic loader or Linux images
xc_dom_parse_image returned -1
```
Error 9: Unknown boot failure

Booting 'Fallback'

root (hd0)

Filesystem type is ext2fs, using whole disk

kernel /vmlinuz.old root=/dev/sda1 ro

Error 15: File not found

Potential causes

One or both of the following conditions can cause this problem:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

Suggested actions

<table>
<thead>
<tr>
<th>For this instance type</th>
<th>Do this</th>
</tr>
</thead>
</table>
| Amazon EBS-backed      | Use the following procedure:  
  1. Stop the instance.  
  2. Replace with working kernel.  
  3. Install a fallback kernel.  
  4. Modify the AMI by correcting the kernel. |
| Instance store-backed  | Use the following procedure:  
  1. Terminate the instance and launch a new instance with the correct kernel.  
  2. Create an AMI with the correct kernel.  
  3. (Optional) Seek technical assistance for data recovery using AWS Support. |

fsck: No such file or directory while trying to open... (File system not found)

This condition is indicated by a system log similar to the one shown below.

Welcome to Fedora
Press 'I' to enter interactive startup.
Setting clock : Wed Oct 26 05:52:05 EDT 2011 [ OK ]
Starting udev: [ OK ]
Setting hostname localhost: [ OK ]

Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)

This condition is indicated by a system log similar to the one shown below.

```
... Bringing up loopback interface: [ OK ]
Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. [FAILED]
Starting auditd: [ OK ]
```

Potential causes

There is a hardcoded interface MAC in the AMI configuration.
Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)

Potential causes

SELinux has been enabled in error:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

</table>

**Troubleshoot an unreachable instance**

You can use the following methods to troubleshoot an unreachable Linux instance. For information about troubleshooting an unreachable Windows instance, see Troubleshoot an unreachable instance.

**Contents**

- Instance reboot (p. 1515)
- Instance console output (p. 1515)
- Capture a screenshot of an unreachable instance (p. 1516)
- Instance recovery when a host computer fails (p. 1517)

**Instance reboot**

The ability to reboot instances that are otherwise unreachable is valuable for both troubleshooting and general instance management.

Just as you can reset a computer by pressing the reset button, you can reset EC2 instances using the Amazon EC2 console, CLI, or API. For more information, see Reboot your instance (p. 544)

**Warning**

For Windows instances, this operation performs a hard reboot that might result in data corruption.

**Instance console output**

Console output is a valuable tool for problem diagnosis. It is especially useful for troubleshooting kernel problems and service configuration issues that could cause an instance to terminate or become unreachable before its SSH daemon can be started.

For Linux/Unix, the instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. The console output returns buffered information that was posted shortly after an instance transition state (start, stop, reboot, and terminate). The posted output is not continuously updated; only when it is likely to be of the most value.

For Windows instances, the instance console output includes the last three system event log errors.
You can optionally retrieve the latest serial console output at any time during the instance lifecycle. This option is only supported on Instances built on the Nitro System (p. 199). It is not supported through the Amazon EC2 console.

**Note**
Only the most recent 64 KB of posted output is stored, which is available for at least 1 hour after the last posting.

Only the instance owner can access the console output. You can retrieve the console output for your instances using the console or the command line.

Use one of the following methods to get console output.

**New console**

To get console output

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**, and select the instance.
3. Choose **Actions, Monitor and troubleshoot, Get system log**.

**Old console**

To get console output

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**, and select the instance.
3. Choose **Actions, Instance Settings, Get System Log**.

**Command line**

To get console output

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- `get-console-output` (AWS CLI)
- `Get-EC2ConsoleOutput` (AWS Tools for Windows PowerShell)

For more information about common system log errors, see Troubleshoot system log errors for Linux-based instances (p. 1496).

**Capture a screenshot of an unreachable instance**

If you are unable to reach your instance via SSH or RDP, you can capture a screenshot of your instance and view it as an image. The image can provide visibility as to the status of the instance, and allows for quicker troubleshooting. You can generate screenshots while the instance is running or after it has crashed. There is no data transfer cost for this screenshot. The image is generated in JPG format and is no larger than 100 kb. This feature is not supported when the instance is using an NVIDIA GRID driver, is on bare metal instances (instances of type *.metal*), or is powered by Arm-based Graviton or Graviton 2 processors. This feature is available in the following Regions:

- US East (N. Virginia) Region
- US East (Ohio) Region
- US West (Oregon) Region
- US West (N. California) Region
• Europe (Ireland) Region
• Europe (Frankfurt) Region
• Asia Pacific (Tokyo) Region
• Asia Pacific (Seoul) Region
• Asia Pacific (Singapore) Region
• Asia Pacific (Sydney) Region
• South America (São Paulo) Region
• Asia Pacific (Mumbai) Region
• Canada (Central) Region
• Europe (London) Region
• Europe (Paris) Region

To access the instance console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance to capture.
4. Choose Actions, Monitor and troubleshoot.
5. Choose Get instance screenshot.

Right-click the image to download and save it.

To capture a screenshot using the command line

You can use one of the following commands. The returned content is base64-encoded. For more information about these command line interfaces, see Access Amazon EC2 (p. 3).

- get-console-screenshot (AWS CLI)
- GetConsoleScreenshot (Amazon EC2 Query API)

Instance recovery when a host computer fails

If there is an unrecoverable issue with the hardware of an underlying host computer, AWS may schedule an instance stop event. You are notified of such an event ahead of time by email.

To recover an Amazon EBS-backed instance running on a host computer that failed

1. Back up any important data on your instance store volumes to Amazon EBS or Amazon S3.
2. Stop the instance.
3. Start the instance.
4. Restore any important data.

For more information, see Stop and start your instance (p. 524).

To recover an instance store-backed instance running on a host computer that failed

1. Create an AMI from the instance.
2. Upload the image to Amazon S3.
3. Back up important data to Amazon EBS or Amazon S3.
4. Terminate the instance.
5. Launch a new instance from the AMI.
6. Restore any important data to the new instance.

For more information, see Create an instance store-backed Linux AMI (p. 107).

Boot from the wrong volume

In some situations, you may find that a volume other than the volume attached to /dev/xvda or /dev/sda has become the root volume of your instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume.

This is due to how the initial ramdisk in Linux works. It chooses the volume defined as / in the /etc/fstab, and in some distributions, this is determined by the label attached to the volume partition. Specifically, you find that your /etc/fstab looks something like the following:

```
LABEL=/ / ext4 defaults,noatime 1 1
tmpfs /dev/shm tmpfs defaults 0 0
devpts /dev/pts devpts gid=5,mode=620 0 0
sysfs /sys sysfs defaults 0 0
proc /proc proc defaults 0 0
```

If you check the label of both volumes, you see that they both contain the / label:

```
[ec2-user ~]$ sudo e2label /dev/xvda1
LABEL=/
[ec2-user ~]$ sudo e2label /dev/xvdf1
LABEL=old/
```

In this example, you could end up having /dev/xvdf1 become the root device that your instance boots to after the initial ramdisk runs, instead of the /dev/xvda1 volume from which you had intended to boot. To solve this, use the same `e2label` command to change the label of the attached volume that you do not want to boot from.

In some cases, specifying a UUID in /etc/fstab can resolve this. However, if both volumes come from the same snapshot, or the secondary is created from a snapshot of the primary volume, they share a UUID.

```
[ec2-user ~]$ sudo blkid
/dev/xvda1: LABEL="" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"
PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
/dev/xvdf1: LABEL="old/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"
PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
```

To change the label of an attached ext4 volume

1. Use the `e2label` command to change the label of the volume to something other than /.
   ```
   [ec2-user ~]$ sudo e2label /dev/xvdf1 old/
   ```

2. Verify that the volume has the new label.
   ```
   [ec2-user ~]$ sudo e2label /dev/xvdf1 old/
   ```
To change the label of an attached xfs volume

- Use the `xfs_admin` command to change the label of the volume to something other than `/`.

```
[ec2-user ~]$ sudo xfs_admin -L old/ /dev/xvdf1
writing all SBs
new label = "old/"
```

After changing the volume label as shown, you should be able to reboot the instance and have the proper volume selected by the initial ramdisk when the instance boots.

**Important**

If you intend to detach the volume with the new label and return it to another instance to use as the root volume, you must perform the above procedure again and change the volume label back to its original value. Otherwise, the other instance does not boot because the ramdisk is unable to find the volume with the label `/`.

Use EC2Rescue for Linux

EC2Rescue for Linux is an easy-to-use, open-source tool that can be run on an Amazon EC2 Linux instance to diagnose and troubleshoot common issues using its library of over 100 modules. A few generalized use cases for EC2Rescue for Linux include gathering syslog and package manager logs, collecting resource utilization data, and diagnosing/remediating known problematic kernel parameters and common OpenSSH issues.

The `AWSSupport-TroubleshootSSH` runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see AWS Support-TroubleshootSSH.

If you are using a Windows instance, see EC2Rescue for Windows Server.

Contents

- Install EC2Rescue for Linux (p. 1519)
- Work with EC2Rescue for Linux (p. 1522)
- Develop EC2Rescue modules (p. 1524)

Install EC2Rescue for Linux

The EC2Rescue for Linux tool can be installed on an Amazon EC2 Linux instance that meets the following prerequisites.

**Prerequisites**

- Supported operating systems:
  - Amazon Linux 2
  - Amazon Linux 2016.09+
  - SUSE Linux Enterprise Server 12+
  - RHEL 7+
  - Ubuntu 16.04+
- Software requirements:
  - Python 2.7.9+ or 3.2+
The AWS Support-TroubleshootSSH runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see AWS Support-TroubleshootSSH.

If your system has the required Python version, you can install the standard build. Otherwise, you can install the bundled build, which includes a minimal copy of Python.

To install the standard build

1. From a working Linux instance, download the EC2Rescue for Linux tool:

   ```bash
   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz
   ```

2. (Optional) Before proceeding, you can optionally verify the signature of the EC2Rescue for Linux installation file. For more information, see (Optional) Verify the signature of EC2Rescue for Linux (p. 1520).

3. Download the sha256 hash file:

   ```bash
   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sha256
   ```

4. Verify the integrity of the tarball:

   ```bash
   sha256sum -c ec2rl.tgz.sha256
   ```

5. Unpack the tarball:

   ```bash
   tar -xzvf ec2rl.tgz
   ```

6. Verify the installation by listing out the help file:

   ```bash
   cd ec2rl-<version_number>
   ./ec2rl help
   ```

To install the bundled build

For a link to the download and a list of limitations, see EC2Rescue for Linux on github.

(Optional) Verify the signature of EC2Rescue for Linux

The following is the recommended process of verifying the validity of the EC2Rescue for Linux package for Linux-based operating systems.

When you download an application from the internet, we recommend that you authenticate the identity of the software publisher and check that the application has not been altered or corrupted after it was published. This protects you from installing a version of the application that contains a virus or other malicious code.

If, after running the steps in this topic, you determine that the software for EC2Rescue for Linux is altered or corrupted, do not run the installation file. Instead, contact Amazon Web Services.

EC2Rescue for Linux files for Linux-based operating systems are signed using GnuPG, an open-source implementation of the Pretty Good Privacy (OpenPGP) standard for secure digital signatures. GnuPG (also known as GPG) provides authentication and integrity checking through a digital signature. AWS publishes a public key and signatures that you can use to verify the downloaded EC2Rescue for Linux package. For more information about PGP and GnuPG (GPG), see http://www.gnupg.org.
The first step is to establish trust with the software publisher. Download the public key of the software publisher, check that the owner of the public key is who they claim to be, and then add the public key to your keyring. Your keyring is a collection of known public keys. After you establish the authenticity of the public key, you can use it to verify the signature of the application.

Tasks
- Install the GPG tools (p. 1521)
- Authenticate and import the public key (p. 1521)
- Verify the signature of the package (p. 1522)

Install the GPG tools

If your operating system is Linux or Unix, the GPG tools may already be installed. To test whether the tools are installed on your system, enter `gpg2` at a command prompt. If the GPG tools are installed, you see a GPG command prompt. If the GPG tools are not installed, you see an error stating that the command cannot be found. You can install the GnuPG package from a repository.

To install GPG tools on Debian-based Linux
- From a terminal, run the following command:
  
  `apt-get install gnupg2`

To install GPG tools on Red Hat–based Linux
- From a terminal, run the following command:
  
  `yum install gnupg2`

Authenticate and import the public key

The next step in the process is to authenticate the EC2Rescue for Linux public key and add it as a trusted key in your GPG keyring.

To authenticate and import the EC2Rescue for Linux public key
1. At a command prompt, use the following command to obtain a copy of our public GPG build key:

   `curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.key`

2. At a command prompt in the directory where you saved `ec2rl.key`, use the following command to import the EC2Rescue for Linux public key into your keyring:

   `gpg2 --import ec2rl.key`

The command returns results similar to the following:

```
gpg: /home/ec2-user/.gnupg/trustdb.gpg: trustdb created
gpg: key 2FAE2A1C: public key "ec2autodiag@amazon.com <EC2 Rescue for Linux>" imported
gpg: Total number processed: 1
  imported: 1  (RSA: 1)
```
Verify the signature of the package

After you've installed the GPG tools, authenticated and imported the EC2Rescue for Linux public key, and verified that the EC2Rescue for Linux public key is trusted, you are ready to verify the signature of the EC2Rescue for Linux installation script.

To verify the EC2Rescue for Linux installation script signature

1. At a command prompt, run the following command to download the signature file for the installation script:

   ```sh
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sig
   ```

2. Verify the signature by running the following command at a command prompt in the directory where you saved `ec2rl.tgz.sig` and the EC2Rescue for Linux installation file. Both files must be present.

   ```sh
gpg2 --verify ./ec2rl.tgz.sig
   ```

The output should look something like the following:

```
gpg: Signature made Thu 12 Jul 2018 01:57:51 AM UTC using RSA key ID 6991ED45
gpg: Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>
gpg: WARNING: This key is not certified with a trusted signature!
gpg:     There is no indication that the signature belongs to the owner.
Primary key fingerprint: E528 BCC9 0DBF 5AFA 0F6C C36A F780 4843 2FAE 2A1C
Subkey fingerprint: 966B 0D27 85E9 AEEC 1146 7A9D 8851 1153 6991 ED45
```

If the output contains the phrase *Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"*, it means that the signature has successfully been verified, and you can proceed to run the EC2Rescue for Linux installation script.

If the output includes the phrase *BAD signature*, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and do not run the installation file that you downloaded previously.

The following are details about the warnings that you might see:

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.** This refers to your personal level of trust in your belief that you possess an authentic public key for EC2Rescue for Linux. In an ideal world, you would visit an Amazon Web Services office and receive the key in person. However, more often you download it from a website. In this case, the website is an Amazon Web Services website.

- **gpg2: no ultimately trusted keys found.** This means that the specific key is not "ultimately trusted" by you (or by other people whom you trust).

For more information, see [http://www.gnupg.org](http://www.gnupg.org).

Work with EC2Rescue for Linux

The following are common tasks you can perform to get started using this tool.

**Tasks**

- Run EC2Rescue for Linux (p. 1523)
Run EC2Rescue for Linux

You can run EC2Rescue for Linux as shown in the following examples.

Example Example: Run all modules

To run all modules, run EC2Rescue for Linux with no options:

```
./ec2rl run
```

Some modules require root access. If you are not a root user, use `sudo` to run these modules as follows:

```
sudo ./ec2rl run
```

Example Example: Run a specific module

To run only specific modules, use the `--only-modules` parameter:

```
./ec2rl run --only-modules=module_name --arguments
```

For example, this command runs the `dig` module to query the `amazon.com` domain:

```
./ec2rl run --only-modules=dig --domain=amazon.com
```

Example Example: View the results

You can view the results in `/var/tmp/ec2rl`:

```
cat /var/tmp/ec2rl/logfile_location
```

For example, view the log file for the `dig` module:

```
cat /var/tmp/ec2rl/2017-05-11T15_39_21.893145/mod_out/run/dig.log
```

Upload the results

If AWS Support has requested the results or to share the results from an S3 bucket, upload them using the EC2Rescue for Linux CLI tool. The output of the EC2Rescue for Linux commands should provide the commands that you need to use.

Example Example: Upload results to AWS Support

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/2017-05-11T15_39_21.893145 --support-url="URLProvidedByAWSSupport"
```

Example Example: Upload results to an S3 bucket

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/2017-05-11T15_39_21.893145 --presigned-url="YourPresignedS3URL"
```
Create backups

Create a backup for your instance, one or more volumes, or a specific device ID using the following commands.

**Example Example: Back up an instance using an Amazon Machine Image (AMI)**

```
./ec2rl run --backup=ami
```

**Example Example: Back up all volumes associated with the instance**

```
./ec2rl run --backup=allvolumes
```

**Example Example: Back up a specific volume**

```
./ec2rl run --backup=volumeID
```

Get help

EC2Rescue for Linux includes a help file that gives you information and syntax for each available command.

**Example Example: Display the general help**

```
./ec2rl help
```

**Example Example: List the available modules**

```
./ec2rl list
```

**Example Example: Display the help for a specific module**

```
./ec2rl help module_name
```

For example, use the following command to show the help file for the `dig` module:

```
./ec2rl help dig
```

Develop EC2Rescue modules

Modules are written in YAML, a data serialization standard. A module's YAML file consists of a single document, representing the module and its attributes.

**Add module attributes**

The following table lists the available module attributes.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the module. The name should be less than or equal to 18 characters in length.</td>
</tr>
<tr>
<td>version</td>
<td>The version number of the module.</td>
</tr>
<tr>
<td>title</td>
<td>A short, descriptive title for the module. This value should be less than or equal to 50 characters in length.</td>
</tr>
<tr>
<td>helptext</td>
<td>The extended description of the module. Each line should be less than or equal to 75 characters in length. If the module consumes arguments, required or optional, include them in the helptext value. For example:</td>
</tr>
</tbody>
</table>
|             | ```
<p>|             | helptext: ::str |
|             | Collect output from ps for system analysis |
|             | Consumes --times= for number of times to repeat |
|             | Consumes --period= for time period between repetition |
| placement   | The stage in which the module should be run. Supported values: prediagnostic, run, postdiagnostic |
| language    | The language that the module code is written in. Supported values: bash, python |
|             | <strong>Note</strong> Python code must be compatible with both Python 2.7.9+ and Python 3.2+.                                                          |
| remediation | Indicates whether the module supports remediation. Supported values are True or False. The module defaults to False if this is absent, making it an optional attribute for those modules that do not support remediation. |
| content     | The entirety of the script code.                                                                                                           |
| constraint  | The name of the object containing the constraint values.                                                                                   |</p>
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
</table>
| domain | A descriptor of how the module is grouped or classified. The set of included modules uses the following domains:  
  - application  
  - net  
  - os  
  - performance |
| class | A descriptor of the type of task performed by the module. The set of included modules uses the following classes:  
  - collect (collects output from programs)  
  - diagnose (pass/fail based on a set of criteria)  
  - gather (copies files and writes to specific file) |
| distro | The list of Linux distributions that this module supports. The set of included modules uses the following distributions:  
  - alami (Amazon Linux)  
  - rhel  
  - ubuntu  
  - suse |
| required | The required arguments that the module is consuming from the CLI options. |
| optional | The optional arguments that the module can use. |
| software | The software executables used in the module. This attribute is intended to specify software that is not installed by default. The EC2Rescue for Linux logic ensures that these programs are present and executable before running the module. |
| package | The source software package for an executable. This attribute is intended to provide extended details on the package with the software, including a URL for downloading or getting further information. |
| sudo | Indicates whether root access is required to run the module.  
  You do not need to implement sudo checks in the module script. If the value is true, then the EC2Rescue for Linux logic only runs the module when the executing user has root access. |
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>perfimpact</td>
<td>Indicates whether the module can have significant performance impact upon the environment in which it is run. If the value is true and the --perfimpact=true argument is not present, then the module is skipped.</td>
</tr>
<tr>
<td>parallelexclusive</td>
<td>Specifies a program that requires mutual exclusivity. For example, all modules specifying “bpf” run in a serial manner.</td>
</tr>
</tbody>
</table>

### Add environment variables

The following table lists the available environment variables.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC2RL_CALLPATH</td>
<td>The path to ec2rl.py. This path can be used to locate the lib directory and use vendored Python modules.</td>
</tr>
<tr>
<td>EC2RL_WORKDIR</td>
<td>The main tmp directory for the diagnostic tool. Default value: /var/tmp/ec2rl.</td>
</tr>
<tr>
<td>EC2RL_RUNDIR</td>
<td>The directory where all output is stored. Default value: /var/tmp/ec2rl/&lt;date&amp;timestamp&gt;.</td>
</tr>
<tr>
<td>EC2RL_GATHEREDDIR</td>
<td>The root directory for placing gathered module data. Default value:/var/tmp/ec2rl/&lt;date&amp;timestamp&gt;/mod_out/gathered/.</td>
</tr>
<tr>
<td>EC2RL_NET_DRIVER</td>
<td>The driver in use for the first, alphabetically ordered, non-virtual network interface on the instance. Examples: • xen_netfront • ixgbevf • ena</td>
</tr>
<tr>
<td>EC2RL_SUDO</td>
<td>True if EC2Rescue for Linux is running as root; otherwise, false.</td>
</tr>
<tr>
<td>EC2RL_VIRT_TYPE</td>
<td>The virtualization type as provided by the instance metadata. Examples: • default-hvm • default-paravirtual</td>
</tr>
</tbody>
</table>
Use YAML syntax

The following should be noted when constructing your module YAML files:

- The triple hyphen (---) denotes the explicit start of a document.
- The `!ec2rlcore.module.Module` tag tells the YAML parser which constructor to call when creating the object from the data stream. You can find the constructor inside the `module.py` file.
- The `!!str` tag tells the YAML parser to not attempt to determine the type of data, and instead interpret the content as a string literal.
- The pipe character (|) tells the YAML parser that the value is a literal-style scalar. In this case, the parser includes all whitespace. This is important for modules because indentation and newline characters are kept.
- The YAML standard indent is two spaces, which can be seen in the following examples. Ensure that you maintain standard indentation (for example, four spaces for Python) for your script and then indent the entire content two spaces inside the module file.

Example modules

Example one (mod.d/ps.yaml):

```bash
--- !ec2rlcore.module.Module
# Module document. Translates directly into an almost-complete Module object
name: !!str ps
path: !!str
version: !!str 1.0
title: !!str Collect output from ps for system analysis
helptext: !!str |
  Collect output from ps for system analysis
  Requires --times= for number of times to repeat
  Requires --period= for time period between repetition
placement: !!str run
package:
  - !!str
language: !!str bash
content: !!str |
  #!/bin/bash
  error_trap()
  {
    printf "%0.s=" {1..80}
    echo -e "\nERROR: "#BASH_COMMAND" exited with an error on line ${BASH_LINENO[0]}"
    exit 0
  }
  trap error_trap ERR
  # read-in shared function
  source functions.bash
  echo "I will collect ps output from this $EC2RL_DISTRO box for $times times every $period seconds."
  for i in $(seq 1 $times); do
```
EC2 Serial Console for Linux instances

With the EC2 serial console, you have access to your Amazon EC2 instance's serial port, which you can use to troubleshoot boot, network configuration, and other issues. The serial console does not require your instance to have any networking capabilities. With the serial console, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console session lasts during instance reboot and stop. During reboot, you can view all of the boot messages from the start.

Access to the serial console is not available by default. Your organization must grant account access to the serial console and configure IAM policies to grant your users access to the serial console. Serial console access can be controlled at a granular level by using instance IDs, resource tags, and other IAM levers. For more information, see Configure access to the EC2 Serial Console (p. 1529).

The serial console can be accessed by using the EC2 console or the AWS CLI.

The serial console is available at no additional cost.

If you are using a Windows instance, see EC2 Serial Console for Windows instances in the Amazon EC2 User Guide for Windows Instances.

Topics

- Configure access to the EC2 Serial Console (p. 1529)
- Connect to the EC2 Serial Console (p. 1534)
- Terminate an EC2 Serial Console session (p. 1539)
- Troubleshoot your Linux instance using the EC2 Serial Console (p. 1540)

Configure access to the EC2 Serial Console

To configure access to the serial console, you must grant serial console access at the account level and then configure IAM policies to grant access to your IAM users. You must also configure a password-based user on every instance so that your users can use the serial console for troubleshooting.

Topics

- Levels of access to the EC2 Serial Console (p. 1530)
- Manage account access to the EC2 Serial Console (p. 1530)
- Configure IAM policies for EC2 Serial Console access (p. 1532)
- Set an OS user password (p. 1534)
Levels of access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level. For more information, see Manage account access to the EC2 Serial Console (p. 1530).

You can use a service control policy (SCP) to allow access to the serial console within your organization. You can then have granular access control at the IAM user level by using an IAM policy to control access. By using a combination of SCP and IAM policies, you have different levels of access control to the serial console.

Organization level

You can use a service control policy (SCP) to allow access to the serial console for member accounts within your organization. For more information about SCPs, see Service control policies in the AWS Organizations User Guide.

Instance level

You can configure the serial console access policies by using IAM PrincipalTag and ResourceTag constructions and by specifying instances by their ID. For more information, see Configure IAM policies for EC2 Serial Console access (p. 1532).

IAM user level

You can configure access at the user level by configuring an IAM policy to allow or deny a specified user the permission to push the SSH public key to the serial console service of a particular instance. For more information, see Configure IAM policies for EC2 Serial Console access (p. 1532).

OS level

You can set a user password at the guest OS level. This provides access to the serial console for some use cases. However, to monitor the logs, you don't need a password-based user. For more information, see Set an OS user password (p. 1534).

Manage account access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level.

Topics

- Grant permission to IAM users to manage account access (p. 1530)
- View account access status to the serial console (p. 1531)
- Grant account access to the serial console (p. 1531)
- Deny account access to the serial console (p. 1532)

Grant permission to IAM users to manage account access

To allow your IAM users to manage account access to the EC2 serial console, you need to grant them the required IAM permissions.

The following policy grants permissions to view the account status, and to allow and prevent account access to the EC2 serial console.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
```
For more information, see Creating IAM policies in the IAM User Guide.

View account access status to the serial console

To view account access status to the serial console (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose EC2 Dashboard.
3. From Account attributes, choose EC2 Serial Console.

   The EC2 Serial Console access field indicates whether account access is Allowed or Prevented.

   The following screenshot shows that the account is prevented from using the EC2 serial console.

   ![EC2 Serial Console access screenshot]

To view account access status to the serial console (AWS CLI)

Use the get-serial-console-access-status command to view account access status to the serial console.

```
aws ec2 get-serial-console-access-status --region us-east-1
```

In the following output, true indicates that the account is allowed access to the serial console.

```
{
   "SerialConsoleAccessEnabled": true
}
```

Grant account access to the serial console

To grant account access to the serial console (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose EC2 Dashboard.
3. From Account attributes, choose EC2 Serial Console.
4. Choose Manage.
5. To allow access to the EC2 serial console of all instances in the account, select the Allow check box.
6. Choose **Update**.

**To grant account access to the serial console (AWS CLI)**

Use the `enable-serial-console-access` command to allow account access to the serial console.

```bash
aws ec2 enable-serial-console-access --region us-east-1
```

In the following output, `true` indicates that the account is allowed access to the serial console.

```json
{
    "SerialConsoleAccessEnabled": true
}
```

**Deny account access to the serial console**

**To deny account access to the serial console (console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To prevent access to the EC2 serial console of all instances in the account, clear the **Allow** check box.
6. Choose **Update**.

**To deny account access to the serial console (AWS CLI)**

Use the `disable-serial-console-access` command to prevent account access to the serial console.

```bash
aws ec2 disable-serial-console-access --region us-east-1
```

In the following output, `false` indicates that the account is denied access to the serial console.

```json
{
    "SerialConsoleAccessEnabled": false
}
```

**Configure IAM policies for EC2 Serial Console access**

By default, your IAM users do not have access to the serial console. Your organization must configure IAM policies to grant your IAM users the required access. For more information, see [Creating IAM policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/index.html) in the **IAM User Guide**.

For serial console access, create a JSON policy document that includes the `ec2-instance-connect:SendSerialConsoleSSHPublicKey` action. This action grants an IAM user permission to push the public key to the serial console service, which starts a serial console session. We recommend restricting access to specific EC2 instances. Otherwise, all IAM users with this permission can connect to the serial console of all EC2 instances.

**Example IAM policies**

- Explicitly allow access to the serial console (p. 1533)
- Explicitly deny access to the serial console (p. 1533)
- Use resource tags to control access to the serial console (p. 1533)
Explicitly allow access to the serial console

By default, no one has access to the serial console. To grant access to the serial console, you need to configure a policy to explicitly allow access. We recommend configuring a policy that restricts access to specific instances.

The following policy allows access to the serial console of a specific instance, identified by its instance ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowSerialConsoleAccess",
      "Effect": "Allow",
      "Action": [
        "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
      ],
      "Resource": "arn:aws:ec2:region:account-id:instance/i-0598c7d356eb48d7"
    }
  ]
}
```

Explicitly deny access to the serial console

The following IAM policy allows access to the serial console of all instances, denoted by the * (asterisk), and explicitly denies access to the serial console of a specific instance, identified by its ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowSerialConsoleAccess",
      "Effect": "Allow",
      "Action": [
        "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
      ],
      "Resource": "*"
    },
    {
      "Sid": "DenySerialConsoleAccess",
      "Effect": "Deny",
      "Action": [
        "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
      ],
      "Resource": "arn:aws:ec2:region:account-id:instance/i-0598c7d356eb48d7"
    }
  ]
}
```

Use resource tags to control access to the serial console

You can use resource tags to control access to the serial console of an instance.

Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows an IAM user to initiate a serial console connection for an instance only if that instance's resource tag and the principal's tag have the same SerialConsole value for the tag key.

For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the IAM User Guide.
Set an OS user password

You can connect to the serial console without a password. However, to use the serial console for troubleshooting an instance, the instance must have a password-based OS user.

You can set the password for any OS user, including the root user. Note that the root user can modify all files, while each OS user might have limited permissions.

You must set a user password for every instance for which you will use the serial console. This is a one-time requirement for each instance.

**Note**
The following instructions are applicable only if you launched your instance using an AWS-provided AMI because, by default, AWS-provided AMIs are not configured with a password-based user. If you launched your instance using an AMI that already has the root user password configured, you can skip these instructions.

**To set an OS user password**

1. Connect (p. 499) to your instance. You can use any method for connecting to your instance, except the EC2 Serial Console connection method.
2. To set the password for a user, use the `passwd` command. In the following example, the user is root.

   ![Example output](image)

   The following is example output.

   ```
   Changing password for user root.
   New password:
   ```

   3. At the New password prompt, enter the new password.
   4. At the prompt, re-enter the password.

Connect to the EC2 Serial Console

You can connect to the serial console of your EC2 instance by using the Amazon EC2 console or via SSH. After connecting to the serial console, you can use it for troubleshooting boot, network configuration, and other issues. For more information about troubleshooting, see Troubleshoot your Linux instance using the EC2 Serial Console (p. 1540).
Considerations

- Only one active serial console connection is supported per instance.
- The serial console connection typically lasts for one hour unless you terminate it. However, during system maintenance, Amazon EC2 will terminate the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.
- Supported serial console port for Linux: ttyS0
- When you connect to the serial console, you might observe a slight drop in your instance's throughput.

Prerequisites

- Supported AWS Regions: US East (N. Virginia), US East (Ohio), US West (Oregon) Europe (Ireland), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Tokyo), Asia Pacific (Singapore)
- Supported instance families:
  - A1
  - C5, C5a, C5ad, C5d, C5n, C6g, C6gd
  - M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6g, M6gd
  - R5, R5a, R5ad, R5d, R5dn, R5n, R6, R6gd
  - T3, T3a, T4g
  - Z1d
- Configure access to the EC2 Serial Console, as follows:
  - Manage account access to the EC2 Serial Console (p. 1530).
  - Configure IAM policies for EC2 Serial Console access (p. 1532). All IAM users who will use the serial console must have the required permissions.
  - Set an OS user password (p. 1534).
- To connect to the serial console using the browser-based client (p. 1536), your browser must support WebSocket. If your browser does not support WebSocket, connect to the serial console using your own key and an SSH client. (p. 1536)
- The instance must be in the pending, running, stopping, or shutting-down state. If the instance is terminated or stopped, you can't connect to the serial console. For more information about the instance states, see Instance lifecycle (p. 471).
- If the instance uses Amazon EC2 Systems Manager, then SSM Agent version 3.0.854.0 or later must be installed on the instance. For information about SSM Agent, see Working with SSM Agent in the AWS Systems Manager User Guide.

You do not need an sshd server installed or running on your instance.

Connect to the EC2 Serial Console

Connection options
• Connect using the browser-based client (p. 1536)
• Connect using your own key and SSH client (p. 1536)

Connect using the browser-based client

You can connect to your EC2 instance's serial console by using the browser-based client. You do this by selecting the instance in the Amazon EC2 console and choosing to connect to the serial console. The browser-based client handles the permissions and provides a successful connection.

EC2 serial console works from most browsers, and supports keyboard and mouse input.

To connect to your instance's serial port using the browser-based client (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Connect, EC2 Serial Console, Connect.

Alternatively, you can select the instance and choose Actions, Monitor and troubleshoot, EC2 Serial Console, Connect.

An in-browser terminal window opens.

4. Press Enter. If a login prompt returns, you are connected to the serial console.

If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

• Check that you have configured access to the serial console. For more information, see Configure access to the EC2 Serial Console (p. 1529).
• Use SysRq to connect to the serial console. SysRq does not require that you connect via the browser-based client. For more information, see Troubleshoot your Linux instance using SysRq (p. 1543).
• Restart getty. If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

```
[ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
```

• Reboot your instance. You can reboot your instance by using SysRq, the EC2 console, or the AWS CLI. For more information, see Troubleshoot your Linux instance using SysRq (p. 1543) or Reboot your instance (p. 544).

5. At the login prompt, enter the user name of the password-based user that you set up previously (p. 1534), and then press Enter.
6. At the Password prompt, enter the password, and then press Enter.

You are now logged onto the instance and can use the serial console for troubleshooting.

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the serial console API. This enables you to benefit from the serial console capability to push a public key to the instance.

To connect to an instance's serial console using SSH

1. Push your SSH public key to the instance to start a serial console session
Use the `send-serial-console-ssh-public-key` command to push your SSH public key to the instance. This starts a serial console session.

If a serial console session has already been started for this instance, the command fails because you can only have one session open at a time. It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

```
$ aws ec2-instance-connect send-serial-console-ssh-public-key \
   --instance-id i-001234a4bf70dec41EXAMPLE \
   --serial-port 0 \
   --ssh-public-key file://my_rsa_key.pub \
   --region us-east-1
```

2. Connect to the serial console using your private key

Use the `ssh` command to connect to the serial console before the public key is removed from the serial console service. You have 60 seconds before it is removed.

Use the private key that corresponds to the public key.

The user name format is `instance-id.port0`, which comprises the instance ID and port 0. In the following example, the user name is `i-001234a4bf70dec41EXAMPLE.port0`.

**For all supported AWS Regions, except AWS GovCloud (US) Regions:**

The format of the public DNS name of the serial console service is `serial-console.ec2-instance-connect.region.aws`. In the following example, the serial console service is in the `us-east-1` Region.

```
$ ssh -i my_rsa_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.aws
```

**For AWS GovCloud (US) Regions only:**

The format of the public DNS name of the serial console service in the AWS GovCloud (US) Regions is `serial-console.ec2-instance-connect.GovCloud-region.amazonaws.com`. In the following example, the serial console service is in the `us-gov-east-1` Region.

```
$ ssh -i my_rsa_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-gov-east-1.amazonaws.com
```

3. (Optional) Verify the fingerprint

When you connect for the first time to the serial console, you are prompted to verify the fingerprint. You can compare the serial console fingerprint with the fingerprint that's displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to the serial console.

The following fingerprint is for the serial console service in the us-east-1 Region. For the fingerprints for each Region, see EC2 Serial Console fingerprints (p. 1538).

```
SHA256:dxwn5ma/xadVMebZGEru5l2gx+yI5LDi3aLUCz0FMnw
```

**Note**
The fingerprint only appears the first time you connect to the serial console.

4. Press Enter. If a prompt returns, you are connected to the serial console.
If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

- **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console (p. 1529).

- **Use SysRq to connect to the serial console.** SysRq does not require that you connect via SSH. For more information, see Troubleshoot your Linux instance using SysRq (p. 1543).

- **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

  ```bash
  [ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
  ```

- **Reboot your instance.** You can reboot your instance by using SysRq, the EC2 console, or the AWS CLI. For more information, see Troubleshoot your Linux instance using SysRq (p. 1543) or Reboot your instance (p. 544).

5. At the login prompt, enter the user name of the password-based user that you set up previously (p. 1534), and then press Enter.

6. At the Password prompt, enter the password, and then press Enter.

You are now logged onto the instance and can use the serial console for troubleshooting.

**EC2 Serial Console fingerprints**

The EC2 Serial Console fingerprint is unique for each AWS Region.

- us-east-2 – US East (Ohio)

  SHA256:EhwPkTzT7rTY7TR8z26XbB0/HVY9jRM7mCZN0xw/d/0

- us-east-1 – US East (N. Virginia)

  SHA256:dXwn5ma/xadVMeBZGEr5l2gx+yI5LDiJaLucz0Fmmw

- us-west-1 – US West (N. California)

  SHA256:OHldlcMET8u7QLSX3jmRTPARFHVtqobyoLZBMUCqiH3Y

- us-west-2 – US West (Oregon)

  SHA256:EMCIe23TqKabI6yGHaingZcMwqNKhAhAVHa1O2JxVUC

- ap-south-1 – Asia Pacific (Mumbai)

  SHA256:oBLXcYmlqHHebliARxEGh8ISOSlrezTP1SM35Bau0

- ap-northeast-2 – Asia Pacific (Seoul)

  SHA256:FqqXNXmDZ+GuNTztg9PK49WMqBX+FrcZM2dSrqrI

- ap-southeast-1 – Asia Pacific (Singapore)

  SHA256:PLFh7WnCQDHx3qmwLu1Gy/O8TUX7LQzuaC6L45CoY

- ap-southeast-2 – Asia Pacific (Sydney)
Terminate an EC2 Serial Console session

The way to terminate a serial console session depends on the client.

Browser-based client

To terminate the serial console session, close the serial console in-browser terminal window.

Standard OpenSSH client

To terminate the serial console session, use the following command to close the SSH connection. This command must be run immediately following a new line.
Troubleshoot your instance using the EC2 Serial Console

By using EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues by connecting to your instance's serial port.

Topics
- Troubleshoot your Linux instance using GRUB (p. 1540)
- Troubleshoot your Linux instance using SysRq (p. 1543)

For information about troubleshooting your Windows instance, see Troubleshoot your Windows instance using the EC2 Serial Console in the Amazon EC2 User Guide for Windows Instances.

Troubleshoot your Linux instance using GRUB

GNU GRUB (short for GNU GRand Unified Bootloader, commonly referred to as GRUB) is the default boot loader for most Linux operating systems. From the GRUB menu, you can select which kernel to boot into, or modify menu entries to change how the kernel will boot. This can be useful when troubleshooting a failing instance.

The GRUB menu is displayed during the boot process. The menu is not accessible via normal SSH, but you can access it via the EC2 Serial Console.

Topics
- Prerequisites (p. 1540)
- Configure GRUB (p. 1540)
- Use GRUB (p. 1542)

Prerequisites

Before you can configure and use GRUB, you must grant access to the serial console. For more information, see Configure access to the EC2 Serial Console (p. 1529).

Configure GRUB

Before you can use GRUB via the serial console, you must configure your instance to use GRUB via the serial console.

To configure GRUB, choose one of the following procedures based on the AMI that was used to launch the instance.

Amazon Linux 2

1. Connect (p. 499) to your instance.
2. Add or change the following options in `/etc/default/grub`:
   - Set `GRUB_TIMEOUT=1`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

   The following is an example of `/etc/default/grub`. You might need to change the configuration based on your system setup.

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0"
   GRUB_TIMEOUT=1
   GRUB_DISABLE_RECOVERY="true"
   GRUB_TERMINAL="console serial"
   GRUB_SERIAL_COMMAND="serial --speed=115200"
   ```

3. Apply the updated configuration by running the following command.

   ```
   [ec2-user ~]# sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

Ubuntu

To configure GRUB on an Ubuntu instance

1. Connect (p. 499) to your instance.
2. Add or change the following options in `/etc/default/grub.d/50-cloudimg-settings.cfg`:
   - Set `GRUB_TIMEOUT=1`.
   - Add `GRUB_TIMEOUT_STYLE=menu`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Remove `GRUB_HIDDEN_TIMEOUT`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

   The following is an example of `/etc/default/grub.d/50-cloudimg-settings.cfg`. You might need to change the configuration based on your system setup.

   ```
   # Cloud Image specific Grub settings for Generic Cloud Images
   # CLOUD_IMG: This file was created/modified by the Cloud Image build process

   # Set the recordfail timeout
   GRUB_RECORDFAIL_TIMEOUT=0

   # Do not wait on grub prompt
   GRUB_TIMEOUT=1
   GRUB_TIMEOUT_STYLE=menu

   # Set the default commandline
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0
   nvme_core.io_timeout=4294967295"

   # Set the grub console type
   GRUB_TERMINAL="console serial"
   GRUB_SERIAL_COMMAND="serial --speed=115200"
   ```

3. Apply the updated configuration by running the following command.
RHEL

To configure GRUB on a RHEL instance

1. Connect (p. 499) to your instance.
2. Add or change the following options in /etc/default/grub:
   - Remove GRUB_TERMINAL_OUTPUT.
   - Add GRUB_TERMINAL="console serial".
   - Add GRUB_SERIAL_COMMAND="serial --speed=115200".

The following is an example of /etc/default/grub. You might need to change the configuration based on your system setup.

   GRUB_TIMEOUT=1
   GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
   GRUB_DEFAULT=saved
   GRUB_DISABLE_SUBMENU=true
   GRUB_CMDLINE_LINUX="console=ttyS0,115200n8 console=tty0 net.ifnames=0 rd.blacklist=nouveau nvme_core.io_timeout=4294967295 crashkernel=auto"
   GRUB_DISABLE_RECOVERY="true"
   GRUB_ENABLE_BLSCFG=true
   GRUB_TERMINAL="console serial"
   GRUB_SERIAL_COMMAND="serial --speed=115200"

3. Apply the updated configuration by running the following command.

   [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg

CentOS

For instances that are launched using a CentOS AMI, GRUB is configured for the serial console by default.

The following is an example of /etc/default/grub. Your configuration might be different based on your system setup.

   GRUB_TIMEOUT=1
   GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
   GRUB_DEFAULT=saved
   GRUB_DISABLE_SUBMENU=true
   GRUB_TERMINAL="serial console"
   GRUB_SERIAL_COMMAND="serial --speed=115200"
   GRUB_DISABLE_RECOVERY="true"
   GRUB_CSBL_CONF=true
   GRUB_CMDLINE_LINUX="console=tty0 crashkernel=auto console=ttyS0,115200"

Use GRUB

After GRUB is configured, connect to the serial console and reboot the instance with the reboot command. During reboot, you see the GRUB menu. Press any key when the GRUB menu appears to stop the boot process, allowing you to interact with the GRUB menu.
Troubleshoot your instance using the EC2 Serial Console

Topics
- Single user mode (p. 1543)
- Emergency mode (p. 1543)

**Single user mode**

Single user mode will boot the kernel at a lower runlevel. For example, it might mount the filesystem but not activate the network, giving you the opportunity to perform the maintenance necessary to fix the instance.

**To boot into single user mode**

1. Connect (p. 1535) to the instance's serial console.
2. Reboot the instance using the following command.
   
   ```
   [ec2-user ~]$ sudo reboot
   ```

3. During reboot, when the GRUB menu appears, press any key to stop the boot process.
4. In the GRUB menu, use the arrow keys to select the kernel to boot into, and press `e` on your keyboard.
5. Use the arrow keys to locate your cursor on the line containing the kernel. The line begins with either `linux` or `linux16` depending on the AMI that was used to launch the instance. For Ubuntu, two lines begin with `linux`, which must both be modified in the next step.
6. At the end of the line, add the word `single`.

   The following is an example for Amazon Linux 2.

   ```
   linux /boot/vmlinuz-4.14.193-149.317.amzn2.aarch64 root=UUID=d33f9c9a-dadd-4499-938d-ebbf42c3e499 ro console=tt0 console=tt0S0,115200n8 net.ifname= biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0 single
   ```

7. Press `Ctrl+X` to boot into single user mode.
8. At the `login` prompt, enter the user name of the password-based user that you set up previously (p. 1534), and then press `Enter`.
9. At the `Password` prompt, enter the password, and then press `Enter`.

**Emergency mode**

Emergency mode is similar to single user mode except that the kernel runs at the lowest runlevel possible.

To boot into emergency mode, follow the steps in Single user mode (p. 1543) in the preceding section, but at step 6 add the word `emergency` instead of `single`.

**Troubleshoot your Linux instance using SysRq**

The System Request (SysRq) key, which is sometimes referred to as "magic SysRq", can be used to directly send the kernel a command, outside of a shell, and the kernel will respond, regardless of what the kernel is doing. For example, if the instance has stopped responding, you can use the SysRq key to tell the kernel to crash or reboot. For more information, see Magic SysRq key in Wikipedia.

Topics
- Prerequisites (p. 1544)
- Configure SysRq (p. 1544)
Prerequisites

Before you can configure and use SysRq, you must grant access to the serial console. For more information, see Configure access to the EC2 Serial Console (p. 1529).

Configure SysRq

To configure SysRq, you enable the SysRq commands for the current boot cycle. To make the configuration persistent, you can also enable the SysRq commands for subsequent boots.

To enable all SysRq commands for the current boot cycle

1. Connect (p. 499) to your instance.
2. Run the following command.

```
[ec2-user ~]$ sudo sysctl -w kernel.sysrq=1
```

Note
This setting will clear on the next reboot.

To enable all SysRq commands for subsequent boots

1. Create the file `/etc/sysctl.d/99-sysrq.conf` and open it in your favorite editor.

```
[ec2-user ~]$ sudo vi /etc/sysctl.d/99-sysrq.conf
```

2. Add the following line.

```
kernalsysrq=1
```

3. Reboot the instance to apply the changes.

```
[ec2-user ~]$ sudo reboot
```

4. At the login prompt, enter the user name of the password-based user that you set up previously (p. 1534), and then press Enter.
5. At the Password prompt, enter the password, and then press Enter.

Use SysRq

You can use SysRq commands in the EC2 Serial Console browser-based client or in an SSH client. The command to send a break request is different for each client.

To use SysRq, choose one of the following procedures based on the client that you are using.

Browser-based client

**To use SysRq in the serial console browser-based client**

1. Connect (p. 1535) to the instance's serial console.
2. To send a break request, press `CTRL+0` (zero). If your keyboard supports it, you can also send a break request using the Pause or Break key.
Send a diagnostic interrupt

Warning
Diagnostic interrupts are intended for use by advanced users. Incorrect usage could negatively impact your instance. Sending a diagnostic interrupt to an instance could trigger an instance to crash and reboot, which could lead to the loss of data.

You can send a diagnostic interrupt to an unreachable or unresponsive Linux instance to manually trigger a kernel panic.
Linux operating systems typically crash and reboot when a kernel panic occurs. The specific behavior of the operating system depends on its configuration. A kernel panic can also be used to cause the instance's operating system kernel to perform tasks, such as generating a crash dump file. You can then use the information in the crash dump file to conduct root cause analysis and debug the instance.

The crash dump data is generated locally by the operating system on the instance itself.

Before sending a diagnostic interrupt to your instance, we recommend that you consult the documentation for your operating system and then make the necessary configuration changes.

Contents
- Supported instance types (p. 1546)
- Prerequisites (p. 1546)
- Send a diagnostic interrupt (p. 1548)

Supported instance types

Diagnostic interrupt is supported on all Nitro-based instance types, except A1. For more information, see Instances built on the Nitro System (p. 199).

Prerequisites

Before using a diagnostic interrupt, you must configure your instance's operating system. This ensures that it performs the actions that you need when a kernel panic occurs.

To configure Amazon Linux 2 to generate a crash dump when a kernel panic occurs

1. Connect to your instance.
2. Install `kexec` and `kdump`.

```
[ec2-user ~]$ sudo yum install kexec-tools -y
```
3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance. Open the `/etc/default/grub` file using your preferred text editor, locate the line that starts with `GRUB_CMDLINE_LINUX_DEFAULT`, and then add the `crashkernel` parameter in the following format: `crashkernel=memory_to_reserve`. For example, to reserve 160MB, modify the `grub` file as follows:

```
GRUB_CMDLINE_LINUX_DEFAULT="crashkernel=160M console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0"
GRUB_TIMEOUT=0
GRUB_DISABLE_RECOVERY="true"
```
4. Save the changes and close the `grub` file.
5. Rebuild the GRUB2 configuration file.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```
6. On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.
7. Reboot and reconnect to your instance.
8. Verify that the kernel has been booted with the correct crashkernel parameter.

```
$ grep crashkernel /proc/cmdline
```

The following example output indicates successful configuration.

```
BOOT_IMAGE=/boot/vmlinuz-4.14.128-112.105.amzn2.x86_64 root=UUID=a1e1011e-e38f-408e-878b-fed395b47ad6 ro crashkernel=160M console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0
```

9. Verify that the **kdump** service is running.

```
[ec2-user ~]$ systemctl status kdump.service
```

The following example output shows the result if the **kdump** service is running.

```
kdump.service - Crash recovery kernel arming
   Loaded: loaded (/usr/lib/systemd/system/kdump.service; enabled; vendor preset: enabled)
   Active: active (exited) since Fri 2019-05-24 23:29:13 UTC; 22s ago
   Process: 2503 ExecStart=/usr/bin/kdumpctl start (code=exited, status=0/SUCCESS)
   Main PID: 2503 (code=exited, status=0/SUCCESS)
```

**Note**

By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

**To configure Amazon Linux to generate a crash dump when a kernel panic occurs**

1. Connect to your instance.
2. Install **kexec** and **kdump**.

```
[ec2-user ~]$ sudo yum install kexec-tools -y
```

3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance.

```
# sudo grubby --args="crashkernel=memory_to_reserve" --update-kernel=ALL
```

For example, to reserve 160MB for the crash kernel, use the following command.

```
# sudo grubby --args="crashkernel=160M" --update-kernel=ALL
```

4. On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an *unknown non-maskable interrupt* (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.

```
kernel.unknown_nmi_panic=1
```
5. Reboot and reconnect to your instance.
6. Verify that the kernel has been booted with the correct `crashkernel` parameter.

```
# grep crashkernel /proc/cmdline
```

The following example output indicates successful configuration.

```
root=LABEL=/ console=tty1 console=ttyS0 selinux=0 nvme_core.io_timeout=4294967295
LANG=en_US.UTF-8 KEYTABLE=us crashkernel=160M
```

7. Verify that the `kdump` service is running.

```
[ec2-user @ ~] $ sudo service kdump status
```

If the service is running, the command returns the `Kdump is operational` response.

**Note**
By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

**To configure SUSE Linux Enterprise, Ubuntu, or Red Hat Enterprise Linux**

See the following websites:

- SUSE Linux Enterprise
- Ubuntu
- Red Hat Enterprise Linux (RHEL)

**Note**
On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Add the following to your configuration file.

```
kernal.unknown_nmi_panic=1
```

---

**Send a diagnostic interrupt**

After you have completed the necessary configuration changes, you can send a diagnostic interrupt to your instance using the AWS CLI or Amazon EC2 API.

**To send a diagnostic interrupt to your instance (AWS CLI)**

Use the `send-diagnostic-interrupt` command and specify the instance ID.

```
aws ec2 send-diagnostic-interrupt --instance-id i-1234567890abcdef0
```
## Document history

The following table describes important additions to the Amazon EC2 documentation starting in 2019. We also update the documentation frequently to address the feedback that you send us.

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hibernation support for RHEL,</td>
<td>Hibernate your newly-launched instances that were launched from RHEL, Fedora, and CentOS AMIs.</td>
<td>September 9, 2021</td>
</tr>
<tr>
<td>Fedora, and CentOS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>New Local Zones added</td>
<td>Add Local Zones in Chicago, Minneapolis, and Kansas City.</td>
<td>September 8, 2021</td>
</tr>
<tr>
<td>Amazon EC2 Global View</td>
<td>Amazon EC2 Global View enables you to view VPCs, subnets, instances, security groups, and volumes across multiple AWS Regions in a single console.</td>
<td>September 1, 2021</td>
</tr>
<tr>
<td>AMI deprecation support for</td>
<td>Amazon Data Lifecycle Manager EBS-backed AMI policies can deprecate AMIs. The AWSDataLifecycleManagerServiceRoleForAMIManagement AWS managed policy has been updated to support this feature.</td>
<td>August 23, 2021</td>
</tr>
<tr>
<td>Amazon Data Lifecycle Manager</td>
<td></td>
<td></td>
</tr>

</tr>
<tr>
<td>Boot modes</td>
<td>Amazon EC2 now supports UEFI boot on selected AMD- and Intel-based EC2 instances.</td>
<td>March 22, 2021</td>
</tr>
<tr>
<td>X2gd instances (p. 1549)</td>
<td>New memory optimized instances featuring an AWS Graviton2 processor based on 64-bit Arm architecture.</td>
<td>March 16, 2021</td>
</tr>
<tr>
<td>Amazon EBS local snapshots on Outposts</td>
<td>You can now use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally in Amazon S3 on the Outpost itself.</td>
<td>February 4, 2021</td>
</tr>
<tr>
<td>Create a reverse DNS record</td>
<td>You can now set up reverse DNS lookup for your Elastic IP addresses.</td>
<td>February 3, 2021</td>
</tr>
<tr>
<td>Multi-Attach support for io2 volumes</td>
<td>You can now enable Provisioned IOPS SSD (io2) volumes for Amazon EBS Multi-Attach.</td>
<td>December 18, 2020</td>
</tr>
<tr>
<td>C6gn instances (p. 1549)</td>
<td>New computed optimized instances featuring an AWS Graviton2 processor based on 64-bit Arm architecture. These instances can utilize up to 100 Gbps of network bandwidth.</td>
<td>December 18, 2020</td>
</tr>
<tr>
<td>Amazon Data Lifecycle Manager</td>
<td>Use Amazon Data Lifecycle Manager to automate the process of sharing snapshots and copying them across AWS accounts.</td>
<td>December 17, 2020</td>
</tr>
<tr>
<td>G4ad instances (p. 1549)</td>
<td>New instances powered by AMD Radeon Pro V520 GPUs and AMD 2nd Generation EPYC processors.</td>
<td>December 9, 2020</td>
</tr>
<tr>
<td>Tag AMIs and snapshots on AMI creation</td>
<td>When you create an AMI, you can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.</td>
<td>December 4, 2020</td>
</tr>
<tr>
<td>io2 Block Express preview</td>
<td>You can opt in to the io2 Block Express volumes preview. io2 Block Express volumes provide sub-millisecond latency, and support higher IOPS, higher throughput, and larger capacity than io2 volumes.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>gp3 volumes (p. 1549)</td>
<td>A new Amazon EBS General Purpose SSD volume type. You can specify provisioned IOPS and throughput when you create or modify the volume.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>

<td>Configure Spot Fleet or EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation.</td>
<td>November 4, 2020</td>
</tr>
<tr>
<td>P4d instances (p. 1549)</td>
<td>New accelerated computing instances that provide a high-performance platform for machine learning and HPC workloads.</td>
<td>November 2, 2020</td>
</tr>
<tr>
<td>Hibernation support for I3, M5ad, and R5ad</td>
<td>Hibernate your newly-launched instances running on I3, M5ad, and R5ad instance types.</td>
<td>October 21, 2020</td>
</tr>
<tr>
<td>Spot Instance vCPU limits</td>
<td>Spot Instance limits are now managed in terms of the number of vCPUs that your running Spot Instances are either using or will use pending the fulfillment of open requests.</td>
<td>October 1, 2020</td>
</tr>
<tr>
<td>Capacity Reservations in Local Zones</td>
<td>Capacity Reservations can now be created and used in Local Zones.</td>
<td>September 30, 2020</td>
</tr>
<tr>
<td>Amazon Data Lifecycle Manager</td>
<td>Amazon Data Lifecycle Manager policies can be configured with up to four schedules.</td>
<td>September 17, 2020</td>
</tr>
<tr>
<td>T4g instances (p. 1549)</td>
<td>New general purpose instances powered by AWS Graviton2 processors, which are based on 64-bit Arm Neoverse cores and custom silicon designed by AWS for optimized performance and cost.</td>
<td>September 14, 2020</td>
</tr>
<tr>
<td>Hibernation support for M5a and R5a</td>
<td>Hibernate your newly-launched instances running on M5a and R5a instance types.</td>
<td>August 28, 2020</td>
</tr>
<tr>
<td>Provisioned IOPS SSD (io2) volumes for Amazon EBS</td>
<td>Provisioned IOPS SSD (io2) volumes are designed to provide 99.999 percent volume durability with an AFR no higher than 0.001 percent.</td>
<td>August 24, 2020</td>
</tr>
<tr>
<td>Instance metadata provides instance location and placement information</td>
<td>New instance metadata fields under the <code>placement</code> category: Region, placement group name, partition number, host ID, and Availability Zone ID.</td>
<td>August 24, 2020</td>
</tr>
<tr>
<td>C5ad instances (p. 1549)</td>
<td>New compute optimized instances featuring second-generation AMD EYPC processors.</td>

<tr>
<td>Amazon Linux 2 Kernel Live</td>
<td>Kernel Live Patching for Amazon Linux 2 enables you to apply security vulnerability and critical bug patches to a running Linux kernel, without reboots or disruptions to running applications.</td>
<td>April 28, 2020</td>
</tr>
<tr>
<td>Patching</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Amazon EBS Multi-Attach</td>
<td>You can now attach a single Provisioned IOPS SSD (io1) volume to up to 16 Nitro-based instances that are in the same Availability Zone.</td>
<td>February 14, 2020</td>
</tr>
<tr>
<td>Stop and start a Spot Instance</td>
<td>Stop your Spot Instances backed by Amazon EBS and start them at will, instead of relying on the stop interruption behavior.</td>
<td>January 13, 2020</td>
</tr>
<tr>
<td>Resource tagging (p. 1549)</td>
<td>You can tag egress-only internet gateways, local gateways, local gateway route tables, local gateway virtual interfaces, local gateway virtual interface groups, local gateway route table VPC associations, and local gateway route table virtual interface group associations.</td>
<td>January 10, 2020</td>
</tr>
<tr>
<td>Connect to your instance using Session Manager</td>
<td>You can start a Session Manager session with an instance from the Amazon EC2 console.</td>
<td>December 18, 2019</td>
</tr>
<tr>
<td>Inf1 instances (p. 1549)</td>
<td>New instances featuring AWS Inferentia, a machine learning inference chip designed to deliver high performance at a low cost.</td>
<td>December 3, 2019</td>
</tr>
<tr>
<td>Dedicated Hosts and host resource groups</td>
<td>Dedicated Hosts can now be used with host resource groups.</td>
<td>December 2, 2019</td>
</tr>
<tr>
<td>Dedicated Host sharing</td>
<td>You can now share your Dedicated Hosts across AWS accounts.</td>
<td>December 2, 2019</td>
</tr>
<tr>
<td>Default credit specification at the account level</td>
<td>You can set the default credit specification per burstable performance instance family at the account level per AWS Region.</td>
<td>November 25, 2019</td>
</tr>
<tr>
<td>Instance type discovery</td>
<td>You can find an instance type that meets your needs.</td>
<td>November 22, 2019</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>-----------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>Dedicated Hosts (p. 1549)</td>
<td>You can now configure a Dedicated Host to support multiple instance types in an instance family.</td>
<td>November 21, 2019</td>
</tr>
<tr>
<td>Amazon EBS fast snapshot restores</td>
<td>You can enable fast snapshot restores on an EBS snapshot to ensure that EBS volumes created from the snapshot are fully-initialized at creation and instantly deliver all of their provisioned performance.</td>
<td>November 20, 2019</td>
</tr>
<tr>
<td>Instance Metadata Service Version 2</td>
<td>You can use Instance Metadata Service Version 2, which is a session-oriented method for requesting instance metadata.</td>
<td>November 19, 2019</td>
</tr>
<tr>
<td>Elastic Fabric Adapter (p. 1549)</td>
<td>Elastic Fabric Adapters can now be used with Intel MPI 2019 Update 6.</td>
<td>November 15, 2019</td>

<tr>
<td>Resource tagging (p. 1549)</td>
<td>You can assign custom tags to your Dedicated Host Reservations to categorize them in different ways.</td>
<td>March 14, 2019</td>
</tr>
<tr>
<td>Bare metal instances for M5, M5d, R5, R5d, and z1d (p. 1549)</td>
<td>New instances that provide your applications with direct access to the physical resources of the host server.</td>
<td>February 13, 2019</td>
</tr>
</tbody>
</table>
## History for previous years

The following table describes important additions to the Amazon EC2 documentation in 2018 and earlier years.

<table>
<thead>
<tr>
<th>Feature</th>
<th>API version</th>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition placement groups</td>
<td>2016-11-15</td>
<td>Partition placement groups spread instances across logical partitions, ensuring that instances in one partition do not share underlying hardware with instances in other partitions. For more information, see Partition placement groups (p. 1020).</td>
<td>20 December 2018</td>
</tr>
<tr>
<td>p3dn.24xlarge instances</td>
<td>2016-11-15</td>
<td>New p3dn.24xlarge instances provide 100 Gbps of network bandwidth.</td>
<td>7 December 2018</td>
</tr>
<tr>
<td>Hibernate EC2 Linux instances</td>
<td>2016-11-15</td>
<td>You can hibernate a Linux instance if it's enabled for hibernation and it meets the hibernation prerequisites. For more information, see Hibernate your On-Demand or Reserved Linux instance (p. 528).</td>
<td>28 November 2018</td>
</tr>
<tr>
<td>Amazon Elastic Inference Accelerators</td>
<td>2016-11-15</td>
<td>You can attach an Amazon EI accelerator to your instances to add GPU-powered acceleration to reduce the cost of running deep learning inference. For more information, see Amazon Elastic Inference (p. 654).</td>
<td>28 November 2018</td>
</tr>
<tr>
<td>Instances featuring 100 Gbps of network bandwidth</td>
<td>2016-11-15</td>
<td>New C5n instances can utilize up to 100 Gbps of network bandwidth.</td>
<td>26 November 2018</td>
</tr>
<tr>
<td>Instances featuring Arm-based Processors</td>
<td>2016-11-15</td>
<td>New A1 instances deliver significant cost savings and are ideally suited for scale-out and Arm-based workloads.</td>
<td>26 November 2018</td>
</tr>
<tr>
<td>Spot console recommends a fleet of instances</td>
<td>2016-11-15</td>
<td>The Spot console recommends a fleet of instances based on Spot best practice (instance diversification) to meet the minimum hardware specifications (vCPUs, memory, and storage) for your application need. For more information, see Create a Spot Fleet request (p. 717).</td>
<td>20 November 2018</td>
</tr>
<tr>
<td>New EC2 Fleet request type: instant</td>
<td>2016-11-15</td>
<td>EC2 Fleet now supports a new request type, <strong>instant</strong>, that you can use to synchronously provision capacity across instance types and purchase models. The <strong>instant</strong> request returns the launched instances in the API response, and takes no further action, enabling you to control if and when instances are launched. For more information, see EC2 Fleet request types (p. 658).</td>
<td>14 November 2018</td>
</tr>
<tr>
<td>Instances featuring AMD EYPC processors</td>
<td>2016-11-15</td>
<td>New general purpose (M5a) and memory optimized instances (R5a) offer lower-priced options for microservices, small to medium</td>
<td>6 November 2018</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>databases, virtual desktops, development and test environments, business applications, and more.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Spot savings information</td>
<td>2016-11-15</td>
<td>You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. For more information, see Savings from purchasing Spot Instances (p. 375).</td>
<td></td>
</tr>
<tr>
<td>Console support for optimizing CPU options</td>
<td>2016-11-15</td>
<td>When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs using the Amazon EC2 console. For more information, see Optimize CPU options (p. 575).</td>
<td></td>
</tr>
<tr>
<td>Console support for creating a launch template from an instance</td>
<td>2016-11-15</td>
<td>You can create a launch template using an instance as the basis for a new launch template using the Amazon EC2 console. For more information, see Create a launch template (p. 485).</td>
<td></td>
</tr>
<tr>
<td>On-Demand Capacity Reservations</td>
<td>2016-11-15</td>
<td>You can reserve capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This allows you to create and manage capacity reservations independently from the billing discounts offered by Reserved Instances (RI). For more information, see On-Demand Capacity Reservations (p. 451).</td>
<td></td>
</tr>
<tr>
<td>Bring Your Own IP Addresses (BYOIP)</td>
<td>2016-11-15</td>
<td>You can bring part or all of your public IPv4 address range from your on-premises network to your AWS account. After you bring the address range to AWS, it appears in your account as an address pool. You can create an Elastic IP address from your address pool and use it with your AWS resources. For more information, see Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 896).</td>
<td></td>
</tr>
<tr>
<td>g3s.xlarge instances</td>
<td>2016-11-15</td>
<td>Expands the range of the accelerated-computing G3 instance family with the introduction of g3s.xlarge instances.</td>
<td></td>
</tr>
<tr>
<td>Dedicated Host tag on create and console support</td>
<td>2016-11-15</td>
<td>You can tag your Dedicated Hosts on creation, and you can manage your Dedicated Host tags using the Amazon EC2 console. For more information, see Allocate Dedicated Hosts (p. 419).</td>
<td></td>
</tr>
<tr>
<td>High memory instances</td>
<td>2016-11-15</td>
<td>These instances are purpose-built to run large in-memory databases. They offer bare metal performance with direct access to host hardware. For more information, see Memory optimized instances (p. 267).</td>
<td></td>
</tr>
<tr>
<td>f1.4xlarge instances</td>
<td>2016-11-15</td>
<td>Expands the range of the accelerated-computing F1 instance family with the introduction of f1.4xlarge instances.</td>
<td></td>

<tr>
<td>Console support for scheduled scaling for Spot Fleet</td>
<td>2016-11-15</td>
<td>Increase or decrease the current capacity of the fleet based on the date and time. For more information, see Scale Spot Fleet using scheduled scaling (p. 736).</td>
<td>20 September 2018</td>
</tr>
<tr>
<td>T3 instances</td>
<td>2016-11-15</td>
<td>T3 instances are burstable general-purpose instance type that provide a baseline level of CPU performance with the ability to burst CPU usage at any time for as long as required. For more information, see Burstable performance instances (p. 216).</td>
<td>21 August 2018</td>
</tr>
<tr>
<td>Allocation strategies for EC2 Fleets</td>
<td>2016-11-15</td>
<td>You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Allocation strategies for Spot Instances (p. 677).</td>
<td>26 July 2018</td>
</tr>
<tr>
<td>Allocation strategies for Spot Fleets</td>
<td>2016-11-15</td>
<td>You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Allocation strategy for Spot Instances (p. 704).</td>
<td>26 July 2018</td>
</tr>
<tr>
<td>R5 and R5d instances</td>
<td>2016-11-15</td>
<td>R5 and R5d instances are ideally suited for high-performance databases, distributed in-memory caches, and in-memory analytics. R5d instances come with NVMe instance store volumes. For more information, see Memory optimized instances (p. 267).</td>
<td>25 July 2018</td>
</tr>
<tr>
<td>z1d instances</td>
<td>2016-11-15</td>
<td>These instances are designed for applications that require high per-core performance with a large amount of memory, such as electronic design automation (EDA) and relational databases. These instances come with NVME instance store volumes. For more information, see Memory optimized instances (p. 267).</td>
<td>25 July 2018</td>
</tr>
<tr>
<td>Automate snapshot lifecycle</td>
<td>2016-11-15</td>
<td>You can use Amazon Data Lifecycle Manager to automate creation and deletion of snapshots for your EBS volumes. For more information, see Amazon Data Lifecycle Manager (p. 1280).</td>
<td>12 July 2018</td>
</tr>
<tr>
<td>Launch template CPU options</td>
<td>2016-11-15</td>
<td>When you create a launch template using the command line tools, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Create a launch template (p. 485).</td>
<td>11 July 2018</td>
</tr>
<tr>
<td>Tag Dedicated Hosts</td>

<td>9 May 2018</td>
</tr>
<tr>
<td>Optimize CPU options</td>
<td>2016-11-15</td>
<td>When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Optimize CPU options (p. 575).</td>
<td>8 May 2018</td>
</tr>
<tr>
<td>EC2 Fleet</td>
<td>2016-11-15</td>
<td>You can use EC2 Fleet to launch a group of instances across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchasing models. For more information, see EC2 Fleet (p. 656).</td>
<td>2 May 2018</td>
</tr>
<tr>
<td>On-Demand Instances in Spot Fleets</td>
<td>2016-11-15</td>
<td>You can include a request for On-Demand capacity in your Spot Fleet request to ensure that you always have instance capacity. For more information, see Spot Fleet (p. 703).</td>
<td>2 May 2018</td>
</tr>
<tr>
<td>Tag EBS snapshots on creation</td>
<td>2016-11-15</td>
<td>You can apply tags to snapshots during creation. For more information, see Create Amazon EBS snapshots (p. 1231).</td>
<td>2 April 2018</td>
</tr>
<tr>
<td>Change placement groups</td>
<td>2016-11-15</td>
<td>You can move an instance in or out of a placement group, or change its placement group. For more information, see Change the placement group for an instance (p. 1028).</td>
<td>1 March 2018</td>
</tr>
<tr>
<td>Longer resource IDs</td>
<td>2016-11-15</td>
<td>You can enable the longer ID format for more resource types. For more information, see Resource IDs (p. 1453).</td>
<td>9 February 2018</td>
</tr>
<tr>
<td>Network performance improvements</td>
<td>2016-11-15</td>
<td>Instances outside of a cluster placement group can now benefit from increased bandwidth when sending or receiving network traffic between other instances or Amazon S3. For more information, see Networking and storage features (p. 200).</td>
<td>24 January 2018</td>
</tr>
<tr>
<td>Tag Elastic IP addresses</td>
<td>2016-11-15</td>
<td>You can tag your Elastic IP addresses. For more information, see Tag an Elastic IP address (p. 917).</td>
<td>21 December 2017</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td>2016-11-15</td>
<td>Amazon Linux 2 is a new version of Amazon Linux. It provides a high performance, stable, and secure foundation for your applications. For more information, see Amazon Linux (p. 164).</td>
<td>13 December 2017</td>
</tr>
<tr>

<td>Amazon Time Sync Service</td>
<td>2016-11-15</td>
<td>You can use the Amazon Time Sync Service to keep accurate time on your instance. For more information, see [Set the time for your Linux instance](p. 570).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>T2 Unlimited</td>
<td>2016-11-15</td>
<td>T2 Unlimited instances can burst above the baseline for as long as required. For more information, see [Burstable performance instances](p. 216).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>Launch templates</td>
<td>2016-11-15</td>
<td>A launch template can contain all or some of the parameters to launch an instance, so that you don’t have to specify them every time you launch an instance. For more information, see [Launch an instance from a launch template](p. 483).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>Spread placement</td>
<td>2016-11-15</td>
<td>Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. For more information, see [Spread placement groups](p. 1020).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>H1 instances</td>
<td>2016-11-15</td>
<td>H1 instances are designed for high-performance big data workloads. For more information, see [Storage optimized instances](p. 281).</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>M5 instances</td>
<td>2016-11-15</td>
<td>M5 instances are general purpose compute instances. They provide a balance of compute, memory, storage, and network resources.</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>Spot Instance hibernation</td>
<td>2016-11-15</td>
<td>The Spot service can hibernate Spot Instances in the event of an interruption. For more information, see [Hibernate interrupted Spot Instances](p. 404).</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>Spot Fleet target tracking</td>
<td>2016-11-15</td>
<td>You can set up target tracking scaling policies for your Spot Fleet. For more information, see [Scale Spot Fleet using a target tracking policy](p. 734).</td>
<td>17 November 2017</td>
</tr>
<tr>
<td>Spot Fleet integrates with Elastic Load Balancing</td>
<td>2016-11-15</td>
<td>You can attach one or more load balancers to a Spot Fleet.</td>
<td>10 November 2017</td>
</tr>
<tr>
<td>X1e instances</td>
<td>2016-11-15</td>
<td>X1e instances are ideally suited for high-performance databases, in-memory databases, and other memory-intensive enterprise applications. For more information, see [Memory optimized instances](p. 267).</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>C5 instances</td>
<td>2016-11-15</td>
<td>C5 instances are designed for compute-heavy applications. For more information, see [Compute optimized instances](p. 258).</td>
<td>6 November 2017</td>

<tr>
<td>Merge and split Convertible Reserved Instances</td>
<td>2016-11-15</td>
<td>You can exchange (merge) two or more Convertible Reserved Instances for a new Convertible Reserved Instance. You can also use the modification process to split a Convertible Reserved Instance into smaller reservations. For more information, see Exchange Convertible Reserved Instances (p. 361).</td>
<td>6 November 2017</td>
</tr>
<tr>
<td>P3 instances</td>
<td>2016-11-15</td>
<td>P3 instances are compute-optimized GPU instances. For more information, see Linux accelerated computing instances (p. 289).</td>
<td>25 October 2017</td>
</tr>
<tr>
<td>Modify VPC tenancy</td>
<td>2016-11-15</td>
<td>You can change the instance tenancy attribute of a VPC from dedicated to default. For more information, see Change the tenancy of a VPC (p. 450).</td>
<td>16 October 2017</td>
</tr>
<tr>
<td>Per second billing</td>
<td>2016-11-15</td>
<td>Amazon EC2 charges for Linux-based usage by the second, with a one-minute minimum charge.</td>
<td>2 October 2017</td>
</tr>
<tr>
<td>Stop on interruption</td>
<td>2016-11-15</td>
<td>You can specify whether Amazon EC2 should stop or terminate Spot Instances when they are interrupted. For more information, see Interruption behaviors (p. 403).</td>
<td>18 September 2017</td>
</tr>
<tr>
<td>Tag NAT gateways</td>
<td>2016-11-15</td>
<td>You can tag your NAT gateway. For more information, see Tag your resources (p. 1463).</td>
<td>7 September 2017</td>
</tr>
<tr>
<td>Security group rule descriptions</td>
<td>2016-11-15</td>
<td>You can add descriptions to your security group rules. For more information, see Security group rules (p. 1153).</td>
<td>31 August 2017</td>
</tr>
<tr>
<td>Recover Elastic IP addresses</td>
<td>2016-11-15</td>
<td>If you release an Elastic IP address for use in a VPC, you might be able to recover it. For more information, see Recover an Elastic IP address (p. 920).</td>
<td>11 August 2017</td>
</tr>
<tr>
<td>Tag Spot Fleet instances</td>
<td>2016-11-15</td>
<td>You can configure your Spot Fleet to automatically tag the instances that it launches.</td>
<td>24 July 2017</td>
</tr>
<tr>
<td>G3 instances</td>
<td>2016-11-15</td>
<td>G3 instances provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. G3 instances also provide NVIDIA GRID Virtual Workstation features, supporting 4 monitors with resolutions up to 4096x2160. For more information, see Linux accelerated computing instances (p. 289).</td>
<td>13 July 2017</td>
</tr>
<tr>
<td>F1 instances</td>
<td>2016-11-15</td>

</tr>
<tr>
<td>Perform modifications on attached EBS volumes</td>
<td>2016-11-15</td>
<td>With most EBS volumes attached to most EC2 instances, you can modify volume size, type, and IOPS without detaching the volume or stopping the instance. For more information, see Amazon EBS Elastic Volumes (p. 1323).</td>
<td>13 February 2017</td>
</tr>
<tr>
<td>Attach an IAM role</td>
<td>2016-11-15</td>
<td>You can attach, detach, or replace an IAM role for an existing instance. For more information, see IAM roles for Amazon EC2 (p. 1125).</td>
<td>9 February 2017</td>
</tr>
<tr>
<td>Dedicated Spot Instances</td>
<td>2016-11-15</td>
<td>You can run Spot Instances on single-tenant hardware in a virtual private cloud (VPC). For more information, see Specify a tenancy for your Spot Instances (p. 378).</td>
<td>19 January 2017</td>
</tr>
<tr>
<td>IPv6 support</td>
<td>2016-11-15</td>
<td>You can associate an IPv6 CIDR with your VPC and subnets, and assign IPv6 addresses to instances in your VPC. For more information, see Amazon EC2 instance IP addressing (p. 880).</td>
<td>1 December 2016</td>
</tr>
<tr>
<td>R4 instances</td>
<td>2016-09-15</td>
<td>R4 instances are memory optimized instances. R4 instances are well-suited for memory-intensive, latency-sensitive workloads such as business intelligence (BI), data mining and analysis, in-memory databases, distributed web scale in-memory caching, and applications performance real-time processing of unstructured big data. For more information, see Memory optimized instances (p. 267)</td>
<td>30 November 2016</td>
</tr>
<tr>
<td>New t2.xlarge and t2.2xlarge instance types</td>
<td>2016-09-15</td>
<td>T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 216).</td>

</tr>
<tr>
<td>Automatic recovery for EC2 instances</td>
<td></td>
<td>You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. A recovered instance is identical to the original instance, including the instance ID, IP addresses, and all instance metadata. For more information, see Recover your instance (p. 554).</td>
<td>12 January 2015</td>
</tr>
<tr>
<td>C4 instances</td>
<td></td>
<td>Next-generation compute-optimized instances that provide very high CPU performance at an economical price. C4 instances are based on custom 2.9 GHz Intel® Xeon® E5-2666 v3 (Haswell) processors. With additional Turbo boost, the processor clock speed in C4 instances can reach as high as 3.5Ghz with 1 or 2 core turbo. Expanding on the capabilities of C3 compute-optimized instances, C4 instances offer customers the highest processor performance among EC2 instances. These instances are ideally suited for high-traffic web applications, ad serving, batch processing, video encoding, distributed analytics, high-energy physics, genome analysis, and computational fluid dynamics. For more information, see Compute optimized instances (p. 258).</td>
<td>11 January 2015</td>
</tr>
<tr>
<td>ClassicLink</td>
<td>2014-10-01</td>
<td>ClassicLink enables you to link your EC2-Classic instance to a VPC in your account. You can associate VPC security groups with the EC2-Classic instance, enabling communication between your EC2-Classic instance and instances in your VPC using private IP addresses. For more information, see ClassicLink (p. 1041).</td>

<td>19 June 2014</td>
</tr>
<tr>
<td>Amazon EBS General Purpose SSD Volumes</td>
<td>2014-05-01</td>
<td>General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies, the ability to burst to 3,000 IOPS for extended periods of time, and a base performance of 3 IOPS/GiB. General Purpose SSD volumes can range in size from 1 GiB to 1 TiB. For more information, see <a href="#">General Purpose SSD volumes (gp2)</a> (p. 1182).</td>
<td>16 June 2014</td>
</tr>
<tr>
<td>Amazon EBS encryption</td>
<td>2014-05-01</td>
<td>Amazon EBS encryption offers seamless encryption of EBS data volumes and snapshots, eliminating the need to build and maintain a secure key management infrastructure. EBS encryption enables data at rest security by encrypting your data using AWS managed keys. The encryption occurs on the servers that host EC2 instances, providing encryption of data as it moves between EC2 instances and EBS storage. For more information, see <a href="#">Amazon EBS encryption</a> (p. 1335).</td>

</table>
| IAM roles on Amazon EC2 instances | 2012-06-01 | IAM roles for Amazon EC2 provide:  
• AWS access keys for applications running on Amazon EC2 instances.  
• Automatic rotation of the AWS access keys on the Amazon EC2 instance.  
• Granular permissions for applications running on Amazon EC2 instances that make requests to your AWS services. | 11 June 2012 |
| Spot Instance features that make it easier to get started and handle the potential of interruption. | | You can now manage your Spot Instances as follows:  
• Specify the amount you are willing to pay for Spot Instances using Auto Scaling launch configurations, and set up a schedule for specifying the amount you are willing to pay for Spot Instances. For more information, see Launching Spot Instances in Your Auto Scaling Group in the Amazon EC2 Auto Scaling User Guide.  
• Get notifications when instances are launched or terminated.  
• Use AWS CloudFormation templates to launch Spot Instances in a stack with AWS resources. | 7 June 2012 |
| EC2 instance export and timestamps for status checks for Amazon EC2 | 2012-05-01 | Added support for timestamps on instance status and system status to indicate the date and time that a status check failed. | 25 May 2012 |
| EC2 instance export, and timestamps in instance and system status checks for Amazon VPC | 2012-05-01 | Added support for EC2 instance export to Citrix Xen, Microsoft Hyper-V, and VMware vSphere.  
Added support for timestamps in instance and system status checks. | 25 May 2012 |
<p>| Cluster Compute Eight Extra Large instances | 2012-04-01 | Added support for cc2.8xlarge instances in a VPC. | 26 April 2012 |
| AWS Marketplace AMIs | 2012-04-01 | Added support for AWS Marketplace AMIs. | 19 April 2012 |
| New Linux AMI release | | Amazon Linux AMI 2012.03 is released. | 28 March 2012 |
| New AKI version | | We've released AKI version 1.03 and AKIs for the AWS GovCloud (US) region. | 28 March 2012 |
| Medium instances, support for 64-bit on all AMIs, and a Java-based SSH Client | 2011-12-15 | Added support for a new instance type and 64-bit information. Added procedures for using the Java-based SSH client to connect to Linux instances. | 7 March 2012 |</p>
