    --metadata-options "HttpEndpoint=enabled,HttpProtocolIpv6=enabled"
```

PowerShell

To enable the IMDS IPv6 endpoint at instance launch

The following New-EC2Instance Cmdlet example launches a `c6i.large` instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, specify `MetadataOptions_HttpProtocolIpv6` as `enabled`. When you specify a value for MetadataOptions_HttpProtocolIpv6, you must also set MetadataOptions_HttpEndpoint to enabled.

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType c6i.large `
    -MetadataOptions_HttpEndpoint enabled `
    -MetadataOptions_HttpProtocolIpv6 enabled
```

Turn off access to instance metadata

You can turn off access to the instance metadata by disabling the IMDS when you launch an instance. You can turn on access later by re-enabling the IMDS. For more information, see Turn on access to instance metadata.

> **Important**
>
> You can choose to disable the IMDS at launch or after launch. If you disable the IMDS *at launch*, the following might not work:
>
> - You might not have SSH access to your instance. The public-keys/0/openssh-key, which is your instance's public SSH key, will not be accessible because the key is normally provided and accessed from EC2 instance metadata.
> - EC2 user data will not be available and will not run at instance start. EC2 user data is hosted on the IMDS. If you disable the IMDS, you effectively turn off access to user data.
>
> To access this functionality, you can re-enable the IMDS after launch.

Console

To turn off access to instance metadata at launch

- Launch the instance in the Amazon EC2 console with the following specified under **Advanced details**:
  - For **Metadata accessible**, choose **Disabled**.

For more information, see Advanced details.

AWS CLI

To turn off access to instance metadata at launch at launch

Launch the instance with `--metadata-options` set to `HttpEndpoint=disabled`.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type c6i.large \
    ...
    --metadata-options "HttpEndpoint=disabled"
```

PowerShell

To turn off access to instance metadata at launch at launch

The following New-EC2Instance Cmdlet example launches an instance with `MetadataOptions_HttpEndpoint` set to `disabled`.

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType c6i.large `
    -MetadataOptions_HttpEndpoint disabled
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the AWS::EC2::LaunchTemplate MetadataOptions property in the *AWS CloudFormation User Guide*.

Allow access to tags in instance metadata

By default, instance tags are not accessible in the instance metadata. For each instance, you must explicitly allow access. If access is allowed, instance tag *keys* must comply with specific character restrictions, otherwise the instance launch will fail. For more information, see Enable access to tags in instance metadata.

Modify instance metadata options for existing instances

You can modify the instance metadata options for existing instances.

You can also create an IAM policy that prevents users from modifying the instance metadata options on existing instances. To control which users can modify the instance metadata options, specify a policy that prevents all users other than users with a specified role to use the ModifyInstanceMetadataOptions API. For the example IAM policy, see Work with instance metadata.

> **Note**
>
> If a declarative policy was used to configure the instance metadata options, you can't modify them directly within the account. For more information, see Declarative policies in the *AWS Organizations User Guide*.

Require the use of IMDSv2

Use one of the following methods to modify the instance metadata options on an existing instance to require that IMDSv2 is used when requesting instance metadata. When IMDSv2 is required, IMDSv1 cannot be used.

> **Note**
>
> Before requiring that IMDSv2 is used, ensure that the instance isn't making IMDSv1 calls. The `MetadataNoToken` CloudWatch metric tracks IMDSv1 calls. When `MetadataNoToken` records zero IMDSv1 usage for an instance, the instance is then ready to require IMDSv2.

Console

To require the use of IMDSv2 on an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions**, **Instance settings**, **Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:

   a. For **Instance metadata service**, select **Enable**.

   b. For **IMDSv2**, choose **Required**.

c. Choose **Save**.

AWS CLI

To require the use of IMDSv2 on an existing instance

Use the modify-instance-metadata-options CLI command and set the `http-tokens` parameter to `required`. When you specify a value for `http-tokens`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --http-tokens required \
    --http-endpoint enabled
```

PowerShell

To require the use of IMDSv2 on an existing instance

Use the Edit-EC2InstanceMetadataOption Cmdlet and set the `HttpTokens` parameter to `required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to `enabled`.

```
(Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -HttpTokens required `
    -HttpEndpoint enabled).InstanceMetadataOptions
```

Restore the use of IMDSv1

When IMDSv2 is required, IMDSv1 will not work when requesting instance metadata. When IMDSv2 is optional, then both IMDSv2 and IMDSv1 will work. Therefore, to restore IMDSv1, make IMDSv2 optional by using one of the following methods.

Console

To restore the use of IMDSv1 on an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions**, **Instance settings**, **Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:

    a. For **Instance metadata service**, make sure that **Enable** is selected.

    b. For **IMDSv2**, choose **Optional**.

    c. Choose **Save**.

AWS CLI

To restore the use of IMDSv1 on an instance

You can use the modify-instance-metadata-options CLI command with `http-tokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --http-tokens optional \
    --http-endpoint enabled
```

PowerShell

To restore the use of IMDSv1 on an instance

You can use the Edit-EC2InstanceMetadataOption Cmdlet with `HttpTokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
(Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -HttpTokens optional `
    -HttpEndpoint enabled).InstanceMetadataOptions
```

Change the PUT response hop limit

For existing instances, you can change the settings of the PUT response hop limit.

Currently only the AWS CLI and AWS SDKs support changing the PUT response hop limit.

AWS CLI

To change the PUT response hop limit

Use the modify-instance-metadata-options CLI command and set the `http-put-response-hop-limit` parameter to the required number of hops. In the following example, the hop limit is set to `3`. Note that when specifying a value for `http-put-response-hop-limit`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --http-put-response-hop-limit 3 \
    --http-endpoint enabled
```

PowerShell

To change the PUT response hop limit

Use the Edit-EC2InstanceMetadataOption Cmdlet and set the `HttpPutResponseHopLimit` parameter to the required number of hops. In the following example, the hop limit is set to `3`. Note that when specifying a value for `HttpPutResponseHopLimit`, you must also set `HttpEndpoint` to `enabled`.

```
(Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -HttpPutResponseHopLimit 3 `
    -HttpEndpoint enabled).InstanceMetadataOptions
```

Enable the IMDS IPv4 and IPv6 endpoints

The IMDS has two endpoints on an instance: IPv4 (`169.254.169.254`) and IPv6 (`[fd00:ec2::254]`). When you enable the IMDS, the IPv4 endpoint is automatically enabled. The IPv6 endpoint remains disabled even if you launch an instance into an IPv6-only subnet. To enable the IPv6 endpoint, you need to do so explicitly. When you enable the IPv6 endpoint, the IPv4 endpoint remains enabled.

You can enable the IPv6 endpoint at instance launch or after.

Requirements for enabling the IPv6 endpoint

- The selected instance type is a Nitro-based instance.

- The selected subnet supports IPv6, where the subnet is either dual stack or IPv6 only.

Currently only the AWS CLI and AWS SDKs support enabling the IMDS IPv6 endpoint after instance launch.

AWS CLI

To enable the IMDS IPv6 endpoint for your instance

Use the modify-instance-metadata-options CLI command and set the `http-protocol-ipv6` parameter to `enabled`. Note that when specifying a value for `http-protocol-ipv6`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
 --instance-id i-1234567890abcdef0 \
 --http-protocol-ipv6 enabled \
 --http-endpoint enabled
```

PowerShell

To enable the IMDS IPv6 endpoint for your instance

Use the Edit-EC2InstanceMetadataOption Cmdlet and set the `HttpProtocolIpv6` parameter to `enabled`. Note that when specifying a value for `HttpProtocolIpv6`, you must also set `HttpEndpoint` to `enabled`.

```
(Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -HttpProtocolIpv6 enabled `
    -HttpEndpoint enabled).InstanceMetadataOptions
```

Turn on access to instance metadata

You can turn on access to instance metadata by enabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by disabling the HTTP endpoint.

Use one of the following methods to turn on access to instance metadata on an instance.

Console

To turn on access to instance metadata

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions**, **Instance settings**, **Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, select **Enable**.
   b. Choose **Save**.

AWS CLI

To turn on access to instance metadata

Use the modify-instance-metadata-options CLI command and set the `http-endpoint` parameter to `enabled`.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --http-endpoint enabled
```

PowerShell

To turn on access to instance metadata

Use the Edit-EC2InstanceMetadataOption Cmdlet and set the `HttpEndpoint` parameter to `enabled`.

```
(Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -HttpEndpoint enabled).InstanceMetadataOptions
```

Turn off access to instance metadata

You can turn off access to instance metadata by disabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by enabling the HTTP endpoint.

Use one of the following methods to turn off access to instance metadata on an instance.

Console

To turn off access to instance metadata

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions**, **Instance settings**, **Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:

    a. For **Instance metadata service**, clear **Enable**.

    b. Choose **Save**.

AWS CLI

To turn off access to instance metadata

Use the modify-instance-metadata-options CLI command and set the `http-endpoint` parameter to `disabled`.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --http-endpoint disabled
```

PowerShell

To turn off access to instance metadata

Use the Edit-EC2InstanceMetadataOption Cmdlet and set the `HttpEndpoint` parameter to `disabled`.

```
(Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -HttpEndpoint disabled).InstanceMetadataOptions
```

Allow access to tags in instance metadata

You can allow access to tags in the instance metadata on a running or stopped instance. For each instance, you must explicitly allow access. If access is allowed, instance tag *keys* must comply with specific character restrictions, otherwise you get an error. For more information, see [Enable access to tags in instance metadata](#).

Run commands when you launch an EC2 instance with user data input

When you launch an Amazon EC2 instance, you can pass user data to the instance that is used to perform automated configuration tasks, or to run scripts after the instance starts.

If you're interested in more complex automation scenarios, you might consider AWS CloudFormation. For more information, see [Deploying applications on Amazon EC2 with AWS CloudFormation](#) in the *AWS CloudFormation User Guide*.

On Linux instances, you can pass two types of user data to Amazon EC2: shell scripts and cloud-init directives. You can also pass this data into the launch instance wizard as plain text, as a file (this is useful for launching instances with the command line tools), or as base64-encoded text (for API calls).

On Windows instances, the launch agents handle your user data scripts.

Considerations

- User data is treated as opaque data: what you give is what you get back. It is up to the instance to interpret it.
- User data must be base64-encoded. The Amazon EC2 console can perform the base64-encoding for your or accept base64-encoded input. If you retrieve the user data using instance metadata or the console, it's base64-decoded for you automatically.
- User data is limited to 16 KB, in raw form, before it is base64-encoded. The size of a string of length *n* after base64-encoding is ceil(*n*/3)*4.
- User data is an instance attribute. If you create an AMI from an instance, the instance user data is not included in the AMI.

User data in the AWS Management Console

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.

Specify instance user data at launch with the Launch Wizard

You can specify user data when you launch an instance with the Launch Wizard in the EC2 console. To specify user data on launch, follow the procedure for [launching an instance](). The **User data** field is located in the [Advanced details]() section of the launch instance wizard. Enter your PowerShell script in the **User data** field, and then complete the instance launch procedure.

In the following screenshot of the **User data** field, the example script creates a file in the Windows temporary folder, using the current date and time in the file name. When you include `<persist>true</persist>`, the script is run every time you reboot or start the instance. If you leave the **User data has already been base64 encoded** checkbox empty, the Amazon EC2 console performs the base64 encoding for you.

For more information, see Specify instance user data at launch with the Launch Wizard. For a Linux example that uses the AWS CLI, see the section called "User data and the AWS CLI". For a Windows example that uses the Tools for Windows PowerShell, see the section called "User data and the Tools for Windows PowerShell".

View and update the instance user data

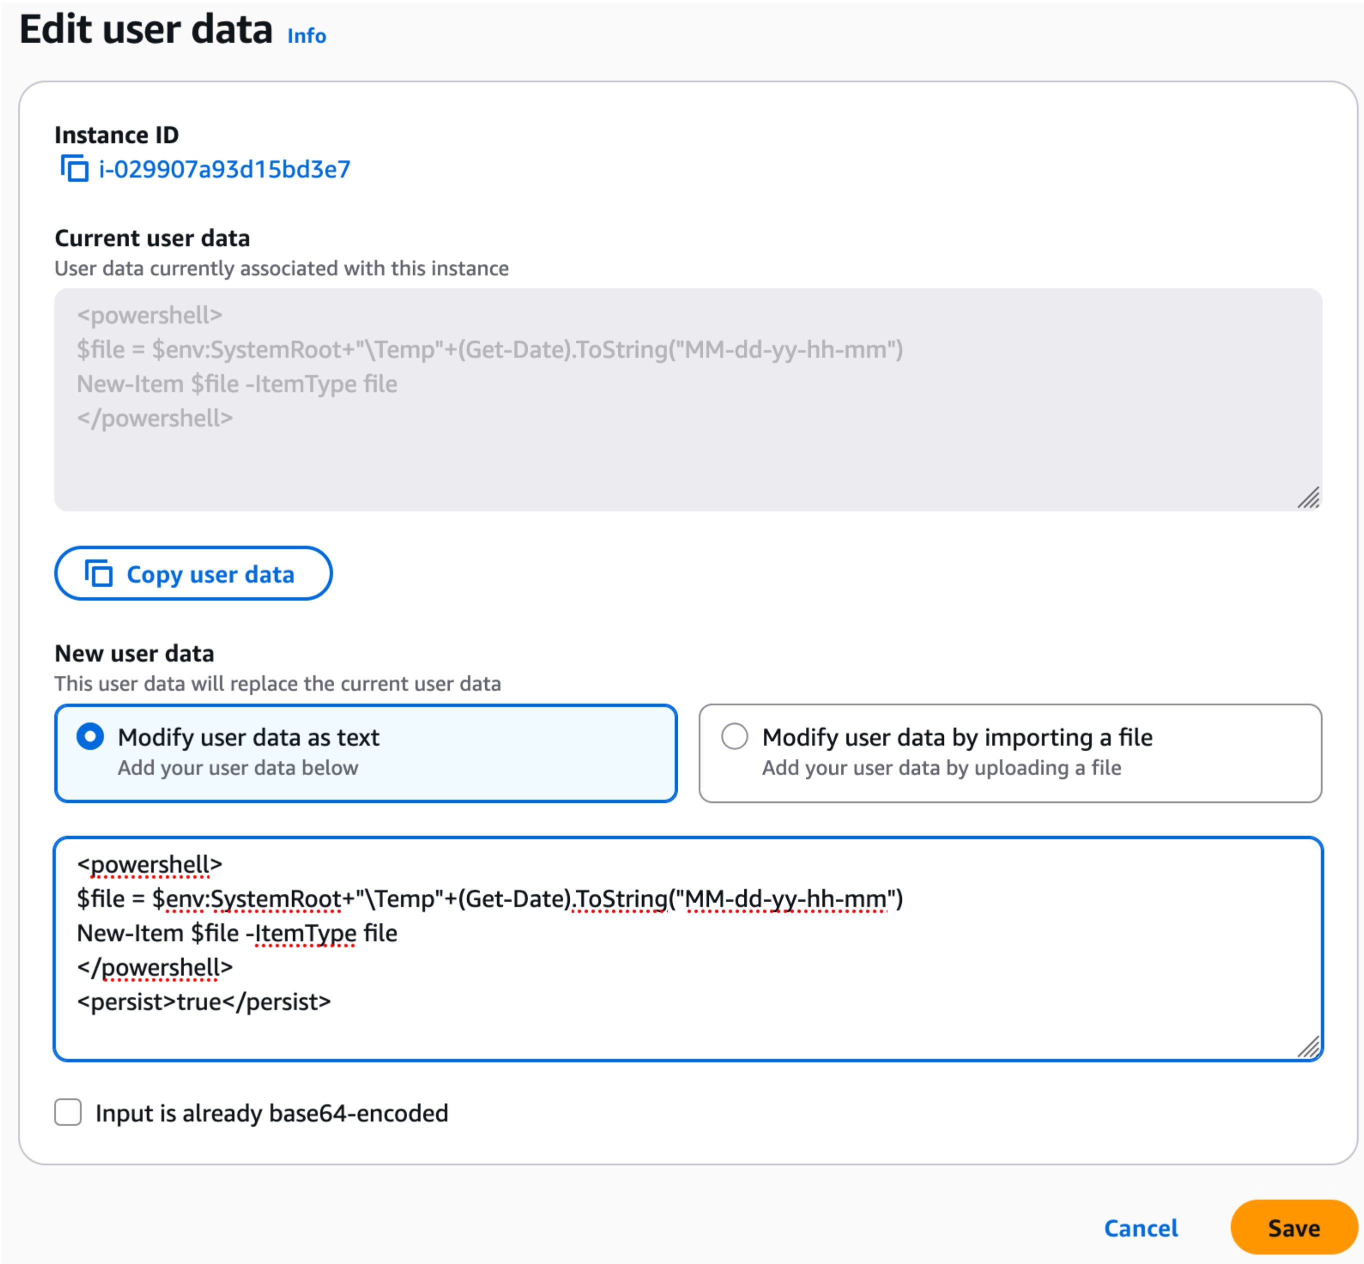
You can view the instance user data for any instance, and you can update the instance user data for a stopped instance.

To update the user data for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Instance state**, **Stop instance**.

   > **Warning**
   >
   > When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions**, **Instance settings**, **Edit user data**. You can't change the user data if the instance is running, but you can view it.
6. In the **Edit user data** dialog box, update the user data, and then choose **Save**. To run user data scripts every time you reboot or start the instance, add `<persist>true</persist>`, as shown in the following example:



7. Start the instance. If you enabled user data execution for subsequent reboots or starts, the updated user data scripts are run as part of the instance start process.

How Amazon EC2 handles user data for Linux instances

The following examples use user data to run commands that set up a LAMP server when the instance launches. In each example, the following tasks are performed:

- The distribution software packages are updated.

- The web server, php, and `mariadb` packages are installed.
- The `httpd` service is started and turned on.
- The user `ec2-user` is added to the apache group.
- The appropriate ownership and file permissions are set for the web directory and the files contained within it.
- A simple web page is created to test the web server and PHP engine.

Contents

Prerequisites

The examples in this topic assume the following:

- Your instance has a public DNS name that is reachable from the internet.
- The security group associated with your instance is configured to allow SSH (port 22) traffic so that you can connect to the instance to view the output log files.
- Your instance is launched using an Amazon Linux AMI. The commands and directives might not work for other Linux distributions. For more information about other distributions, such as their support for cloud-init, see documentation for the specific distribution.

User data and shell scripts

If you are familiar with shell scripting, this is the easiest and most complete way to send instructions to an instance at launch. Adding these tasks at boot time adds to the amount of time it takes to boot the instance. You should allow a few minutes of extra time for the tasks to complete before you test that the user script has finished successfully.

> **Important**
>
> By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance? in the AWS Knowledge Center.

User data shell scripts must start with the `#!` characters and the path to the interpreter you want to read the script (commonly **/bin/bash)**. For an introduction on shell scripting, see the Bash Reference Manual on the *GNU Operating System* website.

Scripts entered as user data are run as the root user, so do not use the **sudo** command in the script. Remember that any files you create will be owned by the root user; if you need a non-root user to have file access, you should modify the permissions accordingly in the script. Also, because the script is not run interactively, you cannot include commands that require user feedback (such as **yum update** without the `-y` flag).

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to issue the API call. For more information, see Use instance profiles in the IAM User Guide. The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see IAM roles for Amazon EC2.

The cloud-init output log file captures console output so it is easy to debug your scripts following a launch if the instance does not behave the way you intended. To view the log file, connect to the instance and open `/var/log/cloud-init-output.log`.

When a user data script is processed, it is copied to and run from `/var/lib/cloud/instances/instance-id/`. The script is not deleted after it is run. Be sure to delete the user data scripts from `/var/lib/cloud/instances/instance-id/` before you create an AMI from the instance. Otherwise, the script will exist in this directory on any instance launched from the AMI.

Update the instance user data

To update the instance user data, you must first stop the instance. If the instance is running, you can view the user data but you cannot modify it.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

To modify instance user data

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state**, **Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions**, **Instance settings**, **Edit user data**.
6. Modify the user data as needed, and then choose **Save**.
7. Start the instance. The new user data is visible on your instance after you start it; however, user data scripts are not run.

User data and cloud-init directives

The cloud-init package configures specific aspects of a new Amazon Linux instance when it is launched; most notably, it configures the `.ssh/authorized_keys` file for the ec2-user so you can log in with your own private key. For more information about the configuration tasks that the cloud-init package performs for Amazon Linux instances, see the following documentation:

- **Amazon Linux 2023 –** Customized cloud-init
- **Amazon Linux 2 –** Using cloud-init on Amazon Linux 2

The cloud-init user directives can be passed to an instance at launch the same way that a script is passed, although the syntax is different. For more information about cloud-init, see https://cloudinit.readthedocs.org/en/latest/index.html.

Important

By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance? in the AWS Knowledge Center.

Adding these tasks at boot time adds to the amount of time it takes to boot an instance. You should allow a few minutes of extra time for the tasks to complete before you test that your user data directives have completed.

To pass cloud-init directives to an Amazon Linux instance

1. Follow the procedure for launching an instance. The **User data** field is located in the Advanced details section of the launch instance wizard. Enter your cloud-init directive text in the **User data** field, and then complete the instance launch procedure.

   In the examples below, the directives create and configure a web server on Amazon Linux. The `#cloud-config` line at the top is required in order to identify the commands as cloud-init directives.

   AL2023

```
#cloud-config
package_update: true
package_upgrade: all

packages:
- httpd
- mariadb105-server
- php8.1
- php8.1-mysqlnd

runcmd:
- systemctl start httpd
- systemctl enable httpd
- [ sh, -c, "usermod -a -G apache ec2-user" ]
- [ sh, -c, "chown -R ec2-user:apache /var/www" ]
- chmod 2775 /var/www
```

```
- [ find, /var/www, -type, d, -exec, chmod, 2775, {}, \; ]
- [ find, /var/www, -type, f, -exec, chmod, 0664, {}, \; ]
- [ sh, -c, 'echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php' ]
```

AL2

```
#cloud-config
package_update: true
package_upgrade: all

packages:
- httpd
- mariadb-server

runcmd:
- [ sh, -c, "amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2" ]
- systemctl start httpd
- systemctl enable httpd
- [ sh, -c, "usermod -a -G apache ec2-user" ]
- [ sh, -c, "chown -R ec2-user:apache /var/www" ]
- chmod 2775 /var/www
- [ find, /var/www, -type, d, -exec, chmod, 2775, {}, \; ]
- [ find, /var/www, -type, f, -exec, chmod, 0664, {}, \; ]
- [ sh, -c, 'echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php' ]
```

2. Allow enough time for the instance to launch and run the directives in your user data, and then check to see that your directives have completed the tasks you intended.

   For this example, in a web browser, enter the URL of the PHP test file the directives created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

   ```
   http://my.public.dns.amazonaws.com/phpinfo.php
   ```

   You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see Configure security group rules.

3. (Optional) If your directives did not accomplish the tasks you were expecting them to, or if you just want to verify that your directives completed without errors, connect to the instance, examine the output log file (`/var/log/cloud-init-output.log`), and look for error

messages in the output. For additional debugging information, you can add the following line to your directives:

```
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends **runcmd** output to `/var/log/cloud-init-output.log`.

User data and the AWS CLI

You can use the AWS CLI to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see Access instance metadata for an EC2 instance.

On Windows, you can use the AWS Tools for Windows PowerShell instead of using the AWS CLI. For more information, see User data and the Tools for Windows PowerShell .

Example: Specify user data at launch

To specify user data when you launch your instance, use the run-instances command with the `--user-data` parameter. With **run-instances**, the AWS CLI performs base64 encoding of the user data for you.

The following example shows how to specify a script as a string on the command line:

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium \
    --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234
 \
    --user-data echo user data
```

The following example shows how to specify a script using a text file. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium \
    --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234
 \
    --user-data file://my_script.txt
```

The following is an example text file with a shell script.

```
#!/bin/bash
```

```
yum update -y
service httpd start
chkconfig httpd on
```

Example: Modify the user data of a stopped instance

You can modify the user data of a stopped instance using the modify-instance-attribute command. With **modify-instance-attribute**, the AWS CLI does not perform base64 encoding of the user data for you.

- On a **Linux** computer, use the base64 command to encode the user data.

```
base64 my_script.txt >my_script_base64.txt
```

- On a **Windows** computer, use the certutil command to encode the user data. Before you can use this file with the AWS CLI, you must remove the first (BEGIN CERTIFICATE) and last (END CERTIFICATE) lines.

```
certutil -encode my_script.txt my_script_base64.txt
notepad my_script_base64.txt
```

Use the `--attribute` and `--value` parameters to use the encoded text file to specify the user data. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --attribute
 userData --value file://my_script_base64.txt
```

Example: Clear the user data of a stopped instance

To delete the existing user data, use the modify-instance-attribute command as follows:

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --user-data Value=
```

Example: View user data

To retrieve the user data for an instance, use the describe-instance-attribute command. With **describe-instance-attribute**, the AWS CLI does not perform base64 decoding of the user data for you.

```
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute
 userData
```

The following is example output with the user data base64 encoded.

```
{
    "UserData": {
        "Value":
 "IyEvYmluL2Jhc2gKeXVtIHVwZGF0ZSAteQpzZXJ2aWNlIGh0dHBkIHN0YXJ0CmNoa2NvbmZpZyBodHRwZCBvbg=="
    },
    "InstanceId": "i-1234567890abcdef0"
}
```

- On a **Linux** computer , use the `--query` option to get the encoded user data and the base64 command to decode it.

  ```
  aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute
   userData --output text --query "UserData.Value" | base64 --decode
  ```

- On a **Windows** computer, use the `--query` option to get the coded user data and the certutil command to decode it. Note that the encoded output is stored in a file and the decoded output is stored in another file.

  ```
  aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute
   userData --output text --query "UserData.Value" >my_output.txt
  certutil -decode my_output.txt my_output_decoded.txt
  type my_output_decoded.txt
  ```

The following is example output.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Combine shell scripts and cloud-init directives

By default, you can include only one content type in user data at a time. However, you can use the `text/cloud-config` and `text/x-shellscript` content-types in a mime-multi part file to include both a shell script and cloud-init directives in your user data.

The following shows the mime-multi part format.

```
Content-Type: multipart/mixed; boundary="//"
MIME-Version: 1.0

--//
Content-Type: text/cloud-config; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="cloud-config.txt"

#cloud-config
cloud-init directives

--//
Content-Type: text/x-shellscript; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="userdata.txt"

#!/bin/bash
shell script commands
--//--
```

For example, the following user data includes cloud-init directives and a bash shell script. The cloud-init directives creates a file (`/test-cloudinit/cloud-init.txt`), and writes `Created by cloud-init` to that file. The bash shell script creates a file (`/test-userscript/userscript.txt`) and writes `Created by bash shell script` to that file.

```
Content-Type: multipart/mixed; boundary="//"
MIME-Version: 1.0

--//
Content-Type: text/cloud-config; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
```

```
Content-Disposition: attachment; filename="cloud-config.txt"

#cloud-config
runcmd:
- [ mkdir, /test-cloudinit ]
write_files:
- path: /test-cloudinit/cloud-init.txt
content: Created by cloud-init

--//
Content-Type: text/x-shellscript; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="userdata.txt"

#!/bin/bash
mkdir test-userscript
touch /test-userscript/userscript.txt
echo "Created by bash shell script" >> /test-userscript/userscript.txt
--//--
```

How Amazon EC2 handles user data for Windows instances

On Windows instances, the launch agent performs the tasks related to user data. For more information, see the following:

- EC2Launch v2
- EC2Launch
- EC2Config service

For examples of the assembly of a `UserData` property in a AWS CloudFormation template, see Base64 Encoded UserData Property and Base64 Encoded UserData Property with AccessKey and SecretKey.

For an example of running commands on an instance within an Auto Scaling group that works with lifecycle hooks, see Tutorial: Configure user data to retrieve the target lifecycle state through instance metadata in the *Amazon EC2 Auto Scaling User Guide*.

Contents

- Compressed user data
- User data execution
- User data and the Tools for Windows PowerShell

User data scripts

For `EC2Config` or `EC2Launch` to run scripts, you must enclose the script within a special tag when you add it to user data. The tag that you use depends on whether the commands run in a Command Prompt window (batch commands) or use Windows PowerShell.

If you specify both a batch script and a Windows PowerShell script, the batch script runs first and the Windows PowerShell script runs next, regardless of the order in which they appear in the instance user data.

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to make the API call. For more information, see Instance profiles. The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see IAM roles for Amazon EC2.

Script type

- Syntax for batch scripts
- Syntax for Windows PowerShell scripts
- Syntax for YAML configuration scripts
- Base64 encoding

Syntax for batch scripts

Specify a batch script using the `script` tag. Separate the commands using line breaks as shown in the following example.

```
<script>
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
```

By default, user data scripts run one time when you launch the instance. To run the user data scripts every time you reboot or start the instance, add `<persist>true</persist>` to the user data.

```
<script>
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
<persist>true</persist>
```

EC2Launch v2 agent

To run an XML user data script as a detached process with the EC2Launch v2 **executeScript** task in the `UserData` stage, add `<detach>true</detach>` to the user data.

> **Note**
>
> The detach tag is not supported by previous launch agents.

```
<script>
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
<detach>true</detach>
```

Syntax for Windows PowerShell scripts

The AWS Windows AMIs include the [AWS Tools for Windows PowerShell](), so you can specify these cmdlets in user data. If you associate an IAM role with your instance, you don't need to specify credentials to the cmdlets, as applications that run on the instance use the role's credentials to access AWS resources (for example, Amazon S3 buckets).

Specify a Windows PowerShell script using the `<powershell>` tag. Separate the commands using line breaks. The `<powershell>` tag is case-sensitive.

For example:

```
<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
```

```
</powershell>
```

By default, the user data scripts run one time when you launch the instance. To run the user data scripts every time you reboot or start the instance, add `<persist>true</persist>` to the user data.

```
<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

You can specify one or more PowerShell arguments with the `<powershellArguments>` tag. If no arguments are passed, EC2Launch and EC2Launch v2 add the following argument by default: `-ExecutionPolicy Unrestricted`.

Example:

```
<powershell>
    $file = $env:SystemRoot + "\Temp" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<powershellArguments>-ExecutionPolicy Unrestricted -NoProfile -NonInteractive</
powershellArguments>
```

EC2Launch v2 agent

To run an XML user data script as a detached process with the EC2Launch v2 **executeScript** task in the `UserData` stage, add `<detach>true</detach>` to the user data.

> **Note**
>
> The detach tag is not supported by previous launch agents.

```
<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<detach>true</detach>
```

Syntax for YAML configuration scripts

If you are using EC2Launch v2 to run scripts, you can use the YAML format. To view configuration tasks, details, and examples for EC2Launch v2, see EC2Launch v2 task configuration.

Specify a YAML script with the `executeScript` task.

Example YAML syntax to run a PowerShell script

```
version: 1.0
tasks:
- task: executeScript
  inputs:
  - frequency: always
    type: powershell
    runAs: localSystem
    content: |-
      $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
      New-Item $file -ItemType file
```

Example YAML syntax to run a batch script

```
version: 1.1
tasks:
- task: executeScript
  inputs:
  - frequency: always
    type: batch
    runAs: localSystem
    content: |-
      echo Current date and time >> %SystemRoot%\Temp\test.log
      echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
```

Base64 encoding

If you're using the Amazon EC2 API or a tool that does not perform base64 encoding of the user data, you must encode the user data yourself. If not, an error is logged about being unable to find `script` or `powershell` tags to run. The following is an example that encodes using Windows PowerShell.

```
$UserData =
 [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Script))
```

The following is an example that decodes using PowerShell.

```
$Script =
 [System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($UserData))
```

For more information about base64 encoding, see https://www.ietf.org/rfc/rfc4648.txt.

Compressed user data

EC2Launch v2 supports zipped user data as a method to submit user data that's larger than the 16 KB limit imposed by IMDS. To use this feature, compress your user data script into a `.zip` archive and pass it to your EC2 instance. When EC2Launch v2 detects compressed user data, it automatically unzips the compressed user data script and runs it.

As with standard user data, if you're using the Amazon EC2 API or a tool that does not perform base64 encoding of the user data, you must encode the compressed user data yourself. For more information about the user data size limit and base64 encoding, see Access instance metadata for an EC2 instance.

User data execution

By default, all AWS Windows AMIs have user data execution enabled for the initial launch. You can specify that user data scripts are run the next time the instance reboots or restarts. Alternatively, you can specify that user data scripts are run every time the instance reboots or restarts.

> **Note**
>
> User data is not enabled to run by default after the initial launch. To enable user data to run when you reboot or start the instance, see Run scripts during subsequent reboots or starts.

User data scripts are run from the local administrator account when a random password is generated. Otherwise, user data scripts are run from the System account.

Instance launch scripts

Scripts in the instance user data are run during the initial launch of the instance. If the `persist` tag is found, user data execution is enabled for subsequent reboots or starts. The log files for EC2Launch v2, EC2Launch, and EC2Config contain the output from the standard output and standard error streams.

EC2Launch v2

The log file for EC2Launch v2 is `C:\ProgramData\Amazon\EC2Launch\log\agent.log`.

> **Note**
>
> The `C:\ProgramData` folder might be hidden. To view the folder, you must show hidden files and folders.

The following information is logged when the user data is run:

- `Info: Converting user-data to yaml format` – If the user data was provided in XML format
- `Info: Initialize user-data state` – The start of user data execution
- `Info: Frequency is: always` – If the user data task is running on every boot
- `Info: Frequency is: once` – If the user data task is running just once
- `Stage: postReadyUserData execution completed` – The end of user data execution

EC2Launch

The log file for EC2Launch is `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\UserdataExecution.log`.

The `C:\ProgramData` folder might be hidden. To view the folder, you must show hidden files and folders.

The following information is logged when the user data is run:

- `Userdata execution begins` – The start of user data execution
- `<persist> tag was provided: true` – If the persist tag is found
- `Running userdata on every boot` – If the persist tag is found
- `<powershell> tag was provided.. running powershell content` – If the powershell tag is found
- `<script> tag was provided.. running script content` – If the script tag is found
- `Message: The output from user scripts` – If user data scripts are run, their output is logged

EC2Config

The log file for EC2Config is `C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2Config.log`. The following information is logged when the user data is run:

- `Ec2HandleUserData: Message: Start running user scripts` – The start of user data execution
- `Ec2HandleUserData: Message: Re-enabled userdata execution` – If the persist tag is found
- `Ec2HandleUserData: Message: Could not find <persist> and </persist>` – If the persist tag is not found
- `Ec2HandleUserData: Message: The output from user scripts` – If user data scripts are run, their output is logged

Run scripts during subsequent reboots or starts

When you update instance user data, the updated user data content is automatically reflected in the instance metadata the next time you reboot or start the instance. However, depending on the installed launch agent, additional configuration may be required to configure user data scripts to run on subsequent reboots or starts.

If you choose the **Shutdown with Sysprep** option, user data scripts run the next time the instance starts or reboots, even if you did not enable user data execution for subsequent reboots or starts.

For instructions to enable user data execution, select the tab that matches your launch agent.

EC2Launch v2

Unlike EC2Launch v1, EC2Launch v2 evaluates the user data task on every boot. It is not necessary to manually schedule the user data task. The user data runs based on the included frequency or persist options.

For XML user data scripts

To run user data scripts on every boot, add the `<persist>true</persist>` flag to the user data. If the persist flag is not included, the user data script only runs on the initial boot.

For YAML user data

- To run a task in user data on the initial boot, set the task `frequency` to `once`.

- To run a task in user data on every boot, set the task `frequency` to `always`.

EC2Launch

1. Connect to your Windows instance.
2. Open a PowerShell command window and run one of the following commands:

   Run once

   To run user data once on the next boot, use the `-Schedule` flag.

   ```
   C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -
   Schedule
   ```

   Run on all subsequent boots

   To run user data on all subsequent boots, use the `-SchedulePerBoot` flag.

   ```
   C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -
   SchedulePerBoot
   ```
3. Disconnect from your Windows instance. To run updated scripts the next time the instance is started, stop the instance and update the user data.

EC2Config

1. Connect to your Windows instance.
2. Open `C:\Program Files\Amazon\Ec2ConfigService\Ec2ConfigServiceSetting.exe`.
3. For **User Data**, select **Enable UserData execution for next service start**.
4. Disconnect from your Windows instance. To run updated scripts the next time the instance is started, stop the instance and update the user data.

User data and the Tools for Windows PowerShell

You can use the Tools for Windows PowerShell to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see

Access instance metadata for an EC2 instance. For information about user data and the AWS CLI, see User data and the AWS CLI.

Example: Specify instance user data at launch

Create a text file with the instance user data. To run user data scripts every time you reboot or start the instance, add `<persist>true</persist>`, as shown in the following example.

```
<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

To specify instance user data when you launch your instance, use the New-EC2Instance command. This command does not perform base64 encoding of the user data for you. Use the following commands to encode the user data in a text file named `script.txt`.

```
PS C:\> $Script = Get-Content -Raw script.txt
PS C:\> $UserData =
 [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Script))
```

Use the `-UserData` parameter to pass the user data to the **New-EC2Instance** command.

```
PS C:\> New-EC2Instance -ImageId ami-abcd1234 -MinCount 1 -MaxCount 1 -
InstanceType m3.medium \
    -KeyName my-key-pair -SubnetId subnet-12345678 -SecurityGroupIds sg-1a2b3c4d \
    -UserData $UserData
```

Example: Update instance user data for a stopped instance

You can modify the user data of a stopped instance using the Edit-EC2InstanceAttribute command.

Create a text file with the new script. Use the following commands to encode the user data in the text file named `new-script.txt`.

```
PS C:\> $NewScript = Get-Content -Raw new-script.txt
PS C:\> $NewUserData =
 [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($NewScript))
```

Use the `-UserData` and `-Value` parameters to specify the user data.

```
PS C:\> Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -Attribute userData -
Value $NewUserData
```

Example: View instance user data

To retrieve the user data for an instance, use the Get-EC2InstanceAttribute command.

```
PS C:\> (Get-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -Attribute
 userData).UserData
```

The following is example output. Note that the user data is encoded.

```
PHBvd2Vyc2hlbGw
+DQpSZW5hbWUtQ29tcHV0ZXIgLU5ld05hbWUgdXNlci1kYXRhLXRlc3QNCjwvcG93ZXJzaGVsbD4=
```

Use the following commands to store the encoded user data in a variable and then decode it.

```
PS C:\> $UserData_encoded = (Get-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -
Attribute userData).UserData
PS C:
\> [System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($UserData_encoded))
```

The following is example output.

```
<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

Example: Rename the instance to match the tag value

You can use the Get-EC2Tag command to read the tag value, rename the instance on first boot to match the tag value, and reboot. To run this command successfully, you must have a role with `ec2:DescribeTags` permissions attached to the instance because tag information is retrieved by the API call. For more information on settings permissions by using IAM roles, see Attach an IAM role to an instance.

IMDSv2

```
<powershell>
    [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-
seconds" = "21600"} -Method PUT -Uri 'http://169.254.169.254/latest/api/token' -
UseBasicParsing
    $instanceId = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" =
 $token} -Method GET -Uri 'http://169.254.169.254/latest/meta-data/instance-id' -
UseBasicParsing
 $nameValue = (Get-EC2Tag -Filter @{Name="resource-id";Value=
$instanceid},@{Name="key";Value="Name"}).Value
 $pattern = "^(?![0-9]{1,15}$)[a-zA-Z0-9-]{1,15}$"
 #Verify Name Value satisfies best practices for Windows hostnames
 If ($nameValue -match $pattern)
     {Try
         {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
     Catch
         {$ErrorMessage = $_.Exception.Message
         Write-Output "Rename failed: $ErrorMessage"}}
 Else
     {Throw "Provided name not a valid hostname. Please ensure Name value is between
 1 and 15 characters in length and contains only alphanumeric or hyphen characters"}
</powershell>
```

IMDSv1

```
<powershell>
 $instanceId = (Invoke-WebRequest http://169.254.169.254/latest/meta-data/instance-
id -UseBasicParsing).content
 $nameValue = (Get-EC2Tag -Filter @{Name="resource-id";Value=
$instanceid},@{Name="key";Value="Name"}).Value
 $pattern = "^(?![0-9]{1,15}$)[a-zA-Z0-9-]{1,15}$"
 #Verify Name Value satisfies best practices for Windows hostnames
 If ($nameValue -match $pattern)
     {Try
         {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
     Catch
         {$ErrorMessage = $_.Exception.Message
         Write-Output "Rename failed: $ErrorMessage"}}
 Else
     {Throw "Provided name not a valid hostname. Please ensure Name value is between
 1 and 15 characters in length and contains only alphanumeric or hyphen characters"}
</powershell>
```

You can also rename the instance using tags in instance metadata, if your instance is configured to access tags from the instance metadata. For more information, see View tags for your EC2 instances using instance metadata.

IMDSv2

```
<powershell>
    [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-
seconds" = "21600"} -Method PUT -Uri 'http://169.254.169.254/latest/api/token' -
UseBasicParsing
 $nameValue = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token}
 -Method GET -Uri 'http://169.254.169.254/latest/meta-data/tags/instance/Name' -
UseBasicParsing
 $pattern = "^(?![0-9]{1,15}$)[a-zA-Z0-9-]{1,15}$"
 #Verify Name Value satisfies best practices for Windows hostnames
 If ($nameValue -match $pattern)
     {Try
         {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
     Catch
         {$ErrorMessage = $_.Exception.Message
         Write-Output "Rename failed: $ErrorMessage"}}
 Else
     {Throw "Provided name not a valid hostname. Please ensure Name value is between
 1 and 15 characters in length and contains only alphanumeric or hyphen characters"}
</powershell>
```

IMDSv1

```
<powershell>
 $nameValue = Get-EC2InstanceMetadata -Path /tags/instance/Name
 $pattern = "^(?![0-9]{1,15}$)[a-zA-Z0-9-]{1,15}$"
 #Verify Name Value satisfies best practices for Windows hostnames
 If ($nameValue -match $pattern)
     {Try
         {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
     Catch
         {$ErrorMessage = $_.Exception.Message
         Write-Output "Rename failed: $ErrorMessage"}}
 Else
     {Throw "Provided name not a valid hostname. Please ensure Name value is between
 1 and 15 characters in length and contains only alphanumeric or hyphen characters"}
</powershell>
```

Identify each instance launched in a single request

This example demonstrates how you can use both user data and instance metadata to configure your Amazon EC2 instances.

> **Note**
>
> The examples in this section use the IPv4 address of the IMDS: `169.254.169.254`. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: `[fd00:ec2::254]`. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Nitro-based instances in IPv6-supported subnets (dual stack or IPv6 only).

Alice wants to launch four instances of her favorite database AMI, with the first acting as the original instance and the remaining three acting as replicas. When she launches them, she wants to add user data about the replication strategy for each replica. She is aware that this data will be available to all four instances, so she needs to structure the user data in a way that allows each instance to recognize which parts are applicable to it. She can do this using the `ami-launch-index` instance metadata value, which will be unique for each instance. If she starts more than one instance at the same time, the `ami-launch-index` indicates the order in which the instances were launched. The value of the first instance launched is `0`.

Here is the user data that Alice has constructed.

```
replicate-every=1min | replicate-every=5min | replicate-every=10min
```

The `replicate-every=1min` data defines the first replica's configuration, `replicate-every=5min` defines the second replica's configuration, and so on. Alice decides to provide this data as an ASCII string with a pipe symbol (`|`) delimiting the data for the separate instances.

Alice launches four instances using the run-instances command, specifying the user data.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count 4 \
    --instance-type t2.micro \
    --user-data "replicate-every=1min | replicate-every=5min | replicate-every=10min"
```

After they're launched, all instances have a copy of the user data and the common metadata shown here:

- AMI ID: ami-0abcdef1234567890
- Reservation ID: r-1234567890abcabc0
- Public keys: none
- Security group name: default
- Instance type: t2.micro

However, each instance has unique metadata, as shown in the following tables.

Metadata	Value
instance-id	i-1234567890abcdef0
ami-launch-index	0
public-hostname	ec2-203-0-113-25.compute-1.amazonaws.com
public-ipv4	67.202.51.223
local-hostname	ip-10-251-50-12.ec2.internal
local-ipv4	10.251.50.35

Metadata	Value
instance-id	i-0598c7d356eba48d7
ami-launch-index	1
public-hostname	ec2-67-202-51-224.compute-1.amazonaws.com
public-ipv4	67.202.51.224
local-hostname	ip-10-251-50-36.ec2.internal
local-ipv4	10.251.50.36

Metadata	Value
instance-id	i-0ee992212549ce0e7
ami-launch-index	2
public-hostname	ec2-67-202-51-225.compute-1.amazonaws.com
public-ipv4	67.202.51.225
local-hostname	ip-10-251-50-37.ec2.internal
local-ipv4	10.251.50.37

Metadata	Value
instance-id	i-1234567890abcdef0
ami-launch-index	3
public-hostname	ec2-67-202-51-226.compute-1.amazonaws.com
public-ipv4	67.202.51.226
local-hostname	ip-10-251-50-38.ec2.internal
local-ipv4	10.251.50.38

Alice can use the `ami-launch-index` value to determine which portion of the user data is applicable to a particular instance.

1. She connects to one of the instances, and retrieves the `ami-launch-index` for that instance to ensure it is one of the replicas:

   IMDSv2

   ```
   [ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/meta-data/api/
   token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
   ```

```
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/ami-launch-index
2
```

For the following steps, the IMDSv2 requests use the stored token from the preceding IMDSv2 command, assuming the token has not expired.

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/ami-launch-index
2
```

2. She saves the `ami-launch-index` as a variable.

   IMDSv2

```
[ec2-user ~]$ ami_launch_index=`curl -H "X-aws-ec2-metadata-token: $TOKEN" 
 http://169.254.169.254/latest/meta-data/ami-launch-index`
```

   IMDSv1

```
[ec2-user ~]$ ami_launch_index=`curl http://169.254.169.254/latest/meta-data/ami-launch-index`
```

3. She saves the user data as a variable.

   IMDSv2

```
[ec2-user ~]$ user_data=`curl -H "X-aws-ec2-metadata-token: $TOKEN" 
 http://169.254.169.254/latest/user-data`
```

   IMDSv1

```
[ec2-user ~]$ user_data=`curl http://169.254.169.254/latest/user-data`
```

4. Finally, Alice uses the **cut** command to extract the portion of the user data that is applicable to that instance.

   IMDSv2

```
[ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index"
replicate-every=5min
```

IMDSv1

```
[ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index"
replicate-every=5min
```

Detect whether a host is an EC2 instance

You might need to know whether your application or website is running on an EC2 instance, especially if you have a mixed computing environment. You can use one of the following options to determine whether the host for your application or website is an EC2 instance.

Options

- Inspect the instance identity document
- Inspect the system UUID
- Inspect the system virtual machine generation identifier

Inspect the instance identity document

Each instance has a signed instance identity document that you can verify cryptographically. You can find these documents using the Instance Metadata Service (IMDS).

For more information, see Instance identity documents.

Inspect the system UUID

You can get the system UUID and look in the beginning octet of the UUID for EC2 (in Linux, this might be lowercase `ec2`). This method is quick, but potentially inaccurate because there's a small chance that a system that is not an EC2 instance could have a UUID that starts with these characters. Furthermore, some versions of SMBIOS use the *little-endian* format, which doesn't include EC2 at the beginning of the UUID. This might be the case for EC2 instances that use SMBIOS 2.4 for Windows, or for Linux distributions other than Amazon Linux that have their own implementation of SMBIOS.

Linux example: Get the UUID from DMI (HVM AMIs only)

Use the following command to get the UUID using the Desktop Management Interface (DMI):

```
[ec2-user ~]$ sudo dmidecode --string system-uuid
```

In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.

```
EC2E1916-9099-7CAF-FD21-012345ABCDEF
```

In the following example output, the UUID is represented in little-endian format.

```
45E12AEC-DCD1-B213-94ED-012345ABCDEF
```

Alternatively, for instances built on the Nitro system, you can use the following command:

```
[ec2-user ~]$ cat /sys/devices/virtual/dmi/id/board_asset_tag
```

If the output is an instance ID, as the following example output, the system is an EC2 instance:

```
i-0af01c0123456789a
```

Linux example: Get the UUID from the hypervisor (PV AMIs only)

Use the following command to get the UUID from the hypervisor:

```
[ec2-user ~]$ cat /sys/hypervisor/uuid
```

In the following example output, the UUID starts with "ec2", which indicates that the system is probably an EC2 instance.

```
ec2e1916-9099-7caf-fd21-012345abcdef
```

Windows example: Get the UUID using WMI or Windows PowerShell

Use the Windows Management Instrumentation command line (WMIC) as follows:

```
wmic path win32_computersystemproduct get uuid
```

Alternatively, if you're using Windows PowerShell, use the **Get-WmiObject** cmdlet as follows:

```
PS C:\> Get-WmiObject -query "select uuid from Win32_ComputerSystemProduct" | Select
 UUID
```

In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.

```
EC2AE145-D1DC-13B2-94ED-012345ABCDEF
```

For instances using SMBIOS 2.4, the UUID might be represented in little-endian format; for example:

```
45E12AEC-DCD1-B213-94ED-012345ABCDEF
```

Inspect the system virtual machine generation identifier

A virtual machine generation identifier consists of a unique buffer of 128-bit interpreted as cryptographic random integer identifier. You can retrieve the virtual machine generation identifier to identify your Amazon Elastic Compute Cloud instance. The generation identifier is exposed within the guest operating system of the instance through an ACPI table entry. The value will change if your machine is cloned, copied, or imported into AWS, such as with VM Import/Export.

Example: Retrieve the virtual machine generation identifier from Linux

You can use the following commands to retrieve the virtual machine generation identifier from your instances running Linux.

Amazon Linux 2

1. Update your existing software packages, as necessary, using the following command:

   ```
   sudo yum update
   ```

2. If necessary, source the busybox package with the following command:

   ```
   sudo curl https://www.rpmfind.net/linux/epel/next/8/Everything/x86_64/Packages/
   b/busybox-1.35.0-2.el8.next.x86_64.rpm --output busybox.rpm
   ```

3. If necessary, install the prerequisite packages using the following command:

```
sudo yum install busybox.rpm iasl -y
```

4. Run the following `iasl` command to produce output from the ACPI table:

```
sudo iasl -p ./SSDT2 -d /sys/firmware/acpi/tables/SSDT2
```

5. Run the following command to review the output of the `iasl` command:

```
cat SSDT2.dsl
```

The output should yield the address space required to retrieve the virtual machine generation identifier:

```
Intel ACPI Component Architecture

 's/0x//' | sed -z '$ s/\n$//' >> vmgenid; done
```

8. Retrieve the virtual machine generation identifier from the output file with the following command:

```
cat vmgenid ; echo
```

Your output should be similar to the following:

```
EC2F335D979132C4165896753E72BD1C
```

Example: Retrieve the virtual machine generation identifier from Windows

You can create a sample application to retrieve the virtual machine generation identifier from your instances running Windows. For more information, see Obtaining the virtual machine generation identifier in the Microsoft documentation.

Instance identity documents for Amazon EC2 instances

Each instance that you launch has an instance identity document that provides information about the instance itself. You can use the instance identity document to validate the attributes of the instance.

The instance identity document is generated when the instance is stopped and started, restarted, or launched. You can access the instance identity document for an instance through the Instance Metadata Service (IMDS). For the instructions, see Retrieve the instance identity document.

The instance identity document uses plaintext JSON format. It includes the following information.

Data	Description
`accountId`	The ID of the AWS account that launched the instance.
`architecture`	The architecture of the AMI used to launch the instance (i386 | x86_64 | arm64).
`availabilityZone`	The Availability Zone in which the instance is running.
`billingProducts`	The billing products of the instance.
`devpayProductCodes`	Deprecated.
`imageId`	The ID of the AMI used to launch the instance.
`instanceId`	The ID of the instance.
`instanceType`	The instance type of the instance.
`kernelId`	The ID of the kernel associated with the instance, if applicable.
`marketplaceProductCodes`	The AWS Marketplace product code of the AMI used to launch the instance.
`pendingTime`	The date and time that the instance was launched.
`privateIp`	The private IPv4 address of the instance.
`ramdiskId`	The ID of the RAM disk associated with the instance, if applicable.
`region`	The Region in which the instance is running.
`version`	The version of the instance identity document format.

Retrieve the instance identity document for an EC2 instance

The instance identity document for an Amazon EC2 instance uses a plaintext JSON format. For a description of the contents of an instance identity document, see the section called “Instance identity documents”.

The instance identity document is stored in the instance metadata for the instance, in the `instance-identity/document` dynamic data category. You access the instance identity document for an instance by connecting to the instance and retrieving it from the instance metadata.

You can access instance metadata using the IPv4 address 169.254.169.254 or the IPv6 address fd00:ec2::254. These are Link-local addresses, meaning that you can access them only from the instance. The examples on this page use the IPv4 address of the IMDS: 169.254.169.254. To retrieve instance metadata for EC2 instances over IPv6, use fd00:ec2::254.

To verify the authenticity of an instance identity document after you retrieve it, see Verify instance identity document.

IMDSv2

Linux

Run the following command from your Linux instance to retrieve the instance identity document.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/dynamic/instance-identity/document
```

Windows

Run the following cmdlet from your Windows instance to retrieve the instance identity document.

```
[string]$token = (Invoke-WebRequest -Headers @{'X-aws-ec2-metadata-token-ttl-seconds' = '21600'} `
    -Method PUT -Uri 'http://169.254.169.254/latest/api/token' -UseBasicParsing).Content
```

```
(Invoke-WebRequest -Headers @{'X-aws-ec2-metadata-token' = $token} `
    -Uri 'http://169.254.169.254/latest/dynamic/instance-identity/document' -
UseBasicParsing).Content
```

IMDSv1

Linux

Run the following command from your Linux instance to retrieve the instance identity document.

```
curl http://169.254.169.254/latest/dynamic/instance-identity/document
```

Windows

Run the following cmdlet from your Windows instance to retrieve the instance identity document.

```
(Invoke-WebRequest http://169.254.169.254/latest/dynamic/instance-identity/
document).Content
```

The following is example output.

```
{
    "devpayProductCodes" : null,
    "marketplaceProductCodes" : [ "1abc2defghijklm3nopqrs4tu" ],
    "availabilityZone" : "us-west-2b",
    "privateIp" : "10.158.112.84",
    "version" : "2017-09-30",
    "instanceId" : "i-1234567890abcdef0",
    "billingProducts" : null,
    "instanceType" : "t2.micro",
    "accountId" : "123456789012",
    "imageId" : "ami-5fb8c835",
    "pendingTime" : "2016-11-19T16:32:11Z",
    "architecture" : "x86_64",
    "kernelId" : null,
    "ramdiskId" : null,
    "region" : "us-west-2"
}
```

Verify the instance identity document for an Amazon EC2 instance

If you intend to use the contents of the instance identity document for an important purpose, you should verify its contents and authenticity before using it.

The plaintext instance identity document is accompanied by three hashed and encrypted signatures. You can use these signatures to verify the origin and authenticity of the instance identity document and the information that it includes. The following signatures are provided:

- Base64-encoded signature—This is a base64-encoded SHA256 hash of the instance identity document that is encrypted using an RSA key pair.
- PKCS7 signature—This is a SHA1 hash of the instance identity document that is encrypted using a DSA key pair.
- RSA-2048 signature—This is a SHA256 hash of the instance identity document that is encrypted using an RSA-2048 key pair.

Each signature is available at a different endpoint in the instance metadata. You can use any one of these signatures depending on your hashing and encryption requirements. To verify the signatures, you must use the corresponding AWS public certificate.

Options

- Option 1: Verify instance identity document using the PKCS7 signature
- Option 2: Verify instance identity document using the base64-encoded signature
- Option 3: Verify instance identity document using the RSA-2048 signature

Option 1: Verify instance identity document using the PKCS7 signature

This topic explains how to verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate.

Linux instances

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.

2. Retrieve the PKCS7 signature from the instance metadata and add it to a new file named `pkcs7` along with the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

   ```
   $ echo "-----BEGIN PKCS7-----" >> pkcs7 \
    && TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/dynamic/instance-identity/pkcs7 >> pkcs7 \
    && echo "" >> pkcs7 \
    && echo "-----END PKCS7-----" >> pkcs7
   ```

   IMDSv1

   ```
   $ echo "-----BEGIN PKCS7-----" >> pkcs7 \
    && curl -s http://169.254.169.254/latest/dynamic/instance-identity/pkcs7
    >> pkcs7 \
    && echo "" >> pkcs7 \
    && echo "-----END PKCS7-----" >> pkcs7
   ```

3. Find the **DSA** public certificate for your Region in [AWS public certificates for instance identity document signatures] and add the contents to a new file named `certificate`.

4. Use the **OpenSSL smime** command to verify the signature. Include the `-verify` option to indicate that the signature needs to be verified, and the `-noverify` option to indicate that the certificate does not need to be verified.

   ```
   $ openssl smime -verify -in pkcs7 -inform PEM -certfile certificate -noverify | tee
    document
   ```

   If the signature is valid, the `Verification successful` message appears.

   The command also writes the contents of the instance identity document to a new file named `document`. You can compare the contents of the of the instance identity document from the instance metadata with the contents of this file using the following commands.

   ```
   $ openssl dgst -sha256 < document
   ```

```
$ curl -s -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/
dynamic/instance-identity/document | openssl dgst -sha256
```

If the signature cannot be verified, contact Support.

Windows instances

Prerequisites

This procedure requires the `System.Security` Microsoft .NET Core class. To add the class to your PowerShell session, run the following command.

```
PS C:\> Add-Type -AssemblyName System.Security
```

> **Note**
>
> The command adds the class to the current PowerShell session only. If you start a new session, you must run the command again.

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.
2. Retrieve the PKCS7 signature from the instance metadata, convert it to a byte array, and add it to a variable named `$Signature`. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

   ```
   PS C:\> [string]$token = (Invoke-WebRequest -Method Put -Headers @{'X-aws-ec2-
   metadata-token-ttl-seconds' = '21600'} -Uri http://169.254.169.254/latest/api/
   token).Content
   ```

   ```
   PS C:\> $Signature = [Convert]::FromBase64String((Invoke-WebRequest -Headers
    @{'X-aws-ec2-metadata-token' = $Token} -Uri http://169.254.169.254/latest/
   dynamic/instance-identity/pkcs7).Content)
   ```

IMDSv1

```
PS C:\> $Signature = [Convert]::FromBase64String((Invoke-WebRequest -Uri
 http://169.254.169.254/latest/dynamic/instance-identity/pkcs7).Content)
```

3. Retrieve the plaintext instance identity document from the instance metadata, convert it to a byte array, and add it to a variable named `$Document`. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

```
PS C:\> $Document = [Text.Encoding]::UTF8.GetBytes((Invoke-WebRequest -Headers
 @{'X-aws-ec2-metadata-token' = $Token} -Uri http://169.254.169.254/latest/
dynamic/instance-identity/document).Content)
```

   IMDSv1

```
PS C:\> $Document =  [Text.Encoding]::UTF8.GetBytes((Invoke-WebRequest
 http://169.254.169.254/latest/dynamic/instance-identity/document).Content)
```

4. Find the **DSA** public certificate for your Region in AWS public certificates for instance identity document signatures and add the contents to a new file named `certificate.pem`.
5. Extract the certificate from the certificate file and store it in a variable named `$Store`.

```
PS C:\> $Store =
 [Security.Cryptography.X509Certificates.X509Certificate2Collection]::new([Security.Cryptog
Path certificate.pem)))
```

6. Verify the signature.

```
PS C:\> $SignatureDocument = [Security.Cryptography.Pkcs.SignedCms]::new()
```

```
PS C:\> $SignatureDocument.Decode($Signature)
```

```
PS C:\> $SignatureDocument.CheckSignature($Store, $true)
```

   If the signature is valid, the command returns no output. If the signature cannot be verified, the command returns `Exception calling "CheckSignature" with "2"` argument(s): "Cannot find the original signer. If your signature cannot be verified, contact AWS Support.

7. Validate the content of the instance identity document.

```
PS C:
\> [Linq.Enumerable]::SequenceEqual($SignatureDocument.ContentInfo.Content, $Document)
```

If the content of the instance identity document is valid, the command returns `True`. If instance identity document can't be validated, contact AWS Support.

Option 2: Verify instance identity document using the base64-encoded signature

This topic explains how to verify the instance identity document using the base64-encoded signature and the AWS RSA public certificate.

Linux instances

To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate

1. Connect to the instance.
2. Retrieve the base64-encoded signature from the instance metadata, convert it to binary, and add it to a file named `signature`. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

   ```
   $ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/dynamic/instance-identity/signature | base64 -d >> signature
   ```

   IMDSv1

   ```
   $ curl -s http://169.254.169.254/latest/dynamic/instance-identity/signature |
    base64 -d >> signature
   ```

3. Retrieve the plaintext instance identity document from the instance metadata and add it to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

   ```
   $ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/dynamic/instance-identity/document >> document
   ```

   IMDSv1

   ```
   $ curl -s http://169.254.169.254/latest/dynamic/instance-identity/document
    >> document
   ```

4. Find the **RSA** public certificate for your Region in AWS public certificates for instance identity document signatures and add the contents to a new file named `certificate`.
5. Extract the public key from the AWS RSA public certificate and save it to a file named `key`.

   ```
   $ openssl x509 -pubkey -noout -in certificate >> key
   ```

6. Use **OpenSSL dgst** command to verify the instance identity document.

   ```
   $ openssl dgst -sha256 -verify key -signature signature document
   ```

   If the signature is valid, the `Verification successful` message appears.

   The command also writes the contents of the instance identity document to a new file named `document`. You can compare the contents of the of the instance identity document from the instance metadata with the contents of this file using the following commands.

   ```
   $ openssl dgst -sha256 < document
   ```

   ```
   $ curl -s -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/dynamic/instance-identity/document | openssl dgst -sha256
   ```

   If the signature cannot be verified, contact Support.

Windows instances

To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate

1. Connect to the instance.
2. Retrieve the base64-encoded signature from the instance metadata, convert it to a byte array, and add it to variable named `$Signature`. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

   ```
   PS C:\> [string]$token = (Invoke-WebRequest -Method Put -Headers @{'X-aws-ec2-metadata-token-ttl-seconds' = '21600'} http://169.254.169.254/latest/api/token).Content
   ```

   ```
   PS C:\> $Signature = [Convert]::FromBase64String((Invoke-WebRequest -Headers @{'X-aws-ec2-metadata-token' = $Token} http://169.254.169.254/latest/dynamic/instance-identity/signature).Content)
   ```

   IMDSv1

   ```
   PS C:\> $Signature = [Convert]::FromBase64String((Invoke-WebRequest http://169.254.169.254/latest/dynamic/instance-identity/signature).Content)
   ```

3. Retrieve the plaintext instance identity document from the instance metadata, convert it to a byte array, and add it to a variable named `$Document`. Use one of the following commands depending on the IMDS version used by the instance.

   IMDSv2

   ```
   PS C:\> $Document = [Text.Encoding]::UTF8.GetBytes((Invoke-WebRequest -Headers @{'X-aws-ec2-metadata-token' = $Token} http://169.254.169.254/latest/dynamic/instance-identity/document).Content)
   ```

   IMDSv1

   ```
   PS C:\> $Document =  [Text.Encoding]::UTF8.GetBytes((Invoke-WebRequest http://169.254.169.254/latest/dynamic/instance-identity/document).Content)
   ```

4. Find the **RSA** public certificate for your Region in [AWS public certificates for instance identity document signatures](#) and add the contents to a new file named `certificate.pem`.

5. Verify the instance identity document.

```
PS C:\> [Security.Cryptography.X509Certificates.X509Certificate2]::new((Resolve-
Path certificate.pem)).PublicKey.Key.VerifyData($Document, 'SHA256', $Signature)
```

If the signature is valid, the command returns `True`. If the signature cannot be verified, contact Support.

Option 3: Verify instance identity document using the RSA-2048 signature

This topic explains how to verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate.

Linux instances

To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate

1. Connect to the instance.

2. Retrieve the RSA-2048 signature from the instance metadata and add it to a file named `rsa2048` along the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
$ echo "-----BEGIN PKCS7-----" >> rsa2048 \
 && TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-
metadata-token-ttl-seconds: 21600"` \
 && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/
dynamic/instance-identity/rsa2048 >> rsa2048 \
 && echo "" >> rsa2048 \
 && echo "-----END PKCS7-----" >> rsa2048
```

IMDSv1

```
$ echo "-----BEGIN PKCS7-----" >> rsa2048 \
```

```
&& curl -s http://169.254.169.254/latest/dynamic/instance-identity/rsa2048
>> rsa2048 \
&& echo "" >> rsa2048 \
&& echo "-----END PKCS7-----" >> rsa2048
```

3. Find the **RSA-2048** public certificate for your Region in [AWS public certificates for instance identity document signatures](#) and add the contents to a new file named `certificate`.
4. Use the **OpenSSL smime** command to verify the signature. Include the `-verify` option to indicate that the signature needs to be verified, and the `-noverify` option to indicate that the certificate does not need to be verified.

   ```
   $ openssl smime -verify -in rsa2048 -inform PEM -certfile certificate -noverify |
    tee document
   ```

   If the signature is valid, the `Verification successful` message appears. If the signature cannot be verified, contact Support.

Windows instances

Prerequisites

This procedure requires the `System.Security` Microsoft .NET Core class. To add the class to your PowerShell session, run the following command.

```
PS C:\> Add-Type -AssemblyName System.Security
```

> **Note**
>
> The command adds the class to the current PowerShell session only. If you start a new session, you must run the command again.

To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate

1. Connect to the instance.
2. Retrieve the RSA-2048 signature from the instance metadata, convert it to a byte array, and add it to a variable named `$Signature`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
PS C:\> [string]$token = (Invoke-WebRequest -Method Put -Headers @{'X-aws-
ec2-metadata-token-ttl-seconds' = '21600'} http://169.254.169.254/latest/api/
token).Content
```

```
PS C:\> $Signature = [Convert]::FromBase64String((Invoke-WebRequest -Headers
 @{'X-aws-ec2-metadata-token' = $Token} http://169.254.169.254/latest/dynamic/
instance-identity/rsa2048).Content)
```

IMDSv1

```
PS C:\> $Signature = [Convert]::FromBase64String((Invoke-WebRequest
 http://169.254.169.254/latest/dynamic/instance-identity/rsa2048).Content)
```

3. Retrieve the plaintext instance identity document from the instance metadata, convert it to a byte array, and add it to a variable named `$Document`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
PS C:\> $Document = [Text.Encoding]::UTF8.GetBytes((Invoke-WebRequest -Headers
 @{'X-aws-ec2-metadata-token' = $Token} http://169.254.169.254/latest/dynamic/
instance-identity/document).Content)
```

IMDSv1

```
PS C:\> $Document =  [Text.Encoding]::UTF8.GetBytes((Invoke-WebRequest
 http://169.254.169.254/latest/dynamic/instance-identity/document).Content)
```

4. Find the **RSA-2048** public certificate for your Region in AWS public certificates for instance identity document signatures and add the contents to a new file named `certificate.pem`.

5. Extract the certificate from the certificate file and store it in a variable named `$Store`.

```
PS C:\> $Store =
 [Security.Cryptography.X509Certificates.X509Certificate2Collection]::new([Security.Cryptog
Path certificate.pem)))
```

6. Verify the signature.

```
PS C:\> $SignatureDocument = [Security.Cryptography.Pkcs.SignedCms]::new()
```

```
PS C:\> $SignatureDocument.Decode($Signature)
```

```
PS C:\> $SignatureDocument.CheckSignature($Store, $true)
```

If the signature is valid, the command returns no output. If the signature cannot be verified, the command returns `Exception calling "CheckSignature" with "2" argument(s): "Cannot find the original signer`. If your signature cannot be verified, contact AWS Support.

7. Validate the content of the instance identity document.

```
PS C:
\> [Linq.Enumerable]::SequenceEqual($SignatureDocument.ContentInfo.Content, $Document)
```

If the content of the instance identity document is valid, the command returns `True`. If instance identity document can't be validated, contact AWS Support.

AWS public certificates for instance identity document signatures

The following AWS public certificates can be used to verify the contents of an instance's instance identity document as described in Verify instance identity document.

Ensure that you use the correct certificate for your Region and for the verification procedure that you're using. If you're verifying the PKCS7 signature, use the DSA certificate. If you're verifying the base64-encoded signature, use the RSA certificate. If you're verifying the RSA-2048 signature, use the RSA-2048 certificate.

Expand each Region below to view the Region-specific certificates.

Precision clock and time synchronization on your EC2 instance

A consistent and accurate time reference on your Amazon EC2 instance is crucial for many server tasks and processes. Time stamps in system logs play an essential role in identifying when issues occurred and the chronological order of events. When you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If your instance's date and time settings are inaccurate, it can result in a discrepancy between the date in the signature and the date of the request, leading to AWS rejecting your requests.

To address this important aspect, Amazon offers the Amazon Time Sync Service, which is accessible from all EC2 instances and used by various AWS services. The service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate and current time readings of the Coordinated Universal Time (UTC) global standard.

For the best performance, we recommend using the local Amazon Time Sync Service on your EC2 instances. For a backup to the local Amazon Time Sync Service on your instances, or to connect resources outside of Amazon EC2 to the Amazon Time Sync Service, you can use the public Amazon Time Sync Service located at `time.aws.com`. The public Amazon Time Sync Service, like the local Amazon Time Sync Service, automatically smears any leap seconds that are added to UTC. The public Amazon Time Sync Service is supported globally by our fleet of satellite-connected and atomic reference clocks in each AWS Region.

Hardware packet timestamping

You can enable hardware packet timestamping on your instance to add a 64-bit nanosecond-precision timestamp to every incoming network packet. Because hardware packet timestamping occurs at the hardware level—before the packet reaches the kernel, socket, or application layer—you bypass any delays added by software timestamping. The underlying reference clock for hardware timestamping is the Amazon Time Sync Service PTP hardware clock.

Benefits

Hardware packet timestamping provides the following benefits:

- Improves event ordering, which can also be used to determine the actual order in which packets arrive at your EC2 instance, ensuring fair packet processing.
- Measures one-way network latency.
- Increases distributed transaction speed with higher precision and accuracy compared to most on-premises solutions.

Prerequisites and configuration

To enable hardware packet timestamping, your instance must meet the following prerequisites:

- Must be a Linux instance.
- Meet the requirements to support the PTP hardware clock.

For the configuration instructions, see Hardware Packet Timestamping on the **Linux kernel driver for Elastic Network Adapter (ENA) family** page on *GitHub*.

Leap seconds

Leap seconds, introduced in 1972, are occasional one-second adjustments to UTC time to factor in irregularities in the earth's rotation in order to accommodate differences between International Atomic Time (TAI) and solar time (Ut1). To manage leap seconds on behalf of customers, we designed leap second smearing within the Amazon Time Sync Service. For more information, see Look Before You Leap – The Coming Leap Second and AWS.

Leap seconds are going away, and we are in full support of the decision made at the 27th General Conference on Weights and Measures to abandon leap seconds by or before 2035.

To support this transition, we still plan on smearing time during a leap second event when accessing the Amazon Time Sync Service over the local NTP connection or our public NTP pools (`time.aws.com`). The PTP hardware clock, however, does not provide a smeared time option. In the event of a leap second, the PTP hardware clock will add the leap second following UTC standards. Leap-smeared and leap second time sources are the same in most cases. But because they differ during a leap second event, we do not recommend using both smeared and non-smeared time sources in your time client configuration during a leap second event.

Topics

Set the time reference on your EC2 instance to use the local Amazon Time Sync Service

The local Amazon Time Sync Service either uses the Network Time Protocol (NTP), or provides a local Precision Time Protocol (PTP) hardware clock on supported instances. The PTP hardware clock supports either an NTP connection (Linux and Windows instances), or a direct PTP connection (Linux instances only). The NTP and direct PTP connections use the same highly accurate time source, but the direct PTP connection is more accurate than the NTP connection. The NTP connection to the Amazon Time Sync Service supports leap smearing while the PTP connection to the PTP hardware clock does not smear time. For more information, see Leap seconds.

Your instances can access the local Amazon Time Sync Service as follows:

- Through NTP at the following IP address endpoints:
  - IPv4: `169.254.169.123`
  - IPv6: `fd00:ec2::123` (Only accessible on Nitro-based instances.)
- (Linux only) Through a direct PTP connection to connect to a local PTP hardware clock:
  - `PHC0`

Amazon Linux AMIs, Windows AMIs, and most partner AMIs configure your instance to use the NTP IPv4 endpoint by default. This is the recommended setting for most customer workloads. No further configuration is required for instances launched from these AMIs unless you want to use the IPv6 endpoint or connect directly to the PTP hardware clock.

NTP and PTP connections do not require any VPC configuration changes, and your instance does not require access to the internet.

Considerations

- There is a 1024 packet per second (PPS) limit to services that use link-local addresses. This limit includes the aggregate of Route 53 Resolver DNS Queries, Instance Metadata Service (IMDS) requests, Amazon Time Service Network Time Protocol (NTP) requests, and Windows Licensing Service (for Microsoft Windows based instances) requests.
- Only Linux instances can use a *direct PTP connection* to connect to the local PTP hardware clock. Windows instances use NTP to connect to the local PTP hardware clock.

Contents

Connect to the IPv4 endpoint of the Amazon Time Sync Service

Your AMI might already have configured the Amazon Time Sync Service by default. Otherwise, use the following procedures to configure your instance to use the local Amazon Time Sync Service through the IPv4 endpoint.

For help troubleshooting issues, see Troubleshoot NTP synchronization issues on Linux instances or Troubleshoot time issues on Windows instances.

Amazon Linux

AL2023 and recent versions of Amazon Linux 2 are configured to use the Amazon Time Sync Service IPv4 endpoint by default. If you confirm that your instance is already configured, you can skip the following procedure.

To verify that chrony is configured to use the IPv4 endpoint

Run the following command. In the output, the line that starts with ^* indicates the preferred time source.

```
chronyc sources -v | grep -F ^*
^* 169.254.169.123               3   4   377    14    +12us[+9653ns] +/-  290us
```

To configure chrony to connect to the IPv4 endpoint on older versions of Amazon Linux 2

1. Connect to your instance and uninstall the NTP service.

```
[ec2-user ~]$ sudo yum erase 'ntp*'
```

2. Install the `chrony` package.

```
[ec2-user ~]$ sudo yum install chrony
```

3. Open the `/etc/chrony.conf` file using a text editor (such as **vim** or **nano**). Add the following line before any other `server` or `pool` statements that may be present in the file, and save your changes:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

4. Restart the `chrony` daemon (`chronyd`).

```
[ec2-user ~]$ sudo service chronyd restart
```

```
Starting chronyd:                                          [  OK  ]
```

> **Note**
>
> On RHEL and CentOS (up to version 6), the service name is `chrony` instead of `chronyd`.

5. To configure `chronyd` to start at each system boot, use the `chkconfig` command.

```
[ec2-user ~]$ sudo chkconfig chronyd on
```

6. Verify that `chrony` is using the `169.254.169.123` IPv4 endpoint to synchronize the time.

```
[ec2-user ~]$ chronyc sources -v | grep -F ^*
```

In the output, `^*` indicates the preferred time source.

```
^* 169.254.169.123               3   6    17     43    -30us[ -226us] +/-   287us
```

7. Verify the time synchronization metrics that are reported by chrony.

```
[ec2-user ~]$ chronyc tracking
```

```

```

Ubuntu

To configure chrony to connect to the IPv4 endpoint on Ubuntu

1. Connect to your instance and use apt to install the chrony package.

```
ubuntu:~$ sudo apt install chrony
```

Note

If necessary, update your instance first by running sudo apt update.

2. Open the /etc/chrony/chrony.conf file using a text editor (such as **vim** or **nano**). Add the following line before any other server or pool statements that are already present in the file, and save your changes:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

3. Restart the chrony service.

```
ubuntu:~$ sudo /etc/init.d/chrony restart
```

```
Restarting chrony (via systemctl): chrony.service.
```

4. Verify that chrony is using the 169.254.169.123 IPv4 endpoint to synchronize the time.

```
ubuntu:~$ chronyc sources -v | grep -F ^*
```

In the output, the line starting with ^* indicates the preferred time source.

```
^* 169.254.169.123               3   6    17    12    +15us[  +57us] +/-  320us
```

5. Verify the time synchronization metrics that are reported by chrony.

```
ubuntu:~$ chronyc tracking
```

```

```

SUSE Linux

Starting with SUSE Linux Enterprise Server 15, chrony is the default implementation of NTP.

To configure chrony to connect to IPv4 endpoint on SUSE Linux

1. Open the /etc/chrony.conf file using a text editor (such as **vim** or **nano**).
2. Verify that the file contains the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If this line is not present, add it.

3. Comment out any other server or pool lines.
4. Open YaST and enable the chrony service.

Windows

Starting with the August 2018 release, Windows AMIs use the Amazon Time Sync Service by default. No further configuration is required for instances launched from these AMIs and you can skip the following procedures.

If you're using an AMI that doesn't have the Amazon Time Sync Service configured by default, first verify your current NTP configuration. If your instance is already using the IPv4 endpoint of the Amazon Time Sync Service, no further configuration is required. If your instance is not using the Amazon Time Sync Service, then complete the procedure to change the NTP server to use the Amazon Time Sync Service.

To verify the NTP configuration

1. From your instance, open a Command Prompt window.
2. Get the current NTP configuration by typing the following command:

```
w32tm /query /configuration
```

This command returns the current configuration settings for the Windows instance and will show if you're connected to the Amazon Time Sync Service.

3. (Optional) Get the status of the current configuration by typing the following command:

```
w32tm /query /status
```

This command returns information such as the last time the instance synced with the NTP server and the poll interval.

To change the NTP server to use the Amazon Time Sync Service

1. From the Command Prompt window, run the following command:

```
w32tm /config /manualpeerlist:169.254.169.123 /syncfromflags:manual /update
```

2. Verify your new settings by using the following command:

```
w32tm /query /configuration
```

   In the output that's returned, verify that `NtpServer` displays the `169.254.169.123` IPv4 endpoint.

Default NTP settings for Amazon Windows AMIs

Amazon Machine Images (AMIs) generally adhere to the out-of-the-box defaults except in cases where changes are required to function on EC2 infrastructure. The following settings have been determined to work well in a virtual environment, as well as to keep any clock drift to within one second of accuracy:

- **Update Interval** – Governs how frequently the time service will adjust system time towards accuracy. AWS configures the update interval to occur once every two minutes.
- **NTP Server** – Starting with the August 2018 release, AMIs use the Amazon Time Sync Service by default. This time service is accessible from any AWS Region at the 169.254.169.123 IPv4 endpoint. Additionally, the 0x9 flag indicates that the time service is acting as a client, and to use `SpecialPollInterval` to determine how frequently to check in with the configured time server.
- **Type** – "NTP" means that the service acts as a standalone NTP client instead of acting as part of a domain.
- **Enabled and InputProvider** – The time service is enabled and provides time to the operating system.
- **Special Poll Interval** – Checks against the configured NTP Server every 900 seconds (15 minutes).

Registry path	Key name	Data
HKLM:\System\CurrentControlSet\services\w32time\Config	UpdateInterval	120
HKLM:\System\CurrentControlSet\services\w32time\Parameters	NtpServer	169.254.169.123,0x9
HKLM:\System\CurrentControlSet\services\w32time\Parameters	Type	NTP
HKLM:\System\CurrentControlSet\services\w32time\TimeProviders\NtpClient	Enabled	1
HKLM:\System\CurrentControlSet\services\w32time\TimeProviders\NtpClient	InputProvider	1
HKLM:\System\CurrentControlSet\services\w32time\TimeProviders\NtpClient	SpecialPollInterval	900

Connect to the IPv6 endpoint of the Amazon Time Sync Service

This section explains how the steps described in Connect to the IPv4 endpoint of the Amazon Time Sync Service differ if you are configuring your instance to use the local Amazon Time Sync Service through the IPv6 endpoint. It doesn't explain the entire Amazon Time Sync Service configuration process.

The IPv6 endpoint is only accessible on Nitro-based instances.

We don't recommend using both the IPv4 and IPv6 endpoint entries together. The IPv4 and IPv6 NTP packets come from the same local server for your instance. Configuring both IPv4 and IPv6 endpoints is unnecessary and will not improve the accuracy of the time on your instance.

Linux

Depending on the Linux distribution you're using, when you reach the step to edit the `chrony.conf` file, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (`fd00:ec2::123`) rather than the IPv4 endpoint (`169.254.169.123`):

```
server fd00:ec2::123 prefer iburst minpoll 4 maxpoll 4
```

Save the file and verify that chrony is using the `fd00:ec2::123` IPv6 endpoint to synchronize time:

```
[ec2-user ~]$ chronyc sources -v
```

In the output, if you see the `fd00:ec2::123` IPv6 endpoint, the configuration is complete.

Windows

When you reach the step to change the NTP server to use the Amazon Time Sync Service, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (`fd00:ec2::123`) rather than the IPv4 endpoint (`169.254.169.123`):

```
w32tm /config /manualpeerlist:fd00:ec2::123 /syncfromflags:manual /update
```

Verify that your new settings are using the `fd00:ec2::123` IPv6 endpoint to synchronize time:

```
w32tm /query /configuration
```

In the output, verify that `NtpServer` displays the `fd00:ec2::123` IPv6 endpoint.

Connect to the PTP hardware clock

The PTP hardware clock is part of the [AWS Nitro System], so it is directly accessible on [supported bare metal and virtualized EC2 instances] without using any customer resources.

The NTP endpoints for the PTP hardware clock are the same as those for the regular Amazon Time Sync Service. If your instance has a PTP hardware clock and you configured the NTP connection (to either the IPv4 or IPv6 endpoint), your instance time is automatically sourced from the PTP hardware clock over NTP.

For Linux instances, you can configure a *direct* PTP connection, which will give you more accurate time than the NTP connection. Windows instances only support an NTP connection to the PTP hardware clock.

Requirements

The PTP hardware clock is available on an instance when the following requirements are met:

- Supported AWS Regions: US East (N. Virginia), US East (Ohio), Asia Pacific (Malaysia), Asia Pacific (Thailand), Asia Pacific (Tokyo), and Europe (Stockholm)
- Supported Local Zones: US East (New York City)
- Supported instance families:
  - **General purpose:** M7a, M7g, M7i
  - **Memory optimized:** R7a, R7g, R7i
  - **Storage optimized:** I8g, I8ge
- (Linux only) ENA driver version 2.10.0 or later installed on a supported operating system. For more information about supported operating systems, see the driver prerequisites on *GitHub*.

(Linux only) Configure a direct PTP connection to the PTP hardware clock

This section describes how to configure your Linux instance to use the local Amazon Time Sync Service through the PTP hardware clock using a direct PTP connection. It requires adding a server entry for the PTP hardware clock in the `chrony` configuration file.

To configure a direct PTP connection to the PTP hardware clock (Linux instances only)

1. **Install prerequisites**

   Connect to your Linux instance and do the following:

   a. Install the Linux kernel driver for Elastic Network Adapter (ENA) version 2.10.0 or later.
   b. Enable the PTP hardware clock.

   For the installation instructions, see Linux kernel driver for Elastic Network Adapter (ENA) family on *GitHub*.

2. **Verify ENA PTP device**

   Verify that the ENA PTP hardware clock device shows up on your instance.

```
[ec2-user ~]$ for file in /sys/class/ptp/*; do echo -n "$file: "; cat "$file/clock_name"; done
```

Expected output

```
/sys/class/ptp/ptp<index>: ena-ptp-<PCI slot>
```

Where:

- *index* is the kernel-registered PTP hardware clock index.
- *PCI slot* is the ENA ethernet controller PCI slot. This is the same slot as shown in `lspci | grep ENA`.

Example output

```
/sys/class/ptp/ptp0: ena-ptp-05
```

If `ena-ptp-<PCI slot>` is not in the output, the ENA driver was not correctly installed. Review step 1 in this procedure for installing the driver.

3. **Configure PTP symlink**

   PTP devices are typically named `/dev/ptp0`, `/dev/ptp1`, and so on, with their index depending on the hardware initialization order. Creating a symlink ensures that applications like chrony consistently reference the correct device, regardless of index changes.

   The latest Amazon Linux 2023 AMIs include a `udev` rule that creates the `/dev/ptp_ena` symlink, pointing to the correct `/dev/ptp` entry associated with the ENA host.

   First check if the symlink is present by running the following command.

```
[ec2-user ~]$ ls -l /dev/ptp*
```

   Example output

```
crw------- 1 root root 245, 0 Jan 31 2025 /dev/ptp0
lrwxrwxrwx 1 root root      4 Jan 31 2025 /dev/ptp_ena -> ptp0
```

Where:

- /dev/ptp*<index>* is the path to the PTP device.
- /dev/ptp_ena is the constant symlink, which points to the same PTP device.

If the /dev/ptp_ena symlink is present, skip to Step 4 in this procedure. If it's missing, do the following:

a. Add the following udev rule.

```
[ec2-user ~]$ echo "SUBSYSTEM==\"ptp\", ATTR{clock_name}==\"ena-ptp-*\",
 SYMLINK += \"ptp_ena\"" | sudo tee -a /etc/udev/rules.d/53-ec2-network-
interfaces.rules
```

b. Reload the udev rule, either by rebooting the instance, or by running the following command.

```
[ec2-user ~]$ sudo udevadm control --reload-rules && udevadm trigger
```

4. **Configure chrony**

chrony must be configured to use the /dev/ptp_ena symlink instead of directly referencing /dev/ptp*<index>*.

a. Edit /etc/chrony.conf using a text editor and add the following line anywhere in the file.

```
refclock PHC /dev/ptp_ena poll 0 delay 0.000010 prefer
```

b. Restart chrony.

```
[ec2-user ~]$ sudo systemctl restart chronyd
```

5. **Verify chrony configuration**

Verify that chrony is using the PTP hardware clock to synchronize the time on this instance.

```
[ec2-user ~]$ chronyc sources
```

Expected output

```
MS Name/IP address         Stratum Poll Reach LastRx Last sample
===============================================================================
#* PHC0                          0   0   377    1   +2ns[ +1ns] +/-   5031ns
```

In the output that's returned, * indicates the preferred time source. PHC0 corresponds to the PTP hardware clock. You might need to wait a few seconds after restarting chrony for the asterisk to appear.

Set the time reference on your EC2 instance or any internet-connected device to use the public Amazon Time Sync Service

You can set your instance, or any internet-connected device such as your local computer or an on-prem server, to use the public Amazon Time Sync Service, which is accessible over the internet at `time.aws.com`. You can use the public Amazon Time Sync Service as a backup for the local Amazon Time Sync Service and to connect resources outside of AWS to the Amazon Time Sync Service.

> **Note**
>
> For the best performance, we recommend using the *local* Amazon Time Sync Service on your instances, and only using the *public* Amazon Time Sync Service as a backup.

Use the instructions for the operating system of your instance or device.

Linux

To set your Linux instance or device to use the public Amazon Time Sync Service using chrony or ntpd

1. Edit `/etc/chrony.conf` (if you use chrony) or `/etc/ntp.conf` (if you use ntpd) using a text editor as follows:

a. To prevent your instance or device from trying to mix smeared and non-smeared servers, remove or comment out lines starting with `server` except any existing connection to the local Amazon Time Sync Service.

> **Important**
>
> If you're setting your EC2 instance to connect to the public Amazon Time Sync Service, do not remove the following line which sets your instance to connect to the local Amazon Time Sync Service. The local Amazon Time Sync Service is a more direct connection and will provide better clock accuracy. The public Amazon Time Sync Service should only be used as a backup.
>
> ```
> server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
> ```

b. Add the following line to connect to the public Amazon Time Sync Service.

```
pool time.aws.com iburst
```

2. Restart the daemon using one of the following commands.

   - chrony

   ```
   sudo service chronyd force-reload
   ```

   - ntpd

   ```
   sudo service ntp reload
   ```

macOS

To set your macOS instance or device to use the public Amazon Time Sync Service

1. Open **System Preferences**.
2. Choose **Date & Time**, and then choose the **Date & Time** tab.
3. To make changes, choose the lock icon, and enter your password when prompted.
4. For **Set date and time automatically**, enter **`time.aws.com`**.

Windows

To set your Windows instance or device to use the public Amazon Time Sync Service

1. Open the **Control Panel**.
2. Choose the **Date and Time** icon.
3. Choose the **Internet Time** tab. This tab is not be available if your PC is part of a domain. In this case, it will synchronize time with the domain controller. You can configure the controller to use the public Amazon Time Sync Service.
4. Choose **Change settings**.
5. Select the checkbox for **Synchronize with an Internet time server**.
6. Next to **Server**, enter **`time.aws.com`**.

To set your Windows Server instance or device to use the public Amazon Time Sync Service

- Follow Microsoft's instructions to update your registry.

Compare timestamps for your Linux instances

If you're using the Amazon Time Sync Service, you can compare the timestamps on your Amazon EC2 Linux instances with ClockBound to determine the true time of an event. ClockBound measures the clock accuracy of your EC2 instance, and allows you to check if a given timestamp is in the past or future with respect to your instance's current clock. This information is valuable for determining the order and consistency of events and transactions across EC2 instances, independent of each instance's geographic location.

ClockBound is an open source daemon and library. To learn more about ClockBound, including installation instructions, see ClockBound on *GitHub*.

ClockBound is only supported for Linux instances.

If you're using the direct PTP connection to the PTP hardware clock, your time daemon, such as chrony, will underestimate the clock error bound. This is because a PTP hardware clock does not pass the correct error bound information to chrony, the way that NTP does. As a result, your clock synchronization daemon assumes the clock is accurate to UTC and thus has an error bound of `0`. To measure the full error bound, the Nitro System calculates the error bound of the PTP hardware clock, and makes it available to your EC2 instance over the ENA driver `sysfs` filesystem. You can read this directly as a value, in nanoseconds.

To retrieve the PTP hardware clock error bound

1. First get the correct location of the PTP hardware clock device by using one of the following commands. The path in the command is different depending on the AMI used to launch the instance.

   - For Amazon Linux 2:

     ```
     cat /sys/class/net/eth0/device/uevent | grep PCI_SLOT_NAME
     ```

   - For Amazon Linux 2023:

     ```
     cat /sys/class/net/ens5/device/uevent | grep PCI_SLOT_NAME
     ```

   The output is the PCI slot name, which is the location of the PTP hardware clock device. In this example, the location is `0000:00:03.0`.

   ```
   PCI_SLOT_NAME=0000:00:03.0
   ```

2. To retrieve the PTP hardware clock error bound, run the following command. Include the PCI slot name from the previous step.

   ```
   cat /sys/bus/pci/devices/0000:00:03.0/phc_error_bound
   ```

   The output is the clock error bound of the PTP hardware clock, in nanoseconds.

To calculate the correct clock error bound at a specific point in time when using the direct PTP connection to the PTP hardware clock, you must add the clock error bound from chrony or ClockBound at the time that chrony polls the PTP hardware clock. For more information about measuring and monitoring clock accuracy, see Manage Amazon EC2 instance clock accuracy using Amazon Time Sync Service and Amazon CloudWatch – Part 1.

Change the time zone of your instance

Amazon EC2 instances are set to the UTC (Coordinated Universal Time) time zone by default. You can change the time on an instance to the local time zone or to another time zone in your network.

Use the instructions for your instance's operating system.

Linux

> **Important**
>
> This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To change the time zone on Amazon Linux

1. View the system's current time zone setting.

   ```
   [ec2-user ~]$ timedatectl
   ```

2. List the available time zones.

   ```
   [ec2-user ~]$ timedatectl list-timezones
   ```

3. Set the chosen time zone.

   ```
   [ec2-user ~]$ sudo timedatectl set-timezone America/Vancouver
   ```

4. (Optional) Confirm that the current time zone is updated to the new time zone by running the **timedatectl** command again.

   ```
   [ec2-user ~]$ timedatectl
   ```

Windows

To change the time zone on a Windows instance

1. From your instance, open a Command Prompt window.

2. Identify the time zone to use on the instance. To get a list of time zones, use the following command:

```
tzutil /l
```

   This command returns a list of all available time zones in the following format:

```
display name
time zone ID
```

3. Locate the time zone ID to assign to the instance.
4. Example: Assign the UTC time zone:

```
tzutil /s "UTC"
```

   Example: Assign Pacific Standard Time:

```
tzutil /s "Pacific Standard Time"
```

When you change the time zone on a Windows instance, you must ensure that the time zone persists through system restarts. Otherwise, when the instance restarts, it reverts back to using UTC time. You can persist your time zone setting by adding a **RealTimeIsUniversal** registry key. This key is set by default on all current generation instances. To verify whether the **RealTimeIsUniversal** registry key is set, see step 3 in the following procedure. If the key is not set, follow these steps from the beginning.

To set the RealTimeIsUniversal registry key

1. From the instance, open a Command Prompt window.
2. Use the following command to add the registry key:

```
reg add "HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation" /
v RealTimeIsUniversal /d 1 /t REG_DWORD /f
```

3. (Optional) Verify that the instance saved the key successfully using the following command:

```
reg query "HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control
\TimeZoneInformation" /s
```

This command returns the subkeys for the **TimeZoneInformation** registry key. You should see the **RealTimeIsUniversal** key at the bottom of the list, similar to the following:

```
HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation
    Bias                            REG_DWORD      0x1e0
    DaylightBias                    REG_DWORD      0xffffffc4
    DaylightName                    REG_SZ         @tzres.dll,-211
    DaylightStart                   REG_BINARY     00000300020002000000000000000000
    StandardBias                    REG_DWORD      0x0
    StandardName                    REG_SZ         @tzres.dll,-212
    StandardStart                   REG_BINARY     00000B00010002000000000000000000
    TimeZoneKeyName                 REG_SZ         Pacific Standard Time
    DynamicDaylightTimeDisabled     REG_DWORD      0x0
    ActiveTimeBias                  REG_DWORD      0x1a4
    RealTimeIsUniversal             REG_DWORD      0x1
```

Manage device drivers for your EC2 instance

Device drivers are software components that communicate with the virtualized hardware for your Amazon EC2 instance. To prevent system errors, performance issues, and other unexpected behavior, it's important to keep your drivers up-to-date. That's especially true for drivers that can have a strong impact on system performance depending on your usage, such as networking, graphics, and storage device drivers. New driver releases can include defect fixes or introduce expanded functionality that you might want to take advantage of for instances that are currently running.

Network drivers

Linux distributions can incorporate networking features like Elastic Network Adapter (ENA) or Elastic Fabric Adapter (EFA) within the kernel. However, the timing may vary for implementation of kernel driver features within the different distributions.

ENA and EFA Linux kernel drivers are available from the Amazon Drivers GitHub repository. For more information and links to the available drivers, see [Amazon Drivers](#) on GitHub.

For more information about ENA drivers, see Enable enhanced networking with ENA on your EC2 instances. For more information about EFA drivers, see **Getting started** topics in the Elastic Fabric Adapter for AI/ML and HPC workloads on Amazon EC2 section of this guide.

To install or update networking drivers on Windows instances, see the following topics:

- Install the ENA driver on Windows
- Install the latest AWS PV drivers

  For more information, see Paravirtual drivers for Windows instances.

Note

EFA is not supported on Windows instances.

Graphics drivers

To install or update graphics drivers, see the following topics:

- AMD drivers for your EC2 instance
- NVIDIA drivers for your Amazon EC2 instance

Storage device drivers

To install or update storage drivers, see the following topics:

- For Linux instances, see Install or upgrade the NVMe driver in the *Amazon EBS User Guide*.
- For Windows instances, see AWS NVMe drivers.

AMD drivers for your EC2 instance

An instance with an attached AMD GPU, such as a G4ad instance, must have the appropriate AMD driver installed. Depending on your requirements, you can either use an AMI with the driver preinstalled or download a driver from Amazon S3.

To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a G4dn instance, see NVIDIA drivers instead.

Contents

AMD Radeon Pro Software for Enterprise Driver

The AMD Radeon Pro Software for Enterprise Driver is built to deliver support for professional-grade graphics use cases. Using the driver, you can configure your instances with two 4K displays per GPU.

Supported APIs

- OpenGL, OpenCL
- Vulkan
- AMD Advanced Media Framework
- Video Acceleration API
- DirectX 9 and later
- Microsoft Hardware Media Foundation Transform

AMIs with the AMD driver installed

AWS offers different Amazon Machine Images (AMIs) that come with the AMD drivers installed. Open Marketplace offerings with the AMD driver.

AMD driver download

If you aren't using an AMI with the AMD driver installed, you can download the AMD driver and install it on your instance. Only the following operating system versions support AMD drivers:

- Amazon Linux 2 with kernel version 5.4
- Ubuntu 20.04
- Ubuntu 22.04
- Ubuntu 24.04
- Windows Server 2016

- Windows Server 2019
- Windows Server 2022

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the AMD Radeon Pro V520 hardware. Upon installation of the software, you are bound by the terms of the AMD End User License Agreement.

Install the AMD driver on your Amazon Linux 2 Linux instance

1. Connect to your Linux instance.
2. Install the AWS CLI on your Linux instance and configure default credentials. For more information, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

   > **Important**
   >
   > Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see AWS managed policy: AmazonS3ReadOnlyAccess in the *Amazon Simple Storage Service User Guide*.

3. Install kernel 5.4

   ```
   $ sudo amazon-linux-extras disable kernel-5.10
   $ sudo amazon-linux-extras enable kernel-5.4
   $ sudo yum install -y kernel
   ```

4. Install **gcc** and **make**, if they are not already installed.

   ```
   $ sudo yum install gcc make
   ```

5. Update your package cache and get the package updates for your instance.

   ```
   $ sudo amazon-linux-extras install epel -y
   $ sudo yum update -y
   ```

6. Reboot the instance.

   ```
   $ sudo reboot
   ```

7. Reconnect to the instance after it reboots.
8. Download the latest AMD driver.

```
$ aws s3 cp --recursive s3://ec2-amd-linux-drivers/latest/ .
```

9. Extract the file.

```
$ tar -xf amdgpu-pro-*rhel*.tar.xz
```

10. Change to the folder for the extracted driver.
11. Run the self install script to install the full graphics stack.

```
$ ./amdgpu-pro-install -y --opencl=pal,legacy
```

12. Reboot the instance.

```
$ sudo reboot
```

13. Confirm that the driver is functional.

```
$ sudo dmesg | grep amdgpu
```

The response should look like the following:

```
Initialized amdgpu
```

Install the AMD driver on your Ubuntu Linux instance

1. Connect to your Linux instance.
2. Update your package cache and get the package updates for your instance.

```
$ sudo apt-get update --fix-missing && sudo apt-get upgrade -y
```

3. Install **gcc** and **make**, if they are not already installed.

```
$ sudo apt install build-essential -y
```

4. Install Linux firmware and kernel modules

```
$ sudo apt install linux-firmware linux-modules-extra-aws -y
```

5. Reboot instance

```
$ sudo reboot
```

6. Reconnect to the instance after it reboots.
7. Install the AMD Linux driver package
   - For Ubuntu 20.04:

   ```
   $ wget https://repo.radeon.com/.preview/afe3e25b8f1beff0bb312e27924d63b5/amdgpu-install/5.4.02.01/ubuntu/focal/amdgpu-install_5.4.02.01.50402-1_all.deb
   $ sudo dpkg --add-architecture i386
   $ sudo apt install ./amdgpu-install_5.4.02.01.50402-1_all.deb
   ```

   - For later Ubuntu versions go to Linux® Drivers for AMD Radeon™ Graphics and download the latest Ubuntu package and install it.

   ```
   $ sudo apt install ./amdgpu-install_{version-you-downloaded}.deb
   ```

8. Run the self install script to install the full graphics stack.

```
$ amdgpu-install --usecase=workstation --vulkan=pro -y
```

9. Reboot the instance.

```
$ sudo reboot
```

10. Confirm that the driver is functional.

```
$ sudo dmesg | grep amdgpu
```

The response should look like the following:

```
Initialized amdgpu
```

Install the AMD driver on your Windows instance

1. Connect to your Windows instance and open a PowerShell window.
2. Configure default credentials for the AWS Tools for Windows PowerShell on your Windows instance. For more information, see Getting Started with the AWS Tools for Windows PowerShell in the *AWS Tools for PowerShell User Guide*.

   Important

   Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see AWS managed policy: AmazonS3ReadOnlyAccess in the *Amazon Simple Storage Service User Guide*.

3. Set the key prefix according to your version of Windows:

   - Windows 10 and Windows 11

   ```
   $KeyPrefix = "latest/AMD_GPU_WINDOWS10"
   ```

   - Windows Server 2016

   ```
   $KeyPrefix = "archives"
   ```

   - Windows Server 2019

   ```
   $KeyPrefix = "latest/AMD_GPU_WINDOWS_2K19" # use "archives" for Windows Server 2016
   ```

   - Windows Server 2022

   ```
   $KeyPrefix = "latest/AMD_GPU_WINDOWS_2K22"
   ```

4. Download the drivers from Amazon S3 to your desktop using the following PowerShell commands.

```
$Bucket = "ec2-amd-windows-drivers"
$LocalPath = "$home\Desktop\AMD"
$Objects = Get-S3Object -BucketName $Bucket -KeyPrefix $KeyPrefix -Region us-east-1
foreach ($Object in $Objects) {
$LocalFileName = $Object.Key
if ($LocalFileName -ne '' -and $Object.Size -ne 0) {
```

```
    $LocalFilePath = Join-Path $LocalPath $LocalFileName
    Copy-S3Object -BucketName $Bucket -Key $Object.Key -LocalFile $LocalFilePath -
Region us-east-1
    }
}
```

5. Unzip the downloaded driver file and run the installer using the following PowerShell commands.

```
Expand-Archive $LocalFilePath -DestinationPath "$home\Desktop\AMD\$KeyPrefix" -
Verbose
```

   Now, check the content of the new directory. The directory name can be retrieved using the `Get-ChildItem` PowerShell command.

```
Get-ChildItem "$home\Desktop\AMD\$KeyPrefix"
```

   The output should be similar to the following:

```
Directory: C:\Users\Administrator\Desktop\AMD\latest

Mode                LastWriteTime         Length Name
----                -------------         ------ ----
d-----       10/13/2021  12:52 AM                210414a-365562C-Retail_End_User.2
```

   Install the drivers:

```
pnputil /add-driver $home\Desktop\AMD\$KeyPrefix\*.inf /install /subdirs
```

6. Follow the instructions to install the driver and reboot your instance as required.
7. To verify that the GPU is working properly, check Device Manager. You should see "AMD Radeon Pro V520 MxGPU" listed as a display adapter.
8. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol, [Amazon DCV](https://docs.aws.amazon.com/dcv/).

NVIDIA drivers for your Amazon EC2 instance

An instance with an attached NVIDIA GPU, such as a P- or G- series instance types, must have the appropriate NVIDIA driver installed. Depending on the instance type, you can either download a public NVIDIA driver, download a driver from Amazon S3 that is available only to AWS customers, or use an AWS AMI with the driver pre-installed.

To install AMD drivers on an instance with an attached AMD GPU, such as a G4ad instance, see AMD drivers instead.

Contents

Types of NVIDIA drivers

The following are the main types of NVIDIA drivers that can be used with GPU-based instances.

Tesla drivers

These drivers are intended primarily for compute workloads, which use GPUs for computational tasks such as parallelized floating-point calculations for machine learning and fast Fourier transforms for high performance computing applications.

GRID drivers

These drivers are certified to provide optimal performance for professional visualization applications that render content such as 3D models or high-resolution videos. You can configure GRID drivers to support two modes. Quadro Virtual Workstations provide access to four 4K displays per GPU. GRID vApps provide RDSH App hosting capabilities.

Gaming drivers

These drivers contain optimizations for gaming and are updated frequently to provide performance enhancements. They support a single 4K display per GPU.

Configured mode

On Windows, the Tesla drivers are configured to run in Tesla Compute Cluster (TCC) mode. The GRID and gaming drivers are configured to run in Windows Display Driver Model (WDDM) mode. In TCC mode, the card is dedicated to compute workloads. In WDDM mode, the card supports both compute and graphics workloads.

NVIDIA control panel

The NVIDIA control panel is supported with GRID and Gaming drivers. It is not supported with Tesla drivers.

Supported APIs for Tesla, GRID, and gaming drivers

- OpenCL, OpenGL, and Vulkan
- NVIDIA CUDA and related libraries (for example, cuDNN, TensorRT, nvJPEG, and cuBLAS)
- NVENC for video encoding and NVDEC for video decoding
- Windows-only APIs: DirectX, Direct2D, DirectX Video Acceleration, DirectX Raytracing

Available drivers by instance type

The following table summarizes the supported NVIDIA drivers for each GPU instance type.

Instance type	Tesla driver	GRID driver	Gaming driver
G3	Yes	Yes	No
G4dn	Yes	Yes	Yes
G5	Yes	Yes	Yes
G5g	Yes [1]	No	No

Instance type	Tesla driver	GRID driver	Gaming driver
G6	Yes	Yes	Yes
G6e	Yes	Yes	Yes
G6f	No	Yes	No
Gr6	Yes	Yes	No
Gr6f	No	Yes	No
P2	Yes	No	No
P3	Yes	No	No
P4d	Yes	No	No
P4de	Yes	No	No
P5	Yes	No	No
P5e	Yes	No	No
P5en	Yes	No	No
P6-B200	Yes	No	No
P6e-GB200	Yes	No	No

[1] This Tesla driver also supports optimized graphics applications specific to the ARM64 platform

Installation options

Use one of the following options to get the NVIDIA drivers required for your GPU instance.

Options

- Option 1: AMIs with NVIDIA drivers installed
- Option 2: Public NVIDIA drivers
- Option 3: GRID drivers (G6, Gr6, G6e, G6f, Gr6f, G5, G4dn, and G3 instances)

- Option 4: NVIDIA gaming drivers (G6, G6e, G5, and G4dn instances)

Option 1: AMIs with NVIDIA drivers installed

AWS and NVIDIA offer different Amazon Machine Images (AMIs) that come with the NVIDIA drivers installed.

- Marketplace offerings with the Tesla driver
- Marketplace offerings with the GRID driver
- Marketplace offerings with the Gaming driver

To review considerations that are dependent on your operating system (OS) platform, choose the tab that applies to your AMI.

Linux

To update the driver version installed using one of these AMIs, you must uninstall the NVIDIA packages from your instance to avoid version conflicts. Use this command to uninstall the NVIDIA packages:

```
[ec2-user ~]$ sudo yum erase nvidia cuda
```

The CUDA toolkit package has dependencies on the NVIDIA drivers. Uninstalling the NVIDIA packages erases the CUDA toolkit. You must reinstall the CUDA toolkit after installing the NVIDIA driver.

Windows

If you create a custom Windows AMI using one of the AWS Marketplace offerings, the AMI must be a standardized image created with Windows Sysprep to ensure that the GRID driver works. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.

Option 2: Public NVIDIA drivers

If the AWS Marketplace AMIs described in Option 1: AMIs with NVIDIA drivers installed don't fit your use case, you can install the public drivers and bring your own license. To install a public driver, download it from the NVIDIA site as described in this section.

Step 1: Download a public NVIDIA driver

Log on to your instance and download the 64-bit NVIDIA driver appropriate for the instance type from http://www.nvidia.com/Download/Find.aspx. For **Product Type**, **Product Series**, and **Product**, use the options in the following table.

Instance	Product type	Product series	Product	Minimum driver version
G3	Tesla	M-Class	M60	--
G4dn	Tesla	T-Series	T4	--
G5	Tesla	A-Series	A10	470.00 or later
G5g[1]	Tesla	T-Series	NVIDIA T4G	470.82.01 or later
G6	Tesla	L-Series	L4	525.0 or later
G6e	Tesla	L-Series	L40S	535.0 or later
Gr6	Tesla	L-Series	L4	525.0 or later
P2	Tesla	K-Series	K80	--
P3	Tesla	V-Series	V100	--
P4d	Tesla	A-Series	A100	--
P4de	Tesla	A-Series	A100	--
P5	Tesla	H-Series	H100	530 or later
P5e	Tesla	H-Series	H200	550 or later
P5en	Tesla	H-Series	H200	550 or later
P6-B200[2]	Tesla	HGX-Series	B200	570 or later
P6e-GB200	Tesla	HGX-Series	B200	570 or later

[1] The operating system for G5g instances is Linux aarch64.

[2] For P6-B200 instance types, there are additional installation requirements to configure NVIDIA Fabric Manager.

Step 2: Install the public driver

Follow the install instructions for your instance type operating system.

Linux

1. To install the NVIDIA Tesla driver on a Linux distribution, see the NVIDIA Driver Installation Guide.
2. P6-B200 instance types require installation and configuration of additional packages that come bundled with the NVIDIA CUDA Toolkit. For more information, see Configure Fabric Manager for P6-B200 instance types.

Windows

To install the NVIDIA driver on Windows, follow these steps:

1. Open the folder where you downloaded the driver and launch the installation file. Follow the instructions to install the driver and reboot your instance as required.
2. Disable the display adapter named **Microsoft Basic Display Adapter** that is marked with a warning icon using Device Manager. Install these Windows features: **Media Foundation** and **Quality Windows Audio Video Experience**.

   > **Important**
   >
   > Don't disable the display adapter named **Microsoft Remote Display Adapter**. If **Microsoft Remote Display Adapter** is disabled your connection might be interrupted and attempts to connect to the instance after it has rebooted might fail.

3. Check Device Manager to verify that the GPU is working correctly.
4. To achieve the best performance from your GPU, complete the optimization steps in Optimize GPU settings on Amazon EC2 instances.

Configure Fabric Manager for P6-B200 instance types

The P6-B200 platform is unique in that it exposes Mellanox ConnectX 7 network interface cards (NICs) to the instance as PCIe devices. These CX7 NICs do not act as typical network interfaces but instead function as NVSwitch bridges providing a control path to initialize and configure the NVFabric, which is the NVLink topology of the GPU interconnect.

To fully initialize the system, the NVIDIA Fabric Manager must configure `NVFabric` and establish the NVSwitch topology. This enables InfiniBand kernel modules to communicate with the CX7 devices.

Installation and configuration steps vary slightly depending on the instance operating system. Follow the instructions on the *NVIDIA Developer* website to get the [CUDA Toolkit]() as either a local or network installer. package for your instance. After you've installed the toolkit, configure NVIDIA Fabric Manager as follows:

Amazon Linux 2023

1. Install NVIDIA Link Subnet Manager and `ibstat`.

```
sudo dnf install nvlink5
```

2. Enable automatic loading of the Infiniband module on startup.

```
echo "ib_umad" | sudo tee -a /etc/modules-load.d/modules.conf
```

3. Enable the NVIDIA Fabric Manager service on startup.

```
sudo dnf install nvidia-fabric-manager
sudo systemctl start nvidia-fabricmanager.service
```

4. Reboot the instance.

```
sudo reboot
```

Ubuntu

1. Install the `mlx5_ib` kernel module.

```
sudo apt install linux-modules-extra-$(uname -r) -y
```

2. Install NVIDIA Link Subnet Manager.

```
sudo apt install nvlsm
```

3. Install `ibstat`.

```
sudo apt install infiniband-diags
```

4. Enable automatic loading of the Infiniband module on startup.

```
echo "ib_umad" | sudo tee -a /etc/modules-load.d/modules.conf
```

5. Enable the NVIDIA Fabric Manager service on startup.

```
sudo apt install nvidia-fabricmanager
sudo systemctl enable nvidia-fabricmanager
```

6. Reboot the instance.

```
sudo reboot
```

Option 3: GRID drivers (G6, Gr6, G6e, G6f, Gr6f, G5, G4dn, and G3 instances)

These downloads are available to AWS customers only. By downloading, in order to adhere to requirements of the AWS solution referred to in the NVIDIA GRID Cloud End User License Agreement (EULA), you agree to use the downloaded software only to develop AMIs for use with the NVIDIA L4, NVIDIA L40S, NVIDIA A10G, NVIDIA Tesla T4, or NVIDIA Tesla M60 hardware. You can use the GRID drivers to both create and use AMIs within the AWS environment. Upon installation of the software, you are bound by the terms of the NVIDIA GRID Cloud End User License Agreement. For information about the version of the NVIDIA GRID driver for your operating system, see the NVIDIA Virtual GPU (vGPU) Software on the NVIDIA website.

Considerations

- G6f and Gr6f instances require GRID 18.4 or later.
- G6e instances require GRID 17.4 or later.
- G6 and Gr6 instances require GRID 17.1 or later.
- G5 instances require GRID 13.1 or later (or GRID 12.4 or later).

- G3 instances require AWS provided DNS resolution for GRID licensing to work.
- IMDSv2 is only supported with NVIDIA driver version 14.0 or greater.
- For Windows instances, if you launch your instance from a custom Windows AMI, the AMI must be a standardized image created with Windows Sysprep to ensure that the GRID driver works. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.
- GRID 17.0 and later do not support Windows Server 2019.
- GRID 14.2 and later do not support Windows Server 2016.
- GRID 17.0 and later is not supported with G3 instances.
- For Linux instances, you might need to install or update packages, such as gcc, if the NVIDIA installer fails with an error message. The specifics depend on the versions of the operating system and the kernel. For more information, see the NVIDIA Enterprise Support Portal.

Prerequisites

- (Linux) Verify that the AWS CLI is installed on your instance and configured with default credentials. For more information, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.
- (Windows) Configure default credentials for the AWS Tools for Windows PowerShell on your instance. For more information, see Getting started with the AWS Tools for Windows PowerShell in the *AWS Tools for PowerShell User Guide*.
- Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy.

Amazon Linux 2023

To install the NVIDIA GRID driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

   ```
   [ec2-user ~]$ sudo dnf update -y
   ```

2. Install **gcc** and **make**, if they are not already installed.

   ```
   [ec2-user ~]$ sudo dnf install gcc make
   ```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers packages.

```
[ec2-user ~]$ sudo dnf install -y kernel-devel kernel-modules-extra
```

6. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

   Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

7. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

8. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

   When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

9. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

10. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the [NVIDIA documentation](#).

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

11. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

12. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

    a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

    b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

Amazon Linux 2

To install the NVIDIA GRID driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install gcc make
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel that is running.

```
[ec2-user ~]$ sudo yum install -y kernel-devel-$(uname -r)
```

6. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

   Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

7. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

8. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

   If you are using Amazon Linux 2 with kernel version 5.10, use the following command to install the GRID driver.

```
[ec2-user ~]$ sudo CC=/usr/bin/gcc10-cc ./NVIDIA-Linux-x86_64*.run
```

   When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

9. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

10. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

11. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

12. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

    a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

    b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

CentOS 7 and Red Hat Enterprise Linux 7

To install the NVIDIA GRID driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install -y gcc make
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel that you are running.

```
[ec2-user ~]$ sudo yum install -y kernel-devel-$(uname -r)
```

6. Disable the nouveau open source driver for NVIDIA graphics cards.

   a. Add nouveau to the /etc/modprobe.d/blacklist.conf blacklist file. Copy the following code block and paste it into a terminal.

   ```
   [ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   blacklist vga16fb
   blacklist nouveau
   blacklist rivafb
   blacklist nvidiafb
   blacklist rivatv
   EOF
   ```

   b. Edit the /etc/default/grub file and add the following line:

   ```
   GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
   ```

   c. Rebuild the Grub configuration.

   ```
   [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

7. Download the GRID driver installation utility using the following command:

   ```
   [ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
   ```

   Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

   ```
   [ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
   ```

8. Add permissions to run the driver installation utility using the following command.

   ```
   [ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
   ```

9. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

   ```
   [ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
   ```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

10. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

11. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

12. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

13. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

    a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

    b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

    c. Install the GUI desktop/workstation package.

    ```
    [ec2-user ~]$ sudo yum groupinstall -y "Server with GUI"
    ```

CentOS Stream 8 and Red Hat Enterprise Linux 8

To install the NVIDIA GRID driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install -y gcc make
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel that you are running.

```
[ec2-user ~]$ sudo dnf install -y elfutils-libelf-devel libglvnd-devel kernel-
devel-$(uname -r)
```

6. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

   Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

7. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

8. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

9. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

10. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

11. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

12. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

    a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

    b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

    c. Install the GUI workstation package.

    ```
    [ec2-user ~]$ sudo dnf groupinstall -y workstation
    ```

Rocky Linux 8

To install the NVIDIA GRID driver on your Linux instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install -y gcc make
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel that you are running.

```
[ec2-user ~]$ sudo dnf install -y elfutils-libelf-devel libglvnd-devel kernel-
devel-$(uname -r)
```

6. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

   Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

7. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

8. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

9. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

10. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

11. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

12. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

    a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

    b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

Ubuntu and Debian

To install the NVIDIA GRID driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
$ sudo apt-get update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo apt-get install -y gcc make
```

3. (Ubuntu) Upgrade the `linux-aws` package to receive the latest version.

```
$ sudo apt-get upgrade -y linux-aws
```

(Debian) Upgrade package to receive the latest version.

```
$ sudo apt-get upgrade -y
```

4. Reboot your instance to load the latest kernel version.

```
$ sudo reboot
```

5. Reconnect to your instance after it has rebooted.
6. Install the kernel headers package for the version of the kernel you are currently running.

```
$ sudo apt-get install -y linux-headers-$(uname -r) linux-modules-extra-$(uname -r)
```

7. Disable the `nouveau` open source driver for NVIDIA graphics cards.

   a. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` blacklist file. Copy the following code block and paste it into a terminal.

```
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

   b. Edit the `/etc/default/grub` file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

c. Rebuild the Grub configuration.

```
$ sudo update-grub
```

8. Download the GRID driver installation utility using the following command:

```
$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

   Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

9. Add permissions to run the driver installation utility using the following command.

```
$ chmod +x NVIDIA-Linux-x86_64*.run
```

10. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

   When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
$ nvidia-smi -q | head
```

12. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /etc/
modprobe.d/nvidia.conf
```

13. Reboot the instance.

```
$ sudo reboot
```

14. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

    a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

    b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

    c. Install the GUI desktop/workstation package.

    ```
    $ sudo apt-get install -y lightdm ubuntu-desktop
    ```

Windows operating systems

To install the NVIDIA GRID driver on your Windows instance

1. Connect to your Windows instance and open a PowerShell window.
2. Download the drivers and the NVIDIA GRID Cloud End User License Agreement from Amazon S3 to your desktop using the following PowerShell commands.

```
$Bucket = "ec2-windows-nvidia-drivers"
$KeyPrefix = "latest"
$LocalPath = "$home\Desktop\NVIDIA"
$Objects = Get-S3Object -BucketName $Bucket -KeyPrefix $KeyPrefix -Region us-east-1
foreach ($Object in $Objects) {
$LocalFileName = $Object.Key
if ($LocalFileName -ne '' -and $Object.Size -ne 0) {
    $LocalFilePath = Join-Path $LocalPath $LocalFileName
    Copy-S3Object -BucketName $Bucket -Key $Object.Key -LocalFile $LocalFilePath -
Region us-east-1
}
}
```

Multiple versions of the NVIDIA GRID driver are stored in this bucket. You can download all of the available Windows versions in the bucket by removing the `-KeyPrefix $KeyPrefix` option. For information about the version of the NVIDIA GRID driver for your operating system, see the [NVIDIA Virtual GPU (vGPU) Software] on the NVIDIA website.

Starting with GRID version 11.0, you can use the drivers under `latest` for both G3 and G4dn instances. We will not add versions later than 11.0 to `g4/latest`, but will keep version 11.0 and the earlier versions specific to G4dn under `g4/latest`.

G5 instances require GRID 13.1 or later (or GRID 12.4 or later).

3. Navigate to the desktop and double-click the installation file to launch it (choose the driver version that corresponds to your instance OS version). Follow the instructions to install the driver and reboot your instance as required. To verify that the GPU is working properly, check Device Manager.
4. (Optional) Use the following command to disable the licensing page in the control panel to prevent users from accidentally changing the product type (NVIDIA GRID Virtual Workstation is enabled by default). For more information, see the [GRID Licensing User Guide].

PowerShell

Run the following PowerShell commands to create the registry value to disable the licensing page in the control panel. The AWS Tools for PowerShell in AWS Windows AMIs defaults to the 32-bit version and this command fails. Instead, use the 64-bit version of PowerShell included with the operating system.

```
New-Item -Path "HKLM:\SOFTWARE\NVIDIA Corporation\Global" -Name GridLicensing
New-ItemProperty -Path "HKLM:\SOFTWARE\NVIDIA Corporation\Global\GridLicensing" -
Name "NvCplDisableManageLicensePage" -PropertyType "DWord" -Value "1"
```

Command Prompt

Run the following registry command to create the registry value to disable the licensing page in the control panel. You can run it using the Command Prompt window or a 64-bit version of PowerShell.

```
reg add "HKLM\SOFTWARE\NVIDIA Corporation\Global\GridLicensing" /v
 NvCplDisableManageLicensePage /t REG_DWORD /d 1
```

5. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

   a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol, Amazon DCV.

   b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances.

Option 4: NVIDIA gaming drivers (G6, G6e, G5, and G4dn instances)

These drivers are available to AWS customers only. By downloading them, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA L4, NVIDIA L40S, NVIDIA A10G, NVIDIA Tesla T4, or NVIDIA Tesla M60 hardware. You can use the GRID drivers to both create and use AMIs within the AWS environment. Upon installation of the software, you are bound by the terms of the NVIDIA GRID Cloud End User License Agreement.

Considerations

- G3 instances require AWS provided DNS resolution for GRID licensing to work.
- IMDSv2 is only supported with NVIDIA driver version 495.x or greater.

Prerequisites

- (Linux) Verify that the AWS CLI is installed on your instance and configured with default credentials. For more information, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.
- Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy.

Amazon Linux 2023

To install the NVIDIA gaming driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo dnf update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo dnf install gcc make
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it is rebooted.
5. Install the kernel headers packages.

```
[ec2-user ~]$ sudo dnf install -y kernel-devel kernel-modules-extra kernel-devel-
$(uname -r) kernel-headers-$(uname -r) dkms
```

6. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

7. Extract the gaming driver installation utility from the downloaded `.zip` archive.

```
[ec2-user ~]$ unzip latest-driver-name.zip -d nvidia-drivers
```

8. Add permissions to run the driver installation utility using the following command:

```
[ec2-user ~]$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
```

9. Run the installer using the following command:

```
[ec2-user ~]$ sudo ./nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

10. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
 vGamingMarketplace=2
 EOF
```

11. Use the following command to download and rename the certification file.

    - For version 460.39 or later:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
    gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2024_02_22.cert"
    ```

    - For version 440.68 to 445.48:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
    gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
    ```

    - For earlier versions:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
    gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
    ```

12. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

13. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

14. Verify the NVIDIA Gaming license using the following command.

```
[ec2-user ~]$ nvidia-smi.exe -q
```

In the output, search for `vGPU Software Licensed Product`.

15. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol [Amazon DCV](https://docs.aws.amazon.com/dcv/).

Amazon Linux 2

To install the NVIDIA gaming driver on your instance

1. Connect to your instance. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

2. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install gcc make
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it is rebooted.
5. Install the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y kernel-devel-$(uname -r)
```

6. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

   Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

7. Extract the gaming driver installation utility from the downloaded `.zip` archive.

```
[ec2-user ~]$ unzip latest-driver-name.zip -d nvidia-drivers
```

8. Add permissions to run the driver installation utility using the following command:

```
[ec2-user ~]$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
```

9. Run the installer using the following command:

```
[ec2-user ~]$ sudo ./nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

If you are using Amazon Linux 2 with kernel version 5.10, use the following command to install the NVIDIA gaming drivers.

```
[ec2-user ~]$ sudo CC=/usr/bin/gcc10-cc ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

10. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

11. Use the following command to download and rename the certification file.

- For version 460.39 or later:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2024_02_22.cert"
```

- For version 440.68 to 445.48:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
```

- For earlier versions:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
```

12. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

13. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

14. Verify the NVIDIA Gaming license using the following command.

```
[ec2-user ~]$ nvidia-smi.exe -q
```

    In the output, search for `vGPU Software Licensed Product`.

15. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

CentOS 7 and Red Hat Enterprise Linux 7

To install the NVIDIA gaming driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install -y gcc make
```

2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y unzip kernel-devel-$(uname -r)
```

6. Disable the `nouveau` open source driver for NVIDIA graphics cards.

   a. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` blacklist file. Copy the following code block and paste it into a terminal.

      ```
      [ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
      blacklist vga16fb
      blacklist nouveau
      blacklist rivafb
      blacklist nvidiafb
      blacklist rivatv
      EOF
      ```

   b. Edit the `/etc/default/grub` file and add the following line:

      ```
      GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
      ```

   c. Rebuild the Grub configuration.

      ```
      [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
      ```

7. Download the gaming driver installation utility using the following command:

   ```
   [ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
   ```

   Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

   ```
   [ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
   ```

8. Extract the gaming driver installation utility from the downloaded `.zip` archive.

   ```
   [ec2-user ~]$ unzip *Gaming-Linux-Guest-Drivers.zip -d nvidia-drivers
   ```

9. Add permissions to run the driver installation utility using the following command:

   ```
   [ec2-user ~]$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
   ```

10. Run the installer using the following command:

```
[ec2-user ~]$ sudo nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

12. Use the following command to download and rename the certification file.

    - For version 460.39 or later:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2024_02_22.cert"
    ```

    - For version 440.68 to 445.48:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
    ```

    - For earlier versions:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
    ```

13. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /etc/modprobe.d/nvidia.conf
```

14. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

15. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol [Amazon DCV](). If you do not require this functionality, do not complete this step.

CentOS Stream 8 and Red Hat Enterprise Linux 8

To install the NVIDIA gaming driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install -y gcc make
```

2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y unzip kernel-devel-$(uname -r)
```

6. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

   Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

7. Extract the gaming driver installation utility from the downloaded `.zip` archive.

```
[ec2-user ~]$ unzip *Gaming-Linux-Guest-Drivers.zip -d nvidia-drivers
```

8. Add permissions to run the driver installation utility using the following command:

```
[ec2-user ~]$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
```

9. Run the installer using the following command:

```
[ec2-user ~]$ sudo nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

   When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

10. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

11. Use the following command to download and rename the certification file.

   - For version 460.39 or later:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2024_02_22.cert"
```

   - For version 440.68 to 445.48:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
```

   - For earlier versions:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
```

12. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /etc/modprobe.d/nvidia.conf
```

13. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

14. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol Amazon DCV.

Rocky Linux 8

To install the NVIDIA gaming driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install -y gcc make
```

2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo dnf install -y unzip elfutils-libelf-devel libglvnd-devel
 kernel-devel-$(uname -r)
```

6. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

7. Extract the gaming driver installation utility from the downloaded `.zip` archive.

```
[ec2-user ~]$ unzip *Gaming-Linux-Guest-Drivers.zip -d nvidia-drivers
```

8. Add permissions to run the driver installation utility using the following command:

```
[ec2-user ~]$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
```

9. Run the installer using the following command:

```
[ec2-user ~]$ sudo nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

   When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

10. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

11. Use the following command to download and rename the certification file.

    - For version 460.39 or later:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2024_02_22.cert"
    ```

    - For version 440.68 to 445.48:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
    ```

    - For earlier versions:

    ```
    [ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
    ```

12. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /
etc/modprobe.d/nvidia.conf
```

13. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

14. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol [Amazon DCV](https://docs.aws.amazon.com/dcv/).

Ubuntu and Debian

To install the NVIDIA gaming driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.

```
$ sudo apt-get install -y gcc make build-essential
```

2. Update your package cache and get the package updates for your instance.

```
$ sudo apt-get update -y
```

3. Upgrade the `linux-aws` package to receive the latest version.

```
$ sudo apt-get upgrade -y linux-aws
```

4. Reboot your instance to load the latest kernel version.

```
$ sudo reboot
```

5. Reconnect to your instance after it has rebooted.
6. Install the kernel headers package for the version of the kernel you are currently running.

```
$ sudo apt install -y unzip dkms linux-headers-$(uname -r)
```

7. Disable the `nouveau` open source driver for NVIDIA graphics cards.

   a. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` blacklist file. Copy the following code block and paste it into a terminal.

```
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

b. Edit the `/etc/default/grub` file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

c. Rebuild the Grub configuration.

```
$ sudo update-grub
```

8. Download the gaming driver installation utility using the following command:

```
$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

9. Extract the gaming driver installation utility from the downloaded `.zip` archive.

```
$ unzip *Gaming-Linux-Guest-Drivers.zip -d nvidia-drivers
```

10. Add permissions to run the driver installation utility using the following command:

```
$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
```

11. Run the installer using the following command:

```
$ sudo nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

12. Use the following command to create the required configuration file.

```
$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

13. Use the following command to download and rename the certification file.

    - For version 460.39 or later:

    ```
    $ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
    gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2024_02_22.cert"
    ```

    - For version 440.68 to 445.48:

    ```
    $ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
    gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
    ```

    - For earlier versions:

    ```
    $ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-
    gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
    ```

14. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information about why this is required, see the NVIDIA documentation.

```
$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /etc/
modprobe.d/nvidia.conf
```

15. Reboot the instance.

```
$ sudo reboot
```

16. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol Amazon DCV. If you do not require this functionality, do not complete this step.

Windows operating systems

Before you install an NVIDIA gaming driver on your instance, you must ensure that the following prerequisites are met in addition to the considerations mentioned for all gaming drivers.

- If you launch your Windows instance using a custom Windows AMI, the AMI must be a standardized image created with Windows Sysprep to ensure that the gaming driver works. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.
- Configure default credentials for the AWS Tools for Windows PowerShell on your Windows instance. For more information, see Getting Started with the AWS Tools for Windows PowerShell in the *AWS Tools for PowerShell User Guide*.

To install the NVIDIA gaming driver on your Windows instance

1. Connect to your Windows instance and open a PowerShell window.
2. Download and install the gaming driver using the following PowerShell commands.

```
$Bucket = "nvidia-gaming"
$KeyPrefix = "windows/latest"
$LocalPath = "$home\Desktop\NVIDIA"
$Objects = Get-S3Object -BucketName $Bucket -KeyPrefix $KeyPrefix -Region us-east-1
foreach ($Object in $Objects) {
$LocalFileName = $Object.Key
if ($LocalFileName -ne '' -and $Object.Size -ne 0) {
    $LocalFilePath = Join-Path $LocalPath $LocalFileName
    Copy-S3Object -BucketName $Bucket -Key $Object.Key -LocalFile $LocalFilePath -
Region us-east-1
}
}
```

   Multiple versions of the NVIDIA GRID driver are stored in this S3 bucket. You can download all of the available versions in the bucket if you change the value of the `$KeyPrefix` variable from *"windows/latest"* to *"windows"*.

3. Navigate to the desktop and double-click the installation file to launch it (choose the driver version that corresponds to your instance OS version). Follow the instructions to install the driver and reboot your instance as required. To verify that the GPU is working properly, check Device Manager.
4. Use one of the following methods to register the driver.

Version 527.27 or above

Create the following registry key with the 64-bit version of PowerShell, or the Command Prompt window.

key: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\nvlddmkm\Global`

name: vGamingMarketplace

type: DWord

value: 2

PowerShell

Run the following PowerShell command to create this registry value. The AWS Tools for PowerShell in AWS Windows AMIs defaults to the 32-bit version and this command fails. Instead, use the 64-bit version of PowerShell included with the operating system.

```
New-ItemProperty -Path "HKLM:\SYSTEM\CurrentControlSet\Services\nvlddmkm\Global"
 -Name "vGamingMarketplace" -PropertyType "DWord" -Value "2"
```

Command Prompt

Run the following registry command to create this registry value. You can run it using the Command Prompt window or a 64-bit version of PowerShell.

```
reg add "HKLM\SYSTEM\CurrentControlSet\Services\nvlddmkm\Global" /v
 vGamingMarketplace /t REG_DWORD /d 2
```

Earlier versions

Create the following registry key with the 64-bit version of PowerShell, or the Command Prompt window.

key: `HKEY_LOCAL_MACHINE\SOFTWARE\NVIDIA Corporation\Global`

name: vGamingMarketplace

type: DWord

value: 2

PowerShell

Run the following PowerShell command to create this registry value. The AWS Tools for PowerShell in AWS Windows AMIs defaults to the 32-bit version and this command fails. Instead, use the 64-bit version of PowerShell included with the operating system.

```
New-ItemProperty -Path "HKLM:\SOFTWARE\NVIDIA Corporation\Global" -Name
 "vGamingMarketplace" -PropertyType "DWord" -Value "2"
```

Command Prompt

Run the following registry command to create this registry key with the Command Prompt window. You can also use this command in the 64-bit version of PowerShell.

```
reg add "HKLM\SOFTWARE\NVIDIA Corporation\Global" /v vGamingMarketplace /t
 REG_DWORD /d 2
```

5. Run the following command in PowerShell. This downloads the certification file, renames the file `GridSwCert.txt`, and moves the file to the Public Documents folder on your system drive. Typically, the folder path is `C:\Users\Public\Documents`.

   - For version 460.39 or later:

   ```
   Invoke-WebRequest -Uri "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-
   Archive/GridSwCertWindows_2024_02_22.cert" -OutFile "$Env:PUBLIC\Documents
   \GridSwCert.txt"
   ```

   - For version 445.87:

   ```
   Invoke-WebRequest -Uri "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-
   Archive/GridSwCert-Windows_2020_04.cert" -OutFile "$Env:PUBLIC\Documents
   \GridSwCert.txt"
   ```

   - For earlier versions:

```
Invoke-WebRequest -Uri "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-
Archive/GridSwCert-Windows_2019_09.cert" -OutFile "$Env:PUBLIC\Documents
\GridSwCert.txt"
```

If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:

```
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
```

6. Reboot your instance.
7. Locate the `nvidia-smi.exe` file on the instance.

```
Get-ChildItem -Path C:\ -Recurse -Filter "nvidia-smi.exe"
```

Verify the NVIDIA Gaming license using the following command. Replace *path* with the name of the folder in the output from the previous command.

```
C:\Windows\System32\DriverStore\FileRepository\path\nvidia-smi.exe -q
```

The output should be similar to the following.

```
vGPU Software Licensed Product
Product Name                  : NVIDIA Cloud Gaming
License Status                : Licensed (Expiry: N/A)
```

8. (Optional) To help take advantage of the single display of up to 4K resolution, set up the high-performance display protocol Amazon DCV. If you do not require this functionality, do not complete this step.

Install an additional version of CUDA

After you install an NVIDIA graphics driver on your instance, you can install a version of CUDA other than the version that is bundled with the graphics driver. The following procedure demonstrates how to configure multiple versions of CUDA on the instance.

Install the CUDA toolkit on Linux

Follow these steps to install the CUDA toolkit on Linux:

1. Connect to your Linux instance.
2. Open the NVIDIA website and select the version of CUDA that you need.
3. Select the architecture, distribution, and version for the operating system on your instance. For **Installer Type**, select **runfile (local)**.
4. Follow the instructions to download the install script.
5. Add run permissions to the install script that you downloaded using the following command.

```
[ec2-user ~]$ chmod +x downloaded_installer_file
```

6. Run the install script as follows to install the CUDA toolkit and add the CUDA version number to the toolkit path.

```
[ec2-user ~]$ sudo sh downloaded_installer_file --silent --override --toolkit --
samples --toolkitpath=/usr/local/cuda-version --samplespath=/usr/local/cuda --no-
opengl-libs
```

7. (Optional) Set the default CUDA version as follows.

```
[ec2-user ~]$ sudo ln -s /usr/local/cuda-version /usr/local/cuda
```

Install the CUDA toolkit on Windows

Follow these steps to install the CUDA toolkit on Windows:

To install the CUDA toolkit

1. Connect to your Windows instance.
2. Open the NVIDIA website and select the version of CUDA that you need.
3. For **Installer Type**, select **exe (local)** and then choose **Download**.
4. Using your browser, run the downloaded install file. Follow the instructions to install the CUDA toolkit. You might be required to reboot the instance.

Install the ENA driver on EC2 Windows instances

If your instance isn't based on one of the latest Windows Amazon Machine Images (AMIs) that Amazon provides, use the following procedure to install the current ENA driver on your instance. You should perform this update at a time when it's convenient to reboot your instance. If the install script doesn't automatically reboot your instance, we recommend that you reboot the instance as the final step.

If you use an instance store volume to store data while the instance is running, that data is erased when you stop the instance. Before you stop your instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

Prerequisites

To install or upgrade the ENA driver, your Windows instance must meet the following prerequisites:

- PowerShell version 3.0 or later is installed.
- The commands shown in this section must run in the 64-bit version of PowerShell. Do not use the x86 version of PowerShell. That is the 32-bit version of the shell, and is not supported for these commands.

Step 1: Back up your data

We recommend that you create a backup AMI, in case you're not able to roll back your changes through the **Device Manager**. To create a backup AMI with the AWS Management Console, follow these steps:

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires the driver upgrade, and choose **Stop instance** from the **Instance state** menu.
4. After the instance is stopped, select the instance again. To create your backup, choose **Image and templates** from the **Actions** menu, then choose **Create image**.
5. To restart your instance, choose **Start instance** from the **Instance state** menu.

Step 2: Install or upgrade your ENA driver

You can install or upgrade your ENA driver with AWS Systems Manager Distributor, or with PowerShell cmdlets. For further instructions, select the tab that matches the method that you want to use.

Systems Manager Distributor

You can use the Systems Manager Distributor feature to deploy packages to your Systems Manager managed nodes. With Systems Manager Distributor, you can install the ENA driver package once, or with scheduled updates. For more information about how to install the ENA driver package (`AwsEnaNetworkDriver`) with Systems Manager Distributor, see Install or update packages in the *AWS Systems Manager User Guide*.

PowerShell

This section covers how to download and install ENA driver packages on your instance with PowerShell cmdlets.

Option 1: Download and extract the latest version

1. Connect to your instance and log in as the local administrator.
2. Use the **invoke-webrequest** cmdlet to download the latest driver package:

```
PS C:\> invoke-webrequest https://ec2-windows-drivers-downloads.s3.amazonaws.com/ENA/Latest/AwsEnaNetworkDriver.zip -outfile $env:USERPROFILE\AwsEnaNetworkDriver.zip
```

> **Note**
>
> If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:
>
> ```
> [Net.ServicePointManager]::SecurityProtocol =
>  [Net.SecurityProtocolType]::Tls12
> ```

Alternatively, you can download the latest driver package from a browser window on your instance.

3. Use the **expand-archive** cmdlet to extract the zip archive that you downloaded to your instance:

```
PS C:\> expand-archive $env:userprofile\AwsEnaNetworkDriver.zip -
DestinationPath $env:userprofile\AwsEnaNetworkDriver
```

Option 2: Download and extract a specific version

1. Connect to your instance and log in as the local administrator.
2. Download the ENA driver package for the specific version you want from the version link in the ENA Windows driver version history table.
3. Extract the zip archive to your instance.

Install the ENA driver with PowerShell

The install steps are the same whether you've downloaded the latest driver or a specific version. To install the ENA driver, follow these steps.

1. To install the driver, run the `install.ps1` PowerShell script from the `AwsEnaNetworkDriver` directory on your instance. If you get an error, make sure that you're using PowerShell 3.0 or later.
2. If the installer doesn't automatically reboot your instance, run the **Restart-Computer** PowerShell cmdlet.

```
PS C:\> Restart-Computer
```

Step 3 (optional): Verify the ENA driver version after installation

To ensure that the ENA driver package was successfully installed on your instance, you can verify the new version as follows:

1. Connect to your instance and log in as the local administrator.

2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.

   Note

   ENA adapters all use the same driver. If you have multiple ENA adapters, you can select any one of them to update the driver for all of the ENA adapters.

6. To verify the current version that's installed, open the **Driver** tab and check the **Driver Version**. If the current version doesn't match your target version, see Troubleshoot the Elastic Network Adapter Windows driver.

Roll back an ENA driver installation

If anything goes wrong with the installation, you might need to roll back the driver. Follow these steps to roll back to the previous version of the ENA driver that was installed on your instance.

1. Connect to your instance and log in as the local administrator.
2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.

   Note

   ENA adapters all use the same driver. If you have multiple ENA adapters, you can select any one of them to update the driver for all of the ENA adapters.

6. To roll back the driver, open the **Driver** tab and choose **Roll Back Driver**. This opens the **Driver Package rollback** window.

> **Note**
>
> If the **Driver** tab doesn't show the **Roll Back Driver** action, or if the action is unavailable, it means that the Driver Store on your instance doesn't contain the previously installed driver package. To troubleshoot this issue, see Troubleshooting scenarios, and expand the **Unexpected ENA driver version installed** section. For more information about the device driver package selection process, see How Windows selects a driver package for a device on the *Microsoft documentation website*.

Track ENA Windows driver version releases

Windows AMIs include the ENA Windows driver to enable enhanced networking.

For Windows Server versions 2016 and above, we recommend that you use the latest driver version. For earlier versions of Windows Server, refer to the following table to determine which ENA driver version to use.

Windows Server version	ENA driver version
Windows Server 2012 R2	2.6.0 and earlier
Windows Server 2012	2.6.0 and earlier
Windows Server 2008 R2	2.2.3 and earlier

ENA Windows driver version history

The following table summarizes the changes for each release.

Driver version	Details	Release date
2.11.0	**New features** •	August 1, 2025

Driver version	Details	Release date
	Added support for dynamic queue allocation with scaling up to 64 I/O queues, subject to instance type limits. **Bug fixes** • Fixed missing handling of error conditions when retrieving the physical DMA address width from the device.	
2.10.0	**Bug fixes** • Fixed improper handling of memory allocation failures during queue initialization to prevent unexpected reboots. • Fixed possible misconfiguration of network offloads where device capabilities were ignored.	June 24, 2025

Driver version	Details	Release date
2.9.0	**New features** • Added support for asynchronous reset requests initiated by the device. • Added support for handling the maximum large LLQ depth value provided by the device. • Added Event ID `58001` in the Windows Event Viewer to enhance visibility into unexpected power state transitions caused by device misconfiguration. **Bug fixes** • Fixed improper handling of memory allocation failures during device initialization to prevent unexpected reboots. • Fixed an issue in the interrupt service routine that could enqueue a DPC during device stop, preventing unexpected reboots.	December 12, 2024
2.8.0	**Bug fixes** • Fixed a race condition in the complete flow of egress network buffer list (NBL) processing, which could lead to memory corruption caused by attempting to release an NBL that was already released. • Fixed misdetection of L3 protocol when disabling all LSO and checksum offloads that could lead to unexpected behavior.	September 30, 2024

Driver version	Details	Release date
2.7.0	**New features** • Removed support for Windows Server 2012 (Windows 8) and Windows Server 2012 R2 (Windows 8.1). These operating system versions have reached the end of support from AWS. Driver install will fail on Windows Server 2012 and earlier. • Added support for offloading IPv6 Tx checksum calculation to the device. • Added wide Low Latency Queuing (LLQ) support. This is dynamically enabled based on device recommend ation. You can override this setting with the new "WideLLQ" registry key. • Added reporting for packet drops resulting from Rx overrun, which indicates insufficient space in the Rx ring for incoming packets. • Added support for suboptimal configuration notificat ions from the device. See event ID `59000` in the Windows event viewer. **Bug fixes** • Avoid unnecessary device reset caused by Tx packets with headers that exceed the maximum Low Latency Queuing (LLQ) header size.	May 1, 2024

Driver version	Details	Release date

2.6.0	**New features**
	• Adds the following network performance metrics for instance types that support ENA Express.
	  • `ena_srd_mode`
	  • `ena_srd_tx_pkts`
	  • `ena_srd_eligible_tx_pkts`
	  • `ena_srd_rx_pkts`
	  • `ena_srd_resource_utilization`
	• Adds `conntrack_allowance_available` network performance metric for Nitro based instance types.
	• Adds new adapter reset reason due to detection of RX data corruption.
	• Updates driver logging infrastructure.
	
	Bug fixes
	• Prevents adapter reset in the event that CPU starvatio n causes a network performance metrics update to fail.
	• Prevents false detection of an interruption to the device heartbeat.
	•
		June 20, 2023

Driver version	Details	Release date
	Fixes driver installation script to support downgrade operation. • Fixes the receive error count statistic.	
2.5.0	**Announcement** ENA Windows driver version 2.5.0 has been rolled back due to failure to initialize on the Windows domain controller. Windows Client and Windows Server are unaffected.	February 17, 2023

Driver version	Details	Release date
2.4.0	**New features** • Adds support for Windows Server 2022. • Removes support for Windows Server 2008 R2. • Sets Low Latency Queuing (LLQ) to always on to improve performance on sixth generation Amazon EC2 instances. **Bug fixes** • Fixes a failure to publish network performance metrics to the Performance Counters for Windows (PCW) system. • Fixes a memory leak during the registry key reading operation. • Prevents an infinite reset loop in the event of an unrecoverable error during the adapter reset process.	April 28, 2022

Driver version	Details	Release date
2.2.4	**Announcement** ENA Windows driver version 2.2.4 has been rolled back due to potential performance degradation on the sixth generation EC2 instances. We recommend that you downgrade the driver, using one of the following methods: • **Install the previous version** 1. Download the previous version package from the link in this table (version 2.2.3). 2. Run the **install.ps1** PowerShell installation script. For more details for pre- and post-installation steps see Enable enhanced networking on Windows. • **Use Amazon EC2 Systems Manager for a bulk update** • Perform a bulk update via SSM document `AWS-ConfigureAWSPackage`, with the following parameters: • **Name**: AwsEnaNetworkDriver • **Version**: 2.2.3	October 26, 2021

Driver version	Details	Release date
2.2.3	**New features** • Adds support for new Nitro cards with up to 400 Gbps instance networking. **Bug fixes** • Fixes race condition between system time change and system time query by the ENA driver, which causes false-positive detection of HW unresponsiveness. **Announcement** Windows ENA driver version 2.2.3 is the final version that supports Windows Server 2008 R2. Currently available instance types that use ENA will continue to be supported on Windows Server 2008 R2, and the drivers are available by download. No future instance types will support Windows Server 2008 R2, and you cannot launch, import, or migrate Windows Server 2008 R2 images to future instance types.	March 25, 2021

Driver version	Details	Release date
2.2.2	**New features** • Adds support to query network adapter performance metrics with CloudWatch and the Performance Counters for Windows consumers. **Bug fixes** • Fixes performance issues on bare metal instances.	December 21, 2020
2.2.1	**New features** • Adds a method to allow the host to query the Elastic Network Adapter for network performance metrics.	October 1, 2020

Driver version	Details	Release date
2.2.0	**New features** • Adds support for next generation hardware types. • Improves instance start time after resuming from stop-hibernate, and eliminates false positive ENA error messages. **Performance optimizations** • Optimizes processing of inbound traffic. • Improves shared memory management in low resource environment. **Bug fixes** • Avoids system crash upon ENA device removal in rare scenario where driver fails to reset.	August 12, 2020
2.1.5	**Bug fixes** • Fixes occasional network adapter initialization failure on bare metal instances.	June 23, 2020

Driver version	Details	Release date
2.1.4	**Bug fixes** • Prevent connectivity issues caused by corrupted LSO packet metadata arriving from the network stack. • Prevent system crash caused by a rare race condition that results in accessing an already released packet memory.	November 25, 2019
2.1.2	**New features** • Added support for vendor ID report to allow OS to generate MAC-based UUIDs. **Bug fixes** • Improved DHCP network configuration performance during initialization. • Properly calculate L4 checksum on inbound IPv6 traffic when the maximum transmission unit (MTU) exceeds 4K. • General improvements to driver stability and minor bug fixes.	November 4, 2019

Driver version	Details	Release date
2.1.1	**Bug fixes** • Prevent drops of highly fragmented TCP LSO packets arriving from operating system. • Properly handle Encapsulating Security Payload (ESP) protocol within the IPSec in IPv6 networks.	September 16, 2019

Driver version	Details	Release date

2.1.0	ENA Windows driver v2.1 introduces new ENA device capabilities, provides a performance boost, adds new features, and includes multiple stability improvements.
	
	New features
	
	• Use standardized Windows registry key for Jumbo frames configuration.
	• Allow VLAN ID setting via the ENA driver properties GUI.
	• Improved Recovery flows
	  ◦ Improved failure identification mechanism.
	  ◦ Added support for tunable recovery parameters.
	• Support up to 32 I/O queues for newer EC2 instances that have more than 8 vCPUs.
	• ~90% reduction of driver memory footprint.
	
	Performance optimizations
	
	• Reduced transmit path latency.
	• Support for receive checksum offload.
	• Performance optimization for heavily loaded system (optimized usage of locking mechanisms).
	• Further enhancements to reduce CPU utilization and improve system responsiveness under load.
		July 1, 2019

Driver version	Details	Release date
	Bug fixes • Fix crash due to invalid parsing of non-contiguous Tx headers. • Fix driver v1.5 crash during the elastic network inte rface detach on Bare Metal instances. • Fix LSO pseudo-header checksum calculation error over IPv6. • Fix potential memory resource leak upon initialization failure. • Disable TCP/UDP checksum offload for IPv4 fragments. • Fix for VLAN configuration. VLAN was incorrectly disabled when only VLAN priority should have been disabled. • Enable correct parsing of custom driver messages by the event viewer. • Fix failure to initialize driver due to invalid timestamp handling. • Fix race condition between data processing and ENA device disabling.	

Driver version	Details	Release date
1.5.0	**Updates** • Improved stability and performance fixes. • Receive Buffers can now be configured up to a value of 8192 in Advanced Properties of the ENA NIC. • Default Receive Buffers of 1k.	October 4, 2018
1.2.3	Includes reliability fixes and unifies support for Windows Server 2008 R2 through Windows Server 2016.	February 13, 2018
1.0.8	The initial release. Included in AMIs for Windows Server 2008 R2, Windows Server 2012 RTM, Windows Server 2012 R2, and Windows Server 2016.	July 2016

Subscribe to ENA Windows driver release notifications from Amazon SNS

Amazon SNS can notify you when new versions of EC2 Windows Drivers are released. Use the following procedure to subscribe to these notifications.

Subscribe to EC2 notifications

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to are in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:

    a. For **TopicARN**, copy the following Amazon Resource Name (ARN):

arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers

   b. For **Protocol**, choose `Email`.
   c. For **Endpoint**, enter an email address where you want notifications sent.
   d. Choose **Create subscription**.

6. You'll receive a confirmation email. Open the email and follow the directions to complete your subscription.

Whenever new EC2 Windows drivers are released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

Unsubscribe from Amazon EC2 Windows driver notification

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Subscriptions**.
3. Select the checkbox for the subscription and then choose **Actions**, **Delete subscriptions**. When prompted for confirmation, choose **Delete**.

Paravirtual drivers for Windows instances

Windows AMIs contain a set of drivers to permit access to virtualized hardware. These drivers are used by Amazon EC2 to map instance store and Amazon EBS volumes to their devices. The following table shows key differences between the different drivers.

	Red Hat PV	Citrix PV	AWS PV
Instance type	Not supported for all instance types. If you specify an unsupported instance type, the instance is impaired.	Supported for Xen instance types.	Supported for Xen instance types.
Attached volumes	Supports up to 16 attached volumes.	Supports more than 16 attached volumes.	Supports more than 16 attached volumes.

	Red Hat PV	Citrix PV	AWS PV
Network	The driver has known issues where the network connection resets under high loads; for example, fast FTP file transfers.		The driver automatically configures jumbo frames on the network adapter when on a compatible instance type. When the instance is in a cluster placement group, this offers better network performance between instances that are in the cluster placement group. For more information, see [Placement groups for your Amazon EC2 instances]().

The following table shows which PV drivers you should run on each version of Windows Server on Amazon EC2.

Windows Server version	PV driver version
Windows Server 2025	Not supported
Windows Server 2022	AWS PV latest version
Windows Server 2019	AWS PV latest version
Windows Server 2016	AWS PV latest version
Windows Server 2012 R2	AWS PV version 8.4.3
Windows Server 2012	AWS PV version 8.4.3
Windows Server 2008 R2	AWS PV version 8.3.5
Windows Server 2008	Citrix PV 5.9
Windows Server 2003	Citrix PV 5.9

Contents

AWS PV drivers

The AWS PV drivers are stored in the `%ProgramFiles%\Amazon\Xentools` directory. This directory also contains public symbols and a command line tool, `xenstore_client.exe`, that enables you to access entries in XenStore. For example, the following PowerShell command returns the current time from the Hypervisor:

```
PS C:\> [DateTime]::FromFileTimeUTC((gwmi -n root\wmi -cl
 AWSXenStoreBase).XenTime).ToString("hh:mm:ss")
11:17:00
```

The AWS PV driver components are listed in the Windows registry under `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services`. These driver components are as follows: xenbus, xeniface, xennet, xenvbd, and xenvif.

AWS PV drivers also have a Windows service named LiteAgent, which runs in user-mode. It handles tasks such as shutdown and restart events from AWS APIs on Xen generation instances. You can access and manage services by running `Services.msc` from the command line. When running on Nitro generation instances, the AWS PV drivers are not used and the LiteAgent service will self-stop starting with driver version 8.2.4. Updating to the latest AWS PV driver also updates the LiteAgent and improves reliability on all instance generations.

Install the latest AWS PV drivers

Amazon Windows AMIs contain a set of drivers to permit access to virtualized hardware. These drivers are used by Amazon EC2 to map instance store and Amazon EBS volumes to their devices. We recommend that you install the latest drivers to improve stability and performance of your EC2 Windows instances.

Installation options

- Use AWS Systems Manager to automatically update the PV drivers. For more information, see Walkthrough: Automatically Update PV Drivers on EC2 Windows Instances in the *AWS Systems Manager User Guide*.
- Download the driver package and run the install program manually. Be sure to check the `readme.txt` file for system requirements. For information about downloading and installing the AWS PV drivers, or upgrading a domain controller, see Upgrade Windows Server instances (AWS PV upgrade) manually.

AWS PV driver package history

The following table shows the changes to AWS PV drivers for each driver release.

Package version	Details	Release date
8.6.0	• Stability fixes to XenStore interactions.	27 May 2025
8.5.0	• Stability fixes to address rare cases of crashes during network device detachment. • Stability fixes to address rare cases of crashes during EBS volume detachment. • Fixed bugs in the package installer. • Updated the PV installer to use `Pnputil`.	31 October 2024
8.4.3	Fixed bugs in the package installer to improve the upgrade experience. This is the last version that can run on Windows Server 2012 and 2012 R2. This version is available for download, however it is no longer supported since Windows Server 2012 and 2012 R2 have reached end of support.	24 January 2023
8.4.2	Stability fixes to address race condition.	13 April 2022
8.4.1	Improved package installer.	7 January 2022
8.4.0	• Stability fixes to address rare cases of stuck disk IO. • Stability fixes to address rare cases of crashes during EBS volume detachment. • Added feature to distribute load across multiple cores for workloads that leverage more than 20,000 IOPS and experience degradation due to bottlenecks. To enable this feature, see Workloads that leverage more than 20,000 disk IOPS experience degradation due to CPU bottlenecks.	2 March 2021
8.3.5	Improved package installer. This is the last version that can run on Windows Server 2008 R2. This version is available for download but no longer	7 January 2022

Package version	Details	Release date
	supported. Windows Server 2008 R2 has reached end-of-life, and is no longer supported by Microsoft.	
8.3.4	Improved reliability of network device attachment.	4 August 2020
8.3.3	• Update to XenStore-facing component to prevent bug check during error-handling paths. • Update to storage component to avoid crashes when an invalid SRB is submitted. To update this driver on Windows Server 2008 R2 instances, you must first verify that the appropriate patches are installed to address the following Microsoft Security Advisory: Microsoft Security Advisory 3033929.	4 February 2020
8.3.2	Enhanced reliability of networking components.	30 July 2019
8.3.1	Improved performance and robustness of storage component.	12 June 2019
8.2.7	Improved efficiency to support migrating to latest generation instance types.	20 May 2019
8.2.6	Improved efficiency of crash dump path.	15 January 2019
8.2.5	Additional security enhancements. PowerShell installer now available in package.	12 December 2018
8.2.4	Reliability improvements.	2 October 2018

Package version	Details	Release date
8.2.3	Bug fixes and performance improvements. Report EBS volume ID as disk serial number for EBS volumes. This enables cluster scenarios such as S2D.	29 May 2018
8.2.1	Network and storage performance improvements plus multiple robustness fixes. To verify that this version has been installed, refer to the following Windows registry value: `HKLM\Software\Amazon\PVDriver\Version 8.2.1` .	8 March 2018
7.4.3	Added support for Windows Server 2016. Stability fixes for all supported Windows OS versions. *AWS PV driver version 7.4.3's signature expires on March 29, 2019. We recommend updating to the latest AWS PV driver.	18 Nov 2016
7.4.2	Stability fixes for support of X1 instance type.	2 Aug 2016
7.4.1	• Performance improvement in AWS PV Storage driver. • Stability fixes in AWS PV Storage driver: Fixed an issue where the instances were hitting a system crash with bug check code 0x0000DEAD. • Stability fixes in AWS PV Network driver. • Added support for Windows Server 2008R2.	12 July 2016
7.3.2	• Improved logging and diagnostics. • Stability fix in AWS PV Storage driver. In some cases disks may not surface in Windows after reattaching the disk to the instance. • Added support for Windows Server 2012.	24 June 2015

Package version	Details	Release date
7.3.1	TRIM update: Fix related to TRIM requests. This fix stabilizes instances and improves instance performance when managing large numbers of TRIM requests.	
7.3.0	TRIM support: The AWS PV driver now sends TRIM requests to the hypervisor. Ephemeral disks will properly process TRIM requests given the underlying storage supports TRIM (SSD). Note that EBS-based storage does not support TRIM as of March 2015.	
7.2.5	• Stability fix in AWS PV Storage drivers: In some cases the AWS PV driver could dereference invalid memory and cause a system failure. • Stability fix while generating a crash dump: In some cases the AWS PV driver could get stuck in a race condition when writing a crash dump. Before this release, the issue could only be resolved by forcing the driver to stop and restart which lost the memory dump.	
7.2.4	Device ID persistence: This driver fix masks the platform PCI device ID and forces the system to always surface the same device ID, even if the instance is moved. More generally, the fix affects how the hypervisor surfaces virtual devices. The fix also includes modifications to the co-installer for the AWS PV drivers so the system persists mapped virtual devices.	
7.2.2	• Load the AWS PV drivers in Directory Services Restore Mode (DSRM) mode: Directory Services Restore Mode is a safe mode boot option for Windows Server domain controllers. • Persist device ID when virtual network adapter device is reattached: This fix forces the system to check the MAC address mapping and persist the device ID. This fix ensures that adapters retain their static settings if the adapters are reattached.	

Package version	Details	Release date
7.2.1	• Run in safe mode: Fixed an issue where the driver would not load in safe mode. Previously the AWS PV Drivers would only instantiate in normal running systems. • Add disks to Microsoft Windows Storage Pools: Previously we synthesized page 83 queries. The fix disabled page 83 support. Note this does not affect storage pools that are used in a cluster environment because PV disks are not valid cluster disks.	
7.2.0	Base: The AWS PV base version.	

Citrix PV drivers

The Citrix PV drivers are stored in the `%ProgramFiles%\Citrix\XenTools` (32-bit instances) or `%ProgramFiles(x86)%\Citrix\XenTools` (64-bit instances) directory.

The Citrix PV driver components are listed in the Windows registry under `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services`. These driver components are as follows: xenevtchn, xeniface, xennet, Xennet6, xensvc, xenvbd, and xenvif.

Citrix also has a driver component named XenGuestAgent, which runs as a Windows service. It handles tasks such as shutdown and restart events from the API. You can access and manage services by running `Services.msc` from the command line.

If you are encountering networking errors while performing certain workloads, you may need to disable the TCP offloading feature for the Citrix PV driver. For more information, see TCP offloading.

Red Hat PV drivers

Red Hat drivers are supported for legacy instances, but are not recommended on newer instances with more than 12GB of RAM due to driver limitations. Instances with more than 12GB of RAM running Red Hat drivers can fail to boot and become inaccessible. We recommend upgrading Red Hat drivers to Citrix PV drivers, and then upgrade Citrix PV drivers to AWS PV drivers.

The source files for the Red Hat drivers are in the `%ProgramFiles%\RedHat` (32-bit instances) or `%ProgramFiles(x86)%\RedHat` (64-bit instances) directory. The two drivers are `rhelnet`, the Red Hat Paravirtualized network driver, and `rhelscsi`, the Red Hat SCSI miniport driver.

Subscribe to notifications

Amazon SNS can notify you when new versions of EC2 Windows Drivers are released. You can subscribe to these notifications.

> **Note**
>
> You must specify the Region in which the SNS topic was created.

Whenever new EC2 Windows drivers are released, we send notifications to subscribers. If you no longer want to receive these notifications, you can unsubscribe. For more information, see [Delete an SNS topic and subscription](#).

Console

To subscribe to notifications

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to are in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:

    a. For **TopicARN**, copy the following Amazon Resource Name (ARN):

       arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers

    b. For **Protocol**, choose `Email`.

    c. For **Endpoint**, type an email address that you can use to receive the notifications.

    d. Choose **Create subscription**.
6. You'll receive a confirmation email. Open the email and follow the directions to complete your subscription.

AWS CLI

To subscribe to notifications

Use the following command.

```
aws sns subscribe \
    --topic-arn arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers \
    --region us-east-1 \
    --protocol email \
    --notification-endpoint YourUserName@YourDomainName.ext
```

PowerShell

To subscribe to notifications

Use the following command.

```
Connect-SNSNotification `
    -TopicArn 'arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers' `
    -Region us-east-1 `
    -Protocol email `
    -Endpoint "YourUserName@YourDomainName.ext"
```

Upgrade PV drivers on EC2 Windows instances

We recommend that you install the latest PV drivers to improve the stability and performance of your EC2 Windows instances. The directions on this page help you download the driver package and run the install program.

To verify which driver your Windows instance uses

Open **Device Manager** and view **Network Adapters**. Check whether the PV driver is one of the following:

- AWS PV Network Device
- Citrix PV Ethernet Adapter
- Red Hat PV NIC Driver

System requirements

Be sure to check the `readme.txt` file in the download for system requirements.

Contents

Upgrade Windows Server instances (AWS PV upgrade) with Distributor

You can use Distributor, a capability of AWS Systems Manager, to install or upgrade the AWS PV driver package. The installation or upgrade can be performed one time, or you can install or update it on a schedule. The `In-place update` option for **Installation Type** isn't supported for this Distributor package.

> **Important**
>
> If your instance is a domain controller, see Upgrade a domain controller (AWS PV upgrade). The upgrade process for domain controller instances is different than standard editions of Windows.

1. We recommend that you create a backup in case you need to roll back your changes.

   > **Tip**
   >
   > Instead of creating the AMI from the Amazon EC2 console, you can use Systems Manager Automation to create the AMI using the `AWS-CreateImage` runbook. For more information, see AWS-CreateImage in the *AWS Systems Manager Automation runbook reference User Guide*.

   a. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

   b. In the navigation pane, choose **Instances**.
   c. Select the instance that requires the driver upgrade, and choose **Instance state**, **Stop instance**.
   d. After the instance is stopped, select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.
   e. Choose **Instance state**, **Start instance**.
2. Connect to the instance using Remote Desktop. For more information, see the section called “Connect using an RDP client”.
3. We recommend that you take all non-system disks offline and note any drive letter mappings to the secondary disks in Disk Management before you perform this upgrade. This step is not required if you are performing an in-place update of AWS PV drivers. We also recommend setting non-essential services to **Manual** start-up in the Services console.
4. For the instructions for how to install or upgrade the AWS PV driver package using Distributor, see the procedures in Install or update packages in the *AWS Systems Manager User Guide*.
5. For **Name**, choose **AWSPVDriver**.
6. For **Installation type**, select **Uninstall and reinstall**.
7. Configure the other parameters for the package as necessary and run installation or upgrade using the referenced procedure in Step 4.

   After running the Distributor package, the instance automatically reboots and then upgrades the driver. The instance will not be available for up to 15 minutes.
8. After the upgrade is complete, and the instance passes both health checks in the Amazon EC2 console, verify that the new driver was installed by connecting to the instance using Remote Desktop.
9. After you are connected, run the following PowerShell command:

```
Get-ItemProperty HKLM:\SOFTWARE\Amazon\PVDriver
```

10. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see AWS PV driver package history Open Disk Management to review any offline secondary volumes and bring them online corresponding to the drive letters noted in Step 3.

If you previously disabled TCP offloading using Netsh for Citrix PV drivers we recommend that you re-enable this feature after upgrading to AWS PV drivers. TCP Offloading issues with Citrix drivers are not present in the AWS PV drivers. As a result, TCP Offloading provides better performance with AWS PV drivers.

If you previously applied a static IP address or DNS configuration to the network interface, you might need to reapply the static IP address or DNS configuration after upgrading AWS PV drivers.

Upgrade Windows Server instances (AWS PV upgrade) manually

Use the following procedure to perform an in-place upgrade of AWS PV drivers, or to upgrade from Citrix PV drivers to AWS PV drivers on Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016, Windows Server 2019, or Windows Server 2022. This upgrade is not available for Red Hat drivers, or for other versions of Windows Server.

Some older versions of Windows Server can't use the latest drivers. To verify which driver version to use for your operating system, see the driver version table in the Paravirtual drivers for Windows instances page.

> **Important**
>
> If your instance is a domain controller, see Upgrade a domain controller (AWS PV upgrade). The upgrade process for domain controller instances is different than standard editions of Windows.

To upgrade AWS PV drivers manually

1. We recommend that you create a backup in case you need to roll back your changes.

   > **Tip**
   >
   > Instead of creating the AMI from the Amazon EC2 console, you can use Systems Manager Automation to create the AMI using the `AWS-CreateImage` runbook. For more information, see AWS-CreateImage in the *AWS Systems Manager Automation runbook reference User Guide*.

   a. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

b. In the navigation pane, choose **Instances**.

c. Select the instance that requires the driver upgrade, and choose **Instance state**, **Stop instance**.

d. After the instance is stopped, select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.

e. Choose **Instance state**, **Start instance**.

2. Connect to the instance using Remote Desktop.
3. We recommend that you take all non-system disks offline and note any drive letter mappings to the secondary disks in Disk Management before you perform this upgrade. This step is not required if you are performing an in-place update of AWS PV drivers. We also recommend setting non-essential services to **Manual** start-up in the Services console.
4. Download the drivers to your instance using one of the following options:

   - **Browser** – Download the latest driver package to the instance and extract the zip archive.
   - **PowerShell** – Run the following commands:

```
Invoke-WebRequest https://s3.amazonaws.com/ec2-windows-drivers-downloads/AWSPV/
Latest/AWSPVDriver.zip -outfile $env:USERPROFILE\pv_driver.zip
Expand-Archive $env:userprofile\pv_driver.zip -DestinationPath $env:userprofile
\pv_drivers
```

   If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:

```
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
```

5. Run `AWSPVDriverSetup.msi`.

After running the MSI, the instance automatically reboots and then upgrades the driver. The instance will not be available for up to 15 minutes. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, you can verify that the new driver was installed by connecting to the instance using Remote Desktop and then running the following PowerShell command:

```
Get-ItemProperty HKLM:\SOFTWARE\Amazon\PVDriver
```

Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see AWS PV driver package history Open Disk Management to review any offline secondary volumes and bring them online corresponding to the drive letters noted in Step 3.

If you previously disabled TCP offloading using Netsh for Citrix PV drivers we recommend that you re-enable this feature after upgrading to AWS PV drivers. TCP Offloading issues with Citrix drivers are not present in the AWS PV drivers. As a result, TCP Offloading provides better performance with AWS PV drivers.

If you previously applied a static IP address or DNS configuration to the network interface, you might need to reapply the static IP address or DNS configuration after upgrading AWS PV drivers.

Upgrade a domain controller (AWS PV upgrade)

Use the following procedure on a domain controller to perform either an in-place upgrade of AWS PV drivers, or to upgrade from Citrix PV drivers to AWS PV drivers. To ensure that your FSMO roles remain operational during the upgrade, we recommend that you transfer those roles to other domain controllers before you start the upgrade. For more information, see How to view and transfer FSMO roles on the *Microsoft Learn* website.

To upgrade a domain controller

1. We recommend that you create a backup of your domain controller in case you need to roll back your changes. Using an AMI as a backup is not supported. For more information, see Backup and restore considerations in the Microsoft documentation.
2. Run the following command to configure Windows to boot into Directory Services Restore Mode (DSRM).

> **Warning**
>
> Before running this command, confirm that you know the DSRM password. You'll need this information so that you can log in to your instance after the upgrade is complete and the instance automatically reboots.

```
bcdedit /set {default} safeboot dsrepair
```

PowerShell:

```
PS C:\> bcdedit /set "{default}" safeboot dsrepair
```

The system must boot into DSRM because the upgrade utility removes Citrix PV storage drivers so it can install AWS PV drivers. Therefore we recommend noting any drive letter and folder mappings to the secondary disks in Disk Management. When Citrix PV storage drivers are not present, secondary drives are not detected. Domain controllers that use an NTDS folder on secondary drives will not boot because the secondary disk is not detected.

> **Warning**
>
> After you run this command do not manually reboot the system. The system will be unreachable because Citrix PV drivers do not support DSRM.

3. Run the following command to add **`DisableDCCheck`** to the registry:

```
reg add HKLM\SOFTWARE\Wow6432Node\Amazon\AWSPVDriverSetup /v DisableDCCheck /t
 REG_SZ /d true
```

4. Download the latest driver package to the instance and extract the zip archive.
5. Run `AWSPVDriverSetup.msi`.

   After running the MSI, the instance automatically reboots and then upgrades the driver. The instance will not be available for up to 15 minutes.
6. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop. Open Disk Management to review any offline secondary volumes and bring them online corresponding to the drive letters and folder mappings noted earlier.

   You must connect to the instance by specifying the username in the following format *hostname*\administrator. For example, Win2k12TestBox\administrator.
7. Run the following command to remove the DSRM boot configuration:

```
bcdedit /deletevalue safeboot
```

8. Reboot the instance.
9. To complete the upgrade process, verify that the new driver was installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see AWS PV driver package history.
10. Run the following command to delete **DisableDCCheck** from the registry:

```
reg delete HKLM\SOFTWARE\Wow6432Node\Amazon\AWSPVDriverSetup /v DisableDCCheck
```

> **Note**
>
> If you previously disabled TCP offloading using Netsh for Citrix PV drivers we recommend that you re-enable this feature after upgrading to AWS PV Drivers. TCP Offloading issues with Citrix drivers are not present in the AWS PV drivers. As a result, TCP Offloading provides better performance with AWS PV drivers.

Upgrade Windows Server 2008 and 2008 R2 instances (Red Hat to Citrix PV upgrade)

Before you start upgrading your Red Hat drivers to Citrix PV drivers, make sure you do the following:

- Install the latest version of the EC2Config service. For more information, see Install the latest version of EC2Config.
- Verify that you have Windows PowerShell 3.0 installed. To verify the version that you have installed, run the following command in a PowerShell window:

  ```
  PS C:\> $PSVersionTable.PSVersion
  ```

  Windows PowerShell 3.0 is bundled in the Windows Management Framework (WMF) version 3.0 install package. If you need to install Windows PowerShell 3.0, see Windows Management Framework 3.0 in the Microsoft Download Center.

- Back up your important information on the instance, or create an AMI from the instance. For more information about creating an AMI, see Create an Amazon EBS-backed AMI.

> **Tip**
>
> Instead of creating the AMI from the Amazon EC2 console, you can use Systems Manager Automation to create the AMI using the `AWS-CreateImage` runbook. For more information, see AWS-CreateImage in the *AWS Systems Manager Automation runbook reference User Guide*.

If you create an AMI, make sure that you do the following:

- Write down your password.
- Do not run the Sysprep tool manually or using the EC2Config service.
- Set your Ethernet adapter to obtain an IP address automatically using DHCP.

To upgrade Red Hat drivers

1. Connect to your instance and log in as the local administrator. For more information about connecting to your instance, see Connect to your Windows instance using RDP.
2. In your instance, download the Citrix PV upgrade package.
3. Extract the contents of the upgrade package to a location of your choice.
4. Double-click the **Upgrade.bat** file. If you get a security warning, choose **Run**.
5. In the **Upgrade Drivers** dialog box, review the information and choose **Yes** if you are ready to start the upgrade.
6. In the **Red Hat Paravirtualized Xen Drivers for Windows uninstaller** dialog box, choose **Yes** to remove the Red Hat software. Your instance will be rebooted.

> **Note**
>
> If you do not see the uninstaller dialog box, choose **Red Hat Paravirtualize** in the Windows taskbar.

7. Check that the instance has rebooted and is ready to be used.

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

   b. On the **Instances** page, select **Actions**, then **Monitor and troubleshoot**, and then choose **Get system log**.

   c. The upgrade operations should have restarted the server 3 or 4 times. You can see this in the log file by the number of times `Windows is Ready to use` is displayed.

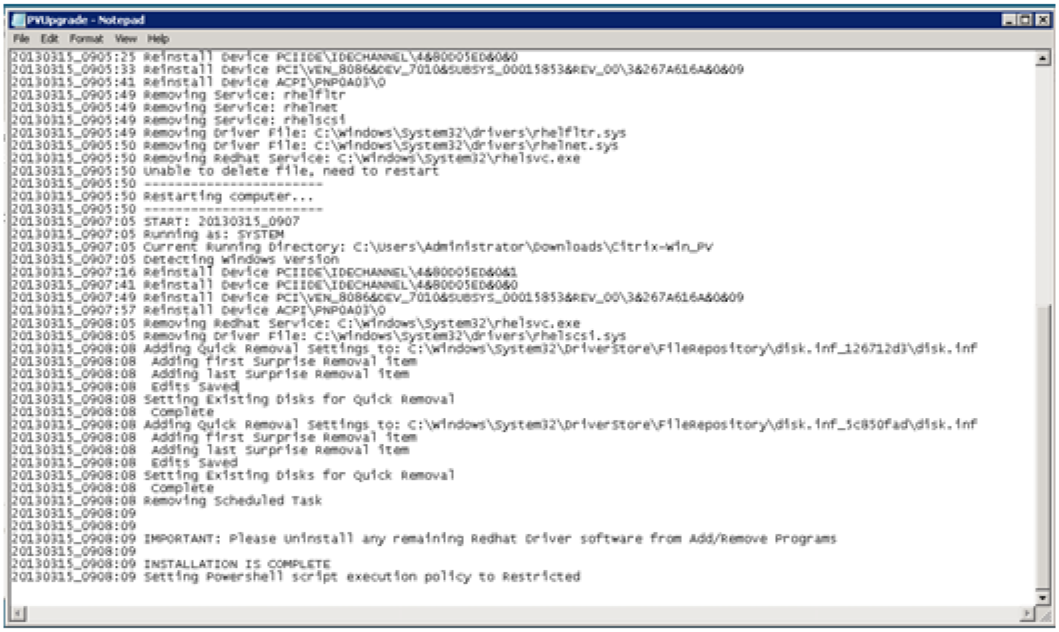
8. Connect to your instance and log in as the local administrator.

9. Close the **Red Hat Paravirtualized Xen Drivers for Windows uninstaller** dialog box.

10. Confirm that the installation is complete. Navigate to the `Citrix-WIN_PV` folder that you extracted earlier, open the `PVUpgrade.log` file, and then check for the text `INSTALLATION IS COMPLETE`.



Upgrade your Citrix Xen guest agent service

If you are using Citrix PV drivers on Windows Server, you can upgrade the Citrix Xen guest agent service. This Windows service handles tasks such as shutdown and restart events from the API. You can run this upgrade package on any version of Windows Server, as long as the instance is running Citrix PV drivers.

> **Important**
>
> For Windows Server 2008 R2 and later, we recommend you upgrade to AWS PV drivers that include the Guest Agent update.

Before you start upgrading your drivers, make sure you back up your important information on the instance, or create an AMI from the instance. For more information about creating an AMI, see [Create an Amazon EBS-backed AMI](#).

> **Tip**
>
> Instead of creating the AMI from the Amazon EC2 console, you can use Systems Manager Automation to create the AMI using the `AWS-CreateImage` runbook. For more

information, see AWS-CreateImage in the *AWS Systems Manager Automation runbook reference User Guide*.

If you create an AMI, make sure you do the following:

- Do not enable the Sysprep tool in the EC2Config service.
- Write down your password.
- Set your Ethernet adapter to DHCP.

To upgrade your Citrix Xen guest agent service

1. Connect to your instance and log in as the local administrator. For more information about connecting to your instance, see Connect to your Windows instance using RDP.
2. On your instance, download the Citrix upgrade package.
3. Extract the contents of the upgrade package to a location of your choice.
4. Double-click the **Upgrade.bat** file. If you get a security warning, choose **Run**.
5. In the **Upgrade Drivers** dialog box, review the information and choose **Yes** if you are ready to start the upgrade.
6. When the upgrade is complete, the `PVUpgrade.log` file will open and contain the text `UPGRADE IS COMPLETE`.
7. Reboot your instance.

Troubleshoot PV drivers on Windows instances

The following are solutions to issues that you might encounter with older Amazon EC2 images and PV drivers.

Contents

Windows Server 2012 R2 loses network and storage connectivity after an instance reboot

> **Important**
>
> This issue occurs only with AMIs made available before September 2014.

Windows Server 2012 R2 Amazon Machine Images (AMIs) made available before September 10, 2014 can lose network and storage connectivity after an instance reboot. The error in the AWS Management Console system log states: "Difficulty detecting PV driver details for Console Output." The connectivity loss is caused by the Plug and Play Cleanup feature. This features scans for and disables inactive system devices every 30 days. The feature incorrectly identifies the EC2 network device as inactive and removes it from the system. When this happens, the instance loses network connectivity after a reboot.

For systems that you suspect could be affected by this issue, you can download and run an in-place driver upgrade. If you are unable to perform the in-place driver upgrade, you can run a helper script. The script determines if your instance is affected. If it is affected, and the Amazon EC2 network device has not been removed, the script disables the Plug and Play Cleanup scan. If the network device was removed, the script repairs the device, disables the Plug and Play Cleanup scan, and enables your instance to reboot with network connectivity enabled.

Contents

Choose how to fix problems

There are two methods for restoring network and storage connectivity to an instance affected by this issue. Choose one of the following methods:

Method	Prerequisites	Procedure Overview
Method 1 - Enhanced networking	Enhanced networking is only available in a virtual private	You change the server instance type to a C3

Method	Prerequisites	Procedure Overview
	cloud (VPC) which requires a C3 instance type. If the server does not currently use the C3 instance type, then you must temporarily change it.	instance. Enhanced networkin g then enables you to connect to the affected instance and fix the problem. After you fix the problem, you change the instance back to the original instance type. This method is typically faster than Method 2 and less likely to result in user error. You will incur additiona l charges as long as the C3 instance is running.
Method 2 - Registry configura tion	Ability to create or access a second server. Ability to change Registry settings.	You detach the root volume from the affected instance, attach it to a different instance, connect, and make changes in the Registry. You will incur additiona l charges as long as the additional server is running. This method is slower than Method 1, but this method has worked in situations where Method 1 failed to resolve the problem.

Method 1 - Enhanced networking

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Locate the affected instance. Select the instance and choose **Instance state**, and then choose **Stop instance**.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. After the instance is stopped, create a backup. Select the instance and choose **Actions**, then **Image and templates**, and then choose **Create image**.
5. Change the instance type to any C3 instance type.
6. Start the instance.
7. Connect to the instance using Remote Desktop and then download the AWS PV Drivers Upgrade package to the instance.
8. Extract the contents of the folder and run `AWSPVDriverSetup.msi`.

   After running the MSI, the instance automatically reboots and then upgrades the drivers. The instance will not be available for up to 15 minutes.
9. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop and verify that the new drivers were installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see AWS PV driver package history.
10. Stop the instance and change the instance back to its original instance type.
11. Start the instance and resume normal use.

Method 2 - Registry configuration

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Locate the affected instance. Select the instance, choose **Instance state**, and then choose **Stop instance**.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. Choose **Launch instances** and create a temporary Windows Server 2008 or Windows Server 2012 instance in the same Availability Zone as the affected instance. Do not create a Windows Server 2012 R2 instance.

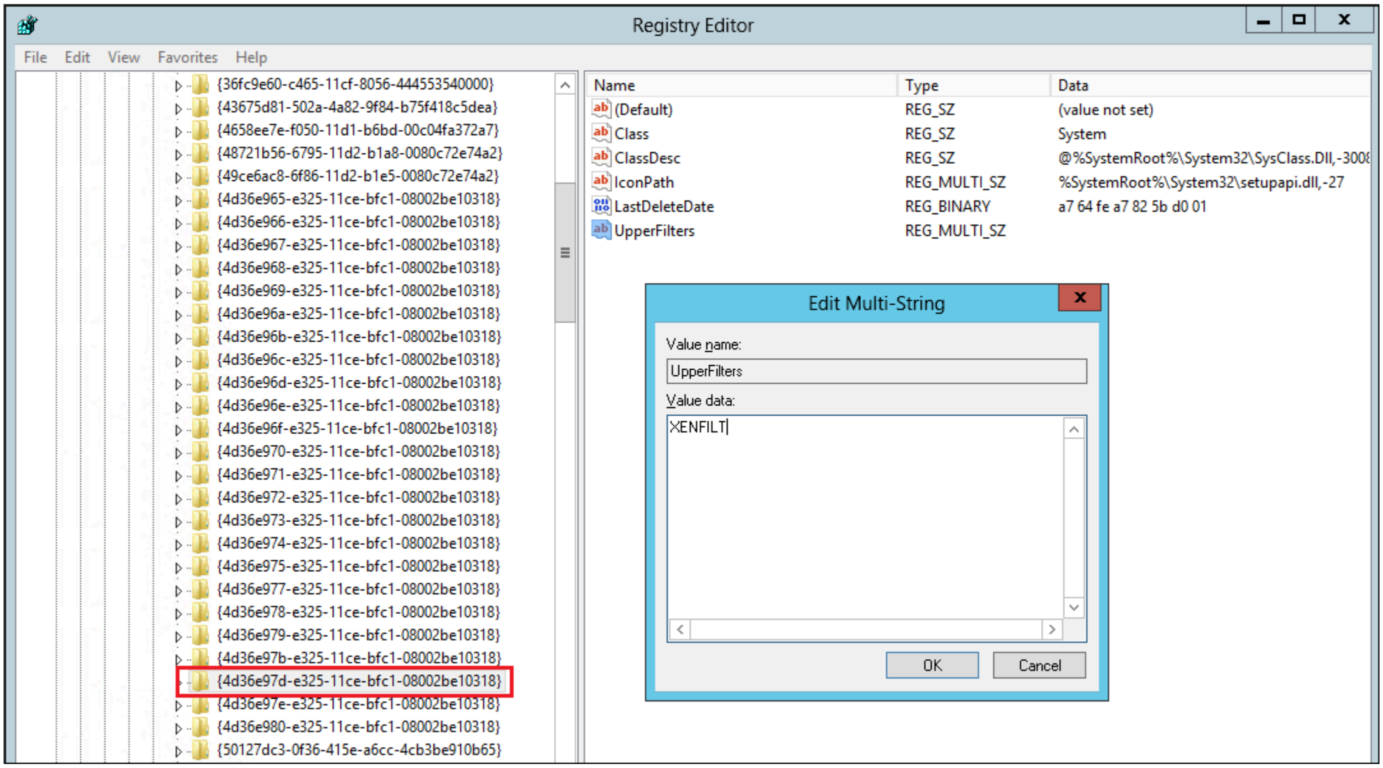
   > **Important**
   >
   > If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the navigation pane, choose **Volumes**.
6. Locate the root volume of the affected instance. Detach the volume and then attach the volume to the temporary instance that you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to make the volume available for use.
8. On the temporary instance, open the **Run** dialog box, type **`regedit`**, and press Enter.
9. In the Registry Editor navigation pane, choose **HKEY_Local_Machine**, and then from the **File** menu choose **Load Hive**.
10. In the **Load Hive** dialog box, navigate to *Affected Volume*\Windows\System32\config\System and type a temporary name in the **Key Name** dialog box. For example, enter OldSys.
11. In the navigation pane of the Registry Editor, locate the following keys:

    HKEY_LOCAL_MACHINE*`your_temporary_key_name`*\ControlSet001\Control\Class\4d36e97d-e325-11ce-bfc1-08002be10318

    HKEY_LOCAL_MACHINE*`your_temporary_key_name`*\ControlSet001\Control\Class\4d36e96a-e325-11ce-bfc1-08002be10318

12. For each key, double-click **UpperFilters**, enter a value of XENFILT, and then choose **OK**.



13. Locate the following key:

    HKEY_LOCAL_MACHINE*your_temporary_key_name*\ControlSet001\Services\XENBUS\Parameters

14. Create a new string (REG_SZ) with the name ActiveDevice and the following value:

    PCI\VEN_5853&DEV_0001&SUBSYS_00015853&REV_01

15. Locate the following key:

    HKEY_LOCAL_MACHINE*your_temporary_key_name*\ControlSet001\Services\XENBUS

16. Change the **Count** from 0 to 1.

17. Locate and delete the following keys:

    HKEY_LOCAL_MACHINE*your_temporary_key_name*\ControlSet001\Services\xenvbd\StartOverride

    HKEY_LOCAL_MACHINE *your_temporary_key_name*\ControlSet001\Services\xenfilt\StartOverride

18. In the Registry Editor navigation pane, choose the temporary key that you created when you first opened the Registry Editor.

19. From the **File** menu, choose **Unload Hive**.
20. In the Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
21. In the Amazon EC2 console, detach the affected volume from the temporary instance and reattach it to your Windows Server 2012 R2 instance with the device name /dev/sda1. You must specify this device name to designate the volume as a root volume.
22. Start the instance.
23. Connect to the instance using Remote Desktop and then download the AWS PV Drivers Upgrade package to the instance.
24. Extract the contents of the folder and run `AWSPVDriverSetup.msi`.

    After running the MSI, the instance automatically reboots and then upgrades the drivers. The instance will not be available for up to 15 minutes.
25. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop and verify that the new drivers were installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see AWS PV driver package history.
26. Delete or stop the temporary instance you created in this procedure.

Run the remediation script

If you are unable to perform an in-place driver upgrade or migrate to a newer instance you can run the remediation script to fix the problems caused by the Plug and Play Cleanup task.

To run the remediation script

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance for which you want to run the remediation script. Choose **Instance state**, and then choose **Stop instance**.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. After the instance is stopped, create a backup. Select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.
5. Choose **Instance state**, and then choose **Start instance**.
6. Connect to the instance by using Remote Desktop and then download the RemediateDriverIssue.zip folder to the instance.
7. Extract the contents of the folder.
8. Run the remediation script according to the instructions in the Readme.txt file. The file is located in the folder where you extracted RemediateDriverIssue.zip.

TCP offloading

> **Important**
>
> This issue does not apply to instances running AWS PV or Intel network drivers.

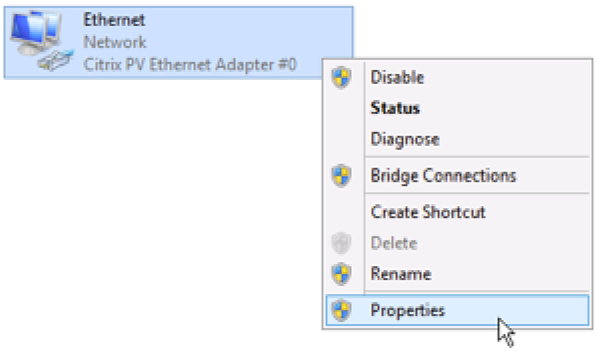
By default, TCP offloading is enabled for the Citrix PV drivers in Windows AMIs. If you encounter transport-level errors or packet transmission errors (as visible on the Windows Performance Monitor)—for example, when you're running certain SQL workloads—you may need to disable this feature.

> **Warning**
>
> Disabling TCP offloading may reduce the network performance of your instance.

To disable TCP offloading for Windows Server 2012 and 2008

1. Connect to your instance and log in as the local administrator.

2. If you're using Windows Server 2012, press **Ctrl+Esc** to access the **Start** screen, and then choose **Control Panel**. If you're using Windows Server 2008, choose **Start** and select **Control Panel**.
3. Choose **Network and Internet**, then **Network and Sharing Center**.
4. Choose **Change adapter settings**.
5. Right-click **Citrix PV Ethernet Adapter #0** and select **Properties**.



6. In the **Local Area Connection Properties** dialog box, choose **Configure** to open the **Citrix PV Ethernet Adapter #0 Properties** dialog box.
7. On the **Advanced** tab, disable each of the properties, except for **Correct TCP/UDP Checksum Value**. To disable a property, select it from **Property** and choose **Disabled** from **Value**.
8. Choose **OK**.
9. Run the following commands from a Command Prompt window.

```
netsh int ip set global taskoffload=disabled
netsh int tcp set global chimney=disabled
netsh int tcp set global rss=disabled
netsh int tcp set global netdma=disabled
```

10. Reboot the instance.

Time synchronization

Prior to the release of the 2013.02.13 Windows AMI, the Citrix Xen guest agent could set the system time incorrectly. This can cause your DHCP lease to expire. If you have issues connecting to your instance, you might need to update the agent.

To determine whether you have the updated Citrix Xen guest agent, check whether the `C:\Program Files\Citrix\XenGuestAgent.exe` file is from March 2013. If the date on this file is earlier than that, update the Citrix Xen guest agent service. For more information, see Upgrade your Citrix Xen guest agent service.

Workloads that leverage more than 20,000 disk IOPS experience degradation due to CPU bottlenecks

You can be affected by this issue if you are using Windows instances running AWS PV drivers that leverage more than 20,000 IOPS, and you experience bug check code `0x9E: USER_MODE_HEALTH_MONITOR`.

Disk reads and writes (IOs) in the AWS PV drivers occur in two phases: **IO preparation** and **IO completion**. By default, the preparation phase runs on a single arbitrary core. The completion phase runs on core `0`. The amount of computation required to process an IO varies based on it size and other properties. Some IOs use more computation in the preparation phase, and others in the completion phase. When an instance drives more than 20,000 IOPS, the preparation or completion phase may result in a bottleneck, where the CPU upon which it runs is at 100% capacity. Whether or not the preparation or completion phase becomes a bottleneck depends on the properties of the IOs used by the application.

Starting with AWS PV drivers 8.4.0, the load of the preparation phase and the completion phase can be distributed across multiple cores, eliminating bottlenecks. Each application uses different IO properties. Therefore, applying one of the following configurations may raise, lower, or not impact the performance of your application. After you apply any of these configurations, monitor the application to verify that it is meeting your desired performance.

1. **Prerequisites**

   Before you begin this troubleshooting procedure, verify the following prerequisites:

   - Your instance uses AWS PV drivers version 8.4.0 or later. To upgrade, see Upgrade PV drivers on EC2 Windows instances.
   - You have RDP access to the instance. For steps to connect to your Windows instance using RDP, see Connect to your Windows instance using an RDP client.
   - You have administrator access on the instance.

2. **Observe CPU load on your instance**

   You can use Windows Task Manager to view the load on each CPU to determine potential bottlenecks to disk IO.

1. Verify that your application is running and handling traffic similar to your production workload.
2. Connect to your instance using RDP.
3. Choose the **Start** menu on your instance.
4. Enter `Task Manager` in the **Start** menu to open Task Manager.
5. If Task Manager displays the Summary View, choose **More details** to expand the detailed view.
6. Choose the **Performance** tab.
7. Select **CPU** in the left pane.
8. Right-click on the graph in the main pane and select **Change graph to**>**Logical processors** to display each individual core.
9. Depending on how many cores are on your instance, you may see lines displaying CPU load over time, or you may just see a number.
   - If you see graphs displaying load over time, look for CPUs where the box is almost entirely shaded.
   - If you see a number on each core, look for cores that consistently show 95% or greater.

10Note whether core `0` or a different core is experiencing a heavy load.

3. **Choose which configuration to apply**

Configuration name	When to apply this configuration	Notes
Default configuration	Workload is driving less than 20,000 IOPS, or other configurations did not improve performance or stability.	For this configuration, IO occurs on a few cores, which may benefit smaller workloads by increasing cache locality and reducing context switching.
Allow driver to choose whether to distribute completion	Workload is driving more than 20,000 IOPS and moderate or high load is observed on core `0`.	This configuration is recommended for all Xen instances using PV 8.4.0 or later and leveraging more than 20,000 IOPS,

Configuration name	When to apply this configuration	Notes
		whether or not problems are encountered.
Distribute both preparation and completion	Workload is driving more than 20,000 IOPS, and either allowing the driver to choose the distribution did not improve performance, or a core other than `0` is experiencing a high load.	This configuration enables distribution of both IO preparation and IO completion.

> **Note**
>
> We recommend that you do not distribute IO preparation without also distributing IO completion (setting `DpcRedirection` without setting `NotifierDistributed`) because the completion phase is sensitive to overload by the preparation phase when the preparation phase is running in parallel.

Registry key values

- *NotifierDistributed*

  Value `0` or not present — The completion phase will run on core `0`.

  Value 1 — The driver chooses to run the completion phase or core `0` or one additional core per attached disk.

  Value 2 — The driver runs the completion phase on one additional core per attached disk.
- *DpcRedirection*

  Value `0` or not present — The preparation phase will run on a single, arbitrary core.

  Value 1 — The preparation phase is distributed across multiple cores.

Default configuration

Apply the default configuration with AWS PV driver versions prior to 8.4.0, or if performance or stability degradation is observed after applying one of the other configurations in this section.

1. Connect to your instance using RDP.
2. Open a new PowerShell command prompt as an administrator.
3. Run the following commands to remove the `NotifierDistributed` and `DpcRedirection` registry keys.

```
Remove-ItemProperty -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Name NotifierDistributed
```

```
Remove-ItemProperty -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Name DpcRedirection
```

4. Reboot your instance.

Allow driver to choose whether to distribute completion

Set `NotiferDistributed` registry key to allow the PV storage driver to choose whether or not to distribute IO completion.

1. Connect to your instance using RDP.
2. Open a new PowerShell command prompt as an administrator.
3. Run the following command to set the `NotiferDistributed` registry key.

```
Set-ItemProperty -Type DWORD -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Value 0x00000001 -Name NotifierDistributed
```

4. Reboot your instance.

Distribute both preparation and completion

Set `NotifierDistributed` and `DpcRedirection` registry keys to always distribute both the preparation and completion phases.

1. Connect to your instance using RDP.
2. Open a new PowerShell command prompt as an administrator.
3. Run the following commands to set the `NotifierDistributed` and `DpcRedirection` registry keys.

```
Set-ItemProperty -Type DWORD -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Value 0x00000002 -Name NotifierDistributed
```

```
Set-ItemProperty -Type DWORD -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Value 0x00000001 -Name DpcRedirection
```

4. Reboot your instance.

AWS NVMe drivers

Amazon EBS volumes and instance store volumes are exposed as NVMe block devices on Nitro-based instances. To fully utilize the performance and capabilities of Amazon EBS features for volumes exposed as NVMe block devices, the instance must have the AWS NVMe driver installed. All current generation AWS Windows AMIs come with the AWS NVMe driver installed by default.

For more information about EBS and NVMe, see Amazon EBS and NVMe in the *Amazon EBS User Guide*. For more information about SSD instance store and NVMe, see SSD instance store volumes for EC2 instances.

Linux instances

The following AMIs include the required NVMe drivers:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 or later with `linux-aws` kernel

> **Note**
>
> AWS Graviton-based instance types require Ubuntu 18.04 or later with `linux-aws` kernel

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

To confirm that your instance has the NVMe driver

You can confirm that your instance has the NVMe driver using the following command.

- Amazon Linux, RHEL, CentOS, and SUSE Linux Enterprise Server

  ```
  $ modinfo nvme
  ```

  If the instance has the NVMe driver, the command returns information about the driver.

- Amazon Linux 2 and Ubuntu

  ```
  $ ls /sys/module/ | grep nvme
  ```

  If the instance has the NVMe driver, the command returns the installed drivers.

To update the NVMe driver

If your instance has the NVMe driver, you can update the driver to the latest version using the following procedure.

1. Connect to your instance.
2. Update your package cache to get necessary package updates as follows.

   - For Amazon Linux 2, Amazon Linux, CentOS, and Red Hat Enterprise Linux:

```
[ec2-user ~]$ sudo yum update -y
```

- For Ubuntu and Debian:

```
[ec2-user ~]$ sudo apt-get update -y
```

3. Ubuntu 16.04 and later include the `linux-aws` package, which contains the NVMe and ENA drivers required by Nitro-based instances. Upgrade the `linux-aws` package to receive the latest version as follows:

```
[ec2-user ~]$ sudo apt-get install --only-upgrade -y linux-aws
```

   For Ubuntu 14.04, you can install the latest `linux-aws` package as follows:

```
[ec2-user ~]$ sudo apt-get install linux-aws
```

4. Reboot your instance to load the latest kernel version.

```
sudo reboot
```

5. Reconnect to your instance after it has rebooted.

Windows instances

PowerShell

If you did not launch your instance from one of the latest AWS Windows AMIs provided by Amazon, use the following procedure to install the current AWS NVMe driver on your instance. Reboot is required for this install. Either the install script will reboot your instance or you must reboot it as the final step.

Prerequisites

- PowerShell version 3.0 or later is installed.
- The commands shown in this section must run in the 64-bit version of PowerShell. Do not use the `x86` version of PowerShell. That is the 32-bit version of the shell, and is not supported for these commands.

To download and install the latest AWS NVMe driver

1. We recommend that you create an AMI as a backup as follows, in case you need to roll back your changes.

   a. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

   b. In the navigation pane, choose **Instances**.

   c. Select the instance that requires the driver upgrade, and choose **Instance state**, **Stop instance**.

   d. After the instance is stopped, select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.

   e. Choose **Instance state**, **Start instance**.

2. Connect to your instance and log in as the local administrator.

3. Download the drivers to your instance using one of the following options:

   - **Browser** – Download the latest driver package to the instance and extract the zip archive.
   - **PowerShell** – Run the following commands:

   ```
   Invoke-WebRequest https://s3.amazonaws.com/ec2-windows-drivers-downloads/
   NVMe/Latest/AWSNVMe.zip -outfile $env:USERPROFILE\nvme_driver.zip
   Expand-Archive $env:userprofile\nvme_driver.zip -DestinationPath
    $env:userprofile\nvme_driver
   ```

   If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:

   ```
   [Net.ServicePointManager]::SecurityProtocol =
    [Net.SecurityProtocolType]::Tls12
   ```

4. Install the driver to your instance by running the `install.ps1` PowerShell script from the `nvme_driver` directory (`.\install.ps1`). If you get an error, make sure you are using PowerShell 3.0 or later.

a. (Optional) Starting with AWS NVMe version `1.5.0`, Small Computer System Interface (SCSI) persistent reservations are supported for Windows Server 2016 and later. This feature adds support for Windows Server Failover Clustering with shared Amazon EBS storage. By default, this feature isn't enabled during installation.

   You can enable the feature when running the `install.ps1` script to install the driver by specifying the `EnableSCSIPersistentReservations` parameter with a value of `$true`.

```
PS C:\> .\install.ps1 -EnableSCSIPersistentReservations $true
```

   You can disable the feature when running the `install.ps1` script to install the driver by specifying the `EnableSCSIPersistentReservations` parameter with a value of `$false`.

```
PS C:\> .\install.ps1 -EnableSCSIPersistentReservations $false
```

b. Starting with AWS NVMe `1.5.0`, the `install.ps1` script always installs the `ebsnvme-id` tool with the driver.

   (Optional) For versions `1.4.0`, `1.4.1`, and `1.4.2`, the `install.ps1` script allows you to specify whether the `ebsnvme-id` tool should be installed with the driver.

   i. To install the `ebsnvme-id` tool, specify `InstallEBSNVMeIdTool ‘Yes’`.

   ii. If you don't want to install the tool, specify `InstallEBSNVMeIdTool ‘No’`.

      If you don't specify `InstallEBSNVMeIdTool`, and the tool is already present at `C:\ProgramData\Amazon\Tools`, the package will upgrade the tool by default. If the tool is not present, `install.ps1` will not upgrade the tool by default.

      If you don't want to install the tool as part of the package, and want to install it later, you can find the latest version or the tool in the driver package. Alternatively, you can download version `1.0.0` from Amazon S3:

      Download the `ebsnvme-id` tool.

5. If the installer does not reboot your instance, reboot the instance.

Distributor

You can use Distributor, a capability of AWS Systems Manager, to install the NVMe driver package one time or with scheduled updates.

To install the latest AWS NVMe driver

1. For the instructions for how to install the NVMe driver package using Distributor, see the procedures in [Install or update packages] in the *Amazon EC2 Systems Manager User Guide*.
2. For **Installation Type**, select **Uninstall and reinstall**.
3. For **Name**, choose **AWSNVMe**.
4. (Optional) For **Additional Arguments**, you can customize the installation by specifying values. The values must be formatted using valid JSON syntax. For examples of how to pass additional arguments for the `aws configure` package, see the [Command document plugin reference].

   a. Starting with AWS NVMe `1.5.0`, the driver supports SCSI persistent reservations for Windows Server 2016 and later. By default, this feature isn't enabled during installation.

      - To enable this feature, specify `{"SSM_EnableSCSIPersistentReservations": "true"}`.
      - If you don't want to enable this feature, specify `{"SSM_EnableSCSIPersistentReservations": "false"}`.

   b. Starting with AWS NVMe `1.5.0`, the `install.ps1` script will always install the `ebsnvme-id` tool.

      (Optional) For versions `1.4.0`, `1.4.1`, and `1.4.2`, the `install.ps1` script allows you to specify whether the ebsnvme-id tool should be installed with the driver.

      - To install the ebsnvme-id tool, specify `{"SSM_InstallEBSNVMeIdTool": "Yes"}`.
      - If you don't want to install the tool, specify `{"SSM_InstallEBSNVMeIdTool": "No"}`.

        If `SSM_InstallEBSNVMeIdTool` is not specified for **Additional Arguments**, and the tool is already present at `C:\ProgramData\Amazon\Tools`, the package will upgrade the tool by default. If the tool is not present, the package will not upgrade the tool by default.

If you don't want to install the tool as part of the package, and want to install it later, you can find the latest version of the tool in the driver package. Alternatively, you can download version `1.0.0` from Amazon S3:

Download the `ebsnvme-id` tool.

5. If the installer does not reboot your instance, reboot the instance.

Configure SCSI persistent reservations for Windows instances

After AWS NVMe driver version `1.5.0` or later has been installed, you can enable or disable SCSI persistent reservations using the Windows registry for Windows Server 2016 and later. You must reboot the instance for these registry changes to take effect.

You can enable SCSI persistent reservations with the following command which sets the `EnableSCSIPersistentReservations` to a value of `1`.

```
PS C:\> $registryPath = "HKLM:\SYSTEM\CurrentControlSet\Services\AWSNVMe\Parameters
\Device"
Set-ItemProperty -Path $registryPath -Name EnableSCSIPersistentReservations -Value 1
```

You can disable SCSI persistent reservations with the following command which sets the `EnableSCSIPersistentReservations` to a value of `0`.

```
PS C:\> $registryPath = "HKLM:\SYSTEM\CurrentControlSet\Services\AWSNVMe\Parameters
\Device"
Set-ItemProperty -Path $registryPath -Name EnableSCSIPersistentReservations -Value 0
```

AWS NVMe Windows driver version history

The following table shows which AWS NVMe drivers run on each version of Windows Server on Amazon EC2.

Windows Server version	AWS NVMe driver version
Windows Server 2025	latest version

Windows Server version	AWS NVMe driver version
Windows Server 2022	latest version
Windows Server 2019	latest version
Windows Server 2016	latest version
Windows Server 2012 R2	version 1.5.1 and earlier
Windows Server 2012	version 1.5.1 and earlier
Windows Server 2008 R2	version 1.3.2 and earlier
Windows Server 2008	version 1.3.2 and earlier

The following table describes the released versions of the AWS NVMe driver.

Package version	Driver version	Details	Release date
1.6.0	1.6.0	• Updated the install script to use PnPUtil. • Updated ebsnvme-id.exe to use NVMe IOCTL.	25 October 2024
1.5.1	1.5.0	Fixed the install script to create a folder for the `ebsnvme-id` tool if it is not present.	17 November 2023
1.5.0	1.5.0	Added support for Small Computer System Interface (SCSI) persistent reservations for instances running Windows Server 2016 and later. The ebsnvme-id tool (`ebsnvme-id.exe`) is now installed by default.	31 August 2023
1.4.2	1.4.2	Fixed a bug where the AWS NVMe driver did not support instance store volumes on D3 instances.	16 March 2023

Package version	Driver version	Details	Release date
1.4.1	1.4.1	Reports Namespace Preferred Write Granularity (NPGW) for EBS volumes that support this optional NVMe feature. For more information, see section 8.25, "Improving Performance through I/O Size and Alignment Adherence," in the [NVMe Base Specification, version 1.4]().	20 May 2022
1.4.0	1.4.0	• Added support for IOCTLs that allow applications to interact with NVMe devices. This support allows applications to get `IdentifyController`, `IdentifyNamespace`, and `NameSpace` list from the NVMe device. For more information, see [Protocol-specific queries]() in the Microsoft documentation. • The 1.4.0 driver version and the latest `ebsnvme-id` tool (`ebsnvme-id.exe`) are combined in a single package. This combination allows you to install both driver and tool from a single package. For more details, see [AWS NVMe drivers](). • Bug fixes and reliability improvements.	23 November 2021
[1.3.2]()	1.3.2	Fixed issue with modifying EBS volumes actively processing IO, which may result in data corruption. Customers who do not modify online EBS volumes (for example, resizing or changing type) are not impacted. This is the last version that can run on Windows Server 2008 and 2008 R2. This version is available for download but no longer supported. Windows Server 2008 and 2008 R2 has reached end-of-life, and is no longer supported by Microsoft.	10 September 2019

Package version	Driver version	Details	Release date
1.3.1	1.3.1	Reliability Improvements.	21 May 2019
1.3.0	1.3.0	Device optimization improvements.	31 August 2018
1.2.0	1.2.0	Performance and reliability improvements for AWS NVMe devices on all supported instances, including bare metal instances.	13 June 2018
>1.0.0	>1.0.0	AWS NVMe driver for supported instance types running Windows Server.	12 February 2018

Subscribe to notifications

Amazon SNS can notify you when new versions of EC2 Windows Drivers are released. Use the following procedure to subscribe to these notifications.

To subscribe to EC2 notifications from the console

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to are in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:

    a. For **TopicARN**, copy the following Amazon Resource Name (ARN):

       arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers

    b. For **Protocol**, choose `Email`.

    c. For **Endpoint**, type an email address that you can use to receive the notifications.

    d. Choose **Create subscription**.

6. You'll receive a confirmation email. Open the email and follow the directions to complete your subscription.

Whenever new EC2 Windows drivers are released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from Amazon EC2 Windows driver notification

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Subscriptions**.
3. Select the checkbox for the subscription and then choose **Actions**, **Delete subscriptions**. When prompted for confirmation, choose **Delete**.

To subscribe to EC2 notifications using the AWS CLI

To subscribe to EC2 notifications with the AWS CLI, use the following command.

```
aws sns subscribe --topic-arn arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers --
protocol email --notification-endpoint YourUserName@YourDomainName.ext
```

To subscribe to EC2 notifications using AWS Tools for Windows PowerShell

To subscribe to EC2 notifications with AWS Tools for Windows PowerShell, use the following command.

```
Connect-SNSNotification -TopicArn 'arn:aws:sns:us-east-1:801119661308:ec2-windows-
drivers' -Protocol email -Region us-east-1 -Endpoint 'YourUserName@YourDomainName.ext'
```

Configure your Amazon EC2 Windows instance

After you've launched a Windows instance, you can log in as an administrator to perform additional configuration for Windows features and system settings. EC2 Windows troubleshooting utilities can help you troubleshoot issues on your instance.

You can configure Windows launch agents and other Windows-specific features as follows.

Windows launch agents

Each AWS Windows AMI (and many other AMIs that are available on the AWS Marketplace) includes a Windows launch agent that's pre-configured with default settings. Launch agents perform tasks during instance startup and run if an instance is stopped and later started, or restarted.

EC2 Fast Launch for Windows

Every Amazon EC2 Windows instance must go through the standard Windows operating system (OS) launch steps, which include several reboots, and often take 15 minutes or longer to complete. Amazon EC2 Windows Server AMIs that have the EC2 Fast Launch feature enabled complete some of those steps and reboots in advance to reduce the time it takes to launch an instance.

Windows-specific system settings

The following list includes some system settings that apply only for Windows operating systems:

Change the Windows Administrator password

When you connect to a Windows instance, you must specify a user account and password that has permission to access the instance. The first time that you connect to an instance, you must use the Administrator account and provide the default password. When you connect to an instance the first time, we recommend that you change the Administrator password from its default value.

Add Windows System components

Windows Server operating systems include many optional components. Including all optional components in each AWS Windows Server AMI is not practical. Instead, we provide installation media EBS snapshots that have the necessary files to configure or install components on your Windows instance.

Install WSL on Windows

Windows Subsystem for Linux (WSL) is a free download that you can install on your Windows instance. By installing WSL, you can run native Linux command line tools directly on your Windows instance and use the Linux tools for scripting, alongside your traditional Windows desktop. You can easily swap between Linux and Windows on a single Windows instance, which you might find useful in a development environment.

AWS device drivers for Windows instances

You can update the AWS device drivers for your Windows instances. For more information, see the section called "Manage device drivers".

The following table summarizes the supported drivers for Nitro-based instances by Windows version.

Version	Storage driver	Enhanced networking driver
Windows Server 2025	AWS NVMe latest version	ENA latest version
Windows Server 2022	AWS NVMe latest version	ENA latest version
Windows Server 2019	AWS NVMe latest version	ENA latest version
Windows Server 2016	AWS NVMe latest version	ENA latest version
Windows Server 2012 R2	AWS NVMe version 1.5.1	ENA version 2.6.0
Windows Server 2008 R2	AWS NVMe version 1.3.2	ENA version 2.2.3

The following table summarizes the supported drivers for Xen-based instances by Windows version.

Version	Storage driver	Enhanced networking driver
Windows Server 2022	AWS PV latest version	• ENA latest version [1] • Intel VF [2] • AWS PV latest version [3]
Windows Server 2019	AWS PV latest version	• ENA latest version [1] • Intel VF [2] • AWS PV latest version [3]
Windows Server 2016	AWS PV latest version	• ENA latest version [1]

Version	Storage driver	Enhanced networking driver
		• Intel VF [2] • AWS PV latest version [3]
Windows Server 2012 R2	AWS PV version 8.4.3	• ENA version 2.6.0 [1] • Intel VF [2] • AWS PV version 8.4.3 [3]
Windows Server 2008 R2	AWS PV version 8.3.5	• ENA version 2.2.3 [1] • Intel VF [2] • AWS PV version 8.3.5 [3]

[1] For instance types G3, H1, I3, `m4.16xlarge`, P2, P3, P3dn, and R4.

[2] For instance types C3, C4, D2, I2, M4 (excluding `m4.16xlarge`), and R3.

[3] For instance types C1, M1, M2, M3, T1, T2, X1, and X1e.

Windows launch agents on Amazon EC2 Windows instances

Each AWS Windows AMI includes a Windows launch agent that's pre-configured with default settings. Launch agents perform tasks during instance startup and run if an instance is stopped and later started, or restarted. For information about a specific agent, see the detail pages in the following list.

For more information about AWS Windows AMIs, see the AWS Windows AMI reference.

- Use the EC2Launch v2 agent to perform tasks during EC2 Windows instance launch
- Use the EC2Launch v1 agent to perform tasks during EC2 Windows instance launch
- Use the EC2Config service to perform tasks during EC2 legacy Windows operating system instance launch

Content

- Configure DNS Suffix for EC2 Windows launch agents
- Subscribe to EC2 Windows launch agent notifications
- Windows Service administration for EC2Launch v2 and EC2Config agents

Compare Amazon EC2 launch agents

The following table shows the major functional differences between EC2Config, EC2Launch v1, and EC2Launch v2.

Feature	EC2Config	EC2Launch v1	EC2Launch v2
Run as	Windows Service	PowerShell Scripts	Windows Service
Supports	Legacy OS only	Windows Server versions: • 2016 • 2019 (LTSC and SAC)	Windows Server versions: • 2016 • 2019 (LTSC and SAC) • 2022 • 2025
Configuration file	XML	JSON	JSON/YAML
Set Administrator username	No	No	Yes
Compressed user data	No	No	Yes
Local user data baked on AMI	No	No	Yes, configurable
Task configuration in user data	No	No	Yes
Configurable wallpaper	No	No	Yes

Feature	EC2Config	EC2Launch v1	EC2Launch v2
Customize task run order	No	No	Yes
Configurable tasks	15	9	20 at launch
Supports Windows Event Viewer	Yes	No	Yes
Number of Event Viewer event types	2	0	30

> **Note**
>
> EC2Config documentation is provided for historical reference only. The operating system versions it runs on are no longer supported by Microsoft. We strongly recommend that you upgrade to the latest launch service.

Configure DNS Suffix for EC2 Windows launch agents

With Amazon EC2 launch agents, you can configure a list of DNS suffixes that Windows instances use for domain name resolution. The launch agents override the standard Windows settings in the `System\CurrentControlSet\Services\Tcpip\Parameters\SearchList` registry key by adding the following values to the DNS suffix search list:

- The domain of the instance
- The suffixes that result from devolution of the instance domain
- NV domain
- The domains specified by each network interface cards

All launch agents support DNS suffix configuration. For more information, see your specific launch agent version:

- For information about the `setDnsSuffix` task and how to configure DNS suffixes in EC2Launch v2, see setDnsSuffix .

- For information about DNS suffix list setup and how to enable or disable devolution for EC2Launch v1, see [Configure the EC2Launch v1 agent on your Windows instance]().
- For information about DNS suffix list setup and how to enable or disable devolution for EC2Config, see [EC2Config settings files]().

Domain name devolution

Domain name devolution is an Active Directory behavior that allows computers in a child domain to access resources in the parent domain without using a fully qualified domain name. By default, domain name devolution continues until there are only two nodes left in the domain name progression.

Launch agents perform devolution on the domain name if the instance is connected to a domain, and add the results to the DNS suffix search list that's maintained in the **`System\CurrentControlSet\Services\Tcpip\Parameters\SearchList`** registry key. The agents use the settings from the following registry keys, to determine the devolution behavior.

- **`System\CurrentControlSet\Services\Tcpip\Parameters\UseDomainNameDevolution`**
  - When not set, disables devolution
  - When set to `1`, enables devolution (default)
  - When set to `0`, disables devolution
- **`System\CurrentControlSet\Services\Dnscache\Parameters\DomainNameDevolutionLevel`**
  - When not set, use level of 2 (default)
  - When set to `3` or greater, use value to set level

When you disable devolution or change your devolution settings to a higher level, the `System\CurrentControlSet\Services\Tcpip\Parameters\SearchList` registry key stil contains the suffixes that were added previously. They are not automatically removed. You can manually update the list, or you can clear the list and let your agent run through the process to set up the new list.

> **Note**
>
> To clear the DNS suffix list from the registry, you can run the following command.

```
PS C:\> Invoke-CimMethod -ClassName Win32_NetworkAdapterConfiguration -
MethodName "SetDNSSuffixSearchOrder" -Arguments @{ DNSDomainSuffixSearchOrder =
 $null } | Out-Null
```

Devolution examples

The following examples show domain name progression through the devolution process.

`corp.example.com`

- Progresses to `example.com`

`locale.region.corp.example.com`

1. Progresses to `region.corp.example.com`
2. Progresses to `corp.example.com`
3. Progresses to `example.com`

`locale.region.corp.example.com` with a setting of `DomainNameDevolutionLevel=3`

1. Progresses to `region.corp.example.com`
2. Progresses to `corp.example.com`. The progression stops here, due to the level setting.

Subscribe to EC2 Windows launch agent notifications

Amazon SNS can notify you when new versions of the EC2 launch agents are released. Use the following procedure to subscribe to these notifications.

Subscribe to EC2Config notifications

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.

4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:

   a. For **Topic ARN**, use the following Amazon Resource Name (ARN) that matches the agent you want to receive notifications for:

      - **EC2Launch v2**:

        ```
        arn:aws:sns:us-east-1:309726204594:amazon-ec2launch-v2
        ```

      - **EC2Launch or EC2Config**:

        ```
        arn:aws:sns:us-east-1:801119661308:ec2-windows-ec2config
        ```

   b. For **Protocol**, choose `Email`.

   c. For **Endpoint**, enter the email address where you want to receive the notifications.

   d. Choose **Create subscription**.
6. You'll receive a email asking you to confirm your subscription. Open the email and follow the directions to complete your subscription.

Whenever a new version of the launch agent is released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

Unsubscribe from launch agent notifications

1. Open the Amazon SNS console.
2. In the navigation pane, choose **Subscriptions**.
3. Select the subscription and then choose **Actions**, **Delete subscriptions**. When prompted for confirmation, choose **Delete**.

Windows Service administration for EC2Launch v2 and EC2Config agents

If you've logged into your instance as a user with administrative rights, you can manage the EC2Launch v2 and EC2Config launch agents just as you would any other Windows service. EC2Launch v1 is a set of PowerShell scripts that is managed via scheduled task by default. This section covers service administration for EC2Launch v2 and EC2Config.

To apply updated settings to your instance, you can stop and restart the EC2Launch v2 agent or the EC2Config service launch agent from the Microsoft Management Console (MMC) interface for Services. Similarly, when you install a new version of the launch agent, you must stop the agent first, then restart it when the installation is complete.

> **Note**
>
> You must open the MMC Services interface as an administrator to select these actions. To do this, you can select **Run as administrator** from the context menu. Alternatively, to open the interface using your keyboard, follow these steps:
>
> 1. Using the `Tab` key or arrow keys, select the **Services** menu item from the **Administrative Tools** menu.
> 2. Use the following keyboard combination to open as an administrator: `Ctrl` + `Shift` + `Enter`.

The following procedures list steps to stop and start the launch agent on your instance.

Stop the launch agent

1. Launch and connect to your Windows instance.
2. Select **Administrative Tools** from the Windows **Start** menu.
3. Open the **Services** console as an administrator, as described at the beginning of this section.
4. In the list of services, select the agent that's running on your instance (**EC2Launch** or **EC2Config**), then choose **Stop** from the **Action** menu. Alternatively, you can use the context menu to stop the agent.

Restart the launch agent

1. Launch and connect to your Windows instance.
2. Select **Administrative Tools** from the Windows **Start** menu.
3. Open the **Services** console as an administrator, as described at the beginning of this section.
4. In the list of services, select the agent that's running on your instance (**EC2Launch** or **EC2Config**), then choose **Start** or **Restart** from the **Action** menu. Alternatively, you can use the context menu to restart the agent.

If you don't need to update the configuration settings, create your own AMI, or use AWS Systems Manager, you can delete or uninstall the launch agent.

Delete

Deleting a service removes its registry subkey.

Uninstall

Uninstalling a service removes the files, the registry subkey, and any shortcuts to the service.

Delete the launch agent

1. Launch and connect to your Windows instance.
2. Start a Windows Command Prompt window.
3. Run one of the following commands to delete the launch agent.

   - Run the following command to delete the EC2Launch or EC2Launch v2:

     ```
     sc delete ec2launch
     ```

   - Run the following command to delete the EC2Config service:

     ```
     sc delete ec2config
     ```

Uninstall the launch agent

1. Launch and connect to your Windows instance.
2. Choose **Windows System**, then **Control Panel** from the Windows **Start** menu.
3. Choose **Programs and Features** to open the list of programs that are installed on your instance.
4. Select your launch agent from the list (**Amazon EC2Launch** or **EC2ConfigService**), then choose **Uninstall** from the **File** menu. Alternatively, you can use the context menu.

   > **Note**
   >
   > You can see what launch agent version is installed in the **Version** column.

Use the EC2Launch v2 agent to perform tasks during EC2 Windows instance launch

All supported instances of Amazon EC2 that are launched from AWS Windows Server 2022 and Windows Server 2025 AMIs include the EC2Launch v2 launch agent (`EC2Launch.exe`) by default. We also provide Windows Server 2016 and 2019 AMIs with EC2Launch v2 installed as the default launch agent. These AMIs are provided in addition to the Windows Server 2016 and 2019 AMIs that include EC2Launch v1. You can search for Windows AMIs that include EC2Launch v2 by default by entering the following prefix in your search from the **AMIs** page in the Amazon EC2 console: `EC2LaunchV2-Windows_Server-*`.

To compare launch agent version features, see Compare Amazon EC2 launch agents.

EC2Launch v2 performs tasks during instance startup and runs if an instance is stopped and later started, or restarted. EC2Launch v2 can also perform tasks on demand. Some of these tasks are automatically enabled, while others must be enabled manually. The EC2Launch v2 service supports all EC2Config and EC2Launch features.

This service uses a configuration file to control its operation. You can update the configuration file using either a graphical tool or by directly editing it as a single .yml file (`agent-config.yml`). For more information about file locations, see EC2Launch v2 directory structure.

EC2Launch v2 publishes Windows event logs to help you troubleshoot errors and set triggers. For more information, see Windows event logs.

Supported OS versions

The EC2Launch v2 agent supports the following Windows Server operating system (OS) versions:

- Windows Server 2025
- Windows Server 2022
- Windows Server 2019 (Long-Term Servicing Channel and Semi-Annual Channel)
- Windows Server 2016

Tasks that run by default

The EC2Launch v2 agent runs the following tasks one time only by default during the initial instance launch. Tasks are organized according to the order in which they run within their launch stage.

`Boot` stage

- extendRootPartition

`PreReady` stage

- activateWindows
- setDnsSuffix
- setAdminAccount
- setWallpaper

`PostReady` stage

- startSsm

EC2Launch v2 concepts

The following concepts are useful to understand when considering EC2Launch v2.

agent-config

`agent-config` is a file that is located in the configuration folder for EC2Launch v2. It includes configuration for the boot, network, PreReady, and PostReady stages. This file is used to specify the instance configuration for tasks that should run when the AMI is either booted for the first time or for subsequent times.

By default, the EC2Launch v2 installation installs an `agent-config` file that includes recommended configurations that are used in standard Amazon Windows AMIs. You can update the configuration file to alter the default boot experience for your AMI that EC2Launch v2 specifies. For more information about file locations, see EC2Launch v2 directory structure.

Frequency

Task frequency determines when tasks should run, depending on the boot context. Most tasks have only one allowed frequency. You can specify a frequency for `executeScript` tasks.

You will see the following frequencies in the EC2Launch v2 task configuration.

- Once – The task runs once, when the AMI has booted for the first time (finished Sysprep).

- Always – The task runs every time that the launch agent runs. The launch agent runs when:
  - an instance starts or restarts
  - the EC2Launch service runs
  - `EC2Launch.exe run` is invoked

Stage

A stage is a logical grouping of tasks that the EC2Launch v2 agent runs. Some tasks can run only in a specific stage. Others can run in multiple stages. When using `agent-config.yml`, you must specify a list of stages, and a list of tasks to run within each stage.

The service runs stages in the following order:

Stage 1: Boot

Stage 2: Network

Stage 3: PreReady

Windows is ready

After the PreReady stage completes, the service sends the `Windows is ready` message to the Amazon EC2 console.

Stage 4: PostReady

User data runs during the *PostReady* stage. Some script versions run before the `agent-config.yml` file *PostReady* stage, and some run after, as follows:

Before `agent-config.yml`

- YAML user data version 1.1
- XML user data

After `agent-config.yml`

- YAML user data version 1.0 (legacy version for backwards compatibility)

For example stages and tasks, see [Example: `agent-config.yml`](#).

When you use user data, you must specify a list of tasks for the launch agent to run. The stage is implied. For example tasks, see [Example: user data](#).

EC2Launch v2 runs the list of tasks in the order that you specify in `agent-config.yml` and in user data. Stages run sequentially. The next stage starts after the previous stage completes. Tasks also run sequentially.

Task

You can invoke a task to perform an action on an instance. You can configure tasks in the `agent-config.yml` file or through user data. For a list of available tasks for EC2Launch v2, see EC2Launch v2 tasks. For task configuration schema and details, see EC2Launch v2 task configuration.

User data

User data is data that is configurable when you launch an instance. You can update user data to dynamically change how custom AMIs or quickstart AMIs are configured. EC2Launch v2 supports 60 kB user data input length. User data includes only the UserData stage, and therefore runs after the `agent-config` file. You can enter user data when you launch an instance using the launch instance wizard, or you can modify user data from the EC2 console. For more information about working with user data, see How Amazon EC2 handles user data for Windows instances.

EC2Launch v2 task overview

EC2Launch v2 can perform the following tasks at each boot:

- Set up new and optionally customized wallpaper that renders information about the instance.
- Set the attributes for the administrator account that is created on the local machine.
- Add DNS suffixes to the list of search suffixes. Only suffixes that do not already exist are added to the list.
- Set drive letters for any additional volumes and extend them to use available space.
- Write files from the configuration to the disk.
- Run scripts specified in the EC2Launch v2 config file or from `user-data`. Scripts from `user-data` can be plain text or zipped and provided as a base64 format.
- Run a program with given arguments.
- Set the computer name.
- Send instance information to the Amazon EC2 console.
- Send the RDP certificate thumbprint to the Amazon EC2 console.

- Dynamically extend the operating system partition to include any unpartitioned space.
- Run user data. For more information about specifying user data, see EC2Launch v2 task configuration.
- Set non-persistent static routes to reach the metadata service and AWS KMS servers.
- Set non-boot partitions to `mbr` or `gpt`.
- Start the Systems Manager service following Sysprep.
- Optimize ENA settings.
- Enable OpenSSH for later Windows versions.
- Enable Jumbo Frames.
- Set Sysprep to run with EC2Launch v2.
- Publish Windows event logs.

EC2Launch v2 directory structure

EC2Launch v2 should be installed in the following directories:

- Service binaries: `%ProgramFiles%\Amazon\EC2Launch`
- Service data (settings, log files, and state files): `%ProgramData%\Amazon\EC2Launch`

> **Note**
>
> By default, Windows hides files and folders under `C:\ProgramData`. To view EC2Launch v2 directories and files, you must either enter the path in Windows Explorer or change the folder properties to show hidden files and folders.

The `%ProgramFiles%\Amazon\EC2Launch` directory contains binaries and supporting libraries. It includes the following subdirectories:

- `settings`
  - `EC2LaunchSettingsUI.exe` – user interface for modifying the `agent-config.yml` file
  - `YamlDotNet.dll` – DLL for supporting some operations in the user interface
- `tools`
  - `ebsnvme-id.exe` – tool for examining the metadata of the EBS volumes on the instance

  - `AWSAcpiSpcrReader.exe` – tool for determining the correct COM port to use
  - `EC2LaunchEventMessage.dll` – DLL for supporting the Windows event logging for EC2Launch
- `service`
  - `EC2LaunchService.exe` – Windows service executable that is launched when the launch agent runs as a service
- `EC2AgentTelemetry.dll` – DLL for supporting EC2 agent telemetry
- `EC2Launch.exe` – main EC2Launch executable
- `EC2LaunchAgentAttribution.txt` – attribution for code used within EC2 Launch

The `%ProgramData%\Amazon\EC2Launch` directory contains the following subdirectories. All of the data produced by the service, including logs, configuration, and state, is stored in this directory.

- `config` – Configuration

  The service configuration file is stored in this directory as `agent-config.yml`. This file can be updated to modify, add, or remove default tasks run by the service. Permission to create files in this directory is restricted to the administrator account to prevent privilege escalation.
- `log` – Instance logs

  Logs for the service (`agent.log`), console (`console.log`), performance (`bench.log`), errors (`err.log`), and telemetry (`telemetry.log` are stored in this directory. Log files are appended to on subsequent executions of the service.
- `state` – Service state data

  The state that the service uses to determine which tasks should run is stored here. There is a `.run-once` file that indicates whether the service has already run after Sysprep (so tasks with a frequency of once will be skipped on the next run). This subdirectory includes a `state.json` and `previous-state.json` to track the status of each task.
- `sysprep` – Sysprep

  This directory contains files that are used to determine which operations to perform by Sysprep when it creates a customized Windows AMI that can be reused.
- `wallpaper` – Wallpaper

  This wallpaper images is stored in this directory.

Telemetry

Telemetry is additional information that helps AWS to better understand your requirements, diagnose issues, and deliver features to improve your experience with AWS services.

EC2Launch v2 version `2.1.592` and later collect telemetry, such as usage metrics and errors. This data is collected from the Amazon EC2 instance on which EC2Launch v2 runs. This includes all Windows AMIs owned by AWS.

The following types of telemetry are collected by EC2Launch v2:

- **Usage information** — agent commands, install method, and scheduled run frequency.
- **Errors and diagnostic information** — agent installation error codes, run error codes, and error call stacks.

Examples of collected data from version 2.0.592 through 2.1.1:

```
2025/07/18 22:38:52Z: EC2LaunchTelemetry: IsTelemetryEnabled=true
2025/07/18 22:38:52Z: EC2LaunchTelemetry: AgentOsArch=windows_amd64
2025/07/18 22:38:52Z: EC2LaunchTelemetry: IsAgentScheduledPerBoot=true
2025/07/18 22:38:52Z: EC2LaunchTelemetry: AgentCommandErrorCode=0
2025/07/18 22:38:52Z: EC2LaunchTelemetry: AdminPasswordTypeCode=0
2025/07/18 22:38:52Z: EC2LaunchTelemetry: IpConflictDetectionCode=0
2025/07/18 22:38:52Z: EC2LaunchTelemetry: AgentErrorLocation=addroutes.go:49
```

Starting with version 2.2.63, EC2 Agent telemetry data is formatted as a JSON object:

```
{"type":"EC2AgentTelemetry","agentId":"WindowsLaunchAgentV2" ... }
```

Telemetry is enabled by default. You can disable telemetry collection at any time.

Disable telemetry on an instance

To disable telemetry for a single instance, you can either set a system environment variable, or use the MSI to modify the installation.

To disable telemetry by setting a system environment variable, run the following command as an administrator.

```
setx /M EC2LAUNCH_TELEMETRY 0
```

To disable telemetry using the MSI, run the following command after you download the MSI.

```
msiexec /i ".\AmazonEC2Launch.msi" Remove="Telemetry" /q
```

More topics for EC2Launch v2

- Install the latest version of EC2Launch v2
- Configure EC2Launch v2 settings for Windows instances
- Task definitions for EC2Launch v2 startup tasks
- Troubleshoot issues with the EC2Launch v2 agent
- EC2Launch v2 version histories

Install the latest version of EC2Launch v2

You can use one of the following methods to install the EC2Launch v2 agent on your EC2 instance:

- Download the agent from Amazon S3 and install with Windows PowerShell. For download URLs, see EC2Launch v2 downloads on Amazon S3.
- Install with SSM Distributor.
- Install from an EC2 Image Builder component when you create a custom image.
- Launch your instance from an AMI that has EC2Launch v2 pre-installed.

> **Warning**
>
> AmazonEC2Launch.msi uninstalls previous versions of the EC2 launch services, such as EC2Launch (v1) and EC2Config.

For install steps, select the tab that matches your preferred method.

PowerShell

To install the latest version of EC2Launch v2 agent with Windows PowerShell, follow these steps.

1. Create your local directory.

```
New-Item -Path "$env:USERPROFILE\Desktop\EC2Launchv2" -ItemType Directory
```

2. Set the URL for your download location. Run the following command with the Amazon S3 URL you'll use. For download URLs, see [EC2Launch v2 downloads on Amazon S3]

```
$Url = "Amazon S3 URL/AmazonEC2Launch.msi"
```

3. Use the following compound command to download the agent and run the install

```
$DownloadFile = "$env:USERPROFILE\Desktop\EC2Launchv2\" + $(Split-Path -Path
 $Url -Leaf)
Invoke-WebRequest -Uri $Url -OutFile $DownloadFile
msiexec /i "$DownloadFile"
```

> **Note**
>
> If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:
>
> ```
> [Net.ServicePointManager]::SecurityProtocol =
>  [Net.SecurityProtocolType]::Tls12
> ```

4. The **msiexec** command installs EC2Launch v2 in the following location on Windows Server instances: `%ProgramFiles%\Amazon\EC2Launch`. To verify that the install ran, you can check the local file system on your instance.

AWS Systems Manager Distributor

To configure automatic updates for EC2Launch v2 with AWS Systems Manager Quick Setup, see Automatically install and update with Distributor Quick Setup.

You can also perform a one-time install of the `AWSEC2Launch-Agent` package from AWS Systems Manager Distributor. For instructions on how to install a package from Systems Manager Distributor, see Install or update packages in the *AWS Systems Manager User Guide*.

EC2 Image Builder component

You can install the `ec2launch-v2-windows` component when you build a custom image with EC2 Image Builder. For instructions on how to build a custom image with EC2 Image Builder, see [Create an image pipeline using the EC2 Image Builder console wizard](#) in the *EC2 Image Builder User Guide*.

AMI

EC2Launch v2 is preinstalled by default on AMIs for the Windows Server 2022 and above operating systems:

- Windows_Server-*version*-English-Full-Base
- Windows_Server-*version*-English-Core-Base
- Windows_Server-*version*-English-Core-EKS_Optimized
- Windows Server *version* AMIs with all other languages
- Windows Server *version* AMIs with SQL installed

EC2Launch v2 is also preinstalled on the following Windows Server AMIs. You can find these AMIs from the Amazon EC2 console, or by using the following search prefix: `EC2LaunchV2-` in the AWS CLI.

- EC2LaunchV2-Windows_Server-2019-English-Core-Base
- EC2LaunchV2-Windows_Server-2019-English-Full-Base
- EC2LaunchV2-Windows_Server-2016-English-Core-Base
- EC2LaunchV2-Windows_Server-2016-English-Full-Base

Automatically install and update EC2Launch v2 with AWS Systems Manager Distributor Quick Setup

With AWS Systems Manager Distributor Quick Setup, you can set up automatic updates for EC2Launch v2. The following process sets up a Systems Manager Association on your instance that automatically updates the EC2Launch v2 agent at a frequency that you specify. The Association that the Distributor Quick Setup creates can include instances within an AWS account and Region, or instances within an AWS Organization. For more information about setting up an organization, see [Tutorial: Creating and configuring an organization](#) in the *AWS Organizations User Guide*.

Before you begin, make sure that your instances meet all of the prerequisites.

Prerequisites

To set up automatic updates with Distributor Quick Setup, your instances must meet the following prerequisites.

- You have at least one running instance that supports EC2Launch v2. See supported operating systems for EC2Launch v2.
- You've performed the Systems Manager set-up tasks on your instances. For more information, see Setting up Systems Manager in the *AWS Systems Manager User Guide*.
- EC2Launch v2 must be the only launch agent installed on your instance. If you have more than one launch agent installed, your Distributor Quick Setup configuration will fail. Before you configure EC2Launch v2 with a Distributor Quick Setup, uninstall EC2Config or EC2Launch v1 launch agents, if they exist.

Configure Distributor Quick Setup for EC2Launch v2

To create a configuration for EC2Launch v2 with Distributor Quick Setup, use the following settings when you complete the steps for Distributor package deployment:

- **Software packages:** Amazon EC2Launch v2 agent.
- **Update frequency:** Select a frequency from the list.
- **Targets:** Choose from the available deployment options.

To check the status of your configuration, navigate to the Systems Manager Quick Setup **Configurations** tab in the AWS Management Console.

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. In the **Configurations** tab, select the row that's associated with the configuration that you created. The **Configurations** tab lists your configurations, and includes a summary of key details, such as **Region**, **Deployment status**, and **Association status**.

> **Note**
>
> The association name for every EC2Launch v2 Distributor configuration begins with the following prefix: `AWS-QuickSetup-Distributor-EC2Launch-Agent-`.

4. To view details, select the configuration and choose **View details**.

For more information and troubleshooting steps, see Troubleshooting Quick Setup results in the *AWS Systems Manager User Guide*.

EC2Launch v2 downloads on Amazon S3

To install the latest version of EC2Launch v2, download the installer from the following location:

- https://s3.amazonaws.com/amazon-ec2launch-v2/windows/amd64/latest/AmazonEC2Launch.msi

Configure install options

When you install or upgrade EC2Launch v2, you can configure installation options with the EC2Launch v2 install dialog or with the **msiexec** command in a command line shell.

The first time the EC2Launch v2 installer runs on an instance, it initializes launch agent settings on your instance as follows:

- It creates the local path and writes the launch agent file to it. This is sometimes referred to as a *clean install*.
- It creates the `EC2LAUNCH_TELEMETRY` environment variable if it doesn't already exist, and sets it based on your configuration.

For configuration details, select the tab that matches the configuration method that you'll use.

Amazon EC2Launch Setup dialog

When you install or upgrade EC2Launch v2, you can configure the following installation options through the EC2Launch v2 install dialog.

Basic Install options

Send Telemetry

When you include this feature in the setup dialog, the installer sets the `EC2LAUNCH_TELEMETRY` environment variable to a value of `1`. If you disable **Send Telemetry**, the installer sets the environment variable to a value of `0`.

When the EC2Launch v2 agent runs, it reads the `EC2LAUNCH_TELEMETRY` environment variable to determine whether to upload telemetry data. If the value equals `1`, it uploads the data. Otherwise, it doesn't upload.

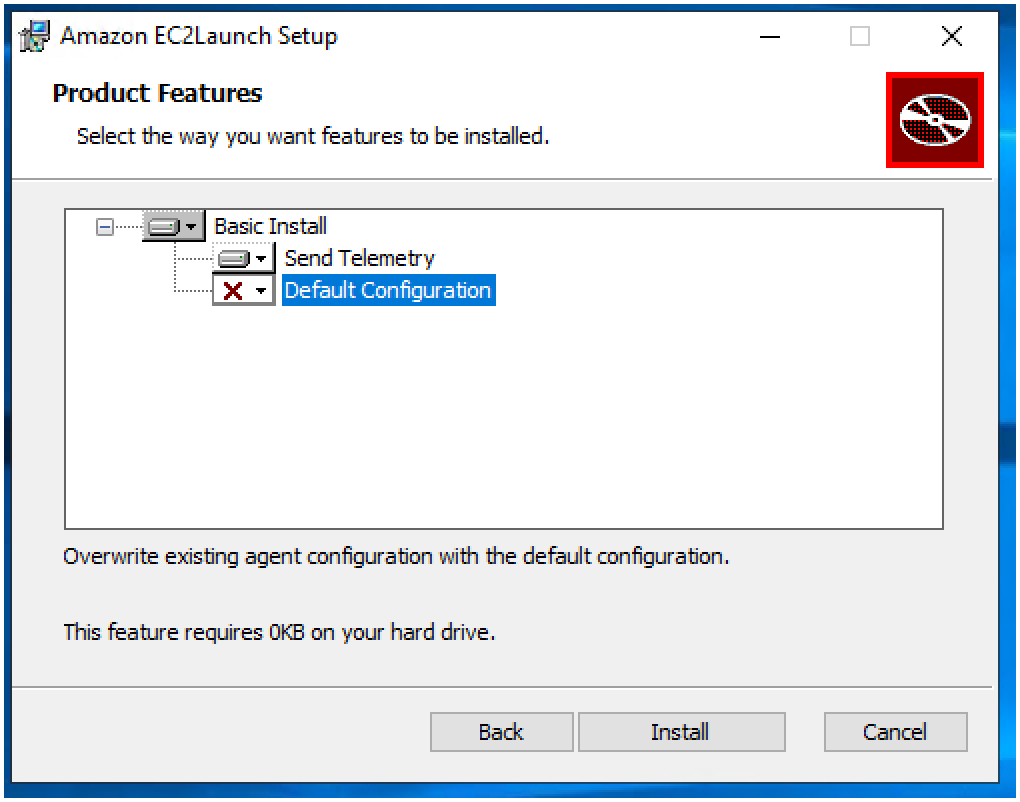
Default configuration

The default configuration for EC2Launch v2 is to overwrite the local launch agent if it exists already. The first time you run an install on an instance, the default configuration performs a clean install. If you disable the default configuration on the initial install, the installation fails.

If you run the install again on the instance, you can disable the default configuration to perform an upgrade that doesn't replace the `%ProgramData%/Amazon/EC2Launch/config/agent-config.yml` file.

Example: Upgrade EC2Launch v2 with telemetry

The following example shows the EC2Launch v2 setup dialog configured to upgrade the current installation and enable telemetry. This configuration performs an install without replacing the agent configuration file, and sets the `EC2LAUNCH_TELEMETRY` environment variable to a value of `1`.



Command line

When you install or upgrade EC2Launch v2, you can configure the following installation options with the **msiexec** command in a command line shell.

`ADDLOCAL` parameter values

Basic (required)

Install the launch agent. If this value is not present in the `ADDLOCAL` parameter, the installation ends.

Clean

When you include the `Clean` value in the `ADDLOCAL` parameter, the installer writes the agent configuration file to the following location: `%ProgramData%/Amazon/EC2Launch/config/agent-config.yml`. If the agent configuration file already exists, it overwrites the file.

When you leave the `Clean` value out of the `ADDLOCAL` parameter, the installer performs an upgrade that doesn't replace the agent configuration file.

Telemetry

When you include the `Telemetry` value in the `ADDLOCAL` parameter, the installer sets the `EC2LAUNCH_TELEMETRY` environment variable to a value of `1`.

When you leave the `Telemetry` value out of the `ADDLOCAL` parameter, the installer sets the environment variable to a value of `0`.

When the EC2Launch v2 agent runs, it reads the `EC2LAUNCH_TELEMETRY` environment variable to determine whether to upload telemetry data. If the value equals `1`, it uploads the data. Otherwise, it doesn't upload.

Example: install EC2Launch v2 with telemetry

```
& msiexec /i "C:\Users\Administrator\Desktop\EC2Launchv2\AmazonEC2Launch.msi"
 ADDLOCAL="Basic,Clean,Telemetry" /q
```

Verify the EC2Launch v2 version

Use one of the following procedures to verify the version of EC2Launch v2 that is installed on your instances.

PowerShell

Verify the installed version of EC2Launch v2 with Windows PowerShell, as follows.

1. Launch an instance from your AMI and connect to it.
2. Run the following command in PowerShell to verify the installed version of EC2Launch v2:

```
& "C:\Program Files\Amazon\EC2Launch\EC2Launch.exe" version
```

Windows Control Panel

Verify the installed version of EC2Launch v2 in the Windows Control Panel, as follows.

1. Launch an instance from your AMI and connect to it.
2. Open the Windows Control Panel and choose **Programs and Features**.

3. Look for `Amazon EC2Launch` in the list of installed programs. Its version number appears in the **Version** column.

To view the latest updates for the AWS Windows AMIs, see Windows AMI version history in the *AWS Windows AMI Reference*.

For the latest version of EC2Launch v2, see EC2Launch v2 version history.

You can receive notifications when new versions of the EC2Launch v2 service are released. For more information, see Subscribe to EC2 Windows launch agent notifications.

Configure EC2Launch v2 settings for Windows instances

This section contains information about how to configure settings for EC2Launch v2.

Topics include:

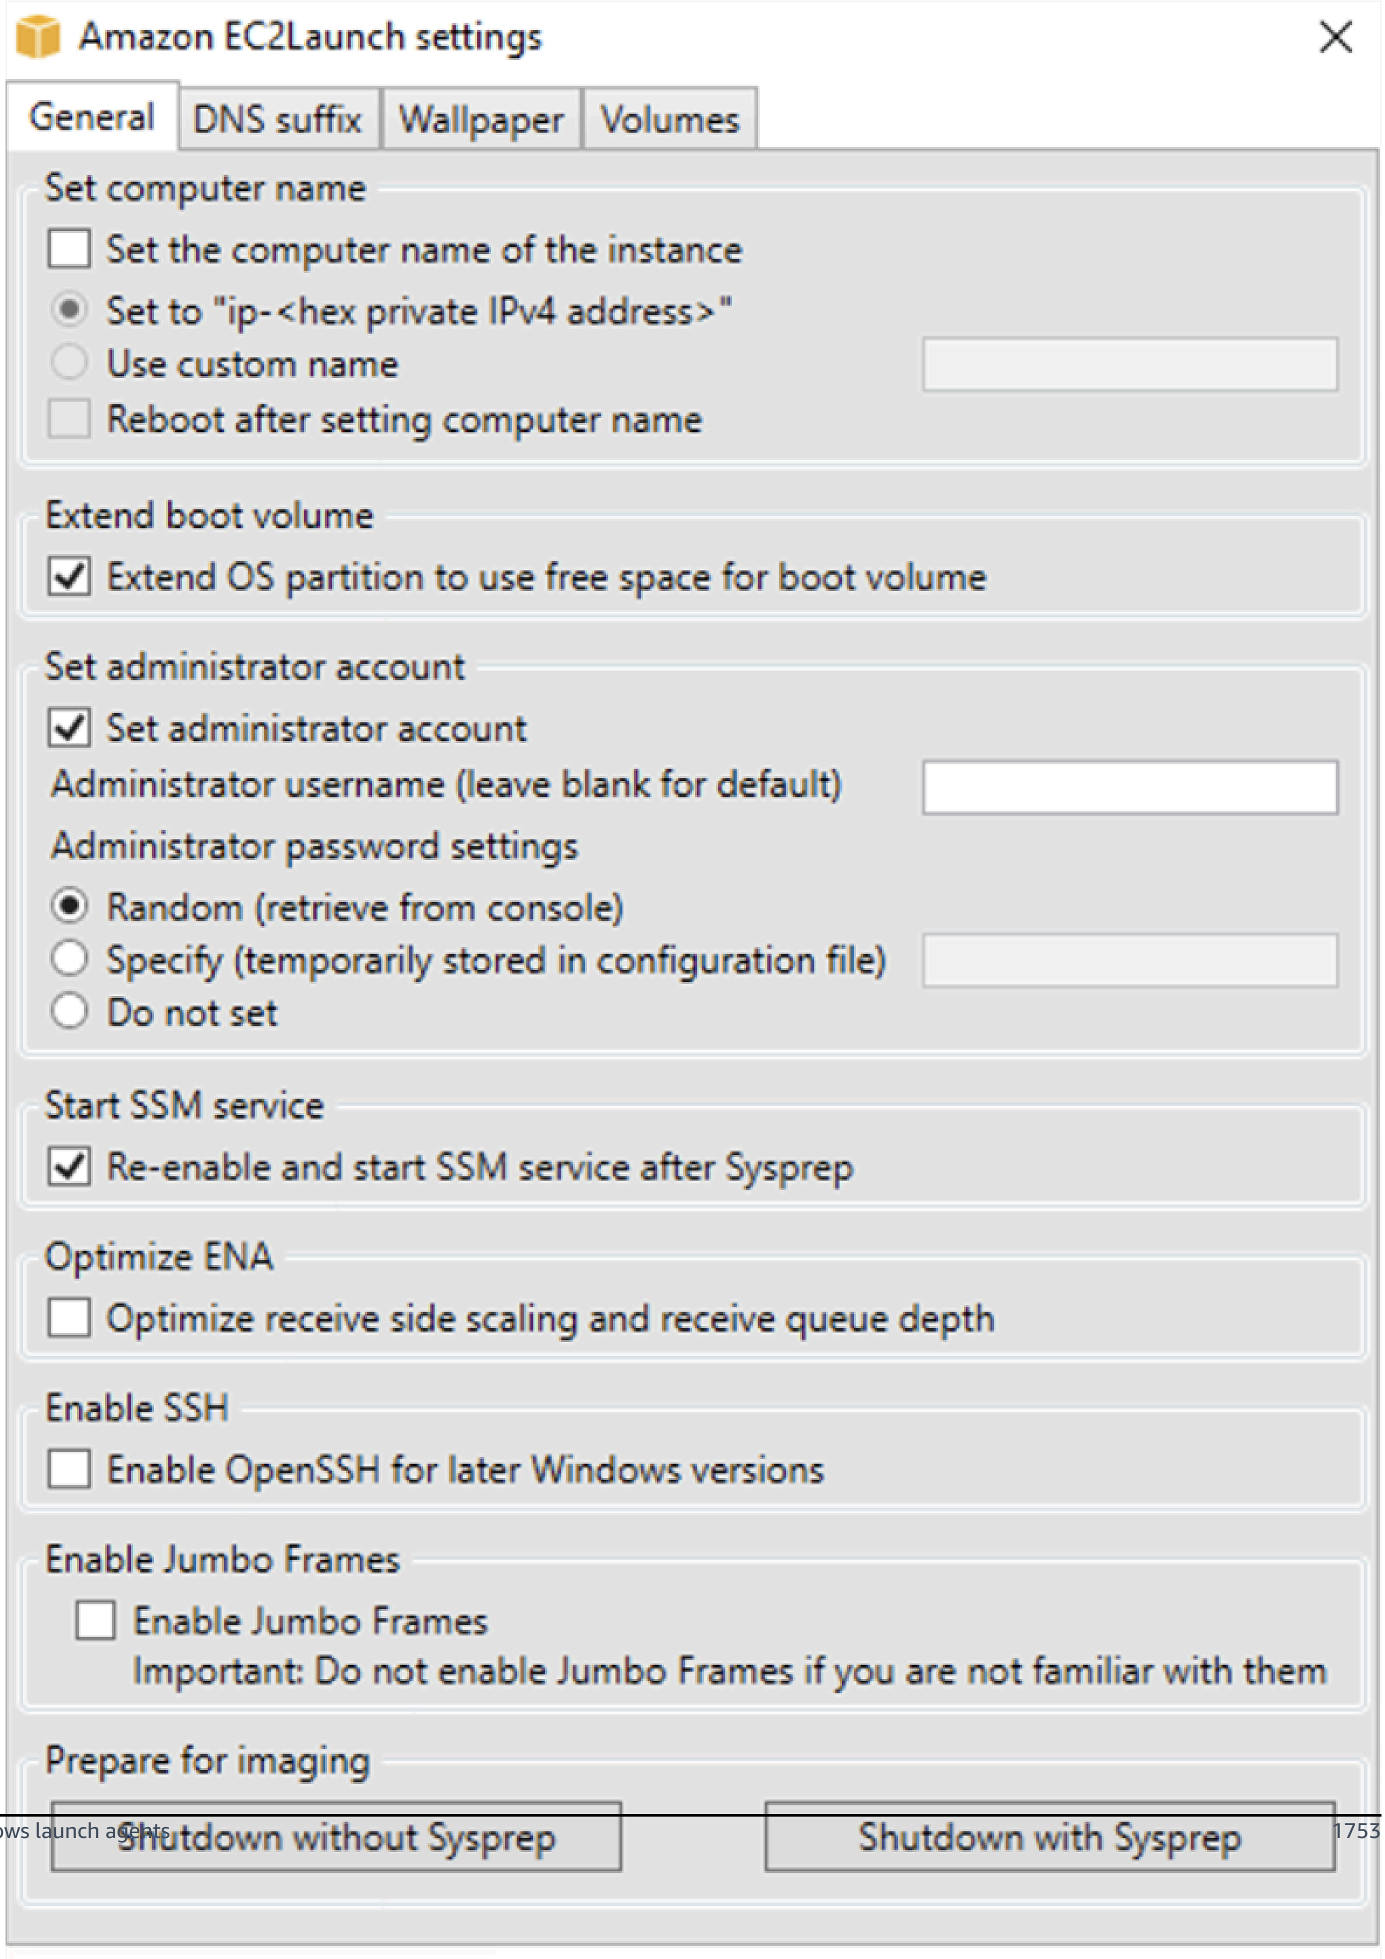
- Change settings using the EC2Launch v2 settings dialog box
- Configure EC2Launch v2 using the CLI
- EC2Launch v2 task configuration
- EC2Launch v2 exit codes and reboots
- EC2Launch v2 and Sysprep

Change settings using the EC2Launch v2 settings dialog box

The following procedure describes how to use the EC2Launch v2 settings dialog box to enable or disable settings.

> **Note**
>
> If you improperly configure custom tasks in the agent-config.yml file, and you attempt to open the Amazon EC2Launch settings dialog box, you will receive an error. For example schema, see Example: `agent-config.yml`.

1. Launch and connect to your Windows instance.
2. From the Start menu, choose **All Programs**, and then navigate to **EC2Launch settings**. Before you choose **Shutdown with Sysprep** or **Shutdown without Sysprep**, make sure that you save any changes that you want to apply when you run the shutdown.



Amazon EC2Launch settings
General
DNS suffix
Wallpaper
Volumes
Set computer name
Set the computer name of the instance
Set to "ip-<hex private IPv4 address>"
Use custom name
Reboot after setting computer name
Extend boot volume
Extend OS partition to use free space for boot volume
Set administrator account
Set administrator account
Administrator username (leave blank for default)
Administrator password settings
Random (retrieve from console)
Specify (temporarily stored in configuration file)
Do not set
Start SSM service
Re-enable and start SSM service after Sysprep
Optimize ENA
Optimize receive side scaling and receive queue depth
Enable SSH
Enable OpenSSH for later Windows versions
Enable Jumbo Frames
Enable Jumbo Frames
Important: Do not enable Jumbo Frames if you are not familiar with them
Prepare for imaging
Shutdown without Sysprep
Shutdown with Sysprep

3. On the **General** tab of the **EC2Launch settings** dialog box, you can enable or disable the following settings.

   a. **Set Computer Name**

      If this setting is enabled (it is disabled by default), the current host name is compared to the desired host name at each boot. If the host names do not match, the host name is reset, and the system then optionally reboots to pick up the new host name. If a custom host name is not specified, it is generated using the hexadecimal-formatted private IPv4 address, for example, `ip-AC1F4E6`. To prevent your existing host name from being modified, do not enable this setting.

   b. **Extend Boot Volume**

      This setting dynamically extends `Disk 0`/`Volume 0` to include any unpartitioned space. This can be useful when the instance is booted from a root device volume that has a custom size.

   c. **Set Administrator Account**

      When enabled, you can set the username and password attributes for the administrator account that is created on your local machine. If this feature is not enabled, an administrator account is not created on the system following Sysprep. Provide a password in `adminPassword` only if `adminPasswordtype` is `Specify`.

      The password types are defined as follows:

      i. `Random`

         EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

      ii. `Specify`

         EC2Launch uses the password that you specify in `adminPassword`. If the password does not meet the system requirements, EC2Launch generates a random password instead. The password is stored in `agent-config.yml` as clear text and is deleted after Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.

      iii. `Do not set`

EC2Launch uses the password that you specify in the unattend.xml file. If you don't specify a password in unattend.xml, the administrator account is disabled.

d. **Start SSM Service**

When selected, the Systems Manager service is enabled to start following Sysprep. EC2Launch v2 performs all of the tasks described earlier, and the SSM Agent processes requests for Systems Manager capabilities, such as Run Command and State Manager.

You can use Run Command to upgrade your existing instances to use the latest version of the EC2Launch v2 service and SSM Agent. For more information, see Update SSM Agent using Run Command in the *AWS Systems Manager User Guide*.

e. **Optimize ENA**

When selected, ENA settings are configured to ensure that ENA Receive Side Scaling and Receive Queue Depth settings are optimized for AWS. For more information, see Configure Receive side scaling CPU affinity.

f. **Enable SSH**

This setting enables OpenSSH for later Windows versions to allow for remote system administration.

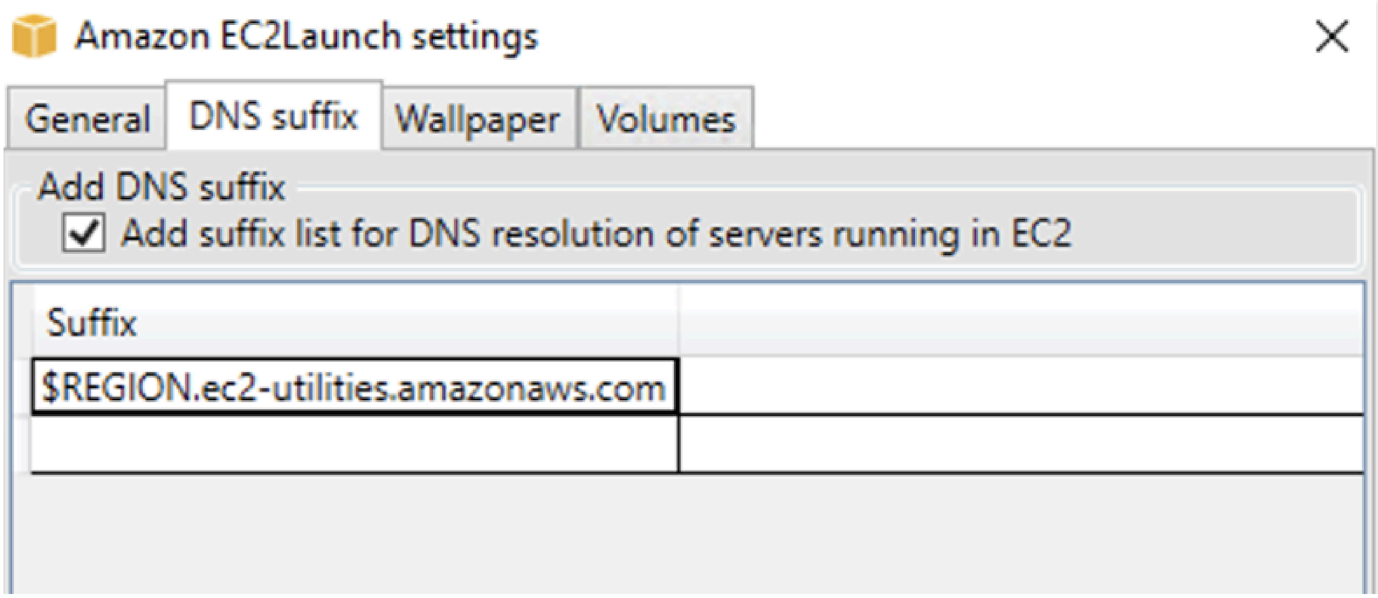
g. **Enable Jumbo Frames**

Select to enable Jumbo Frames. Jumbo Frames can have unintended effects on your network communications, so ensure you understand how Jumbo Frames will impact your system before enabling. For more information about Jumbo Frames, see Jumbo frames (9001 MTU).

h. **Prepare for Imaging**

Select whether you want your EC2 instance to shut down with or without Sysprep. When you want to run Sysprep with EC2Launch v2, choose **Shutdown with Sysprep**.

4. On the **DNS Suffix** tab, you can select whether you want to add a DNS suffix list for DNS resolution of servers running in EC2, without providing the fully qualified domain name. DNS suffixes can contain the variables `$REGION` and `$AZ`. Only suffixes that do not already exist will be added to the list.

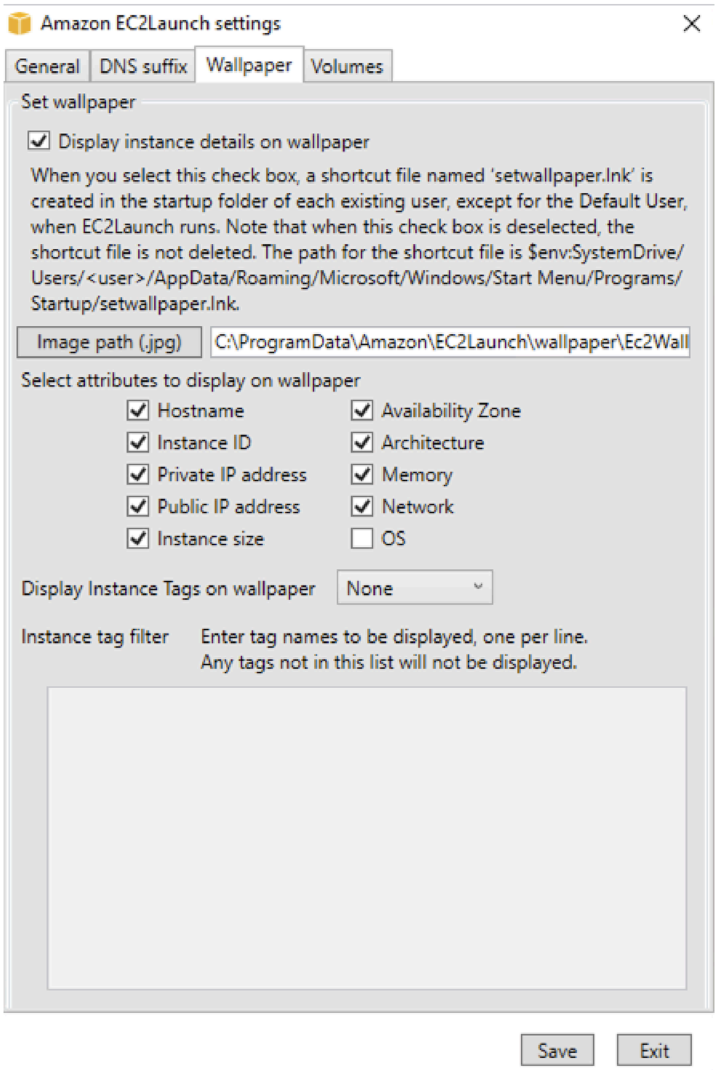


5. On the **Wallpaper** tab, you can configure your instance wallpaper with a background image, and specify instance details for the wallpaper to display. Amazon EC2 generates the details each time you log in.

   You can configure your wallpaper with the following controls.

   - **Display instance details on wallpaper** – This checkbox activates or deactivates instance detail display on the wallpaper.
   - **Image path (.jpg)** – Specify the path to the image to use as the wallpaper background.
   - **Select attributes to display on wallpaper** – Select the check boxes for the instance details that you want to appear on the wallpaper. Clear the check boxes for previously selected instance details that you want to remove from the wallpaper.
   - **Display Instance Tags on wallpaper** – Select one of the following settings to display instance tags on the wallpaper:
     - **None** – Don't display any instance tags on the wallpaper.
     - **Show all** – Display all instance tags on the wallpaper.
     - **Show filtered** – Display specified instance tags on the wallpaper. When you select this setting, you can add instance tags that you want to display on your wallpaper in the **Instance tag filter** box.

> **Note**
>
> You must enable tags in metadata to show tags on the wallpaper. For more information about instance tags and metadata, see [View tags for your EC2 instances using instance metadata](#).



6. On the **Volumes** tab, select whether you want to initialize the volumes that are attached to the instance. Enabling sets drive letters for any additional volumes and extends them to use available space. If you select **All**, all of the storage volumes are initialized. If you select **Devices**, only devices that are specified in the list are initialized. You must enter the device for each device to be initialized. Use the devices listed on the EC2 console, for example, `xvdb` or `/dev/`

`nvme0n1`. The dropdown list displays the storage volumes that are attached to the instance. To enter a device that is not attached to the instance, enter it in the text field.

Name, **Letter**, and **Partition** are optional fields. If no value is specified for **Partition**, storage volumes larger than 2 TB are initialized with the `gpt` partition type, and those smaller than 2 TB are initialized with the `mbr` partition type. If devices are configured, and a non-NTFS device either contains a partition table, or the first 4 KB of the disk contain data, then the disk is skipped and the action logged.

The following is an example configuration YAML file created from the settings entered in the EC2Launch dialog.

```
version: 1.0
config:
  - stage: boot
 tasks:
      - task: extendRootPartition
  - stage: preReady
    tasks:
      - task: activateWindows
        inputs:
          activation:
            type: amazon
      - task: setDnsSuffix
        inputs:
          suffixes:
            - $REGION.ec2-utilities.amazonaws.com
      - task: setAdminAccount
        inputs:
          password:
            type: random
      - task: setWallpaper
        inputs:
          path: C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg
          attributes:
            - hostName
            - instanceId
            - privateIpAddress
            - publicIpAddress
            - instanceSize
            - availabilityZone
            - architecture
            - memory
            - network
  - stage: postReady
    tasks:
      - task: startSsm
```

Configure EC2Launch v2 using the CLI

You can use the Command Line Interface (CLI) to configure your EC2Launch settings and manage the service. The following section contains descriptions and usage information for the CLI commands that you can use to manage EC2Launch v2.

Commands

- collect-logs
- get-agent-config
- list-volumes
- reset
- run
- status
- sysprep
- validate
- version
- wallpaper

collect-logs

Collects log files for EC2Launch, zips the files, and places them in a specified directory.

Example

```
ec2launch collect-logs -o C:\Mylogs.zip
```

Usage

`ec2launch collect-logs [flags]`

Flags

`-h`, `--help`

help for `collect-logs`

`-o`, `--output string`

path to zipped output log files

get-agent-config

Prints `agent-config.yml` in the format specified (JSON or YAML). If no format is specified, `agent-config.yml` is printed in the format previously specified.

Example

```
ec2launch get-agent-config -f json
```

Usage

`ec2launch get-agent-config [flags]`

Flags

`-h`, `--help`

help for `get-agent-config`

`-f`, `--format string`

output format of `agent-config` file: `json`, `yaml`

list-volumes

Lists all of the storage volumes attached to the instance, including ephemeral and EBS volumes.

Example

```
ec2launch list-volumes
```

Usage

`ec2launch list-volumes`

Flags

`-h`, `--help`

help for `list-volumes`

reset

The main goal of this task is to reset the agent for the next time that it runs. To do that, the **reset** command deletes all of the agent state data for EC2Launch v2 from the local `EC2Launch` directory (see EC2Launch v2 directory structure). Reset optionally deletes the service and Sysprep logs.

Script behavior depends on what mode the agent runs the scripts in – inline, or detached.

Inline (default)

The EC2Launch v2 agent runs scripts one at a time (`detach: false`). This is the default setting.

> **Note**
>
> When your inline script issues a **reset** or **sysprep** command, it runs immediately and resets the agent. The current task finishes, then the agent shuts down without running any further tasks.
> For example, if the task that issues the command would have been followed by a `startSsm` task (included by default after user data runs), the task doesn't run and the Systems Manager service never starts.

Detached

The EC2Launch v2 agent runs scripts concurrently with other tasks (`detach: true`).

> **Note**
>
> When your detached script issues a **reset** or **sysprep** command, those commands wait for the agent to finish before they run. Tasks after the executeScript will still run.

Example

```
ec2launch reset -c
```

Usage

```
ec2launch reset [flags]
```

Flags

`-c`, `--clean`

cleans instance logs before `reset`

`-h`, `--help`

help for `reset`

run

Runs EC2Launch v2.

Example

```
ec2launch run
```

Usage

`ec2launch run [flags]`

Flags

`-h`, `--help`

help for `run`

status

Gets the status of the EC2Launch v2 agent. Optionally blocks the process until the agent is finished. The process exit code determines the agent state:

- `0` –the agent ran and was successful.
- 1 – the agent ran and failed.
- 2 – the agent is still running.
- 3 – the agent is in an unknown state. The agent state is not running or stopped.
- 4 – an error occurred when attempting to retrieve the agent state.
- 5 – the agent is not running and the status of the last known run is unknown. This could mean one of the following:

- both the `state.json` and `previous-state.json` are deleted.
- the `previous-state.json` is corrupted.

This is the agent state after running the `reset` command.

Example:

```
ec2launch status -b
```

Usage

`ec2launch status [flags]`

Flags

`-b`,`--block`

blocks the process until the agent finishes running

`-h`,`--help`

help for `status`

sysprep

The main goal of this task is to reset the agent for the next time that it runs. To do that, the **sysprep** command resets the agent state, updates the `unattend.xml` file, disables RDP, and runs Sysprep.

Script behavior depends on what mode the agent runs the scripts in – inline, or detached.

Inline (default)

The EC2Launch v2 agent runs scripts one at a time (`detach: false`). This is the default setting.

> **Note**
>
> When your inline script issues a **reset** or **sysprep** command, it runs immediately and resets the agent. The current task finishes, then the agent shuts down without running any further tasks.

For example, if the task that issues the command would have been followed by a `startSsm` task (included by default after user data runs), the task doesn't run and the Systems Manager service never starts.

Detached

The EC2Launch v2 agent runs scripts concurrently with other tasks (`detach: true`).

> **Note**
>
> When your detached script issues a **reset** or **sysprep** command, those commands wait for the agent to finish before they run. Tasks after the executeScript will still run.

Example:

```
ec2launch sysprep
```

Usage

`ec2launch sysprep [flags]`

Flags

`-c`,`--clean`

cleans instance logs before `sysprep`

`-h`,`--help`

help for Sysprep

`-s`,`--shutdown`

shuts down the instance after `sysprep`

validate

Validates the `agent-config` file `C:\ProgramData\Amazon\EC2Launch\config\agent-config.yml`.

Example

```
ec2launch validate
```

Usage

`ec2launch validate [flags]`

Flags

`-h` , `--help`

help for `validate`

version

Gets the executable version.

Example

```
ec2launch version
```

Usage

`ec2launch version [flags]`

Flags

`-h`, `--help`

help for `version`

wallpaper

Sets new wallpaper to the wallpaper path that is provided (.jpg file), and displays the selected instance details.

Syntax

```
ec2launch wallpaper ^
--path="C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg" ^
--all-tags ^
--
attributes=hostName,instanceId,privateIpAddress,publicIpAddress,instanceSize,availabilityZone,a
```

Inputs

Parameters

--allowed-tags [*`tag-name-1`*, *`tag-name-n`*]

(Optional) Base64 encoded JSON array of instance tag names to display on the wallpaper. You can use this tag or the `--all-tags`, but not both.

--attributes *`attribute-string-1`*, *`attribute-string-n`*

(Optional) A comma-separated list of `wallpaper` attribute strings to apply settings to the wallpaper.

[--path | -p] *`path-string`*

(Required) Specifies the `wallpaper` background image file path.

Flags

--all-tags

(Optional) Displays all of the instance tags on the wallpaper. You can use this tag or the `--allowed-tags`, but not both.

[--help | -h]

Displays help for the **wallpaper** command.

EC2Launch v2 task configuration

This section includes the configuration schema, tasks, details, and examples for `agent-config.yml` and user data.

Tasks and examples

- Schema: agent-config.yml
- Configure EC2Launch v2 user data scripts that run during launch or reboot

Schema: `agent-config.yml`

The structure of the `agent-config.yml` file is shown below. Note that a task cannot be repeated in the same stage. For task properties, see the task descriptions that follow.

Document structure: agent-config.yml

JSON

```
{
 "version": "1.1",
 "config": [
  {
   "stage": "string",
   "tasks": [
    {
     "task": "string",
     "inputs": {
      ...
     }
    },
    ...
   ]
  },
  ...
 ]
}
```

YAML

```
version: 1.1
config:
- stage: string
  tasks:
  - task: string
 inputs:
    ...
  ...
...
```

Example: `agent-config.yml`

The following example shows settings for the `agent-config.yml` configuration file.

```
version: 1.1
config:
- stage: boot
  tasks:
```

```
  - task: extendRootPartition
- stage: preReady
  tasks:
  - task: activateWindows
    inputs:
      activation:
        type: amazon
  - task: setDnsSuffix
    inputs:
      suffixes:
      - $REGION.ec2-utilities.amazonaws.com
  - task: setAdminAccount
    inputs:
      password:
        type: random
  - task: setWallpaper
    inputs:
      path: C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg
      attributes:
      - hostName
      - instanceId
      - privateIpAddress
      - publicIpAddress
      - instanceSize
      - availabilityZone
      - architecture
      - memory
      - network
- stage: postReady
  tasks:
  - task: startSsm
```

Configure EC2Launch v2 user data scripts that run during launch or reboot

The following JSON and YAML examples show the document structure for user data. Amazon EC2 parses each task named in the `tasks` array that you specify in the document. Each task has its own set of properties and requirements. For details, see the Task definitions for EC2Launch v2 startup tasks.

> **Note**
>
> A task must only appear once in the user data tasks array.

Document structure: user data

JSON

```
{
 "version": "1.1",
 "tasks": [
  {
   "task": "string",
   "inputs": {
    ...
   },
  },
  ...
 ]
}
```

YAML

```
version: 1.1
tasks:
- task: string
  inputs:
    ...
...
```

Example: user data

For more information about user data, see [How Amazon EC2 handles user data for Windows instances](#).

The following YAML document example shows a PowerShell script that EC2Launch v2 runs as user data to create a file.

```
version: 1.1
tasks:
- task: executeScript
  inputs:
  - frequency: always
    type: powershell
    runAs: localSystem
```

```
    content: |-
      New-Item -Path 'C:\PowerShellTest.txt' -ItemType File
```

You can use an XML format for the user data that's compatible with previous versions of the launch agent. EC2Launch v2 runs the script as an `executeScript` task in the `UserData` stage. To conform with EC2Launch v1 and EC2Config behavior, the user data script runs as an attached/ inline process by default.

You can add optional tags to customize how your script runs. For example, to run the user data script when the instance reboots in addition to one time when the instance launches, you can use the following tag:

`<persist>true</persist>`

Example:

```
<powershell>
  $file = $env:SystemRoot + "\Temp" + (Get-Date).ToString("MM-dd-yy-hh-mm")
  New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

You can specify one or more PowerShell arguments with the `<powershellArguments>` tag. If no arguments are passed, EC2Launch v2 adds the following argument by default: `-ExecutionPolicy Unrestricted`.

Example:

```
<powershell>
  $file = $env:SystemRoot + "\Temp" + (Get-Date).ToString("MM-dd-yy-hh-mm")
  New-Item $file -ItemType file
</powershell>
<powershellArguments>-ExecutionPolicy Unrestricted -NoProfile -NonInteractive</
powershellArguments>
```

To run an XML user data script as a detached process, add the following tag to your user data.

`<detach>true</detach>`

Example:

```
<powershell>
  $file = $env:SystemRoot + "\Temp" + (Get-Date).ToString("MM-dd-yy-hh-mm")
  New-Item $file -ItemType file
</powershell>
<detach>true</detach>
```

> **Note**
>
> The detach tag is not supported on previous launch agents.

Change log: user data

The following table lists changes for user data, and cross-references them to the EC2Launch v2 agent version that applies.

User data version	Details	Introduced in
1.1	• User data tasks run before the `PostReady` stage in the agent config file. • Runs user data before starting the Systems Manager Agent (same behavior as EC2Launch v1 and EC2Config).*	EC2Launch v2 version 2.0.1245
1.0	• Will be deprecated. • User data tasks run after the `PostReady` stage in the agent config file. This is not backwards compatible with EC2Launch v1. • Impacted by a race condition between Systems Manager Agent start and user data tasks.	EC2Launch v2 version 2.0.0

* When used with the default `agent-config.yml` file.

EC2Launch v2 exit codes and reboots

You can use EC2Launch v2 to define how exit codes are handled by your scripts. By default, the exit code of the last command that is run in a script is reported as the exit code for the entire script. For example, if a script includes three commands and the first command fails but the following ones succeed, the run status is reported as `success` because the final command succeeded.

If you want a script to reboot an instance, then you must specify `exit 3010` in your script, even when the reboot is the last step in your script. `exit 3010` instructs EC2Launch v2 to reboot the instance and call the script again until it returns an exit code that is not `3010`, or until the maximum reboot count has been reached. EC2Launch v2 permits a maximum of 5 reboots per task. If you attempt to reboot an instance from a script by using a different mechanism, such as `Restart-Computer`, then the script run status will be inconsistent. For example, it may get stuck in a restart loop or not perform the restart.

If you are using an XML user data format that is compatible with older agents, the user data may run more times than you intend it to. For more information, see Service runs user data more than once in the Troubleshooting section.

EC2Launch v2 and Sysprep

The EC2Launch v2 service runs Sysprep, a Microsoft tool that enables you to create a customized Windows AMI that can be reused. When EC2Launch v2 calls Sysprep, it uses the files in `%ProgramData%\Amazon\EC2Launch` to determine which operations to perform. You can edit these files indirectly using the **EC2Launch settings** dialog box, or directly using a YAML editor or a text editor. However, there are some advanced settings that aren't available in the **EC2Launch settings** dialog box, so you must edit those entries directly.

If you create an AMI from an instance after updating its settings, the new settings are applied to any instance that's launched from the new AMI. For information about creating an AMI, see Create an Amazon EBS-backed AMI.

Task definitions for EC2Launch v2 startup tasks

Each task that EC2Launch v2 runs during launch or statup has its own set of properties and requirements. Task details include settings for how often a task runs – once, or always, what stage of the agent boot process it runs in, syntax, and YAML document examples. For more information, review the task details shown in this reference.

EC2Launch v2 Tasks

- activateWindows
- enableJumboFrames
- enableOpenSsh
- executeProgram
- executeScript
- extendRootPartition
- initializeVolume
- optimizeEna
- setAdminAccount
- setDnsSuffix
- setHostName
- setWallpaper
- startSsm
- sysprep
- writeFile

activateWindows

Activates Windows against a set of AWS KMS servers. Activation is skipped if the instance is detected as Bring-Your-Own-License (BYOL).

Frequency — once

AllowedStages — `[PreReady]`

Inputs —

`activation`: (map)

`type`: (string) activation type to use, set to `amazon`

Example

```
task: activateWindows
```

```
  inputs:
    activation:
    type: amazon
```

enableJumboFrames

Enables Jumbo Frames, which increase the maximum transmission unit (MTU) of the network adapter. For more information, see Jumbo frames (9001 MTU).

Frequency — always

AllowedStages — `[PostReady, UserData]`

Inputs — none

Example

```
task: enableJumboFrames
```

enableOpenSsh

Enables Windows OpenSSH and adds the public key for the instance to the authorized keys folder.

Frequency — once

AllowedStages — `[PreReady, UserData]`

Inputs — none

Example

The following example shows how to enable OpenSSH on an instance, and to add the public key for the instance to the authorized keys folder. This configuration works only on instances running Windows Server 2019 and later versions.

```
task: enableOpenSsh
```

executeProgram

Runs a program with optional arguments and a specified frequency.

Stages: You can run the `executeProgram` task during the `PreReady`, `PostReady`, and `UserData` stages.

Frequency: configurable, see *Inputs*.

Inputs

This section contains one or more programs for the **executeProgram** task to run (inputs). Each input can include the following configurable settings:

frequency (string)

(Required) Specify exactly one of the following values:

- `once`
- `always`

path (string)

(Required) The file path for the executable to run.

arguments (list of strings)

(Optional) A comma separated list of arguments to provide to the program as input.

runAs (string)

(Required) Must be set to `localSystem`

Output

All of the tasks write logfile entries to the `agent.log` file. Additional output from the `executeProgram` task is stored separately in a dynamically named folder, as follows:

`%LocalAppData%\Temp\`*`EC2Launch#########`*`\`*`outputfilename.tmp`*

The exact path to the output files is included in the `agent.log` file, for example:

```
Program file is created at: C:\Windows\system32\config\systemprofile\AppData\Local
\Temp\EC2Launch123456789\ExecuteProgramInputs.tmp
Output file is created at: C:\Windows\system32\config\systemprofile\AppData\Local
\Temp\EC2Launch123456789\Output.tmp
Error file is created at: C:\Windows\system32\config\systemprofile\AppData\Local
\Temp\EC2Launch123456789\Err.tmp
```

Output files for the `executeProgram` task

`ExecuteProgramInputs.tmp`

Contains the path for the executable, and all of the input parameters that the `executeProgram` task passes to it when it runs.

`Output.tmp`

Contains runtime output from the program that the `executeProgram` task runs.

`Err.tmp`

Contains runtime error messages from the program that the `executeProgram` task runs.

Examples

The following examples show how to run an executable file from a local directory on an instance with the `executeProgram` task.

Example 1: Setup executable with one argument

This example shows an `executeProgram` task that runs a setup executable in quiet mode.

```
task: executeProgram
  inputs:
    - frequency: always
      path: C:\Users\Administrator\Desktop\setup.exe
      arguments: ['-quiet']
```

Example 2: VLC executable with two arguments

This example shows an `executeProgram` task that runs a VLC executable file with two arguments passed as input parameters.

```
task: executeProgram
  inputs:
    - frequency: always
      path: C:\vlc-3.0.11-win64.exe
      arguments: ['/L=1033','/S']
      runAs: localSystem
```

executeScript

Runs a script with optional arguments and a specified frequency. Script behavior depends on what mode the agent runs the scripts in – inline, or detached.

Inline (default)

The EC2Launch v2 agent runs scripts one at a time (`detach: false`). This is the default setting.

> **Note**
>
> When your inline script issues a **reset** or **sysprep** command, it runs immediately and resets the agent. The current task finishes, then the agent shuts down without running any further tasks.
> For example, if the task that issues the command would have been followed by a `startSsm` task (included by default after user data runs), the task doesn't run and the Systems Manager service never starts.

Detached

The EC2Launch v2 agent runs scripts concurrently with other tasks (`detach: true`).

> **Note**
>
> When your detached script issues a **reset** or **sysprep** command, those commands wait for the agent to finish before they run. Tasks after the executeScript will still run.

Stages: You can run the `executeScript` task during the `PreReady`, `PostReady`, and `UserData` stages.

Frequency: configurable, see *Inputs*.

Inputs

This section contains one or more scripts for the **executeScript** task to run (inputs). Each input can include the following configurable settings:

frequency (string)

(Required) Specify exactly one of the following values:

- `once`
- `always`

type (string)

(Required) Specify exactly one of the following values:

- `batch`
- `powershell`

arguments (list of strings)

(Optional) A list of string arguments to pass to the shell (not to the PowerShell script). This parameter isn't supported for `type: batch`. If no arguments are passed, EC2Launch v2 adds the following argument by default: `-ExecutionPolicy Unrestricted`.

content (string)

(Required) Script content.

runAs (string)

(Required) Specify exactly one of the following values:

- `admin`
- `localSystem`

detach (Boolean)

(Optional) The EC2Launch v2 agent defaults to run scripts one at a time (`detach: false`). To run the script concurrently with other tasks, set the value to `true` (`detach: true`).

> **Note**
>
> Script exit codes (including `3010`) have no effect when `detach` is set to `true`.

Output

All of the tasks write logfile entries to the `agent.log` file. Additional output from script that the `executeScript` task runs is stored separately in a dynamically named folder, as follows:

`%LocalAppData%\Temp\`*`EC2Launch#########`*`\`*`outputfilename.ext`*

The exact path to the output files is included in the `agent.log` file, for example:

```
Program file is created at: C:\Windows\system32\config\systemprofile\AppData\Local
\Temp\EC2Launch123456789\UserScript.ps1
Output file is created at: C:\Windows\system32\config\systemprofile\AppData\Local
\Temp\EC2Launch123456789\Output.tmp
Error file is created at: C:\Windows\system32\config\systemprofile\AppData\Local
\Temp\EC2Launch123456789\Err.tmp
```

Output files for the `executeScript` task

`UserScript.`*`ext`*

Contains the script that the `executeScript` task ran. The file extension depends on the type of script you specified in the `type` parameter for the `executeScript` task, as follows:

- If the type is `batch`, then the file extension is `.bat`.
- If the type is `powershell`, then the file extension is `.ps1`.

`Output.tmp`

Contains runtime output from the script that the `executeScript` task runs.

`Err.tmp`

Contains runtime error messages from the script that the `executeScript` task runs.

Examples

The following examples show how to run an inline script with the `executeScript` task.

Example 1: Hello world output text file

This example shows an `executeScript` task that runs a PowerShell script to create a "Hello world" text file on the `C:` drive.

```
task: executeScript
  inputs:
    - frequency: always
      type: powershell
      runAs: admin
      content: |-
        New-Item -Path 'C:\PowerShellTest.txt' -ItemType File
```

```
        Set-Content 'C:\PowerShellTest.txt' "Hello world"
```

Example 2: Run two scripts

This example shows that the `executeScript` task can run more than one script, and the script type doesn't necessarily need to match.

The first script (`type: powershell`) writes a summary of the processes that are currently running on the instance to a text file located on the `C:` drive.

The second script (`batch`) writes the system information to the `Output.tmp` file.

```
task: executeScript
  inputs:
    - frequency: always
      type: powershell
      runAs: localSystem
      content: |
        Get-Process | Out-File -FilePath C:\Process.txt
    - frequency: always
      type: batch
      runAs: localSystem
      content: |
        systeminfo
```

Example 3: Idempotent system configuration with reboots

This example shows an `executeScript` task that runs an idempotent script to perform the following system configuration with a reboot between each step:

- Rename the computer.
- Join the computer to the domain.
- Enable Telnet.

The script ensures that each operation runs one time only. This prevents a reboot loop and makes the script idempotent.

```
task: executeScript
  inputs:
    - frequency: always
      type: powershell
      runAs: localSystem
```

```
      content: |-
        $name = $env:ComputerName
        if ($name -ne $desiredName) {
          Rename-Computer -NewName $desiredName
          exit 3010
        }
        $domain = Get-ADDomain
        if ($domain -ne $desiredDomain)
        {
          Add-Computer -DomainName $desiredDomain
          exit 3010
        }
        $telnet = Get-WindowsFeature -Name Telnet-Client
        if (-not $telnet.Installed)
        {
          Install-WindowsFeature -Name "Telnet-Client"
          exit 3010
        }
```

extendRootPartition

Extends the root volume to use all of the available space on the disk.

Frequency — once

AllowedStages — `[Boot]`

Inputs — none

Example

```
task: extendRootPartition
```

initializeVolume

Initializes empty volumes that are attached to the instance so that they're activated and partitioned. The launch agent skips initialization if it detects that the volume is not empty. A volume is considered empty if the first 4 KiB of the volume are empty, or if the volume doesn't have a Windows-recognizable drive layout.

The `letter` input parameter is always applied when this task runs, regardless of whether the drive is already initialized.

The `initializeVolume` task performs the following actions.

- Set disk attributes `offline` and `readonly` to false.
- Create a partition. If no partition type is specified in the `partition` input parameter, the following defaults apply:
  - If the disk size is smaller than 2 TB, set the partition type to `mbr`.
  - If the disk size is 2 TB or larger, set the partition type to `gpt`.
- Format the volume as NTFS.
- Set the volume label as follows:
  - Use the value of the `name` input parameter, if specified.
  - If the volume is ephemeral, and no name was specified, set the volume label to `Temporary Storage Z`.
- If the volume is ephemeral (SSD or HDD – not Amazon EBS), create an `Important.txt` file at the root of the volume with the following content:

```
This is an 'Instance Store' disk and is provided at no additional charge.

*This disk offers increased performance since it is local to the host
*The number of Instance Store disks available to an instance vary by instance type
*DATA ON THIS DRIVE WILL BE LOST IN CASES OF IMPAIRMENT OR STOPPING THE INSTANCE.
 PLEASE ENSURE THAT ANY IMPORTANT DATA IS BACKED UP FREQUENTLY

For more information, please refer to: Instance store temporary block storage for EC2
 instances.
```

- Set the drive letter to the value specified in the `letter` input parameter.

Stages: You can run the `initializeVolume` task during the `PostReady` and `UserData` stages.

Frequency: always.

Inputs

You can configure runtime parameters as follows:

devices (list of maps)

(Conditional) Configuration for each device that the launch agent initializes. This is required if the `initialize` input parameter is set to `devices`.

- **device (string, required) –** Identifies the device during instance creation. For example, `xvdb`, `xvdf`, or `\dev\nvme0n1`.
- **letter (string, optional) –** One character. The drive letter to assign.
- **name (string, optional) –** The volume name to assign.
- **partition (string, optional) –** Specify one of the following values for the type of partition to create, or let the launch agent default based on volume size:
  - mbr
  - gpt

initialize (string)

(Required) Specify exactly one of the following values:

- `all`
- `devices`

Examples

The following examples show sample input configurations for the `initializeVolume` task.

Example 1: Initialize two volumes on an instance

This example shows an `initializeVolume` task that initializes two secondary volumes on an instance. The device named `DataVolume2` in the example is ephemeral.

```
task: initializeVolume
inputs:
  initialize: devices
  devices:
  - device: xvdb
    name: DataVolume1
    letter: D
    partition: mbr
  - device: /dev/nvme0n1
    name: DataVolume2
    letter: E
    partition: gpt
```

Example 2: Initialize EBS volumes attached to an instance

This example shows an `initializeVolume` task that initializes all empty EBS volumes that are attached to the instance.

```
task: initializeVolume
inputs:
  initialize: all
```

optimizeEna

Optimizes ENA settings based on the current instance type; might reboot the instance.

Frequency — always

AllowedStages — `[PostReady, UserData]`

Inputs — none

Example

```
task: optimizeEna
```

setAdminAccount

Sets attributes for the default administrator account that is created on the local machine.

Frequency — once

AllowedStages — `[PreReady]`

Inputs —

`name`: (string) name of the administrator account

`password`: (map)

`type`: (string) strategy to set the password, either as `static`, `random`, or `doNothing`

`data`: (string) stores data if the `type` field is static

Example

```
task: setAdminAccount
```

```
inputs:
  name: Administrator
  password:
  type: random
```

setDnsSuffix

Adds DNS suffixes to the list of search suffixes. Only suffixes that do not already exist are added to the list. For more information about how launch agents set DNS suffixes, see Configure DNS Suffix for EC2 Windows launch agents.

Frequency — always

AllowedStages — `[PreReady]`

Inputs —

`suffixes`: (list of strings) list of one or more valid DNS suffixes; valid substitution variables are `$REGION` and `$AZ`

Example

```
task: setDnsSuffix
inputs:
  suffixes:
  - $REGION.ec2-utilities.amazonaws.com
```

setHostName

Sets the hostname of the computer to a custom string or, if `hostName` is not specified, the private IPv4 address.

Frequency — always

AllowedStages — `[PostReady, UserData]`

Inputs —

`hostName`: (string) optional host name, which must be formatted as follows.

- Must be 15 characters or less
- Must contain only alphanumeric (a-z, A-Z, 0-9) and hyphen (-) characters.

- Must not consist entirely of numerical characters.

`reboot`: (boolean) denotes whether a reboot is permitted when the hostname is changed

Example

```
task: setHostName
inputs:
  reboot: true
```

setWallpaper

Creates the `setwallpaper.lnk` shortcut file in the startup folder of each existing user except for `Default User`. This shortcut file runs when the user logs in for the first time after instance boot. It sets up the instance with a custom wallpaper that displays the instance attributes.

The shortcut file path is:

```
$env:SystemDrive/Users/<user>/AppData/Roaming/Microsoft/Windows/Start Menu/Programs/
Startup/setwallpaper.lnk
```

> **Note**
>
> When you remove the `setWallpaper` task, it does not delete this shortcut file. For more information, see `setWallpaper` task is not enabled but the wallpaper resets at reboot.

Stages: You can configure wallpaper during the `PreReady` and `UserData` stages.

Frequency: `always`

Wallpaper configuration

You can use the following settings to configure your wallpaper.

Inputs

Input parameters that you provide, and attributes that you can set to configure your wallpaper:

attributes (list of strings)

(Optional) You can add one or more of the following attributes to your wallpaper:

- `architecture`
- `availabilityZone`
- `hostName`
- `instanceId`
- `instanceSize`
- `memory`
- `network`
- `privateIpAddress`
- `publicIpAddress`

instanceTags

(Optional) You can use exactly one of the following options for this setting.

- **AllTags** (string) – Add all instance tags to your wallpaper.

```
instanceTags: AllTags
```

- **instanceTags** (list of strings) – Specify a list of instance tag names to add to your wallpaper. For example:

```
instanceTags:
  - Tag 1
  - Tag 2
```

path (string)

(Required) The filename path of the local .jpg format image file to use for your wallpaper image.

Example

The following example shows wallpaper configuration inputs that set the file path for the wallpaper background image, along with instance tags named `Tag 1` and `Tag 2`, and attributes that include the host name, instance ID, and private and public IP addresses for the instance.

```
task: setWallpaper
inputs:
```

```
  path: C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg
  attributes:
  - hostName
  - instanceId
  - privateIpAddress
  - publicIpAddress
instanceTags:
  - Tag 1
  - Tag 2
```

Note

You must enable tags in metadata to show tags on the wallpaper. For more information about instance tags and metadata, see View tags for your EC2 instances using instance metadata.

startSsm

Starts the Systems Manager (SSM) service following Sysprep.

Frequency — always

AllowedStages — `[PostReady, UserData]`

Inputs — none

Example

```
task: startSsm
```

sysprep

Resets the service state, updates `unattend.xml`, disables RDP, and runs Sysprep. This task runs only after all other tasks are completed.

Frequency — once

AllowedStages — `[UserData]`

Inputs —

`clean`: (boolean) cleans instance logs before running Sysprep

`shutdown`: (boolean) shuts down the instance after running Sysprep

Example

```
task: sysprep
inputs:
clean: true
shutdown: true
```

writeFile

Writes a file to a destination.

Frequency — see *Inputs*

AllowedStages — `[PostReady, UserData]`

Inputs —

`frequency`: (string) one of `once` or `always`

`destination`: (string) path to which to write the content

`content`: (string) text to write to the destination

Example

```
task: writeFile
inputs:
  - frequency: once
  destination: C:\Users\Administrator\Desktop\booted.txt
  content: Windows Has Booted
```

Troubleshoot issues with the EC2Launch v2 agent

This section shows common troubleshooting scenarios for EC2Launch v2, information about viewing Windows event logs, and console log output and messages.

Troubleshooting topics

- Common troubleshooting scenarios

- Windows event logs
- EC2Launch v2 console log output

Common troubleshooting scenarios

This section shows common troubleshooting scenarios and steps for resolution.

Scenarios

- Service fails to set the wallpaper
- Service fails to run user data
- Service runs a task only one time
- Service fails to run a task
- Service runs user data more than once
- Scheduled tasks from EC2Launch v1 fail to run after migration to EC2Launch v2
- Service initializes an EBS volume that is not empty
- setWallpaper task is not enabled but the wallpaper resets at reboot
- Service stuck in running status
- Invalid agent-config.yml prevents opening EC2Launch v2 settings dialog box
- task:executeScript should be unique and only invoked once

Service fails to set the wallpaper

Resolution

1. Check that `%AppData%\Roaming\Microsoft\Windows\Start Menu\Programs\Startup\setwallpaper.lnk` exists.
2. Check `%ProgramData%\Amazon\EC2Launch\log\agent.log` to see if any errors occurred.

Service fails to run user data

Possible cause: Service may have failed before running user data.

Resolution

1. Check `%ProgramData%\Amazon\EC2Launch\state\previous-state.json`.

2. See if `boot`, `network`, `preReady`, and `postReadyLocalData` have all been marked as success.
3. If one of the stages failed, check `%ProgramData%\Amazon\EC2Launch\log\agent.log` for specific errors.

Service runs a task only one time

Resolution

1. Check the frequency of the task.
2. If the service already ran after Sysprep, and the task frequency is set to `once`, the task will not run again.
3. Set the frequency of the task to `always` if you want it to run the task every time EC2Launch v2 runs.

Service fails to run a task

Resolution

1. Check the latest entries in `%ProgramData%\Amazon\EC2Launch\log\agent.log`.
2. If no errors occurred, try running the service manually from `"%ProgramFiles%\Amazon\EC2Launch\EC2Launch.exe" run` to see if the tasks succeed.

Service runs user data more than once

Resolution

User data is handled differently between EC2Launch v1 and EC2Launch v2. EC2Launch v1 runs user data as a scheduled task on the instance when `persist` is set to `true`. If `persist` is set to `false`, the task is not scheduled even when it exits with a reboot or is interrupted while running.

EC2Launch v2 runs user data as an agent task and tracks its run state. If user data issues a computer restart or if user data was interrupted while running, the run state persists as `pending` and the user data will run again at the next instance boot. If you want to prevent the user data script from running more than once, make the script idempotent.

The following example idempotent script sets the computer name and joins a domain.

```
<powershell>
  $name = $env:computername
  if ($name -ne $desiredName) {
 Rename-Computer -NewName $desiredName
  }
  $domain = Get-ADDomain
  if ($domain -ne $desiredDomain)
  {
 Add-Computer -DomainName $desiredDomain
  }
  $telnet = Get-WindowsFeature -Name Telnet-Client
  if (-not $telnet.Installed)
  {
 Install-WindowsFeature -Name "Telnet-Client"
  }
</powershell>
<persist>false</persist>
```

Scheduled tasks from EC2Launch v1 fail to run after migration to EC2Launch v2

Resolution

The migration tool does not detect any scheduled tasks linked to EC2Launch v1 scripts; therefore, it does not automatically set up those tasks in EC2Launch v2. To configure these tasks, edit the `agent-config.yml` file, or use the EC2Launch v2 settings dialog box. For example, if an instance has a scheduled task that runs `InitializeDisks.ps1`, then after you run the migration tool, you must specify the volumes you want to initialize in the EC2Launch v2 settings dialog box. See Step 6 of the procedure to Change settings using the EC2Launch v2 settings dialog box.

Service initializes an EBS volume that is not empty

Resolution

Before it initializes a volume, EC2Launch v2 attempts to detect whether it is empty. If a volume is not empty, it skips the initialization. Any volumes that are detected as not empty are not initialized. A volume is considered empty if the first 4 KiB of a volume are empty, or if a volume does not have a Windows-recognizable drive layout. A volume that was initialized and formatted on a Linux system does not have a Windows-recognizable drive layout, for example MBR or GPT. Therefore, it will be considered as empty and initialized. If you want to preserve this data, do not rely on EC2Launch v2 empty drive detection. Instead, specify volumes that you would like to initialize in the EC2Launch v2 settings dialog box (see step 6) or in the `agent-config.yml`.

`setWallpaper` task is not enabled but the wallpaper resets at reboot

The `setWallpaper` task creates the `setwallpaper.lnk` shortcut file in the startup folder of each existing user. This shortcut file runs when the user logs in for the first time after instance boot. It sets up the instance with a custom wallpaper that displays the instance attributes. Removing the `setWallpaper` task does not delete this shortcut file. You must manually delete this file or delete it using a script.

The shortcut path is:

`$env:SystemDrive/Users/<user>/AppData/Roaming/Microsoft/Windows/Start Menu/Programs/Startup/setwallpaper.lnk`

Resolution

Manually delete this file, or delete it using a script.

Example PowerShell script to delete shortcut file

```
foreach ($userDir in (Get-ChildItem "C:\Users" -Force -Directory).FullName)
{
 $startupPath = Join-Path $userDir -ChildPath "AppData\Roaming\Microsoft\Windows\Start
 Menu\Programs\Startup"
 if (Test-Path $startupPath)
 {
  $wallpaperSetupPath = Join-Path $startupPath -ChildPath "setwallpaper.lnk"
  if (Test-Path $wallpaperSetupPath)
  {
   Remove-Item $wallpaperSetupPath -Force -Confirm:$false
  }
 }
}
```

Service stuck in running status

Description

EC2Launch v2 is blocked, with log messages (`agent.log`) similar to the following:

```
2022-02-24 08:08:58 Info:
 ******************************************************************************************
```

```
2022-02-24 08:08:58 Info: EC2Launch Service starting
2022-02-24 08:08:58 Info: Windows event custom log exists: Amazon EC2Launch
2022-02-24 08:08:58 Info: ACPI SPCR table not supported. Bailing Out
2022-02-24 08:08:58 Info: Serial port is in use. Waiting for Serial Port...
2022-02-24 08:09:00 Info: ACPI SPCR table not supported. Use default console port.
2022-02-24 08:09:02 Info: ACPI SPCR table not supported. Use default console port.
2022-02-24 08:09:04 Info: ACPI SPCR table not supported. Use default console port.
2022-02-24 08:09:06 Info: ACPI SPCR table not supported. Use default console port.
```

Possible cause

SAC is enabled and using the serial port. For more information, see Use SAC to troubleshoot your Windows instance.

Resolution

Try the following steps to resolve this issue:

- Disable the service that is using the serial port.
- If you want the service to continue to use the serial port, write custom scripts to perform launch agent tasks and invoke them as scheduled tasks.

Invalid `agent-config.yml` prevents opening EC2Launch v2 settings dialog box

Description

EC2Launch v2 settings attempts to parse the `agent-config.yml` file before it opens the dialog box. If the YAML configuration file does not follow the supported schema, the dialog box will show the following error:

```
Unable to parse configuration file agent-config.yml. Review configuration
file. Exiting application.
```

Resolution

1. Verify that the configuration file follows the supported schema.
2. If you want to start from scratch, copy the default configuration file into `agent-config.yml`. You can use the example `agent-config.yml` provided in the Task Configuration section.
3. You can also start over by deleting `agent-config.yml`. EC2Launch v2 settings generates an empty configuration file.

`task:executeScript should be unique and only invoked once`

Description

A task cannot be repeated in the same stage.

Resolution

Some tasks must be input as an array, such as **executeScript** and **executeProgram**. For an example of how to write the script as an array, see **executeScript**.

Windows event logs

EC2Launch v2 publishes Windows event logs for important events, such as service starting, Windows is ready, and task success and failure. Event identifiers uniquely identify a particular event. Each event contains stage, task, and level information, and a description. You can set triggers for specific events using the event identifier.

Event IDs provide information about an event and uniquely identify some events. The least significant digit of an event ID indicates the severity of an event.

Event	Least significant digit
`Success`	`. . .0`
`Informational`	`. . .1`
`Warning`	`. . .2`
`Error`	`. . .3`

Service-related events that are generated when the service starts or stops include a single digit event identifier.

Event	Single digit identifier
`Success`	`0`
`Informational`	`1`

Event	Single digit identifier
`Warning`	2
`Error`	3

The event messages for `EC2LaunchService.exe` events begin with `Service:`. The event messages for `EC2Launch.exe` events do not begin with `Service:`.

Four digit event IDs include information about the stage, task, and severity of an event.

Topics

- Event ID format
- Event ID examples
- Windows event log schema

Event ID format

The following table shows the format of an EC2Launch v2 event identifier.

3	2 1	0
S	T	L

The letters and numbers in the table represent the following event type and definitions.

Event type	Definition
S (Stage)	0 - Service-level message 1 - Boot 2 - Network 3 - PreReady

Event type	Definition
	5 - Windows is Ready 6 - PostReady 7 - User Data
T (Task)	The tasks represented by the corresponding two values are different for each stage. To view the complete list of events, see [Windows Event log schema](#).
L (Level of the event)	0 - Success 1 - Informational 2 - Warning 3 - Error

Event ID examples

The following are example event IDs.

- `5000` - Windows is ready to use
- `3010` - Activate windows task in PreReady stage was successful
- `6013` - Set wallpaper task in PostReady Local Data stage encountered an error

Windows event log schema

MessageId/Event Id	Event message
`. . .0`	`Success`
`. . .1`	`Informational`

MessageId/Event Id	Event message
. . .2	Warning
. . .3	Error
x	EC2Launch service-level logs
0	EC2Launch service exited successfully
1	EC2Launch service informational logs
2	EC2Launch service warning logs
3	EC2Launch service error logs
10	Replace state.json with previous-state.json
100	Serial Port
200	Sysprep
300	PrimaryNic
400	Metadata
x000	Stage (1 digit), Task (2 digits), Status (1 digit)
1000	Boot
1010	Boot - extend_root_partition
2000	Network
2010	Network - add_routes
3000	PreReady

MessageId/Event Id	Event message
3010	PreReady - activate_windows
3020	PreReady - install_egpu_manager
3030	PreReady - set_monitor_on
3040	PreReady - set_hibernation
3050	PreReady - set_admin_account
3060	PreReady - set_dns_suffix
3070	PreReady - set_wallpaper
3080	PreReady - set_update_schedule
3090	PreReady - output_log
3100	PreReady - enable_open_ssh
5000	Windows is Ready to use
6000	PostReadyLocalData
7000	PostReadyUserData
6010/7010	PostReadyLocal/UserData - set_wallpaper
6020/7020	PostReadyLocal/UserData - set_update_schedule
6030/7030	PostReadyLocal/UserData - set_hostname
6040/7040	PostReadyLocal/UserData - execute_program

MessageId/Event Id	Event message
6050/7050	PostReadyLocal/UserData - execute_script
6060/7060	PostReadyLocal/UserData - manage_package
6070/7070	PostReadyLocal/UserData - initialize_volume
6080/7080	PostReadyLocal/UserData - write_file
6090/7090	PostReadyLocal/UserData - start_ssm
7100	PostReadyUserData - enable_open_ssh
6110/7110	PostReadyLocal/UserData - enable_jumbo_frames

EC2Launch v2 console log output

This section contains sample console log output for EC2Launch v2 and lists all of the EC2Launch v2 console log error messages to help you to troubleshoot issues. For more information about instance console output and how to access it, see the section called "Instance console output".

Outputs

- EC2Launch v2 console log output
- EC2Launch v2 console log messages

EC2Launch v2 console log output

The following is sample console log output for EC2Launch v2. Some values in this example are substituted with representative text surrounded by curly braces.

```
2025/07/22 21:26:53Z: Windows sysprep configuration complete.

EC2Launch v2 version histories

Version histories

- EC2Launch v2 version history

EC2Launch v2 version history

To ensure that you have the latest launch agent installed, see Install the latest version of EC2Launch v2. You can receive notifications when new versions of the EC2Launch v2 agent are released. For more information, see Subscribe to EC2 Windows launch agent notifications.

The following table describes the released versions of EC2Launch v2.

Version	Details	Release date
2.2.63	• Updated launch agent to improve [Telemetry]().	July 29, 2025
2.1.1	• Added full support for IPv6.	May 14, 2025
2.0.2107	• Enhanced route addition to handle scenarios when IPv4 or IPv6 addresses are not available on the interface.	March 27, 2025
2.0.2081	• Fixed an issue where RDP certificate information was not properly retrieved or validated. Added functionality to automatically start the Remote Desktop Services if needed. • Adjusted EC2Launch v2 service permissions to fix an issue that occurs when querying the service status.	February 4, 2025
2.0.2046	• Updated the wallpaper path in the `agent-config.yml` file to use the default operating system wallpaper path. • Added telemetry to monitor the locations where agent errors occurred. • Updated agent log messaging.	October 3, 2024
2.0.1981	• Updated `EC2Launch.exe` CLI command error messages for non-Administrator users.	August 6, 2024
2.0.1948	• Added telemetry to monitor usage of admin password options. • Modified EC2Launch permissions.	July 1, 2024
2.0.1924	• Updated the EC2Launch Settings UI.	June 10, 2024

Version	Details	Release date
	• Updated the wallpaper CLI command. • Updated the EC2Launch installer.	
2.0.1914	• Add routes with unspecified gateway addresses (`0.0.0.0` for IPv4 or `::` for IPv6). • Always add both IPv4 and IPv6 routes. • Fixed an issue where the `Administrator` username was added to the `agent-config.yml` file when it wasn't specified. • Modified EC2Launch v2 permissions.	June 5, 2024
2.0.1881	• Added an encrypted password option to `setAdminAccount` task. • Added CLI command to encrypt static password in agent-config.yml. • Fixed an issue where XML user data doesn't add PowerShell arguments when it runs with Administrator permissions. For more details, see How Amazon EC2 handles user data for Windows instances. • Adjusted PowerShell arguments for the `executeScript` task and user data scripts when they run with `LocalSystem` permissions. When arguments are empty, the agent uses the following default value: `-ExecutionPolicy Unrestricted`. • Prevented printing duplicate driver versions to the console log.	May 8, 2024

Version	Details	Release date
2.0.1815	• Adjusted error handling to fail on critical setup issues before sysprep. • Fixed an issue where wallpaper and hostname tasks could use an incorrect IP address on instances with multiple IP addresses assigned to the primary network interface. • Wallpaper and hostname tasks changed to get private IP from IMDS first, then fail back to WMI if IMDS is disabled. • Fixed an issue with the `initializeVolume` task where `sc1` volumes failed to initialize due to a transient error.	March 6, 2024
2.0.1739	• Fixed an issue that prevented exit codes from being captured by `executeScript` tasks that were run as the Windows Administrator user.	January 17, 2024
2.0.1702	• Restricted `Telemetry.log` permissions to `read-execute` only for standard users. • Configured the EC2Launch Windows service to restart on start-up failure. • Made `add-routes` failures actionable by logging `route.exe` `stderr` output. • Fixed an issue that occurs when route metrics are outside of the range [1, 9999]. • Added wallpaper support to several new instance types. • Fixed an issue caused by user data scripts that run as the Windows Administrator user and send output to `stderr`.	January 4, 2024

Version	Details	Release date
2.0.1643	• Updated the `ebsnvme-id.exe` tool to version 1.1.0.7. • Fixed an issue with receive side scaling (RSS) and receive queue depth settings on metal instance types that begin with 'metal-*', such as metal-48x1. • Removed telemetry event that reports on XML userdata commands that block the agent. • Updated `setDnsSuffix` task to limit domain name devolution based on registry entry: `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Dnscache\Parameters\DomainNameDevolutionLevel` . • Added a public task and CLI that adds network routes. • *Note* – This is the last version to officially support Windows Server 2012. • *Note* – This is the last version to officially support 32-bit operating systems.	October 4, 2023
2.0.1580	• Changed the way that the launch agent handles errors when you modify log file permissions. • Added a timeout for connecting to the serial port. The time out allows the launch agent to continue running if the serial port is in use.	September 5, 2023

Version	Details	Release date

2.0.1521	• Deprecated the –`block` flag of the `EC2Launch.exe` **reset** and **sysprep** commands.
	• Updated `EC2Launch.exe` to detect and handle the **reset** and **sysprep** commands that are used in inline `executeScript` tasks. Those commands cause the agent to stop running after the `executeScript` task runs them.
	• Updated XML userdata scripts to run inline by default.
	• Enable XML userdata scripts to run detached with the new `detach` tag. For more details, see User data scripts.
	• Made the following changes to the agent log.
	  ◦ Updated agent log messages.
	  ◦ Removed `executeScript` content and output from the agent log.
	  ◦ Removed `executeProgram` arguments and output from the agent log.
	• Made the following changes to the console log.
	  ◦ Added `EnableSCSIPersistentReservations` value to the console log.
		July 3, 2023

Version	Details	Release date
2.0.1303	• Added additional error handling and log lines when adding network routes. • Allowed `executeScript` and `executeProgram` tasks in the PreReady stage. • Updated `executeProgram` task to generate output files similar to the output from the executeScript task. For more information, see executeProgram. • Added telemetry to monitor usage of blocking agent co mmands in XML user data.	May 3, 2023
2.0.1245	• Improved visibility into crashes by logging crash call stacks in clear text. • Added the EventLog service as a startup dependency to fix a crash when the Amazon EC2Launch service starts up faster t han the EventLog service. • Made XML user data run before PostReady stage from the agent config file (like EC2Launch v1 and EC2Config). • Added YAML user data version 1.1 to make user data run before PostReady stage from the agent config file (YAML user data version 1.0 runs after PostReady stage from the agent config file).	March 8, 2023

Version	Details	Release date
2.0.1173	• Adds an optional feature to display instance tags on wallp aper. For more information, see setWallpaper . • Adds error handling when the security group for Elastic Graphics is not properly set up. • Fixes a timeout when the Instance Metadata Service is not enabled.	February 6, 2023
2.0.1121	• Fixes an issue where a 404 error is printed to the wallpaper when no public IPv4 address is assigned. • Fixes an issue where the volume's file system is formatted as `RAW` instead of `NTFS` when its device's drive letter is set to `D`. • Fixes an issue where NVMe SSD volumes are incorrectly identified as EBS volumes. • Fixes an error when activating Windows when IMDS is disab led.	January 4, 2023

Version	Details	Release date
2.0.1082	• Fixes an issue where the `setWallpaper : privateIpAddress` field is blank when IMDS is disabled. • Fixes an issue with setting the hostname to the private IPv4 address when IMDS is disabled. • Fixes an issue with initializing volumes on Windows Server 2012. • Fixes an issue with setting jumbo frames. • Fixes an error when no SSH key is specified at instance launch. • Fixes an error on Windows Server 2012 when Windows does not have a 'ReleaseId' registry key.	December 7, 2022
2.0.1011	• Fixes logic for finding network adapter when PnPDeviceID is empty.	November 11, 2022
2.0.1009	• Uses PCI segment information to select the console port.	November 8, 2022
2.0.982	• Adds retry logic to get RDP information. • Fixes errors during volume initialization on `d2.8xlarge` instances. • Fixes issue where an incorrect network adapter can be selected after a reboot. • Removes false alarm error message when ACPI SPCR is unavailable.	October 31, 2022

Version	Details	Release date
2.0.863	• Updates IMDS wait logic to make only IMDSv2 requests. • Adds logic to assign drive letter to volumes that are already initialized but not mounted. • Prints a more specific error message when key pair type is not supported. • Fixes 3010 reboot code bug. • Adds check for invalid base64-encoded user data.	July 6, 2022
2.0.698	• Fixes typo in log output when executing scripts.	January 30, 2022
2.0.674	• Telemetry uploads the enabled/disabled privacy control. • Fixes `index out of bounds` bug. • Removes wallpaper shortcuts during `sysprep`.	November 15, 2021
2.0.651	• Adds logic to uninstall legacy agents during EC2Launch v2 installation. • Fixes `list-volume` CLI issue when root volume is not listed as volume 0.	October 7, 2021
2.0.592	• Fixes bug to correctly report stage status. • Removes false alarm error messages when log files are closed. • Adds telemetry.	August 31, 2021

Version	Details	Release date
2.0.548	• Adds leading zeros for hex IP hostname. • Fixes file permissions for `enableOpenSsh` task. • Fixes sysprep command crash.	August 4, 2021
2.0.470	• Fixes bug in network stage to wait for DHCP to assign an IP to the instance. • Fixes bug with `setDnsSuffix` when `SearchList` registry key does not exist. • Fixes bug in DNS devolution logic in `setDnsSuffix` . • Adds network routes after intermediate reboots. • Allows `initializeVolume` to re-letter existing volumes. • Removes extra information from version subcommand.	July 20, 2021
2.0.285	• Adds option to run user scripts in a detached process. • Legacy userdata (XML userdata) now runs in a detached process, which is similar behavior to the prior launch agent. • Adds CLI flag to the `sysprep` and `reset` commands, which allows them to block until the service stops. • Restricts the config folder permissions.	March 8, 2021

Version	Details	Release date
2.0.207	• Adds optional `hostName` field to `setHostName` task. • Fixes reboot bug. Reboot tasks `executeScript` and `executeProgram` will be marked as running. • Adds more return codes to the status command. • Adds bootstrap service to fix startup issue when running on `t2.nano` instance type. • Fixes clean installation mode to remove files not tracked by installer.	February 2, 2021
2.0.160	• Fixes `validate` command to detect invalid stage name. • Adds `w32tm resync` command in `addroutes` task. • Fixes issue with changing DNS suffix search order. • Adds check conditions to better report invalid user data.	December 4, 2020
2.0.153	Adds Sysprep functionality in UserData.	November 3, 2020

Version	Details	Release date
2.0.146	• Fixes issue with RootExtend on non-English AMIs. • Grants users group write permission to log files. • Creates MS Reserved partition for GPT volumes. • Adds list-volumes command and volume dropdown in Amazon EC2Launch settings. • Adds get-agent-config command for printing agent-config.yml file in yaml or json format. • Erases static password if no public key detected.	October 6, 2020
2.0.124	• Adds option to display OS version on wallpaper. • Initializes encrypted EBS volumes. • Adds routes for VPCs with no local DNS name.	September 10, 2020
2.0.104	• Creates DNS suffix search list if it does not exist. • Skips Hibernation if not requested.	August 12, 2020
2.0.0	Initial release.	June 30, 2020

Use the EC2Launch v1 agent to perform tasks during EC2 Windows instance launch

Amazon managed AMIs for Windows Server 2016 and 2019 include a set of Windows Powershell scripts called EC2Launch. EC2Launch performs tasks during the initial instance boot. For information about the EC2Launch versions that are included in AWS Windows AMIs, see the AWS Windows AMI Reference.

> **Note**
>
> The latest launch agent for Windows Server 2016 and later operating system versions is EC2Launch v2, which replaces both EC2Config and EC2Launch, and comes pre-installed on AWS Windows Server 2016 and 2019 AMIs with names that begin with `EC2LaunchV2-Windows_Server-*`. You can also manually install and configure the agent on Windows Server 2016 and 2019. For more information, see Install EC2Launch v2.
> To use EC2Launch with IMDSv2, the version must be 1.3.2002730 or later.

You can use the following Windows PowerShell command to verify the installed version of EC2Launch.

```
Test-ModuleManifest -Path "C:\ProgramData\Amazon\EC2-Windows\Launch\Module
\Ec2Launch.psd1" | Select Version
```

EC2Launch tasks

EC2Launch performs the following tasks by default during the initial instance boot:

- Sets up new wallpaper that renders information about the instance.
- Sets the computer name to the private IPv4 address of the instance.
- Sends instance information to the Amazon EC2 console.
- Sends the RDP certificate thumbprint to the EC2 console.
- Sets a random password for the administrator account.
- Adds DNS suffixes.
- Dynamically extends the operating system partition to include any unpartitioned space.
- Executes user data (if specified). For more information about specifying user data, see Run commands when you launch an EC2 instance with user data input.
- Sets persistent static routes to reach the metadata service and AWS KMS servers.

> **Important**
>
> If a custom AMI is created from this instance, these routes are captured as part of the OS configuration and any new instances launched from the AMI will retain the same routes,

regardless of subnet placement. In order to update the routes, see Update metadata/ KMS routes for Server 2016 and later when launching a custom AMI.

The following tasks help to maintain backward compatibility with the EC2Config service. You can also configure EC2Launch to perform these tasks during startup:

- Initialize secondary EBS volumes.
- Send Windows Event logs to the EC2 console logs.
- Send the *Windows is ready to use* message to the EC2 console.

EC2Launch directory structure

EC2Launch is installed by default on Windows Server 2016 and later AMIs in the root directory `C:\ProgramData\Amazon\EC2-Windows\Launch`.

> **Note**
>
> By default, Windows hides files and folders under `C:\ProgramData`. To view EC2Launch directories and files, you must either type the path in Windows Explorer or change the folder properties to show hidden files and folders.

The `Launch` directory contains the following subdirectories.

- `Scripts` — Contains the PowerShell scripts that make up EC2Launch.
- `Module` — Contains the module for building scripts related to Amazon EC2.
- `Config` — Contains script configuration files that you can customize.
- `Sysprep` — Contains Sysprep resources.
- `Settings` — Contains an application for the Sysprep graphical user interface.
- `Library` — Contains shared libraries for EC2 launch agents.
- `Log` — Contains subdirectories for scripts and the log files that are generated by the scripts.

Telemetry

Telemetry is additional information that helps AWS to better understand your requirements, diagnose issues, and deliver features to improve your experience with AWS services.

EC2Launch version `1.3.2003498` and later collect telemetry, such as usage metrics and errors. This data is collected from the Amazon EC2 instance on which EC2Launch runs. This includes all Windows AMIs owned by AWS.

The following types of telemetry are collected by EC2Launch:

- **Usage information** — agent commands, install method, and scheduled run frequency.
- **Errors and diagnostic information** — agent installation and run error codes.

Examples of collected data:

```
2021/07/15 21:44:12Z: EC2LaunchTelemetry: IsAgentScheduledPerBoot=true
2021/07/15 21:44:12Z: EC2LaunchTelemetry: IsUserDataScheduledPerBoot=true
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentCommandCode=1
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentCommandErrorCode=5
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentInstallCode=2
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentInstallErrorCode=0
```

Telemetry is enabled by default. You can disable telemetry collection at any time. If telemetry is enabled, EC2Launch sends telemetry data without additional customer notifications.

Your choice to enable or disable telemetry is collected.

You can opt in or out of telemetry collection. Your selection to opt in or out of telemetry is collected to ensure that we adhere to your telemetry option.

Telemetry visibility

When telemetry is enabled, it appears in the Amazon EC2 console output as follows:

```
2021/07/15 21:44:12Z: Telemetry: <Data>
```

Disable telemetry on an instance

To disable telemetry by setting a system environment variable, run the following command as an administrator:

```
setx /M EC2LAUNCH_TELEMETRY 0
```

To disable telemetry during installation, run `install.ps1` as follows:

```
. .\install.ps1 -EnableTelemetry:$false
```

More topics for EC2Launch

- Install the latest version of EC2Launch
- Configure the EC2Launch v1 agent on your Windows instance
- EC2Launch version history

Install the latest version of EC2Launch

Use the following procedure to download and install the latest version of EC2Launch on your instances.

To download and install the latest version of EC2Launch

1. If you have already installed and configured EC2Launch on an instance, make a backup of the EC2Launch configuration file. The installation process does not preserve changes in this file. By default, the file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.
2. Download EC2-Windows-Launch.zip to a directory on the instance.
3. Download install.ps1 to the same directory where you downloaded `EC2-Windows-Launch.zip`.
4. Run `install.ps1`
5. If you made a backup of the EC2Launch configuration file, copy it to the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.

To download and install the latest version of EC2Launch using PowerShell

If you have already installed and configured EC2Launch on an instance, make a backup of the EC2Launch configuration file. The installation process does not preserve changes in this file. By default, the file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.

To install the latest version of EC2Launch using PowerShell, run the following commands from a PowerShell window as an administrator:

```
mkdir $env:USERPROFILE\Desktop\EC2Launch
$Url = "https://s3.amazonaws.com/ec2-downloads-windows/EC2Launch/latest/EC2-Windows-Launch.zip"
$DownloadZipFile = "$env:USERPROFILE\Desktop\EC2Launch\" + $(Split-Path -Path $Url -Leaf)
Invoke-WebRequest -Uri $Url -OutFile $DownloadZipFile
$Url = "https://s3.amazonaws.com/ec2-downloads-windows/EC2Launch/latest/install.ps1"
$DownloadZipFile = "$env:USERPROFILE\Desktop\EC2Launch\" + $(Split-Path -Path $Url -Leaf)
Invoke-WebRequest -Uri $Url -OutFile $DownloadZipFile
& $env:USERPROFILE\Desktop\EC2Launch\install.ps1
```

Note

If you receive an error when downloading the file, and you are using Windows Server 2016, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:

```
[Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
```

Verify the installation by checking the launch agent. Run the following commands from a PowerShell window as an administrator:

```
Import-Module C:\ProgramData\Amazon\EC2-Windows\Launch\Module\Ec2Launch.psm1
Import-LocalizedData -BaseDirectory C:\ProgramData\Amazon\EC2-Windows\Launch\Module\ -FileName 'Ec2Launch.psd1' -BindingVariable moduleManifest
$moduleManifest.Get_Item('ModuleVersion')
```

Configure the EC2Launch v1 agent on your Windows instance

After your instance has been initialized the first time, you can configure EC2Launch to run again and perform different start-up tasks.

Tasks

- Configure initialization tasks

- Schedule EC2Launch to run on every boot
- Initialize drives and map drive letters
- Send Windows event logs to the EC2 console
- Send Windows is ready message after a successful boot

Configure initialization tasks

Specify settings in the `LaunchConfig.json` file to enable or disable the following initialization tasks:

- Set the computer name to the instance private IPv4 address.
- Set the monitor to always stay on.
- Set up new wallpaper.
- Add DNS suffix list.

> **Note**
>
> This adds a DNS suffix lookup for the following domain and configures other standard suffixes. For more information about how launch agents set DNS suffixes, see Configure DNS Suffix for EC2 Windows launch agents.
>
> ```
> region.ec2-utilities.amazonaws.com
> ```

- Extend the boot volume size.
- Set the administrator password.

To configure initialization settings

1. On the instance to configure, open the following file in a text editor: `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\LaunchConfig.json`.
2. Update the following settings as needed and save your changes. Provide a password in `adminPassword` only if `adminPasswordtype` is `Specify`.

```
{
 "setComputerName": false,
```

```
 "setMonitorAlwaysOn": true,
 "setWallpaper": true,
 "addDnsSuffixList": true,
 "extendBootVolumeSize": true,
 "handleUserData": true,
 "adminPasswordType": "Random | Specify | DoNothing",
 "adminPassword": "password that adheres to your security policy (optional)"
}
```

The password types are defined as follows:

`Random`

EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

`Specify`

EC2Launch uses the password you specify in `adminPassword`. If the password does not meet the system requirements, EC2Launch generates a random password instead. The password is stored in `LaunchConfig.json` as clear text and is deleted after Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.

`DoNothing`

EC2Launch uses the password you specify in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.

3. In Windows PowerShell, run the following command to schedule the script to run as a Windows Scheduled Task. The script runs one time during the next boot and then disables these tasks from running again.

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -Schedule
```

Schedule EC2Launch to run on every boot

You can schedule EC2Launch to run on every boot instead of only the initial boot.

To enable EC2Launch to run on every boot:

1. Open Windows PowerShell and run the following command:

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -
SchedulePerBoot
```

2. Or, run the executable with the following command:

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Settings\Ec2LaunchSettings.exe
```

Then select `Run EC2Launch on every boot`. You can specify that your EC2 instance `Shutdown without Sysprep` or `Shutdown with Sysprep`.

> **Note**
>
> When you enable EC2Launch to run on every boot, the following happens the next time EC2Launch runs:
>
> - If `AdminPasswordType` is still set to `Random`, EC2Launch will generate a new password at the next boot. After that boot, `AdminPasswordType` is automatically set to `DoNothing` to prevent EC2Launch from generating new passwords on subsequent boots. To prevent EC2Launch from generating a new password on the first boot, manually set `AdminPasswordType` to `DoNothing` before you reboot.
> - `HandleUserData` will be set back to `false` unless the user data has `persist` set to `true`. For more information, see the section called "User data scripts".

Initialize drives and map drive letters

Specify settings in the `DriveLetterMappingConfig.json` file to map drive letters to volumes on your EC2 instance. The script initializes drives that are not already initialized and partitioned. For more information about getting volume details in Windows, see Get-Volume in the Microsoft documentation.

To map drive letters to volumes

1. Open the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\DriveLetterMappingConfig.json` file in a text editor.
2. Specify the following volume settings and save your changes:

```
{
 "driveLetterMapping": [
  {
   "volumeName": "sample volume",
   "driveLetter": "H"
  }
 ]
}
```

3. Open Windows PowerShell and use the following command to run the EC2Launch script that initializes the disks:

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1
```

To initialize the disks each time the instance boots, add the `-Schedule` flag as follows:

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1 -Schedule
```

Send Windows event logs to the EC2 console

Specify settings in the `EventLogConfig.json` file to send Windows Event logs to EC2 console logs.

To configure settings to send Windows Event logs

1. On the instance, open the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\EventLogConfig.json` file in a text editor.
2. Configure the following log settings and save your changes:

```
{
 "events": [
  {
   "logName": "System",
   "source": "An event source (optional)",
   "level": "Error | Warning | Information",
   "numEntries": 3
  }
 ]
}
```

3. In Windows PowerShell, run the following command so that the system schedules the script to run as a Windows Scheduled Task each time the instance boots.

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\SendEventLogs.ps1 -Schedule
```

The logs can take three minutes or more to appear in the EC2 console logs.

Send Windows is ready message after a successful boot

The EC2Config service sent the "Windows is ready" message to the EC2 console after every boot. EC2Launch sends this message only after the initial boot. For backwards compatibility with the EC2Config service, you can schedule EC2Launch to send this message after every boot. On the instance, open Windows PowerShell and run the following command. The system schedules the script to run as a Windows Scheduled Task.

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\SendWindowsIsReady.ps1 -Schedule
```

EC2Launch version history

> **Important**
>
> Beginning January 1, 2025, only the last two versions are supported. When a new version is released, the oldest previously supported version will automatically be marked private and will no longer be available for download.

To download and install the latest version of EC2Launch, see Install the latest version of EC2Launch.

You can receive notifications when new versions of the EC2Launch agent are released. For more information, see Subscribe to EC2 Windows launch agent notifications.

The following EC2Launch agent versions are supported and are available for download.

Version	Details	Release date
1.3.2005119	•	11 February 2025

Version	Details	Release date
	Fixed an issue where `Invoke-Userdata` would fail when called without any parameters.	
1.3.2005065	• Fixed an issue where RDP certificate information was not properly retrieved or validated. Added functionality to automatically start the Remote Desktop Services if needed.	22 October 2024

The following prior versions of EC2Launch are no longer available for download.

Version	Details	Release date
1.3.2005008	• Updated `Set-Wallpaper` to fall back to a solid color background if the default wallpaper image is not found.	6 August 2024
1.3.2004959	• Updated installer logic to prevent unsupported installation on Windows Server 2025 or later.	2 July 2024
1.3.2004891	• Fixed an issue where `HandleUserData` was not set to `false` as expected. • Added an `Encrypted` password option to `LaunchConfig.json`. • Changed `Settings UI` behavior to encrypt the user specified password by default. • Added `SetAdminPasswordConfig.ps1` to convert the `Specify` password option to the `Encrypted` password option in the agent configuration file.	31 May 2024
1.3.2004617	• Fixed an error when setting the wallpaper.	15 January 2024

Version	Details	Release date
1.3.2004592	• Updated access permissions set by install.ps1 for `%ProgramData%\Amazon\EC2-Windows\Launch` . • Restricted EC2Launch folder/file access to read-execute only for standard user accounts. • Changed the agent to stop waiting for the Instance Metadata Service (IMDS) to initialize if IMDS is not enabled for the instance. • Added a five minute timeout when waiting for the IMDS to initialize. • Changed the agent to write telemetry to the instance console log before the `Windows is Ready` message instead of after. • Added wallpaper support to several new instance types. For more information about access permissions and user account permissions of EC2Launch directories, see the section called "EC2Launch directory structure".	2 January 2024
1.3.2004491	• Added telemetry to monitor usage of the **Specify admin password** option.	9 November 2023
1.3.2004462	• Added flush after every write to the serial console.	18 October 2023

Version	Details	Release date
1.3.2004438	• Limit domain name devolution based on registry entry: `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Dnscache\Parameters\DomainNameDevolutionLevel` . • Limited `UserdataExecution.log` permissions to `Administrators` only. • Added error messages in the Windows Event Log when log initialization fails.	4 October 2023
1.3.2004256	• Added `EnableSCSIPersistentReservations` value to console log. • Added retry capability for **Get-ConsolePort**.	7 July 2023
1.3.2004052	• Fixed an error that occurred when no SSH key is specified at instance launch. • Updated to retry starting the AmazonSSMAgent Windows service on failure. • Updated to fail SysprepInstance.ps1 if BeforeSysprep.cmd fails with a non-zero exit code.	8 March 2023
1.3.2003975	• Fixed issue impacting Packer AMI builds where `SysprepInstance.ps1` returns a `$LastErrorCode` of 1.	24 December 2022

Version	Details	Release date
1.3.2003961	• Fixed issue where explicitly specified administrator passwords are overwritten with a random password on fast-launched instances. • Fixed issue where SSM Agent fails to start on smaller instance types. • Fixed an issue where the instance console log contains `RDPCERTIFICATE-THUMBPRINT: 0000000 0000000000000000` instead of a valid RDP certificate thumbprint value.	6 December 2022
1.3.2003923	• Fixes logic for finding network adapter when PnPDeviceID is empty.	9 November 2022
1.3.2003919	• Updated Get-ConsolePort to use PCI segment information. • Fixed issue where an incorrect network adapter can be selected after reboot. • Fixed start-SSM-Agent timeout logic. • Fixed backwards compatibility for Send-AdminCredentials function alias.	8 November 2022
1.3.2003857	• Prioritizes adapters with a default gateway when the primary network adapter is selected. • Extended in-memory password encryption.	3 October 2022

Version	Details	Release date
1.3.2003824	• Fixed error during `setComputerName` . • Added logic to skip Windows activation when a BYOL billing code is detected. • Added in-memory password encryption. • Fixed error during volume initialization on `m6id.4xlarge` .	30 August 2022
1.3.2003691	• Updated IMDS wait logic to make only IMDSv2 requests. • Fixed bug impacting eGPU installation.	21 June 2022
1.3.2003639	• Added network-adapter wait logic to prevent use before initialization. • Fixed minor issues.	10 May 2022
1.3.2003498	• Added telemetry. • Added shortcut to Settings UI. • Formatted PowerShell scripts. • Fixed issue with shutdown occurring before BeforeSysprep.cmd completes.	31 January 2022
1.3.2003411	Changed password generation logic to exclude passwords with low complexity.	04 August 2021
1.3.2003364	Updated Install-EgpuManager with IMDSv2 support.	07 June 2021

Version	Details	Release date
1.3.2003312	• Added log lines before and after `setMonitorAlwaysOn` setting. • Added AWS Nitro Enclaves package version to console log.	04 May 2021
1.3.2003284	Improved permission model by updating location for storing user data to `LocalAppData` .	23 March 2021
1.3.2003236	• Updated method for setting user password in `Set-AdminAccount` and `Randomize-LocalAdminPassword` . • Fixed`InitializeDisks` to check whether disk is set to read only before setting it to writable.	11 February 2021
1.3.2003210	Localization fix for `install.ps1` .	7 January 2021
1.3.2003205	Security fix for `install.ps1` to update permissions on `%ProgramData%AmazonEC2-WindowsLaunchModuleScripts` directory.	28 December 2020
1.3.2003189	Added `w32tm resync` after adding routes.	4 December 2020
1.3.2003155	Updated instance type information.	25 August 2020
1.3.2003150	Added `OsCurrentBuild` and `OsReleaseId` to console output .	22 April 2020
1.3.2003040	Fixed IMDS version 1 fallback logic.	7 April 2020
1.3.2002730	Added support for IMDS V2.	3 March 2020

Version	Details	Release date
1.3.2002240	Fixed minor issues.	31 October 2019
1.3.2001660	Fixed automatic login issue for users without password after first time executing Sysprep.	2 July 2019
1.3.2001360	Fixed minor issues.	27 March 2019
1.3.2001220	All PowerShell scripts signed.	28 February 2019
1.3.2001200	Fixed issue with InitializeDisks.ps1 where running the script on a node in a Windows Server Failover Cluster would format drives on remote nodes whose drive letter matched the local drive letter.	27 February 2019
1.3.2001160	Fixed missing wallpaper in Windows 2019.	22 February 2019
1.3.2001040	• Added plugin for setting the monitor to never turn off to fix ACPI issues. • SQL Server edition and version written to console.	21 January 2019
1.3.2000930	Fix for adding routes to metadata on ipv6-enabled ENIs.	2 January 2019
1.3.2000760	• Added default configuration for RSS and Receive Queue se ttings for ENA devices. • Disabled hibernation during Sysprep.	5 December 2018

Version	Details	Release date
1.3.2000630	• Added route 169.254.169.253/32 for DNS server. • Added filter of setting Admin user. • Improvements made to instance hibernation. • Added option to schedule EC2Launch to run on every boot.	9 November 2018
1.3.2000430.0	• Added route 169.254.169.123/32 to AMZN time service. • Added route 169.254.169.249/32 to GRID license service. • Added timeout of 25 seconds when attempting to start Systems Manager.	19 September 2018
1.3.200039.0	• Fixed improper drive lettering for EBS NVME volumes. • Added additional logging for NVME driver versions.	15 August 2018
1.3.2000080	Fixed minor issues.	
1.3.610	Fixed issue with redirecting output and errors to files from user data.	
1.3.590	• Added missing instances types in the wallpaper. • Fixed an issue with drive letter mapping and disk installation.	

Version	Details	Release date
1.3.580	• Fixed `Get-Metadata` to use the default system proxy settings for web requests. • Added a special case for NVMe in disk initialization. • Fixed minor issues.	
1.3.550	Added a `-NoShutdown` option to enable Sysprep with no shutdown.	
1.3.540	Fixed minor issues.	
1.3.530	Fixed minor issues.	
1.3.521	Fixed minor issues.	
1.3.0	• Fixed a hexadecimal length issue for computer name change. • Fixed a possible reboot loop for computer name change. • Fixed an issue in wallpaper setup.	
1.2.0	• Update to display information about installed operating system (OS) in EC2 system log. • Update to display EC2Launch and SSM Agent version in EC2 system log. • Fixed minor issues.	

Version	Details	Release date
1.1.2	• Update to display ENA driver information in EC2 system log. • Update to exclude Hyper-V from primary NIC filter logic. • Added AWS KMS server and port into registry key for KMS activation. • Improved wallpaper setup for multiple users. • Update to clear routes from persistent store. • Update to remove the z from availability zone in DNS suffix list. • Update to address an issue with the <runAsLocalSystem> tag in user data.	
1.1.1	Initial release.	

Use the EC2Config service to perform tasks during EC2 legacy Windows operating system instance launch

> **Note**
>
> EC2Config has reached the end of support. The operating system versions that it runs on are no longer supported by Microsoft. We strongly recommend that you upgrade to the latest launch agent.
> The latest launch agent for Windows Server 2022 and later operating system versions is EC2Launch v2, which replaces both EC2Config and EC2Launch, and comes pre-installed on AWS Windows Server 2022 and 2025 AMIs. You can also manually install and configure the agent on Windows Server 2016 and 2019. For more information, see Install EC2Launch v2.

Windows AMIs for Windows Server versions prior to Windows Server 2016 include an optional service, the EC2Config service (`EC2Config.exe`). EC2Config starts when the instance boots and performs tasks during startup and each time you stop or start the instance. EC2Config can also perform tasks on demand. Some of these tasks are automatically enabled, while others must be enabled manually. Although optional, this service provides access to advanced features that aren't otherwise available. This service runs in the LocalSystem account.

The EC2Config service runs Sysprep, a Microsoft tool that enables you to create a customized Windows AMI that can be reused. When EC2Config calls Sysprep, it uses the files in `%ProgramFiles%\Amazon\EC2ConfigService\Settings` to determine which operations to perform. You can edit these files indirectly using the **EC2 Service Properties** system dialog, or directly using an XML editor or a text editor. However, there are some advanced settings that aren't available in the **Ec2 Service Properties** system dialog, so you must edit those entries directly.

If you create an AMI from an instance after updating its settings, the new settings are applied to any instance that's launched from the new AMI. For information about creating an AMI, see Create an Amazon EBS-backed AMI.

EC2Config uses settings files to control its operation. You can update these settings files using either a graphical tool or by directly editing XML files. The service binaries and additional files are contained in the `%ProgramFiles%\Amazon\EC2ConfigService` directory.

Contents

EC2Config and AWS Systems Manager

The EC2Config service processes Systems Manager requests on instances created from AMIs for versions of Windows Server prior to Windows Server 2016 that were published before November 2016.

Instances created from AMIs for versions of Windows Server prior to Windows Server 2016 that were published after November 2016 include the EC2Config service *and* SSM Agent. EC2Config performs all of the tasks described earlier, and SSM Agent processes requests for Systems Manager capabilities like Run Command and State Manager.

You can use Run Command to upgrade your existing instances to use to the latest version of the EC2Config service and SSM Agent. For more information, see Update SSM Agent using Run Command in the *AWS Systems Manager User Guide*.

EC2Config tasks

EC2Config runs initial startup tasks when the instance is first started and then disables them. To run these tasks again, you must explicitly enable them prior to shutting down the instance, or by running Sysprep manually. These tasks are as follows:

- Set a random, encrypted password for the administrator account.
- Generate and install the host certificate used for Remote Desktop Connection.
- Dynamically extend the operating system partition to include any unpartitioned space.
- Execute the specified user data (and Cloud-Init, if it's installed). For more information about specifying user data, see Run commands when you launch an EC2 instance with user data input.

EC2Config performs the following tasks every time the instance starts:

- Change the host name to match the private IP address in Hex notation (this task is disabled by default and must be enabled in order to run at instance start).
- Configure the key management server (AWS KMS), check for Windows activation status, and activate Windows as necessary.
- Mount all Amazon EBS volumes and instance store volumes, and map volume names to drive letters.
- Write event log entries to the console to help with troubleshooting (this task is disabled by default and must be enabled in order to run at instance start).
- Write to the console that Windows is ready.
- Add a custom route to the primary network adapter to enable the following IP addresses when a single NIC or multiple NICs are attached: `169.254.169.250`, `169.254.169.251`, and `169.254.169.254`. These addresses are used by Windows Activation and when you access instance metadata.

> **Note**
>
> If the Windows OS is configured to use IPv4, these IPv4 link-local addresses can be used. If the Windows OS has the IPv4 network protocol stack disabled and uses IPv6 instead, add `[fd00:ec2::250]` in place of `169.254.169.250` and `169.254.169.251`. Then add `[fd00:ec2::254]` in place of `169.254.169.254`.

EC2Config performs the following task every time a user logs in:

- Display wallpaper information to the desktop background.

While the instance is running, you can request that EC2Config perform the following task on demand:

- Run Sysprep and shut down the instance so that you can create an AMI from it. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.

EC2Config settings files

The settings files control the operation of the EC2Config service. These files are located in the `C:\Program Files\Amazon\Ec2ConfigService\Settings` directory:

- `ActivationSettings.xml`—Controls product activation using a key management server (AWS KMS).
- `AWS.EC2.Windows.CloudWatch.json`—Controls which performance counters to send to CloudWatch and which logs to send to CloudWatch Logs.
- `BundleConfig.xml`—Controls how EC2Config prepares an instance store-backed instance for AMI creation.
- `Config.xml`—Controls the primary settings.
- `DriveLetterConfig.xml`—Controls drive letter mappings.
- `EventLogConfig.xml`—Controls the event log information that's displayed on the console while the instance is booting.
- `WallpaperSettings.xml`—Controls the information that's displayed on the desktop background.

ActivationSettings.xml

This file contains settings that control product activation. When Windows boots, the EC2Config service checks whether Windows is already activated. If Windows is not already activated, it attempts to activate Windows by searching for the specified AWS KMS server.

- `SetAutodiscover`—Indicates whether to detect a AWS KMS automatically.
- `TargetKMSServer`—Stores the private IP address of a AWS KMS. The AWS KMS must be in the same Region as your instance.
- `DiscoverFromZone`—Discovers the AWS KMS server from the specified DNS zone.
- `ReadFromUserData`—Gets the AWS KMS server from UserData.
- `LegacySearchZones`—Discovers the AWS KMS server from the specified DNS zone.
- `DoActivate`—Attempts activation using the specified settings in the section. This value can be `true` or `false`.
- `LogResultToConsole`—Displays the result to the console.

BundleConfig.xml

This file contains settings that control how EC2Config prepares an instance for AMI creation.

- `AutoSysprep`—Indicates whether to use Sysprep automatically. Change the value to `Yes` to use Sysprep.
- `SetRDPCertificate`—Sets a self-signed certificate to the Remote Desktop server. This enables you to securely RDP into the instances. Change the value to `Yes` if the new instances should have the certificate.

  This setting is not used for instances with operating system versions prior to Windows Server 2016, because they can generate their own certificates.
- `SetPasswordAfterSysprep`—Sets a random password on a newly launched instance, encrypts it with the user launch key, and outputs the encrypted password to the console. Change the value of this setting to `No` if the new instances should not be set to a random encrypted password.

Config.xml

Plug-ins

- `Ec2SetPassword`—Generates a random encrypted password each time you launch an instance. This feature is disabled by default after the first launch so that reboots of this instance don't change a password set by the user. Change this setting to `Enabled` to continue to generate passwords each time you launch an instance.

  This setting is important if you are planning to create an AMI from your instance.
- `Ec2SetComputerName`—Sets the host name of the instance to a unique name based on the IP address of the instance and reboots the instance. To set your own host name, or prevent your existing host name from being modified, you must disable this setting.
- `Ec2InitializeDrives`—Initializes and formats all volumes during startup. This feature is enabled by default.
- `Ec2EventLog`—Displays event log entries in the console. By default, the three most recent error entries from the system event log are displayed. To specify the event log entries to display, edit the `EventLogConfig.xml` file located in the `EC2ConfigService\Settings` directory. For information about the settings in this file, see [Eventlog Key].
- `Ec2ConfigureRDP`—Sets up a self-signed certificate on the instance, so users can securely access the instance using Remote Desktop. This setting is not used for instances with operating system versions prior to Windows Server 2016, because they can generate their own certificates.
- `Ec2OutputRDPCert`—Displays the Remote Desktop certificate information to the console so that the user can verify it against the thumbprint.
- `Ec2SetDriveLetter`—Sets the drive letters of the mounted volumes based on user-defined settings. By default, when an Amazon EBS volume is attached to an instance, it can be mounted using the drive letter on the instance. To specify your drive letter mappings, edit the `DriveLetterConfig.xml` file located in the `EC2ConfigService\Settings` directory.
- `Ec2WindowsActivate`—The plug-in handles Windows activation. It checks to see if Windows is activated. If not, it updates the AWS KMS client settings, and then activates Windows.

  To modify the AWS KMS settings, edit the `ActivationSettings.xml` file located in the `EC2ConfigService\Settings` directory.
- `Ec2DynamicBootVolumeSize`—Extends Disk 0/Volume 0 to include any unpartitioned space.
- `Ec2HandleUserData`—Creates and runs scripts created by the user on the first launch of an instance after Sysprep is run. Commands wrapped in script tags are saved to a batch file, and commands wrapped in PowerShell tags are saved to a .ps1 file (corresponds to the User Data checkbox on the Ec2 Service Properties system dialog).

- `Ec2ElasticGpuSetup`—Installs the Elastic GPU software package if the instance is associated with an elastic GPU.
- `Ec2FeatureLogging`—Sends Windows feature installation and corresponding service status to the console. Supported only for the Microsoft Hyper-V feature and corresponding vmms service.

Global Settings

- `ManageShutdown`—Ensures that instances launched from instance store-backed AMIs do not terminate while running Sysprep.
- `SetDnsSuffixList`—Sets the DNS suffix of the network adapter for Amazon EC2. This allows DNS resolution of servers running in Amazon EC2 without providing the fully qualified domain name.

> **Note**
>
> This adds a DNS suffix lookup for the following domain and configures other standard suffixes. For more information about how launch agents set DNS suffixes, see [Configure DNS Suffix for EC2 Windows launch agents](#).
>
> ```
> region.ec2-utilities.amazonaws.com
> ```

- `WaitForMetaDataAvailable`—Ensures that the EC2Config service will wait for metadata to be accessible and the network available before continuing with the boot. This check ensures that EC2Config can obtain information from metadata for activation and other plug-ins.
- `ShouldAddRoutes`—Adds a custom route to the primary network adapter to enable the following IP addresses when multiple NICs are attached: 169.254.169.250, 169.254.169.251, and 169.254.169.254. These addresses are used by Windows Activation and when you access instance metadata.
- `RemoveCredentialsfromSyspreponStartup`—Removes the administrator password from `Sysprep.xml` the next time the service starts. To ensure that this password persists, edit this setting.

DriveLetterConfig.xml

This file contains settings that control drive letter mappings. By default, a volume can be mapped to any available drive letter. You can mount a volume to a particular drive letter as follows.

```
<?xml version="1.0" standalone="yes"?>
<DriveLetterMapping>
  <Mapping>
    <VolumeName></VolumeName>
    <DriveLetter></DriveLetter>
  </Mapping>
  . . .
  <Mapping>
    <VolumeName></VolumeName>
    <DriveLetter></DriveLetter>
  </Mapping>
</DriveLetterMapping>
```

- `VolumeName`—The volume label. For example, *`My Volume`*. To specify a mapping for an instance storage volume, use the label `Temporary Storage X`, where `X` is a number from 0 to 25.
- `DriveLetter`—The drive letter. For example, *`M:`*. The mapping fails if the drive letter is already in use.

EventLogConfig.xml

This file contains settings that control the event log information that's displayed on the console while the instance is booting. By default, we display the three most recent error entries from the System event log.

- `Category`—The event log key to monitor.
- `ErrorType`—The event type (for example, `Error`, `Warning`, `Information`.)
- `NumEntries`—The number of events stored for this category.
- `LastMessageTime`—To prevent the same message from being pushed repeatedly, the service updates this value every time it pushes a message.
- `AppName`—The event source or application that logged the event.

WallpaperSettings.xml

This file contains settings that control the information that's displayed on the desktop background. The following information is displayed by default.

- `Hostname`—Displays the computer name.

- `Instance ID`—Displays the ID of the instance.
- `Public IP Address`—Displays the public IP address of the instance.
- `Private IP Address`—Displays the private IP address of the instance.
- `Availability Zone`—Displays the Availability Zone in which the instance is running.
- `Instance Size`—Displays the type of instance.
- `Architecture`—Displays the setting of the `PROCESSOR_ARCHITECTURE` environment variable.

You can remove any of the information that's displayed by default by deleting its entry. You can add additional instance metadata to display as follows.

```
<WallpaperInformation>
  <name>display_name</name>
  <source>metadata</source>
  <identifier>meta-data/path</identifier>
</WallpaperInformation>
```

You can add additional System environment variables to display as follows.

```
<WallpaperInformation>
  <name>display_name</name>
  <source>EnvironmentVariable</source>
  <identifier>variable-name</identifier>
</WallpaperInformation>
```

InitializeDrivesSettings.xml

This file contains settings that control how EC2Config initializes drives.

By default, EC2Config initialize drives that were not brought online with the operating system. You can customize the plugin as follows.

```
<InitializeDrivesSettings>
    <SettingsGroup>setting</SettingsGroup>
</InitializeDrivesSettings>
```

Use a settings group to specify how you want to initialize drives:

FormatWithTRIM

Enables the TRIM command when formatting drives. After a drive has been formatted and initialized, the system restores TRIM configuration.

Starting with EC2Config version 3.18, the TRIM command is disabled during the disk format operation by default. This improves formatting times. Use this setting to enable TRIM during the disk format operation for EC2Config version 3.18 and later.

FormatWithoutTRIM

Disables the TRIM command when formatting drives and improves formatting times in Windows. After a drive has been formatted and initialized, the system restores TRIM configuration.

DisableInitializeDrives

Disables formatting for new drives. Use this setting to initialize drives manually.

Install the latest version of EC2Config

> **Note**
>
> The latest launch agent for Windows Server 2022 and later operating system versions is EC2Launch v2, which replaces both EC2Config and EC2Launch. EC2Launch v2 comes pre-installed on AWS Windows Server 2022 and 2025 AMIs. You can also manually install and configure the agent on Windows Server 2016 and 2019. For more information, see Install EC2Launch v2.

For information about how to receive notifications for EC2Config updates, see Subscribe to EC2 Windows launch agent notifications. For information about the changes in each version, see the EC2Config version history.

Before you begin

- Verify that you have .NET framework 3.5 SP1 or greater.
- By default, Setup replaces your settings files with default settings files during installation and restarts the EC2Config service when the installation is completed. If you changed EC2Config service settings, copy the `config.xml` file from the `%Program Files%\Amazon`

`\Ec2ConfigService\Settings` directory. After you update the EC2Config service, you can restore this file to retain your configuration changes.

Verify the EC2Config version

Use the following procedure to verify the version of EC2Config that is installed on your instances.

To verify the installed version of EC2Config

1. Launch an instance from your AMI and connect to it.
2. In Control Panel, select **Programs and Features**.
3. In the list of installed programs, look for `Ec2ConfigService`. Its version number appears in the **Version** column.

Update EC2Config

Use the following procedure to download and install the latest version of EC2Config on your instances.

To download and install the latest version of EC2Config

1. Download and unzip the EC2Config installer.
2. Run `EC2Install.exe`. For a complete list of options, run `EC2Install` with the `/?` option. By default, setup displays prompts. To run the command with no prompts, use the `/quiet` option.

   > **Important**
   >
   > To keep the custom settings from the `config.xml` file that you saved, run `EC2Install` with the `/norestart` option, restore your settings, and then restart the EC2Config service manually.

3. If you are running EC2Config version 4.0 or later, you must restart SSM Agent on the instance from the Microsoft Services snap-in.

> **Note**
>
> The updated EC2Config version information will not appear in the instance System Log or Trusted Advisor check until you reboot or stop and start your instance.

To download and install the latest version of EC2Config using PowerShell

To download, unzip, and install the latest version of EC2Config using PowerShell, run the following commands from a PowerShell window:

```
$Url = "https://s3.amazonaws.com/ec2-downloads-windows/EC2Config/EC2Install.zip"
$DownloadZipFile = "$env:USERPROFILE\Desktop\" + $(Split-Path -Path $Url -Leaf)
$ExtractPath = "$env:USERPROFILE\Desktop\"
Invoke-WebRequest -Uri $Url -OutFile $DownloadZipFile
$ExtractShell = New-Object -ComObject Shell.Application
$ExtractFiles = $ExtractShell.Namespace($DownloadZipFile).Items()
$ExtractShell.NameSpace($ExtractPath).CopyHere($ExtractFiles)
Start-Process $ExtractPath
Start-Process `
    -FilePath $env:USERPROFILE\Desktop\EC2Install.exe `
    -ArgumentList "/S"
```

> **Note**
>
> If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:
>
> ```
> [Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
> ```

Verify the installation by checking `C:\Program Files\Amazon\` for the `Ec2ConfigService` directory.

Configure .NET proxy settings for the EC2Config service

You can configure the EC2Config service to communicate through a proxy using one of the following methods: the AWS SDK for .NET, the `system.net` element, or Microsoft Group Policy and Internet Explorer. Using the AWS SDK for .NET is the preferred method because you can specify sign-in credentials.

Methods

- Configure proxy settings using the AWS SDK for .NET (Preferred)
- Configure proxy settings using the system.net element
- Configure proxy settings using Microsoft Group Policy and Microsoft Internet Explorer

Configure proxy settings using the AWS SDK for .NET (Preferred)

You can configure proxy settings for the EC2Config service by specifying the `proxy` element in the `Ec2Config.exe.config` file. For more information, see Configuration Files Reference for AWS SDK for .NET.

To specify the proxy element in Ec2Config.exe.config

1. Edit the `Ec2Config.exe.config` file on an instance where you want the EC2Config service to communicate through a proxy. By default, the file is located in the following directory: `%ProgramFiles%\Amazon\Ec2ConfigService`.
2. Add the following `aws` element to the `configSections`. Do not add this to any existing `sectionGroups`.

   For EC2Config versions 3.17 or earlier

   ```
   <configSections>
      <section name="aws" type="Amazon.AWSSection, AWSSDK"/>
   </configSections>
   ```

   For EC2Config versions 3.18 or later

   ```
   <configSections>
        <section name="aws" type="Amazon.AWSSection, AWSSDK.Core"/>
   </configSections>
   ```
3. Add the following `aws` element to the `Ec2Config.exe.config` file.

   ```
   <aws>
      <proxy
        host="string value"
   ```

```
        port="string value"
        username="string value"
        password="string value" />
</aws>
```

4. Save your changes.

Configure proxy settings using the system.net element

You can specify proxy settings in a `system.net` element in the `Ec2Config.exe.config` file. For more information, see [defaultProxy element (network settings)](#).

To specify the system.net element in Ec2Config.exe.config

1. Edit the `Ec2Config.exe.config` file on an instance where you want the EC2Config service to communicate through a proxy. By default, the file is located in the following directory: `%ProgramFiles%\Amazon\Ec2ConfigService`.
2. Add a `defaultProxy` entry to `system.net`. For more information, see [defaultProxy element (network settings)](#).

   For example, the following configuration routes all traffic to use the proxy that is currently configured for Internet Explorer, with the exception of the metadata and licensing traffic, which will bypass the proxy.

```
<defaultProxy>
    <proxy usesystemdefault="true" />
    <bypasslist>
        <add address="169.254.169.250" />
        <add address="169.254.169.251" />
        <add address="169.254.169.254" />
        <add address="[fd00:ec2::250]" />
        <add address="[fd00:ec2::254]" />
    </bypasslist>
</defaultProxy>
```

3. Save your changes.

Configure proxy settings using Microsoft Group Policy and Microsoft Internet Explorer

The EC2Config service runs under the Local System user account. You can specify instance-wide proxy settings for this account in Internet Explorer after you change Group Policy settings on the instance.

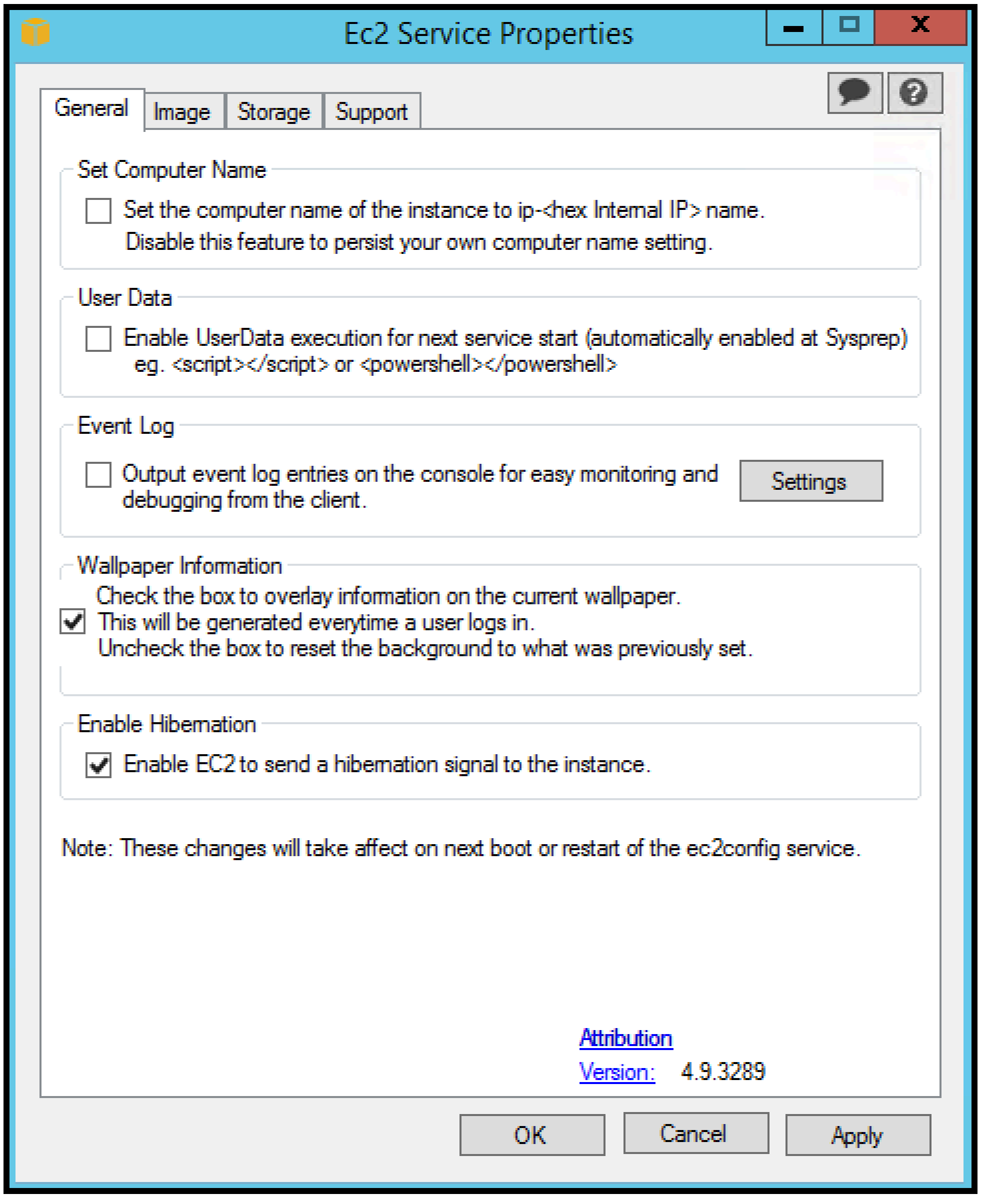
To configure proxy settings using Group Policy and Internet Explorer

1. On an instance where you want the EC2Config service to communicate through a proxy, open a Command prompt as an Administrator, type **`gpedit.msc`**, and press Enter.
2. In the Local Group Policy Editor, under **Local Computer Policy**, choose **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Internet Explorer**.
3. In the right-pane, choose **Make proxy settings per-machine (rather than per-user)** and then choose **Edit policy setting**.
4. Choose **Enabled**, and then choose **Apply**.
5. Open Internet Explorer, and then choose the **Tools** button.
6. Choose **Internet Option**, and then choose the **Connections** tab.
7. Choose **LAN settings**.
8. Under **Proxy server**, choose the **Use a proxy server for your LAN** option.
9. Specify address and port information and then choose **OK**.

Set EC2Config service properties from the system dialog on your EC2 Windows instance

The following procedure describes how to use the **EC2 Service Properties** system dialog to enable or disable settings.

1. Launch and connect to your Windows instance.
2. From the **Start** menu, click **All Programs**, and then click **EC2ConfigService Settings**.



3. On the **General** tab of the **EC2 Service Properties** system dialog, you can enable or disable the following settings.

   Set Computer Name

      If this setting is enabled (it is disabled by default), the host name is compared to the current internal IP address at each boot; if the host name and internal IP address do not match, the host name is reset to contain the internal IP address and then the system reboots to pick up the new host name. To set your own host name, or to prevent your existing host name from being modified, do not enable this setting.

User Data

User data execution enables you to specify scripts in the instance metadata. By default, these scripts are run during the initial launch. You can also configure them to run the next time you reboot or start the instance, or every time you reboot or start the instance.

If you have a large script, we recommend that you use user data to download the script, and then run it.

For more information, see User data execution.

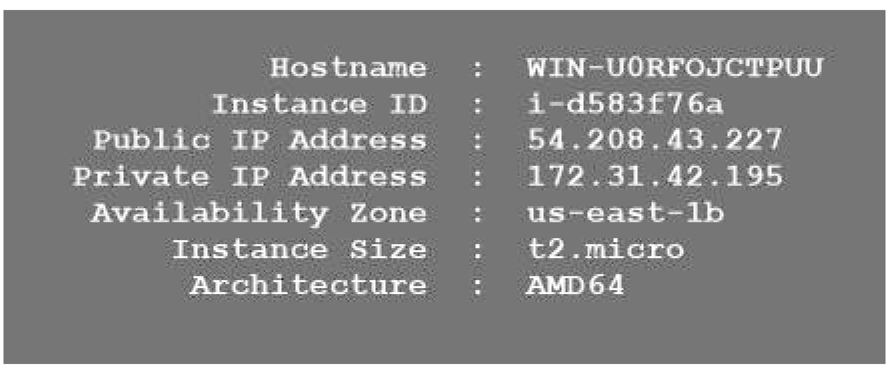
Event Log

Use this setting to display event log entries on the console during boot for easy monitoring and debugging.

Click **Settings** to specify filters for the log entries sent to the console. The default filter sends the three most recent error entries from the system event log to the console.

Wallpaper Information

Use this setting to display system information on the desktop background. The following is an example of the information displayed on the desktop background.

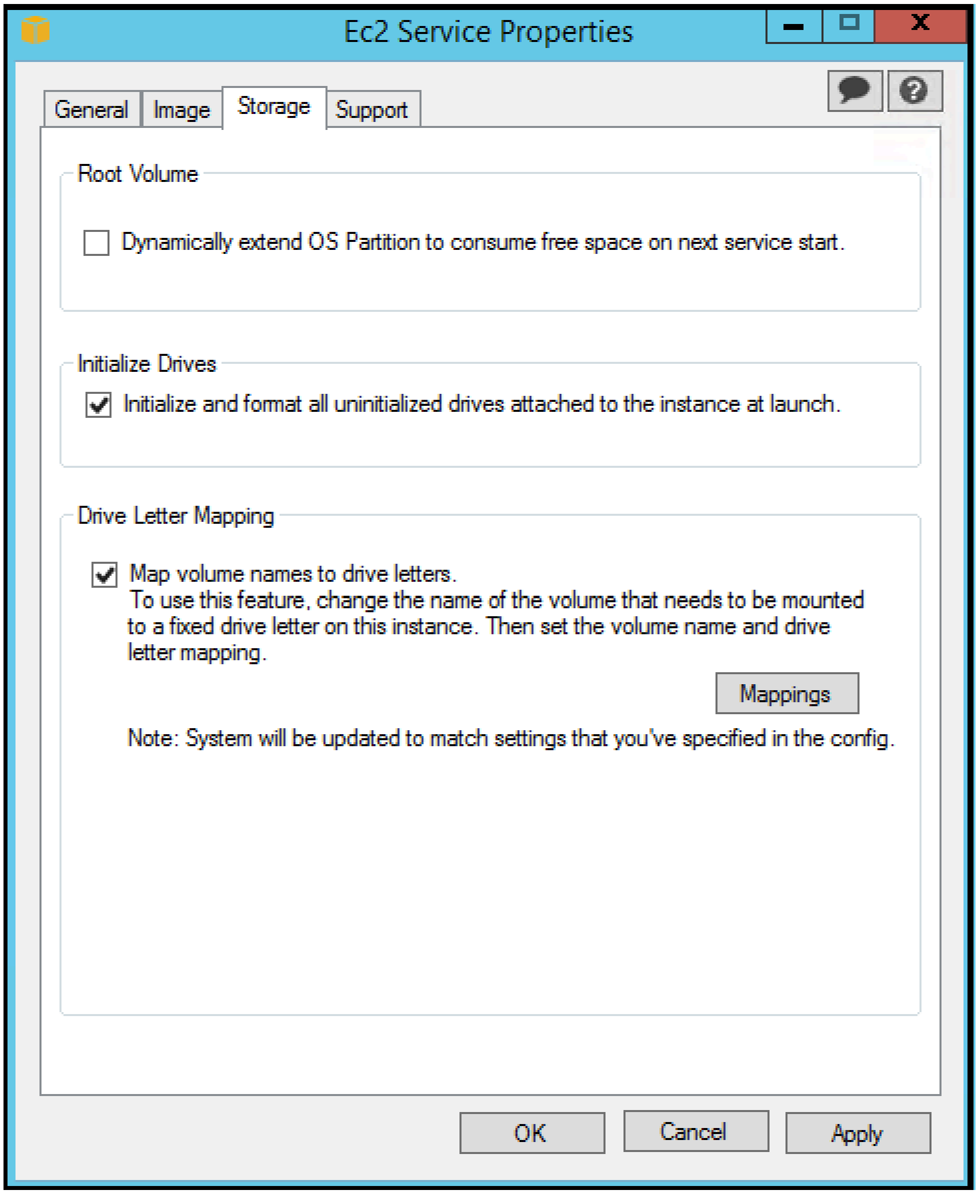


The information displayed on the desktop background is controlled by the settings file `EC2ConfigService\Settings\WallpaperSettings.xml`.

Enable Hibernation

Use this setting to allow EC2 to signal the operating system to perform hibernation.

4. Click the **Storage** tab. You can enable or disable the following settings.



Root Volume

This setting dynamically extends Disk 0/Volume 0 to include any unpartitioned space. This can be useful when the instance is booted from a root device volume that has a custom size.

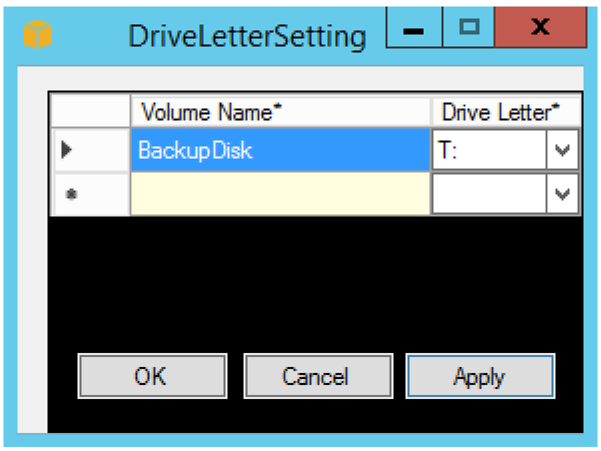
Initialize Drives

This setting formats and mounts all volumes attached to the instance during start.

Drive Letter Mapping

The system maps the volumes attached to an instance to drive letters. For Amazon EBS volumes, the default is to assign drive letters going from D: to Z:. For instance store volumes, the default depends on the driver. AWS PV drivers and Citrix PV drivers assign instance store volumes drive letters going from Z: to A:. Red Hat drivers assign instance store volumes drive letters going from D: to Z:.

To choose the drive letters for your volumes, click **Mappings**. In the **DriveLetterSetting** dialog box, specify the **Volume Name** and **Drive Letter** values for each volume, click **Apply**, and then click **OK**. We recommend that you select drive letters that avoid conflicts with drive letters that are likely to be in use, such as drive letters in the middle of the alphabet.



After you specify a drive letter mapping and attach a volume with same label as one of the volume names that you specified, EC2Config automatically assigns your specified drive letter to that volume. However, the drive letter mapping fails if the drive letter is already in use. Note that EC2Config doesn't change the drive letters of volumes that were already mounted when you specified the drive letter mapping.

5. To save your settings and continue working on them later, click **OK** to close the **EC2 Service Properties** system dialog. If you have finished customizing your instance and want to create an AMI from that instance, see [Create an Amazon EC2 AMI using Windows Sysprep](#).

Troubleshoot issues with the EC2Config launch agent

The following information can help you troubleshoot issues with the EC2Config service.

Update EC2Config on an unreachable instance

Use the following procedure to update the EC2Config service on a Windows Server instance that is inaccessible using Remote Desktop.

To update EC2Config on an Amazon EBS-backed Windows instance that you can't connect to

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Locate the affected instance. Select the instance and choose **Instance state**, and then choose **Stop instance**.

   > **Warning**
   >
   > When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. Choose **Launch instances** and create a temporary `t2.micro` instance in the same Availability Zone as the affected instance. Use a different AMI than the one that you used to launch the affected instance.

   > **Important**
   >
   > If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the EC2 console, choose **Volumes**.
6. Locate the root volume of the affected instance. Detach the volume and then attach the volume to the temporary instance that you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to make the volume available for use.
8. Download the latest version of the EC2Config service. Extract the files from the `.zip` file to the `Temp` directory on the drive you attached.
9. On the temporary instance, open the Run dialog box, type **`regedit`**, and press Enter.

10. Choose HKEY_LOCAL_MACHINE. From the **File** menu, choose **Load Hive**. Choose the drive and then navigate to and open the following file: Windows\System32\config\SOFTWARE. When prompted, specify a key name.
11. Select the key you just loaded and navigate to Microsoft\Windows\CurrentVersion. Choose the RunOnce key. If this key doesn't exist, choose CurrentVersion from the context (right-click) menu, choose **New** and then choose **Key**. Name the key RunOnce.
12. From the context (right-click) menu choose the RunOnce key, choose **New** and then choose **String Value**. Enter Ec2Install as the name and C:\Temp\Ec2Install.exe /quiet as the data.
13. Choose the HKEY_LOCAL_MACHINE*specified key name*\Microsoft\Windows NT \CurrentVersion\Winlogon key. From the context (right-click) menu choose **New**, and then choose **String Value**. Enter **AutoAdminLogon** as the name and **1** as the value data.
14. Choose the HKEY_LOCAL_MACHINE*specified key name*\Microsoft\Windows NT \CurrentVersion\Winlogon> key. From the context (right-click) menu choose **New**, and then choose **String Value**. Enter **DefaultUserName** as the name and **Administrator** as the value data.
15. Choose the HKEY_LOCAL_MACHINE*specified key name*\Microsoft\Windows NT \CurrentVersion\Winlogon key. From the context (right-click) menu choose **New**, and then choose **String Value**. Type **DefaultPassword** as the name and enter a password in the value data.
16. In the Registry Editor navigation pane, choose the temporary key that you created when you first opened Registry Editor.
17. From the **File** menu, choose **Unload Hive**.
18. In Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
19. In the Amazon EC2 console, detach the affected volume from the temporary instance and reattach it to your instance with the device name /dev/sda1. You must specify this device name to designate the volume as a root volume.
20. Stop and start Amazon EC2 instances the instance.
21. After the instance starts, check the system log and verify that you see the message Windows is ready to use.
22. Open Registry Editor and choose HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon. Delete the String Value keys you created earlier: **AutoAdminLogon**, **DefaultUserName**, and **DefaultPassword**.

23. Delete or stop the temporary instance you created in this procedure.

EC2Config version history

The following table describes the released versions of EC2Config. For information about the updates for SSM Agent, see Systems Manager SSM Agent Release Notes.

Important

EC2Config has reached the end of support. Only the latest version of the EC2Config agent is available for download. Prior versions are marked as private.

Version	Details	Release date
4.9.5777	• Fixed issue where RSS configuration was set incorrectly for some instance types. • New version of SSM Agent `3.3.484.0` .	17 June 2024
4.9.5554	• Limit domain name devolution based on registry entry: `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Dnscache\Parameters\DomainNameDevolutionLevel` . • New version of SSM Agent `3.2.1630.0` .	4 October 2023
4.9.5467	• Added retry capability for discovering console port. • New version of SSM Agent `3.1.2282.0` .	1 August 2023
4.9.5288	• Updated AWS Core SDK to version `3.7.103.23` . • Fixed issue where the `AWS-UpdateEC2Config` SSM document fails to update `EC2Config` on instances enabled with only IMDSv2.	8 March 2023

Version	Details	Release date
	• New version of SSM Agent `3.1.2144.0` .	
4.9.5231	• New version of SSM Agent 3.1.1927.0.	14 February 2023
4.9.5103	• Fixed issue where ephemeral volumes are incorrectly identified on r5d and i4i instance families. • New version of SSM Agent 3.1.1856.0.	5 December 2022
4.9.5064	• Updated to use PCI segment information to select the console port. • Signed PowerShell scripts and added copyright headers. • Fixed primary network adapter selection logic. • New version of SSM Agent 3.1.1732.0.	16 November 2022
4.9.4588	• Updated IMDS wait logic to make only IMDSv2 requests. • Added libec2launch.dll launch-agent shared library. • New version of SSM Agent 3.1.1188.0.	31 May 2022
4.9.4556	• Added wait logic to ensure full initialization of NIC before use. • New version of Log4Net 2.0.14.0 picks up security patch. • New version of SSM Agent 3.1.1045.0 picks up security patch.	1 March 2022
4.9.4536	• Fixed issue where userdata crashes when the Temp folder is missing. • New version of SSM Agent 3.1.804.0.	31 January 2022

Version	Details	Release date
4.9.4508	• Fixed issue to correctly compute diskpart script path. • New version of SSM Agent 3.1.338.0.	6 October 2021
4.9.4500	• Updated `Install-EgpuManagerConfig` with IMDS v2 support. • Updated web links to use https. • New version of SSM Agent 3.1.282.0	7 September 2021
4.9.4419	• Fixed IMDS version 1 fallback logic • Updated all usage of Windows temp directory to EC2Config temp directory • New version of SSM Agent 3.0.1124.0	2 June 2021
4.9.4381	• Added support for SSM document schema version 2.2 in EC2ConfigUpdater • Added AWS Nitro Enclaves package version to console log • New version of SSM Agent 3.0.529.0	4 May 2021
4.9.4326	• Removed all links in the settings UI • This is the last EC2Config version that supports Windows Server 2008.	3 March 2021

Version	Details	Release date
4.9.4279	• Fixed security issue related to `Ec2ConfigMonitor` scheduled task • Fixed drive letter mapping issue and incorrect ephemeral disk count • Added `OsCurrentBuild` and `OsReleaseId` to console output • New version of SSM Agent 2.3.871.0	11 December 2020
4.9.4222	• Fixed IMDS version 1 fallback logic • New version of SSM Agent 2.3.842.0	7 April 2020
4.9.4122	• Added support for IMDS v2 • New version of SSM Agent 2.3.814.0	4 March 2020
4.9.3865	• Fixed issue detecting COM port for Windows Server 2008 R2 on metal instances • New version of SSM Agent 2.3.722.0	31 October 2019
4.9.3519	• New version of SSM Agent 2.3.634.0	18 June 2019
4.9.3429	• New version of SSM Agent 2.3.542.0	25 April 2019
4.9.3289	• New version of SSM Agent 2.3.444.0	11 February 2019
4.9.3270	• Added plugin for setting the monitor to never turn off to fix ACPI issues • SQL Server edition and version written to console • New version of SSM Agent 2.3.415.0	22 January 2019
4.9.3230	• Drive Letter Mapping description updated to better align to functionality • New version of SSM Agent 2.3.372.0	10 January 2019

Version	Details	Release date
4.9.3160	• Increased wait time for primary NIC • Added default configuration for RSS and Receive Queue settings for ENA devices • Disabled hibernation during Sysprep • New version of SSM Agent 2.3.344.0 • Upgraded AWS SDK to 3.3.29.13	15 December 2018
4.9.3067	• Improvements made to instance hibernation • New version of SSM Agent 2.3.235.0	8 November 2018
4.9.3034	• Added route 169.254.169.253/32 for DNS server • New version of SSM Agent 2.3.193.0	24 October 2018
4.9.2986	• Added signing for all EC2Config related binaries • New version of SSM Agent 2.3.136.0	11 October 2018
4.9.2953	New version of SSM Agent (2.3.117.0)	2 October 2018
4.9.2926	New version of SSM Agent (2.3.68.0)	18 September 2018
4.9.2905	• New version of SSM Agent (2.3.50.0) • Added route 169.254.169.123/32 to AMZN time service • Added route 169.254.169.249/32 to GRID license service • Fixed an issue causing EBS NVMe volumes to be marked as ephemeral	17 September 2018
4.9.2854	New version of SSM Agent (2.3.13.0)	17 August 2018
4.9.2831	New version of SSM Agent (2.2.916.0)	7 August 2018

Version	Details	Release date
4.9.2818	New version of SSM Agent (2.2.902.0)	31 July 2018
4.9.2756	New version of SSM Agent (2.2.800.0)	27 June 2018
4.9.2688	New version of SSM Agent (2.2.607.0)	25 May 2018
4.9.2660	New version of SSM Agent (2.2.546.0)	11 May 2018
4.9.2644	New version of SSM Agent (2.2.493.0)	26 April 2018
4.9.2586	New version of SSM Agent (2.2.392.0)	28 March 2018
4.9.2565	• New version of SSM Agent (2.2.355.0) • Fixed an issue on M5 and C5 instances (unable to find PV drivers) • Add console logging for instance type, newest PV drivers, and NVMe drivers	13 March 2018
4.9.2549	New version of SSM Agent (2.2.325.0)	8 March 2018
4.9.2461	New version of SSM Agent (2.2.257.0)	15 February 2018
4.9.2439	New version of SSM Agent (2.2.191.0)	6 February 2018
4.9.2400	New version of SSM Agent (2.2.160.0)	16 January 2018

Version	Details	Release date
4.9.2327	• New version of SSM Agent (2.2.120.0) • Added COM port discovery on Amazon EC2 bare metal instances • Added Hyper-V status logging on Amazon EC2 bare metal instances	2 January 2018
4.9.2294	New version of SSM Agent (2.2.103.0)	4 December 2017
4.9.2262	New version of SSM Agent (2.2.93.0)	15 November 2017
4.9.2246	New version of SSM Agent (2.2.82.0)	11 November 2017
4.9.2218	New version of SSM Agent (2.2.64.0)	29 October 2017
4.9.2212	New version of SSM Agent (2.2.58.0)	23 October 2017
4.9.2203	New version of SSM Agent (2.2.45.0)	19 October 2017
4.9.2188	New version of SSM Agent (2.2.30.0)	10 October 2017
4.9.2180	• New version of SSM Agent (2.2.24.0) • Added the Elastic GPU plugin for GPU instances	5 October 2017
4.9.2143	New version of SSM Agent (2.2.16.0)	1 October 2017
4.9.2140	New version of SSM Agent (2.1.10.0)	
4.9.2130	New version of SSM Agent (2.1.4.0)	

Version	Details	Release date
4.9.2106	New version of SSM Agent (2.0.952.0)	
4.9.2061	New version of SSM Agent (2.0.922.0)	
4.9.2047	New version of SSM Agent (2.0.913.0)	
4.9.2031	New version of SSM Agent (2.0.902.0)	
4.9.2016	• New version of SSM Agent (2.0.879.0) • Fixed the CloudWatch Logs directory path for Windows Server 2003	
4.9.1981	• New version of SSM Agent (2.0.847.0) • Fixed the issue with `important.txt` being generated in EBS volumes.	
4.9.1964	New version of SSM Agent (2.0.842.0)	
4.9.1951	• New version of SSM Agent (2.0.834.0) • Fixed the issue with drive letter not being mapped from Z: for ephemeral drives.	
4.9.1925	• New version of SSM Agent (2.0.822.0) • [Bug] This version is not a valid update target from SSM Agent v4.9.1775.	
4.9.1900	New version of SSM Agent (2.0.805.0)	

Version	Details	Release date
4.9.1876	• New version of SSM Agent (2.0.796.0) • Fixed an issue with output/error redirection for admin us erdata execution.	
4.9.1863	• New version of SSM Agent (2.0.790.0) • Fixed problems with attaching multiple EBS volumes to an Amazon EC2 instance. • Improved CloudWatch to take a configuration path, keeping the backwards compatibility.	
4.9.1791	New version of SSM Agent (2.0.767.0)	
4.9.1775	New version of SSM Agent (2.0.761.0)	
4.9.1752	New version of SSM Agent (2.0.755.0)	
4.9.1711	New version of SSM Agent (2.0.730.0)	
4.8.1676	New version of SSM Agent (2.0.716.0)	
4.7.1631	New version of SSM Agent (2.0.682.0)	
4.6.1579	• New version of SSM Agent (2.0.672.0) • Fixed agent update issue with v4.3, v4.4, and v4.5	
4.5.1534	New version of SSM Agent (2.0.645.1)	
4.4.1503	New version of SSM Agent (2.0.633.0)	
4.3.1472	New version of SSM Agent (2.0.617.1)	
4.2.1442	New version of SSM Agent (2.0.599.0)	

Version	Details	Release date
4.1.1378	New version of SSM Agent (2.0.558.0)	
4.0.1343	• Run Command, State Manager, the CloudWatch agent, and domain join support have been moved into another agent called SSM Agent. SSM Agent will be installed as part of the EC2Config upgrade. For more information, see EC2Config and AWS Systems Manager. • If you have a proxy set up in EC2Config, you will need to update your proxy settings for SSM Agent before upgrading. If you do not update the proxy settings, you will not be able to use Run Command to manage your instances. To avoid this, see the following information before updating to the newer version: Installing and Configuring SSM Agent on Windows Instances in the *AWS Systems Manager User Guide*. • If you previously enabled CloudWatch integration on your instances by using a local configuration file (`AWS.EC2.Windows.CloudWatch.json`), you will need to configure the file to work with SSM Agent.	
3.19.1153	• Re-enabled activation plugin for instances with old AWS KMS configuration. Skip activation for BYOL users. • Change default TRIM behavior to be disabled during disk format operation and added FormatWithTRIM for overriding InitializeDisks plugin with userdata.	
3.18.1118	• Fix to reliably add routes to the primary network adapter. • Updates to improve support for AWS services.	

Version	Details	Release date
3.17.1032	• Fixes duplicate system logs appearing when filters set to same category. • Fixes to prevent from hanging during disk initialization.	
3.16.930	Added support to log "Window is Ready to use" event to Windows Event Log on start.	
3.15.880	Fix to allow uploading Systems Manager Run Command output to S3 bucket names with '.' character.	
3.14.786	Added support to override InitializeDisks plugin settings. For example: To speed up SSD disk initialize, you can temporarily disable TRIM by specifying this in userdata: <InitializeDrivesSettings><SettingsGroup>FormatWithout TRIM</SettingsGroup></InitializeDrivesSettings	
3.13.727	Systems Manager Run Command - Fixes to process commands reliably after windows reboot.	
3.12.649	• Fix to gracefully handle reboot when running commands/ scripts. • Fix to reliably cancel running commands. • Add support for (optionally) uploading MSI logs to S3 when installing applications via Systems Manager Run Command.	

Version	Details	Release date
3.11.521	• Fixes to enable RDP thumbprint generation for Windows Server 2003. • Fixes to include timezone and UTC offset in the EC2Config log lines. • Systems Manager support to run Run Command commands in parallel. • Roll back previous change to bring partitioned disks online.	
3.10.442	• Fix Systems Manager configuration failures when installing MSI applications. • Fix to reliably bring storage disks online. • Updates to improve support for AWS services.	
3.9.359	• Fix in post Sysprep script to leave the configuration of windo ws update in a default state. • Fix the password generation plugin to improve the reliability in getting GPO password policy settings. • Restrict EC2Config/SSM log folder permissions to the local Administrators group. • Updates to improve support for AWS services.	

Version	Details	Release date
3.8.294	• Fixed an issue with CloudWatch that prevented logs from getting uploaded when not on primary drive. • Improved the disk initialization process by adding retry logic. • Added improved error handling when the SetPassword plugin occasionally failed during AMI creation. • Updates to improve support for AWS services.	
3.7.308	• Improvements to the ec2config-cli utility for config testing and troubleshooting within instance. • Avoid adding static routes for AWS KMS and meta-data service on an OpenVPN adapter. • Fixed an issue where user-data execution was not honoring the "persist" tag. • Improved error handling when logging to the EC2 console is not available. • Updates to improve support for AWS services.	
3.6.269	• Windows activation reliability fix to first use link local address 169.254.0.250/251 for activating windows via AWS KMS • Improved proxy handling for Systems Manager, Windows Activation and Domain Join scenarios • Fixed an issue where duplicate lines of user accounts were added to the Sysprep answer file	

Version	Details	Release date
3.5.228	• Addressed a scenario where the CloudWatch plugin may consume excessive CPU and memory reading Windows Event Logs • Added a link to the CloudWatch configuration documentation in the EC2Config Settings UI	
3.4.212	• Fixes to EC2Config when used in combination with VM-Import. • Fixed service naming issue in the WiX installer.	
3.3.174	• Improved exception handling for Systems Manager and domain join failures. • Change to support Systems Manager SSM schema versioning. • Fixed formatting ephemeral disks on Win2K3. • Change to support configuring disk size greater than 2TB. • Reduced virtual memory usage by setting GC mode to default. • Support for downloading artifacts from UNC path in `aws:psModule` and `aws:application` plugin. • Improved logging for Windows activation plugin.	

Version	Details	Release date
3.2.97	• Performance improvements by delay loading Systems Manager SSM assemblies. • Improved exception handling for malformed sysprep 2008.xml. • Command line support for Systems Manager "Apply" configuration. • Change to support domain join when there is a pending computer rename. • Support for optional parameters in the `aws:applications` plugin. • Support for command array in `aws:psModule` plugin.	
3.0.54	• Enable support for Systems Manager. • Automatically domain join EC2 Windows instances to an AWS directory via Systems Manager. • Configure and upload CloudWatch logs/metrics via Systems Manager. • Install PowerShell modules via Systems Manager. • Install MSI applications via Systems Manager.	

Version	Details	Release date
2.4.233	• Added scheduled task to recover EC2Config from service startup failures. • Improvements to the Console log error messages. • Updates to improve support for AWS services.	
2.3.313	• Fixed an issue with large memory consumption in some cases when the CloudWatch Logs feature is enabled. • Fixed an upgrade bug so that ec2config versions lower than 2.1.19 can now upgrade to latest. • Updated COM port opening exception to be more friendly and useful in logs. • Ec2configServiceSettings UI disabled resizing and fixed the attribution and version display placement in UI.	
2.2.12	• Handled NullPointerException while querying a registry key for determining Windows Sysprep state which returned null occasionally. • Freed up unmanaged resources in finally block.	
2.2.11	Fixed a issue in CloudWatch plugin for handling empty log lines.	
2.2.10	• Removed configuring CloudWatch Logs settings through UI. • Enable users to define CloudWatch Logs settings in `%ProgramFiles%\Amazon\Ec2ConfigService\Settings\AWS.EC2.Windows.CloudWatch.json` file to allow future enhancements.	

Version	Details	Release date
2.2.9	Fixed unhandled exception and added logging.	
2.2.8	• Fixes Windows OS version check in EC2Config Installer to support Windows Server 2003 SP1 and later. • Fixes null value handling when reading registry keys related to updating Sysprep config files.	
2.2.7	• Added support for EC2Config to run during Sysprep execution for Windows 2008 and greater. • Improved exception handling and logging for better d iagnostics	
2.2.6	• Reduced the load on the instance and on CloudWatch Logs when uploading log events. • Addressed an upgrade issue where the CloudWatch Logs plug-in did not always stay enabled	
2.2.5	• Added support to upload logs to CloudWatch Log Service. • Fixed a race condition issue in Ec2OutputRDPCert plug-in • Changed EC2Config Service recovery option to Restart from TakeNoAction • Added more exception information when EC2Config Crashes	
2.2.4	• Fixed a typo in PostSysprep.cmd • Fixed the bug which EC2Config does not pin itself onto start menu for OS2012+	

Version	Details	Release date
2.2.3	• Added option to install EC2Config without service starting immediately upon install. To use, run 'Ec2Install.exe s tart=false' from the command prompt • Added parameter in wallpaper plugin to control adding/re moving wallpaper. To use, run 'Ec2WallpaperInfo.exe set' or 'Ec2WallpaperInfo.exe revert' from the command prompt • Added checking for RealTimeIsUniversal key, output i ncorrect settings of the RealTimeIsUniveral registry key to the Console • Removed EC2Config dependency on Windows temp folder • Removed UserData execution dependency on .Net 3.5	
2.2.2	• Added check to service stop behavior to check that res ources are being released • Fixed issue with long execution times when joined to domai n	
2.2.1	• Updated Installer to allow upgrades from older versions • Fixed Ec2WallpaperInfo bug in .Net4.5 only environment • Fixed intermittent driver detection bug • Added silent install option. Execute Ec2Install.exe with the '-q' option. eg: 'Ec2Install.exe -q'	
2.2.0	• Added support for .Net4 and .Net4.5 only environments • Updated Installer	

Version	Details	Release date
2.1.19	• Added ephemeral disk labeling support when using Intel ne twork driver (eg. C3 instance Type). For more information, see Enhanced networking on Amazon EC2 instances. • Added AMI Origin Version and AMI Origin Name support to the console output • Made changes to the Console Output for consistent format ting/parsing • Updated Help File	
2.1.18	• Added EC2Config WMI Object for Completion notification (-Namespace root\Amazon -Class EC2_ConfigService) • Improved Performance of Startup WMI query with large Event Logs; could cause prolonged high CPU during initial execution	
2.1.17	• Fixed UserData execution issue with Standard Output and Standard Error buffer filling • Fixed incorrect RDP thumbprint sometimes appearing in Console Output for >= w2k8 OS • Console Output now contains 'RDPCERTIFICATE-Su bjectName:' for Windows 2008+, which contains the machine name value • Added D:\ to Drive Letter Mapping dropdown • Moved Help button to top right and changed look/feel • Added Feedback survey link to top right	

Version	Details	Release date
2.1.16	• General Tab includes link to EC2Config download page for new Versions • Desktop Wallpaper overlay now stored in Users Local Ap pdata folder instead of My Documents to support MyDoc re direction • MSSQLServer name sync'd with system in Post-Sysprep script (2008+) • Reordered Application Folder (moved files to Plugin d irectory and removed duplicate files) • Changed System Log Output (Console): • *Moved to a date, name, value format for easier parsing (Please start migrating dependencies to new format) • *Added 'Ec2SetPassword' plugin status • *Added Sysprep Start and End times • Fixed issue of Ephemeral Disks not being labeled as 'Temp orary Storage' for non-english Operating Systems • Fixed EC2Config Uninstall failure after running Sysprep	

Version	Details	Release date
2.1.15	• Optimized requests to the Metadata service • Metadata now bypass Proxy Settings • Ephemeral Disks labeled as 'Temporary Storage' and Impo rtant.txt placed on volume when found (Citrix PV drivers only). For more information, see [Upgrade PV drivers on EC2 Windows instances](#). • Ephemeral Disks assigned drive letters from Z to A (Citrix PV drivers only) - assignment can be overwritten using Drive Le tter Mapping plugin with Volume labels 'Temporary Storage X' where x is a number 0-25) • UserData now runs immediately following 'Windows is Ready'	
2.1.14	Desktop wallpaper fixes	
2.1.13	• Desktop wallpaper will display hostname by default • Removed dependency on Windows Time service • Route added in cases where multiple IPs are assigned to a single interface	
2.1.11	• Changes made to Ec2Activation Plugin • -Verifies Activation status every 30 days • -If Grace Period has 90 days remaining (out of 180), re attempts activation	

Version	Details	Release date
2.1.10	• Desktop wallpaper overlay no longer persists with Sysprep or Shutdown without Sysprep • Userdata option to run on every service start with <persist>true</persist> • Changed location and name of /DisableWinUpdate.cmd to /Scripts/PostSysprep.cmd • Administrator password set to not expire by default in /Scripts/PostSysprep.cmd • Uninstall will remove EC2Config PostSysprep script from c:\windows\setup\script\CommandComplete.cmd • Add Route supports custom interface metrics	
2.1.9	UserData Execution no longer limited to 3851 Characters	

Version	Details	Release date
2.1.7	• OS Version and language identifier written to console • EC2Config version written to console • PV driver version written to console • Detection of Bug Check and output to the console on next boot when found • Option added to config.xml to persist Sysprep credentials • Add Route Retry logic in cases of ENI being unavailable at start • User Data execution PID written to console • Minimum generated password length retrieved from GPO • Set service start to retry 3 attempts • Added S3_DownloadFile.ps1 and S3_Upload file.ps1 examples to /Scripts folder	

Version	Details	Release date
2.1.6	• Version information added to General tab • Renamed the Bundle tab to Image • Simplified the process of specifying passwords and moved the password-related UI from the General tab to the Image tab • Renamed the Disk Settings tab to Storage • Added a Support tab with common tools for troubleshooting • Windows Server 2003 `sysprep.ini` set to extend OS partition by default • Added the private IP address to the wallpaper • Private IP address displayed on wallpaper • Added retry logic for Console output • Fixed Com port exception for metadata accessibility -- caused EC2Config to terminate before console output is displayed • Checks for activation status on every boot -- activates as necessary • Fixed issue of relative paths -- caused when manually executing wallpaper shortcut from startup folder; pointing to Administrator/logs • Fixed default background color for Windows Server 2003 user (other than Administrator)	

Version	Details	Release date
2.1.2	• Console timestamps in UTC (Zulu) • Removed appearance of hyperlink on Sysprep tab • Addition of feature to dynamically expand Root Volume on first boot for Windows 2008+ • When Set-Password is enabled, now automatically enables EC2Config to set the password • EC2Config checks activation status prior to running Sysprep (presents warning if not activated) • Windows Server 2003 `Sysprep.xml` now defaults to UTC timezone instead of Pacific • Randomized Activation Servers • Renamed Drive Mapping tab to Disk Settings • Moved Initialize Drives UI items from General to the Disk Settings tab • Help button now points to HTML help file • Updated HTML help file with changes • Updated 'Note' text for Drive Letter Mappings • Added InstallUpdates.ps1 to /Scripts folder for automating Patches and cleanup prior to Sysprep	

Version	Details	Release date
2.1.0	• Desktop wallpaper displays instance information by default upon first logon (not disconnect/reconnect) • PowerShell can be run from the userdata by surrounding the code with <powershell></powershell>	

Use EC2 Fast Launch for your Windows instances

When you configure a Windows Server AMI for EC2 Fast Launch, Amazon EC2 creates a set of pre-provisioned snapshots to use for faster launching, as follows.

1. Amazon EC2 launches a set of temporary t3 instances, based on your settings.
2. As each temporary instance completes the standard launch steps, Amazon EC2 creates a pre-provisioned snapshot of the instance. It stores the snapshot in your Amazon S3 bucket.
3. When the snapshot is ready, Amazon EC2 terminates the associated t3 instance to keep resource costs as low as possible.
4. The next time Amazon EC2 launches an instance from the EC2 Fast Launch enabled AMI, it uses one of the snapshots to significantly reduce the time it takes to launch.

Amazon EC2 automatically replenishes the snapshots you have on hand as it uses them to launch instances from the EC2 Fast Launch enabled AMI.

Any account that has access to an AMI with EC2 Fast Launch enabled can benefit from reduced launch times. When the AMI owner grants access for you to launch instances, the pre-provisioned snapshots come from the AMI owner’s account.

If an AMI that supports EC2 Fast Launch is shared with you, you can enable or disable faster launching on the shared AMI yourself. If you enable a shared AMI for EC2 Fast Launch, Amazon EC2 creates the pre-provisioned snapshots directly in your account. If you deplete the snapshots in your account, you can still use snapshots from the AMI owner's account.

> **Note**
>
> EC2 Fast Launch deletes pre-provisioned snapshots as soon as they're consumed by a launch to minimize storage costs and prevent reuse. However, if the deleted snapshots match a retention rule, Recycle Bin automatically retains them. We recommend that you review the scope of your Recycle Bin retention rules so that this doesn't happen. For more information, see Recycle Bin in the *Amazon EBS User Guide*.
>
> This feature is not the same as EBS fast snapshot restore. You must explicitly enable EBS fast snapshot restore on a per-snapshot basis, and it has its own associated costs.

The following video demonstrates how to configure your Windows AMI for faster launching with a quick overview of the related key terms and their definitions: Launching EC2 Windows instances up to 65% faster on AWS.

Resource costs

There is no service charge to configure Windows AMIs for EC2 Fast Launch. However, standard pricing applies for any underlying AWS resources that Amazon EC2 uses. To learn more about associated resource costs and how to manage them, see Manage costs for EC2 Fast Launch underlying resources.

Contents

Key terms

The EC2 Fast Launch feature uses the following key terms:

Pre-provisioned snapshot

A snapshot of an instance that was launched from a Windows AMI with EC2 Fast Launch enabled, and that has completed the following Windows launch steps, rebooting as required.

- Sysprep specialize
- Windows Out of Box Experience (OOBE)

When these steps are complete, EC2 Fast Launch stops the instance, and creates a snapshot that is later used for faster launching from the AMI, based on your configuration.

Launch frequency

Controls the number of pre-provisioned snapshots that Amazon EC2 can launch within the specified timeframe. When you enable EC2 Fast Launch for your AMI, Amazon EC2 creates the initial set of pre-provisioned snapshots in the background. For example, if the launch frequency is set to five launches per hour, which is the default, then EC2 Fast Launch creates an initial set of five pre-provisioned snapshots.

When Amazon EC2 launches an instance from an AMI with EC2 Fast Launch enabled, it uses one of the pre-provisioned snapshots to reduce the launch time. As snapshots are used, they are automatically replenished, up to the number specified by the launch frequency.

If you expect a spike in the number of instances that are launched from your AMI – during a special event, for example – you can increase the launch frequency in advance to cover the additional instances that you'll need. When your launch rate returns to normal, you can adjust the frequency back down.

When you experience a higher number of launches than anticipated, you might use up all the pre-provisioned snapshots that you have available. This doesn't cause any launches to fail. However, it can result in some instances going through the standard launch process, until snapshots can be replenished.

Target resource count

The number of pre-provisioned snapshots to keep on hand for an Amazon EC2 Windows Server AMI with EC2 Fast Launch enabled.

Max parallel launches

Controls how many instances Amazon EC2 can launch at the same time to create the pre-provisioned snapshots for EC2 Fast Launch. If your target resource count is higher than the maximum parallel launches that you've configured, then Amazon EC2 launches the number of instances specified by **Max parallel launches** to start creating the snapshots. As those instances complete the process, Amazon EC2 takes the snapshot and stops the instance. Then it continues to launch more instances until the total number of snapshots available has reached the target resource count. The value for **Max parallel launches** must be 6 or greater.

EC2 Fast Launch prerequisites for Windows

Before you set up EC2 Fast Launch, verify that you've met the following prerequisites that are required to create snapshots for the AMIs in your AWS account:

- If you provide a custom launch template when you configure EC2 Fast Launch, the service uses the VPC and other configuration settings that you've defined in the launch template. For more information, see Use a launch template when you set up EC2 Fast Launch.
- If you don't use a custom launch template to configure your settings, you must attach the EC2FastLaunchFullAccess policy to your current IAM role before you enable EC2 Fast Launch. Then the service automatically creates an AWS CloudFormation stack with the following resources in your AWS account.
  - A virtual private cloud (VPC)
  - Private subnets across multiple Availability Zones
  - A launch template configured with Instance Metadata Service Version 2 (IMDSv2)
  - A security group with no inbound or outbound rules
- Private EC2 Fast Launch AMIs must support user data script execution.
- To configure EC2 Fast Launch for an AMI, you must create the AMI using **Sysprep** with the shutdown option. The EC2 Fast Launch feature doesn't currently support AMIs that were created from a running instance.

  To create an AMI using **Sysprep**, see Create an Amazon EC2 AMI using Windows Sysprep.
- To enable EC2 Fast Launch for an encrypted AMI that uses a customer managed key for encryption, you must grant the service-linked role for EC2 Fast Launch permission to use the CMK. For more information, see the section called “Access to customer managed keys”.
- The default quota for **Max parallel launches** across all AMIs in an AWS account is 40 per Region. You can request a Service Quotas increase for your account, as follows.

  1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.
  2. In the navigation pane, choose AWS services.

3. In the search bar, enter **`EC2 Fast Launch`**, and select the result.
4. Select the link for **Parallel instance launches** to open the service quota detail page.
5. Choose **Request increase at account level**.

For more information, see Requesting a quota increase in the *Service Quotas User Guide*.

Configure EC2 Fast Launch settings for your Amazon EC2 Windows Server AMI

You can configure EC2 Fast Launch for Windows AMIs that you own, or AMIs that are shared with you from the AWS Management Console, API, SDKs, CloudFormation, or AWS Command Line Interface (AWS CLI). Before you configure EC2 Fast Launch, verify that your AMI meets all of the prerequisites that are required to create the pre-provisioned snapshots. For more information, see EC2 Fast Launch prerequisites for Windows.

When you enable faster launching for Windows instances, Amazon EC2 checks to make sure that you have the required permissions to launch instances from the specified AMI and Launch Template (if provided), including permissions for encrypted AMIs. To prevent errors during the instance launch process, the service validates your permissions before EC2 Fast Launch is enabled. If you don't have the required permissions, the service returns an error, and does not enable EC2 Fast Launch.

EC2 Fast Launch integrates with EC2 Image Builder to help you create custom images with EC2 Fast Launch enabled. For more information, see Create distribution settings for a Windows AMI with EC2 Fast Launch enabled (AWS CLI) in the *EC2 Image Builder User Guide*.

Enable EC2 Fast Launch

Before changing these settings, make sure that your AMI, and the Region that you run in meet all EC2 Fast Launch prerequisites for Windows.

Console

To enable EC2 Fast Launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under **Images**, choose **AMIs**.
3. Choose the AMI to update by selecting the check box next to the **Name**.

4. From the **Actions** menu above the list of AMIs, choose **Configure fast launch**. This opens the **Configure fast launch** page, where you configure the settings for EC2 Fast Launch.
5. To start using pre-provisioned snapshots to launch instances from your Windows AMI faster, select the **Enable fast launch for Windows** checkbox.
6. From the **Set anticipated launch frequency** drop-down list, choose a value to specify the number of snapshots that are created and maintained to cover your expected instance launch volume.
7. When you're done making changes, choose **Save changes**.

> **Note**
>
> If you need to use a launch template to specify a VPC, or to configure metadata settings for IMDSv2, see Use a launch template when you set up EC2 Fast Launch.

AWS CLI

To enable EC2 Fast Launch

Use the following enable-fast-launch command to enable EC2 Fast Launch for the specified AMI, launching six parallel instances for pre-provisioning.

```
aws ec2 enable-fast-launch \
    --image-id ami-0abcdef1234567890  \
    --max-parallel-launches 6 \
    --resource-type snapshot
```

The following is example output.

```
{
 "ImageId": "ami-0abcdef1234567890",
 "ResourceType": "snapshot",
 "SnapshotConfiguration": {
     "TargetResourceCount": 10
 },
 "LaunchTemplate": {},
 "MaxParallelLaunches": 6,
 "OwnerId": "0123456789123",
```

```
  "State": "enabling",
  "StateTransitionReason": "Client.UserInitiated",
  "StateTransitionTime": "2022-01-27T22:16:03.199000+00:00"
}
```

PowerShell

To enable EC2 Fast Launch

Use the Enable-EC2FastLaunch cmdlet to enable EC2 Fast Launch for the specified AMI, launching six parallel instances for pre-provisioning.

```
Enable-EC2FastLaunch `
 -ImageId ami-0abcdef1234567890 `
 -MaxParallelLaunch 6 `
 -Region us-west-2 `
 -ResourceType snapshot
```

The following is example output.

```
ImageId                 : ami-0abcdef1234567890
 LaunchTemplate          :
 MaxParallelLaunches     : 6
 OwnerId                 : 0123456789123
 ResourceType            : snapshot
 SnapshotConfiguration : Amazon.EC2.Model.FastLaunchSnapshotConfigurationResponse
 State                   : enabling
 StateTransitionReason : Client.UserInitiated
 StateTransitionTime     : 2/25/2022 12:24:11 PM
```

Disable EC2 Fast Launch

Before changing these settings, make sure that your AMI, and the Region that you run in meet all EC2 Fast Launch prerequisites for Windows.

Console

To disable EC2 Fast Launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under **Images**, choose **AMIs**.

3. Choose the AMI to update by selecting the check box next to the **Name**.
4. From the **Actions** menu above the list of AMIs, choose **Configure fast launch**. This opens the **Configure fast launch** page, where you configure the settings for EC2 Fast Launch.
5. Clear the **Enable fast launch for Windows** checkbox to disable EC2 Fast Launch and to remove pre-provisioned snapshots. This results in the AMI using the standard launch process for each instance, going forward.

   > **Note**
   >
   > When you disable Windows image optimization, any existing pre-provisioned snapshots are automatically deleted. This step must be completed before you can start using the feature again.

6. When you're done making changes, choose **Save changes**.

AWS CLI

To disable EC2 Fast Launch

Use the following disable-fast-launch command to disable EC2 Fast Launch on the specified AMI, and clean up existing pre-provisioned snapshots.

```
aws ec2 disable-fast-launch --image-id ami-01234567890abcedf
```

The following is example output.

```
{
    "ImageId": "ami-01234567890abcedf",
    "ResourceType": "snapshot",
    "SnapshotConfiguration": {},
    "LaunchTemplate": {
        "LaunchTemplateId": "lt-01234567890abcedf",
        "LaunchTemplateName": "EC2FastLaunchDefaultResourceCreation-
a8c6215d-94e6-441b-9272-dbd1f87b07e2",
        "Version": "1"
    },
    "MaxParallelLaunches": 6,
    "OwnerId": "0123456789123",
    "State": "disabling",
```

```
    "StateTransitionReason": "Client.UserInitiated",
    "StateTransitionTime": "2022-01-27T22:47:29.265000+00:00"
}
```

PowerShell

To disable EC2 Fast Launch

Use the Disable-EC2FastLaunch cmdlet to disable EC2 Fast Launch on the specified AMI, and clean up existing pre-provisioned snapshots.

```
Disable-EC2FastLaunch -ImageId ami-0abcdef1234567890
```

The following is example output.

```
ImageId                : ami-0abcdef1234567890
 LaunchTemplate         :
 Amazon.EC2.Model.FastLaunchLaunchTemplateSpecificationResponse
 MaxParallelLaunches    : 6
 OwnerId                : 0123456789123
 ResourceType           : snapshot
 SnapshotConfiguration :
 State                  : disabling
 StateTransitionReason : Client.UserInitiated
 StateTransitionTime    : 2/25/2022 1:10:08 PM
```

Use a launch template when you set up EC2 Fast Launch

With a launch template, you can configure a set of launch parameters that Amazon EC2 uses each time it launches an instance from that template. You can specify such things as an AMI to use for your base image, instance types, storage, network settings, and more.

Launch templates are optional, except for the following specific cases, where you must use a launch template for your Windows AMI when you configure faster launching:

- You must use a launch template to specify an existing VPC for your Windows AMI. This doesn't apply if you use the default VPC for your AWS account.
- If your account includes a policy that enforces IMDSv2 for Amazon EC2 instances, you must create a launch template that specifies the metadata configuration to enforce IMDSv2.

Use the launch template that includes your metadata configuration from the EC2 console, or when you run the enable-fast-launch command in the AWS CLI, or call the EnableFastLaunch API action.

Amazon EC2 EC2 Fast Launch doesn't support the following configuration when you use a launch template. If you use a launch template for EC2 Fast Launch, you must not specify any of the following:

- User data scripts
- Termination protection
- Disabled metadata
- Spot option
- Shutdown behavior that terminates the instance
- Resource tags for network interface, elastic graphic, or spot instance requests

Specify a VPC

Step 1: Create a launch template

Create a launch template that specifies the following details for your Windows instances:

- The VPC subnet.
- An instance type of `t3.xlarge`.

For more information, see Create an Amazon EC2 launch template.

Step 2: Specify the launch template for your EC2 Fast Launch AMI

Console

To specify the launch template for EC2 Fast Launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under **Images**, choose **AMIs**.
3. Choose the AMI to update by selecting the check box next to the **Name**.

4. From the **Actions** menu above the list of AMIs, choose **Configure fast launch**. This opens the **Configure fast launch** page, where you configure the settings for EC2 Fast Launch.

5. The **Launch template** box performs a filtered search that finds launch templates in your account in the current Region that match the text you've entered. Specify all or part of the launch template name or ID in the box to show a list of matching launch templates. For example, if you enter `fast` in the box, Amazon EC2 finds all of the launch templates in your account in the current Region that have "fast" in the name.

   To create a new launch template, you can choose **Create launch template**.

6. When you select a launch template, Amazon EC2 shows the default version for that template in the **Source template version** box. To specify a different version, highlight the default version to replace it, and enter the version number you want in the box.

7. When you're done making changes, choose **Save changes**.

AWS CLI

To specify the launch template for EC2 Fast Launch

Use the enable-fast-launch command with the `--launch-template` option, specifying either the name or the ID of the launch template.

```
--launch-template LaunchTemplateName=my-launch-template
```

PowerShell

To specify the launch template for EC2 Fast Launch

Use the Enable-EC2FastLaunch cmdlet with the `-LaunchTemplate_LaunchTemplateId` or `-LaunchTemplate_LaunchTemplateName` parameter.

```
-LaunchTemplate_LaunchTemplateName my-launch-template
```

For more information about EC2 launch templates, see Store instance launch parameters in Amazon EC2 launch templates.

View AMIs with EC2 Fast Launch enabled

You can use the describe-fast-launch-images command in the AWS CLI, or the Get-EC2FastLaunchImage Tools for PowerShell Cmdlet to get details for AMIs that have EC2 Fast Launch enabled.

Amazon EC2 provides the following details for each Windows AMI that is returned in the results:

- The image ID for an AMI with EC2 Fast Launch enabled.
- The resource type that is used for pre-provisioning the associated Windows AMI. Supported value: `snapshot`.
- The snapshot configuration, which is a group of parameters that configure pre-provisioning for the associated Windows AMI using snapshots.
- Launch template information, including the ID, name, and version of the launch template that the associated AMI uses when it launches Window instances from pre-provisioned snapshots.
- The maximum number of instances that can be launched at the same time for creating resources.
- The owner ID for the associated AMI. This is not populated for AMIs that are shared with you.
- The current state of EC2 Fast Launch for the associated AMI. Supported values include: `enabling | enabling-failed | enabled | enabled-failed | disabling | disabling-failed`.

> **Note**
>
> You can also see the current state displayed in the **Manage image optimization** page in the EC2 console, as **Image optimization state**.

- The reason that EC2 Fast Launch for the associated AMI changed to the current state.
- The time that EC2 Fast Launch for the associated AMI changed to the current state.

AWS CLI

To find AMIs configured for EC2 Fast Launch

Use the following describe-fast-launch-images command to describe the details for each of the AMIs in the account that are configured for EC2 Fast Launch. In this example, only one AMI in the account is configured for EC2 Fast Launch.

```
aws ec2 describe-fast-launch-images
```

The following is example output.

```
{
    "FastLaunchImages": [
        {
            "ImageId": "ami-01234567890abcedf",
            "ResourceType": "snapshot",
            "SnapshotConfiguration": {},
            "LaunchTemplate": {
                "LaunchTemplateId": "lt-01234567890abcedf",
                "LaunchTemplateName": "EC2FastLaunchDefaultResourceCreation-
a8c6215d-94e6-441b-9272-dbd1f87b07e2",
                "Version": "1"
            },
            "MaxParallelLaunches": 6,
            "OwnerId": "0123456789123",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated",
            "StateTransitionTime": "2022-01-27T22:20:06.552000+00:00"
        }
    ]
}
```

PowerShell

To find AMIs configured for EC2 Fast Launch

Use the following Get-EC2FastLaunchImage cmdlet to describe the details for each of the AMIs in the account that are configured for EC2 Fast Launch. In this example, only one AMI in the account is configured for EC2 Fast Launch.

```
Get-EC2FastLaunchImage -ImageId ami-0abcdef1234567890
```

The following is example output.

```
ImageId               : ami-0abcdef1234567890
LaunchTemplate        :
 Amazon.EC2.Model.FastLaunchLaunchTemplateSpecificationResponse
MaxParallelLaunches   : 6
```

```
OwnerId                 : 012345678912
ResourceType            : snapshot
SnapshotConfiguration   :
State                   : enabled
StateTransitionReason   : Client.UserInitiated
StateTransitionTime     : 2/25/2022 12:54:43 PM
```

Manage costs for EC2 Fast Launch underlying resources

There is no service charge to configure Windows AMIs for EC2 Fast Launch. However, when you enable EC2 Fast Launch for an Amazon EC2 Windows AMI, standard pricing applies for underlying AWS resources that Amazon EC2 uses to prepare and store the pre-provisioned snapshots. You can configure cost allocation tags to help you track and manage the costs that are associated with EC2 Fast Launch resources. For more information about how to configure cost allocation tags, see Track EC2 Fast Launch costs on your bill.

The following example demonstrates how the costs associated with EC2 Fast Launch snapshots costs might be allocated.

Example scenario: The AtoZ Example company has a Windows AMI with a 50 GiB EBS root volume. They enable EC2 Fast Launch for their AMI, and set the target resource count to five. Over the course of a month, using EC2 Fast Launch for their AMI costs them around $5.00, and the cost breakdown is as follows:

1. When AtoZ Example enables EC2 Fast Launch, Amazon EC2 launches five small instances. Each instance runs through the Sysprep and OOBE Windows launch steps, rebooting as required. This takes several minutes for each instance (time can vary, based on how busy that Region or Availability Zone (AZ) is, and on the size of the AMI).

   Costs

   - Instance runtime costs (or minimum runtime, if applicable): five instances
   - Volume costs: five EBS root volumes
2. When the pre-provisioning process completes, Amazon EC2 takes a snapshot of the instance, which it stores in Amazon S3. Snapshots are typically stored for 4–8 hours before they are consumed by a launch. In this case, the cost is roughly $0.02 to $0.05 per snapshot.

   Costs

   - Snapshot storage (Amazon S3): five snapshots

3. After Amazon EC2 takes the snapshot, it stops the instance. At that point, the instance is no longer accruing costs. However EBS volume costs continue to accrue.

   Costs

   - EBS volumes: costs continue for the associated EBS root volumes.

> **Note**
>
> The costs shown here are for demonstration purposes only. Your costs will vary, depending on your AMI configuration and pricing plan.

Track EC2 Fast Launch costs on your bill

Cost allocation tags can help you organize your AWS bill to reflect the costs associated with EC2 Fast Launch. You can use the following tag that Amazon EC2 adds to the resources it creates when it prepares and stores pre-provisioned snapshots for EC2 Fast Launch:

Tag key: `CreatedBy`, **Value:** `EC2 Fast Launch`

After you activate the tag in the Billing and Cost Management console, and set up your detailed billing report, the `user:CreatedBy` column appears on the report. The column includes values from all services. However, if you download the CSV file, you can import the data into a spreadsheet, and filter for `EC2 Fast Launch` in the value. This information also appears in the AWS Cost and Usage Report when the tag is activated.

Step 1: Activate user-defined cost allocation tags

To include resource tags in your cost reports, you must first activate the tag in the Billing and Cost Management console. For more information, see Activating User-Defined Cost Allocation Tags in the *AWS Billing and Cost Management User Guide*.

> **Note**
>
> Activation can take up to 24 hours.

Step 2: Set up a cost report

If you already have a cost report set up, a column for your tag appears the next time the report runs after activation is complete. To set up cost reports for the first time, choose one of the following.

- See [Setting up a monthly cost allocation report] in the *AWS Billing and Cost Management User Guide*.
- See [Creating Cost and Usage Reports] in the *AWS Cost and Usage Report User Guide*.

> **Note**
>
> It can take up to 24 hours for AWS to start delivering reports to your S3 bucket.

You can configure EC2 Fast Launch for Windows AMIs that you own, or AMIs that are shared with you from the Amazon EC2 console, API, SDKs, [CloudFormation], or **ec2** commands in the AWS CLI. The following sections cover configuration steps for the Amazon EC2 console and AWS CLI.

You can also create custom Windows AMIs that are configured for EC2 Fast Launch with EC2 Image Builder. For more information, see [Create distribution settings for a Windows AMI with EC2 Fast Launch enabled (AWS CLI)].

Monitor EC2 Fast Launch

This section covers how to monitor the Amazon EC2 Windows Server AMIs in your account that have EC2 Fast Launch enabled.

Monitor EC2 Fast Launch state changes with EventBridge

When the state changes for a Windows AMI with EC2 Fast Launch enabled, Amazon EC2 generates an `EC2 Fast Launch State-change Notification` event. Then Amazon EC2 sends the state change event to Amazon EventBridge (formerly known as Amazon CloudWatch Events).

You can create EventBridge rules that trigger one or more actions in response to the state change event. For example, you can create an EventBridge rule that detects when EC2 Fast Launch is enabled and performs the following actions:

- Sends a message to an Amazon SNS topic that notifies its subscribers.
- Invokes a Lambda function that performs some action.
- Sends the state change data to Amazon Data Firehose for analytics.

For more information, see [Creating Amazon EventBridge rules that react to events]() in the *Amazon EventBridge User Guide*.

State change events

The EC2 Fast Launch feature emits JSON formatted state change events on a best-effort basis. Amazon EC2 sends the events to EventBridge in near real time. This section describes the event fields and shows an example of the event format.

`EC2 Fast Launch State-change Notification`

imageId

Identifies the AMI with the EC2 Fast Launch state change.

resourceType

The type of resource to use for pre-provisioning. Supported value: `snapshot`. The default value is `snapshot`.

state

The current state of the EC2 Fast Launch feature for the specified AMI. Valid values include the following:

- **enabling** – You've enabled the EC2 Fast Launch feature for the AMI, and Amazon EC2 has started creating snapshots for the pre-provisioning process.
- **enabling-failed** – Something went wrong that caused the pre-provisioning process to fail the first time that you enabled the EC2 Fast Launch for an AMI. This can happen anytime during the pre-provisioning process.
- **enabled** – The EC2 Fast Launch feature is enabled. The state changes to `enabled` as soon as Amazon EC2 creates the first pre-provisioned snapshot for a newly enabled EC2 Fast Launch AMI. If the AMI was already enabled and goes through pre-provisioning again, the state change happens right away.
- **enabled-failed** – This state applies only if this is not the first time your EC2 Fast Launch AMI goes through the pre-provisioning process. This can happen if the EC2 Fast Launch feature is disabled and then later enabled again, or if there is a configuration change or other error after pre-provisioning is completed for the first time.
- **disabling** – The AMI owner has turned off the EC2 Fast Launch feature for the AMI, and Amazon EC2 has started the clean up process.

- **disabled** – The EC2 Fast Launch feature is disabled. The state changes to `disabled` as soon as Amazon EC2 completes the clean up process.
- **disabling-failed** – Something went wrong that caused the clean up process to fail. This means that some pre-provisioned snapshots may still remain in the account.

stateTransitionReason

The reason that the state changed for the EC2 Fast Launch AMI.

> **Note**
>
> All fields in this event message are required.

The following example shows a newly enabled EC2 Fast Launch AMI that has launched the first instance to start the pre-provisioning process. At this point, the state is `enabling`. After Amazon EC2 creates the first pre-provisioned snapshot, the state changes to `enabled`.

```
{
 "version": "0",
 "id": "01234567-0123-0123-0123-012345678901",
 "detail-type": "EC2 Fast Launch State-change Notification",
 "source": "aws.ec2",
 "account": "123456789012",
 "time": "2022-08-31T20:30:12Z",
 "region": "us-east-1",
 "resources": [
  "arn:aws:ec2:us-east-1:123456789012:image/ami-123456789012"
 ],
 "detail": {
  "imageId": "ami-123456789012",
  "resourceType": "snapshot",
  "state": "enabling",
  "stateTransitionReason": "Client.UserInitiated"
 }
}
```

Monitor EC2 Fast Launch metrics with CloudWatch

Amazon EC2 AMIs with EC2 Fast Launch enabled send metrics to Amazon CloudWatch. You can use the AWS Management Console, the AWS CLI, or an API to list the metrics that EC2 Fast Launch sends to CloudWatch. The `AWS/EC2` namespace includes the following EC2 Fast Launch metrics:

Metric	Description
NumberOfAvailableFastLaunchSnapshots	The number of pre-provisioned snapshots available per EC2 Fast Launch enabled AMI.
NumberOfInstancesFastLaunched	The number of instances per EC2 Fast Launch enabled AMI that were launched from pre-provisioned snapshots.
NumberOfInstancesNotFastLaunched	The number of instances per EC2 Fast Launch enabled AMI that resulted in a cold boot due to the lack of available pre-provisioned snapshots at launch time.
FastLaunchSnapshotUsedToRefillStartTime	The timestamp when Amazon EC2 launched a new image from a EC2 Fast Launch enabled AMI to create another snapshot after an existing snapshot was used.
FastLaunchSnapshotCreationTime	Measures the time it took for Amazon EC2 to launch an instance and create a snapshot for a EC2 Fast Launch enabled AMI.

Service-linked role for EC2 Fast Launch

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information about how Amazon EC2 uses IAM roles, including service-linked roles, see IAM roles for Amazon EC2.

Amazon EC2 uses the service-linked role named AWSServiceRoleForEC2FastLaunch to create and manage a set of pre-provisioned snapshots that reduce the time it takes to launch instances from your Windows AMI.

Permissions granted by AWSServiceRoleForEC2FastLaunch

The AWSServiceRoleForEC2FastLaunch service-linked role trusts the following service to assume the role:

- `ec2fastlaunch.amazonaws.com`

Amazon EC2 uses the EC2FastLaunchServiceRolePolicy managed policy to complete the following actions:

- **AWS CloudFormation** – Allow EC2 Fast Launch to get a description of associated CloudFormation stacks.
- **Amazon CloudWatch** – Post metric data associated with EC2 Fast Launch to the Amazon EC2 namespace.
- **Amazon EC2** – Access is granted for EC2 Fast Launch to perform the following actions:
  - Launch instances from an Amazon EC2 Windows Server AMI with EC2 Fast Launch enabled, in order to perform provisioning steps. Additionally specify resource pattern that allows `ec2:RunInstances` for an AMI that's associated with License Manager.
  - Stop and terminate an instance that was launched by EC2 Fast Launch after it creates the pre-provisioned snapshot.
  - Describe image and instance type resources used to launch instances from an Amazon EC2 Windows Server AMI with EC2 Fast Launch enabled and create snapshots from them.
  - Describe launch template resources and launch instances from a launch template.
  - Describe instances, instance attributes and instance status, volumes and volume attributes.
  - Describe network interfaces.
  - Delete resources that EC2 Fast Launch created, including snapshots, launch templates, volumes and network interfaces.
  - Tag resources that EC2 Fast Launch creates to launch and pre-provision, Windows instances, and create snapshots for the final launch process to consume.
- **Amazon EventBridge** – Includes access to create EventBridge event rules and retrieve details about or delete rules that it created. EC2 Fast Launch may also get a list of target services that

receive EC2 Fast Launch events that are forwarded based on event rules, and add target services to or remove them from event rules that it created.

- **IAM –** Allows EC2 Fast Launch to create the `EC2FastLaunchServiceRolePolicy` service-linked role, to get and use instance profiles whose name contains `ec2fastlaunch`, and to launch instances on your behalf using the instance profile from your launch template.
- **AWS KMS –** Includes access to create grants and list grants that were created by EC2 Fast Launch that can be retired. Also to describe or use keys for the purpose of encrypting or decrypting volumes attached to instances that EC2 Fast Launch creates, and to generate data keys that are not plaintext.

To view the permissions for this policy, see EC2FastLaunchServiceRolePolicy in the *AWS Managed Policy Reference*.

For more information about using managed policies for Amazon EC2, see AWS managed policies for Amazon EC2.

Create a service-linked role

You don't need to create this service-linked role manually. When you start using EC2 Fast Launch for your AMI, Amazon EC2 creates the service-linked role for you, if it doesn't already exist.

If the service-linked role is deleted from your account, you can enable EC2 Fast Launch for another Windows AMI to re-create the role in your account. Alternatively, you can disable EC2 Fast Launch for your current AMI, and then enable it again. However, disabling the feature results in your AMI using the standard launch process for all new instances while Amazon EC2 removes all of your pre-provisioned snapshots. After all of the pre-provisioned snapshots are gone, you can enable using EC2 Fast Launch for your AMI again.

Access to customer managed keys

To enable EC2 Fast Launch for an encrypted AMI that uses a customer managed key for encryption, you must grant the AWSServiceRoleForEC2FastLaunch role permission to use the CMK. To do this, call the create-grant command. For `--grantee-principal`, specify the ARN for the AWSServiceRoleForEC2FastLaunch role in your account. For `--operations`, specify `CreateGrant`.

```
aws kms create-grant \
    --key-id arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab \
```

```
    --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2FastLaunch \
    --operations CreateGrant
```

Edit a service-linked role

Amazon EC2 does not allow you to edit the AWSServiceRoleForEC2FastLaunch service-linked role. After you create a service-linked role, you can't change the name of the role, because various entities might reference the role. However, you can edit the description of the role by using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Delete a service-linked role

You can delete a service-linked role only after first deleting all of the related resources. This protects the Amazon EC2 resources that are associated with your Amazon EC2 Windows Server AMI with EC2 Fast Launch enabled, because you can't inadvertently remove permission to access the resources.

Use the IAM console, the AWS CLI, or the AWS API to delete the **AWSServiceRoleForEC2FastLaunch** service-linked role. For more information, see Delete a service-linked role in the *IAM User Guide*.

Supported Regions

Amazon EC2 supports the EC2 Fast Launch service-linked role in all of the Regions where the Amazon EC2 service is available.

Troubleshoot Windows EC2 Fast Launch

Troubleshooting scenarios

The following scenarios can help you diagnose and fix common issues that you might encounter when you try to enable EC2 Fast Launch.

Unable to stop instance for snapshot creation

Description

When you enable EC2 Fast Launch, the service launches a set of instances that are used to create the pre-provisioned snapshots. Each instance is given 30 minutes to complete the process. If any of the instances complete successfully, then the service sets the Fast Launch status for the AMI to `Enabled`. However, if an instance fails to complete the process in the allotted time, and none of the other instances have completed the process, the service terminates all of the instances and sets the Fast Launch status for the AMI to `enabling_failed` and the Fast Launch status reason to the following:

```
Unable to stop instance ID=i-1234567890abcdef0 for snapshot creation.
```

Cause

Most often, this is caused by trying to enable EC2 Fast Launch for a Windows AMI that was created from a running instance, or an AMI that doesn't meet all of the EC2 Fast Launch prerequisites.

Solution

Ensure that the AMI you use meets all EC2 Fast Launch prerequisites.

To configure EC2 Fast Launch for an AMI, you must create the AMI using **Sysprep** with the shutdown option. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.

You've reached your VPC limit

Description

If you don't use a launch template to specify an existing VPC, and don't have a default VPC defined for your account, the service automatically creates an AWS CloudFormation stack that includes a VPC and other resources, as described in EC2 Fast Launch prerequisites.

Cause

You've reached the maximum number of VPCs that are allowed in your AWS account for the Region, and you have not specified an existing VPC for EC2 Fast Launch to use. This causes the process to fail.

Solution

You can address this issue with either of the following options:

- You can request a quota increase
- You can provide a launch template that specifies an existing VPC

To request an increase to the number of VPCs that your account can define per Region, follow these steps:

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.

2. In the **Service Console Dashboard**, choose **Amazon Virtual Private Cloud (Amazon VPC)**. This opens the VPC service quotas.
3. Filter on `VPCs per Region` to go directly to the quota.
4. Select **VPCs per Region**, and choose **Request increase at account level**.

If you have an urgent quota request, or if your quota increase request is denied, contact Support for assistance. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.

Insufficient permissions to enable EC2 Fast Launch

Description

When you enable EC2 Fast Launch for the first time without specifying a Launch Template, EC2 Fast Launch creates a service-owned AWS CloudFormation stack with service default resources. However, the CloudFormation templates will fail to deploy if your IAM principal (role or user) lacks the necessary permissions.

The log message might look something like the following:

```
Can't enable EC2 Fast Launch. The IAM credentials that you are using do not have
 sufficient permissions. Attach EC2FastLaunchFullAccess in the IAM console.
```

Cause

Your IAM user or role lacks the necessary permissions to enable EC2 Fast Launch.

Solution

Verify that your IAM principal (user or role) that enables EC2 Fast Launch has the `EC2FastLaunchFullAccess` policy attached. This AWS managed policy grants full access to all EC2 Fast Launch resources. To view the permissions for this policy, see the EC2FastLaunchFullAccess policy in the *AWS Managed Policy Reference*.

Change the Windows Administrator password for your Amazon EC2 instance

If you launch your instance from an AWS Windows AMI, the launch agents that are pre-installed set the default password as follows:

- For Windows Server 2022 and later, EC2Launch v2 generates the default password.
- For Windows Server 2016 and 2019, the EC2Launch agent generates the default password.
- For Windows Server 2012 R2 and earlier, the EC2Config service generates the default password.

> **Note**
>
> For Windows Server 2016 and later AMIs, `Password never expires` is disabled for the local administrator. For AMI versions prior to Windows Server 2016, `Password never expires` is enabled for the local administrator.

Change the Administrator password after connecting

When you connect to an instance the first time, we recommend that you change the Administrator password from its default value. Use the following procedure to change the Administrator password for a Windows instance.

> **Important**
>
> Store the new password in a safe place. You won't be able to retrieve the new password using the Amazon EC2 console. The console can only retrieve the default password. If you attempt to connect to the instance using the default password after changing it, you'll get a "Your credentials did not work" error.

To change the local Administrator password

1. Connect to the instance and open a command prompt.
2. Run the following command. If your new password includes special characters, enclose the password in double quotes.

   ```
   net user Administrator "new_password"
   ```

3. Store the new password in a safe place.

Change a lost or expired password

If you lose your password or it expires, you can generate a new password. For password reset procedures, see Reset the Windows administrator password for an Amazon EC2 Windows instance.

Add optional Windows Server components to Amazon EC2 Windows instances

To access and install the optional components, you must find the correct EBS snapshot for your version of Windows Server, create a volume from the snapshot, and attach the volume to your instance.

Before you begin

Use the AWS Management Console or a command line tool to get the instance ID and Availability Zone of your instance. You must create your EBS volume in the same Availability Zone as your instance.

Use one of the following procedures to add Windows Server components to your instance.

Console

To add Windows components to your instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Snapshots**.
3. From the **Filter** bar, choose **Public snapshots**.
4. Add the **Owner Alias** filter and choose **amazon**.
5. Add the **Description** filter and enter **`Windows`**.
6. Press Enter
7. Select the snapshot that matches your system architecture and language preference. For example, select **Windows 2019 English Installation Media** if your instance is running Windows Server 2019.
8. Choose **Actions**, **Create volume from snapshot**.
9. For **Availability Zone**, select the Availability Zone that matches your Windows instance. Choose **Add tag** and enter **Name** for the tag key and a descriptive name for the tag value. Choose **Create volume**.

10. In the **Successfully created volume** message (green banner), choose the volume that you just created.
11. Choose **Actions**, **Attach volume**.
12. From **Instance**, select the instance ID.
13. For **Device name**, enter the name of the device for the attachment. If you need help with the device name, see [Device names for volumes on Amazon EC2 instances](#).
14. Choose **Attach volume**.
15. Connect to your instance and make the volume available. For more information, see [Make an Amazon EBS volume available for use](#) in the *Amazon EBS User Guide*.

> **Important**
>
> Do not initialize the volume.

16. Open **Control Panel**, **Programs and Features**. Choose **Turn Windows features on or off**. If you are prompted for installation media, specify the EBS volume with the installation media.
17. (Optional) When you are finished with the installation media, you can detach the volume. After you detach the volume, you can delete it.

AWS CLI

To add Windows components to your instance

1. Use the [describe-snapshots](#) command with the `owner-ids` parameter and `description` filter to get a list of the available installation media snapshots.

```
aws ec2 describe-snapshots \
    --owner-ids amazon \
    --filters Name=description,Values=Windows*
```

2. In the output, note the ID of the snapshot that matches your system architecture and language preference. For example:

```
{
    "Snapshots": [
    ...
        {
```

```
                "OwnerAlias": "amazon",
                "Description": "Windows 2019 English Installation Media",
                "Encrypted": false,
                "VolumeId": "vol-be5eafcb",
                "State": "completed",
                "VolumeSize": 6,
                "Progress": "100%",
                "StartTime": "2019-10-25T20:00:47.000Z",
                "SnapshotId": "snap-22da283e",
                "OwnerId": "123456789012"
            },
        ...
      ]
}
```

3. Use the [create-volume](#) command to create a volume from the snapshot. Specify the same Availability Zone as your instance.

```
aws ec2 create-volume \
    --snapshot-id snap-0abcdef1234567890 \
    --volume-type gp2 \
    --availability-zone us-east-1a
```

4. In the output, note the volume ID.

```
{
    "AvailabilityZone": "us-east-1a",
    "Encrypted": false,
    "VolumeType": "gp2",
    "VolumeId": "vol-01234567890abcdef",
    "State": "creating",
    "Iops": 100,
    "SnapshotId": "snap-0abcdef1234567890",
    "CreateTime": "2017-04-18T10:33:10.940Z",
    "Size": 6
}
```

5. Use the [attach-volume](#) command to attach the volume to your instance.

```
aws ec2 attach-volume \
    --volume-id vol-0c98b37f30bcbc290 \
    --instance-id i-01474ef662b89480 \
```

```
    --device xvdg
```

6. Connect to your instance and make the volume available. For more information, see Make an Amazon EBS volume available for use in the *Amazon EBS User Guide*.

> **Important**
>
> Do not initialize the volume.

7. Open **Control Panel**, **Programs and Features**. Choose **Turn Windows features on or off**. If you are prompted for installation media, specify the EBS volume with the installation media.

8. (Optional) When you are finished with the installation media, use the detach-volume command to detach the volume from your instance. After you detach the volume, you can use the delete-volume command to delete the volume.

PowerShell

To add Windows components to your instance

1. Use the Get-EC2Snapshot cmdlet with the `Owner` and `description` filters to get a list of the available installation media snapshots.

```
Get-EC2Snapshot `
    -Owner amazon `
    -Filter @{ Name="description"; Values="Windows*" }
```

2. In the output, note the ID of the snapshot that matches your system architecture and language preference. For example:

```
...
DataEncryptionKeyId :
Description         : Windows 2019 English Installation Media
Encrypted           : False
KmsKeyId            :
OwnerAlias          : amazon
OwnerId             : 123456789012
Progress            : 100%
SnapshotId          : snap-0abcdef1234567890
StartTime           : 10/25/2019 8:00:47 PM
```

```
State                : completed
StateMessage         :
Tags                 : {}
VolumeId             : vol-01234567890abcdef
VolumeSize           : 6
...
```

3. Use the [New-EC2Volume](#) cmdlet to create a volume from the snapshot. Specify the same Availability Zone as your instance.

```
New-EC2Volume `
    -AvailabilityZone us-east-1a `
    -VolumeType gp2 `
    -SnapshotId snap-0abcdef1234567890
```

4. In the output, note the volume ID.

```
Attachments      : {}
AvailabilityZone : us-east-1a
CreateTime       : 4/18/2017 10:50:25 AM
Encrypted        : False
Iops             : 100
KmsKeyId         :
Size             : 6
SnapshotId       : snap-0abcdef1234567890
State            : creating
Tags             : {}
VolumeId         : vol-01234567890abcdef
VolumeType       : gp2
```

5. Use the [Add-EC2Volume](#) cmdlet to attach the volume to your instance.

```
Add-EC2Volume `
    -InstanceId i-1234567890abcdef0 `
    -VolumeId vol-01234567890abcdef `
    -Device xvdh
```

6. Connect to your instance and make the volume available. For more information, see [Make an Amazon EBS volume available for use](#) in the *Amazon EBS User Guide*.

> **Important**
>
> Do not initialize the volume.

7. Open **Control Panel**, **Programs and Features**. Choose **Turn Windows features on or off**. If you are prompted for installation media, specify the EBS volume with the installation media.
8. (Optional) When you are finished with the installation media, use the Dismount-EC2Volume cmdlet to detach the volume from your instance. After you detach the volume, you can use the Remove-EC2Volume cmdlet to delete the volume.

Install Windows Subsystem for Linux on your EC2 Windows instance

The Windows Subsystem for Linux (WSL) is a feature of Microsoft Windows. By installing WSL on your EC2 Windows instance, you can run native Linux command line tools directly on your Windows instance.

There are two versions of Windows Subsystem for Linux (WSL): WSL 1 and WSL 2. For more information, see Windows Subsystem for Linux Documentation on the Microsoft website.

Requirements

- The operating system must be Windows Server 2019 or later.
- You must install WSL 1 on virtualized Windows instances (the instance size is not `.metal`).
- You can install either WSL 1 or WSL 2 on bare metal instances (the instance size is `.metal`). Bare metal instances provide the required support for nested virtualization.

Install WSL on your Windows instance

To install WSL 1

1. Install WSL. The process that you'll use depends on the version of Windows Server running on the instance.
   - **Windows Server 2022 and later** - Run the following standard installation command on your EC2 instance.

```
wsl --install --enable-wsl1 --no-launch
```

- **Windows Server 2019** - Enable WSL and then install WSL as described in [Install WSL on previous versions of Windows Server] on the Microsoft website.

2. Restart your EC2 instance.

```
shutdown -r -t 20
```

3. To configure WSL to use WSL 1, run the following command on your instance. This step is required for virtualized instances (the instance size is not `.metal`).

```
wsl --set-default-version 1
```

4. Install the default distribution.

```
wsl --install
```

To install WSL 2 (bare metal instances only)

Run the following standard installation command on your EC2 instance. By default, WSL 2 is installed.

```
wsl --install
```

EC2 Windows troubleshooting utilities

The `EC2WinUtil` driver provides the following types of troubleshooting support for your Windows instance.

Crash call stacks

`EC2WinUtil` collects basic crash information from your instance and writes it out to the serial console. The following list includes some of the key details that the utility writes to the console.

- Identification of the module that generated the fault.
- The Windows error code associated with the event.
- A stack trace of the most recent calls.

With these details, you can perform initial root cause analysis and determine if further analysis is needed. Output to the serial console also enables AWS to track crash trends for Amazon EC2 drivers, and diagnose large scale crash events.

> **Note**
>
> `EC2WinUtil` doesn't collect any customer data in its crash call stacks.

Hibernate/resume stability

`EC2WinUtil` tracks the virtualization settings of the instance across hibernate/resume cycles. This helps to improve the long-term stability of instances that have enabled hibernation.

For driver release notes, see EC2 Windows Utility Driver version history

EC2 Windows Utility Driver version history

The following table shows which `EC2WinUtil` drivers run on each version of Windows Server on Amazon EC2. Earlier versions of the operating system use the driver that's preinstalled on AWS Windows Server AMIs that the instance launched from. AMIs that are shared with you or that you subscribe to through AWS Marketplace don't have the driver preinstalled.

Windows Server version	EC2WinUtil driver version
Windows Server 2025	latest version
Windows Server 2022	latest version
Windows Server 2019	latest version
Windows Server 2016	latest version

> **Note**
>
> Prior to driver version 3.0.0, the `EC2WinUtil` driver was not available to download for manual installation. Earlier versions were only available as preinstalled drivers for AWS Windows AMIs.

The following table describes the released versions of the `EC2WinUtil` driver.

Package download link	Driver version	Details	Release date
3.0.0	3.0.0	Modernized the driver for Windows 10 and added support for installation as a primitive driver.	June 13, 2024
Download not available for this version.	2.0.0	Added support for output on MMIO serial ports for metal instance types. Also improved crash parsing and updated the output format.	August 23, 2018
Download not available for this version.	1.0.1	Changed the driver name to `EC2WinUtil` due to a namespace conflict with Amazon Inspector. Several bug fixes are included.	March 1, 2018
Download not available for this version.	1.0.0	Initial release. The driver was initially called `AwsAgent`.	November 28, 2017

Upgrade an EC2 Windows instance to a newer version of Windows Server

If it's time to upgrade the Windows Server operating system on your EC2 Windows instance from an earlier version, you can use one of the following methods.

In-place upgrade

An in-place upgrade operates on an existing instance. Only the operating system files are affected during this process, while your settings, server roles, and data are left intact.

Migration (also known as a side-by-side upgrade)

A migration involves capturing settings, configurations, and data, and porting these to a newer operating system on a fresh EC2 Windows instance. You can launch your instance from a public or private Windows AMI that you subscribe to from the AWS Marketplace, or an AMI that's shared with you. You can also create a custom AMI with EC2 Image Builder. See the Image Builder User Guide for more information.

> **Note**
>
> AWS provides a set of publicly available Amazon Machine Images (AMIs) for Windows Server versions that run on EC2 instances. These AMIs are updated on a monthly basis. For information about the latest Windows AMIs, see the AWS Windows AMI Reference.

Microsoft has traditionally recommended migrating to a newer version of Windows Server instead of upgrading in place. Migrating can result in fewer upgrade errors or issues, but can take longer than an in-place upgrade because of the need to provision a new instance, plan for and port applications, and adjust configuration settings on the new instance. An in-place upgrade can be faster, but software incompatibilities can produce errors.

Contents

Perform an in-place upgrade on your EC2 Windows instance

Before you perform an in-place upgrade, you must determine which network drivers the instance is running. PV network drivers enable you to access your instance using Remote Desktop. Instances use either AWS PV, Intel Network Adapter, or the Enhanced Networking drivers. For more information, see Paravirtual drivers for Windows instances.

Before you begin an in-place upgrade

Complete the following tasks and note the following important details before you begin your in-place upgrade.

- Read the Microsoft documentation to understand the upgrade requirements, known issues, and restrictions. Also review the official instructions for upgrading.
  - Upgrade Options for Windows Server 2012
  - Upgrade Options for Windows Server 2012 R2
  - Upgrade and conversion options for Windows Server 2016 and above
  - Windows Server Upgrades
- We recommend performing an operating system upgrade on instances with at least 2 vCPUs and 4GB of RAM. If needed, you can change the instance to a larger size of the same type (t2.small to t2.large, for example), perform the upgrade, and then resize it back to the original size. If you are required to retain the instance size, you can monitor the progress using the instance console screenshot. For more information, see Amazon EC2 instance type changes.
- Verify that the root volume on your Windows instance has enough free disk space. The Windows Setup process might not warn you of insufficient disk space. For information about how much disk space is required to upgrade a specific operating system, see the Microsoft documentation. If the volume does not have enough space, it can be expanded. For more information, see Amazon EBS Elastic Volumes in the *Amazon EBS User Guide*.
- Determine your upgrade path. You must upgrade the operating system to the same architecture. For example, you must upgrade a 32-bit system to a 32-bit system. Windows Server 2008 R2 and later are 64-bit only.
- Disable antivirus and anti-spyware software and firewalls. These types of software can conflict with the upgrade process. Re-enable antivirus and anti-spyware software and firewalls after the upgrade completes.
- Update to the latest drivers as described in Migrate an EC2 Windows instance to a Nitro-based instance type.
- The Upgrade Helper Service only supports instances running Citrix PV drivers. If the instance is running Red Hat drivers, you must manually upgrade those drivers first.

Upgrade an instance in-place with AWS PV, Intel Network Adapter, or the Enhanced Networking drivers

Use the following procedure to upgrade a Windows Server instance using the AWS PV, Intel Network Adapter, or the Enhanced Networking network drivers.

To perform the in-place upgrade

1. Create an AMI of the system you plan to upgrade for either backup or testing purposes. You can then perform the upgrade on the copy to simulate a test environment. If the upgrade completes, you can switch traffic to this instance with little downtime. If the upgrade fails, you can revert to the backup. For more information, see Create an Amazon EBS-backed AMI.
2. Ensure that your Windows Server instance is using the latest network drivers.
   a. To update your AWS PV driver, see Upgrade PV drivers on EC2 Windows instances.
   b. To update your ENA driver, see Install the ENA driver on EC2 Windows instances.
   c. To update your Intel drivers, see Enhanced networking with the Intel 82599 VF interface
3. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
4. In the navigation pane, choose **Instances**. Locate the instance. Make a note of the instance ID and Availability Zone for the instance. You need this information later in this procedure.
5. If you are upgrading from Windows Server 2012 or 2012 R2 to Windows Server 2016 or later, perform the following on your instance before you proceed.
   a. Uninstall the EC2Config service. For more information, see Windows Service administration for EC2Launch v2 and EC2Config agents.
   b. Install EC2Launch v1 or the EC2Launch v2 agent. For more information, see Use the EC2Launch v1 agent to perform tasks during EC2 Windows instance launch and Use the EC2Launch v2 agent to perform tasks during EC2 Windows instance launch.
   c. Install the AWS Systems Manager SSM Agent. For more information, see Manually install SSM Agent on Amazon EC2 for Windows Server in the *AWS Systems Manager User Guide*.
6. Create a new volume from a Windows Server installation media snapshot.
   a. In the left navigation pane, under **Elastic Block Store**, choose **Snapshots**.
   b. From the filter bar, choose **Public snapshots**.
   c. In the search bar, specify the following filters:
      - Choose **Owner Alias**, then **=**, then **amazon**.
      - Choose **Description**, and then start typing **`Windows`**. Select the Windows filter that matches the system architecture and language preference you're upgrading to. For example, choose **Windows 2019 English Installation Media** to upgrade to Windows Server 2019.

   d. Select the checkbox next to the snapshot that matches the system architecture and language preference you're upgrading to, and then choose **Actions**, **Create volume from snapshot**.

   e. On the **Create volume** page, choose the Availability Zone that matches your Windows instance, and then choose **Create volume**.

7. In the **Successfully created volume vol-*1234567890example*** banner at the top of the page, choose the ID of the volume that you just created.

8. Choose **Actions**, **Attach volume**.

9. On the **Attach volume** page, for **Instance**, select the instance ID of your Windows instance, and then choose **Attach volume**.

10. Make the new volume available for use by following the steps at [Make an Amazon EBS volume available for use](#).

> **Important**
>
> Do not initialize the disk because doing so will delete the existing data.

11. In Windows PowerShell, switch to the new volume drive. Begin the upgrade by opening the installation media volume you attached to the instance.

   a. If you are upgrading to Windows Server 2016 or later, run the following:

   ```
   .\setup.exe /auto upgrade /dynamicupdate disable
   ```

   > **Note**
   >
   > Running the setup.exe with the `/dynamicupdate` option set to disabled prevents Windows from installing updates during the Windows Server upgrade process, as installing updates during the upgrade can cause failures. You can install updates with Windows Update after the upgrade completes.

   If you are upgrading to an earlier version of Windows Server, run the following:

   ```
   Sources\setup.exe
   ```

b. For **Select the operating system you want to install**, select the full installation option for your Windows Server instance, and choose **Next**.

c. For **Which type of installation do you want?**, choose **Upgrade**.

d. Complete the wizard.

Windows Server Setup copies and processes files. After several minutes, your Remote Desktop session closes. The time it takes to upgrade depends on the number of applications and server roles running on your Windows Server instance. The upgrade process could take as little as 40 minutes or several hours. The instance may fail one or more status checks during the upgrade process. When the upgrade completes, all status checks pass. You can check the system log for console output or use Amazon CloudWatch metrics for disk and CPU activity to determine whether the upgrade is progressing.

> **Note**
>
> If upgrading to Windows Server 2019, after the upgrade is complete you can change the desktop background manually to remove the previous operating system name if desired.

If the instance has not passed all status checks after several hours, see Troubleshoot an operating system upgrade on an EC2 Windows instance.

Post upgrade tasks

1. Log in to the instance to initiate an upgrade for the .NET Framework and reboot the system when prompted.
2. If you haven't already done so in a prior step, install the EC2Launch v1 or EC2Launch v2 agent. For more information, see Use the EC2Launch v1 agent to perform tasks during EC2 Windows instance launch and Use the EC2Launch v2 agent to perform tasks during EC2 Windows instance launch.
3. If you upgraded to Windows Server 2012 R2, we recommend that you upgrade the PV drivers to AWS PV drivers. If you upgraded on a Nitro-based instance, we recommend that you install or upgrade the NVME and ENA drivers. For more information, see AWS NVMe drivers or Enable enhanced networking on Windows.
4. Re-enable antivirus and anti-spyware software and firewalls.

Use Automation runbooks to upgrade an EC2 Windows instance

You can perform an automated upgrade of your Windows and SQL Server instances on AWS with AWS Systems Manager Automation runbooks.

Contents

Related services

The following AWS services are used in the automated upgrade process:

- **AWS Systems Manager**. AWS Systems Manager is a powerful, unified interface for centrally managing your AWS resources. For more information, see the *AWS Systems Manager User Guide*.
- AWS Systems Manager Agent (SSM Agent) is Amazon software that can be installed and configured on an Amazon EC2 instance, an on-premises server, or a virtual machine (VM). SSM Agent makes it possible for Systems Manager to update, manage, and configure these resources. The agent processes requests from the Systems Manager service in the AWS Cloud, and then runs them as specified in the request. For more information, see Working with SSM Agent in the *AWS Systems Manager User Guide*.
- **AWS Systems Manager SSM runbooks**. An SSM runbook defines the actions that Systems Manager performs on your managed instances. SSM runbooks use JavaScript Object Notation (JSON) or YAML, and they include steps and parameters that you specify. This topic uses two Systems Manager SSM runbooks for automation. For more information, see AWS Systems Manager Automation runbook reference in the *AWS Systems Manager User Guide*.

Execution options

When you select **Automation** on the Systems Manager console, select **Execute**. After you select an Automation document, you are then prompted to choose an automation execution option. You choose from the following options. In the steps for the paths provided later in this topic, we use the **Simple execution** option.

Simple execution

Choose this option if you want to update a single instance but do not want to go through each automation step to audit the results. This option is explained in further detail in the upgrade steps that follow.

Rate control

Choose this option if you want to apply the upgrade to more than one instance. You define the following settings.

- **Parameter**

  This setting, which is also set in Multi-Account and Region settings, defines how your automation branches out.

- **Targets**

  Select the target to which you want to apply the automation. This setting is also set in Multi-Account and Region settings.

- **Parameter Values**

  Use the values defined in the automation document parameters.

- **Resource Group**

  In AWS, a resource is an entity you can work with. Examples include Amazon EC2 instances, AWS CloudFormation stacks, or Amazon S3 buckets. If you work with multiple resources, it might be useful to manage them as a group as opposed to moving from one AWS service to another for every task. In some cases, you may want to manage large numbers of related resources, such as EC2 instances that make up an application layer. In this case, you will likely need to perform bulk actions on these resources at one time.

- **Tags**

  Tags help you categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This categorization is useful when you have many resources of the same type. You can quickly identify a specific resource using the assigned tags.

- **Rate Control**

Rate Control is also set in Multi-Account and Region settings. When you set the rate control parameters, you define how many of your fleet to apply the automation to, either by target count or by percentage of the fleet.

Multi-Account and Region

In addition to the parameters specified under Rate Control that are also used in the Multi-Account and Region settings, there are two additional settings:

- **Accounts and organizational units (OUs)**

  Specify multiple accounts on which you want to run the automation.
- **AWS Regions**

  Specify multiple AWS Regions where you want to run the automation.

Manual execution

This option is similar to **Simple execution**, but allows you to step through each automation step and audit the results.

Upgrade Windows Server

The `AWSEC2-CloneInstanceAndUpgradeWindows` runbook creates an Amazon Machine Image (AMI) from a Windows Server instance in your account and upgrades this AMI to a supported version of your choice. This multi-step process can take up to two hours to complete.

There are two AMIs included in the automated upgrade process:

- **Current running instance**. The first AMI is the current running instance, which is not upgraded. This AMI is used to launch another instance to run the in-place upgrade. When the process is complete, this AMI is deleted from your account, unless you specifically request to keep the original instance. This setting is handled by the parameter `KeepPreUpgradeImageBackUp` (default value is `false`, which means the AMI is deleted by default).
- **Upgraded AMI**. This AMI is the outcome of the automation process.

The final result is one AMI, which is the upgraded instance of the AMI.

When the upgrade is complete, you can test your application functionality by launching the new AMI in your Amazon VPC. After testing, and before you perform another upgrade, schedule application downtime before completely switching to the upgraded instance.

Prerequisites

In order to automate your Windows Server upgrade with the AWS Systems Manager Automation document, you must perform the following tasks:

- Create an IAM role with the specified IAM policies to allow Systems Manager to perform automation tasks on your Amazon EC2 instances and verify that you meet the prerequisites to use Systems Manager. For more information, see Creating a role to delegate permissions to an AWS service in the *AWS Identity and Access Management User Guide*.
- Select the option for how you want the automation to be run. The options for execution are **Simple execution**, **Rate control**, **Multi-account and Region**, and **Manual execution**. For more information about these options, see Execution options.
- Verify that SSM Agent is installed on your instance. For more information see Installing and configuring SSM Agent on Amazon EC2 instances for Windows Server.
- Windows PowerShell 3.0 or later must be installed on your instance.
- For instances that are joined to a Microsoft Active Directory domain, we recommend specifying a `SubnetId` that does not have connectivity to your domain controllers to help avoid hostname conflicts.
- The instance subnet must have outbound connectivity to the internet, which provides access to AWS services such as Amazon S3 and access to download patches from Microsoft. This requirement is met if either the subnet is a public subnet and the instance has a public IP address, or if the subnet is a private subnet with a route that sends internet traffic to a public NAT device.
- This Automation works with instances running Windows Server 2008 R2, Windows Server 2012 R2, Windows Server 2016, and Windows Server 2019.
- Verify that the instance has 20 GB of free disk space in the boot disk.
- If the instance does not use a Windows license provided by AWS, then specify an Amazon EBS snapshot ID that includes Windows Server 2012 R2 installation media. To do this:
  1. Verify that the Amazon EC2 instance is running Windows Server 2012 or later.
  2. Create a 6 GB Amazon EBS volume in the same Availability Zone where the instance is running. Attach the volume to the instance. Mount it, for example, as drive D.

3. Right-click the ISO and mount it to an instance as, for example, drive E.
4. Copy the content of the ISO from drive E:\ to drive D:\
5. Create an Amazon EBS snapshot of the 6 GB volume created in step 2 above.

Windows Server upgrade limitations

This automation doesn't support upgrading Windows domain controllers, clusters, or Windows desktop operating systems. In addition, this automation doesn't support Amazon EC2 instances for Windows Server with the following roles installed:

- Remote Desktop Session Host (RDSH)
- Remote Desktop Connection Broker (RDCB)
- Remote Desktop Virtualization Host (RDVH)
- Remote Desktop Web Access (RDWA)

Steps to perform an automated upgrade of Windows Server

Follow these steps to upgrade your Windows Server instance using the AWSEC2-CloneInstanceAndUpgradeWindows automation runbook.

1. Open Systems Manager from the **AWS Management Console**.
2. From the left navigation pane, under **Change Management**, choose **Automation**.
3. Choose **Execute automation**.
4. Search for the automation document called `AWSEC2-CloneInstanceAndUpgradeWindows`.
5. When the document name appears, select it. When you select it, the document details appear.
6. Choose **Execute automation** to input the parameters for this document. Leave **Simple execution** selected at the top of the page.
7. Enter the requested parameters based on the following guidance.

   - `InstanceID`

     Type: String

     (Required) The instance running Windows Server 2008 R2, 2012 R2, 2016, or 2019 with the SSM agent installed.

- `InstanceProfile`.

  Type: String

  (Required) The IAM instance profile. This is the IAM role used to perform the Systems Manager automation against the Amazon EC2 instance and AWS AMIs. For more information, see Configure EC2 instance permissions in the *AWS Systems Manager User Guide*.

- `TargetWindowsVersion`

  Type: String

  (Required) Select the target Windows version.

- `SubnetId`

  Type: String

  (Required) This is the subnet for the upgrade process and where your source EC2 instance resides. Verify that the subnet has outbound connectivity to AWS services, including Amazon S3, and also to Microsoft (in order to download patches).

- `KeepPreUpgradedBackUp`

  Type: String

  (Optional) If this parameter is set to `true`, the automation retains the image created from the instance. The default setting is `false`.

- `RebootInstanceBeforeTakingImage`

  Type: String

  (Optional) The default is `false` (no reboot). If this parameter is set to `true`, Systems Manager reboots the instance before creating an AMI for the upgrade.

8. After you have entered the parameters, choose **Execute**. When the automation begins, you can monitor the execution progress.

9. When the automation completes, you will see the AMI ID. You can launch the AMI to verify that the Windows OS is upgraded.

> **Note**
>
> It is not necessary for the automation to run all of the steps. The steps are conditional based on the behavior of the automation and instance. Systems Manager might skip some steps that are not required.
> Additionally, some steps may time out. Systems Manager attempts to upgrade and install all of the latest patches. Sometimes, however, patches time out based on a definable timeout setting for the given step. When this happens, the Systems Manager automation continues to the next step to ensure that the internal OS is upgraded to the target Windows Server version.

10. After the automation completes, you can launch an Amazon EC2 instance using the AMI ID to review your upgrade. For more information about how to create an Amazon EC2 instance from an AWS AMI, see How do I launch an EC2 instance from a custom AMI?

Upgrade SQL Server

The AWSEC2-CloneInstanceAndUpgradeSQLServer script creates an AMI from an Amazon EC2 instance running SQL Server in your account, and then upgrades the AMI to a later version of SQL Server. This multi-step process can take up to two hours to complete.

In this workflow, the automation creates an AMI from the instance and then launches the new AMI in the subnet you provide. The automation then performs an in-place upgrade of SQL Server. After the upgrade is complete, the automation creates a new AMI before terminating the upgraded instance.

There are two AMIs included in the automated upgrade process:

- **Current running instance**. The first AMI is the current running instance, which is not upgraded. This AMI is used to launch another instance to run the in-place upgrade. When the process is complete, this AMI is deleted from your account, unless you specifically request to keep the original instance. This setting is handled by the parameter `KeepPreUpgradeImageBackUp` (default value is `false`, which means the AMI is deleted by default).
- **Upgraded AMI**. This AMI is the outcome of the automation process.

The final result is one AMI, which is the upgraded instance of the AMI.

When the upgrade is complete, you can test your application functionality by launching the new AMI in your Amazon VPC. After testing, and before you perform another upgrade, schedule application downtime before completely switching to the upgraded instance.

Prerequisites

In order to automate your SQL Server upgrade with the AWS Systems Manager Automation document, you must perform the following tasks:

- Create an IAM role with the specified IAM policies to allow Systems Manager to perform automation tasks on your Amazon EC2 instances and verify that you meet the prerequisites to use Systems Manager. For more information, see Creating a role to delegate permissions to an AWS service in the *AWS Identity and Access Management User Guide*.
- Select the option for how you want the automation to be run. The options for execution are **Simple execution**, **Rate control**, **Multi-account and Region**, and **Manual execution**. For more information about these options, see Execution options.
- The Amazon EC2 instance must use Windows Server 2008 R2 or later and SQL Server 2008 or later.
- Verify that SSM Agent is installed on your instance. For more information, see Working with SSM Agent on Amazon EC2 instances for Windows Server.
- Verify that the instance has enough free disk space:
  - If you are upgrading from Windows Server 2008 R2 to 2012 R2, or from Windows Server 2012 R2 to a later operating system, verify that you have 20 GB of free disk space in the instance boot disk.
  - If you are upgrading from Windows Server 2008 R2 to 2016 or later, verify that the instance has 40 GB of free disk space in the instance boot disk.
- For instances that use a Bring Your Own License (BYOL) SQL Server version, the following additional prerequisites apply:
  - Provide an Amazon EBS snapshot ID that includes the target SQL Server installation media. To do this:
    1. Verify that the Amazon EC2 instance is running Windows Server 2008 R2 or later.
    2. Create a 6 GB Amazon EBS volume in the same Availability Zone where the instance is running. Attach the volume to the instance. Mount it, for example, as drive D.
    3. Right-click the ISO and mount it to an instance as, for example, drive E.
    4. Copy the content of the ISO from drive E:\ to drive D:\

5. Create an Amazon EBS snapshot of the 6 GB volume created in step 2.

SQL Server automated upgrade limitations

The following limitations apply when using the AWSEC2-CloneInstanceAndUpgradeSQLServer runbook to perform an automated upgrade:

- The upgrade can be performed on only a SQL Server using Windows authentication.
- Verify that no security patch updates are pending on the instances. Open **Control Panel**, then choose **Check for updates**.
- SQL Server deployments in HA and mirroring mode are not supported.

Steps to perform an automated upgrade of SQL Server

Follow these steps to upgrade your SQL Server using the AWSEC2-CloneInstanceAndUpgradeSQLServer automation runbook.

1. If you haven't already, download the SQL Server 2016 .iso file and mount it to the source server.
2. After the .iso file is mounted, copy all of the component files and place them on any volume of your choice.
3. Take an Amazon EBS snapshot of the volume and copy the snapshot ID onto a clipboard for later use. For more information, see Create Amazon EBS snapshots in the **Amazon EBS User Guide**.
4. Attach the instance profile to the Amazon EC2 source instance. This allows Systems Manager to communicate with the EC2 instance and run commands on it after it is added to the AWS Systems Manager service. For this example, we named the role `SSM-EC2-Profile-Role` with the `AmazonSSMManagedInstanceCore` policy attached to the role.
5. In the AWS Systems Manager console, in the left navigation pane, choose **Managed Instances**. Verify that your EC2 instance is in the list of managed instance. If you don't see your instance after a few minutes, see Where Are My Instances? in the *AWS Systems Manager User Guide*.
6. In the left navigation pane, under **Change Management** choose **Automation**.
7. Choose **Execute automation**.
8. Search for the automation document called `AWSEC2-CloneInstanceAndUpgradeSQLServer`.

9. Choose the `AWSEC2-CloneInstanceAndUpgradeSQLServer` SSM document, and then choose **Next**.
10. Ensure that the **Simple execution** option is selected.
11. Enter the requested parameters based on the following guidance.

    - `InstanceId`

      Type: String

      (Required) The instance running SQL Server 2008 R2 (or later).
    - `IamInstanceProfile`

      Type: String

      (Required) The IAM instance profile.
    - `SQLServerSnapshotId`

      Type: String

      (Required) The Snapshot ID for the target SQL Server installation media. This parameter is not required for SQL Server license-included instances.
    - `SubnetId`

      Type: String

      (Required) This is the subnet for the upgrade process and where your source EC2 instance resides. Verify that the subnet has outbound connectivity to AWS services, including Amazon S3, and also to Microsoft (in order to download patches).
    - `KeepPreUpgradedBackUp`

      Type: String

      (Optional) If this parameter is set to `true`, the automation retains the image created from the instance. The default setting is `false`.
    - `RebootInstanceBeforeTakingImage`

      Type: String

(Optional) The default is `false` (no reboot). If this parameter is set to `true`, Systems Manager reboots the instance before creating an AMI for the upgrade.

- `TargetSQLVersion`

  Type: String

  (Optional) The target SQL Server version. The default is `2016`.

12. After you have entered the parameters, choose **Execute**. When the automation begins, you can monitor the execution progress.
13. When **Execution status** shows **Success**, expand **Outputs** to view the AMI information. You can use the AMI ID to launch your SQL Server instance for the VPC of your choice.
14. Open the Amazon EC2 console. In the left navigation pane, choose **AMIs**. You should see the new AMI.
15. To verify that the new SQL Server version has been successfully installed, choose the new AMI and choose **Launch**.
16. Choose the type of instance that you want for the AMI, the VPC and subnet that you want to deploy to, and the storage that you want to use. Because you're launching the new instance from an AMI, the volumes are presented to you as an option to include within the new EC2 instance you are launching. You can remove any of these volumes, or you can add volumes.
17. Add a tag to help you identify your instance.
18. Add the security group or groups to the instance.
19. Choose **Launch Instance**.
20. Choose the tag name for the instance and select **Connect** under the **Actions** dropdown.
21. Verify that the new SQL Server version is the database engine on the new instance.

Migrate an EC2 Windows instance to a Nitro-based instance type

The AWS Windows AMIs are configured with the default settings used by the Microsoft installation media, with some customizations. The customizations include drivers and configurations that support Nitro-based instances, such as M5 and C5.

When migrating from Xen-based instances to Nitro-based instances, including bare metal instances, we recommend that you follow the steps in this topic in the following cases:

- If you are launching instances from custom Windows AMIs

- If you are launching instances from Windows AMIs provided by Amazon that were created before August 2018

Alternatively, you can use the `AWSSupport-UpgradeWindowsAWSDrivers` automation document to automate the procedures described in Part 1, Part 2, and Part 3. If you choose to use the automated procedure, see (Alternative) Upgrade the AWS PV, ENA, and NVMe drivers using AWS Systems Manager, and then continue with Part 4 and Part 5.

For more information, see Amazon EC2 Update — Additional Instance Types, Nitro System, and CPU Options.

Note

The following migration procedures can be performed on Windows Server version 2016 and later. Earlier operating system versions that have reached end of life are not tested, and might not be compatible with the latest instance types.
To migrate Linux instances, see the section called "Instance type changes".

Contents

Before you begin

This procedure assumes that you have a Xen-based instance, such as an M4 or C4, and you are migrating to a Nitro-based instance.

You must use PowerShell version 3.0 or later to successfully perform the upgrade.

> **Note**
>
> When migrating, the static IP or custom DNS network settings on the existing network interface card may be lost as the instance will default to a new Enhanced Networking Adapter device.

Before following the steps in this procedure, we recommend that you create a backup of the instance. From the EC2 console, choose the instance that requires the migration, open the context (right-click) menu, and choose **Instance State**, **Stop**.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To preserve data on instance store volumes, ensure that you back up the data to persistent storage.

Open the context (right-click) menu for the instance in the EC2 console, choose **Image**, and then choose **Create Image**.

> **Note**
>
> Parts 4 and 5 of these instructions can be completed after you migrate or change the instance type. However, we recommend that you complete them before you migrate, especially if you are migrating to a bare metal instance type.

Part 1: Install and upgrade AWS PV drivers

Though AWS PV drivers are not used in the Nitro system, you should still upgrade them if you are on previous versions of either Citrix PV or AWS PV. The latest AWS PV drivers resolve bugs in previous versions of the drivers that may appear while you are on a Nitro system, or if you need to migrate back to a Xen-based instance. As a best practice, we recommend always updating to the latest drivers for Windows instances on AWS.

Use the following procedure to perform an in-place upgrade of AWS PV drivers, or to upgrade from Citrix PV drivers to AWS PV drivers on Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016, or Windows Server 2019. For more information, see Upgrade PV drivers on EC2 Windows instances.

To upgrade a Domain Controller, see Upgrade a domain controller (AWS PV upgrade).

To perform an upgrade of or to AWS PV drivers

1. Connect to the instance using Remote Desktop and prepare the instance for upgrade. Take all non-system disks offline before you perform the upgrade. If you are performing an in-place update of AWS PV drivers, this step is not required. Set non-essential services to **Manual** start-up in the Services console.
2. Download the latest driver package to the instance.
3. Extract the contents of the folder and run `AWSPVDriverSetup.msi`.

After running the MSI, the instance automatically reboots and upgrades the driver. The instance may not be available for up to 15 minutes.

After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop and verify that the new driver was installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see AWS PV driver package history.

Part 2: Install and upgrade ENA

Upgrade to the latest Elastic Network Adapter driver to ensure that all network features are supported. If you launched your instance and it does not have enhanced networking already enabled, you must download and install the required network adapter driver on your instance. Then, set the enaSupport instance attribute to **activate enhanced networking**. You can only enable this attribute on supported instance types and only if the ENA driver is installed. For more information, see Enable enhanced networking with ENA on your EC2 instances.

1. Download the latest driver to the instance. If you need a previous version of the driver, see ENA Windows driver version history.
2. Extract the zip archive.
3. Install the driver by running the `install.ps1` PowerShell script from the extracted folder.

> **Note**
>
> To avoid installation errors, run the `install.ps1` script as an administrator.

4. Check if your AMI has enaSupport activated. If not, continue by following the documentation at Enable enhanced networking with ENA on your EC2 instances.

Part 3: Upgrade AWS NVMe drivers

AWS NVMe drivers are used to interact with Amazon EBS and SSD instance store volumes that are exposed as NVMe block devices in the Nitro system for better performance.

> **Important**
>
> The following instructions are modified specifically for when you install or upgrade AWS NVMe on a Xen-based instance with the intention to migrate the instance to a Nitro-based instance.

1. Download the latest driver package to the instance.

   If you need a previous version of the driver, see NVMe Windows driver releases for supported versions.
2. Extract the zip archive.
3. Install the driver as described in `Readme.txt`.
4. Open a **PowerShell** session and run the following command:

   ```
   PS C:\> start rundll32.exe sppnp.dll,Sysprep_Generalize_Pnp -wait
   ```

   > **Note**
   >
   > To apply the command, you must run the PowerShell session as an administrator. PowerShell (x86) versions will result in an error.
   > This command only runs sysprep on the device drivers. It does not run the full sysprep preparation.
5. For Windows Server 2008 R2 and Windows Server 2012, shut down the instance, change the instance type and start the instance, then proceed to Part 4. If you start the instance again on a Xen-based instance type before migrating to a Nitro-based instance type, it will not boot. For other supported Windows AMIs, you can change the instance type anytime after the device sysprep.

Part 4: Update EC2Config and EC2Launch

For Windows instances, the latest EC2Config and EC2Launch utilities provide additional functionality and information when running on the Nitro system, including on EC2 Bare Metal. By default, the EC2Config service is included in AMIs prior to Windows Server 2016. EC2Launch replaces EC2Config on Windows Server 2016 and later AMIs.

When the EC2Config and EC2Launch services are updated, new Windows AMIs from AWS include the latest version of the service. However, you must update your own Windows AMIs and instances with the latest version of EC2Config and EC2Launch.

To install or update EC2Config

1. Download and unzip the EC2Config Installer.
2. Run `EC2Install.exe`. For a complete list of options, run `EC2Install` with the `/?` option. By default, setup displays prompts. To run the command with no prompts, use the `/quiet` option.

For more information, see Install the latest version of EC2Config.

To install or update EC2Launch

1. If you have already installed and configured EC2Launch on an instance, make a backup of the EC2Launch configuration file. The installation process does not preserve changes in this file. By default, the file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.
2. Download EC2-Windows-Launch.zip to a directory on the instance.
3. Download install.ps1 to the same directory where you downloaded `EC2-Windows-Launch.zip`.
4. Run `install.ps1`.

   > **Note**
   >
   > To avoid installation errors, run the `install.ps1` script as an administrator.

5. If you made a backup of the EC2Launch configuration file, copy it to the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.

For more information, see Use the EC2Launch v1 agent to perform tasks during EC2 Windows instance launch.

Part 5: Install the serial port driver for bare metal instances

The `i3.metal` instance type uses a PCI-based serial device rather than an I/O port-based serial device. The latest Windows AMIs automatically use the PCI-based serial device and have the serial port driver installed. If you are not using an instance launched from an Amazon-provided Windows AMI dated 2018.04.11 or later, you must install the Serial Port Driver to enable the serial device for EC2 features such as Password Generation and Console Output. The latest EC2Config and EC2Launch utilities also support i3.metal and provide additional functionality. Follow the steps in Part 4, if you have not yet done so.

To install the serial port driver

1. Download the serial driver package to the instance.
2. Extract the contents of the folder, open the context (right-click) menu for `aws_ser.INF`, and choose **install**.
3. Choose **Okay**.

Part 6: Update power management settings

The following update to power management settings sets displays to never turn off, which allows for graceful OS shutdowns on the Nitro system. All Windows AMIs provided by Amazon as of 2018.11.28 already have this default configuration.

1. Open a command prompt or PowerShell session.
2. Run the following commands:

```
powercfg /setacvalueindex 381b4222-f694-41f0-9685-ff5bb260df2e 7516b95f-
f776-4464-8c53-06167f40cc99 3c0bc021-c8a8-4e07-a973-6b14cbcb2b7e 0
powercfg /setacvalueindex 8c5e7fda-e8bf-4a96-9a85-a6e23a8c635c 7516b95f-
f776-4464-8c53-06167f40cc99 3c0bc021-c8a8-4e07-a973-6b14cbcb2b7e 0
powercfg /setacvalueindex a1841308-3541-4fab-bc81-f71556f20b4a 7516b95f-
f776-4464-8c53-06167f40cc99 3c0bc021-c8a8-4e07-a973-6b14cbcb2b7e 0
```

Part 7: Update Intel chipset drivers for new instance types

The `u-6tb1.metal`, `u-9tb1.metal`, and `u-12tb1.metal` instance types use hardware that requires chipset drivers that were not previously installed on Windows AMIs. If you are not using an instance launched from an Amazon-provided Windows AMI dated 2018.11.19 or later, you must install the drivers using the Intel Chipset INF Utility.

To install the chipset drivers

1. Chipset INF Utility to the instance.
2. Extract the files.
3. Run `SetupChipset.exe`.
4. Accept the Intel software license agreement and install the chipset drivers.
5. Reboot the instance.

(Alternative) Upgrade the AWS PV, ENA, and NVMe drivers using AWS Systems Manager

The `AWSSupport-UpgradeWindowsAWSDrivers` automation document automates the steps described in Part 1, Part 2, and Part 3. This method can also repair an instance where the driver upgrades have failed.

The `AWSSupport-UpgradeWindowsAWSDrivers` automation document upgrades or repairs storage and network AWS drivers on the specified EC2 instance. The document attempts to install the latest versions of AWS drivers online by calling the AWS Systems Manager Agent (SSM Agent). If SSM Agent is not contactable, the document can perform an offline installation of the AWS drivers if explicitly requested.

> **Note**
>
> This procedure will fail on a domain controller. To update drivers on a domain controller, see Upgrade a domain controller (AWS PV upgrade).

To automatically upgrade the AWS PV, ENA, and NVMe drivers using AWS Systems Manager

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager.
2. Choose **Automation**, **Execute Automation**.

3. Search for and then select the **AWSSupport-UpgradeWindowsAWSDrivers** automation document, and then choose **Execute automation**.
4. In the **Input Parameters** section, configure the following options:

    Instance ID

        Enter the unique ID of the instance to upgrade.

    AllowOffline

        (Optional) Choose one of the following options:

        - `True` — Choose this option to perform an offline installation. The instance is stopped and restarted during the upgrade process.

        > **Warning**
        >
        > When you stop an instance, the data on any instance store volumes is erased. To preserve data on instance store volumes, ensure that you back up the data to persistent storage.

        - `False` — (Default) To perform an online installation, leave this option selected. The instance is restarted during the upgrade process.

        > **Important**
        >
        > Online and offline upgrades create an AMI before attempting the upgrade operations. The AMI persists after the automation completes. Secure your access to the AMI, or delete it if it is no longer needed.

    SubnetId

        (Optional) Enter one of the following values:

        - `SelectedInstanceSubnet` — (Default) The upgrade process launches the *helper* instance into the same subnet as the instance that is to be upgraded. The subnet must allow communication to the Systems Manager endpoints (`ssm.*`).
        - `CreateNewVPC` — The upgrade process launches the *helper* instance into a new VPC. Use this option if you're not sure whether the target instance's subnet allows communication to the `ssm.*` endpoints. Your user must have permission to create a VPC.

- A specific subnet ID — Specify the ID of a specific subnet into which to launch the *helper* instance. The subnet must be in the same Availability Zone as the instance that is to be upgraded, and it must allow communication with the `ssm.*` endpoints.

5. Choose **Execute**.
6. Allow the upgrade to complete. It could take up to 10 minutes to complete an online upgrade, and up to 25 minutes to complete an offline upgrade.

Troubleshoot an operating system upgrade on an EC2 Windows instance

AWS provides upgrade support for issues or problems with the Upgrade Helper Service, an AWS utility that helps you perform in-place upgrades involving Citrix PV drivers.

After the upgrade, the instance might temporarily experience higher than average CPU utilization while the .NET Runtime Optimization service optimizes the .NET framework. This is expected behavior.

If the instance has not passed all status checks after several hours, check the following.

- If you upgraded to Windows Server 2008 and all status checks fail after several hours, the upgrade may have failed and be presenting a prompt to **Click OK** to confirm rolling back. Because the console is not accessible at this state, there is no way to click the button. To get around this, perform a reboot via the Amazon EC2 console or API. The reboot takes ten minutes or more to initiate. The instance might become available after 25 minutes.
- Remove applications or server roles from the server and try again.

If the instance does not pass all status checks after removing applications or server roles from the server, do the following.

- Stop the instance and attach the root volume to another instance. For more information, see the description of how to stop and attach the root volume to another instance in "Waiting for the metadata service".
- Analyze Windows Setup log files and event logs for failures.

For other issues or problems with an operating system upgrade or migration, we recommend reviewing the articles listed in Before you begin an in-place upgrade.

Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database

Tutorial objective

The objective of this tutorial is to learn how to configure a secure connection between an Amazon EC2 instance and an Amazon RDS database by using the AWS Management Console.

There are different options for configuring the connection. In this tutorial, we explore the following three options:

- Option 1: Automatically connect an instance to an RDS database using the EC2 console

  Use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.
- Option 2: Automatically connect an instance to an RDS database using the RDS console

  Use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.
- Option 3: Manually connect an instance to an RDS database by creating security groups

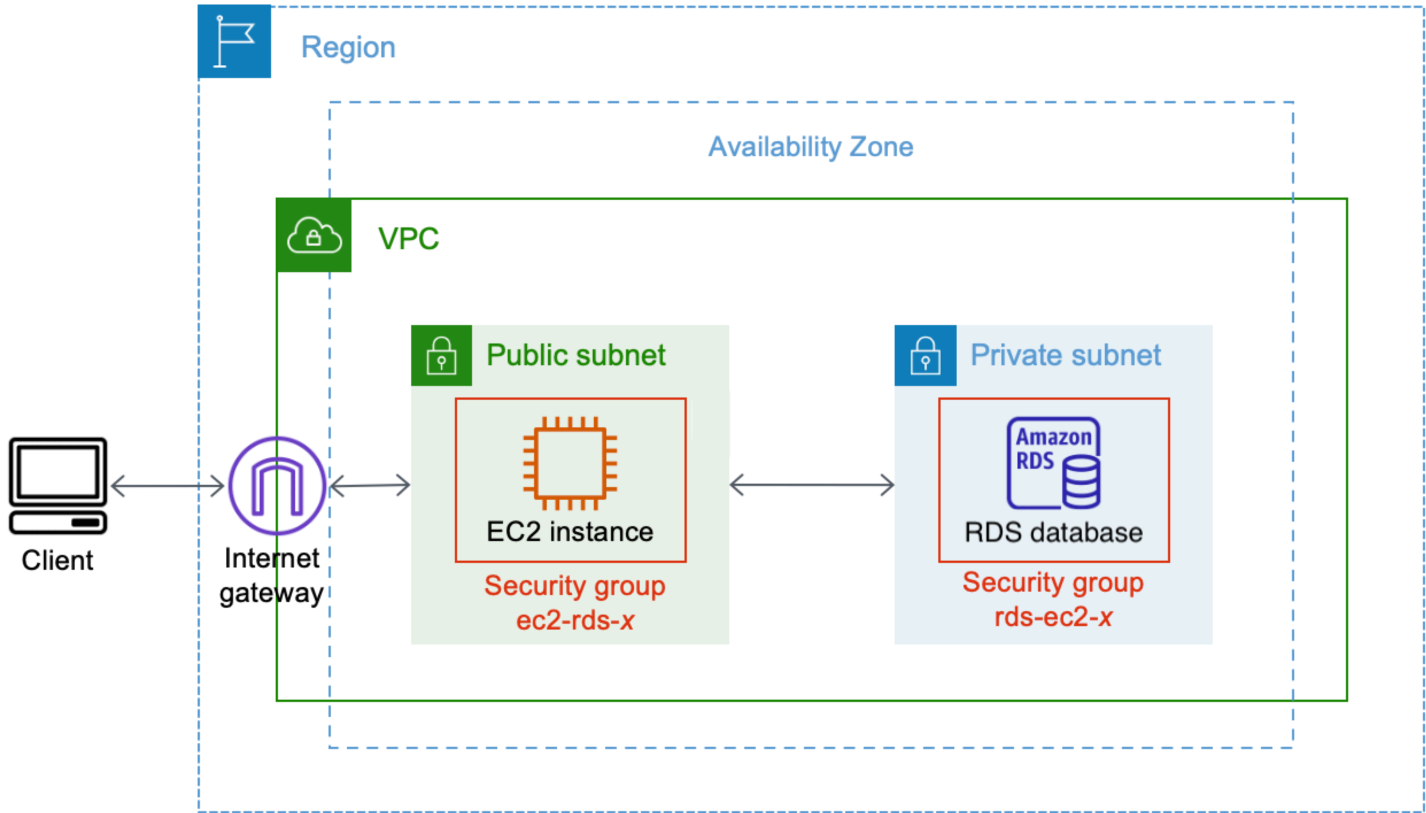
  Configure the connection between your EC2 instance to your RDS database by manually configuring and assigning the security groups to reproduce the configuration that is automatically created by the automatic connection feature in Option 1 and Option 2.

Context

As context for why you'd want to configure a connection between your EC2 instance and an RDS database, let's consider the following scenario: Your website presents a form to your users to fill in. You need to capture the form data in a database. You can host your website on an EC2 instance that's been configured as a web server, and you can capture the form data in an RDS database. The EC2 instance and the RDS database need to be connected to each other so that the form data can go from the EC2 instance to the RDS database. This tutorial explains how to configure that connection. Note that this is just one example of a use case for connecting an EC2 instance and an RDS database.

Architecture

The following diagram shows the resources that are created and the architectural configuration that results from completing all the steps in this tutorial.



The diagram illustrates the following resources that you'll create:

- You'll create an EC2 instance and an RDS database in the same AWS Region, VPC, and Availability Zone.
- You'll create the EC2 instance in a public subnet.
- You'll create the RDS database in a private subnet.

  When you use the RDS console to create the RDS database and automatically connect the EC2 instance, the VPC, DB subnet group, and public access settings for the database are automatically selected. The RDS database is automatically created in a private subnet within the same VPC as the EC2 instance.
- Internet users can connect to the EC2 instance by using SSH or HTTP/HTTPS via an Internet gateway.

- Internet users cannot connect directly to the RDS database; only the EC2 instance is connected to the RDS database.
- When you use the automatic connection feature to allow traffic between the EC2 instance and the RDS database, the following security groups are automatically created and added:
  - Security group **ec2-rds-*x*** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-*x*** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-*x*** security group.
  - Security group **rds-ec2-*x*** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-*x*** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-*x*** security group to reach the RDS database.

  By using separate security groups (one for the EC2 instance, and one for the RDS database), you have better control over the security of the instance and the database. If you were to use the same security group on both the instance and the database, and then modified the security group to suit, say, only the database, the modification would affect both the instance and the database. In other words, if you were to use one security group, you could unintentionally modify the security of a resource (either the instance or the database) because you'd forgotten that the security group was attached to it.

  The security groups that are automatically created also respect least privilege as they only allow the mutual connection for this workload on the database port by creating a workload-specific security group pair.

Considerations

Consider the following when you complete the tasks in this tutorial:

- **Two consoles** – You will use the following two consoles for this tutorial:
  - Amazon EC2 console – You will use the EC2 console to launch instances, to automatically connect an EC2 instance to an RDS database, and for the manual option to configure the connection by creating the security groups.
  - Amazon RDS console – You will use the RDS console to create an RDS database and to automatically connect an EC2 instance to an RDS database.
- **One VPC –** To use the automatic connection feature, your EC2 instance and your RDS database must be in the same VPC.

If you were to manually configure the connection between your EC2 instance and your RDS database, you could launch your EC2 instance in one VPC and your RDS database in another VPC; however, you'd need to set up additional routing and VPC configuration. This scenario is not covered in this tutorial.

- **One AWS Region –** The EC2 instance and RDS database must be located in the same Region.
- **Two security groups –** The connectivity between the EC2 instance and the RDS database is configured by two security groups—a security group for your EC2 instance, and a security group for your RDS database.

  When you use the automatic connection feature in the EC2 console or RDS console to configure the connectivity (Option 1 and Option 2 of this tutorial), the security groups are automatically created and assigned to the EC2 instance and RDS database.

  If you do not use the automatic connection feature, you'll need to manually create and assign the security groups. You do this in Option 3 of this tutorial.

Time to complete the tutorial

30 minutes

You can complete the entire tutorial in one sitting, or you can complete it one task at a time.

Costs

By completing this tutorial, you might incur costs for the AWS resources that you create.

You can use Amazon EC2 under the Free Tier provided your AWS account qualifies for the Free Tier and you configure your resources according to the Free Tier requirements. For more information, Free Tier benefits before and after July 15, 2025.

If your EC2 instance and your RDS database are in different Availability Zones, you will incur data transfer fees. To avoid incurring these fees, the EC2 instance and the RDS database must be in the same Availability Zone. For information about data transfer fees, see Data Transfer on the Amazon EC2 On-Demand Pricing page.

To prevent incurring costs after you've completed the tutorial, make sure to delete the resources if they are no longer needed. For the steps to delete the resources, see Task 4 (*Optional*): Clean up.

Option 1: Automatically connect an instance to an RDS database using the EC2 console

The objective of Option 1 is to explore the automatic connection feature in the EC2 console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Tasks

Before you begin

You'll need the following to complete this tutorial:

- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 1 to create a new RDS database.
- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 2 to create a new EC2 instance.
- Permissions to call the following operations:
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSecurityGroup`
  - `ec2:CreateSubnet`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeRouteTables`

- `ec2:DescribeSecurityGroups`
- `ec2:DescribeSubnets`
- `ec2:ModifyNetworkInterfaceAttribute`
- `ec2:RevokeSecurityGroupEgress`

Task 1 (*Optional*): Create an RDS database

> **Note**
>
> Creating a Amazon RDS database is not the focus of this tutorial. If you already have an RDS database and would like to use it in this tutorial, you can skip this task.
> If you use an existing RDS database, make sure that it is in the same VPC as your EC2 instance so that you can use the automatic connection feature.

The objective of this task is to create an RDS database so that you can complete Task 3 where you configure the connection between your EC2 instance and your RDS database. The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **`tutorial-database-1`**
- DB instance class: `db.t3.micro`

> **Important**
>
> In a production environment, you should configure your database to meet your specific needs.

To create a MySQL RDS database

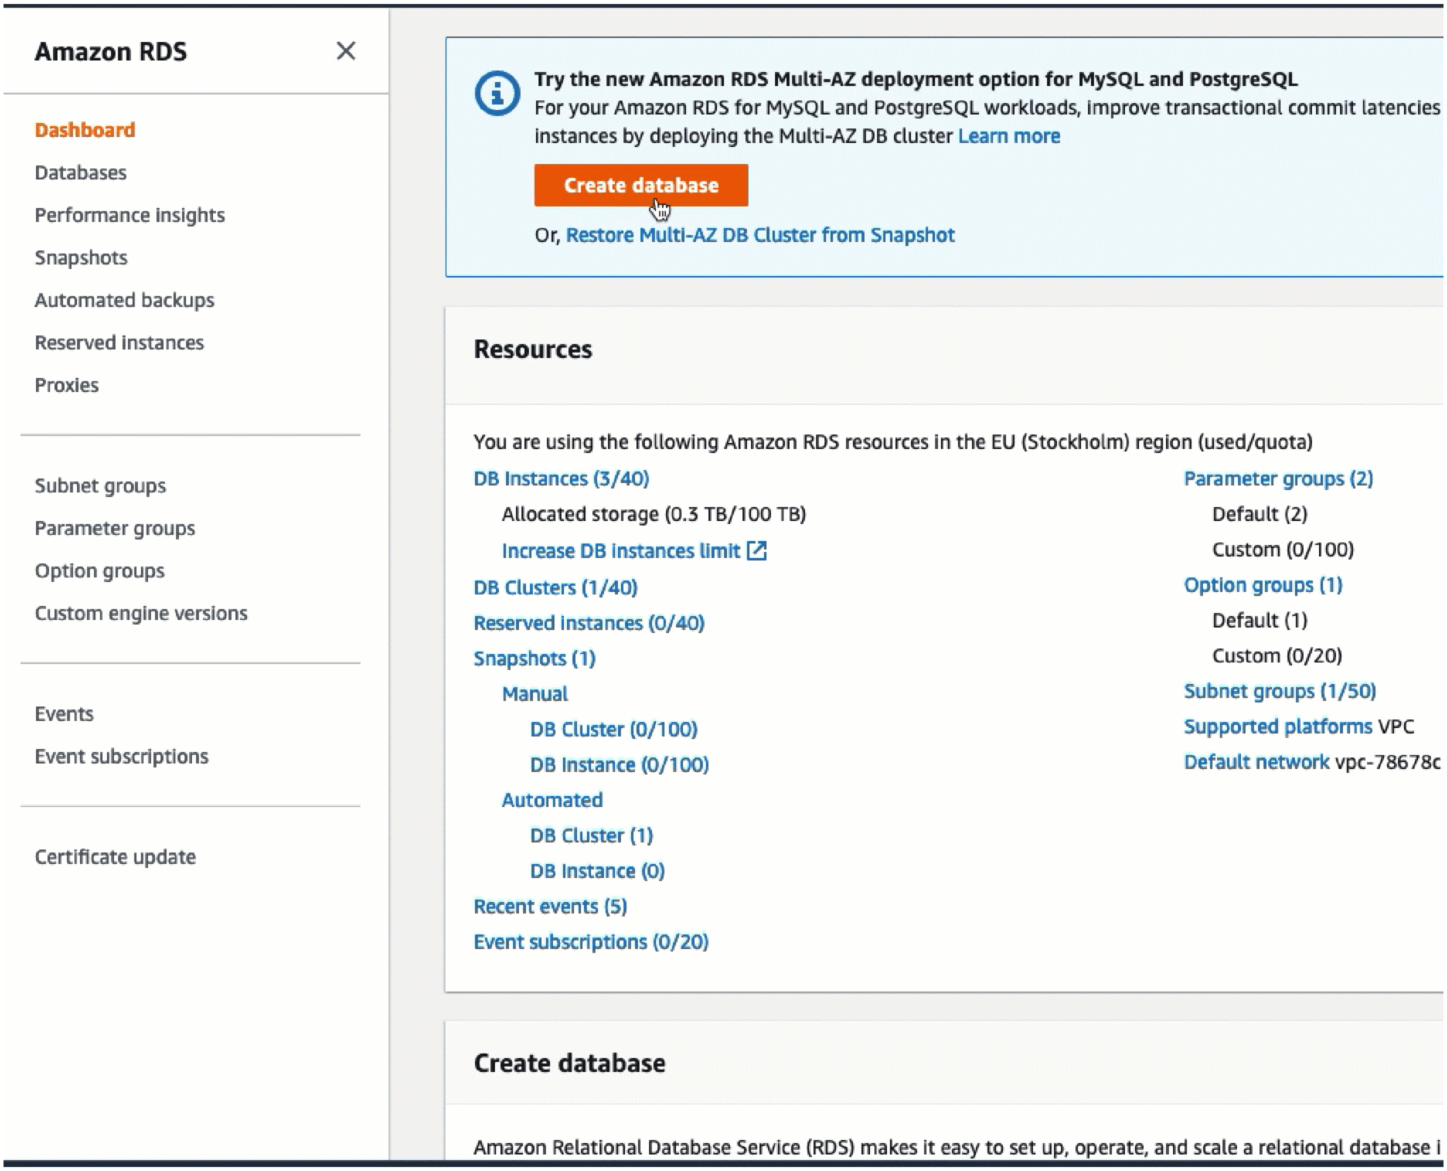
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. From the Region selector (at top right), choose an AWS Region. The database and the EC2 instance must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the VPC selector is not available. You must ensure that your database is in the same VPC as your EC2 instance in order to use the automatic connection feature in the EC2 console.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create an RDS database at no cost. However, note that the Free Tier is only available for accounts that qualify for the Free Tier. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:
    a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter **`tutorial-database-1`**.
    b. For **Master username**, leave the default name, which is **`admin`**.
    c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**.If your account qualifies for the Free Tier, you can use this database class for free. For more information, see [AWS Free Tier].
9. Under **Connectivity**, for **Compute resource**, choose **Don't connect to an EC2 compute resource** because you'll connect the EC2 instance and the RDS database later in Task 3.

    (Later, in Option 2 of this tutorial, you'll try out the automatic connection feature in the RDS console by choosing **Connect to an EC2 compute resource**.)
10. For **Virtual private cloud (VPC)**, choose a VPC. The VPC must have a DB subnet group. To use the automatic connection feature, your EC2 instance and RDS database must be in the same VPC.
11. Keep all the default values for the other fields on this page.
12. Choose **Create database**.

On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

View an animation: Create an RDS database



Task 2 (*Optional*): Launch an EC2 instance

> **Note**
>
> Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.
> If you use an existing EC2 instance, make sure that it is in the same VPC as your RDS database so that you can use the automatic connection feature.

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database. The steps in this task configure the EC2 instance as follows:

- Instance name: **`tutorial-instance-1`**
- AMI: Amazon Linux 2
- Instance type: `t2.micro`
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

> **Important**
>
> In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Region selector (at top right), choose an AWS Region. The instance and the RDS database must be in the same Region in order to use the automatic connection feature in the EC2 console.

3. On the **EC2 Dashboard**, choose **Launch instance**.
4. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **`tutorial-instance-1`**. While the instance name is not mandatory, when you select your instance in the EC2 console, the name will help you easily identify it.
5. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux 2**.
6. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses `t2.micro`.

> **Note**
>
> Depending on when you created your account, you might be eligible to use Amazon EC2 under the Free Tier.
> If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type, or the **t3.micro** instance type in Regions where **t2.micro** is unavailable. Be aware that when you launch a **t3.micro** instance, it defaults to **Unlimited** mode, which might incur additional charges based on CPU usage. If an instance type can be used under the Free Tier, it is labeled **Free tier eligible**.
> If you created your AWS account on or after July 15, 2025, you can use **t3.micro**, **t3.small**, **t4g.micro**, **t4g.small**, **c7i-flex.large**, and **m7i-flex.large** instance types for 6 months or until your credits are used up.
> For more information, see Free Tier benefits before and after July 15, 2025.

7. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
8. Under **Network settings**, do the following:

   a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

      If you have made changes to your default VPC or subnets, check the following:

      i. The instance must be in the same VPC as the RDS database to use the automatic connection feature. By default you have only one VPC.
      ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.

iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.

b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

   To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** checkbox, choose **My IP**.

c. To allow traffic from the internet to your instance, select the following checkboxes:

   - **Allow HTTPs traffic from the internet**
   - **Allow HTTP traffic from the internet**

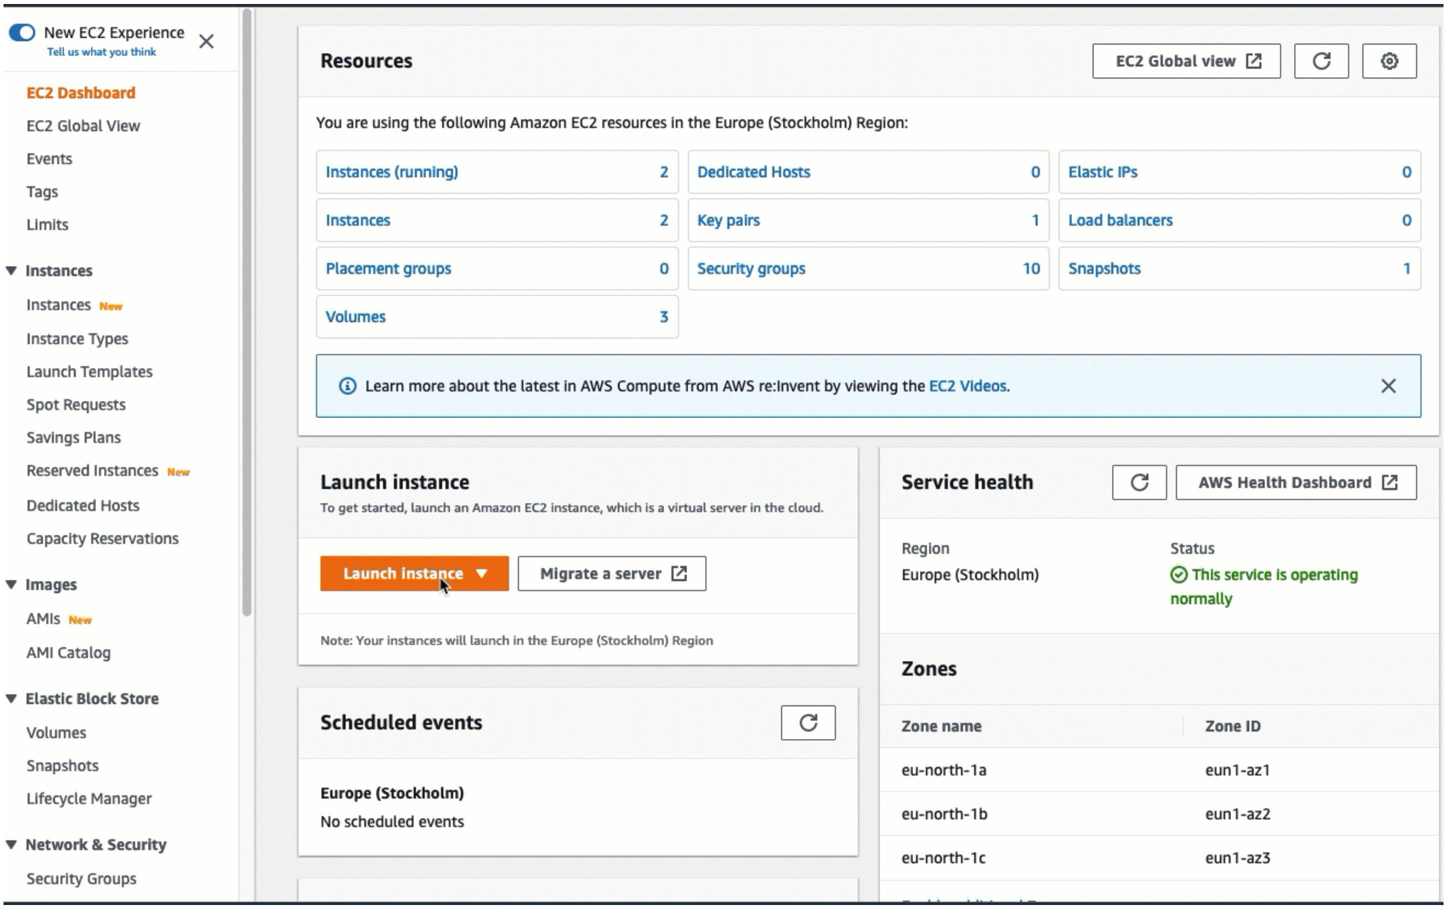
9. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.

10. Keep the confirmation page open. You'll need it for the next task when you automatically connect your instance to your database.

    If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

For more information about launching an instance, see Launch an EC2 instance using the launch instance wizard in the console.

View an animation: Launch an EC2 instance



Task 3: Automatically connect your EC2 instance to your RDS database

The objective of this task is to use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database.

To automatically connect an EC2 instance to an RDS database using the EC2 console

1. On the instance launch confirmation page (it should be open from the previous task), choose **Connect an RDS database**.

   If you closed the confirmation page, follow these steps:

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

   b. In the navigation pane, choose **Instances**.

   c. Select the EC2 instance that you just created, and then choose **Actions**, **Networking**, **Connect RDS database**.

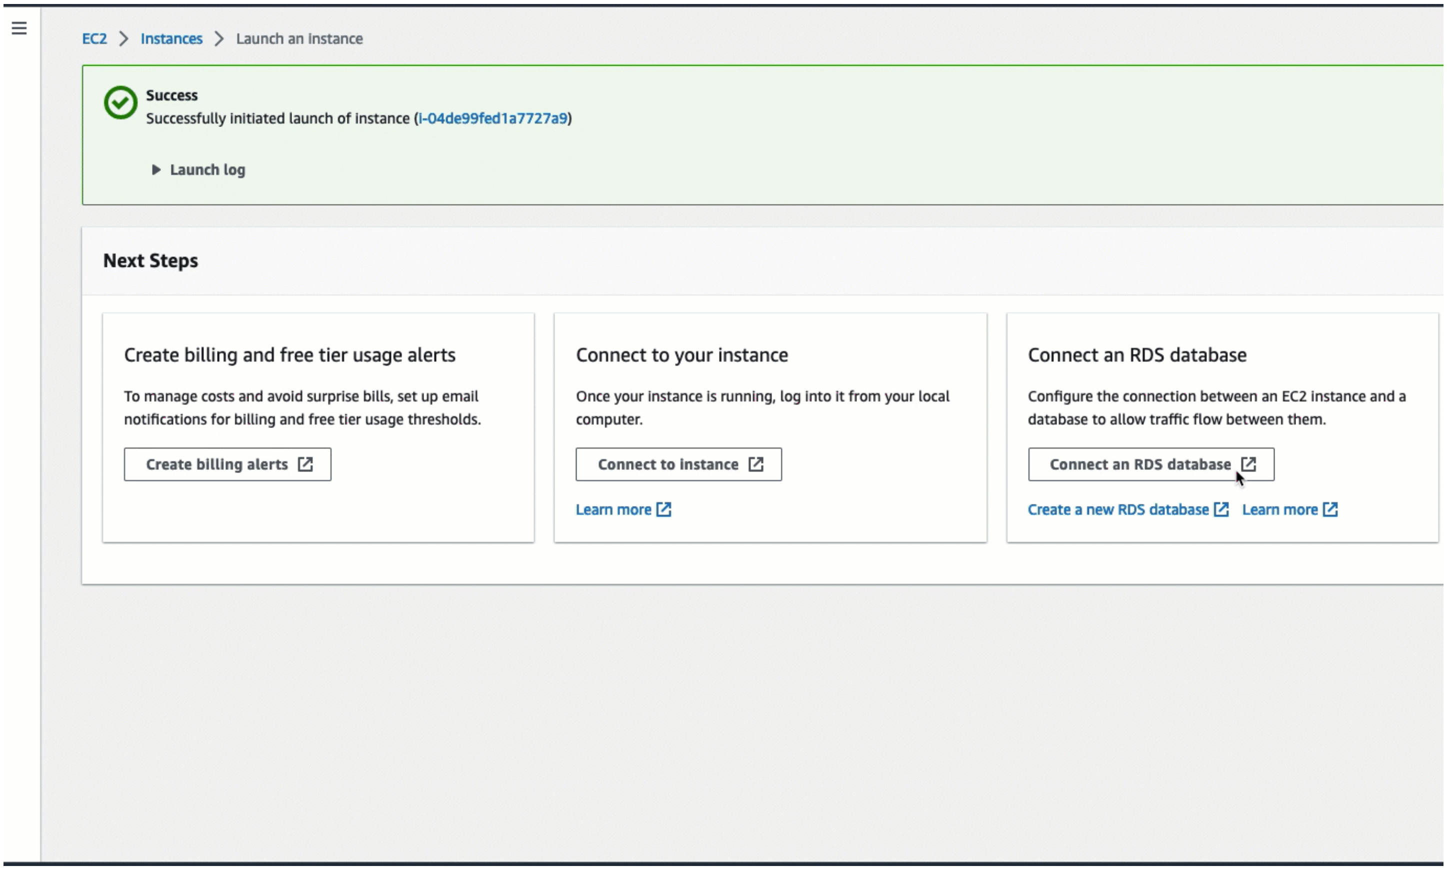
If **Connect RDS database** is not available, check that the EC2 instance is in the **Running** state.

2. For **Database role**, choose **Instance**. *Instance* in this case refers to the database instance.
3. For **RDS database**, choose the RDS database that you created in Task 1.

> **Note**
>
> The EC2 instance and the RDS database must be in the same VPC in order to connect to each other.

4. Choose **Connect**.

View an animation: Automatically connect a newly-launched EC2 instance to an RDS database



Task 4: Verify the connection configuration

The objective of this task is to verify that the two security groups were created and assigned to the instance and database.

When you use the automatic connection feature in the console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-*x*** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-*x*** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-*x*** security group to reach the RDS database.
- Security group **ec2-rds-*x*** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-*x*** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-*x*** security group.

To verify the connection configuration using the console

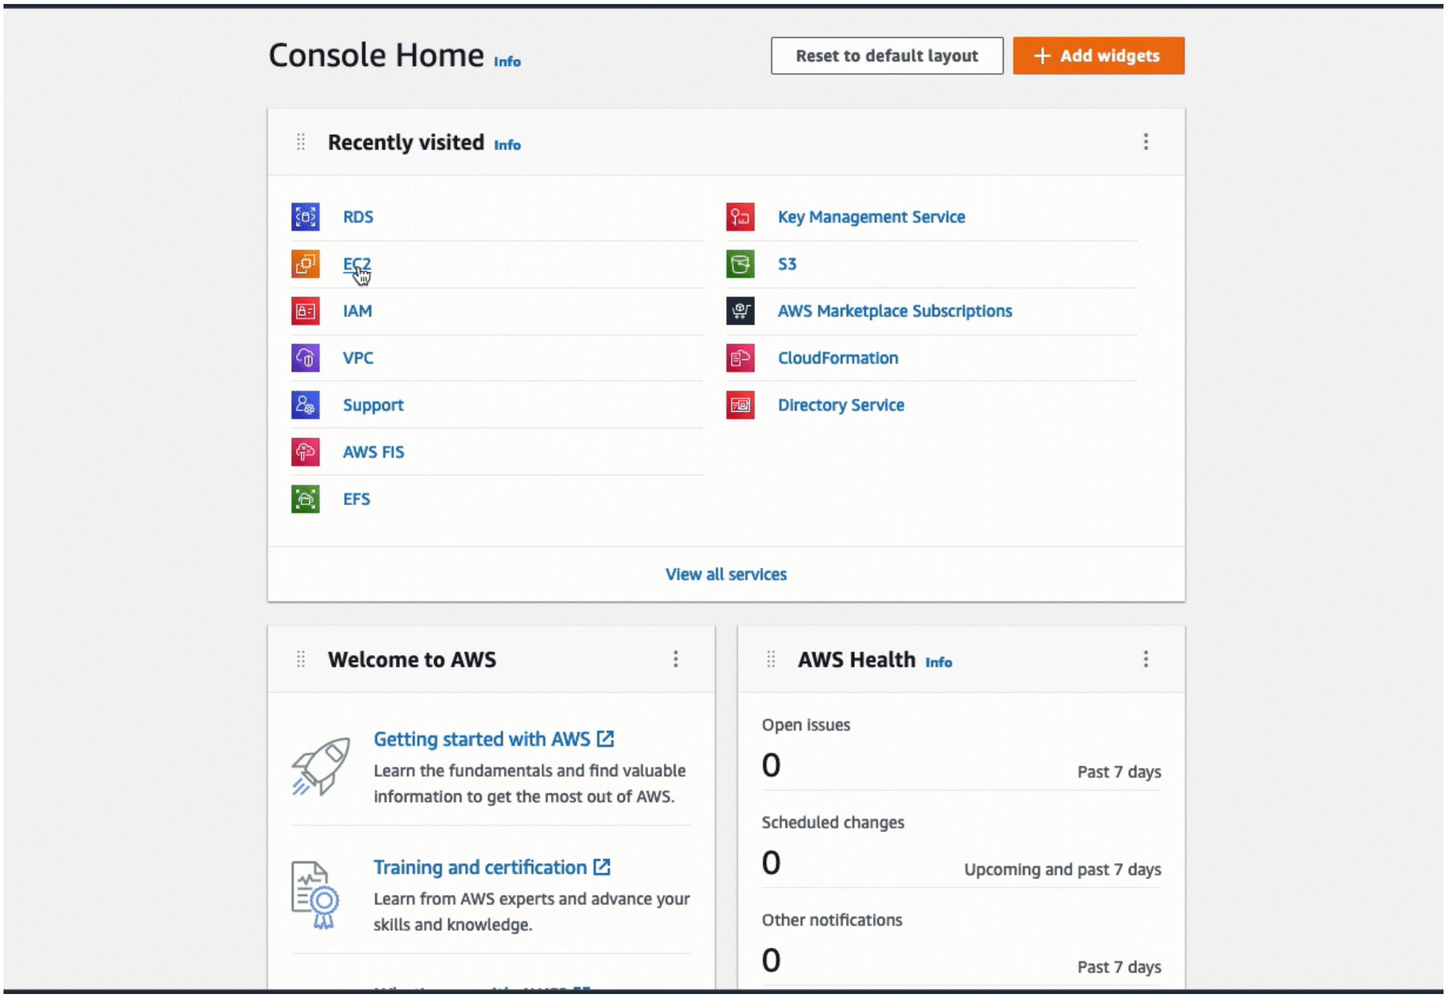
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation page, choose **Databases**.
3. Choose the RDS database that you created for this tutorial.
4. On the **Connectivity & security** tab, under **Security**, **VPC security groups**, verify that a security group called **rds-ec2-*x*** is displayed.
5. Choose the **rds-ec2-*x*** security group. The **Security Groups** screen in the EC2 console opens.
6. Choose the **rds-ec2-*x*** security group to open it.
7. Choose the **Inbound rules** tab.
8. Verify that the following security group rule exists, as follows:
   - Type: **MYSQL/Aurora**
   - Port range: **3306**
   - Source: ***sg-0987654321example*** **/ ec2-rds-*x*** – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
   - Description: **Rule to allow connections from EC2 instances with *sg-1234567890example* attached**
9. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
10. In the navigation pane, choose **Instances**.
11. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
12. Under **Security details**, **Security groups**, verify that a security group called **ec2-rds-*x*** is in the list. *x* is a number.

13. Choose the **ec2-rds-*x*** security group to open it.
14. Choose the **Outbound rules** tab.
15. Verify that the following security group rule exists, as follows:

    - Type: **MYSQL/Aurora**
    - Port range: **3306**
    - Destination: ***sg-1234567890example* / rds-ec2-*x***
    - Description: **Rule to allow connections to `database-tutorial` from any instances this security group is attached to**

By verifying that these security groups and security group rules exist and that they are assigned to the RDS database and EC2 instance as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

View an animation: Verify the connection configuration



You have completed Option 1 of this tutorial. You can now either complete Option 2, which teaches you how to use the RDS console to automatically connect an EC2 instance to an RDS database, or you can complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 1.

Task 5 (*Optional*): Clean up

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

To terminate an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you created for this tutorial, and choose **Instance state**, **Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

To delete an RDS database using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Select the RDS database that you created for this tutorial, and choose **Actions**, **Delete**.
4. Enter **`delete me`** in the box, and then choose **Delete**.

Option 2: Automatically connect an instance to an RDS database using the RDS console

The objective of Option 2 is to explore the automatic connect feature in the RDS console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Tasks

- Before you begin
- Task 1 (Optional): Launch an EC2 instance
- Task 2: Create an RDS database and automatically connect it to your EC2 instance
- Task 3: Verify the connection configuration
- Task 4 (Optional): Clean up

Before you begin

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- Permissions to call the following operations:
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSecurityGroup`
  - `ec2:CreateSubnet`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeRouteTables`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

Task 1 (*Optional*): Launch an EC2 instance

> **Note**
>
> Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

The objective of this task is to launch an EC2 instance so that you can complete Task 2 where you configure the connection between your EC2 instance and your Amazon RDS database. The steps in this task configure the EC2 instance as follows:

- Instance name: **`tutorial-instance-2`**
- AMI: Amazon Linux 2
- Instance type: `t2.micro`
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

> **Important**
>
> In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the **EC2 Dashboard**, choose **Launch instance**.
3. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **`tutorial-instance-2`**. While the instance name is not mandatory, when you select your instance in the RDS console, the name will help you easily identify it.

4. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux**.

5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses `t2.micro`.

> **Note**
>
> Depending on when you created your account, you might be eligible to use Amazon EC2 under the Free Tier.
> If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type, or the **t3.micro** instance type in Regions where **t2.micro** is unavailable. Be aware that when you launch a **t3.micro** instance, it defaults to **Unlimited** mode, which might incur additional charges based on CPU usage. If an instance type can be used under the Free Tier, it is labeled **Free tier eligible**.
> If you created your AWS account on or after July 15, 2025, you can use **t3.micro**, **t3.small**, **t4g.micro**, **t4g.small**, **c7i-flex.large**, and **m7i-flex.large** instance types for 6 months or until your credits are used up.
> For more information, see Free Tier benefits before and after July 15, 2025.

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.

7. Under **Network settings**, do the following:

   a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

      If you have made changes to your default VPC or subnets, check the following:

      i. The instance must be in the same VPC as the RDS database to use the automatic connection configuration. By default you have only one VPC.

      ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.

      iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.

b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

   To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** checkbox, choose **My IP**.

c. To allow traffic from the internet to your instance, select the following checkboxes:

   - **Allow HTTPs traffic from the internet**
   - **Allow HTTP traffic from the internet**

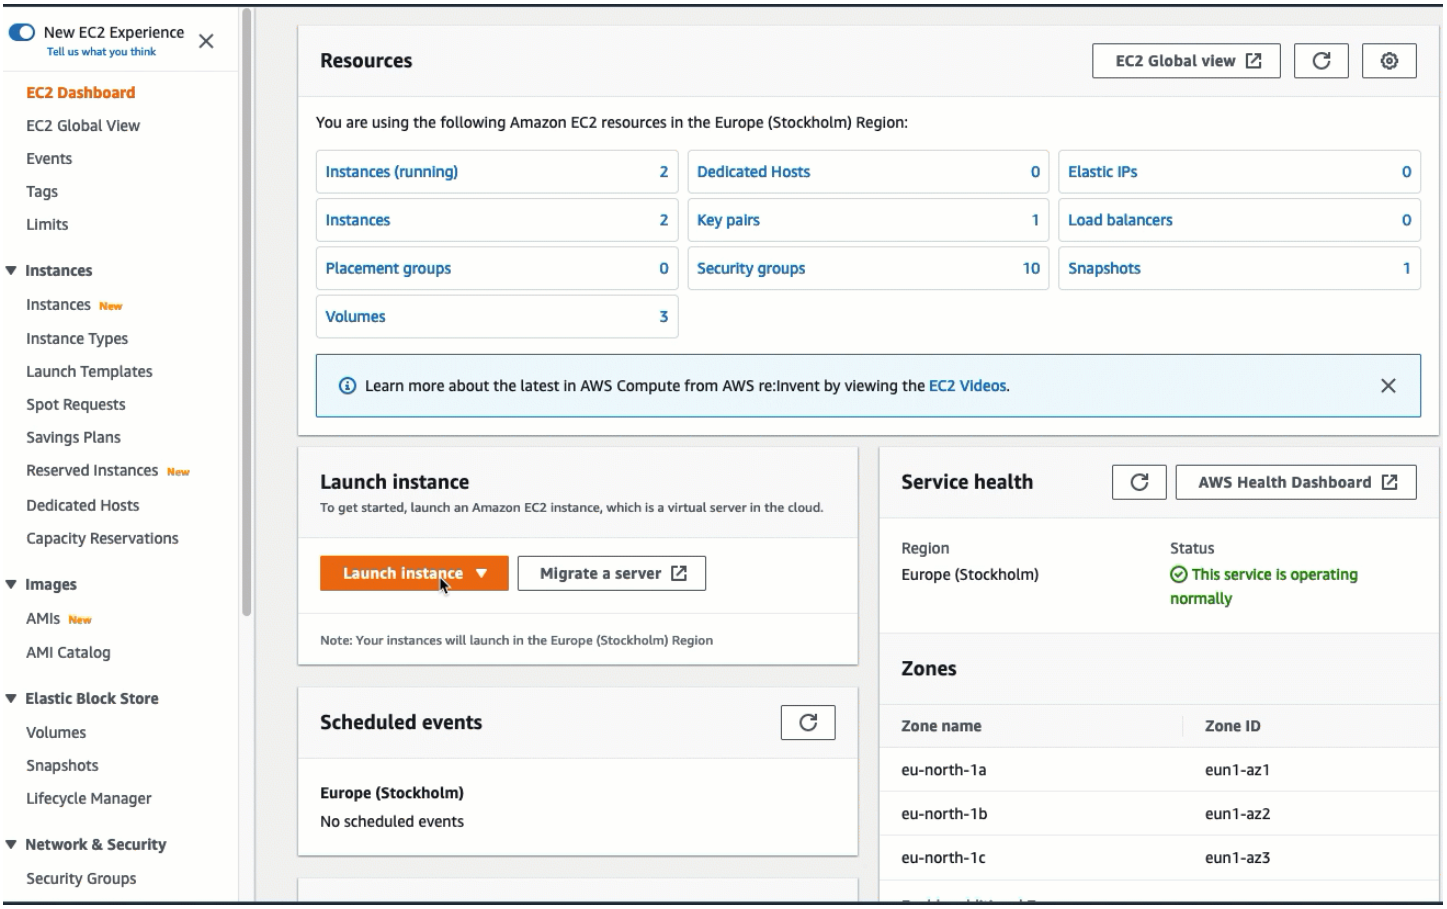
8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.

9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a `pending` state, and will then go into the `running` state.

   If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

For more information about launching an instance, see Launch an EC2 instance using the launch instance wizard in the console.

View an animation: Launch an EC2 instance



Task 2: Create an RDS database and automatically connect it to your EC2 instance

The objective of this task is to create an RDS database and use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database. The steps in this task configure the DB instance as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **`tutorial-database`**
- DB instance class: `db.t3.micro`

> **Important**
>
> In a production environment, you should configure your instance to meet your specific needs.

To create an RDS database and automatically connect it to an EC2 instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the RDS database must be in the same Region.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the automatic connection feature is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create an RDS database at no cost. However, note that the Free Tier is only available if your account qualifies for the Free Tier. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:

    a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter **`tutorial-database`**.

    b. For **Master username**, leave the default name, which is **`admin`**.

    c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.

8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**. If your account qualifies for the Free Tier, you can use this instance for free. For more information, see [AWS Free Tier](#).
9. Under **Connectivity**, for **Compute resource**, choose **Connect to an EC2 compute resource**. This is the automatic connection feature in the RDS console .
10. For **EC2 instance**, choose the EC2 instance that you want to connect to. For the purposes of this tutorial, you can either choose the instance that you created in the previous task, which you named **`tutorial-instance`**, or choose another existing instance. If you don't see your instance in the list, choose the refresh icon to the right of **Connectivity**.

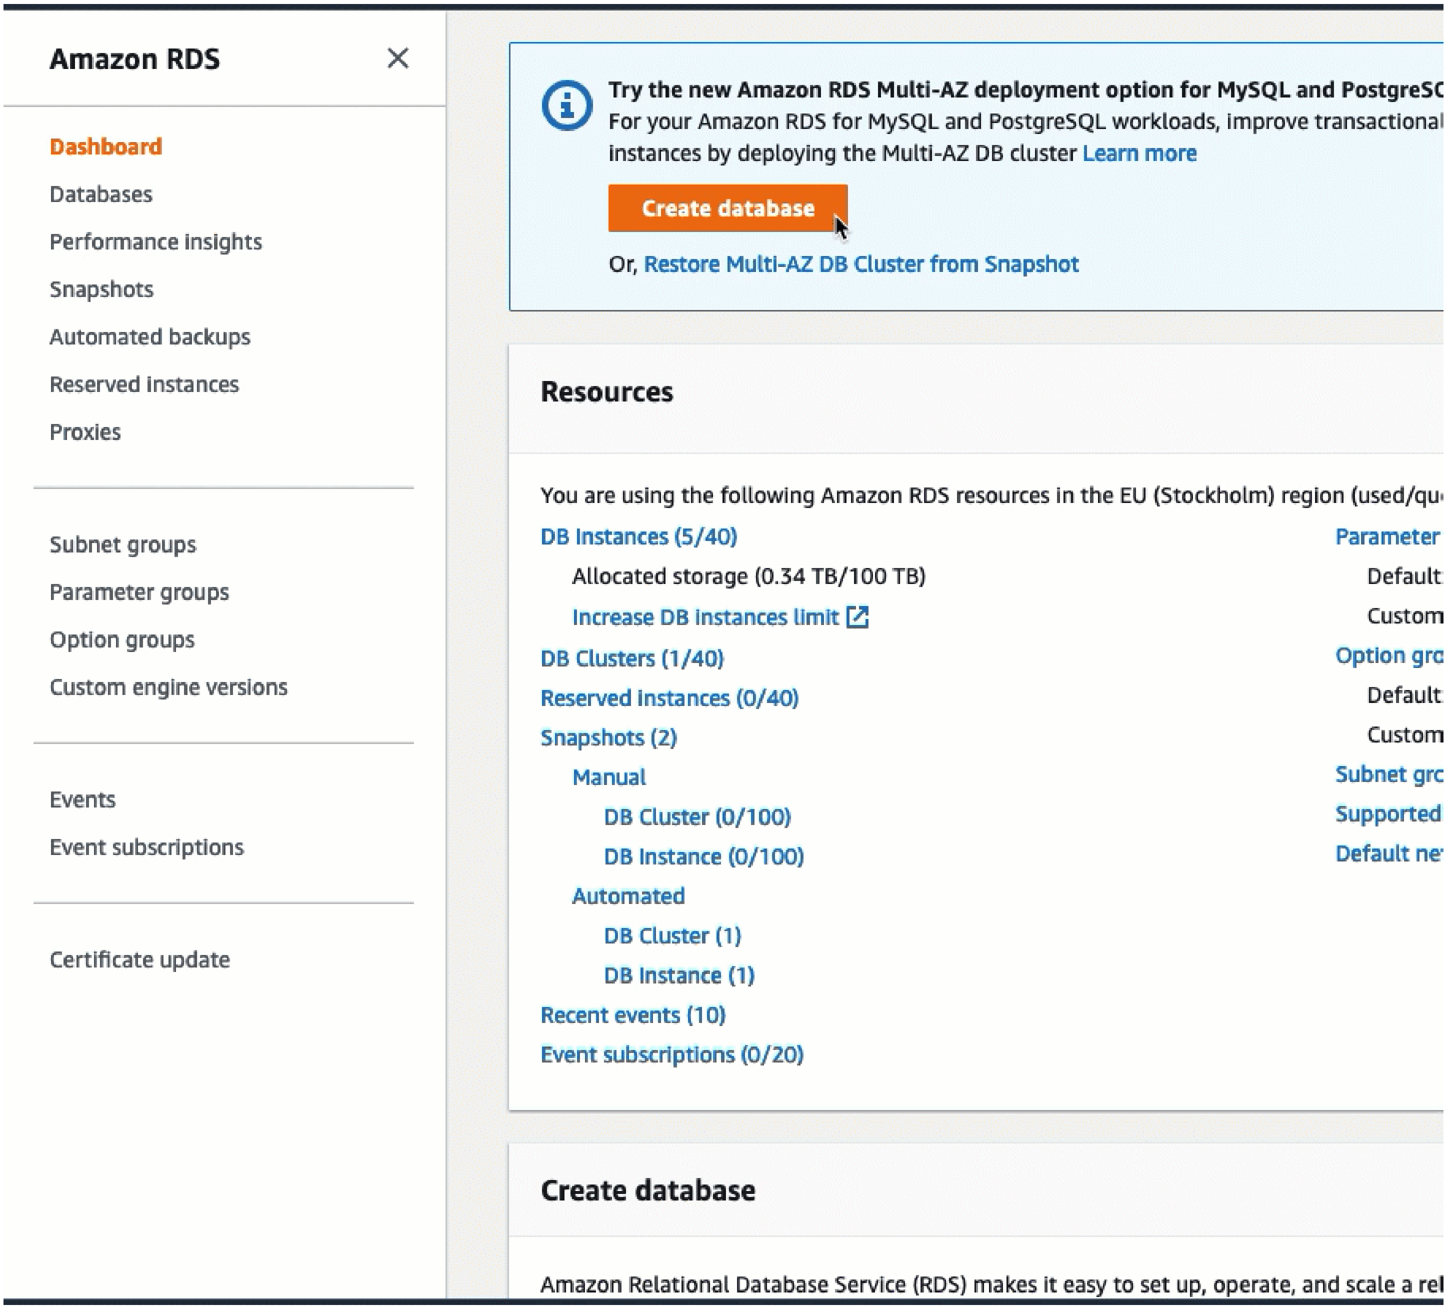
When you use the automatic connection feature, a security group is added to this EC2 instance, and another security group is added to the RDS database. The security groups are automatically configure to allow traffic between the EC2 instance and the RDS database. In the next task, you'll verify that the security groups were created and assigned to the EC2 instance and RDS database.

11. Choose **Create database**.

    On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

To learn more, see Configure automatic network connectivity with an EC2 instance in the *Amazon RDS User Guide*.

View an animation: Create an RDS database and automatically connect it to an EC2 instance



Task 3: Verify the connection configuration

The objective of this task is to verify that the two security groups were created and assigned to the instance and database.

When you use the automatic connection feature in the console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-*x*** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-*x*** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-*x*** security group to reach the RDS database.
- Security group **ec2-rds-*x*** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-*x*** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-*x*** security group.

To verify the connection configuration using the console

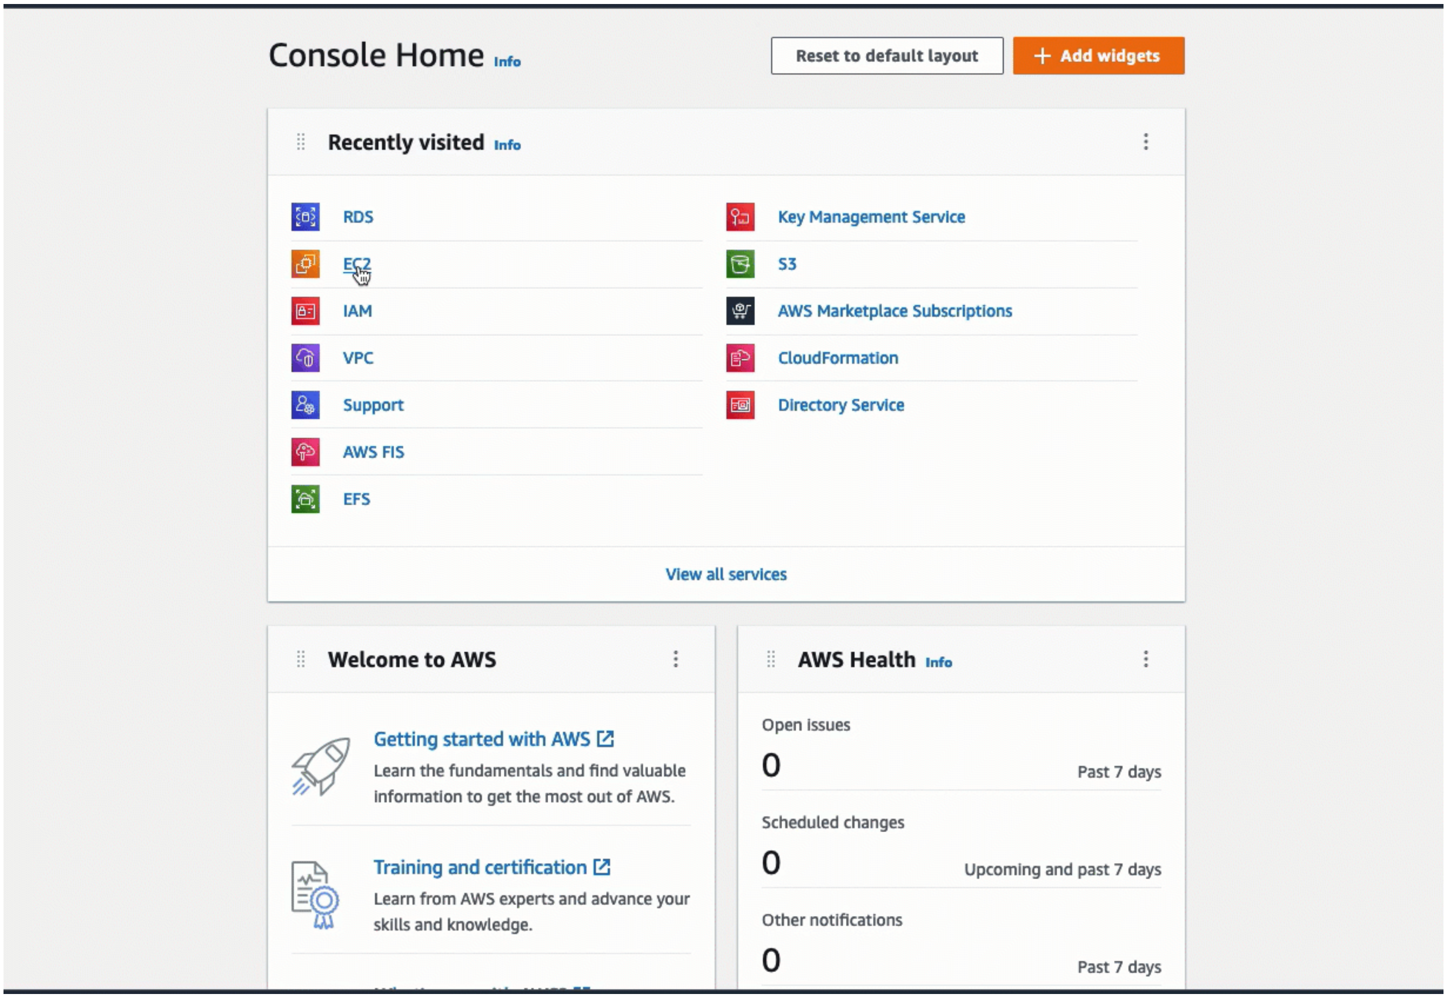
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation page, choose **Databases**.
3. Choose the RDS database that you created for this tutorial.
4. On the **Connectivity & security** tab, under **Security**, **VPC security groups**, verify that a security group called **rds-ec2-*x*** is displayed.
5. Choose the **rds-ec2-*x*** security group. The **Security Groups** screen in the EC2 console opens.
6. Choose the **rds-ec2-*x*** security group to open it.
7. Choose the **Inbound rules** tab.
8. Verify that the following security group rule exists, as follows:
   - Type: **MYSQL/Aurora**
   - Port range: **3306**
   - Source: ***`sg-0987654321example`*** **/ ec2-rds-*x*** – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
   - Description: **Rule to allow connections from EC2 instances with *`sg-1234567890example`* attached**
9. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
10. In the navigation pane, choose **Instances**.
11. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
12. Under **Security details**, **Security groups**, verify that a security group called **ec2-rds-*x*** is in the list. *x* is a number.
13. Choose the **ec2-rds-*x*** security group to open it.
14. Choose the **Outbound rules** tab.

15. Verify that the following security group rule exists, as follows:

    * Type: **MYSQL/Aurora**
    * Port range: **3306**
    * Destination: ***sg-1234567890example*** **/ rds-ec2-*x***
    * Description: **Rule to allow connections to `database-tutorial` from any instances this security group is attached to**

By verifying that these security groups and security group rules exist and that they are assigned to the RDS database and EC2 instance as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

View an animation: Verify the connection configuration



You have completed Option 2 of this tutorial. You can now either complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 2.

Task 4 (*Optional*): Clean up

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

To terminate an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you created for this tutorial, and choose **Instance state**, **Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

To delete an RDS database using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Select the RDS database that you created for this tutorial, and choose **Actions**, **Delete**.
4. Enter **`delete me`** in the box, and then choose **Delete**.

Option 3: Manually connect an instance to an RDS database by creating security groups

The objective of Option 3 is to learn how to manually configure the connection between an EC2 instance and an RDS database by manually reproducing the configuration of the automatic connection feature.

Tasks

Before you begin

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 2 to create a new database.
- Permissions to call the following operations:
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSecurityGroup`
  - `ec2:CreateSubnet`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeRouteTables`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

Task 1 (*Optional*): Launch an EC2 instance

> **Note**
>
> Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database. The steps in this task configure the EC2 instance as follows:

- Instance name: **`tutorial-instance`**
- AMI: Amazon Linux 2
- Instance type: `t2.micro`
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

> **Important**
>
> In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the **EC2 Dashboard**, choose **Launch instance**.
3. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **`tutorial-instance-manual-1`**. While the instance name is not mandatory, the name will help you easily identify it.

4. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux**.

5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses `t2.micro`.

> **Note**
>
> Depending on when you created your account, you might be eligible to use Amazon EC2 under the Free Tier.
> If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type, or the **t3.micro** instance type in Regions where **t2.micro** is unavailable. Be aware that when you launch a **t3.micro** instance, it defaults to **Unlimited** mode, which might incur additional charges based on CPU usage. If an instance type can be used under the Free Tier, it is labeled **Free tier eligible**.
> If you created your AWS account on or after July 15, 2025, you can use **t3.micro**, **t3.small**, **t4g.micro**, **t4g.small**, **c7i-flex.large**, and **m7i-flex.large** instance types for 6 months or until your credits are used up.
> For more information, see Free Tier benefits before and after July 15, 2025.

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.

7. Under **Network settings**, do the following:

   a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

      If you have made changes to your default VPC or subnets, check the following:

      i. The instance must be in the same VPC as the RDS database. By default you have only one VPC.

      ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.

      iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.

b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

   To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** checkbox, choose **My IP**.

c. To allow traffic from the internet to your instance, select the following checkboxes:

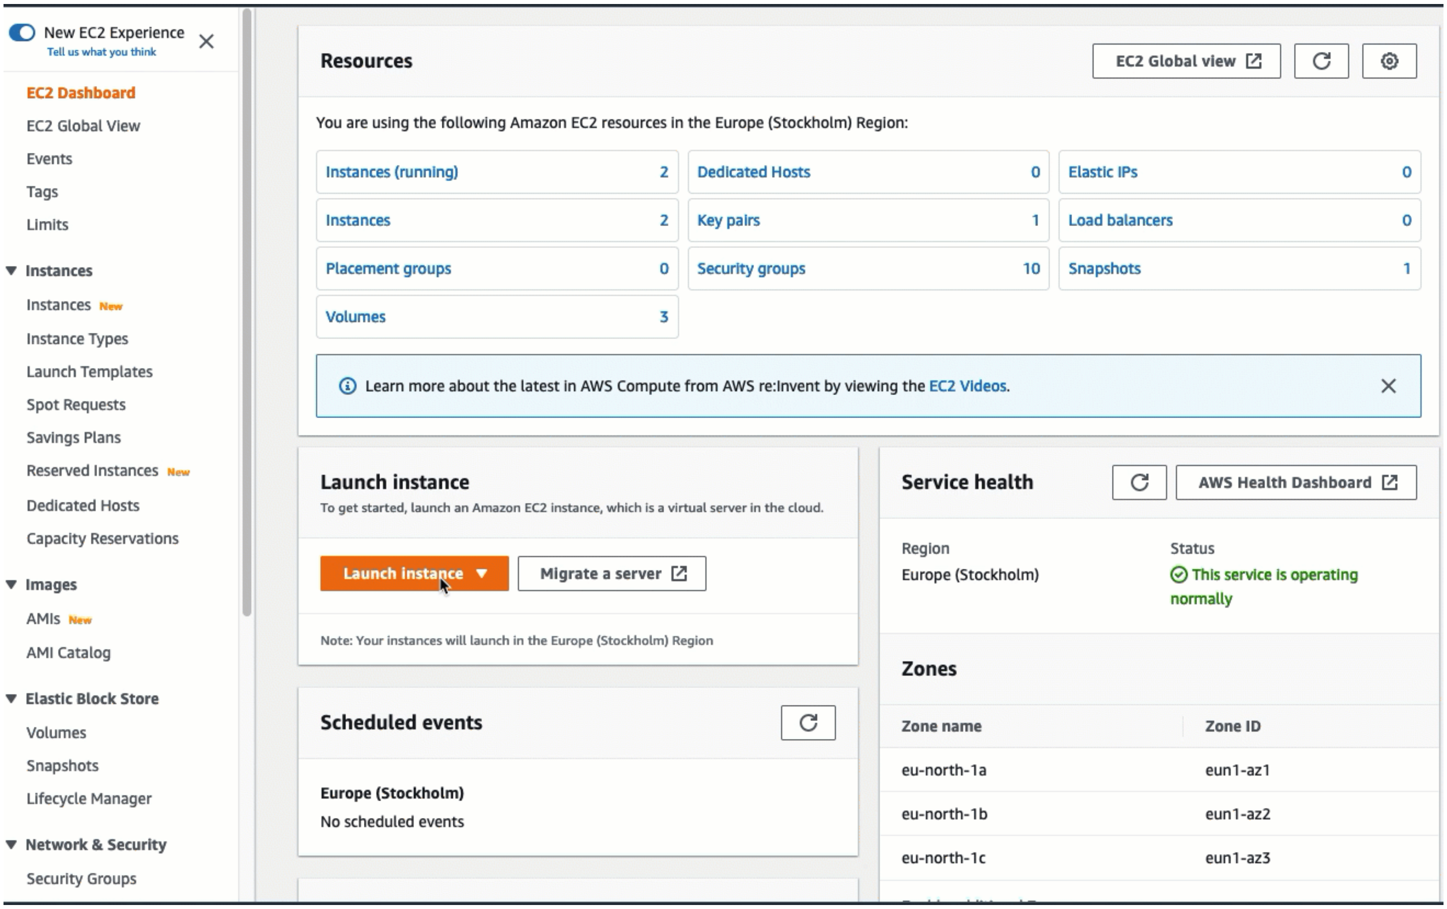
   - **Allow HTTPs traffic from the internet**
   - **Allow HTTP traffic from the internet**

8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.
9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a `pending` state, and will then go into the `running` state.

   If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

For more information about launching an instance, see Launch an EC2 instance using the launch instance wizard in the console.

View an animation: Launch an EC2 instance



Task 2 (*Optional*): Create an RDS database

> **Note**
>
> Creating an RDS database is not the focus of this part of the tutorial. If you already have an RDS database and would like to use it for this tutorial, you can skip this task.

The objective of this task is to create an RDS database. You'll use this instance in Task 3 when you connect it to your EC2 instance. The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **`tutorial-database-manual`**
- DB instance class: `db.t3.micro`

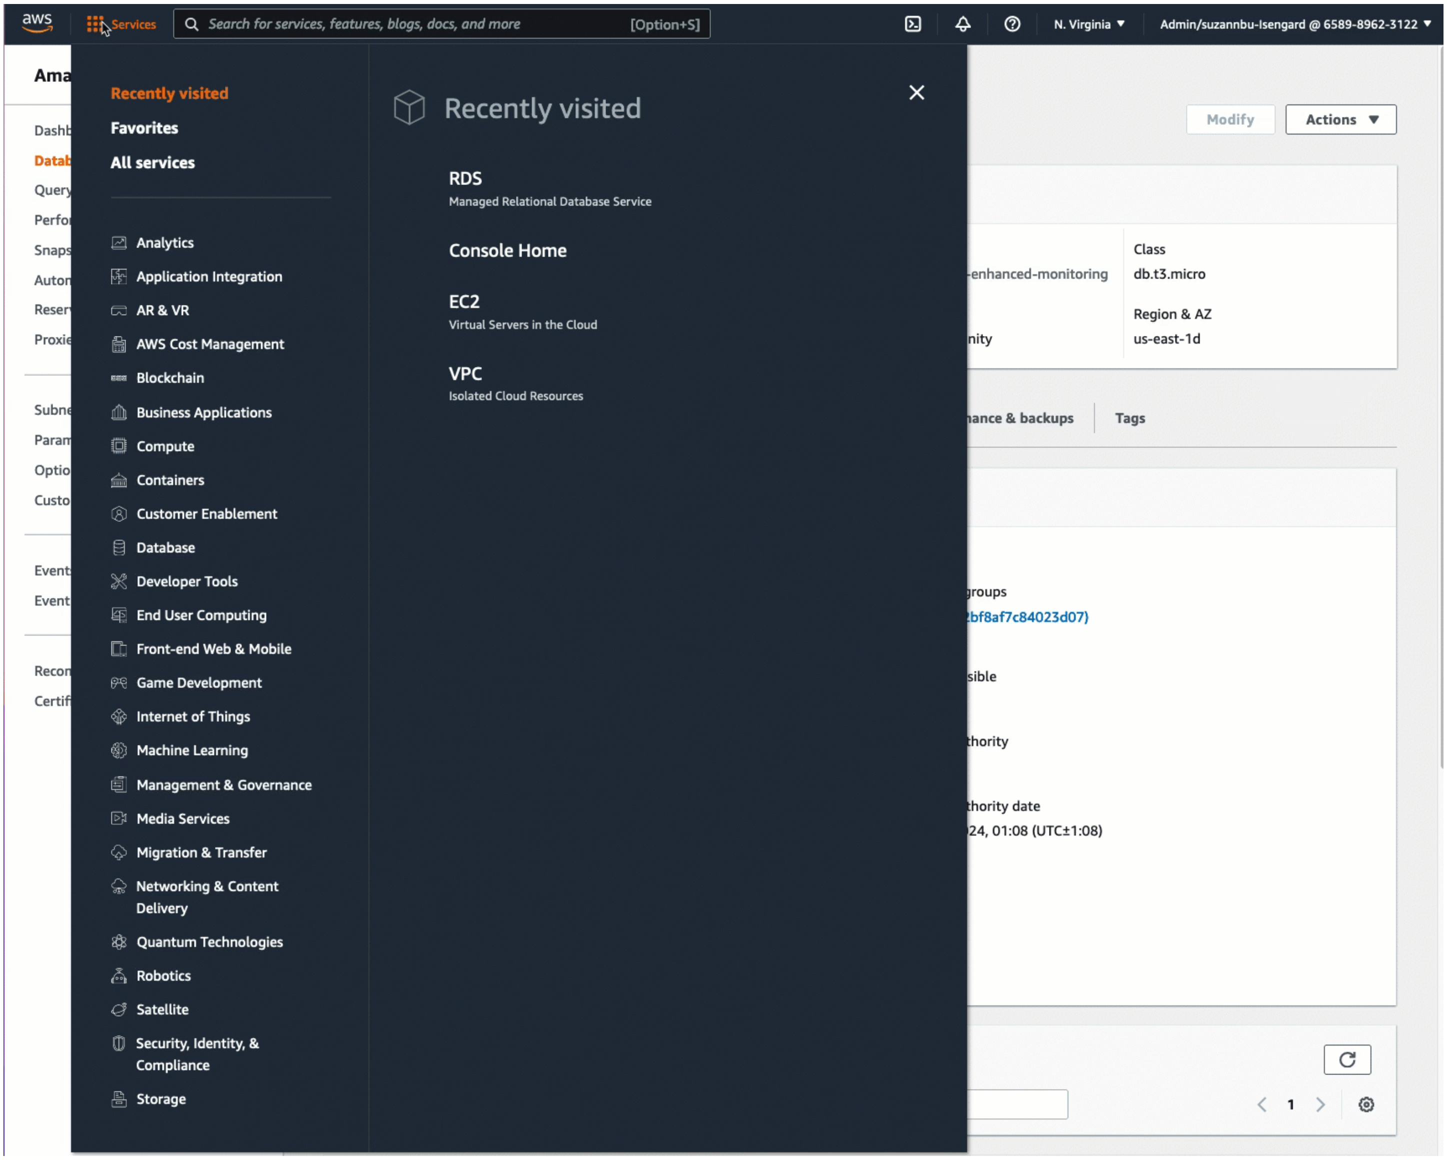
> **Important**
>
> In a production environment, you should configure your instance to meet your specific needs.

To create a MySQL DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the DB instance must be in the same Region.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, choose **Easy create**. When you choose this option, the automatic connection feature to automatically configure the connection is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier** enter a name for the RDS database. For this tutorial, enter **`tutorial-database-manual`**.
8. For **Master username**, leave the default name, which is **`admin`**.
9. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
10. Choose **Create database**.

    On the **Databases** screen, the **Status** of the new DB instance is **Creating** until the DB instance is ready to use. When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

View an animation: Create a DB instance



Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances

The objective of this task is to reproduce the connection configuration of the automatic connection feature by performing the following manually: You create two new security groups, and then add a security group each to the EC2 instance and the RDS database.

To create two new security groups and assign one each to the EC2 instance and RDS database

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. First create the security group to add to the EC2 instance, as follows:

a. In the navigation pane, choose **Security Groups**.

b. Choose **Create security group**.

c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter **`ec2-rds-manual-configuration`**.

d. For **Description**, enter a brief description. For this tutorial, enter **`EC2 instance security group to allow EC2 instance to securely connect to RDS database`**.

e. Choose **Create security group**. You'll come back to this security group to add an outbound rule after you've created the RDS database security group.

3. Now, create the security group to add to the RDS database, as follows:

   a. In the navigation pane, choose **Security Groups**.

   b. Choose **Create security group**.

   c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter **`rds-ec2-manual-configuration`**.

   d. For **Description**, enter a brief description. For this tutorial, enter **`RDS database security group to allow EC2 instance to securely connect to RDS database`**.

   e. Under **Inbound rules**, choose **Add rule**, and do the following:

      i. For **Type**, choose **MYSQL/Aurora**.

      ii. For **Source**, choose the EC2 instance security group **ec2-rds-manual-configuration** that you created in Step 2 of this procedure.

   f. Choose **Create security group**.

4. Edit the EC2 instance security group to add an outbound rule, as follows:

   a. In the navigation pane, choose **Security Groups**.

   b. Select the EC2 instance security group (you named it **`ec2-rds-manual-configuration`**), and choose the **Outbound rules** tab.

   c. Choose **Edit outbound rules**.

   d. Choose **Add rule**, and do the following:

      i. For **Type**, choose **MYSQL/Aurora**.

    ii. For **Destination**, choose the RDS database security group **rds-ec2-manual-configuration** that you created in Step 3 of this procedure.

    iii. Choose **Save rules**.

5. Add the EC2 instance security group to the EC2 instance as follows:

    a. In the navigation pane, choose **Instances**.

    b. Select your EC2 instance, and choose **Actions**, **Security**, **Change security groups**.

    c. Under **Associated security groups**, choose the **Select security groups** field, choose **ec2-rds-manual-configuration** that you created earlier, and then choose **Add security group**.

    d. Choose **Save**.

6. Add the RDS database security group to the RDS database as follows:

    a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

    b. In the navigation pane, choose **Databases** and select your database.

    c. Choose **Modify**.

    d. Under **Connectivity**, for **Security group**, choose **rds-ec2-manual-configuration** that you created earlier, and then choose **Continue**.

    e. Under **Scheduling of modifications**, choose **Apply immediately**.

    f. Choose **Modify DB instance**.

    You have now completed the manual steps that mimic the automatic steps that occur when you use the automatic connection feature.

You have completed Option 3 of this tutorial. If you've completed Options 1, 2, and 3, and you no longer need the resources that were created in this tutorial, you should delete them to prevent incurring unnecessary costs. For more information, see Task 4 (*Optional*): Clean up.

Task 4 (*Optional*): Clean up

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

To terminate an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you created for this tutorial, and choose **Instance state**, **Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

To delete an RDS database using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Select the RDS database that you created for this tutorial, and choose **Actions**, **Delete**.
4. Enter **`delete me`** in the box, and then choose **Delete**.

EC2 Fleet and Spot Fleet

EC2 Fleet and Spot Fleet are designed to be a useful way to launch a fleet of tens, hundreds, or thousands of Amazon EC2 instances in a single operation. Each instance in a fleet is either configured by a launch template or a set of launch parameters that you configure manually at launch.

Topics

Features and benefits

Fleets provide the following features and benefits, enabling you to maximize cost savings and optimize availability and performance when running applications on multiple EC2 instances.

Multiple instance types

A fleet can launch multiple instance types, ensuring it isn't dependent on the availability of any single instance type. This increases the overall availability of instances in your fleet.

Distributing instances across Availability Zones

A fleet can launch into multiple Availability Zones, enabling you to reduce costs and improve availability. If your fleet includes Spot Instances, the fleet automatically selects Availability Zones based on your preferences regarding price and interruptions.

Multiple purchasing options

A fleet can launch multiple purchase options (Spot and On-Demand Instances), allowing you to optimize costs through Spot Instance usage. You can also take advantage of Reserved Instance and Savings Plans discounts by using them in conjunction with On-Demand Instances in the fleet.

Automated replacement of Spot Instances

If your fleet includes Spot Instances, it can automatically request replacement Spot capacity if your Spot Instances are interrupted. Through Capacity Rebalancing, a fleet can also monitor and proactively replace your Spot Instances that are at an elevated risk of interruption.

Reserve On-Demand capacity

A fleet can use an On-Demand Capacity Reservation to reserve On-Demand capacity. A fleet can also include Capacity Blocks for ML, allowing you to reserve GPU instances on a future date to support short duration machine learning (ML) workloads.

Which is the best fleet method to use?

As a general best practice, we recommend launching fleets of Spot and On-Demand Instances with Amazon EC2 Auto Scaling because it provides additional features you can use to manage your fleet. The list of additional features includes automatic health check replacements for both Spot and On-Demand Instances, application-based health checks, and an integration with Elastic Load Balancing to ensure an even distribution of application traffic to your healthy instances. You can also use Auto Scaling groups when you use AWS services such as Amazon ECS, Amazon EKS (self-managed node groups), and Amazon VPC Lattice. For more information, see the Amazon EC2 Auto Scaling User Guide.

If you can't use Amazon EC2 Auto Scaling, then you might consider using EC2 Fleet or Spot Fleet. EC2 Fleet and Spot Fleet offer the same core functionality. However, EC2 Fleet is only available using a command line and does not provide console support. Spot Fleet provides console support, but is based on a legacy API with no planned investment.

Use the following table to determine which fleet method to use.

Fleet method	When to use?	Use case
[Amazon EC2 Auto Scaling]()	• You need multiple instances with either a single configuration or a mixed configuration. • You want to automate the lifecycle management of your instances.	Create an Auto Scaling group that manages the lifecycle of your instances while maintaini ng the desired number of instances. Supports horizontal scaling (adding more instances) between specified minimum and maximum limits.
[EC2 Fleet]()	• You need multiple instances with either a single configuration or a mixed configuration. • You want to self-manage your instance lifecycle. • If you don't need auto scaling, we recommend that you use an `instant` type EC2 Fleet.	Create an `instant` fleet of both On-Demand Instances and Spot Instances in a single operation, with multiple launch specifications that vary by instance type, AMI, Availability Zone, or subnet. The Spot Instance allocation strategy defaults to `lowest-price` per unit, but we recommend changing it to `price-capacity-optimized`.
[Spot Fleet]()	• We strongly discourage using Spot Fleet because it is based on a legacy API with no planned investmen t. • If you want to manage your instance lifecycle, rather use EC2 Fleet. • If you don't want to manage your instance	Use Spot Fleet only if you need console support for a use case for when you would use EC2 Fleet.

Fleet method	When to use?	Use case
	lifecycle, rather use an Auto Scaling group.	

Configuration options for your EC2 Fleet or Spot Fleet

When planning your EC2 Fleet or Spot Fleet, we recommend that you consider the following options when deciding how to configure your fleet.

Configuration option	Question	Documentation
Fleet request type	Do you want a fleet that submits a one-time request for the desired target capacity, or a fleet that maintains target capacity over time?	EC2 Fleet and Spot Fleet request types
Spot Instances	Do you plan to include Spot Instances in your fleet? Review the Spot best practices and use them when you plan your fleet so that you can provision the instances at the lowest possible price.	Best practices for Amazon EC2 Spot
Spending limit for your fleet	Do you want to limit how much you'll pay for your fleet per hour?	Set a spending limit for your EC2 Fleet or Spot Fleet
Instance types and attribute-based instance type selection	Do you want to specify the instance types in your fleet, or let Amazon EC2 select the instance types that meet your application requirements?	Specify attributes for instance type selection for EC2 Fleet or Spot Fleet

Configuration option	Question	Documentation
Instance weighting	Do you want to assign weights to each instance type to represent their compute capacity and performance, so that Amazon EC2 can select any combination of available instance types to fulfil your desired target capacity?	Use instance weighting to manage cost and performance of your EC2 Fleet or Spot Fleet
Allocation strategies	Do you want to decide whether to optimize for available capacity, price, or instance types to use for the Spot Instances and On-Demand Instances in your fleet?	Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity
Capacity Rebalancing	Do you want your fleet to automatically replace at-risk Spot Instances?	Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances
On-Demand Capacity Reservation	Do you want to reserve capacity for the On-Demand Instances in your fleet?	Use Capacity Reservations to reserve On-Demand capacity in EC2 Fleet

EC2 Fleet and Spot Fleet request types

The request type for an EC2 Fleet or Spot Fleet determines whether the request is synchronous or asynchronous, and whether it is a one-time request for the desired target capacity or an ongoing effort to maintain the capacity over time. When configuring your fleet, you must specify the request type.

Both EC2 Fleet and Spot Fleet offer two request types: `request` and `maintain`. In addition, EC2 Fleet offers a third request type called `instant`.

Fleet request types

`instant` (EC2 Fleet only)

If you configure the request type as `instant`, EC2 Fleet places a synchronous one-time request for your desired capacity. In the API response, it returns the instances that launched and provides errors for those instances that could not be launched. For more information, see Configure an EC2 Fleet of type instant.

`request`

If you configure the request type as `request`, the fleet places an asynchronous one-time request for your desired capacity. If capacity diminishes due to Spot interruptions, the fleet does not attempt to replenish Spot Instances, nor does it submit requests in alternative Spot capacity pools if capacity is unavailable. When creating a Spot Fleet of type `request` using the console, clear the **Maintain target capacity** checkbox.

`maintain` (default)

If you configure the request type as `maintain`, the fleet places an asynchronous request for your desired capacity, and maintains it by automatically replenishing any interrupted Spot Instances. When creating a Spot Fleet of type `maintain` using the console, select the **Maintain target capacity** checkbox

Configure an EC2 Fleet of type instant

The EC2 Fleet of type *instant* is a synchronous one-time request that makes only one attempt to launch your desired capacity. The API response lists the instances that launched, along with errors for those instances that could not be launched. There are several benefits to using an EC2 Fleet of type *instant*, which are described in this article. Example configurations are provided at the end of the article.

For workloads that need a launch-only API to launch EC2 instances, you can use the RunInstances API. However, with RunInstances, you can only launch On-Demand Instances or Spot Instances, but not both in the same request. Furthermore, when you use RunInstances to launch Spot Instances, your Spot Instance request is limited to one instance type and one Availability Zone. This targets a single Spot capacity pool (a set of unused instances with the same instance type and Availability Zone). If the Spot capacity pool does not have sufficient Spot Instance capacity for your request, the RunInstances call fails.

Instead of using RunInstances to launch Spot Instances, we recommend that you rather use the CreateFleet API with the `type` parameter set to `instant` for the following benefits:

- **Launch On-Demand Instances and Spot Instances in one request.** An EC2 Fleet can launch On-Demand Instances, Spot Instances, or both. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price.
- **Increase the availability of Spot Instances.** By using an EC2 Fleet of type `instant`, you can launch Spot Instances following [Spot best practices]() with the resulting benefits:
  - **Spot best practice: Be flexible about instance types and Availability Zones.**

    Benefit: By specifying several instance types and Availability Zones, you increase the number of Spot capacity pools. This gives the Spot service a better chance of finding and allocating your desired Spot compute capacity. A good rule of thumb is to be flexible across at least 10 instance types for each workload and make sure that all Availability Zones are configured for use in your VPC.
  - **Spot best practice: Use the price-capacity-optimized allocation strategy.**

    Benefit: The `price-capacity-optimized` allocation strategy identifies instances from the most-available Spot capacity pools, and then automatically provisions instances from the lowest priced of these pools. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances will be interrupted when Amazon EC2 needs the capacity back.
- **Get access to a wider set of capabilities.** For workloads that need a launch-only API, and where you prefer to manage the lifecycle of your instance rather than let EC2 Fleet manage it for you, use the EC2 Fleet of type `instant` instead of the [RunInstances]() API. EC2 Fleet provides a wider set of capabilities than RunInstances, as demonstrated in the following examples. For all other workloads, you should use Amazon EC2 Auto Scaling because it supplies a more comprehensive feature set for a wide variety of workloads, like ELB-backed applications, containerized workloads, and queue processing jobs.

You can use EC2 Fleet of type *instant* to launch instances into Capacity Blocks. For more information, see [Tutorial: Configure your EC2 Fleet to launch instances into Capacity Blocks]().

AWS services like Amazon EC2 Auto Scaling and Amazon EMR use EC2 Fleet of type *instant* to launch EC2 instances.

Prerequisites for EC2 Fleet of type instant

For the prerequisites for creating an EC2 Fleet, see EC2 Fleet prerequisites.

How instant EC2 Fleet works

When working with an EC2 Fleet of type `instant`, the sequence of events is as follows:

1. **Configure:** Configure the CreateFleet request type as `instant`. For more information, see Create an EC2 Fleet. Note that after you make the API call, you can't modify it.
2. **Request:** When you make the API call, Amazon EC2 places a synchronous one-time request for your desired capacity.
3. **Response:** The API response lists the instances that launched, along with errors for those instances that could not be launched.
4. **Describe:** You can describe your EC2 Fleet, list the instances associated with your EC2 Fleet, and view the history of your EC2 Fleet.
5. **Terminate instances:** You can terminate the instances at any time.
6. **Delete fleet request:** The fleet request can be deleted either manually or automatically:
   - Manual: You can delete the fleet request after your instances launch.

     Note that a deleted `instant` fleet with running instances is not supported. When you delete an `instant` fleet, Amazon EC2 automatically terminates all its instances. For fleets with more than 1000 instances, the deletion request might fail. If your fleet has more than 1000 instances, first terminate most of the instances manually, leaving 1000 or fewer. Then delete the fleet, and the remaining instances will be terminated automatically.
   - Automatic: Amazon EC2 deletes the fleet request some time after either:
     - All the instances are terminated.
     - The fleet fails to launch any instances.

Examples

The following examples show how to use EC2 Fleet of type `instant` for different use cases. For more information about using the EC2 CreateFleet API parameters, see CreateFleet in the *Amazon EC2 API Reference*.

Examples

- Example 1: Launch Spot Instances with the capacity-optimized allocation strategy

Example 1: Launch Spot Instances with the capacity-optimized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type `instant`: a launch template, target capacity, default purchasing option, and launch template overrides.

- The launch template is identified by its launch template name and version number.
- The 12 launch template overrides specify 4 different instance types and 3 different subnets, each in a separate Availability Zone. Each instance type and subnet combination defines a Spot capacity pool, resulting in 12 Spot capacity pools.
- The target capacity for the fleet is 20 instances.
- The default purchasing option is `spot`, which results in the fleet attempting to launch 20 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```

            },
            {
               "InstanceType":"m5.large",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"m5.large",
               "SubnetId":"subnet-49e41922"
            },
            {
               "InstanceType":"m5d.large",
               "SubnetId":"subnet-fae8c380"
            },
```

```
            {
               "InstanceType":"m5d.large",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"m5d.large",
               "SubnetId":"subnet-49e41922"
            }
         ]
      }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

Example 2: Launch a single Spot Instance with the capacity-optimized allocation strategy

You can optimally launch one Spot Instance at a time by making multiple EC2 Fleet API calls of type `instant`, by setting the TotalTargetCapacity to 1.

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch template overrides have 4 different instance types and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 1 instance, and the default purchasing option is spot, which results in the fleet attempting to launch a Spot Instance from one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy, to launch a Spot Instance from the most-available capacity pool.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification":{
            "LaunchTemplateName":"ec2-fleet-lt1",
            "Version":"$Latest"
         },
```

```

```

Example 3: Launch Spot Instances using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight based on how many units of the workload can run on the instance assuming a unit of the workload requires a 15 GB of memory and 4 vCPUs. For example an m5.xlarge (4 vCPUs and 16 GB of memory) can run one unit and is weighted 1, m5.2xlarge (8 vCPUs and 32 GB of memory) can run 2 units and is weighted 2, and so on. The total target capacity is set to 40 units. The default purchasing option is spot, and the allocation strategy is capacity-optimized, which results in either 40 m5.xlarge (40 divided by 1), 20 m5.2xlarge (40 divided by 2), 10 m5.4xlarge (40 divided by 4), 5 m5.8xlarge (40 divided by 8), or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

For more information, see Use instance weighting to manage cost and performance of your EC2 Fleet or Spot Fleet.

            },
            {
                "InstanceType":"m5d.4xlarge",
                "SubnetId":"subnet-49e41922"
            }
        ]
      }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

Example 5: Launch Spot Instances of single instance type within single Availability zone

You can configure a fleet to launch all instances of the same instance type and in a single Availability Zone by setting the SpotOptions SingleInstanceType to true and SingleAvailabilityZone to true.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity is 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances of the same instance type all in a single AZ from the Spot Instance pool with optimal capacity using the launch specifications.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "SingleInstanceType": true,
        "SingleAvailabilityZone": true
    },
    "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification":{
            "LaunchTemplateName":"ec2-fleet-lt1",
            "Version":"$Latest"
```

```
         },
         "Overrides":[
            {
               "InstanceType":"c5.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"c5.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"c5.4xlarge",
               "SubnetId":"subnet-49e41922"
            },
            {
               "InstanceType":"c5d.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"c5d.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"c5d.4xlarge",
               "SubnetId":"subnet-49e41922"
            },
            {
               "InstanceType":"m5.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"m5.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"m5.4xlarge",
               "SubnetId":"subnet-49e41922"
            },
            {
               "InstanceType":"m5d.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"m5d.4xlarge",
```

```
                "SubnetId":"subnet-e7188bab"
             },
             {
                "InstanceType":"m5d.4xlarge",
                "SubnetId":"subnet-49e41922"
             }
          ]
       }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

Example 6: Launch Spot Instances only if minimum target capacity can be launched

You can configure a fleet to launch instances only if the minimum target capacity can be launched by setting the Spot options MinTargetCapacity to the minimum target capacity you want to launch together.

When specifying MinTargetCapacity, you must specify at least one of these parameters: SingleInstanceType or SingleAvailabilityZone. In this example, SingleInstanceType is specified, so that all 20 instances must use the same instance type.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity and the minimum target capacity are both set to 20 instances, the default purchasing option is spot, and the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances from the Spot capacity pool with optimal capacity using the launch template overrides, only if it can launch all 20 instances at the same time.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "SingleInstanceType": true,
        "MinTargetCapacity": 20
    },
    "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification":{
```

```
            "LaunchTemplateName":"ec2-fleet-lt1",
            "Version":"$Latest"
         },
         "Overrides":[
            {
               "InstanceType":"c5.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"c5.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"c5.4xlarge",
               "SubnetId":"subnet-49e41922"
            },
            {
               "InstanceType":"c5d.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"c5d.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"c5d.4xlarge",
               "SubnetId":"subnet-49e41922"
            },
            {
               "InstanceType":"m5.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
            {
               "InstanceType":"m5.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"m5.4xlarge",
               "SubnetId":"subnet-49e41922"

            {
               "InstanceType":"m5d.4xlarge",
               "SubnetId":"subnet-fae8c380"
            },
```

```
            {
               "InstanceType":"m5d.4xlarge",
               "SubnetId":"subnet-e7188bab"
            },
            {
               "InstanceType":"m5d.4xlarge",
               "SubnetId":"subnet-49e41922"
            }
         ]
      }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

Example 7: Launch Spot Instances only if minimum target capacity can be launched of same Instance Type in a single Availability Zone

You can configure a fleet to launch instances only if the minimum target capacity can be launched with a single instance type in a single Availability Zone by setting the Spot options MinTargetCapacity to the minimum target capacity you want to launch together along with SingleInstanceType and SingleAvailabilityZone options.

The 12 launch specifications which override the launch template, have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity and the minimum target capacity are both set to 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized, the SingleInstanceType is true and SingleAvailabilityZone is true. The EC2 Fleet launches 20 Spot Instances of the same Instance type all in a single AZ from the Spot capacity pool with optimal capacity using the launch specifications, only if it can launch all 20 instances at the same time.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "SingleInstanceType": true,
        "SingleAvailabilityZone": true,
        "MinTargetCapacity": 20
    },
    "LaunchTemplateConfigs": [
```

```
        {
            "LaunchTemplateSpecification":{
                "LaunchTemplateName":"ec2-fleet-lt1",
                "Version":"$Latest"
            },
            "Overrides":[
                {
                    "InstanceType":"c5.4xlarge",
                    "SubnetId":"subnet-fae8c380"
                },
                {
                    "InstanceType":"c5.4xlarge",
                    "SubnetId":"subnet-e7188bab"
                },
                {
                    "InstanceType":"c5.4xlarge",
                    "SubnetId":"subnet-49e41922"
                },
                {
                    "InstanceType":"c5d.4xlarge",
                    "SubnetId":"subnet-fae8c380"
                },
                {
                    "InstanceType":"c5d.4xlarge",
                    "SubnetId":"subnet-e7188bab"

```

Example 8: Launch instances with multiple Launch Templates

You can configure a fleet to launch instances with different launch specifications for different instance types or a group of instance types, by specifying multiple launch templates. In this example we want have different EBS volume sizes for different instance types and we have that configured in the launch templates ec2-fleet-lt-4xl, ec2-fleet-lt-9xl and ec2-fleet-lt-18xl.

In this example, we are using 3 different launch templates for the 3 instance types based on their size. The launch specification overrides on all the launch templates use instance weights based on the vCPUs on the instance type. The total target capacity is 144 units, the default purchasing option is spot, and the Spot allocation strategy is capacity-optimized. The EC2 Fleet can either launch 9 c5n.4xlarge (144 divided by 16) using the launch template ec2-fleet-4xl or 4 c5n.9xlarge (144 divided by 36) using the launch template ec2-fleet-9xl, or 2 c5n.18xlarge (144 divided by 72) using the launch template ec2-fleet-18xl, or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

        "TotalTargetCapacity": 144,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

Example 9: Launch Spot Instance with a base of On-Demand Instances

The following example specifies the total target capacity of 20 instances for the fleet, and a target capacity of 5 On-Demand Instances. The default purchasing option is spot. The fleet launches 5 On-Demand Instance as specified, but needs to launch 15 more instances to fulfill the total target capacity. The purchasing option for the difference is calculated as TotalTargetCapacity – OnDemandTargetCapacity = DefaultTargetCapacityType, which results in the fleet launching 15 Spot Instances form one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy.

    },
    "Type": "instant"
}
```

Example 10: Launch Spot Instances using capacity-optimized allocation strategy with a base of On-Demand Instances using Capacity Reservations and the prioritized allocation strategy

You can configure a fleet to use On-Demand Capacity Reservations first when launching a base of On-Demand Instances with the default target capacity type as spot by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if multiple instance pools have unused Capacity Reservations, the chosen On-Demand allocation strategy is applied. In this example, the On-Demand allocation strategy is prioritized.

In this example, there are 6 available unused Capacity Reservations. This is less than the fleet's target On-Demand capacity of 10 On-Demand Instances.

The account has the following 6 unused Capacity Reservations in 2 pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 3,
    "InstanceMatchCriteria": "open",
    "State": "active"
}

{
    "CapacityReservationId": "cr-222",
    "InstanceType": "c5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 3,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is prioritized, and the usage strategy for Capacity Reservations is use-capacity-reservations-first. The Spot allocation strategy is capacity-optimized. The total target capacity is 20, the On-Demand target capacity is 10, and the default target capacity type is spot.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "OnDemandOptions":{
       "CapacityReservationOptions": {
         "UsageStrategy": "use-capacity-reservations-first"
       },
       "AllocationStrategy":"prioritized"
    },
    "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification":{
            "LaunchTemplateName":"ec2-fleet-lt1",
            "Version":"$Latest"
         },
         "Overrides":[

            {
               "InstanceType":"c5d.large",
               "SubnetId":"subnet-fae8c380",
               "Priority": 4.0
            },
            {
               "InstanceType":"c5d.large",
               "SubnetId":"subnet-e7188bab",
               "Priority": 5.0
            },
            {
               "InstanceType":"c5d.large",
               "SubnetId":"subnet-49e41922",
               "Priority": 6.0
            },
            {
               "InstanceType":"m5.large",
               "SubnetId":"subnet-fae8c380",
               "Priority": 7.0
            },
            {
               "InstanceType":"m5.large",
               "SubnetId":"subnet-e7188bab",
               "Priority": 8.0
            },
            {
               "InstanceType":"m5.large",
               "SubnetId":"subnet-49e41922",
               "Priority": 9.0
```

```
            },
            {
               "InstanceType":"m5d.large",
               "SubnetId":"subnet-fae8c380",
               "Priority": 10.0
            },
            {
               "InstanceType":"m5d.large",
               "SubnetId":"subnet-e7188bab",
               "Priority": 11.0
            },
            {
               "InstanceType":"m5d.large",
               "SubnetId":"subnet-49e41922",
               "Priority": 12.0
            }
         ]
      }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "OnDemandTargetCapacity": 10,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

After you create the instant fleet using the preceding configuration, the following 20 instances are launched to meet the target capacity:

- 7 c5.large On-Demand Instances in us-east-1a – c5.large in us-east-1a is prioritized first, and there are 3 available unused c5.large Capacity Reservations. The Capacity Reservations are used first to launch 3 On-Demand Instances plus 4 additional On-Demand Instances are launched according to the On-Demand allocation strategy, which is prioritized in this example.
- 3 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is prioritized second, and there are 3 available unused c3.large Capacity Reservations.
- 10 Spot Instances from one of the 12 Spot capacity pools that has the optimal capacity according to the capacity-optimized allocation strategy.

After the fleet is launched, you can run [describe-capacity-reservations](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-capacity-reservations.html) to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the c5.large and m5.large Capacity Reservations were used.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "AvailableInstanceCount": 0
}

{
    "CapacityReservationId": "cr-222",
    "InstanceType": "c5.large",
    "AvailableInstanceCount": 0
}
```

Example 11: Launch Spot Instances using capacity-optimized-prioritized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch specifications which override the launch template have 4 different instance types with a priority assigned, and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 20 instances, and the default purchasing option is spot, which results in the fleet attempting to launch 20 Spot Instances from one of the 12 Spot capacity pools based on the capacity-optimized-prioritized allocation strategy, which implements priorities on a best-effort basis, but optimizes for capacity first.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized-prioritized"
    },
    "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification":{

                "SubnetId":"subnet-e7188bab",
                "Priority": 4.0
             },
             {
                "InstanceType":"m5d.large",
                "SubnetId":"subnet-49e41922",
                "Priority": 4.0
             }
          ]
       }
     ],
     "TargetCapacitySpecification": {
         "TotalTargetCapacity": 20,
         "DefaultTargetCapacityType": "spot"
     },
     "Type": "instant"
}
```

Example 12: Specify a Systems Manager parameter instead of an AMI ID

The following example uses a launch template to specify the configuration for the instances in the fleet. In this example, for `ImageId`, instead of specifying an AMI ID, the AMI is referenced with a System Manager parameter. On instance launch, the Systems Manager parameter will resolve to an AMI ID.

In this example, the Systems Manager parameter is specified in a valid format: `resolve:ssm:golden-ami`. There are other valid formats for the Systems Manager parameter. For more information, see [Use a Systems Manager parameter instead of an AMI ID](#).

> **Note**
>
> The fleet type must be of type `instant`. Other fleet types do not support specifying a System Manager parameter instead of an AMI ID.

```
{
```

```
    "LaunchTemplateData": {
        "ImageId": "resolve:ssm:golden-ami",
        "InstanceType": "m5.4xlarge",
        "TagSpecifications": [{
            "ResourceType": "instance",
            "Tags": [{
                "Key": "Name",
                "Value": "webserver"
            }]
        }]
    }
}
```

Set a spending limit for your EC2 Fleet or Spot Fleet

You can set a limit on how much you're willing to spend per hour on your EC2 Fleet or Spot Fleet. When your spending limit is reached, the fleet stops launching instances, even if the target capacity hasn't been reached.

There are separate spending limits for On-Demand Instances and Spot Instances.

To configure a spending limit for On-Demand Instances and Spot Instances in your EC2 Fleet

Use the create-fleet command and the following parameters:

- For On-Demand Instances: In the `OnDemandOptions` structure, specify your spending limit in the `MaxTotalPrice` field.
- For Spot Instances: In the `SpotOptions` structure, specify your spending limit in the `MaxTotalPrice` field.

To configure a spending limit for On-Demand Instances and Spot Instances in your Spot Fleet

You can use the Amazon EC2 console or the AWS CLI to configure your spending limit.

(Console) When creating the Spot Fleet, select the **Set maximum cost for Spot Instances** checkbox, and then enter a value for **Set your max cost (per hour)**. For more information, see step 6.e. in Create a Spot Fleet request using defined parameters.

(AWS CLI) Use the request-spot-fleet command and the following parameters:

- For On-Demand Instances: Specify your spending limit in the `OnDemandMaxTotalPrice` field.

- For Spot Instances: Specify your spending limit in the `SpotMaxTotalPrice` field.

Examples

The following examples show two different scenarios. In the first example, the fleet stops launching On-Demand Instances when it has met the target capacity set for On-Demand Instances (`OnDemandTargetCapacity`). In the second example, the fleet stops launching On-Demand Instances when it has reached the maximum amount you're willing to pay per hour for On-Demand Instances (`MaxTotalPrice`).

Example: Stop launching On-Demand Instances when target capacity is reached

Given a request for `m4.large` On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- `OnDemandTargetCapacity`: 10
- `MaxTotalPrice`: $1.50

The fleet launches 10 On-Demand Instances because the total of $1.00 (10 instances x $0.10) does not exceed the `MaxTotalPrice` of $1.50 for On-Demand Instances.

Example: Stop launching On-Demand Instances when maximum total price is reached

Given a request for `m4.large` On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- `OnDemandTargetCapacity`: 10
- `MaxTotalPrice`: $0.80

If the fleet launches the On-Demand target capacity (10 On-Demand Instances), the total cost per hour would be $1.00. This is more than the amount ($0.80) specified for `MaxTotalPrice` for On-Demand Instances. To prevent spending more than you're willing to pay, the fleet launches only 8 On-Demand Instances (below the On-Demand target capacity) because launching more would exceed the `MaxTotalPrice` for On-Demand Instances.

Burstable performance instances

If you launch your Spot Instances using a burstable performance instance type, and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in Standard mode to avoid paying higher costs. If you launch burstable performance Spot Instances in Unlimited mode and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see When to use unlimited mode versus fixed CPU.

Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use Unlimited mode for T2 Spot Instances, or use an instance type with dedicated CPU.

Specify attributes for instance type selection for EC2 Fleet or Spot Fleet

When you create an EC2 Fleet or Spot Fleet, you must specify one or more instance types for configuring the On-Demand Instances and Spot Instances in the fleet. As an alternative to manually specifying the instance types, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. This is known as *attribute-based instance type selection*. For example, you can specify the minimum and maximum number of vCPUs required for your instances, and the fleet will launch the instances using any available instance types that meet those vCPU requirements.

Attribute-based instance type selection is ideal for workloads and frameworks that can be flexible about what instance types they use, such as when running containers or web fleets, processing big data, and implementing continuous integration and deployment (CI/CD) tooling.

Benefits

Attribute-based instance type selection has the following benefits:

- **Easily use the right instance types** – With so many instance types available, finding the right instance types for your workload can be time consuming. When you specify instance attributes, the instance types will automatically have the required attributes for your workload.
- **Simplified configuration** – To manually specify multiple instance types for a fleet, you must create a separate launch template override for each instance type. But with attribute-based instance type selection, to provide multiple instance types, you need only specify the instance attributes in the launch template or in a launch template override.
- **Automatic use of new instance types** – When you specify instance attributes rather than instance types, your fleet can use newer generation instance types as they're released, "future proofing" the fleet's configuration.
- **Instance type flexibility** – When you specify instance attributes rather than instance types, the fleet can select from a wide range of instance types for launching Spot Instances, which adheres to the Spot best practice of instance type flexibility.

Topics

How attribute-based instance type selection works

To use attribute-based instance type selection in your fleet configuration, you replace the list of instance types with a list of instance attributes that your instances require. EC2 Fleet or Spot Fleet will launch instances on any available instance types that have the specified instance attributes.

Topics

- How EC2 Fleet or Spot Fleet uses attribute-based instance type selection when provisioning a fleet

Types of instance attributes

There are several instance attributes that you can specify to express your compute requirements, such as:

- **vCPU count** – The minimum and maximum number of vCPUs per instance.
- **Memory** – The minimum and maximum GiBs of memory per instance.
- **Local storage** – Whether to use EBS or instance store volumes for local storage.
- **Burstable performance** – Whether to use the T instance family, including T4g, T3a, T3, and T2 types.

For a description of each attribute and the default values, see InstanceRequirements in the *Amazon EC2 API Reference*.

Where to configure attribute-based instance type selection

Depending on whether you use the console or the AWS CLI, you can specify the instance attributes for attribute-based instance type selection as follows:

In the console, you can specify the instance attributes in the following fleet configuration components:

- In a launch template, and then reference the launch template in the fleet request
- (Spot Fleet only) In the fleet request

In the AWS CLI, you can specify the instance attributes in one or all of the following fleet configuration components:

- In a launch template, and then reference the launch template in the fleet request
- In a launch template override

  If you want a mix of instances that use different AMIs, you can specify instance attributes in multiple launch template overrides. For example, different instance types can use x86 and Arm-based processors.

- (Spot Fleet only) In a launch specification

How EC2 Fleet or Spot Fleet uses attribute-based instance type selection when provisioning a fleet

EC2 Fleet or Spot Fleet provisions a fleet in the following way:

- It identifies the instance types that have the specified attributes.
- It uses price protection to determine which instance types to exclude.
- It determines the capacity pools from which it will consider launching the instances based on the AWS Regions or Availability Zones that have matching instance types.
- It applies the specified allocation strategy to determine from which capacity pools to launch the instances.

  Note that attribute-based instance type selection does not pick the capacity pools from which to provision the fleet; that's the job of the allocation strategies.

  If you specify an allocation strategy, the fleet will launch instances according to the specified allocation strategy.

  - For Spot Instances, attribute-based instance type selection supports the **price capacity optimized**, **capacity optimized**, and **lowest price** allocation strategies. Note that we don't recommend the **lowest price** Spot allocation strategy because it has the highest risk of interruption for your Spot Instances.
  - For On-Demand Instances, attribute-based instance type selection supports the **lowest price** allocation strategy.
- If there is no capacity for the instance types with the specified instance attributes, no instances can be launched, and the fleet returns an error.

Price protection

Price protection is a feature that prevents your EC2 Fleet or Spot Fleet from using instance types that you would consider too expensive even if they happen to fit the attributes that you specified. To use price protection, you set a price threshold. Then, when Amazon EC2 selects instance types with your attributes, it excludes instance types priced above your threshold.

The way that Amazon EC2 calculates the price threshold is as follows:

- Amazon EC2 first identifies the lowest priced instance type from those that match your attributes.
- Amazon EC2 then takes the value (expressed as a percentage) that you specified for the price protection parameter and multiplies it with the price of the identified instance type. The result is the price that is used as the price threshold.

There are separate price thresholds for On-Demand Instances and Spot Instances.

When you create a fleet with attribute-based instance type selection, price protection is enabled by default. You can keep the default values, or you can specify your own.

You can also turn off price protection. To indicate no price protection threshold, specify a high percentage value, such as 999999.

Topics

How the lowest priced instance type is identified

Amazon EC2 determines the price to base the price threshold on by identifying the instance type with the lowest price from those that match your specified attributes. It does this in the following way:

- It first looks at the current generation C, M, or R instance types that match your attributes. If it finds any matches, it identifies the lowest priced instance type.
- If there is no match, it then looks at any current generation instance types that match your attributes. If it finds any matches, it identifies the lowest priced instance type.
- If there is no match, it then looks at any previous generation instance types that match your attributes, and identifies the lowest priced instance type.

On-Demand Instance price protection

The price protection threshold for On-Demand instance types is calculated *as a percentage higher* than the identified lowest priced On-Demand instance type

(`OnDemandMaxPricePercentageOverLowestPrice`). You specify the percentage higher that you're willing to pay. If you don't specify this parameter, then a default value of `20` is used to calculate a price protection threshold of 20% higher than the identified price.

For example, if the identified On-Demand instance price is `0.4271`, and you specify 25, then the price threshold is 25% more than `0.4271`. It is calculated as follows: `0.4271 * 1.25 = 0.533875`. The calculated price is the maximum you're willing to pay for On-Demand Instances, and, in this example, Amazon EC2 will exclude any On-Demand instance types that cost more than `0.533875`.

Spot Instance price protection

By default, Amazon EC2 will automatically apply optimal Spot Instance price protection to consistently select from a wide range of instance types. You can also manually set the price protection yourself. However, letting Amazon EC2 do it for you can improve the likelihood that your Spot capacity is fulfilled.

You can manually specify the price protection using one of the following options. If you manually set the price protection, we recommend using the first option.

- **A *percentage of* the identified lowest priced *On-Demand* instance type** [`MaxSpotPriceAsPercentageOfOptimalOnDemandPrice`]

  For example, if the identified On-Demand instance type price is `0.4271`, and you specify `60`, then the price threshold is 60% of `0.4271`. It is calculated as follows: `0.4271 * 0.60 = 0.25626`. The calculated price is the maximum you're willing to pay for Spot Instances, and, in this example, Amazon EC2 will exclude any Spot instance types that cost more than `0.25626`.
- **A *percentage higher than* the identified lowest priced *Spot* instance type** [`SpotMaxPricePercentageOverLowestPrice`]

  For example, if the identified Spot instance type price is `0.1808`, and you specify 25, then the price threshold is 25% more than `0.1808`. It is calculated as follows: `0.1808 * 1.25 = 0.226`. The calculated price is the maximum you're willing to pay for Spot Instances, and, in this example, Amazon EC2 will exclude any Spot instance types that cost more than `0.266`. We do not recommend using this parameter because Spot prices can fluctuate, and therefore your price protection threshold might also fluctuate.

Specify the price protection threshold

To specify the price protection threshold using the AWS CLI

While creating an EC2 Fleet or Spot Fleet using the AWS CLI, configure the fleet for attribute-based instance type selection, and then do the following:

- To specify the On-Demand Instance price protection threshold, in the JSON configuration file, in the `InstanceRequirements` structure, for `OnDemandMaxPricePercentageOverLowestPrice`, enter the price protection threshold as a percentage.
- To specify the Spot Instance price protection threshold, in the JSON configuration file, in the `InstanceRequirements` structure, specify *one* of the following parameters:
  - For `MaxSpotPriceAsPercentageOfOptimalOnDemandPrice`, enter the price protection threshold as a percentage.
  - For `SpotMaxPricePercentageOverLowestPrice`, enter the price protection threshold as a percentage.

For more information, see Create an EC2 Fleet with attribute-based instance type selection or Create a Spot Fleet with attribute-based instance type selection.

(Spot Fleet only) To specify the price protection threshold using the console

While creating a Spot Fleet in the console, configure the fleet for attribute-based instance type selection, and then do the following:

- To specify the On-Demand Instance price protection threshold, under **Additional instance attribute**, choose **On-demand price protection**, choose **Add attribute**, and then enter the price protection threshold as a percentage.
- To specify the Spot Instance price protection threshold, **Additional instance attribute**, choose **Spot price protection**, choose **Add attribute**, choose a base value on which to base your price, and then enter the price protection threshold as a percentage.

> **Note**
>
> When creating the fleet, if you set `TargetCapacityUnitType` to `vcpu` or `memory-mib`, the price protection threshold is applied based on the per-vCPU or per-memory price instead of the per-instance price.

Performance protection

Performance protection is a feature that ensures your EC2 Fleet or Spot Fleet uses instance types that are similar to or exceed a specified performance baseline. To use performance protection, you specify an instance family as a baseline reference. The capabilities of the specified instance family establish the lowest acceptable level of performance. When Amazon EC2 selects instance types for your fleet, it considers your specified attributes and the performance baseline. Instance types that fall below the performance baseline are automatically excluded from selection, even if they match your other specified attributes. This ensures that all selected instance types offer performance similar to or better than the baseline established by the specified instance family. Amazon EC2 uses this baseline to guide instance type selection, but there is no guarantee that the selected instance types will always exceed the baseline for every application.

Currently, this feature only supports CPU performance as a baseline performance factor. The CPU performance of the specified instance family's CPU processor serves as the performance baseline, ensuring that selected instance types are similar to or exceed this baseline. Instance families with the same CPU processors lead to the same filtering results, even if their network or disk performance differs. For example, specifying either `c6in` or `c6i` as the baseline reference would produce identical performance-based filtering results because both instance families use the same CPU processor.

Unsupported instance families

The following instance families are not supported for performance protection:

- `c1`
- `g3` | `g3s`
- `hpc7g`
- `m1` | `m2`
- `mac1` | `mac2` | `mac2-m1ultra` | `mac2-m2` | `mac2-m2pro`

- p3dn | p4d | p5
- t1
- u-12tb1 | u-18tb1 | u-24tb1 | u-3tb1 | u-6tb1 | u-9tb1 | u7i-12tb | u7in-16tb | u7in-24tb | u7in-32tb

If you enable performance protection by specifying a supported instance family, the returned instance types will exclude the above unsupported instance families.

If you specify an unsupported instance family as a value for baseline performance, the API returns an empty response for GetInstanceTypesFromInstanceRequirements and an exception for CreateFleet, RequestSpotFleet, ModifyFleet, and ModifySpotFleetRequest.

Example: Set a CPU performance baseline

In the following example, the instance requirement is to launch with instance types that have CPU cores that are as performant as the `c6i` instance family. This will filter out instance types with less performant CPU processors, even if they meet your other specified instance requirements such as the number of vCPUs. For example, if your specified instance attributes include 4 vCPUs and 16 GB of memory, an instance type with these attributes but with lower CPU performance than `c6i` will be excluded from selection.

```
"BaselinePerformanceFactors": {
        "Cpu": {
            "References": [
                {
                    "InstanceFamily": "c6i"
                }
            ]
        }
```

Considerations

- You can specify either instance types or instance attributes in an EC2 Fleet or Spot Fleet, but not both at the same time.

  When using the CLI, the launch template overrides will override the launch template. For example, if the launch template contains an instance type and the launch template override contains instance attributes, the instances that are identified by the instance attributes will override the instance type in the launch template.

- When using the CLI, when you specify instance attributes as overrides, you can't also specify weights or priorities.
- You can specify a maximum of four `InstanceRequirements` structures in a request configuration.

Create an EC2 Fleet with attribute-based instance type selection

You can configure an EC2 Fleet to use attribute-based instance type selection. It is not possible to create an EC2 Fleet using the Amazon EC2 console.

The attributes for attribute-based instance type selection are specified in the `InstanceRequirements` structure. When `InstanceRequirements` is included in the fleet configuration, `InstanceType` and `WeightedCapacity` must be excluded; they can't determine the fleet configuration at the same time as instance attributes.

In the AWS CLI and PowerShell examples, the following attributes are specified:

- `VCpuCount` – A minimum of 2 vCPUs and a maximum of 4 vCPUs. If you don't need a maximum limit, you can omit the maximum value.
- `MemoryMiB` – A minimum of 8 GiB of memory and a maximum of 16 GiB. If you don't need a maximum limit, you can omit the maximum value.

This configuration identifies any instance types with 2 to 4 vCPUs and 8 to 16 GiB of memory. However, price protection and the allocation strategy might exclude some instance types when [EC2 Fleet provisions the fleet](#).

AWS CLI

To create an EC2 Fleet with attribute-based instance type selection

Use the [create-fleet](#) command to create an EC2 Fleet. Specify the fleet configuration in a JSON file.

```
aws ec2 create-fleet \
    --region us-east-1 \
    --cli-input-json file://file_name.json
```

The following example *`file_name`*`.json` file contains the parameters that configure an EC2 Fleet to use attribute-based instance type selection.

```
{
    "SpotOptions": {
        "AllocationStrategy": "price-capacity-optimized"
    },
    "LaunchTemplateConfigs": [{
        "LaunchTemplateSpecification": {
            "LaunchTemplateName": "my-launch-template",
            "Version": "1"
        },
        "Overrides": [{
            "InstanceRequirements": {
                "VCpuCount": {
                    "Min": 2,
                    "Max": 4
                },
                "MemoryMiB": {
                    "Min": 8192,
                    "Max": 16384
                }
            }
        }]
    }],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

PowerShell

To create an EC2 Fleet with attribute-based instance type selection

Use the New-EC2Fleet cmdlet.

```
$vcpuCount = New-Object Amazon.EC2.Model.VCpuCountRangeRequest
$vcpuCount.Min = 2
$vcpuCount.Max = 4
$memoryMiB = New-Object Amazon.EC2.Model.MemoryMiBRequest
$memoryMiB.Min = 8192
$memoryMiB.Max = 16384
$instanceRequirements = New-Object Amazon.EC2.Model.InstanceRequirementsRequest
$instanceRequirements.VCpuCount = $vcpuCount
```

```
$instanceRequirements.MemoryMiB = $memoryMiB

$launchTemplateSpec = New-Object
 Amazon.EC2.Model.FleetLaunchTemplateSpecificationRequest
$launchTemplateSpec.LaunchTemplateName = "my-launch-template"
$launchTemplateSpec.Version = "1"
$override = New-Object Amazon.EC2.Model.FleetLaunchTemplateOverridesRequest
$override.InstanceRequirements = $instanceRequirements
$launchTemplateConfig = New-Object Amazon.EC2.Model.FleetLaunchTemplateConfigRequest
$launchTemplateConfig.LaunchTemplateSpecification = $launchTemplateSpec
$launchTemplateConfig.Overrides = @($override)

New-EC2Fleet `
    -SpotOptions_AllocationStrategy "price-capacity-optimized" `
    -LaunchTemplateConfig @($launchTemplateConfig) `
    -TargetCapacitySpecification_DefaultTargetCapacityType "spot" `
    -TargetCapacitySpecification_TotalTargetCapacity 20 `
    -Type "instant"
```

Create a Spot Fleet with attribute-based instance type selection

You can configure a fleet to use attribute-based instance type selection.

The attributes for attribute-based instance type selection are specified in the `InstanceRequirements` structure. When `InstanceRequirements` is included in the fleet configuration, `InstanceType` and `WeightedCapacity` must be excluded; they can't determine the fleet configuration at the same time as instance attributes.

In the AWS CLI and PowerShell examples, the following attributes are specified:

- `VCpuCount` – A minimum of 2 vCPUs and a maximum of 4 vCPUs. If you don't need a maximum limit, you can omit the maximum value.
- `MemoryMiB` – A minimum of 8 GiB of memory and a maximum of 16 GiB. If you don't need a maximum limit, you can omit the maximum value.

This configuration identifies any instance types that have 2 to 4 vCPUs and 8 to 16 GiB of memory. However, price protection and the allocation strategy might exclude some instance types when Spot Fleet provisions the fleet.

Console

To configure a Spot Fleet for attribute-based instance type selection

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**, and then choose **Request Spot Instances**.
3. Follow the steps to create a Spot Fleet. For more information, see Create a Spot Fleet request using defined parameters.

   While creating the Spot Fleet, configure the fleet for attribute-based instance type selection as follows:

   a. For **Instance type requirements**, choose **Specify instance attributes that match your compute requirements**.
   b. For **vCPUs**, enter the desired minimum and maximum number of vCPUs. To specify no limit, select **No minimum**, **No maximum**, or both.
   c. For **Memory (GiB)**, enter the desired minimum and maximum amount of memory. To specify no limit, select **No minimum**, **No maximum**, or both.
   d. (Optional) For **Additional instance attributes**, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds further constraints to your request.
   e. (Optional) Expand **Preview matching instance types** to view the instance types that have your specified attributes.

AWS CLI

To configure a Spot Fleet for attribute-based instance type selection

Use the request-spot-fleet command to create a Spot Fleet. Specify the fleet configuration in a JSON file.

```
aws ec2 request-spot-fleet \
    --region us-east-1 \
    --spot-fleet-request-config file://file_name.json
```

The following example *file_name*.json file contains the parameters that configure a Spot Fleet to use attribute-based instance type selection.

```
{
    "AllocationStrategy": "priceCapacityOptimized",
    "TargetCapacity": 20,
    "Type": "request",
    "LaunchTemplateConfigs": [{
        "LaunchTemplateSpecification": {
            "LaunchTemplateName": "my-launch-template",
            "Version": "1"
        },
        "Overrides": [{
            "InstanceRequirements": {
                "VCpuCount": {
                    "Min": 2,
                    "Max": 4
                },
                "MemoryMiB": {
                    "Min": 8192,
                    "Max": 16384
                }
            }
        }]
    }]
}
```

PowerShell

To configure a Spot Fleet for attribute-based instance type selection

Use the Request-EC2SpotFleet cmdlet.

```
$vcpuCount = New-Object Amazon.EC2.Model.VCpuCountRange
$vcpuCount.Min = 2
$vcpuCount.Max = 4
$memoryMiB = New-Object Amazon.EC2.Model.MemoryMiB
$memoryMiB.Min = 8192
$memoryMiB.Max = 16384
$instanceRequirements = New-Object Amazon.EC2.Model.InstanceRequirements
$instanceRequirements.VCpuCount = $vcpuCount
$instanceRequirements.MemoryMiB = $memoryMiB

$launchTemplateSpec = New-Object Amazon.EC2.Model.FleetLaunchTemplateSpecification
$launchTemplateSpec.LaunchTemplateName = "my-launch-template"
$launchTemplateSpec.Version = "1"
```

```
$override = New-Object Amazon.EC2.Model.LaunchTemplateOverrides
$override.InstanceRequirements = $instanceRequirements
$launchTemplateConfig = New-Object Amazon.EC2.Model.LaunchTemplateConfig
$launchTemplateConfig.LaunchTemplateSpecification = $launchTemplateSpec
$launchTemplateConfig.Overrides = @($override)

Request-EC2SpotFleet `
    -SpotFleetRequestConfig_AllocationStrategy "PriceCapacityOptimized" `
    -SpotFleetRequestConfig_TargetCapacity 20 `
    -SpotFleetRequestConfig_Type "Request" `
    -SpotFleetRequestConfig_LaunchTemplateConfig $launchTemplateConfig
```

Examples of EC2 Fleet configurations that are valid and not valid

If you use the AWS CLI to create an EC2 Fleet, you must make sure that your fleet configuration is valid. The following examples show configurations that are valid and not valid.

Configurations are considered not valid when they contain the following:

- A single `Overrides` structure with both `InstanceRequirements` and `InstanceType`
- Two `Overrides` structures, one with `InstanceRequirements` and the other with `InstanceType`
- Two `InstanceRequirements` structures with overlapping attribute values within the same `LaunchTemplateSpecification`

Example configurations

- Valid configuration: Single launch template with overrides
- Valid configuration: Single launch template with multiple InstanceRequirements
- Valid configuration: Two launch templates, each with overrides
- Valid configuration: Only InstanceRequirements specified, no overlapping attribute values
- Configuration not valid: Overrides contain InstanceRequirements and InstanceType
- Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType
- Configuration not valid: Overlapping attribute values

Valid configuration: Single launch template with overrides

The following configuration is valid. It contains one launch template and one `Overrides` structure containing one `InstanceRequirements` structure. A text explanation of the example configuration follows.

```
{
        "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "My-launch-template",
                "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 2,
                            "Max": 8
                        },
                        "MemoryMib": {
                            "Min": 0,
                            "Max": 10240
                        },
                        "MemoryGiBPerVCpu": {
                            "Max": 10000
                        },
                        "RequireHibernateSupport": true
                    }
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 5000,
        "DefaultTargetCapacityType": "spot",
        "TargetCapacityUnitType": "vcpu"
        }
    }
}
```

`InstanceRequirements`

To use attribute-based instance selection, you must include the `InstanceRequirements` structure in your fleet configuration, and specify the desired attributes for the instances in the fleet.

In the preceding example, the following instance attributes are specified:

- `VCpuCount` – The instance types must have a minimum of 2 and a maximum of 8 vCPUs.
- `MemoryMiB` – The instance types must have a maximum of 10240 MiB of memory. A minimum of 0 indicates no minimum limit.
- `MemoryGiBPerVCpu` – The instance types must have a maximum of 10,000 GiB of memory per vCPU. The `Min` parameter is optional. By omitting it, you indicate no minimum limit.

`TargetCapacityUnitType`

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is `5000` and the target capacity unit type is `vcpu`, which together specify a desired target capacity of 5,000 vCPUs. EC2 Fleet will launch enough instances so that the total number of vCPUs in the fleet is 5,000 vCPUs.

Valid configuration: Single launch template with multiple InstanceRequirements

The following configuration is valid. It contains one launch template and one `Overrides` structure containing two `InstanceRequirements` structures. The attributes specified in `InstanceRequirements` are valid because the values do not overlap—the first `InstanceRequirements` structure specifies a `VCpuCount` of 0-2 vCPUs, while the second `InstanceRequirements` structure specifies 4-8 vCPUs.

```
{
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
```

```
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                },
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 4,
                            "Max": 8
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 1,
        "DefaultTargetCapacityType": "spot"
    }
  }
}
```

Valid configuration: Two launch templates, each with overrides

The following configuration is valid. It contains two launch templates, each with one `Overrides` structure containing one `InstanceRequirements` structure. This configuration is useful for `arm` and `x86` architecture support in the same fleet.

```
{
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "armLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
```

```
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                },
                {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "x86LaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            }
        ],
         "TargetCapacitySpecification": {
            "TotalTargetCapacity": 1,
            "DefaultTargetCapacityType": "spot"
        }
    }
}
```

Valid configuration: Only `InstanceRequirements` specified, no overlapping attribute values

The following configuration is valid. It contains two `LaunchTemplateSpecification` structures, each with a launch template and an `Overrides` structure containing an `InstanceRequirements` structure. The attributes specified in `InstanceRequirements` are valid because the values do not overlap—the first `InstanceRequirements` structure specifies a `VCpuCount` of 0-2 vCPUs, while the second `InstanceRequirements` structure specifies 4-8 vCPUs.

```
{
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            },
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyOtherLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 4,
                            "Max": 8
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            }
        ],
        "TargetCapacitySpecification": {
            "TotalTargetCapacity": 1,
```

```
            "DefaultTargetCapacityType": "spot"
        }
    }
}
```

Configuration not valid: `Overrides` contain `InstanceRequirements` and `InstanceType`

The following configuration is not valid. The `Overrides` structure contains both `InstanceRequirements` and `InstanceType`. For the `Overrides`, you can specify either `InstanceRequirements` or `InstanceType`, but not both.

```
{
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                },
                {
                    "InstanceType": "m5.large"
                }
              ]
            }
        ],
        "TargetCapacitySpecification": {
            "TotalTargetCapacity": 1,
            "DefaultTargetCapacityType": "spot"
        }
    }
}
```

Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The `Overrides` structures contain both `InstanceRequirements` and `InstanceType`. You can specify either `InstanceRequirements` or `InstanceType`, but not both, even if they're in different `Overrides` structures.

```
{
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            },
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyOtherLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceType": "m5.large"
                }
              ]
            }
        ],
         "TargetCapacitySpecification": {
            "TotalTargetCapacity": 1,
            "DefaultTargetCapacityType": "spot"
        }
```

```
    }
}
```

Configuration not valid: Overlapping attribute values

The following configuration is not valid. The two `InstanceRequirements` structures each contain `"VCpuCount": {"Min": 0, "Max": 2}`. The values for these attributes overlap, which will result in duplicate capacity pools.

```
{
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    },
                    {
                      "InstanceRequirements": {
                          "VCpuCount": {
                              "Min": 0,
                              "Max": 2
                          },
                          "MemoryMiB": {
                              "Min": 0
                          }
                      }
                  }
                }
              ]
            }
        ],
         "TargetCapacitySpecification": {
```

```
                "TotalTargetCapacity": 1,
                "DefaultTargetCapacityType": "spot"
            }
        }
}
```

Examples of Spot Fleet configurations that are valid and not valid

If you use the AWS CLI to create a Spot Fleet, you must make sure that your fleet configuration is valid. The following examples show configurations that are valid and not valid.

Configurations are considered not valid when they contain the following:

- A single `Overrides` structure with both `InstanceRequirements` and `InstanceType`
- Two `Overrides` structures, one with `InstanceRequirements` and the other with `InstanceType`
- Two `InstanceRequirements` structures with overlapping attribute values within the same `LaunchTemplateSpecification`

Example configurations

- Valid configuration: Single launch template with overrides
- Valid configuration: Single launch template with multiple InstanceRequirements
- Valid configuration: Two launch templates, each with overrides
- Valid configuration: Only InstanceRequirements specified, no overlapping attribute values
- Configuration not valid: Overrides contain InstanceRequirements and InstanceType
- Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType
- Configuration not valid: Overlapping attribute values

Valid configuration: Single launch template with overrides

The following configuration is valid. It contains one launch template and one `Overrides` structure containing one `InstanceRequirements` structure. A text explanation of the example configuration follows.

```
{
    "SpotFleetRequestConfig": {
```

```
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "My-launch-template",
                "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 2,
                            "Max": 8
                        },
                        "MemoryMib": {
                            "Min": 0,
                            "Max": 10240
                        },
                        "MemoryGiBPerVCpu": {
                            "Max": 10000
                        },
                        "RequireHibernateSupport": true
                    }
                }
            ]
        }
    ],
        "TargetCapacity": 5000,
            "OnDemandTargetCapacity": 0,
            "TargetCapacityUnitType": "vcpu"
    }
}
```

`InstanceRequirements`

To use attribute-based instance selection, you must include the `InstanceRequirements` structure in your fleet configuration, and specify the desired attributes for the instances in the fleet.

In the preceding example, the following instance attributes are specified:

- `VCpuCount` – The instance types must have a minimum of 2 and a maximum of 8 vCPUs.
- `MemoryMiB` – The instance types must have a maximum of 10240 MiB of memory. A minimum of 0 indicates no minimum limit.
- `MemoryGiBPerVCpu` – The instance types must have a maximum of 10,000 GiB of memory per vCPU. The `Min` parameter is optional. By omitting it, you indicate no minimum limit.

`TargetCapacityUnitType`

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is `5000` and the target capacity unit type is `vcpu`, which together specify a desired target capacity of 5,000 vCPUs. Spot Fleet will launch enough instances so that the total number of vCPUs in the fleet is 5,000 vCPUs.

Valid configuration: Single launch template with multiple InstanceRequirements

The following configuration is valid. It contains one launch template and one `Overrides` structure containing two `InstanceRequirements` structures. The attributes specified in `InstanceRequirements` are valid because the values do not overlap—the first `InstanceRequirements` structure specifies a `VCpuCount` of 0-2 vCPUs, while the second `InstanceRequirements` structure specifies 4-8 vCPUs.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
```

```
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                },
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 4,
                            "Max": 8
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
            ]
        }
    ],
    "TargetCapacity": 1,
    "OnDemandTargetCapacity": 0,
    "Type": "maintain"
  }
}
```

Valid configuration: Two launch templates, each with overrides

The following configuration is valid. It contains two launch templates, each with one `Overrides` structure containing one `InstanceRequirements` structure. This configuration is useful for `arm` and `x86` architecture support in the same fleet.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "armLaunchTemplate",
                    "Version": "1"
                },
```

```
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                },
                {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "x86LaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            }
        ],
        "TargetCapacity": 1,
        "OnDemandTargetCapacity": 0,
        "Type": "maintain"
    }
}
```

Valid configuration: Only `InstanceRequirements` specified, no overlapping attribute values

The following configuration is valid. It contains two `LaunchTemplateSpecification` structures, each with a launch template and an `Overrides` structure containing an `InstanceRequirements` structure. The attributes specified in `InstanceRequirements` are valid because the values do not overlap—the first `InstanceRequirements` structure specifies a `VCpuCount` of 0-2 vCPUs, while the second `InstanceRequirements` structure specifies 4-8 vCPUs.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            },
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyOtherLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 4,
                            "Max": 8
                        },
                        "MemoryMiB": {
                            "Min": 0
```

```
                        }
                    }
                }
              ]
            }
        ],
        "TargetCapacity": 1,
        "OnDemandTargetCapacity": 0,
        "Type": "maintain"
    }
}
```

Configuration not valid: `Overrides` contain `InstanceRequirements` and `InstanceType`

The following configuration is not valid. The `Overrides` structure contains both `InstanceRequirements` and `InstanceType`. For the `Overrides`, you can specify either `InstanceRequirements` or `InstanceType`, but not both.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                },
                {
```

```
                    "InstanceType": "m5.large"
                }
              ]
            }
        ],
        "TargetCapacity": 1,
        "OnDemandTargetCapacity": 0,
        "Type": "maintain"
    }
}
```

Configuration not valid: Two `Overrides` contain `InstanceRequirements` and `InstanceType`

The following configuration is not valid. The `Overrides` structures contain both `InstanceRequirements` and `InstanceType`. You can specify either `InstanceRequirements` or `InstanceType`, but not both, even if they're in different `Overrides` structures.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
              ]
            },
```

```
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyOtherLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceType": "m5.large"
                }
              ]
            }
        ],
        "TargetCapacity": 1,
        "OnDemandTargetCapacity": 0,
        "Type": "maintain"
    }
}
```

Configuration not valid: Overlapping attribute values

The following configuration is not valid. The two `InstanceRequirements` structures each contain `"VCpuCount": {"Min": 0, "Max": 2}`. The values for these attributes overlap, which will result in duplicate capacity pools.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
```

```
                        "MemoryMiB": {
                            "Min": 0
                        }
                    },
                    {
                      "InstanceRequirements": {
                          "VCpuCount": {
                              "Min": 0,
                              "Max": 2
                          },
                          "MemoryMiB": {
                              "Min": 0
                          }
                      }
                  }
              }
          ]
        }
    ],
    "TargetCapacity": 1,
    "OnDemandTargetCapacity": 0,
    "Type": "maintain"
  }
}
```

Preview instance types with specified attributes

You can use the get-instance-types-from-instance-requirements command to preview the instance types that match the attributes that you specify. This is especially useful for working out what attributes to specify in your request configuration without launching any instances. Note that the command does not consider available capacity.

To preview a list of instance types by specifying attributes using the AWS CLI

1. (Optional) To generate all of the possible attributes that can be specified, use the get-instance-types-from-instance-requirements command and the `--generate-cli-skeleton` parameter. You can optionally direct the output to a file to save it by using `input > attributes.json`.

```
aws ec2 get-instance-types-from-instance-requirements \
    --region us-east-1 \
```

```
    --generate-cli-skeleton input > attributes.json
```

Expected output

```
{
    "DryRun": true,
    "ArchitectureTypes": [
        "i386"
    ],
    "VirtualizationTypes": [
        "hvm"
    ],
    "InstanceRequirements": {
        "VCpuCount": {
            "Min": 0,
            "Max": 0
        },
        "MemoryMiB": {
            "Min": 0,
            "Max": 0
        },
        "CpuManufacturers": [
            "intel"
        ],
        "MemoryGiBPerVCpu": {
            "Min": 0.0,
            "Max": 0.0
        },
        "ExcludedInstanceTypes": [
            ""
        ],
        "InstanceGenerations": [
            "current"
        ],

            "Max": 0
        },
        "AcceleratorManufacturers": [
            "nvidia"
        ],
        "AcceleratorNames": [
            "a100"
        ],
        "AcceleratorTotalMemoryMiB": {
            "Min": 0,
            "Max": 0
        },
        "NetworkBandwidthGbps": {
            "Min": 0.0,
            "Max": 0.0
        },
        "AllowedInstanceTypes": [
            ""
        ]
    },
    "MaxResults": 0,
    "NextToken": ""
}
```

2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

Note

You must provide values for `ArchitectureTypes`, `VirtualizationTypes`, `VCpuCount`, and `MemoryMiB`. You can omit the other attributes; when omitted, the default values are used.
For a description of each attribute and their default values, see get-instance-types-from-instance-requirements.

a. For `ArchitectureTypes`, specify one or more types of processor architecture.

b. For `VirtualizationTypes`, specify one or more types of virtualization.

c. For `VCpuCount`, specify the minimum and maximum number of vCPUs. To specify no minimum limit, for `Min`, specify `0`. To specify no maximum limit, omit the `Max` parameter.

d. For `MemoryMiB`, specify the minimum and maximum amount of memory in MiB. To specify no minimum limit, for `Min`, specify `0`. To specify no maximum limit, omit the `Max` parameter.

e. You can optionally specify one or more of the other attributes to further constrain the list of instance types that are returned.

3. To preview the instance types that have the attributes that you specified in the JSON file, use the get-instance-types-from-instance-requirements command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter. You can optionally format the output to appear in a table format.

```
aws ec2 get-instance-types-from-instance-requirements \
    --cli-input-json file://attributes.json \
    --output table
```

Example *`attributes.json`* file

In this example, the required attributes are included in the JSON file. They are `ArchitectureTypes`, `VirtualizationTypes`, `VCpuCount`, and `MemoryMiB`. In addition, the optional `InstanceGenerations` attribute is also included. Note that for `MemoryMiB`, the `Max` value can be omitted to indicate that there is no limit.

```
{
```

```
    "ArchitectureTypes": [
        "x86_64"
    ],
    "VirtualizationTypes": [
        "hvm"
    ],
    "InstanceRequirements": {
        "VCpuCount": {

4. After identifying instance types that meet your needs, make note of the instance attributes that you used so that you can use them when configuring your fleet request.

Use instance weighting to manage cost and performance of your EC2 Fleet or Spot Fleet

With instance weighting, you assign a weight to each instance type in your EC2 Fleet or Spot Fleet to represent their compute capacity and performance relative to each other. Based on the weights, the fleet can use any combination of the specified instance types, as long as it can fulfil the desired target capacity. This can help you manage the cost and performance of your fleet.

The weight represents the capacity units that an instance type contributes to the total target capacity.

Example: Use instance weighting for performance management

Suppose your fleet has two instance types, and you assign a different weight to each instance type to reflect how many you need of each to achieve the same performance, as follows:

- `m5.large` – weight: 1
- `m5.2xlarge` – weight: 4

By assigning these weights, you're saying that you'd need 4 `m5.large` instances to achieve the same performance as 1 `m5.2xlarge`.

To calculate how many instances of each instance type are needed for a given target capacity, use the following formula:

`target capacity / weight = number of instances`

If your target capacity is 8 units, the fleet could fulfill the target capacity with either `m5.large` or `m5.2xlarge`, or a mix of both, as follows:

- 8 `m5.large` instances (capacity of 8 / weight of 1 = 8 instances)
- 2 `m5.2xlarge` instances (capacity of 8 / weight of 4 = 2 instances)
- 4 `m5.large` and 1 `m5.2xlarge`

Example: Use instance weighting for cost management

By default, the price that you specify is per *instance* hour. When you use the instance weighting feature, the price that you specify is per *unit* hour. You can calculate your price per unit hour by dividing your price for an instance type by the number of units that it represents. The fleet calculates the number of instances to launch by dividing the target capacity by the instance weight. If the result isn't an integer, the fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity. The fleet can select any pool that you specify in your launch specification, even if the capacity of the instances launched exceeds the requested target capacity.

The following table includes examples of calculations to determine the price per unit for a fleet with a target capacity of 10.

Instance type	Instance weight	Target capacity	Number of instances launched	Price per instance hour	Price per unit hour
`r3.xlarge`	2	10	5 (10 divided by 2)	$0.05	$0.025 (.05 divided by 2)
`r3.8xlarge`	8	10	2 (10 divided by 8, result rounded up)	$0.10	$0.0125 (.10 divided by 8)

Use the fleet instance weighting as follows to provision the target capacity that you want in the pools with the lowest price per unit at the time of fulfillment:

1. Set the target capacity for your fleet either in instances (the default) or in the units of your choice, such as vCPU, memory, storage, or throughput.
2. Set the price per unit.
3. For each launch specification, specify the weight, which is the number of units that the instance type represents toward the target capacity.

Instance weighting example

Consider a fleet request with the following configuration:

- A target capacity of 24

- A launch specification with an instance type `r3.2xlarge` and a weight of 6
- A launch specification with an instance type `c3.xlarge` and a weight of 5

The weights represent the number of units that instance type represents toward the target capacity. If the first launch specification provides the lowest price per unit (price for `r3.2xlarge` per instance hour divided by 6), the fleet would launch four of these instances (24 divided by 6).

If the second launch specification provides the lowest price per unit (price for `c3.xlarge` per instance hour divided by 5), the fleet would launch five of these instances (24 divided by 5, result rounded up).

Instance weighting and allocation strategy

Consider a fleet request with the following configuration:

- A target capacity of 30 Spot Instances
- A launch specification with an instance type `c3.2xlarge` and a weight of 8
- A launch specification with an instance type `m3.xlarge` and a weight of 8
- A launch specification with an instance type `r3.xlarge` and a weight of 8

The fleet would launch four instances (30 divided by 8, result rounded up). With the `diversified` strategy, the fleet launches one instance in each of the three pools, and the fourth instance in whichever of the three pools provides the lowest price per unit.

Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity

When you use multiple capacity pools (each comprising an instance type and Availability Zone) in an EC2 Fleet or Spot Fleet, you can use an *allocation strategy* to manage how Amazon EC2 fulfills your Spot and On-Demand capacities from these pools. The allocation strategies can optimize for available capacity, price, and the instance types to use. There are different allocation strategies for Spot Instances and On-Demand Instances.

Topics

- [Allocation strategies for Spot Instances]
- [Allocation strategies for On-Demand Instances]

- Choose the appropriate Spot allocation strategy
- Maintain target capacity for Spot Instances
- Prioritize instance types for On-Demand capacity

Allocation strategies for Spot Instances

Your launch configuration determines all the possible Spot capacity pools (instance types and Availability Zones) from which EC2 Fleet or Spot Fleet can launch Spot Instances. However, when launching instances, the fleet uses the allocation strategy that you specify to pick the specific pools from all your possible pools.

> **Note**
>
> (Linux instances only) If you configure your Spot Instance to launch with AMD SEV-SNP turned on, you are charged an additional hourly usage fee that is equivalent to 10% of the On-Demand hourly rate for the selected instance type. If the allocation strategy uses price as an input, the fleet does not include this additional fee; only the Spot price is used.

You can specify one of the following allocation strategies for Spot Instances:

Price capacity optimized (recommended)

The fleet identifies the pools with the highest capacity availability for the number of instances that are launching. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term. The fleet then requests Spot Instances from the lowest priced of these pools.

The **price capacity optimized** allocation strategy is the best choice for most Spot workloads, such as stateless containerized applications, microservices, web applications, data and analytics jobs, and batch processing.

If you're using the AWS CLI, the parameter name is `price-capacity-optimized` for EC2 Fleet and `priceCapacityOptimized` for Spot Fleet.

Capacity optimized

The fleet identifies the pools with the highest capacity availability for the number of instances that are launching. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term. You can optionally set a priority for each instance type in your fleet, where the fleet optimizes for capacity first, but honors instance type priorities on a best-effort basis.

With Spot Instances, pricing changes slowly over time based on long-term trends in supply and demand, but capacity fluctuates in real time. The **capacity optimized** strategy automatically launches Spot Instances into the most available pools by looking at real-time capacity data and predicting which are the most available. This works well for workloads that may have a higher cost of interruption associated with restarting work, such as long Continuous Integration (CI), image and media rendering, Deep Learning, and High Performance Compute (HPC) workloads that may have a higher cost of interruption associated with restarting work. By offering the possibility of fewer interruptions, the **capacity optimized** strategy can lower the overall cost of your workload.

Alternatively, you can use the **capacity optimized prioritized** allocation strategy with a priority parameter to order instance types from highest to lowest priority. You can set the same priority for different instance types. The fleet will optimize for capacity first, but will honor instance type priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect the fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters. Note that when you set the priority for instance types for your Spot capacity, the same priority is also applied to your On-Demand Instances if the On-Demand allocation strategy is set to **prioritized**. For Spot Fleet, using priorities is supported only if your fleet uses a launch template.

If you're using the AWS CLI, the parameter names are `capacity-optimized` and `capacity-optimized-prioritized` for EC2 Fleet and `capacityOptimized` and `capacityOptimizedPrioritized` for Spot Fleet.

Diversified

The Spot Instances are distributed across all Spot capacity pools. If you're using the AWS CLI, the parameter name is `diversified` for both EC2 Fleet and Spot Fleet.

Lowest price (not recommended)

> **Warning**
>
> We don't recommend the **lowest price** allocation strategy because it has the highest risk of interruption for your Spot Instances.

The Spot Instances come from the lowest priced pool that has available capacity. When using the AWS CLI, this is the default strategy. However, we recommend that you override the default by specifying the **price capacity optimized** allocation strategy.

With the lowest price strategy, if the lowest priced pool doesn't have available capacity, the Spot Instances come from the next lowest priced pool that has available capacity. If a pool runs out of capacity before fulfilling your desired capacity, the fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your desired capacity is met, you might receive Spot Instances from several pools.

Because this strategy only considers instance price and not capacity availability, it might lead to high interruption rates.

The lowest price allocation strategy is only available when using the AWS CLI. The parameter name is `lowest-price` for EC2 Fleet and `lowestPrice` for Spot Fleet.

Number of pools to use

The number of Spot pools across which to allocate your target Spot capacity. Valid only when the allocation strategy is set to **lowest price**. The fleet selects the lowest priced Spot pools and evenly allocates your target Spot capacity across the number of Spot pools that you specify.

Note that the fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, the fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.

This parameter is only available when specifying the **lowest price** allocation strategy and only when using the AWS CLI. The parameter name is `InstancePoolsToUseCount` for both EC2 Fleet and Spot Fleet.

Allocation strategies for On-Demand Instances

Your launch configuration determines all the possible capacity pools (instance types and Availability Zones) from which EC2 Fleet or Spot Fleet can launch On-Demand Instances. However, when launching instances, the fleet uses the allocation strategy that you specify to pick the specific pools from all your possible pools.

You can specify one of the following allocation strategies for On-Demand Instances:

Lowest price

The On-Demand Instances come from the lowest priced pool that has available capacity. This is the default strategy.

If the lowest priced pool doesn't have available capacity, the On-Demand Instances come from the next lowest priced pool that has available capacity.

If a pool runs out of capacity before fulfilling your desired capacity, the fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your desired capacity is met, you might receive On-Demand Instances from several pools.

Prioritized

The fleet uses the priority that you assigned to each launch template override, launching instance types in order of the highest priority first. This strategy can't be used with attribute-based instance type selection. For an example of how to use this allocation strategy, see Prioritize instance types for On-Demand capacity.

Choose the appropriate Spot allocation strategy

You can optimize your fleet for your use case by choosing the appropriate Spot allocation strategy.

Balance lowest price and capacity availability

To balance the trade-offs between the lowest priced Spot capacity pools and the Spot capacity pools with the highest capacity availability, we recommend that you use the **price capacity optimized** allocation strategy. This strategy makes decisions about which pools to request Spot Instances from based on both the price of the pools and the capacity availability of Spot Instances in those pools. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term, while still taking price into consideration.

If your fleet runs resilient and stateless workloads, including containerized applications, microservices, web applications, data and analytics jobs, and batch processing, then use the **price capacity optimized** allocation strategy for optimal cost savings and capacity availability.

If your fleet runs workloads that might have a higher cost of interruption associated with restarting work, then you should implement checkpointing so that applications can restart from that point if they're interrupted. By using checkpointing, you make the **price capacity optimized** allocation strategy a good fit for these workloads because it allocates capacity from the lowest priced pools that also offer a low Spot Instance interruption rate.

For example JSON configurations that use the **price capacity optimized** allocation strategy, see the following:

- EC2 Fleet – Example 10: Launch Spot Instances in a price-capacity-optimized fleet
- Spot Fleet – Example 11: Launch Spot Instances in a priceCapacityOptimized fleet

When workloads have a high cost of interruption

You can optionally use the **capacity optimized** strategy if you run workloads that either use similarly priced instance types, or where the cost of interruption is so significant that any cost saving is inadequate in comparison to a marginal increase in interruptions. This strategy allocates capacity from the most available Spot capacity pools that offer the possibility of fewer interruptions, which can lower the overall cost of your workload.

When the possibility of interruptions must be minimized but the preference for certain instance types matters, you can express your pool priorities by using the **capacity optimized prioritized** allocation strategy and then setting the order of instance types to use from highest to lowest priority.

Note that when you set priorities for **capacity optimized prioritized**, the same priorities are also applied to your On-Demand Instances if the On-Demand allocation strategy is set to **prioritized**. Also note that, for Spot Fleet, using priorities is supported only if your fleet uses a launch template.

For example JSON configurations that use the **capacity optimized** allocation strategy, see the following:

- EC2 Fleet – Example 8: Launch Spot Instances in a capacity-optimized fleet
- Spot Fleet – Example 9: Launch Spot Instances in a capacity-optimized fleet

For example JSON configurations that use the **capacity optimized prioritized** allocation strategy, see the following:

- EC2 Fleet – Example 9: Launch Spot Instances in a capacity-optimized fleet with priorities
- Spot Fleet – Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities

When your workload is time flexible and capacity availability is not a factor

If your fleet is small or runs for a short time, you can use **price capacity optimized** to maximize cost savings while still considering capacity availability.

When your fleet is large or runs for a long time

If your fleet is large or runs for a long time, you can improve the availability of your fleet by distributing the Spot Instances across multiple pools using the **diversified** strategy. For example, if your fleet specifies 10 pools and a target capacity of 100 instances, the fleet launches 10 Spot Instances in each pool. If the Spot price for one pool exceeds your maximum price for this pool, only 10% of your fleet is affected. Using this strategy also makes your fleet less sensitive to increases in the Spot price in any one pool over time. With the **diversified** strategy, the fleet does not launch Spot Instances into any pools with a Spot price that is equal to or higher than the On-Demand price.

Maintain target capacity for Spot Instances

After Spot Instances are terminated due to a change in the Spot price or available capacity of a Spot capacity pool, a fleet of type `maintain` launches replacement Spot Instances. The allocation strategy determines the pools from which the replacement instances are launched, as follows:

- If the allocation strategy is **price capacity optimized**, the fleet launches replacement instances in the pools that have the most Spot Instance capacity availability while also taking price into consideration and identifying lowest priced pools with high capacity availability.
- If the allocation strategy is **capacity optimized**, the fleet launches replacement instances in the pools that have the most Spot Instance capacity availability.
- If the allocation strategy is **diversified**, the fleet distributes the replacement Spot Instances across the remaining pools.

Prioritize instance types for On-Demand capacity

When an EC2 Fleet or Spot Fleet attempts to fulfill your On-Demand capacity, it defaults to launching the lowest priced instance type first. If the On-Demand allocation strategy is set to **prioritized**, the fleet uses priority to determine which instance type to use first when fulfilling On-Demand capacity. The priority is assigned to the launch template override, and the highest priority is launched first.

Example: Prioritize instance types

In this example, you configure three launch template overrides, each with a different instance type.

The On-Demand price for the instance types range in price. The following are the instance types used in this example, listed in order of price, starting with the least expensive instance type:

- `m4.large` – least expensive
- `m5.large`
- `m5a.large`

If you do not use priority to determine the order, the fleet fulfills the On-Demand capacity by starting with the least expensive instance type.

However, say you have unused `m5.large` Reserved Instances that you want to use first. You can set the launch template override priority so that the instance types are used in the order of priority, as follows:

- `m5.large` – priority 1
- `m4.large` – priority 2
- `m5a.large` – priority 3

Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances

With Capacity Rebalancing, your EC2 Fleet or Spot Fleet can maintain the desired Spot capacity by proactively replacing Spot Instances at risk of interruption. When a Spot Instance is at an elevated risk of interruption, Amazon EC2 sends a rebalance recommendation. If Capacity Rebalancing is enabled, the rebalance recommendation triggers the launch of a new Spot Instance before the at-risk instance is interrupted.

Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with new Spot Instances before running instances are interrupted by Amazon EC2.

To configure EC2 Fleet to use Capacity Rebalancing to launch a replacement Spot Instance

Use the create-fleet command and the relevant parameters in the `MaintenanceStrategies` structure. For an example JSON configuration, see Example 7: Configure Capacity Rebalancing to launch replacement Spot Instances.

To configure Spot Fleet to use Capacity Rebalancing to launch a replacement Spot Instance

You can use the Amazon EC2 console or the AWS CLI to configure Capacity Rebalancing.

(Console) When creating the Spot Fleet, select the **Capacity rebalance** checkbox. For more information, see step 6.d. in Create a Spot Fleet request using defined parameters.

(AWS CLI) Use the request-spot-fleet command and the relevant parameters in the `SpotMaintenanceStrategies` structure. For an example JSON configuration, see Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances.

Topics

- Limitations
- Configuration options
- Considerations

Limitations

- Capacity Rebalancing is available only for fleets of type `maintain`.
- When the fleet is running, you can't modify the Capacity Rebalancing setting. To change the Capacity Rebalancing setting, you must delete the fleet and create a new fleet.

Configuration options

The `ReplacementStrategy` for EC2 Fleet and Spot Fleet supports the following two values:

`launch-before-terminate`

Amazon EC2 terminates the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched. When you specify `launch-before-terminate`, you must also specify a value for `termination-delay`. After the new replacement instances are launched, Amazon EC2 waits for the duration of the `termination-delay`, and then terminates the old instances. For `termination-delay`, the minimum is 120 seconds (2 minutes), and the maximum is 7200 seconds (2 hours).

We recommend that you use `launch-before-terminate` only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed. Note that Amazon EC2 can interrupt the old instances with a two-minute warning before the `termination-delay`.

We strongly recommend against using the `lowest-price` (EC2 Fleet) or `lowestPrice` (Spot Fleet) allocation strategy in combination with `launch-before-terminate` to avoid having replacement Spot Instances that are also at an elevated risk of interruption.

`launch`

Amazon EC2 launches replacement Spot Instances when a rebalance notification is emitted for existing Spot Instances. Amazon EC2 does not terminate the instances that receive a rebalance notification. You can terminate the old instances, or you can leave them running. You are charged for all instances while they are running.

Considerations

If you configure an EC2 Fleet or Spot Fleet for Capacity Rebalancing, consider the following:

Provide as many Spot capacity pools in the request as possible

Configure your fleet to use multiple instance types and Availability Zones. This provides the flexibility to launch Spot Instances in various Spot capacity pools. For more information, see Be flexible about instance types and Availability Zones.

Avoid an elevated risk of interruption of replacement Spot Instances

To avoid an elevated risk of interruption, we recommend the `capacity-optimized` or `capacity-optimized-prioritized` allocation strategy. These strategies ensure that replacement Spot Instances are launched in the most optimal Spot capacity pools, and are therefore less likely to be interrupted in the near future. For more information, see Use the price and capacity optimized allocation strategy.

If you use the `lowest-price` allocation strategy, your replacement Spot Instances might be at an elevated risk of interruption. This is because Amazon EC2 will always launch instances in the lowest priced pool that has available capacity at that moment, even if your replacement Spot Instances are likely to be interrupted soon after being launched.

Amazon EC2 will only launch a new instance if availability is the same or better

One of the goals of Capacity Rebalancing is to improve a Spot Instance's availability. If an existing Spot Instance receives a rebalance recommendation, Amazon EC2 will only launch a new instance if the new instance provides the same or better availability than the existing instance. If the risk of interruption of a new instance will be worse than the existing instance, then Amazon EC2 will not launch a new instance. Amazon EC2 will, however, continue to assess the Spot capacity pools, and will launch a new instance if availability improves.

There is a chance that your existing instance will be interrupted without Amazon EC2 proactively launching a new instance. When this happens, Amazon EC2 will attempt to launch a new instance regardless of whether the new instance has a high risk of interruption.

Capacity Rebalancing does not increase your Spot Instance interruption rate

When you enable Capacity Rebalancing, it does not increase your Spot Instance interruption rate (the number of Spot Instances that are reclaimed when Amazon EC2 needs the capacity back). However, if Capacity Rebalancing detects an instance is at risk of interruption, Amazon EC2 will immediately attempt to launch a new instance. The result is that more instances might be replaced than if you'd waited for Amazon EC2 to launch a new instance after the at-risk instance was interrupted.

While you might replace more instances with Capacity Rebalancing enabled, you benefit from being proactive rather than reactive by having more time to take action before your instances are interrupted. With a Spot Instance interruption notice, you typically only have up to two minutes to gracefully shut down your instance. With Capacity Rebalancing launching a new instance in advance, you give existing processes a better chance of completing on your at-risk instance, you can start your instance shutdown procedures, and prevent new work from being scheduled on your at-risk instance. You can also start preparing the newly-launched instance to take over the application. With Capacity Rebalancing's proactive replacement, you benefit from graceful continuity.

As a theoretical example to demonstrate the risks and benefits of using Capacity Rebalancing, consider the following scenario:

- 2:00 PM – A rebalance recommendation is received for instance-A, and Amazon EC2 immediately starts attempting to launch a replacement instance-B, giving you time to start your shutdown procedures.*
- 2:30 PM – A rebalance recommendation is received for instance-B, replaced with instance-C, giving you time to start your shutdown procedures.*
- 2:32 PM – If Capacity Rebalancing wasn't enabled, and if a Spot Instance interruption notice would've been received at 2:32 PM for instance-A, you would only have had up to two minutes to take action, but Instance-A would have been running up till this time.

* If `launch-before-terminate` is specified, Amazon EC2 will terminate the at-risk instance after the replacement instance comes online.

Amazon EC2 can launch new replacement Spot Instances until fulfilled capacity is double target capacity

When a fleet is configured for Capacity Rebalancing, the fleet attempts to launch a new replacement Spot Instance for every Spot Instance that receives a rebalance recommendation. After a Spot Instance receives a rebalance recommendation, it is no longer counted as part of the fulfilled capacity. Depending on the replacement strategy, Amazon EC2 either terminates the instance after a preconfigured termination delay, or leaves it running. This gives you the opportunity to perform rebalancing actions on the instance.

If your fleet reaches double its target capacity, it stops launching new replacement instances even if the replacement instances themselves receive a rebalance recommendation.

For example, you create a fleet with a target capacity of 100 Spot Instances. All of the Spot Instances receive a rebalance recommendation, which causes Amazon EC2 to launch 100 replacement Spot Instances. This raises the number of fulfilled Spot Instances to 200, which is double the target capacity. Some of the replacement instances receive a rebalance recommendation, but no more replacement instances are launched because the fleet can't exceed double its target capacity.

Note that you are charged for all of the instances while they are running.

We recommend that you configure your fleet to terminate Spot Instances that receive a rebalance recommendation

If you configure your fleet for Capacity Rebalancing, we recommend that you choose `launch-before-terminate` with an appropriate termination delay only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed.

If you choose to terminate the instances that are recommended for rebalance yourself, we recommend that you monitor the rebalance recommendation signal that is received by the Spot Instances in the fleet. By monitoring the signal, you can quickly perform rebalancing actions on the affected instances before Amazon EC2 interrupts them, and then you can manually terminate them. If you do not terminate the instances, you continue paying for them while they are running. Amazon EC2 does not automatically terminate the instances that receive a rebalance recommendation.

You can set up notifications using Amazon EventBridge or instance metadata. For more information, see Monitor rebalance recommendation signals.

The fleet does not count instances that receive a rebalance recommendation when calculating fulfilled capacity during scale in or out

If your fleet is configured for Capacity Rebalancing, and you change the target capacity to either scale in or scale out, the fleet does not count the instances that are marked for rebalance as part of the fulfilled capacity, as follows:

- Scale in – If you decrease your desired target capacity, Amazon EC2 terminates instances that are not marked for rebalance until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

  For example, you create a fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so Amazon EC2 launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then reduce the target capacity to 50 (scale in), but the fulfilled capacity is actually 60 instances because the 10 instances that are marked for rebalance are not terminated by Amazon EC2. You need to manually terminate these instances, or you can leave them running.
- Scale out – If you increase your desired target capacity, Amazon EC2 launches new instances until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

  For example, you create a fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then increase the target capacity to 200 (scale out), but the fulfilled capacity is actually 210 instances because the 10 instances that are marked for rebalance are not counted by the fleet as part of the target capacity. You need to manually terminate these instances, or you can leave them running.

Use Capacity Reservations to reserve On-Demand capacity in EC2 Fleet

With On-Demand Capacity Reservations, you can reserve compute capacity for your On-Demand Instances in a specified Availability Zone for any duration. You can configure an EC2 Fleet to use the Capacity Reservations first when launching On-Demand Instances.

On-Demand Capacity Reservations are available only for EC2 Fleet with the request type set to `instant`.

Capacity Reservations are configured as either `open` or `targeted`. EC2 Fleet can launch On-Demand Instances into either `open` or `targeted` Capacity Reservations, as follows:

- If a Capacity Reservation is `open`, On-Demand Instances that have matching attributes automatically run in the reserved capacity.
- If a Capacity Reservation is `targeted`, On-Demand Instances must specifically target it to run in the reserved capacity. This is useful for using up specific Capacity Reservations or for controlling when to use specific Capacity Reservations.

If you use `targeted` Capacity Reservations in your EC2 Fleet, there must be enough Capacity Reservations to fulfil the target On-Demand capacity, otherwise the launch fails. To avoid a launch fail, rather add the `targeted` Capacity Reservations to a resource group, and then target the resource group. The resource group doesn't need to have enough Capacity Reservations; if it runs out of Capacity Reservations before the target On-Demand capacity is fulfilled, the fleet can launch the remaining target capacity into regular On-Demand capacity.

To use Capacity Reservations with EC2 Fleet

1. Configure the fleet as type `instant`. You can't use Capacity Reservations for fleets of other types.
2. Configure the usage strategy for Capacity Reservations as `use-capacity-reservations-first`.
3. In the launch template, for **Capacity reservation**, choose either **Open** or **Target by group**. If you choose **Target by group**, specify the Capacity Reservations resource group ID.

When the fleet attempts to fulfil the On-Demand capacity, if it finds that multiple instance pools have unused matching Capacity Reservations, it determines the pools in which to launch the On-Demand Instances based on the On-Demand allocation strategy (`lowest-price` or `prioritized`).

Work with EC2 Fleet

To start using an EC2 Fleet, create a request that includes the total target capacity, On-Demand capacity, Spot capacity, and a launch template specifying the configuration for the instances in the fleet. You can optionally specify additional parameters, or let the fleet use default values. You can also tag the fleet request, and its instances and volumes, when you create the fleet.

The fleet launches On-Demand Instances when there is available capacity, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available.

Once your fleet is launched, you can describe the fleet request, the instances in the fleet, and any fleet events. You can also assign additional tags as needed.

If you need to change any fleet parameters, such as the total target capacity, you can modify the fleet, provided it was configured to maintain capacity. You can't modify the capacity of a one-time request after it's been submitted.

The fleet request remains active until it expires or you delete it. When you delete the fleet request, you can either terminate the instances or leave them running. If you choose to leave them running, the On-Demand Instances run until you terminate them, and the Spot Instances run until they're interrupted or you terminate them.

- Tag a new or existing EC2 Fleet request and the instances and volumes it launches
- Describe an EC2 Fleet, its instances, and its events
- Modify an EC2 Fleet
- Delete an EC2 Fleet request and the instances in the fleet

EC2 Fleet request states

An EC2 Fleet request can be one of various states, with each state indicating a different stage of the request's lifecycle and its management of instances.

An EC2 Fleet request can be in one of the following states:

`submitted`

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances. If a request would exceed your fleet limits, it is deleted immediately.

`active`

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances. The request remains in this state until it is modified or deleted.

`modifying`

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed or the request is deleted. Only a `maintain` fleet type can be modified. This state does not apply to other request types.

`deleted_running`

The EC2 Fleet request is deleted and does not launch additional Spot Instances. Its existing instances continue to run until they are interrupted or terminated manually. The request remains in this state until all instances are interrupted or terminated. Only an EC2 Fleet of type `maintain` or `request` can have running instances after the EC2 Fleet request is deleted. A deleted `instant` fleet with running instances is not supported. This state does not apply to `instant` fleets.

`deleted_terminating`

The EC2 Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

`deleted`

The EC2 Fleet request is deleted and has no running instances. The request is deleted two days after its instances are terminated.

EC2 Fleet prerequisites

To create an EC2 Fleet, the following prerequisites must be in place:

- Launch template
- Service-linked role for EC2 Fleet
- Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots
- Permissions for EC2 Fleet users

Launch template

A launch template specifies the configuration information about the instances to launch, such as the instance type and Availability Zone. For more information about launch templates, see Store instance launch parameters in Amazon EC2 launch templates.

Service-linked role for EC2 Fleet

The `AWSServiceRoleForEC2Fleet` role grants the EC2 Fleet permission to request, launch, terminate, and tag instances on your behalf. Amazon EC2 uses this service-linked role to complete the following actions:

- `ec2:RunInstances` – Launch instances.
- `ec2:RequestSpotInstances` – Request Spot Instances.
- `ec2:TerminateInstances` – Terminate instances.
- `ec2:DescribeImages` – Describe Amazon Machine Images (AMIs) for the instances.
- `ec2:DescribeInstanceStatus` – Describe the status of the instances.
- `ec2:DescribeSubnets` – Describe the subnets for instances.
- `ec2:CreateTags` – Add tags to the EC2 Fleet, instances, and volumes.

Ensure that this role exists before you use the AWS CLI or an API to create an EC2 Fleet.

> **Note**
>
> An `instant` EC2 Fleet does not require this role.

To create the role, use the IAM console as follows.

To create the AWSServiceRoleForEC2Fleet role for EC2 Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select trusted entity** page, do the following:

    a. For **Trusted entity type**, choose **AWS service**.

    b. Under **Use case**, for **Service or use case**, choose **EC2 - Fleet**.

    > **Tip**
    >
    > Be sure to choose **EC2 - Fleet**. If you choose **EC2**, the **EC2 - Fleet** use case does not appear in the **Use case** list. The **EC2 - Fleet** use case will automatically create a policy with the required IAM permissions and will suggest **AWSServiceRoleForEC2Fleet** as the role name.

    c. Choose **Next**.
5. On the **Add permissions page**, choose **Next**.
6. On the **Name, review, and create** page, choose **Create role**.

If you no longer need to use EC2 Fleet, we recommend that you delete the **AWSServiceRoleForEC2Fleet** role. After this role is deleted from your account, you can create the role again if you create another fleet.

For more information, see Service-linked roles in the *IAM User Guide*.

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an encrypted AMI or an encrypted Amazon EBS snapshot in your EC2 Fleet and you use an AWS KMS key for encryption, you must grant the **AWSServiceRoleForEC2Fleet** role permission to use the customer managed key so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using grants and Using key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

To grant the AWSServiceRoleForEC2Fleet role permissions to use the customer managed key

- Use the create-grant command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Fleet** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the `key-id` parameter and the ARN of the customer managed key. The principal is specified by the `grantee-principal` parameter and the ARN of the **AWSServiceRoleForEC2Fleet** service-linked role.

```
aws kms create-grant \
    --region us-east-1 \
    --key-id arn:aws:kms:us-
east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
    --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2Fleet \
    --operations "Decrypt" "Encrypt" "GenerateDataKey"
 "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
 "ReEncryptTo"
```

Permissions for EC2 Fleet users

If your users will create or manage an EC2 Fleet, be sure to grant them the required permissions.

To create a policy for EC2 Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create policy** page, choose the **JSON** tab, replace the text with the following, and choose **Review policy**.

   JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
              "iam:ListRoles",
              "iam:PassRole",
              "iam:ListInstanceProfiles"
            ],
            "Resource":"arn:aws:iam::123456789012:role/DevTeam*"
        }
    ]
}
```

The `ec2:*` grants a user permission to call all Amazon EC2 API actions. To limit the user to specific Amazon EC2 API actions, specify those actions instead.

The user must have permission to call the `iam:ListRoles` action to enumerate existing IAM roles, the `iam:PassRole` action to specify the EC2 Fleet role, and the `iam:ListInstanceProfiles` action to enumerate existing instance profiles.

(Optional) To enable a user to create roles or instance profiles using the IAM console, you must also add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
- `iam:AttachRolePolicy`
- `iam:CreateInstanceProfile`
- `iam:CreateRole`
- `iam:GetRole`
- `iam:ListPolicies`

5. On the **Review policy** page, enter a policy name and description, and choose **Create policy**.
6. To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Create an EC2 Fleet

To create an EC2 Fleet, define the fleet configuration in a JSON file and reference the file with the create-fleet command. In the JSON file, you must specify the total target capacity for the fleet, separate target capacities for Spot Instances and On-Demand Instances, and a launch template that defines the configuration for the instances in the fleet, such as an AMI, instance type, subnet or Availability Zone, and one or more security groups. You can optionally specify additional configurations, such as parameters to override the launch template configuration, allocation strategies for selecting Spot Instances and On-Demand Instances from the EC2 capacity pools, and the maximum amount you're willing to pay for the fleet. For more information, see Configuration options for your EC2 Fleet or Spot Fleet.

The EC2 Fleet launches On-Demand Instances when capacity is available, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available.

If your fleet includes Spot Instances and is of type `maintain`, Amazon EC2 will attempt to maintain your fleet target capacity when your Spot Instances are interrupted.

EC2 Fleet limitations

The following limitations apply to EC2 Fleet:

- Creating an EC2 Fleet is available only through the Amazon EC2 API, AWS CLI, AWS SDKs, and AWS CloudFormation.
- An EC2 Fleet request can't span AWS Regions. You need to create a separate EC2 Fleet for each Region.
- An EC2 Fleet request can't span different subnets from the same Availability Zone.

Create an EC2 Fleet

To launch a fleet of instances using EC2 Fleet, you need only specify the following parameters in your fleet request, and the fleet will use the default values for the other parameters:

- `LaunchTemplateId` or `LaunchTemplateName` – Specifies the launch template to use (which contains the parameters for the instances to launch, such as the instance type and Availability Zone)
- `TotalTargetCapacity` – Specifies the total target capacity for the fleet
- `DefaultTargetCapacityType` – Specifies whether the default purchasing option is On-Demand or Spot

To override the parameters specified in the launch template, you can specify one or more overrides. Each override can vary by instance type, Availability Zone, subnet, and maximum price, and can include a different weighted capacity. As an alternative to specifying an instance type, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. For more information, see Specify attributes for instance type selection for EC2 Fleet or Spot Fleet.

For EC2 Fleets of type `instant`, you can specify a Systems Manager parameter instead of the AMI ID. You can specify the Systems Manager parameter in the override or in the launch template. For more information, see Use a Systems Manager parameter instead of an AMI ID.

You can specify the fleet parameters in a JSON file. For information about all the possible parameters you can specify, see View all the EC2 Fleet configuration options.

For fleet configuration examples, see Example CLI configurations for EC2 Fleet.

There is currently no console support for creating an EC2 Fleet.

To create an EC2 Fleet

Use the create-fleet command to create the fleet and specify the JSON file that contains the fleet configuration parameters.

```
aws ec2 create-fleet --cli-input-json file://file_name.json
```

The following is example output for a fleet of type `request` or `maintain`.

```
{
    "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE"
}
```

The following is example output for a fleet of type `instant` that launched the target capacity.

```
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [],
  "Instances": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a"
        }
      },
      "Lifecycle": "on-demand",
      "InstanceIds": [
        "i-1234567890abcdef0",
        "i-9876543210abcdef9"
      ],
      "InstanceType": "c5.large",
      "Platform": null
    },
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
```

```
          "Overrides": {
            "InstanceType": "c4.large",
            "AvailabilityZone": "us-east-1a"
          }
        },
        "Lifecycle": "on-demand",
        "InstanceIds": [
          "i-5678901234abcdef0",
          "i-5432109876abcdef9"
        ]
    ]
}
```

The following is example output for a fleet of type `instant` that launched part of the target capacity with errors for instances that were not launched.

```
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c4.xlarge",
          "AvailabilityZone": "us-east-1a",
        }
      },
      "Lifecycle": "on-demand",
      "ErrorCode": "InsufficientInstanceCapacity",
      "ErrorMessage": ""
    },
  ],
  "Instances": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
```

```
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a"
        }
      },
      "Lifecycle": "on-demand",
      "InstanceIds": [
        "i-1234567890abcdef0",
        "i-9876543210abcdef9"
      ]
  ]
}
```

The following is example output for a fleet of type `instant` that launched no instances.

```
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c4.xlarge",
          "AvailabilityZone": "us-east-1a",
        }
      },
      "Lifecycle": "on-demand",
      "ErrorCode": "InsufficientCapacity",
      "ErrorMessage": ""
    },
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a",
        }
      },
```

```
      "Lifecycle": "on-demand",
      "ErrorCode": "InsufficientCapacity",
      "ErrorMessage": ""
    },
  ],
  "Instances": []
}
```

Create an EC2 Fleet that replaces unhealthy Spot Instances

EC2 Fleet checks the health status of the instances in the fleet every two minutes. The health status of an instance is either `healthy` or `unhealthy`.

EC2 Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as `unhealthy` when the status of either the instance status check or the system status check is `impaired` for three consecutive health status checks. For more information, see Status checks for Amazon EC2 instances.

You can configure your fleet to replace unhealthy Spot Instances. After setting `ReplaceUnhealthyInstances` to `true`, a Spot Instance is replaced when it is reported as `unhealthy`. The fleet can go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

Requirements

- Health check replacement is supported only for EC2 Fleets that maintain a target capacity (fleets of type `maintain`), and not for fleets of type `request` or `instant`.
- Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.
- You can configure your EC2 Fleet to replace unhealthy instances only when you create it.
- Users can use health check replacement only if they have permission to call the `ec2:DescribeInstanceStatus` action.

To configure an EC2 Fleet to replace unhealthy Spot Instances

1. Use the information for creating an EC2 Fleet in Create an EC2 Fleet.
2. To configure the fleet to replace unhealthy Spot Instances, in the JSON file, for `ReplaceUnhealthyInstances`, specify `true`.

View all the EC2 Fleet configuration options

To view the full list of EC2 Fleet configuration parameters, you can generate a JSON file. For a description of each parameter, see create-fleet.

To generate a JSON file with all possible EC2 Fleet parameters

Use the create-fleet (AWS CLI) command and the `--generate-cli-skeleton` parameter to generate an EC2 Fleet JSON file, and direct the output to a file to save it.

```
aws ec2 create-fleet \
    --generate-cli-skeleton input > ec2createfleet.json
```

The following is example output.

```
{
    "DryRun": true,
    "ClientToken": "",
    "SpotOptions": {
        "AllocationStrategy": "price-capacity-optimized",
        "MaintenanceStrategies": {
            "CapacityRebalance": {
                "ReplacementStrategy": "launch"
            }
        },
        "InstanceInterruptionBehavior": "hibernate",
        "InstancePoolsToUseCount": 0,
        "SingleInstanceType": true,
        "SingleAvailabilityZone": true,
        "MinTargetCapacity": 0,
        "MaxTotalPrice": ""
    },
    "OnDemandOptions": {
        "AllocationStrategy": "prioritized",
        "CapacityReservationOptions": {
            "UsageStrategy": "use-capacity-reservations-first"
        },
        "SingleInstanceType": true,
        "SingleAvailabilityZone": true,
        "MinTargetCapacity": 0,
        "MaxTotalPrice": ""
    },
    "ExcessCapacityTerminationPolicy": "termination",
```

```
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "",

Tag a new or existing EC2 Fleet request and the instances and volumes it launches

To help categorize and manage your EC2 Fleet requests and the instances and volumes that it launches, you can tag them with custom metadata. You can assign a tag to an EC2 Fleet request when you create it, or afterward. Similarly, you can assign a tag to the instances and volumes when they're launched by the fleet, or afterward.

When you tag a fleet request, the instances and volumes that are launched by the fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the fleet. You can choose to assign tags to only the fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all of them.

> **Note**
>
> For `instant` fleet types, you can tag volumes that are attached to On-Demand Instances and Spot Instances. For `request` or `maintain` fleet types, you can only tag volumes that are attached to On-Demand Instances.

For more information about how tags work, see Tag your Amazon EC2 resources.

Prerequisite

Grant the user the permission to tag resources. For more information, see Example: Tag resources.

To grant a user the permission to tag resources

Create a IAM policy that includes the following:

- The `ec2:CreateTags` action. This grants the user permission to create tags.
- The `ec2:CreateFleet` action. This grants the user permission to create an EC2 Fleet request.
- For `Resource`, we recommend that you specify `"*"`. This allows users to tag all resource types.

> **Important**
>
> We currently do not support resource-level permissions for the `create-fleet` resource. If you specify `create-fleet` as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how *not* to set the policy.
>
> ```
> {
>     "Effect": "Allow",
>     "Action": [
>         "ec2:CreateTags",
>         "ec2:CreateFleet"
>     ],
>     "Resource": "arn:aws:ec2:us-east-1:111122223333:create-fleet/*"
> }
> ```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

To tag a new EC2 Fleet request

To tag an EC2 Fleet request when you create it, specify the key-value pair in the JSON file used to create the fleet. The value for `ResourceType` must be `fleet`. If you specify another value, the fleet request fails.

To tag instances and volumes launched by an EC2 Fleet

To tag instances and volumes when they are launched by the fleet, specify the tags in the launch template that is referenced in the EC2 Fleet request.

> **Note**
>
> You can't tag volumes attached to Spot Instances that are launched by a `request` or `maintain` fleet type.

To tag an existing EC2 Fleet request, instance, and volume

Use the create-tags command to tag existing resources.

```
aws ec2 create-tags \
    --resources fleet-12a34b55-67cd-8ef9-
ba9b-9208dEXAMPLE i-1234567890abcdef0 vol-1234567890EXAMPLE \
    --tags Key=purpose,Value=test
```

Describe an EC2 Fleet, its instances, and its events

You can describe your EC2 Fleet configuration, the instances in your EC2 Fleet, and the event history of your EC2 Fleet.

Tasks

- Describe your EC2 Fleet
- Describe all instances in your EC2 Fleet
- Describe the event history for your EC2 Fleet

Describe your EC2 Fleet

AWS CLI

To describe your EC2 Fleet

Use the describe-fleets command.

```
aws ec2 describe-fleets \
    --fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

The following is example output.

```
{
    "Fleets": [
        {
            "ActivityStatus": "fulfilled",
            "CreateTime": "2022-02-09T03:35:52+00:00",
            "FleetId": "fleet-364457cd-3a7a-4ed9-83d0-7b63e51bb1b7",
            "FleetState": "active",
            "ExcessCapacityTerminationPolicy": "termination",
            "FulfilledCapacity": 2.0,
            "FulfilledOnDemandCapacity": 0.0,
            "LaunchTemplateConfigs": [
                {
                    "LaunchTemplateSpecification": {
                        "LaunchTemplateName": "my-launch-template",
                        "Version": "$Latest"
                    }
                }
```

```
            ],
            "TargetCapacitySpecification": {
                "TotalTargetCapacity": 2,
                "OnDemandTargetCapacity": 0,
                "SpotTargetCapacity": 2,
                "DefaultTargetCapacityType": "spot"
            },
            "TerminateInstancesWithExpiration": false,
            "Type": "maintain",
            "ReplaceUnhealthyInstances": false,
            "SpotOptions": {
                "AllocationStrategy": "capacity-optimized",
                "InstanceInterruptionBehavior": "terminate"
            },
            "OnDemandOptions": {
                "AllocationStrategy": "lowestPrice"
            }
        }
    ]
}
```

PowerShell

To describe your EC2 Fleet

Use the Get-EC2FleetList cmdlet.

```
Get-EC2FleetList `
    -FleetId fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

Describe all instances in your EC2 Fleet

The returned list of running instances is refreshed periodically and might be out of date.

AWS CLI

To describe the instances for the specified EC2 Fleet

Use the describe-fleet-instances command.

```
aws ec2 describe-fleet-instances \
    --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

The following is example output.

```
{
    "ActiveInstances": [
        {
            "InstanceId": "i-09cd595998cb3765e",
            "InstanceHealth": "healthy",
            "InstanceType": "m4.large",
            "SpotInstanceRequestId": "sir-86k84j6p"
        },
        {
            "InstanceId": "i-09cf95167ca219f17",
            "InstanceHealth": "healthy",
            "InstanceType": "m4.large",
            "SpotInstanceRequestId": "sir-dvxi7fsm"
        }
    ],
    "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE"
}
```

PowerShell

To describe the instances for the specified EC2 Fleet

Use the Get-EC2FleetInstanceList cmdlet.

```
Get-EC2FleetInstanceList `
    -FleetId fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

Describe the event history for your EC2 Fleet

For more information about the events in the event history, see EC2 Fleet event types.

AWS CLI

To describe the events for the specified EC2 Fleet

Use the describe-fleet-history command.

```
aws ec2 describe-fleet-history \
    --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --start-time 2020-06-01T00:00:00Z
```

The following is example output.

```
{
    "HistoryRecords": [
        {
            "EventInformation": {
                "EventSubType": "submitted"
            },
            "EventType": "fleetRequestChange",
            "Timestamp": "2020-09-01T18:26:05.000Z"
        },
        {
            "EventInformation": {
                "EventSubType": "active"
            },
            "EventType": "fleetRequestChange",
            "Timestamp": "2020-09-01T18:26:15.000Z"
        },
        {
            "EventInformation": {
                "EventDescription": "t2.small, ami-07c8bc5c1ce9598c3, ...",
                "EventSubType": "progress"
            },
            "EventType": "fleetRequestChange",
            "Timestamp": "2020-09-01T18:26:17.000Z"
        },
        {
            "EventInformation": {
                "EventDescription": "{\"instanceType\":\"t2.small\", ...}",
                "EventSubType": "launched",
                "InstanceId": "i-083a1c446e66085d2"
            },
            "EventType": "instanceChange",
            "Timestamp": "2020-09-01T18:26:17.000Z"
        },
        {
            "EventInformation": {
                "EventDescription": "{\"instanceType\":\"t2.small\", ...}",
                "EventSubType": "launched",
                "InstanceId": "i-090db02406cc3c2d6"
            },
            "EventType": "instanceChange",
            "Timestamp": "2020-09-01T18:26:17.000Z"
        }
```

```
    ],
    "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
    "LastEvaluatedTime": "1970-01-01T00:00:00.000Z",
    "StartTime": "2020-06-01T00:00:00.000Z"
}
```

PowerShell

To describe the events for the specified EC2 Fleet

Use the Get-EC2FleetHistory cmdlet.

```
Get-EC2FleetHistory `
    -FleetId fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE `
    -UtcStartTime 2020-06-01T00:00:00Z
```

Modify an EC2 Fleet

You can modify the total target capacity, Spot capacity, and On-Demand capacity of an EC2 Fleet. You can also modify whether running instances should be terminated if the new total target capacity is reduced below the current size of the fleet.

Considerations

Consider the following when modifying an EC2 Fleet:

- **Fleet type** – You can only modify an EC2 Fleet of type `maintain`. You can't modify an EC2 Fleet of type `request` or `instant`.
- **Fleet parameters** – You can modify the following parameters of an EC2 Fleet:
  - `target-capacity-specification` – Increase or decrease the target capacity for:
    - `TotalTargetCapacity`
    - `OnDemandTargetCapacity`
    - `SpotTargetCapacity`
  - `excess-capacity-termination-policy` – Whether running instances should be terminated if the total target capacity of the EC2 Fleet is decreased below the current size of the fleet. Valid values are:
    - `no-termination`
    - `termination`

- **Fleet behavior when increasing total target capacity** – When you increase the total target capacity, the EC2 Fleet launches the additional instances according to the instance purchasing option specified for `DefaultTargetCapacityType`, which is either On-Demand Instances or Spot Instances, and according to the specified allocation strategy.
- **Fleet behavior when decreasing Spot target capacity** – When you decrease the Spot target capacity, the EC2 Fleet deletes any open requests that exceed the new target capacity. You can request that the fleet terminate Spot Instances until the size of the fleet reaches the new target capacity. When an EC2 Fleet terminates a Spot Instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

  Instances are selected for termination based on the allocation strategy:

  - `capacity-optimized` – Terminates instances from pools with the least available capacity.
  - `price-capacity-optimized` – Uses a combination of price and available capacity: terminates instances from pools with the least available capacity and which are the highest-priced among these pools.
  - `diversified` – Terminates instances across all pools.
  - `lowest-price` – Terminates instances from highest-priced pools.

  Alternatively, you can request that EC2 Fleet keep the fleet at its current size, but not replace any Spot Instances that are interrupted or that you terminate manually.
- **Fleet state** – You can modify an EC2 Fleet that is in the `submitted` or `active` state. When you modify a fleet, it enters the `modifying` state.

Commands for modifying an EC2 Fleet

AWS CLI

To modify the total target capacity of an EC2 Fleet

Use the modify-fleet command.

```
aws ec2 modify-fleet \
    --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --target-capacity-specification TotalTargetCapacity=20
```

If you are decreasing the target capacity but want to keep the fleet at its current size, you can modify the previous example as follows.

```
aws ec2 modify-fleet \
    --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --target-capacity-specification TotalTargetCapacity=10 \
    --excess-capacity-termination-policy no-termination
```

PowerShell

To modify the total target capacity of an EC2 Fleet

Use the Edit-EC2Fleet cmdlet.

```
Edit-EC2Fleet `
    -FleetId "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TargetCapacitySpecification_TotalTargetCapacity 20
```

If you are decreasing the target capacity but want to keep the fleet at its current size, you can modify the previous example as follows.

```
Edit-EC2Fleet `
    -FleetId "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TargetCapacitySpecification_TotalTargetCapacity 20 `
    -ExcessCapacityTerminationPolicy "NoTermination"
```

Delete an EC2 Fleet request and the instances in the fleet

If you no longer require an EC2 Fleet request, you can delete it. After you delete a fleet request, all Spot requests associated with the fleet are canceled, so that no new Spot Instances are launched.

When you delete an EC2 Fleet request, you must also specify if you want to terminate all of its instances. These include both On-Demand Instances and Spot Instances. For `instant` fleets, EC2 Fleet must terminate the instances when the fleet is deleted. A deleted `instant` fleet with running instances is not supported.

If you specify that the instances must be terminated when the fleet request is deleted, the fleet request enters the `deleted_terminating` state. Otherwise, it enters the `deleted_running` state, and the instances continue to run until they are interrupted or you terminate them manually.

Restrictions

- You can delete up to 25 fleets of type `instant` in a single operation.

- You can delete up to 100 fleets of type `maintain` or `request` in a single operation.
- You can delete up to 125 fleets in a single operation, provided you do not exceed the quota for each fleet type, as specified above.
- If you exceed the specified number of fleets to delete, no fleets are deleted.
- A deleted `instant` fleet with running instances is not supported. When you delete an `instant` fleet, Amazon EC2 automatically terminates all its instances. For `instant` fleets with more than 1000 instances, the deletion request might fail. If your fleet has more than 1000 instances, first terminate most of the instances manually, leaving 1000 or fewer. Then delete the fleet, and the remaining instances will be terminated automatically.

AWS CLI

To delete an EC2 Fleet request and terminate its instances

Use the delete-fleets command with the `--terminate-instances` option.

```
aws ec2 delete-fleets \
    --fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --terminate-instances
```

The following is example output.

```
{
    "UnsuccessfulFleetDeletions": [],
    "SuccessfulFleetDeletions": [
        {
            "CurrentFleetState": "deleted_terminating",
            "PreviousFleetState": "active",
            "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE"
        }
    ]
}
```

To delete an EC2 Fleet request without terminating its instances

Modify the previous example by using the `--no-terminate-instances` option instead. Note that `--no-terminate-instances` is not supported for `instant` fleets.

```
aws ec2 delete-fleets \
    --fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
```

```
    --no-terminate-instances
```

The following is example output.

```
{
    "UnsuccessfulFleetDeletions": [],
    "SuccessfulFleetDeletions": [
        {
            "CurrentFleetState": "deleted_running",
            "PreviousFleetState": "active",
            "FleetId": "fleet-4b8aaae8-dfb5-436d-a4c6-3dafa4c6b7dcEXAMPLE"
        }
    ]
}
```

PowerShell

To delete an EC2 Fleet request and terminate its instances

Use the Remove-EC2Fleet cmdlet with the `-TerminateInstance` parameter.

```
Remove-EC2Fleet `
    -FleetId "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TerminateInstance $true
```

To delete an EC2 Fleet request without terminating its instances

Modify the previous example by changing the value of the `-TerminateInstance` parameter.

```
Remove-EC2Fleet `
    -FleetId "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TerminateInstance $false
```

Troubleshoot when a fleet fails to delete

If an EC2 Fleet request fails to delete, `UnsuccessfulFleetDeletions` in the output returns the ID of the EC2 Fleet request, an error code, and an error message.

The error codes are:

- `ExceededInstantFleetNumForDeletion`

- `fleetIdDoesNotExist`
- `fleetIdMalformed`
- `fleetNotInDeletableState`
- `NoTerminateInstancesNotSupported`
- `UnauthorizedOperation`
- `unexpectedError`

Troubleshoot `ExceededInstantFleetNumForDeletion`

If you try to delete more than 25 `instant` fleets in a single request, the `ExceededInstantFleetNumForDeletion` error is returned. The following is example output for this error.

```
{
    "UnsuccessfulFleetDeletions": [
     {
          "FleetId": " fleet-5d130460-0c26-bfd9-2c32-0100a098f625",
          "Error": {
                  "Message": "Can’t delete more than 25 instant fleets in a single
 request.",
                  "Code": "ExceededInstantFleetNumForDeletion"
           }
     },
     {
           "FleetId": "fleet-9a941b23-0286-5bf4-2430-03a029a07e31",
           "Error": {
                  "Message": "Can’t delete more than 25 instant fleets in a single
 request.",
                  "Code": "ExceededInstantFleetNumForDeletion"
            }
     }
     .
     .
     .
     ],
     "SuccessfulFleetDeletions": []
}
```

Troubleshoot `NoTerminateInstancesNotSupported`

If you specify that the instances in an `instant` fleet must not be terminated when you delete the fleet, the `NoTerminateInstancesNotSupported` error is returned. `--no-terminate-instances` is not supported for `instant` fleets. The following is example output for this error.

```
{
      "UnsuccessfulFleetDeletions": [
            {
                  "FleetId": "fleet-5d130460-0c26-bfd9-2c32-0100a098f625",
                  "Error": {
                          "Message": "NoTerminateInstances option is not supported for
 instant fleet",
                          "Code": "NoTerminateInstancesNotSupported"
                   }
            }
       ],
       "SuccessfulFleetDeletions": []
}
```

Troubleshoot `UnauthorizedOperation`

If you do not have permission to terminate instances, you get the `UnauthorizedOperation` error when deleting a fleet that must terminate its instances. The following is the error response.

```
<Response><Errors><Error><Code>UnauthorizedOperation</Code><Message>You are not
 authorized to perform this
operation. Encoded authorization failure message: VvuncIxj7Z_CPGNYXWqnuFV-
YjByeAU66Q9752NtQ-I3-qnDLWs6JLFd

</Message></Error></Errors><RequestID>89b1215c-7814-40ae-a8db-41761f43f2b0</
RequestID></Response>
```

To resolve the error, you must add the `ec2:TerminateInstances` action to the IAM policy, as shown in the following example.

Work with Spot Fleet

To start using a Spot Fleet, create a request that includes the total target capacity for Spot Instances, an optional On-Demand portion, and either manually specify an AMI and a key pair, or specify a launch template that includes the configuration for the instances in the fleet. You can optionally specify additional parameters, or let the fleet use default values. You can also tag the fleet request, and its instances and volumes, when you create the fleet.

The fleet launches On-Demand Instances when there is available capacity, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available.

Once your fleet is launched, you can describe the fleet request, the instances in the fleet, and any fleet events. You can also assign additional tags as needed.

If you need to change any fleet parameters, such as the total target capacity, you can modify the fleet, provided it was configured to maintain capacity. You can't modify the capacity of a one-time request after it's been submitted.

The fleet request remains active until it expires or you cancel (delete) it. When you cancel the fleet request, you can either terminate the instances or leave them running. If you choose to leave them running, the On-Demand Instances run until you terminate them, and the Spot Instances run until they're interrupted or you terminate them.

Topics

Spot Fleet request states

A Spot Fleet request can be one of various states, with each state indicating a different stage of the request's lifecycle and its management of instances.

A Spot Fleet request can be in one of the following states:

`submitted`

The Spot Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances. If a request would exceed your Spot Fleet quotas, it is canceled immediately.

`active`

The Spot Fleet has been validated and Amazon EC2 is attempting to maintain the target number of running Spot Instances. The request remains in this state until it is modified or canceled.

`modifying`

The Spot Fleet request is being modified. The request remains in this state until the modification is fully processed or the request is canceled. Only a `maintain` fleet type can be modified. This state does not apply to a one-time `request` fleet type.

`cancelled_running`

The Spot Fleet is canceled (deleted) and does not launch additional Spot Instances. Its existing instances continue to run until they are interrupted or terminated manually. The request remains in this state until all instances are interrupted or terminated.

`cancelled_terminating`

The Spot Fleet is canceled (deleted) and its instances are terminating. The request remains in this state until all instances are terminated.

`cancelled`

The Spot Fleet is canceled (deleted) and has no running instances. The request is deleted two days after its instances are terminated.

Spot Fleet permissions

If your users will create or manage a Spot Fleet, you need to grant them the required permissions.

If you use the Amazon EC2 console to create a Spot Fleet, it creates two service-linked roles named `AWSServiceRoleForEC2SpotFleet` and `AWSServiceRoleForEC2Spot`, and a role named `aws-ec2-spot-fleet-tagging-role` that grant the Spot Fleet the permissions to request, launch, terminate, and tag resources on your behalf. If you use the AWS CLI or an API, you must ensure that these roles exist.

Use the following instructions to grant the required permissions and create the roles.

Permissions and roles

- Grant permission to users for Spot Fleet
- Service-linked role for Spot Fleet
- Service-linked role for Spot Instances
- IAM role for tagging a Spot Fleet

Grant permission to users for Spot Fleet

If your users will create or manage a Spot Fleet, be sure to grant them the required permissions.

To create a policy for Spot Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**, **Create policy**.
3. On the **Create policy** page, choose **JSON**, and replace the text with the following.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances",
                "ec2:CreateTags",
                "ec2:RequestSpotFleet",
                "ec2:ModifySpotFleetRequest",
                "ec2:CancelSpotFleetRequests",
                "ec2:DescribeSpotFleetRequests",
                "ec2:DescribeSpotFleetInstances",
                "ec2:DescribeSpotFleetRequestHistory"
            ],
            "Resource": "*"
```

```
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::*:role/aws-ec2-spot-fleet-tagging-role"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateServiceLinkedRole",
                "iam:ListRoles",
                "iam:ListInstanceProfiles"
            ],
            "Resource": "*"
        }
    ]
}
```

The preceding example policy grants a user the permissions required for most Spot Fleet use cases. To limit the user to specific API actions, specify only those API actions instead.

Required EC2 and IAM APIs

The following APIs must be included in the policy:

- `ec2:RunInstances` – Required to launch instances in a Spot Fleet
- `ec2:CreateTags` – Required to tag the Spot Fleet request, instances, or volumes
- `iam:PassRole` – Required to specify the Spot Fleet role
- `iam:CreateServiceLinkedRole` – Required to create the service-linked role
- `iam:ListRoles` – Required to enumerate existing IAM roles
- `iam:ListInstanceProfiles` – Required to enumerate existing instance profiles

Important

If you specify a role for the IAM instance profile in the launch specification or launch template, you must grant the user the permission to pass the role to the service. To do this, in the IAM policy include `"arn:aws:iam::*:role/`*`IamInstanceProfile-`*

role" as a resource for the `iam:PassRole` action. For more information, see [Granting a user permissions to pass a role to an AWS service]() in the *IAM User Guide*.

Spot Fleet APIs

Add the following Spot Fleet API actions to your policy, as needed:

- `ec2:RequestSpotFleet`
- `ec2:ModifySpotFleetRequest`
- `ec2:CancelSpotFleetRequests`
- `ec2:DescribeSpotFleetRequests`
- `ec2:DescribeSpotFleetInstances`
- `ec2:DescribeSpotFleetRequestHistory`

Optional IAM APIs

(Optional) To enable a user to create roles or instance profiles using the IAM console, you must add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
- `iam:AttachRolePolicy`
- `iam:CreateInstanceProfile`
- `iam:CreateRole`
- `iam:GetRole`
- `iam:ListPolicies`

4. Choose **Review policy**.
5. On the **Review policy** page, enter a policy name and description, and choose **Create policy**.
6. To provide access, add permissions to your users, groups, or roles:

   - Users and groups in AWS IAM Identity Center:

     Create a permission set. Follow the instructions in [Create a permission set]() in the *AWS IAM Identity Center User Guide*.

   - Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Service-linked role for Spot Fleet

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see Service-linked roles in the *IAM User Guide*.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2SpotFleet** to launch and manage instances on your behalf.

> **Important**
>
> If you specify an encrypted AMI or an encrypted Amazon EBS snapshot in your Spot Fleet, you must grant the **AWSServiceRoleForEC2SpotFleet** role permission to use the CMK so that Amazon EC2 can launch instances on your behalf. For more information, see Grant access to CMKs for use with encrypted AMIs and EBS snapshots.

Permissions granted by AWSServiceRoleForEC2SpotFleet

The **AWSServiceRoleForEC2SpotFleet** role grants the Spot Fleet permission to request, launch, terminate, and tag instances on your behalf. Amazon EC2 uses this service-linked role to complete the following actions:

- `ec2:RequestSpotInstances` - Request Spot Instances
- `ec2:RunInstances` - Launch instances
- `ec2:TerminateInstances` - Terminate instances

- `ec2:DescribeImages` - Describe Amazon Machine Images (AMIs) for the instances
- `ec2:DescribeInstanceStatus` - Describe the status of the instances
- `ec2:DescribeSubnets` - Describe the subnets for the instances
- `ec2:CreateTags` - Add tags to the Spot Fleet request, instances, and volumes
- `elasticloadbalancing:RegisterInstancesWithLoadBalancer` - Add the specified instances to the specified load balancer
- `elasticloadbalancing:RegisterTargets` - Register the specified targets with the specified target group

Create the service-linked role

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2SpotFleet** service-linked role the first time you create a Spot Fleet using the console.

If you had an active Spot Fleet request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2SpotFleet** role in your AWS account. For more information, see [A new role appeared in my AWS account](#) in the *IAM User Guide*.

If you use the AWS CLI or an API to create a Spot Fleet, you must first ensure that this role exists.

To create the AWSServiceRoleForEC2SpotFleet role for Spot Fleet using the console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select trusted entity** page, do the following:

   a. For **Trusted entity type**, choose **AWS service**.

   b. Under **Use case**, for **Service or use case**, choose **EC2**.

   c. For **Use case**, choose **EC2 - Spot Fleet**.

> **Note**
>
> The **EC2 - Spot Fleet** use case will automatically create a policy with the required IAM permissions and will suggest **AWSEC2SpotFleetServiceRolePolicy** as the role name.

   d. Choose **Next**.

5. On the **Add permissions** page, choose **Next**.
6. On the **Name, review, and create** page, choose **Create role**.

To create the AWSServiceRoleForEC2SpotFleet role for Spot Fleet using the AWS CLI

Use the create-service-linked-role command as follows.

```
aws iam create-service-linked-role --aws-service-name spotfleet.amazonaws.com
```

If you no longer need to use Spot Fleet, we recommend that you delete the **AWSServiceRoleForEC2SpotFleet** role. After this role is deleted from your account, Amazon EC2 will create the role again if you request a Spot Fleet using the console. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Grant access to CMKs for use with encrypted AMIs and EBS snapshots

If you specify an encrypted AMI or an encrypted Amazon EBS snapshot in your Spot Fleet request and you use a customer managed key for encryption, you must grant the **AWSServiceRoleForEC2SpotFleet** role permission to use the CMK so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the CMK, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using Grants and Using Key Policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

To grant the AWSServiceRoleForEC2SpotFleet role permissions to use the CMK

- Use the create-grant command to add a grant to the CMK and to specify the principal (the **AWSServiceRoleForEC2SpotFleet** service-linked role) that is given permission to perform the operations that the grant permits. The CMK is specified by the `key-id` parameter and the ARN of the CMK. The principal is specified by the `grantee-principal` parameter and the ARN of the **AWSServiceRoleForEC2SpotFleet** service-linked role.

```
aws kms create-grant \
    --region us-east-1 \
    --key-id arn:aws:kms:us-
east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
    --grantee-principal arn:aws:iam::111122223333:role/aws-service-role/
spotfleet.amazonaws.com/AWSServiceRoleForEC2SpotFleet \
    --operations "Decrypt" "Encrypt" "GenerateDataKey"
 "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
 "ReEncryptTo"
```

Service-linked role for Spot Instances

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests.

IAM role for tagging a Spot Fleet

The `aws-ec2-spot-fleet-tagging-role` IAM role grants the Spot Fleet permission to tag the Spot Fleet request, instances, and volumes. For more information, see Tag a new or existing Spot Fleet request and the instances and volumes it launches.

Important

If you choose to tag instances in the fleet and you also choose to maintain target capacity (the Spot Fleet request is of type `maintain`), the differences in the permissions that are set for the user and the `IamFleetRole` might lead to inconsistent tagging behavior of instances in the fleet. If the `IamFleetRole` does not include the `CreateTags` permission, some of the instances launched by the fleet might not be tagged. While we are working to fix this inconsistency, to ensure that all instances launched by the fleet are tagged, we recommend that you use the `aws-ec2-spot-fleet-tagging-role` role for the `IamFleetRole`. Alternatively, to use an existing role, attach the `AmazonEC2SpotFleetTaggingRole` AWS Managed Policy to the existing role. Otherwise, you need to manually add the `CreateTags` permission to your existing policy.

To create the IAM role for tagging a Spot Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select trusted entity** page, under **Trusted entity type**, choose **AWS service**.
5. Under **Use case**, from **Use cases for other AWS services**, choose **EC2**, and then choose **EC2 - Spot Fleet Tagging**.
6. Choose **Next**.
7. On the **Add permissions** page, choose **Next**.
8. On the **Name, review, and create** page, for **Role name**, enter a name for the role (for example, **`aws-ec2-spot-fleet-tagging-role`**).
9. Review the information on the page, and then choose **Create role**.

Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. We recommend that you use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in the `aws-ec2-spot-fleet-tagging-role` trust policy to limit the permissions that Spot Fleet gives another service to the resource.

To add the aws:SourceArn and aws:SourceAccount condition keys to the `aws-ec2-spot-fleet-tagging-role` trust policy

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Find the `aws-ec2-spot-fleet-tagging-role` that you created previously and choose the link (not the checkbox).
4. Under **Summary**, choose the **Trust relationships** tab, and then choose **Edit trust policy**.
5. In the JSON statement, add a `Condition` element containing your `aws:SourceAccount` and `aws:SourceArn` global condition context keys to prevent the confused deputy problem, as follows:

   ```
   "Condition": {
   ```

```
      "ArnLike": {
        "aws:SourceArn": "arn:aws:ec2:us-east-1:111122223333:spot-fleet-request/
sfr-*"
      },
      "StringEquals": {
        "aws:SourceAccount": "111122223333"
      }
```

> **Note**
>
> If the aws:SourceArn value contains the account ID and you use both global condition context keys, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same policy statement.

The final trust policy will be as follows:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "spotfleet.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:ec2:us-east-1:111122223333:spot-fleet-
request/sfr-*"
      },
      "StringEquals": {
        "aws:SourceAccount": "111122223333"
      }
    }
  }
}
```

6. Choose **Update policy**.

The following table provides potential values for `aws:SourceArn` to limit the scope of the your `aws-ec2-spot-fleet-tagging-role` in varying degrees of specificity.

API operation	Called service	Scope	`aws:SourceArn`
RequestSpotFleet	AWS STS (`AssumeRole`)	Limit the `AssumeRole` capability on `aws-ec2-spot-fleet-tagging-role` to spot-fleet-requests in the specified account.	`arn:aws:ec2:*:` *`123456789012`* `:spot-fleet-request/sfr-*`
RequestSpotFleet	AWS STS (`AssumeRole`)	Limit the `AssumeRole` capability on `aws-ec2-spot-fleet-tagging-role` to spot-fleet-requests in the specified account and specified Region. Note that this role will not be usable in other Regions.	`arn:aws:ec2:` *`us-east-1`* `:`*`123456789012`* `:spot-fleet-request/sfr-*`
RequestSpotFleet	AWS STS (`AssumeRole`)	Limit the `AssumeRole` capability on `aws-ec2-spot-fleet-tagging-role` to only actions affecting the fleet sfr-11111111-1111-1111-1111-111111111111.	`arn:aws:ec2:` *`us-east-1`* `:`*`123456789012`* `:spot-fleet-request/sfr-`*`11111111-1111-1111-1111-111111111111`*

API operation	Called service	Scope	aws:SourceArn
		Note that this role may not be usable for other Spot Fleets. A lso, this role cannot be used to launch any new Spot Fleets th rough request-spot-fleet.	

Create a Spot Fleet

Using the AWS Management Console, you can quickly create a Spot Fleet request by choosing only an AMI and your desired total target capacity. Amazon EC2 will configure a fleet that best meets your needs and follows Spot best practices. Alternatively, you can modify any of the default settings.

If you want to include On-Demand Instances in your fleet, you must specify a launch template in your request and specify you desired On-Demand capacity.

The fleet launches On-Demand Instances when capacity is available, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available.

If your fleet includes Spot Instances and is of type `maintain`, Amazon EC2 will attempt to maintain your fleet target capacity when your Spot Instances are interrupted.

Required permissions

For more information, see the section called “Spot Fleet permissions”.

Tasks

- Quickly create a Spot Fleet request
- Create a Spot Fleet request using defined parameters
- Create a Spot Fleet that replaces unhealthy Spot Instances

Quickly create a Spot Fleet request

Follow these steps to quickly create a Spot Fleet request using the Amazon EC2 console.

To create a Spot Fleet request using the recommended settings

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. If you are new to Spot, you see a welcome page; choose **Get started**. Otherwise, choose **Create Spot Fleet Request**.
4. Under **Launch parameters**, choose **Manually configure launch parameters**.
5. For **AMI**, choose an AMI.
6. Under **Target capacity**, for **Total target capacity**, specify the number of units to request. For the type of unit, you can choose **Instances**, **vCPUs**, or **Memory (GiB)**.
7. Under **Your fleet request at a glance**, review your fleet configuration, and choose **Launch**.

Create a Spot Fleet request using defined parameters

You can create a Spot Fleet by using parameters that you define.

Console

To create a Spot Fleet request using defined parameters

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. If you are new to Spot, you see a welcome page; choose **Get started**. Otherwise, choose **Create Spot Fleet Request**.
4. For **Launch parameters**, you can either manually configure the launch parameters or you can use a launch template, as follows:
   a. [Manually configure] To define the launch parameters in the Amazon EC2 console, choose **Manually configure launch parameters**, and then do the following:
      i. For **AMI**, choose one of the basic AMIs provided by AWS, or choose **Search for AMI** to use an AMI from our user community, the AWS Marketplace, or one of your own.

> **Note**
>
> If an AMI specified in the launch parameters is deregistered or disabled, no new instances can be launched from the AMI. For fleets that are set to maintain target capacity, the target capacity will not be maintained.

ii. (Optional) For **Key pair name**, choose an existing key pair or create a new one.

    [Existing key pair] Choose the key pair.

    [New key pair] Choose **Create new key pair** to go the **Key pairs** page. When you are done, return to the **Spot Requests** page and refresh the list.

iii. (Optional) Expand **Additional launch parameters**, and do the following:

    A. (Optional) To enable Amazon EBS optimization, for **EBS-optimized**, select **Launch EBS-optimized instances**.

    B. (Optional) To add temporary block-level storage for your instances, for **Instance store**, choose **Attach at launch**.

    C. (Optional) To add storage, choose **Add new volume**, and specify additional instance store volumes or Amazon EBS volumes, depending on the instance type.

    D. (Optional) By default, basic monitoring is enabled for your instances. To enable detailed monitoring, for **Monitoring**, select **Enable CloudWatch detailed monitoring**.

    E. (Optional) To run a Dedicated Spot Instance, for **Tenancy**, choose **Dedicated - run a dedicated instance**.

    F. (Optional) For **Security groups**, choose one or more security groups or create a new one.

       [Existing security group] Choose one or more security groups.

       [New security group] Choose **Create new security group** to go the **Security Groups** page. When you are done, return to the **Spot Requests** and refresh the list.

    G. (Optional) To make your instances reachable from the internet, for **Auto-assign IPv4 Public IP**, choose **Enable**.

H. (Optional) To launch your Spot Instances with an IAM role, for **IAM instance profile**, choose the role.

I. (Optional) To run a start-up script, copy it to **User data**.

J. (Optional) To add a tag, choose **Create tag** and enter the key and value for the tag, and choose **Create**. Repeat for each tag.

   For each tag, to tag the instances and the Spot Fleet request with the same tag, ensure that both **Instances** and **Fleet** are selected. To tag only the instances launched by the fleet, clear **Fleet**. To tag only the Spot Fleet request, clear **Instances**.

b. [Launch template] To use a configuration you created in a launch template, choose **Use a launch template**, and for **Launch template**, choose a launch template.

> **Note**
>
> If you want On-Demand capacity in your Spot Fleet, you must specify a launch template.

5. For **Additional request details**, do the following:

   a. Review the additional request details. To make changes, clear **Apply defaults**.

   b. (Optional) For **IAM fleet role**, you can use the default role or choose a different role. To use the default role after changing the role, choose **Use default role**.

   c. (Optional) To create a request that is valid only during a specific time period, edit **Request valid from** and **Request valid until**.

   d. (Optional) By default, Amazon EC2 terminates your Spot Instances when the Spot Fleet request expires. To keep them running after your request expires, clear **Terminate the instances when the request expires**.

   e. (Optional) To register your Spot Instances with a load balancer, choose **Receive traffic from one or more load balancers** and choose one or more Classic Load Balancers or target groups.

6. For **Target capacity**, do the following:

   a. For **Total target capacity**, specify the number of units to request. For the type of unit, you can choose **Instances**, **vCPUs**, or **Memory (MiB)**. To specify a target capacity of 0 so that you can add capacity later, you must first select **Maintain target capacity**.

b. (Optional) For **Include On-Demand base capacity**, specify the number of On-Demand units to request. The number must be less than the **Total target capacity**. Amazon EC2 calculates the difference, and allocates the difference to Spot units to request.

> **Important**
>
> To specify optional On-Demand capacity, you must first choose a launch template.

c. (Optional) By default, Amazon EC2 terminates Spot Instances when they are interrupted. To maintain the target capacity, select **Maintain target capacity**. You can then specify that Amazon EC2 terminates, stops, or hibernates Spot Instances when they are interrupted. To do so, choose the corresponding option from **Interruption behavior**.

> **Note**
>
> If an AMI specified in the launch parameters is deregistered or disabled, no new instances can be launched from the AMI. In this case, for fleets that are set to maintain target capacity, the target capacity will not be maintained.

d. (Optional) To allow Spot Fleet to launch a replacement Spot Instance when an instance rebalance notification is emitted for an existing Spot Instance in the fleet, select **Capacity rebalance**, and then choose an instance replacement strategy. If you choose **Launch before terminate**, specify the delay (in seconds) before Amazon EC2 terminates the old instances. For more information, see Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances.

e. (Optional) To control the amount you pay per hour for all the Spot Instances in your fleet, select **Set maximum cost for Spot Instances** and then enter the maximum total amount you're willing to pay per hour. When the maximum total amount is reached, Spot Fleet stops launching Spot Instances even if it hasn’t met the target capacity. For more information, see Set a spending limit for your EC2 Fleet or Spot Fleet.

7. For **Network**, do the following:

a. For **Network**, choose an existing VPC or create a new one.

[Existing VPC] Choose the VPC.

[New VPC] Choose **Create new VPC** to go the Amazon VPC console. When you're done, return to this screen and refresh the list.

b. (Optional) For **Availability Zone**, let Amazon EC2 choose the Availability Zones for your Spot Instances, or specify one or more Availability Zones.

   If you have more than one subnet in an Availability Zone, choose the appropriate subnet from **Subnet**. To add subnets, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to this screen and refresh the list.

8. For **Instance type requirements**, you can either specify instance attributes and let Amazon EC2 identify the optimal instance types with these attributes, or you can specify a list of instances. For more information, see Specify attributes for instance type selection for EC2 Fleet or Spot Fleet.

   a. If you choose **Specify instance attributes that match your compute requirements**, specify your instance attributes as follows:

      i. For **vCPUs**, enter the desired minimum and maximum number of vCPUs. To specify no limit, select **No minimum** or **No maximum**, or both.

      ii. For **Memory (GiB)**, enter the desired minimum and maximum amount of memory. To specify no limit, select **No minimum** or **No maximum**, or both.

      iii. (Optional) For **Additional instance attribute**, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see get-spot-placement-scores.

      iv. (Optional) To view the instance types with your specified attributes, expand **Preview matching instance types**. To exclude instance types from being used in your request, select the instances and then choose **Exclude selected instance types**.

   b. If you choose **Manually select instance types**, Spot Fleet provides a default list of instance types. To select more instance types, choose **Add instance types**, select the instance types to use in your request, and choose **Select**. To delete instance types, select the instance types and choose **Delete**.

9. For **Allocation strategy**, choose a Spot allocation strategy and an On-Demand allocation strategy that meets your needs. For more information, see Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity.
10. For **Your fleet request at a glance**, review your fleet configuration, and make any adjustments if necessary.
11. (Optional) To download a copy of the launch configuration for use with the AWS CLI, choose **JSON config**.
12. When you're ready to launch your Spot Fleet, choose **Launch**.

    The Spot Fleet request type is `fleet`. When the request is fulfilled, requests of type `instance` are added, where the state is `active` and the status is `fulfilled`.

AWS CLI

To create a Spot Fleet request

Use the request-spot-fleet command.

```
aws ec2 request-spot-fleet --spot-fleet-request-config file://config.json
```

For example configuration files, see Example CLI configurations Spot Fleet.

PowerShell

To create a Spot Fleet request

Use the Request-EC2SpotFleet cmdlet. The following example launches Spot Instances in a capacity-optimized fleet.

```
Request-EC2SpotFleet `
    -SpotFleetRequestConfig_TargetCapacity 50 `
    -SpotFleetRequestConfig_AllocationStrategy "CapacityOptimized" `
    -SpotFleetRequestConfig_IamFleetRole "arn:aws:iam::123456789012:role/my-spot-fleet-role" `
    -SpotFleetRequestConfig_LaunchTemplateConfig @($launchConfig)
```

Define the launch configuration as follows, setting the launch template and override properties that you need. For example configurations, see Example CLI configurations Spot Fleet.

```
$lcSpec = Amazon.EC2.Model.FleetLaunchTemplateSpecification
```

```
# To do - Set FleetLaunchTemplateSpecification properties
$lcOverrides = New-Object Amazon.EC2.Model.LaunchTemplateOverrides
# To do - Set LaunchTemplateOverrides properties
$launchConfig = New-Object Amazon.EC2.Model.LaunchTemplateConfig
$launchConfig.LaunchTemplateSpecification $lcSpec
$launchConfig.Overrides @($lcOverrides)
```

Create a Spot Fleet that replaces unhealthy Spot Instances

Spot Fleet checks the health status of the Spot Instances in the fleet every two minutes. The health status of an instance is either `healthy` or `unhealthy`.

Spot Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as `unhealthy` when the status of either the instance status check or the system status check is `impaired` for three consecutive health checks. For more information, see Status checks for Amazon EC2 instances.

You can configure your fleet to replace unhealthy Spot Instances. After enabling health check replacement, a Spot Instance is replaced when it is reported as `unhealthy`. The fleet could go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

Requirements

- Health check replacement is supported only for Spot Fleets that maintain a target capacity (fleets of type `maintain`), not for one-time Spot Fleets (fleets of type `request`).
- Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.
- You can configure your Spot Fleet to replace unhealthy instances only when you create it.
- Users can use health check replacement only if they have permission to call the `ec2:DescribeInstanceStatus` action.

Console

To configure a Spot Fleet to replace unhealthy Spot Instances

1. Follow the steps for creating a Spot Fleet in Create a Spot Fleet request using defined parameters.

2. To configure the fleet to replace unhealthy Spot Instances, expand **Additional launch parameters**, and under **Health check**, select **Replace unhealthy instances**. To enable this option, you must first choose **Maintain target capacity**.

AWS CLI

To configure a Spot Fleet to replace unhealthy Spot Instances

Use the request-spot-fleet command with the `ReplaceUnhealthyInstances` property of `SpotFleetRequestConfig`.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "lowestPrice",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
        "TargetCapacity": 10,
        "ReplaceUnhealthyInstances": true
    }
}
```

PowerShell

To configure a Spot Fleet request to replace unhealthy Spot Instances

Use the Request-EC2SpotFleet cmdlet with the `-SpotFleetRequestConfig_ReplaceUnhealthyInstance` parameter.

```
-SpotFleetRequestConfig_ReplaceUnhealthyInstance $true
```

Tag a new or existing Spot Fleet request and the instances and volumes it launches

To help categorize and manage your Spot Fleet requests and the instances and volumes that it launches, you can tag them with custom metadata. You can assign a tag to a Spot Fleet request when you create it, or afterward. Similarly, you can assign a tag to the instances and volumes when they're launched by the fleet, or afterward.

When you tag a fleet request, the instances and volumes that are launched by the fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the fleet. You can choose to assign tags to only the fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all of them.

Note

You can only tag volumes that are attached to On-Demand Instances. You can't tag volumes that are attached to Spot Instances.

You can assign tags using the Amazon EC2 console or a command line tool.

For more information about how tags work, see Tag your Amazon EC2 resources.

Contents

Prerequisite

Grant the user the permission to tag resources. For more information, see Example: Tag resources.

To grant a user the permission to tag resources

Create an IAM policy that includes the following:

- The `ec2:CreateTags` action. This grants the user permission to create tags.
- The `ec2:RequestSpotFleet` action. This grants the user permission to create a Spot Fleet request.
- For `Resource`, you must specify `"*"`. This allows users to tag all resource types.

JSON

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "TagSpotFleetRequest",
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags",
                "ec2:RequestSpotFleet"
            ],
            "Resource": "*"
        }
    ]
}
```

> **Important**
>
> We currently do not support resource-level permissions for the `spot-fleet-request` resource. If you specify `spot-fleet-request` as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how *not* to set the policy.
>
> ```
> {
>     "Effect": "Allow",
>     "Action": [
>         "ec2:CreateTags",
>         "ec2:RequestSpotFleet"
>     ],
>     "Resource": "arn:aws:ec2:us-east-1:111122223333:spot-fleet-request/*"
> }
> ```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Tag a new Spot Fleet and the instances and volumes that it launches

To tag a new Spot Fleet request and the instances and volumes that it launches using the console

1. Follow the Create a Spot Fleet request using defined parameters procedure.
2. The way you add a tag depends on whether you manually configured the fleet or used a launch template.
   - If you manually configured the fleet, do the following:

     To add a tag, expand **Additional launch parameters**, choose **Create tag**, and enter the key and value for the tag. Repeat for each tag.

     For each tag, you can tag the Spot Fleet request and the instances with the same tag. To tag both, ensure that both **Instances** and **Fleet** are selected. To tag only the Spot Fleet request, clear **Instances**. To tag only the instances launched by the fleet, clear **Fleet**.

     > **Note**
     > When you manually configure a fleet, there is no option to tag volumes. Volume tags are only supported for volumes that are attached to On-Demand Instances. When you manually configure a fleet, you can't specify On-Demand Instances.

   - If you used a launch template, do the following:

     To add a tag to the fleet request, under **Tags**, choose **Create Tag**, and enter the key and value for the tag. Repeat for each tag.

To tag the resources in your fleet, you must specify tags in the launch template.

To tag a new Spot Fleet request and the instances and volumes that it launches using the AWS CLI

To tag a Spot Fleet request when you create it, and to tag the instances and volumes when they are launched by the fleet, configure the Spot Fleet request configuration as follows:

Spot Fleet request tags:

- Specify the tags for the Spot Fleet request in `SpotFleetRequestConfig`.
- For `ResourceType`, specify `spot-fleet-request`. If you specify another value, the fleet request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

Instance tags:

- Specify the tags for the instances in `LaunchSpecifications`.
- For `ResourceType`, specify `instance`. If you specify another value, the fleet request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

  Alternatively, you can specify the tags for the instance in the launch template that is referenced in the Spot Fleet request.

Volume tags:

- Specify the tags for the volumes in the launch template that is referenced in the Spot Fleet request. Volume tagging in `LaunchSpecifications` is not supported.

In the following example, the Spot Fleet request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123. The instances that are launched by the fleet are tagged with one tag (which is the same as one of the tags for the Spot Fleet request): Key=Cost-Center and Value=123.

```
{
    "SpotFleetRequestConfig": {
```

```
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchSpecifications": [
            {
                "ImageId": "ami-0123456789EXAMPLE",
                "InstanceType": "c4.large",
                "TagSpecifications": [
                    {
                        "ResourceType": "instance",
                        "Tags": [
                            {
                                "Key": "Cost-Center",
                                "Value": "123"
                            }
                        ]
                    }
                ]
            }
        ],
        "SpotPrice": "5",
        "TargetCapacity": 2,
        "TerminateInstancesWithExpiration": true,
        "Type": "maintain",
        "ReplaceUnhealthyInstances": true,
        "InstanceInterruptionBehavior": "terminate",
        "InstancePoolsToUseCount": 1,
        "TagSpecifications": [
            {
                "ResourceType": "spot-fleet-request",
                "Tags": [
                    {
                        "Key": "Environment",
                        "Value":"Production"
                    },
                    {
                        "Key": "Cost-Center",
                        "Value":"123"
                    }
                ]
            }
        ]
    }
```

```
}
```

To tag instances launched by a Spot Fleet using the AWS CLI

To tag instances when they are launched by the fleet, you can either specify the tags in the [launch template](#) that is referenced in the Spot Fleet request, or you can specify the tags in the Spot Fleet request configuration as follows:

- Specify the tags for the instances in `LaunchSpecifications`.
- For `ResourceType`, specify `instance`. If you specify another value, the fleet request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the instances that are launched by the fleet are tagged with one tag: Key=Cost-Center and Value=123.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchSpecifications": [
            {
                "ImageId": "ami-0123456789EXAMPLE",
                "InstanceType": "c4.large",
                "TagSpecifications": [
                    {
                        "ResourceType": "instance",
                        "Tags": [
                            {
                                "Key": "Cost-Center",
                                "Value": "123"
                            }
                        ]
                    }
                ]
            }
        ],
        "SpotPrice": "5",
        "TargetCapacity": 2,
        "TerminateInstancesWithExpiration": true,
```

```
        "Type": "maintain",
        "ReplaceUnhealthyInstances": true,
        "InstanceInterruptionBehavior": "terminate",
        "InstancePoolsToUseCount": 1
    }
}
```

To tag volumes attached to On-Demand Instances launched by a Spot Fleet using the AWS CLI

To tag volumes when they are created by the fleet, you must specify the tags in the [launch template](#) that is referenced in the Spot Fleet request.

> **Note**
>
> Volume tags are only supported for volumes that are attached to On-Demand Instances. You can't tag volumes that are attached to Spot Instances.
> Volume tagging in `LaunchSpecifications` is not supported.

Tag an existing Spot Fleet

To tag an existing Spot Fleet request using the console

After you create a Spot Fleet request, you can add tags to the fleet request using the console.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose the **Tags** tab and choose **Create Tag**.

To tag an existing Spot Fleet request using the AWS CLI

You can use the create-tags command to tag existing resources. In the following example, the existing Spot Fleet request is tagged with Key=purpose and Value=test.

```
aws ec2 create-tags \
    --resources sfr-11112222-3333-4444-5555-66666EXAMPLE \
    --tags Key=purpose,Value=test
```

View Spot Fleet request tags

To view Spot Fleet request tags using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request and choose the **Tags** tab.

To describe Spot Fleet request tags

Use the describe-tags command to view the tags for the specified resource. In the following example, you describe the tags for the specified Spot Fleet request.

```
aws ec2 describe-tags \
    --filters "Name=resource-id,Values=sfr-11112222-3333-4444-5555-66666EXAMPLE"
```

```
{
    "Tags": [
        {
            "Key": "Environment",
            "ResourceId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
            "ResourceType": "spot-fleet-request",
            "Value": "Production"
        },
        {
            "Key": "Another key",
            "ResourceId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
            "ResourceType": "spot-fleet-request",
            "Value": "Another value"
        }
    ]
}
```

You can also view the tags of a Spot Fleet request by describing the Spot Fleet request.

Use the describe-spot-fleet-requests command to view the configuration of the specified Spot Fleet request, which includes any tags that were specified for the fleet request.

```
aws ec2 describe-spot-fleet-requests \
```

```
    --spot-fleet-request-ids sfr-11112222-3333-4444-5555-66666EXAMPLE
```

```
{
    "SpotFleetRequestConfigs": [
        {
            "ActivityStatus": "fulfilled",
            "CreateTime": "2020-02-13T02:49:19.709Z",
            "SpotFleetRequestConfig": {
                "AllocationStrategy": "capacityOptimized",
                "OnDemandAllocationStrategy": "lowestPrice",
                "ExcessCapacityTerminationPolicy": "Default",
                "FulfilledCapacity": 2.0,
                "OnDemandFulfilledCapacity": 0.0,

tagging-role",
                "LaunchSpecifications": [
                    {
                        "ImageId": "ami-0123456789EXAMPLE",
                        "InstanceType": "c4.large"
                    }
                ],
                "TargetCapacity": 2,
                "OnDemandTargetCapacity": 0,
                "Type": "maintain",
                "ReplaceUnhealthyInstances": false,
                "InstanceInterruptionBehavior": "terminate"
            },
            "SpotFleetRequestId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
            "SpotFleetRequestState": "active",
            "Tags": [
                {
                    "Key": "Environment",
                    "Value": "Production"
                },
                {
                    "Key": "Another key",
                    "Value": "Another value"
                }
            ]
        }
    ]
}
```

Describe a Spot Fleet request, its instances, and event history

You can describe your Spot Fleet configuration, the instances in your Spot Fleet, and the event history of your Spot Fleet.

Console

To describe your Spot Fleet

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request. The ID begins with **sfr-**. To see the configuration details, choose **Description**.
4. To list the Spot Instances for the Spot Fleet, choose **Instances**.
5. To view the history for the Spot Fleet, choose **History**.

AWS CLI

To describe your Spot Fleet request

Use the describe-spot-fleet-requests command.

```
aws ec2 describe-spot-fleet-requests \
    --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

To describe the running instances for the specified Spot Fleet request

Use the describe-spot-fleet-instances command.

```
aws ec2 describe-spot-fleet-instances \
    --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

To describe the event history for the specified Spot Fleet request

Use the describe-spot-fleet-request-history command.

```
aws ec2 describe-spot-fleet-request-history \
    --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
```

```
    --start-time 2024-05-18T00:00:00Z
```

PowerShell

To describe your Spot Fleet request

Use the Get-EC2SpotFleetRequest cmdlet.

```
Get-EC2SpotFleetRequest
```

To describe the running instances for the specified Spot Fleet request

Use the Get-EC2SpotFleetInstance cmdlet.

```
Get-EC2SpotFleetInstance `
    -SpotFleetRequestId "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE"
```

To describe the event history for the specified Spot Fleet request

Use the Get-EC2SpotFleetRequestHistory cmdlet.

```
Get-EC2SpotFleetRequestHistory `
    -SpotFleetRequestId "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -UtcStartTime 2024-05-18T00:00:00Z
```

Modify a Spot Fleet request

You can modify an active Spot Fleet request to complete the following tasks:

- Increase the total target capacity and On-Demand portion
- Decrease the total target capacity and On-Demand portion

When you increase the total target capacity, the Spot Fleet launches additional Spot Instances according to the allocation strategy for its Spot Fleet request. When you increase the On-Demand portion, the Spot Fleet launches additional On-Demand Instances.

When you decrease the total target capacity, the Spot Fleet cancels any open requests that exceed the new target capacity. You can request that the Spot Fleet terminate Spot Instances until the size of the fleet reaches the new target capacity. If the allocation strategy is `diversified`, the Spot Fleet terminates instances across the pools. Alternatively, you can request that the Spot Fleet keep the fleet at its current size, but not replace any Spot Instances that are interrupted or that you terminate manually.

Considerations

- You can't modify a one-time Spot Fleet request. You can only modify a Spot Fleet request if you selected **Maintain target capacity** when you created the Spot Fleet request.
- When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

Console

To modify a Spot Fleet request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose **Actions**, **Modify target capacity**.
5. In **Modify target capacity**, do the following:
   a. Enter the new target capacity and On-Demand portion.
   b. (Optional) If you are decreasing the target capacity but want to keep the fleet at its current size, clear **Terminate instances**.
   c. Choose **Submit**.

AWS CLI

To modify a Spot Fleet request

Use the modify-spot-fleet-request command to update the target capacity of the specified Spot Fleet request.

```
aws ec2 modify-spot-fleet-request \
    --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --target-capacity 20
```

You can modify the previous command as follows to decrease the target capacity of the specified Spot Fleet without terminating any Spot Instances as a result.

```
aws ec2 modify-spot-fleet-request \
    --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --target-capacity 10 \
    --excess-capacity-termination-policy NoTermination
```

PowerShell

To modify a Spot Fleet request

Use the Edit-EC2SpotFleetRequest cmdlet to update the target capacity of the specified Spot Fleet request.

```
Edit-EC2SpotFleetRequest `
    -SpotFleetRequestId "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TargetCapacity 20
```

You can modify the previous command as follows to decrease the target capacity of the specified Spot Fleet without terminating any Spot Instances as a result.

```
Edit-EC2SpotFleetRequest `
    -SpotFleetRequestId "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TargetCapacity 20 `
    -ExcessCapacityTerminationPolicy "NoTermination"
```

Cancel (delete) a Spot Fleet request

If you no longer require a Spot Fleet, you can cancel the Spot Fleet request, which deletes the request. After you cancel a fleet request, all Spot requests associated with the fleet are also canceled, so that no new Spot Instances are launched.

When you cancel a Spot Fleet request, you must also specify if you want to terminate all of its instances. These include both On-Demand Instances and Spot Instances.

If you specify that the instances must be terminated when the fleet request is canceled, the fleet request enters the `cancelled_terminating` state. Otherwise, it enters the `cancelled_running` state, and the instances continue to run until they are interrupted or you terminate them manually.

Restrictions

- You can cancel up to 100 fleets in a single request. If you exceed the specified number, no fleets are canceled.

Console

To cancel (delete) a Spot Fleet request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose **Actions**, **Cancel request**.
5. In the **Cancel Spot request** dialog box, do the following:

   a. To terminate the associated instances at the same time as canceling the Spot Fleet request, leave the **Terminate instances** checkbox selected. To cancel the Spot Fleet request without terminating the associated instances, clear the **Terminate instances** checkbox.

   b. Choose **Confirm**.

AWS CLI

To cancel (delete) a Spot Fleet request and terminate its instances

Use the [cancel-spot-fleet-requests](#) command with the `--terminate-instances` option.

```
aws ec2 cancel-spot-fleet-requests \
    --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --terminate-instances
```

The following is example output.

```
{
    "SuccessfulFleetRequests": [
        {
```

```
            "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
            "CurrentSpotFleetRequestState": "cancelled_terminating",
            "PreviousSpotFleetRequestState": "active"
        }
    ],
    "UnsuccessfulFleetRequests": []
}
```

To cancel (delete) a Spot Fleet request without terminating its instances

Modify the previous example by using the `--no-terminate-instances` option instead.

```
aws ec2 cancel-spot-fleet-requests \
    --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --no-terminate-instances
```

The following is example output.

```
{
    "SuccessfulFleetRequests": [
        {
            "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
            "CurrentSpotFleetRequestState": "cancelled_running",
            "PreviousSpotFleetRequestState": "active"
        }
    ],
    "UnsuccessfulFleetRequests": []
}
```

PowerShell

To cancel (delete) a Spot Fleet request and terminate its instances

Use the Stop-EC2SpotFleetRequest cmdlet with the `-TerminateInstance` parameter.

```
Stop-EC2SpotFleetRequest `
    -SpotFleetRequestId "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TerminateInstance $true
```

To cancel (delete) a Spot Fleet request without terminating its instances

Modify the previous example by changing the value of the `-TerminateInstance` parameter.

```
Stop-EC2SpotFleetRequest `
    -SpotFleetRequestId "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE" `
    -TerminateInstance $false
```

Understand automatic scaling for Spot Fleet

Automatic scaling enables your Spot Fleet to increase or decrease its target capacity based on demand. With automatic scaling, a Spot Fleet can either launch instances (scale out) or terminate instances (scale in) within a specified range, in response to one or more scaling policies.

Automatic scaling for Spot Fleet is made possible by a combination of the Amazon EC2, Amazon CloudWatch, and Application Auto Scaling APIs. Spot Fleet requests are created with Amazon EC2, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling.

Types of automatic scaling

Spot Fleet supports the following types of automatic scaling:

- Target tracking scaling – Increase or decrease the current capacity of the fleet by targeting a value for a specific metric. This is similar to the way that your thermostat maintains the temperature of your home—you select the desired temperature and the thermostat does the rest.
- Step scaling – Increase or decrease the current capacity of the fleet based on a set of scaling adjustments, known as step adjustments, that vary based on the size of the alarm breach.
- Scheduled scaling – Increase or decrease the current capacity of the fleet based on the date and time.

Considerations

When using automatic scaling for your Spot Fleet, consider the following:

- **Instance weighting** – If you're using instance weighting, keep in mind that Spot Fleet can exceed the target capacity as needed. Fulfilled capacity can be a floating-point number but target capacity must be an integer, so Spot Fleet rounds up to the next integer. You must take these behaviors into account when you look at the outcome of a scaling policy when an alarm is triggered. For example, suppose that the target capacity is 30, the fulfilled capacity is 30.1, and the scaling policy subtracts 1. When the alarm is triggered, the automatic scaling process

subtracts 1 from 30.1 to get 29.1 and then rounds it up to 30, so no scaling action is taken.
As another example, suppose that you selected instance weights of 2, 4, and 8, and a target capacity of 10, but no weight 2 instances were available so Spot Fleet provisioned instances of weights 4 and 8 for a fulfilled capacity of 12. If the scaling policy decreases target capacity by 20% and an alarm is triggered, the automatic scaling process subtracts 12*0.2 from 12 to get 9.6 and then rounds it up to 10, so no scaling action is taken.

- **Cooldown period** – The scaling policies that you create for Spot Fleet support a cooldown period. This is the number of seconds after a scaling activity completes where previous trigger-related scaling activities can influence future scaling events. For scale-out policies, while the cooldown period is in effect, the capacity that has been added by the previous scale-out event that initiated the cooldown is calculated as part of the desired capacity for the next scale out. The intention is to continuously (but not excessively) scale out. For scale in policies, the cooldown period is used to block subsequent scale in requests until it has expired. The intention is to scale in conservatively to protect your application's availability. However, if another alarm triggers a scale-out policy during the cooldown period after a scale-in, automatic scaling scales out your scalable target immediately.
- **Use detailed monitoring** – We recommend that you scale based on instance metrics with a 1-minute frequency because that ensures a faster response to utilization changes. Scaling on metrics with a 5-minute frequency can result in slower response time and scaling on stale metric data. To send metric data for your instances to CloudWatch in 1-minute periods, you must specifically enable detailed monitoring. For more information, see Manage detailed monitoring for your EC2 instances and Create a Spot Fleet request using defined parameters.
- **AWS CLI** – If you use the AWS CLI for configuring scaling for Spot Fleet, you'll use the application-autoscaling commands.

IAM permissions required for Spot Fleet automatic scaling

Automatic scaling for Spot Fleet is made possible by a combination of the Amazon EC2, Amazon CloudWatch, and Application Auto Scaling APIs. Spot Fleet requests are created with Amazon EC2, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling. In addition to the IAM permissions required for using Spot Fleet and Amazon EC2, the user that accesses the fleet scaling settings must have the appropriate permissions for the services that support automatic scaling.

To use automatic scaling for Spot Fleet, users must have permissions to use the actions shown in the following example policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "application-autoscaling:*",
                "ec2:DescribeSpotFleetRequests",
                "ec2:ModifySpotFleetRequest",
                "cloudwatch:DeleteAlarms",
                "cloudwatch:DescribeAlarmHistory",
                "cloudwatch:DescribeAlarms",
                "cloudwatch:DescribeAlarmsForMetric",
                "cloudwatch:GetMetricStatistics",
                "cloudwatch:ListMetrics",
                "cloudwatch:PutMetricAlarm",
                "cloudwatch:DisableAlarmActions",
                "cloudwatch:EnableAlarmActions",
                "iam:CreateServiceLinkedRole",
                "sns:CreateTopic",
                "sns:Subscribe",
                "sns:Get*",
                "sns:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

You can also create your own IAM policies that allow more fine-grained permissions for calls to the Application Auto Scaling API. For more information, see Identity and Access Management for Application Auto Scaling in the *Application Auto Scaling User Guide*.

The Application Auto Scaling service also needs permission to describe your Spot Fleet and CloudWatch alarms, and permissions to modify your Spot Fleet target capacity on your behalf. If you enable automatic scaling for your Spot Fleet, it creates a service-linked role named `AWSServiceRoleForApplicationAutoScaling_EC2SpotFleetRequest`. This service-linked role grants Application Auto Scaling permission to describe the alarms for your policies, to monitor the current capacity of the fleet, and to modify the capacity of the fleet. The original managed Spot Fleet role for Application Auto Scaling was `aws-ec2-spot-fleet-autoscale-role`, but it is no longer required. The service-linked role is the default role for Application Auto Scaling. For more information, see [Service-linked roles for Application Auto Scaling]() in the *Application Auto Scaling User Guide*.

Target tracking scaling: Scale Spot Fleet by targeting a value for a specific metric

With target tracking scaling, you create a target tracking scaling policy by selecting a metric and setting a target value. Spot Fleet then creates and manages the CloudWatch alarms that trigger the scaling policy, and calculates the scaling adjustment based on the chosen metric and target value. The scaling policy adjusts capacity by adding or removing instances as needed to keep the metric at, or close to, the specified target value. A target tracking policy not only keeps the metric close to the target value, but also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid capacity fluctuations.

You can create multiple target tracking scaling policies for a Spot Fleet, provided each policy uses a different metric. The fleet scales based on the policy that specifies the largest fleet capacity. This allows you to cover multiple scenarios to ensure sufficient capacity for your application workloads.

To ensure application availability, the fleet scales out proportionally to the metric as fast as it can, but scales in more gradually.

When a Spot Fleet terminates a Spot Instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

> **Note**
>
> Do not edit or delete the CloudWatch alarms that Spot Fleet manages for a target tracking scaling policy. Spot Fleet deletes the alarms automatically when you delete the target tracking scaling policy.

Prerequisites

- The Spot Fleet request must have a request type of `maintain`. Automatic scaling is not supported for requests of type `request`.
- Configure the [IAM permissions required for Spot Fleet automatic scaling]().
- Review the [Considerations]().

To configure a target tracking policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose the **Auto Scaling** tab near the bottom of the screen. If you selected the link for your Spot Fleet, there is no tab; instead, scroll down to the **Auto Scaling** section.
5. If automatic scaling is not configured, choose **Configure**.
6. Use **Scale capacity between** to set the minimum and maximum capacity for your fleet. Automatic scaling does not scale your fleet below the minimum capacity or above the maximum capacity.
7. For **Policy name**, enter a name for the policy.
8. Choose a **Target metric**.
9. Enter a **Target value** for the metric.
10. For **Cooldown period**, specify a new value (in seconds) or keep the default.
11. (Optional) To omit creating a scale-in policy based on the current configuration, select **Disable scale-in**. You can create a scale-in policy using a different configuration.
12. Choose **Save**.

To configure a target tracking policy using the AWS CLI

1. Register the Spot Fleet request as a scalable target using the register-scalable-target command.
2. Create a scaling policy using the put-scaling-policy command.

Step scaling: Scale Spot Fleet using step scaling policies

With step scaling policies, you specify CloudWatch alarms to trigger the scaling process. For example, if you want to scale out when CPU utilization reaches a certain level, create an alarm using the `CPUUtilization` metric provided by Amazon EC2.

When you create a step scaling policy, you must specify one of the following scaling adjustment types:

- **Add** – Increase the target capacity of the fleet by a specified number of capacity units or a specified percentage of the current capacity.
- **Remove** – Decrease the target capacity of the fleet by a specified number of capacity units or a specified percentage of the current capacity.
- **Set to** – Set the target capacity of the fleet to the specified number of capacity units.

When an alarm is triggered, the automatic scaling process calculates the new target capacity using the fulfilled capacity and the scaling policy, and then updates the target capacity accordingly. For example, suppose that the target capacity and fulfilled capacity are 10 and the scaling policy adds 1. When the alarm is triggered, the automatic scaling process adds 1 to 10 to get 11, so Spot Fleet launches 1 instance.

When a Spot Fleet terminates a Spot Instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

Prerequisites

- The Spot Fleet request must have a request type of `maintain`. Automatic scaling is not supported for requests of type `request`.
- Configure the IAM permissions required for Spot Fleet automatic scaling.
- Consider which CloudWatch metrics are important to your application. You can create CloudWatch alarms based on metrics provided by AWS or your own custom metrics.
- For the AWS metrics that you will use in your scaling policies, enable CloudWatch metrics collection if the service that provides the metrics does not enable it by default.
- Review the Considerations.

To create a CloudWatch alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, expand **Alarms** and choose **All alarms**.
3. Choose **Create alarm**.
4. On the **Specify metric and conditions** page, choose **Select metric**.
5. Choose **EC2 Spot**, then **Fleet Request Metrics**, and then select a metric (for example, **TargetCapacity**), and then choose **Select metric**.

The **Specify metric and conditions** page appears, showing a graph and other information about the metric you selected.

6. For **Period**, choose the evaluation period for the alarm, for example, **1 minute**. When evaluating the alarm, each period is aggregated into one data point.

> **Note**
>
> A shorter period creates a more sensitive alarm.

7. For **Conditions**, define the alarm by defining the threshold condition. For example, you can define a threshold to trigger the alarm whenever the value of the metric is greater than or equal to 80 percent.
8. Under **Additional configuration**, for **Datapoints to alarm**, specify how many datapoints (evaluation periods) must be in the ALARM state to trigger the alarm, for example, 1 evaluation period or 2 out of 3 evaluation periods. This creates an alarm that goes to ALARM state if that many consecutive periods are breaching. For more information, see Evaluating an alarm in the *Amazon CloudWatch User Guide*.
9. For **Missing data treatment**, choose one of the options (or leave the default of **Treat missing data as missing**). For more information, see Configuring how CloudWatch alarms treat missing data in the *Amazon CloudWatch User Guide*.
10. Choose **Next**.
11. (Optional) To receive notification of a scaling event, for **Notification**, you can choose or create the Amazon SNS topic you want to use to receive notifications. Otherwise, you can delete the notification now and add one later as needed.
12. Choose **Next**.
13. Under **Add name and description**, enter a name and description for the alarm and choose **Next**.
14. Choose **Create alarm**.

To configure a step scaling policy for your Spot Fleet

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.

4. Choose the **Auto Scaling** tab near the bottom of the screen. If you selected the link for your Spot Fleet, there is no tab; instead, scroll down to the **Auto Scaling** section.
5. If automatic scaling is not configured, choose **Configure**.
6. Use **Scale capacity between** to set the minimum and maximum capacity for your fleet. Scaling policies do not scale your fleet below the minimum capacity or above the maximum capacity.
7. Under **Scaling policies**, for **Policy type**, choose **Step scaling policy**.
8. Initially, **Scaling policies** contain step scaling policies named **ScaleUp** and **ScaleDown**. You can complete these policies, or choose **Remove policy** to delete them. You can also choose **Add policy**.
9. To define a policy, do the following:

   a. For **Policy name**, enter a name for the policy.

   b. For **Policy trigger**, select an existing alarm, or choose **Create alarm** to open the Amazon CloudWatch console and create an alarm.

   c. For **Modify capacity**, define the amount by which to scale and the lower and upper bound of the step adjustment. You can add or remove a specific number of instances or a percentage of the existing fleet size, or set the fleet to an exact size.

      For example, to create a step scaling policy that increases the capacity of the fleet by 30 percent, choose **Add**, enter **30** in the next field, and then choose **percent**. By default, the lower bound for an add policy is the alarm threshold and the upper bound is positive (+) infinity. By default, the upper bound for a remove policy is the alarm threshold and the lower bound is negative (-) infinity.

   d. (Optional) To add another step, choose **Add step**.

   e. For **Cooldown period**, specify a new value (in seconds) or keep the default.
10. Choose **Save**.

To configure step scaling policies for your Spot Fleet using the AWS CLI

1. Register the Spot Fleet request as a scalable target using the [register-scalable-target] command.
2. Create a scaling policy using the [put-scaling-policy] command.
3. Create an alarm that triggers the scaling policy using the [put-metric-alarm] command.

Scheduled scaling: Scale Spot Fleet on a schedule

Scaling your fleet on a schedule enables you to scale your application in response to predictable changes in demand. By creating *scheduled actions*, you can instruct Spot Fleet to perform scaling activities at specific times. To create a scheduled action, you must specify an existing Spot Fleet, the time when the scaling activity must occur, and the desired minimum and maximum capacity. Scheduled actions can be configured to scale once or on a recurring schedule. If you needs change, you can edit or delete scheduled actions.

Prerequisites

- Sheduled actions can only be created for existing Spot Fleets. You can't create a scheduled action when you create a Spot Fleet.
- The Spot Fleet request must have a request type of `maintain`. Automatic scaling is not supported for requests of type `request`.
- Configure the IAM permissions required for Spot Fleet automatic scaling.
- Review the Considerations.

To create a one-time scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose the **Scheduled Scaling** tab near the bottom of the screen. If you selected the link for your Spot Fleet, there is no tab; instead, scroll down to the **Scheduled Scaling** section.
5. Choose **Create scheduled action**.
6. For **Name**, specify a name for the scheduled action.
7. Enter a value for **Minimum capacity**, **Maximum capacity**, or both.
8. For **Recurrence**, choose **Once**.
9. (Optional) Choose a date and time for **Start time**, **End time**, or both.
10. Choose **Create**.

To create a recurring scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose the **Scheduled Scaling** tab near the bottom of the screen. If you selected the link for your Spot Fleet, there is no tab; instead, scroll down to the **Scheduled Scaling** section.
5. For **Name**, specify a name for the scheduled action.
6. Enter a value for **Minimum capacity**, **Maximum capacity**, or both.
7. For **Recurrence**, choose one of the predefined schedules (for example, **Every day**), or choose **Custom** and enter a cron expression. For more information about the cron expressions supported by scheduled scaling, see Cron expressions in the *Amazon EventBridge User Guide*.
8. (Optional) Choose a date and time for **Start time**, **End time**, or both.
9. Choose **Submit**.

To edit a scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose the **Scheduled Scaling** tab near the bottom of the screen. If you selected the link for your Spot Fleet, there is no tab; instead, scroll down to the **Scheduled Scaling** section.
5. Select the scheduled action and choose **Actions**, **Edit**.
6. Make the needed changes and choose **Submit**.

To delete a scheduled action

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose the **Scheduled Scaling** tab near the bottom of the screen. If you selected the link for your Spot Fleet, there is no tab; instead, scroll down to the **Scheduled Scaling** section.
5. Select the scheduled action and choose **Actions**, **Delete**.
6. When prompted for confirmation, choose **Delete**.

To manage scheduled scaling using the AWS CLI

Use the following commands:

- put-scheduled-action
- describe-scheduled-actions
- delete-scheduled-action

Monitor your EC2 Fleet or Spot Fleet

Effective monitoring of your EC2 Fleet or Spot Fleet is essential for maintaining optimal performance and ensuring reliability. There are various tools to help you achieve this, including Amazon CloudWatch and Amazon EventBridge, which are covered in this topic.

With CloudWatch, you can collect and track metrics, set alarms, and automatically react to changes in your fleet's status.

With EventBridge, you can monitor and respond programmatically to events emitted by your fleet. By defining rules in EventBridge, you can automate responses to specific fleet events, such as instance termination or fleet state changes, improving your operational efficiency.

Topics

Monitor your EC2 Fleet or Spot Fleet using CloudWatch

You can monitor your EC2 Fleet or Spot Fleet using the Amazon CloudWatch metrics described in this section.

> **Important**
>
> To ensure accuracy, we recommend that you enable detailed monitoring when using these metrics. For more information, see Manage detailed monitoring for your EC2 instances.

For more information about using CloudWatch, see Monitor your instances using CloudWatch.

EC2 Fleet and Spot Fleet metrics

The `AWS/EC2Spot` namespace includes the following metrics for your fleet, plus the CloudWatch metrics for the Spot Instances in your fleet. For more information, see Instance metrics.

Metric	Description
`AvailableInstancePoolsCount`	The Spot capacity pools specified in the fleet request. Units: Count
`BidsSubmittedForCapacity`	The capacity for which Amazon EC2 has submitted fleet requests. Units: Count
`EligibleInstancePoolCount`	The Spot capacity pools specified in the fleet request where Amazon EC2 can fulfill requests. Amazon EC2 does not fulfill requests in pools where the maximum price you're willing to pay for Spot Instances is less than the Spot price or the Spot price is greater than the price for On-Demand Instances. Units: Count
`FulfilledCapacity`	The capacity that Amazon EC2 has fulfilled. Units: Count
`MaxPercentCapacityAllocation`	The maximum value of `PercentCapacityAllocation` across all fleet pools specified in the fleet request. Units: Percent
`PendingCapacity`	The difference between `TargetCapacity` and `FulfilledCapacity` . Units: Count
`PercentCapacityAllocation`	The capacity allocated for the Spot capacity pool for the specified dimensions. To get the maximum value recorded

Metric	Description
	across all Spot capacity pools, use `MaxPercentCapacityAllocation` . Units: Percent
`TargetCapacity`	The target capacity of the fleet request. Units: Count
`TerminatingCapacity`	The capacity that is being terminated because the provisioned capacity is greater than the target capacity. Units: Count

If the unit of measure for a metric is `Count`, the most useful statistic is `Average`.

EC2 Fleet and Spot Fleet dimensions

To filter the data for your fleet, use the following dimensions.

Dimensions	Description
`AvailabilityZone`	Filter the data by Availability Zone.
`FleetRequestId`	Filter the data by fleet request.
`InstanceType`	Filter the data by instance type.

View the CloudWatch metrics for your EC2 Fleet or Spot Fleet

You can view the CloudWatch metrics for your fleet using the Amazon CloudWatch console. These metrics are displayed as monitoring graphs. These graphs show data points if the fleet is active.

Metrics are grouped first by namespace, and then by the various combinations of dimensions within each namespace. For example, you can view all fleet metrics or fleet metrics groups by fleet request ID, instance type, or Availability Zone.

To view fleet metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, expand **Metrics**, and choose **All metrics**.
3. Choose the **EC2 Spot** namespace.

> **Note**
>
> If the **EC2 Spot** namespace is not displayed, there are two reasons for this. Either you have never used EC2 Fleet or Spot Fleet in the Region—only the AWS services that you're using send metrics to Amazon CloudWatch. Or, if you have used EC2 Fleet or Spot Fleet in the Region, but not for the past two weeks, the namespace does not appear.

4. To filter the metrics by dimension, choose one of the following:
   - **Fleet Request Metrics** – Group by fleet request
   - **By Availability Zone** – Group by fleet request and Availability Zone
   - **By Instance Type** – Group by fleet request and instance type
   - **By Availability Zone/Instance Type** – Group by fleet request, Availability Zone, and instance type
5. To view the data for a metric, select the checkbox next to the metric.

Monitor and programmatically respond to the events emitted by your EC2 Fleet or Spot Fleet using Amazon EventBridge

When the state of an EC2 Fleet or Spot Fleet changes, it emits a notification. The notification is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). Events are emitted on a best effort basis.

You can use Amazon EventBridge to create rules that trigger programmatic actions in response to an event. For example, you can create two EventBridge rules: one triggered when a fleet state changes, and another triggered when an instance in the fleet is terminated. In this example, you can configure the first rule so that, if the fleet state changes, the rule invokes an SNS topic, sending an email notification to you. You can configure the second rule so that, if an instance in the fleet is terminated, the rule invokes a Lambda function to launch a new instance.

> **Note**
>
> Only fleets of type `maintain` and `request` emit events. Fleets of type `instant` do not emit events because they submit synchronous one-time requests, and the state of the fleet is known immediately in the response. To use Amazon EventBridge to monitor fleet events, the request type must be `maintain` or `request`.

For instructions on how to describe a fleet's event history, see Describe the event history for your EC2 Fleet.

Topics

- Create Amazon EventBridge rules to monitor EC2 Fleet or Spot Fleet events
- EC2 Fleet event types
- Spot Fleet event types

Create Amazon EventBridge rules to monitor EC2 Fleet or Spot Fleet events

When a state change notification is emitted for an EC2 Fleet or Spot Fleet, it is sent as an event to Amazon EventBridge as a JSON file. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes the target (or targets) specified in the rule.

You can write EventBridge rules to automate actions based on matching event patterns.

The following fields in the event form the event pattern that is defined in the rule:

`"source": "aws.ec2fleet"`

Identifies that the event is from EC2 Fleet.

`"detail-type": "EC2 Fleet State Change"`

Identifies the event type.

`"detail": { "sub-type": "submitted" }`

Identifies the event sub-type.

For the list of EC2 Fleet and Spot Fleet events and example event data, see EC2 Fleet event types and Spot Fleet event types.

Examples

- Create an EventBridge rule to send a notification
- Create an EventBridge rule to trigger a Lambda function

Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time that Amazon EC2 emits an EC2 Fleet state change notification. The signal in this example is emitted as an `EC2 Fleet State Change` event, which triggers the action defined by the rule.

Prerequisite

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule to send a notification when an EC2 Fleet state changes

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:

   a. Enter a **Name** for the rule, and, optionally, a description.

      A rule can't have the same name as another rule in the same Region and on the same event bus.

   b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
   c. For **Rule type**, choose **Rule with an event pattern**.
   d. Choose **Next**.
4. For **Build event pattern**, do the following:

   a. For **Event source**, choose **AWS events or EventBridge partner events**.
   b. For **Event pattern**, for this example you'll specify the following event pattern to match the `EC2 Fleet Instance Change` event.

```
{
 "source": ["aws.ec2fleet"],
```

```
  "detail-type": ["EC2 Fleet Instance Change"]
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

i. To use a template to create the event pattern, do the following:

   A. Choose **Event pattern form**.
   B. For **Event source**, choose **AWS services**.
   C. For **AWS Service**, choose **EC2 Fleet**.
   D. For **Event type**, choose **EC2 Fleet Instance Change**.
   E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.

ii. (Alternative) To specify a custom event pattern, do the following:

   A. Choose **Custom pattern (JSON editor)**.
   B. In the **Event pattern** box, add the event pattern for this example.

c. Choose **Next**.

5. For **Select target(s)**, do the following:

   a. For **Target types**, choose **AWS service**.
   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
   c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person (A2P) messaging] in the *Amazon Simple Notification Service Developer Guide*.
   d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see [Creating Amazon EventBridge rules that react to events] (step 16) in the *Amazon EventBridge User Guide*.
   e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.
7. For **Review and create**, do the following:

   a. Review the details of the rule and modify them as necessary.

b. Choose **Create rule**.

For more information, see Amazon EventBridge rules and Amazon EventBridge event patterns in the *Amazon EventBridge User Guide*

Create an EventBridge rule to trigger a Lambda function

The following example creates an EventBridge rule to trigger a Lambda function every time that Amazon EC2 emits an EC2 Fleet instance change notification for when an instance is launched. The signal in this example is emitted as an `EC2 Fleet Instance Change` event, sub-type `launched`, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Lambda function.

To create the Lambda function to use in the EventBridge rule

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose **Create function**.
3. Enter a name for your function, configure the code, and then choose **Create function**.

   For more information, see Create your first Lambda function in the *AWS Lambda Developer Guide*.

To create an EventBridge rule to trigger a Lambda function when an instance in an EC2 Fleet changes state

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:

   a. Enter a **Name** for the rule, and, optionally, a description.

      A rule can't have the same name as another rule in the same Region and on the same event bus.

   b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.

   c. For **Rule type**, choose **Rule with an event pattern**.

   d. Choose **Next**.

4. For **Build event pattern**, do the following:

   a. For **Event source**, choose **AWS events or EventBridge partner events**.

   b. For **Event pattern**, for this example you'll specify the following event pattern to match the `EC2 Fleet Instance Change` event and `launched` sub-type.

   ```
   {
    "source": ["aws.ec2fleet"],
    "detail-type": ["EC2 Fleet Instance Change"],
    "detail": {
      "sub-type": ["launched"]
   }
   ```

   To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

   i. To use a template to create the event pattern, do the following:

      A. Choose **Event pattern form**.

      B. For **Event source**, choose **AWS services**.

      C. For **AWS Service**, choose **EC2 Fleet**.

      D. For **Event type**, choose **EC2 Fleet Instance Change**.

      E. Choose **Edit pattern**, and add `"detail": {"sub-type": ["launched"]` to match the example event pattern. For proper JSON format, insert a comma (`,`) after the preceding square bracket (`]`).

   ii. (Alternative) To specify a custom event pattern, do the following:

      A. Choose **Custom pattern (JSON editor)**.

      B. In the **Event pattern** box, add the event pattern for this example.

   c. Choose **Next**.

5. For **Select target(s)**, do the following:

   a. For **Target types**, choose **AWS service**.

   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.

   c. For **Topic**, choose **Lambda function**, and for **Function**, choose the function that you created to respond when the event occurs.

   d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see Creating Amazon EventBridge rules that react to events (step 16) in the *Amazon EventBridge User Guide*.

   e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:

   a. Review the details of the rule and modify them as necessary.

   b. Choose **Create rule**.

For a tutorial on how to create a Lambda function and an EventBridge rule that runs the Lambda function, see Tutorial: Log the State of an Amazon EC2 Instance Using EventBridge in the *AWS Lambda Developer Guide*.

EC2 Fleet event types

There are five EC2 Fleet event types. For each event type, there are several sub-types.

Event types

- EC2 Fleet State Change
- EC2 Fleet Spot Instance Request Change
- EC2 Fleet Instance Change
- EC2 Fleet Information
- EC2 Fleet Error

EC2 Fleet State Change

EC2 Fleet sends an `EC2 Fleet State Change` event to Amazon EventBridge when an EC2 Fleet changes state.

The following is example data for this event.

```
{
    "version": "0",
```

```
    "id": "715ed6b3-b8fc-27fe-fad6-528c7b8bf8a2",
    "detail-type": "EC2 Fleet State Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:20Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-598fb973-87b7-422d-be4d-6b0809bfff0a"
    ],
    "detail": {
        "sub-type": "active"
    }
}
```

The possible values for `sub-type` are:

`active`

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances.

`deleted`

The EC2 Fleet request is deleted and has no running instances. The EC2 Fleet will be deleted two days after its instances are terminated.

`deleted_running`

The EC2 Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

`deleted_terminating`

The EC2 Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

`expired`

The EC2 Fleet request has expired. If the request was created with `TerminateInstancesWithExpiration` set, a subsequent `terminated` event indicates that the instances are terminated.

`modify_in_progress`

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed.

`modify_succeeded`

The EC2 Fleet request was modified.

`submitted`

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.

`progress`

The EC2 Fleet request is in the process of being fulfilled.

EC2 Fleet Spot Instance Request Change

EC2 Fleet sends an `EC2 Fleet Spot Instance Request Change` event to Amazon EventBridge when a Spot Instance request in the fleet changes state.

The following is example data for this event.

```
{
    "version": "0",
    "id": "19331f74-bf4b-a3dd-0f1b-ddb1422032b9",
    "detail-type": "EC2 Fleet Spot Instance Request Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:05Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/
fleet-83fd4e48-552a-40ef-9532-82a3acca5f10"
    ],
    "detail": {
        "spot-instance-request-id": "sir-rmqske6h",
        "description": "SpotInstanceRequestId sir-rmqske6h, PreviousState:
 cancelled_running",
        "sub-type": "cancelled"
    }
}
```

The possible values for `sub-type` are:

`active`

The Spot Instance request is fulfilled and has an associated Spot Instance.

`cancelled`

You cancelled the Spot Instance request, or the Spot Instance request expired.

`disabled`

You stopped the Spot Instance.

`submitted`

The Spot Instance request is submitted.

EC2 Fleet Instance Change

EC2 Fleet sends an `EC2 Fleet Instance Change` event to Amazon EventBridge when an instance in the fleet changes state.

The following is example data for this event.

```
{
    "version": "0",
    "id": "542ce428-c8f1-0608-c015-e8ed6522c5bc",
    "detail-type": "EC2 Fleet Instance Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:23Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-598fb973-87b7-422d-
be4d-6b0809bfff0a"
    ],
    "detail": {
        "instance-id": "i-0c594155dd5ff1829",
        "description": "{\"instanceType\":\"c5.large\",\"image\":\"ami-6057e21a\",
\"productDescription\":\"Linux/UNIX\",\"availabilityZone\":\"us-east-1d\"}",
        "sub-type": "launched"
    }
}
```

The possible values for `sub-type` are:

`launched`

A new instance was launched.

`terminated`

The instance was terminated.

`termination_notified`

An instance termination notification was sent when a Spot Instance was terminated by Amazon EC2 during scale-down, when the target capacity of the fleet was modified down, for example, from a target capacity of 4 to a target capacity of 3.

EC2 Fleet Information

EC2 Fleet sends an `EC2 Fleet Information` event to Amazon EventBridge when there is an error during fulfillment. The information event does not block the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "76529817-d605-4571-7224-d36cc1b2c0c4",
    "detail-type": "EC2 Fleet Information",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T08:17:07Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-8becf5fe-
bb9e-415d-8f54-3fa5a8628b91"
    ],
    "detail": {
        "description": "c4.xlarge, ami-0947d2ba12ee1ff75, Linux/UNIX, us-east-1a,
 Spot price in either SpotFleetRequestConfigData or SpotFleetLaunchSpecification or
 LaunchTemplate or LaunchTemplateOverrides is less than Spot market price $0.0619",
        "sub-type": "launchSpecUnusable"
    }
}
```

The possible values for `sub-type` are:

`fleetProgressHalted`

The price in every launch specification is not valid because it is below the Spot price (all the launch specifications have produced `launchSpecUnusable` events). A launch specification might become valid if the Spot price changes.

`launchSpecTemporarilyBlacklisted`

The configuration is not valid and several attempts to launch instances have failed. For more information, see the description of the event.

`launchSpecUnusable`

The price in a launch specification is not valid because it is below the Spot price.

`registerWithLoadBalancersFailed`

An attempt to register instances with load balancers failed. For more information, see the description of the event.

EC2 Fleet Error

EC2 Fleet sends an `EC2 Fleet Error` event to Amazon EventBridge when there is an error during fulfillment. The error event blocks the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "69849a22-6d0f-d4ce-602b-b47c1c98240e",
    "detail-type": "EC2 Fleet Error",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-10-07T01:44:24Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-9bb19bc6-60d3-4fd2-ae47-
d33e68eafa08"
    ],
    "detail": {
        "description": "m3.large, ami-00068cd7555f543d5, Linux/UNIX: IPv6 is not
 supported for the instance type 'm3.large'. ",
```

```
        "sub-type": "spotFleetRequestConfigurationInvalid"
    }
}
```

The possible values for `sub-type` are:

`iamFleetRoleInvalid`

The EC2 Fleet does not have the required permissions to either launch or terminate an instance.

`allLaunchSpecsTemporarilyBlacklisted`

None of the configurations are valid, and several attempts to launch instances have failed. For more information, see the description of the event.

`spotInstanceCountLimitExceeded`

You've reached the limit on the number of Spot Instances that you can launch.

`spotFleetRequestConfigurationInvalid`

The configuration is not valid. For more information, see the description of the event.

Spot Fleet event types

There are five Spot Fleet event types. For each event type, there are several sub-types.

Event types

- EC2 Spot Fleet State Change
- EC2 Spot Fleet Spot Instance Request Change
- EC2 Spot Fleet Instance Change
- EC2 Spot Fleet Information
- EC2 Spot Fleet Error

EC2 Spot Fleet State Change

Spot Fleet sends an `EC2 Spot Fleet State Change` event to Amazon EventBridge when a Spot Fleet changes state.

The following is example data for this event.

```
{
```

```
    "version": "0",
    "id": "d1af1091-6cc3-2e24-203a-3b870e455d5b",
    "detail-type": "EC2 Spot Fleet State Change",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T08:57:06Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-4b6d274d-0cea-4b2c-b3be-9dc627ad1f55"
    ],
    "detail": {
        "sub-type": "submitted"
    }
}
```

The possible values for `sub-type` are:

`active`

The Spot Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances.

`cancelled`

The Spot Fleet request is canceled and has no running instances. The Spot Fleet will be deleted two days after its instances are terminated.

`cancelled_running`

The Spot Fleet request is canceled and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

`cancelled_terminating`

The Spot Fleet request is canceled and its instances are terminating. The request remains in this state until all instances are terminated.

`expired`

The Spot Fleet request has expired. If the request was created with `TerminateInstancesWithExpiration` set, a subsequent `terminated` event indicates that the instances are terminated.

`modify_in_progress`

The Spot Fleet request is being modified. The request remains in this state until the modification is fully processed.

`modify_succeeded`

The Spot Fleet request was modified.

`submitted`

The Spot Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.

`progress`

The Spot Fleet request is in the process of being fulfilled.

EC2 Spot Fleet Spot Instance Request Change

Spot Fleet sends an `EC2 Spot Fleet Spot Instance Request Change` event to Amazon EventBridge when a Spot Instance request in the fleet changes state.

The following is example data for this event.

```
{
    "version": "0",
    "id": "cd141ef0-14af-d670-a71d-fe46e9971bd2",
    "detail-type": "EC2 Spot Fleet Spot Instance Request Change",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T08:53:21Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-
a98d2133-941a-47dc-8b03-0f94c6852ad1"
    ],
    "detail": {
        "spot-instance-request-id": "sir-a2w9gc5h",
        "description": "SpotInstanceRequestId sir-a2w9gc5h, PreviousState:
 cancelled_running",
        "sub-type": "cancelled"
    }
}
```

The possible values for `sub-type` are:

`active`

The Spot Instance request is fulfilled and has an associated Spot Instance.

`cancelled`

You cancelled the Spot Instance request, or the Spot Instance request expired.

`disabled`

You stopped the Spot Instance.

`submitted`

The Spot Instance request is submitted.

EC2 Spot Fleet Instance Change

Spot Fleet sends an `EC2 Spot Fleet Instance Change` event to Amazon EventBridge when an instance in the fleet changes state.

The following is example data for this event.

```
{
    "version": "0",
    "id": "11591686-5bd7-bbaa-eb40-d46529c2710f",
    "detail-type": "EC2 Spot Fleet Instance Change",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T07:25:02Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-c8a764a4-bedc-4b62-
af9c-0095e6e3ba61"
    ],
    "detail": {
        "instance-id": "i-08b90df1e09c30c9b",
        "description": "{\"instanceType\":\"r4.2xlarge\",\"image\":
\"ami-032930428bf1abbff\",\"productDescription\":\"Linux/UNIX\",\"availabilityZone\":
\"us-east-1a\"}",
        "sub-type": "launched"
    }
```

```
}
```

The possible values for `sub-type` are:

`launched`

A new instance was launched.

`terminated`

The instance was terminated.

`termination_notified`

An instance termination notification was sent when a Spot Instance was terminated by Amazon EC2 during scale-down, when the target capacity of the fleet was modified down, for example, from a target capacity of 4 to a target capacity of 3.

EC2 Spot Fleet Information

Spot Fleet sends an `EC2 Spot Fleet Information` event to Amazon EventBridge when there is an error during fulfillment. The information event does not block the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "73a60f70-3409-a66c-635c-7f66c5f5b669",
    "detail-type": "EC2 Spot Fleet Information",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-08T20:56:12Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-2531ea06-
af18-4647-8757-7d69c94971b1"
    ],
    "detail": {
        "description": "r3.8xlarge, ami-032930428bf1abbff, Linux/UNIX, us-east-1a, Spot
 bid price is less than Spot market price $0.5291",
        "sub-type": "launchSpecUnusable"
    }
```

```
}
```

The possible values for `sub-type` are:

`fleetProgressHalted`

The price in every launch specification is not valid because it is below the Spot price (all the launch specifications have produced `launchSpecUnusable` events). A launch specification might become valid if the Spot price changes.

`launchSpecTemporarilyBlacklisted`

The configuration is not valid and several attempts to launch instances have failed. For more information, see the description of the event.

`launchSpecUnusable`

The price in a launch specification is not valid because it is below the Spot price.

`registerWithLoadBalancersFailed`

An attempt to register instances with load balancers failed. For more information, see the description of the event.

EC2 Spot Fleet Error

Spot Fleet sends an `EC2 Spot Fleet Error` event to Amazon EventBridge when there is an error during fulfillment. The error event blocks the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
    "version": "0",
    "id": "10adc4e7-675c-643e-125c-5bfa1b1ba5d2",
    "detail-type": "EC2 Spot Fleet Error",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T06:56:07Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/
sfr-38725d30-25f1-4f30-83ce-2907c56dba17"
```

```
    ],
    "detail": {
        "description": "r4.2xlarge, ami-032930428bf1abbff, Linux/UNIX: The
 associatePublicIPAddress parameter can only be specified for the network interface
 with DeviceIndex 0. ",
        "sub-type": "spotFleetRequestConfigurationInvalid"
    }
}
```

The possible values for `sub-type` are:

`iamFleetRoleInvalid`

The Spot Fleet does not have the required permissions to either launch or terminate an instance.

`allLaunchSpecsTemporarilyBlacklisted`

None of the configurations are valid, and several attempts to launch instances have failed. For more information, see the description of the event.

`spotInstanceCountLimitExceeded`

You've reached the limit on the number of Spot Instances that you can launch.

`spotFleetRequestConfigurationInvalid`

The configuration is not valid. For more information, see the description of the event.

Tutorials for EC2 Fleet

There are different ways to configure an EC2 Fleet. The configuration you choose depends on your specific use case.

The following tutorials cover some of the possible use cases and provide the tasks required to implement them.

Use case	Link to tutorial
Use instance weighting to manage the availability and performance of your EC2 Fleet.	[Tutorial: Configure EC2 Fleet to use instance weighting]()

Use case	Link to tutorial
With instance weighting, you assign a weight to each instance type in your EC2 Fleet to represent their compute capacity and performance relative to each other. Based on the weights, the fleet can use any combination of the specified instance types, as long as it can fulfil the desired target capacity.	
Use On-Demand capacity to ensure availability during peak periods, but benefit from additional Spot capacity at a lower cost. Configure your EC2 Fleet to use On-Demand Instances as the primary capacity to ensure available capacity during peak periods. In addition, allocate some capacity to Spot Instances to benefit from discounted pricing, while keeping in mind that Spot Instances can be interrupted if Amazon EC2 needs the capacity back.	Tutorial: Configure EC2 Fleet to use On-Demand Instances as the primary capacity
Use Capacity Reservations to reserve compute capacity for your On-Demand Instances. Configure your EC2 Fleet to use `targeted` Capacity Reservations first when launching On-Demand Instances. If you have strict capacity requirements, and are running business-critical workloads that require a certain level of long or short-term capacity assurance, we recommend that you create a Capacity Reservation to ensure that you always have access to Amazon EC2 capacity when you need it, for as long as you need it.	Tutorial: Configure EC2 Fleet to launch On-Demand Instances using targeted Capacity Reservations

Use case	Link to tutorial
Use Capacity Blocks to reserve highly sought-after GPU instances for your ML workloads. Configure your EC2 Fleet to launch instances into Capacity Blocks.	Tutorial: Configure your EC2 Fleet to launch instances into Capacity Blocks

Tutorial: Configure EC2 Fleet to use instance weighting

This tutorial uses a fictitious company called Example Corp to illustrate the process of requesting an EC2 Fleet using instance weighting.

Objective

Example Corp, a pharmaceutical company, wants to use the computational power of Amazon EC2 for screening chemical compounds that might be used to fight cancer.

Planning

Example Corp first reviews Spot Best Practices. Next, Example Corp determines the requirements for their EC2 Fleet.

Instance types

Example Corp has a compute- and memory-intensive application that performs best with at least 60 GB of memory and eight virtual CPUs (vCPUs). They want to maximize these resources for the application at the lowest possible price. Example Corp decides that any of the following EC2 instance types would meet their needs:

Instance type	Memory (GiB)	vCPUs
r3.2xlarge	61	8
r3.4xlarge	122	16

Instance type	Memory (GiB)	vCPUs
r3.8xlarge	244	32

Target capacity in units

With instance weighting, target capacity can equal a number of instances (the default) or a combination of factors such as cores (vCPUs), memory (GiBs), and storage (GBs). By considering the base for their application (60 GB of RAM and eight vCPUs) as one unit, Example Corp decides that 20 times this amount would meet their needs. So the company sets the target capacity of their EC2 Fleet request to 20 units.

Instance weights

After determining the target capacity, Example Corp calculates instance weights. To calculate the instance weight for each instance type, they determine the units of each instance type that are required to reach the target capacity as follows:

- r3.2xlarge (61.0 GB, 8 vCPUs) = 1 unit of 20
- r3.4xlarge (122.0 GB, 16 vCPUs) = 2 units of 20
- r3.8xlarge (244.0 GB, 32 vCPUs) = 4 units of 20

Therefore, Example Corp assigns instance weights of 1, 2, and 4 to the respective launch configurations in their EC2 Fleet request.

Price per unit hour

Example Corp uses the On-Demand price per instance hour as a starting point for their price. They could also use recent Spot prices, or a combination of the two. To calculate the price per unit hour, they divide their starting price per instance hour by the weight. For example:

Instance type	On-Demand price	Instance weight	Price per unit hour
r3.2xLarge	$0.7	1	$0.7
r3.4xLarge	$1.4	2	$0.7

Instance type	On-Demand price	Instance weight	Price per unit hour
r3.8xLarge	$2.8	4	$0.7

Example Corp could use a global price per unit hour of $0.7 and be competitive for all three instance types. They could also use a global price per unit hour of $0.7 and a specific price per unit hour of $0.9 in the `r3.8xlarge` launch specification.

Verify permissions

Before creating an EC2 Fleet, Example Corp verifies that it has an IAM role with the required permissions. For more information, see EC2 Fleet prerequisites.

Create a launch template

Next, Example Corp creates a launch template. The launch template ID is used in the following step. For more information, see Create an Amazon EC2 launch template.

Create the EC2 Fleet

Example Corp creates a file, `config.json`, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-07b3bc7625cdab851",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "r3.2xlarge",
                    "SubnetId": "subnet-482e4972",
                    "WeightedCapacity": 1
                },
                {
                    "InstanceType": "r3.4xlarge",
                    "SubnetId": "subnet-482e4972",
                    "WeightedCapacity": 2
```

```
                },
                {
                    "InstanceType": "r3.8xlarge",
                    "MaxPrice": "0.90",
                    "SubnetId": "subnet-482e4972",
                    "WeightedCapacity": 4
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "DefaultTargetCapacityType": "spot"
    }
}
```

Example Corp creates the EC2 Fleet using the following create-fleet command.

```
aws ec2 create-fleet --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet.

Fulfillment

The allocation strategy determines which Spot capacity pools your Spot Instances come from.

With the `lowest-price` strategy (which is the default strategy), the Spot Instances come from the pool with the lowest price per unit at the time of fulfillment. To provide 20 units of capacity, the EC2 Fleet launches either 20 `r3.2xlarge` instances (20 divided by 1), 10 `r3.4xlarge` instances (20 divided by 2), or 5 `r3.8xlarge` instances (20 divided by 4).

If Example Corp used the `diversified` strategy, the Spot Instances would come from all three pools. The EC2 Fleet would launch 6 `r3.2xlarge` instances (which provide 6 units), 3 `r3.4xlarge` instances (which provide 6 units), and 2 `r3.8xlarge` instances (which provide 8 units), for a total of 20 units.

Tutorial: Configure EC2 Fleet to use On-Demand Instances as the primary capacity

This tutorial uses a fictitious company called ABC Online to illustrate the process of requesting an EC2 Fleet with On-Demand as the primary capacity, and Spot capacity if available.

Objective

ABC Online, a restaurant delivery company, aims to provision Amazon EC2 capacity across EC2 instance types and purchasing options to achieve their desired scale, performance, and cost.

Plan

ABC Online requires a fixed capacity to handle peak periods, but would like to benefit from additional capacity at a lower cost. The company determines the following requirements for their EC2 Fleet:

- On-Demand Instance capacity – ABC Online requires 15 On-Demand Instances to ensure that they can accommodate traffic at peak periods.
- Spot Instance capacity – To enhance performance, but at a lower price, ABC Online plans to provision 5 Spot Instances.

Verify permissions

Before creating an EC2 Fleet, ABC Online verifies that it has an IAM role with the required permissions. For more information, see EC2 Fleet prerequisites.

Create a launch template

Next, ABC Online creates a launch template. The launch template ID is used in the following step. For more information, see Create an Amazon EC2 launch template.

Create the EC2 Fleet

ABC Online creates a file, `config.json`, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-07b3bc7625cdab851",
                "Version": "2"
            }
```

```
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 20,
        "OnDemandTargetCapacity":15,
        "DefaultTargetCapacityType": "spot"
    }
}
```

ABC Online creates the EC2 Fleet using the following create-fleet command.

```
aws ec2 create-fleet --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet.

Fulfillment

The allocation strategy determines that the On-Demand capacity is always fulfilled, while the balance of the target capacity is fulfilled as Spot if there is available capacity.

Tutorial: Configure EC2 Fleet to launch On-Demand Instances using targeted Capacity Reservations

This tutorial walks you through all the steps that you must perform so that your EC2 Fleet launches On-Demand Instances into `targeted` Capacity Reservations.

You will learn how to configure a fleet to use `targeted` On-Demand Capacity Reservations first when launching On-Demand Instances. You will also learn how to configure the fleet so that, when the total On-Demand target capacity exceeds the number of available unused Capacity Reservations, the fleet uses the specified allocation strategy for selecting the instance pools in which to launch the remaining target capacity.

EC2 Fleet configuration

In this tutorial, the fleet is configured as follows:

- Target capacity: 10 On-Demand Instances
- Total unused `targeted` Capacity Reservations: 6 (less than the fleet's On-Demand target capacity of 10 On-Demand Instances)

- Number of Capacity Reservation pools: 2 (`us-east-1a` and `us-east-1b`)
- Number of Capacity Reservations per pool: 3
- On-Demand allocation strategy: `lowest-price` (When the number of unused Capacity Reservations is less than the On-Demand target capacity, the fleet determines the pools in which to launch the remaining On-Demand capacity based on the On-Demand allocation strategy.)

  Note that you can also use the `prioritized` allocation strategy instead of the `lowest-price` allocation strategy.

To launch On-Demand Instances into targeted Capacity Reservations, you must perform a number of steps, as follows:

- Step 1: Create Capacity Reservations
- Step 2: Create a Capacity Reservation resource group
- Step 3: Add the Capacity Reservations to the Capacity Reservation resource group
- (Optional) Step 4: View the Capacity Reservations in the resource group
- Step 5: Create a launch template that specifies that the Capacity Reservation targets a specific resource group
- (Optional) Step 6: Describe the launch template
- Step 7: Create an EC2 Fleet
- (Optional) Step 8: View the number of remaining unused Capacity Reservations

Step 1: Create Capacity Reservations

Use the create-capacity-reservation command to create the Capacity Reservations, three for `us-east-1a` and another three for `us-east-1b`. Except for the Availability Zone, the other attributes of the Capacity Reservations are identical.

3 Capacity Reservations in `us-east-1a`

```
aws ec2 create-capacity-reservation \
    --availability-zone us-east-1a \
    --instance-type c5.xlarge \
    --instance-platform Linux/UNIX \
    --instance-count 3 \
    --instance-match-criteria targeted
```

Example of resulting Capacity Reservation ID

```
cr-1234567890abcdef1
```

3 Capacity Reservations in `us-east-1b`

```
aws ec2 create-capacity-reservation \
    --availability-zone us-east-1b \
    --instance-type c5.xlarge \
    --instance-platform Linux/UNIX \
    --instance-count 3 \
    --instance-match-criteria targeted
```

Example of resulting Capacity Reservation ID

```
cr-54321abcdef567890
```

Step 2: Create a Capacity Reservation resource group

Use the `resource-groups` service and the create-group command to create a Capacity Reservation resource group. In this example, the resource group is named `my-cr-group`. For information about why you must create a resource group, see Use Capacity Reservations to reserve On-Demand capacity in EC2 Fleet.

```
aws resource-groups create-group \
    --name my-cr-group \
    --configuration '{"Type":"AWS::EC2::CapacityReservationPool"}'
 '{"Type":"AWS::ResourceGroups::Generic", "Parameters": [{"Name": "allowed-resource-
types", "Values": ["AWS::EC2::CapacityReservation"]}]}'
```

Step 3: Add the Capacity Reservations to the Capacity Reservation resource group

Use the `resource-groups` service and the group-resources command to add the Capacity Reservations that you created in Step 1 to the Capacity Reservations resource group. Note that you must reference the On-Demand Capacity Reservations by their ARNs.

```
aws resource-groups group-resources \
    --group my-cr-group \
    --resource-arns \
      arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1 \
```

```
    arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

Example output

```
{
   "Failed": [],
   "Succeeded": [
   "arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1",
   "arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"
   ]
}
```

(Optional) Step 4: View the Capacity Reservations in the resource group

Use the `resource-groups` service and the list-group-resources command to optionally describe the resource group to view its Capacity Reservations.

```
aws resource-groups list-group-resources --group my-cr-group
```

Example output

```
{
    "ResourceIdentifiers": [
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
            "ResourceArn": "arn:aws:ec2:us-east-1:123456789012:capacity-reservation/
cr-1234567890abcdef1"
        },
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
            "ResourceArn": "arn:aws:ec2:us-east-1:123456789012:capacity-reservation/
cr-54321abcdef567890"
        }
    ]
}
```

Step 5: Create a launch template that specifies that the Capacity Reservation targets a specific resource group

Use the create-launch-template command to create a launch template in which to specify the Capacity Reservations to use. In this example, the fleet will use `targeted` Capacity Reservations, which have been added to a resource group. Therefore, the launch template data specifies that the Capacity Reservation targets a specific resource group. In this example, the launch template is named `my-launch-template`.

```
aws ec2 create-launch-template \
    --launch-template-name my-launch-template \
    --launch-template-data \
        '{"ImageId": "ami-0123456789example",
          "CapacityReservationSpecification":
            {"CapacityReservationTarget":
                { "CapacityReservationResourceGroupArn": "arn:aws:resource-groups:us-east-1:123456789012:group/my-cr-group" }
            }
        }'
```

(Optional) Step 6: Describe the launch template

Use the describe-launch-template-versions command to optionally describe the launch template to view its configuration.

```
aws ec2 describe-launch-template-versions --launch-template-name my-launch-template
```

Example output

```
{
    "LaunchTemplateVersions": [
        {
            "LaunchTemplateId": "lt-01234567890example",
            "LaunchTemplateName": "my-launch-template",
            "VersionNumber": 1,
            "CreateTime": "2021-01-19T20:50:19.000Z",
            "CreatedBy": "arn:aws:iam::123456789012:user/Admin",
            "DefaultVersion": true,
            "LaunchTemplateData": {
                "ImageId": "ami-0947d2ba12ee1ff75",
                "CapacityReservationSpecification": {
                    "CapacityReservationTarget": {
                        "CapacityReservationResourceGroupArn": "arn:aws:resource-groups:us-east-1:123456789012:group/my-cr-group"
                    }
                }
```

```
            }
        }
    ]
}
```

Step 7: Create an EC2 Fleet

Create an EC2 Fleet that specifies the configuration information for the instances that it will launch. The following EC2 Fleet configuration shows only the pertinent configurations for this example. The launch template `my-launch-template` is the launch template you created in Step 5. There are two instance pools, each with the same instance type (`c5.xlarge`), but with different Availability Zones (`us-east-1a` and `us-east-1b`). The price of the instance pools is the same because pricing is defined for the Region, not per Availability Zone. The total target capacity is 10, and the default target capacity type is `on-demand`. The On-Demand allocation strategy is `lowest-price`. The usage strategy for Capacity Reservations is `use-capacity-reservations-first`.

> **Note**
>
> The fleet type must be `instant`. Other fleet types do not support `use-capacity-reservations-first`.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
            "Overrides": [
               {
                   "InstanceType": "c5.xlarge",
                   "AvailabilityZone": "us-east-1a"
               },
               {
                    "InstanceType": "c5.xlarge",
                    "AvailabilityZone": "us-east-1b"
               }
            ]
```

```
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 10,
        "DefaultTargetCapacityType": "on-demand"
    },
    "OnDemandOptions": {
        "AllocationStrategy": "lowest-price",
        "CapacityReservationOptions": {
             "UsageStrategy": "use-capacity-reservations-first"
         }
    },
    "Type": "instant"
}
```

After you create the `instant` fleet using the preceding configuration, the following 10 instances are launched to meet the target capacity:

- The Capacity Reservations are used first to launch 6 On-Demand Instances as follows:
  - 3 On-Demand Instances are launched into the 3 `c5.xlarge` `targeted` Capacity Reservations in `us-east-1a`
  - 3 On-Demand Instances are launched into the 3 `c5.xlarge` `targeted` Capacity Reservations in `us-east-1b`
- To meet the target capacity, 4 additional On-Demand Instances are launched into regular On-Demand capacity according to the On-Demand allocation strategy, which is `lowest-price` in this example. However, because the pools are the same price (because price is per Region and not per Availability Zone), the fleet launches the remaining 4 On-Demand Instances into either of the pools.

(Optional) Step 8: View the number of remaining unused Capacity Reservations

After the fleet is launched, you can optionally run [describe-capacity-reservations]() to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```
{ "CapacityReservationId":  "cr-111",
     "InstanceType":  "c5.xlarge",
     "AvailableInstanceCount":  0
}
```

```
 { "CapacityReservationId":  "cr-222",
     "InstanceType":  "c5.xlarge",
     "AvailableInstanceCount":  0
}
```

Tutorial: Configure your EC2 Fleet to launch instances into Capacity Blocks

This tutorial walks you through the steps that you must perform so that your EC2 Fleet launches instances into Capacity Blocks.

In most cases, the target capacity of the EC2 Fleet request should be less than or equal to the available capacity of the Capacity Block reservation that you are targeting. Target capacity requests that exceed the limits of the Capacity Block reservation will not be fulfilled. If the target capacity request exceeds the limits of your Capacity Block reservation, you will receive an `Insufficient Capacity Exception` for the capacity that exceeds the limits of your Capacity Block reservation.

> **Note**
>
> For Capacity Blocks, EC2 Fleet will not fallback to launching On-Demand Instances for the remainder of the desired target capacity.

If EC2 Fleet is unable to fulfill the requested target capacity in an available Capacity Block reservation, EC2 Fleet will fulfill as much capacity as it can and return the instances that it was able to launch. You can repeat the call to EC2 Fleet again until all the instances are provisioned.

After configuring the EC2 Fleet request, you must wait until the start date of your Capacity Block reservation. If you make requests to EC2 Fleet to launch into a Capacity Block that hasn't started yet, you will receive an `Insufficient Capacity Error`.

After your Capacity Block reservation becomes active, you can make EC2 Fleet API calls and provision the instances into your Capacity Block based on the parameters you selected. Instances running in the Capacity Block continue to run until you manually stop or terminate them or until Amazon EC2 terminates the instances when the Capacity Block reservation ends.

For more information about Capacity Blocks, see Capacity Blocks for ML.

Considerations

- Only EC2 Fleet requests of type `instant` are supported for launching instances into Capacity Blocks. For more information, see [Configure an EC2 Fleet of type instant](#).
- Multiple Capacity Blocks in the same EC2 Fleet request aren't supported.
- Using `OnDemandTargetCapacity` or `SpotTargetCapacity` while also setting `capacity-block` as the `DefaultTargetCapacity` isn't supported.
- If `DefaultTargetCapacityType` is set to `capacity-block`, you can't provide `OnDemandOptions::CapacityReservationOptions`. An exception will occur.

To configure an EC2 Fleet to launch instances into Capacity Blocks

1. **Create a launch template.**

   In the launch template, do the following:

   - For `InstanceMarketOptionsRequest`, set `MarketType` to `capacity-block`.
   - To target the Capacity Block reservation, for `CapacityReservationID`, specify the Capacity Block reservation ID.

   Make note of launch template name and version. You'll use this information in the next step.

   For more information about creating a launch template, see [Create an Amazon EC2 launch template](#).

2. **Configure the EC2 Fleet.**

   Create a file, `config.json`, with the following configuration for your EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

   For more information about configuring an EC2 Fleet, see [Create an EC2 Fleet](#).

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "CBR-launch-template",
                "Version": "1"
            },
```

```
                "Overrides": [
                    {
                        "InstanceType": "p5.48xlarge",
                        "AvailabilityZone": "us-east-1a"
                    },
                ]
            }
        ],
        "TargetCapacitySpecification": {
            "TotalTargetCapacity": 10,
            "DefaultTargetCapacityType": "capacity-block"
        },
        "Type": "instant"
}
```

3. **Launch the fleet.**

   Use the following create-fleet command.

   ```
   aws ec2 create-fleet --cli-input-json file://config.json
   ```

   For more information, see Create an EC2 Fleet.

Example CLI configurations for EC2 Fleet

You can define your EC2 Fleet configuration in a JSON file, and then reference that file with the create-fleet command to create your fleet, as follows:

```
aws ec2 create-fleet --cli-input-json file://file_name.json
```

The following examples illustrate launch configurations for various EC2 Fleet use cases. For more information about the configuration parameters, see create-fleet.

Examples

- Example 1: Launch Spot Instances as the default purchasing option
- Example 2: Launch On-Demand Instances as the default purchasing option
- Example 3: Launch On-Demand Instances as the primary capacity
- Example 4: Launch On-Demand Instances using multiple Capacity Reservations

For more CLI examples for fleets of type `instant`, see Configure an EC2 Fleet of type instant.

Example 1: Launch Spot Instances as the default purchasing option

The following example specifies the minimum parameters required in an EC2 Fleet: a launch template, target capacity, and default purchasing option. The launch template is identified by its launch template ID and version number. The target capacity for the fleet is 2 instances, and the default purchasing option is `spot`, which results in the fleet launching 2 Spot Instances.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }

        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 2,
        "DefaultTargetCapacityType": "spot"
    }
}
```

Example 2: Launch On-Demand Instances as the default purchasing option

The following example specifies the minimum parameters required in an EC2 Fleet: a launch template, target capacity, and default purchasing option. The launch template is identified by its launch template ID and version number. The target capacity for the fleet is 2 instances, and the default purchasing option is `on-demand`, which results in the fleet launching 2 On-Demand Instances.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }

        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 2,
        "DefaultTargetCapacityType": "on-demand"
    }
}
```

Example 3: Launch On-Demand Instances as the primary capacity

The following example specifies the total target capacity of 2 instances for the fleet, and a target capacity of 1 On-Demand Instance. The default purchasing option is `spot`. The fleet launches 1 On-Demand Instance as specified, but needs to launch one more instance to fulfill the total target capacity. The purchasing option for the difference is calculated as `TotalTargetCapacity` – `OnDemandTargetCapacity` = `DefaultTargetCapacityType`, which results in the fleet launching 1 Spot Instance.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
```

```
            }

        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 2,
        "OnDemandTargetCapacity": 1,
        "DefaultTargetCapacityType": "spot"
    }
}
```

Example 4: Launch On-Demand Instances using multiple Capacity Reservations

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to `use-capacity-reservations-first`. This example demonstrates how the fleet selects the Capacity Reservations to use when there are more Capacity Reservations than are needed to fulfil the target capacity.

In this example, the fleet configuration is as follows:

- Target capacity: 12 On-Demand Instances
- Total unused Capacity Reservations: 15 (more than the fleet's target capacity of 12 On-Demand Instances)
- Number of Capacity Reservation pools: 3 (`m5.large`, `m4.xlarge`, and `m4.2xlarge`)
- Number of Capacity Reservations per pool: 5
- On-Demand allocation strategy: `lowest-price` (When there are multiple unused Capacity Reservations in multiple instance pools, the fleet determines the pools in which to launch the On-Demand Instances based on the On-Demand allocation strategy.)

  Note that you can also use the `prioritized` allocation strategy instead of the `lowest-price` allocation strategy.

Capacity Reservations

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by `AvailableInstanceCount`.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}

{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}

{
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount":5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

Fleet configuration

The following fleet configuration shows only the pertinent configurations for this example. The total target capacity is 12, and the default target capacity type is `on-demand`. The On-Demand allocation strategy is `lowest-price`. The usage strategy for Capacity Reservations is `use-capacity-reservations-first`.

In this example, the On-Demand Instance price is:

- `m5.large` – $0.096 per hour
- `m4.xlarge` – $0.20 per hour
- `m4.2xlarge` – $0.40 per hour

> **Note**
>
> The fleet type must be of type `instant`. Other fleet types do not support `use-capacity-reservations-first`.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-abc1234567example",
                "Version": "1"
            },
            "Overrides": [
                {
                  "InstanceType": "m5.large",
                  "AvailabilityZone": "us-east-1a",
                  "WeightedCapacity": 1
                },
                {
                  "InstanceType": "m4.xlarge",
                  "AvailabilityZone": "us-east-1a",
                  "WeightedCapacity": 1
                },
                {
                  "InstanceType": "m4.2xlarge",
                  "AvailabilityZone": "us-east-1a",
                  "WeightedCapacity": 1
                }
              ]

        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 12,
        "DefaultTargetCapacityType": "on-demand"
    },
    "OnDemandOptions": {
        "AllocationStrategy": "lowest-price",
        "CapacityReservationOptions": {
            "UsageStrategy": "use-capacity-reservations-first"
        }
```

```
    },
    "Type": "instant"
}
```

After you create the `instant` fleet using the preceding configuration, the following 12 instances are launched to meet the target capacity:

- 5 `m5.large` On-Demand Instances in `us-east-1a` – `m5.large` in `us-east-1a` is the lowest price, and there are 5 available unused `m5.large` Capacity Reservations
- 5 `m4.xlarge` On-Demand Instances in us-east-1a – `m4.xlarge` in `us-east-1a` is the next lowest price, and there are 5 available unused `m4.xlarge` Capacity Reservations
- 2 `m4.2xlarge` On-Demand Instances in us-east-1a – `m4.2xlarge` in `us-east-1a` is the third lowest price, and there are 5 available unused `m4.2xlarge` Capacity Reservations of which only 2 are needed to meet the target capacity

After the fleet is launched, you can run [describe-capacity-reservations](#) to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the `m5.large` and `m4.xlarge` Capacity Reservations were used, with 3 `m4.2xlarge` Capacity Reservations remaining unused.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "AvailableInstanceCount": 0
}

{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "AvailableInstanceCount": 0
}

{
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "AvailableInstanceCount": 3
}
```

Example 5: Launch On-Demand Instances using Capacity Reservations when the total target capacity exceeds the number of unused Capacity Reservations

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to `use-capacity-reservations-first`. This example demonstrates how the fleet selects the instance pools in which to launch On-Demand Instances when the total target capacity exceeds the number of available unused Capacity Reservations.

In this example, the fleet configuration is as follows:

- Target capacity: 16 On-Demand Instances
- Total unused Capacity Reservations: 15 (less than the fleet's target capacity of 16 On-Demand Instances)
- Number of Capacity Reservation pools: 3 (`m5.large`, `m4.xlarge`, and `m4.2xlarge`)
- Number of Capacity Reservations per pool: 5
- On-Demand allocation strategy: `lowest-price` (When the number of unused Capacity Reservations is less than the On-Demand target capacity, the fleet determines the pools in which to launch the remaining On-Demand capacity based on the On-Demand allocation strategy.)

  Note that you can also use the `prioritized` allocation strategy instead of the `lowest-price` allocation strategy.

Capacity Reservations

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by `AvailableInstanceCount`.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
```

```
}

{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}

{
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount":5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

Fleet configuration

The following fleet configuration shows only the pertinent configurations for this example. The total target capacity is 16, and the default target capacity type is `on-demand`. The On-Demand allocation strategy is `lowest-price`. The usage strategy for Capacity Reservations is `use-capacity-reservations-first`.

In this example, the On-Demand Instance price is:

- m5.large – $0.096 per hour
- m4.xlarge – $0.20 per hour
- m4.2xlarge – $0.40 per hour

> **Note**
>
> The fleet type must be `instant`. Other fleet types do not support `use-capacity-reservations-first`.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            },
            "Overrides": [
                {
                  "InstanceType": "m5.large",
                  "AvailabilityZone": "us-east-1a",
                  "WeightedCapacity": 1
                },
                {
                  "InstanceType": "m4.xlarge",
                  "AvailabilityZone": "us-east-1a",
                  "WeightedCapacity": 1
                },
                {
                  "InstanceType": "m4.2xlarge",
                  "AvailabilityZone": "us-east-1a",
                  "WeightedCapacity": 1
                }
              ]

        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 16,
        "DefaultTargetCapacityType": "on-demand"
    },
    "OnDemandOptions": {
        "AllocationStrategy": "lowest-price"
        "CapacityReservationOptions": {
            "UsageStrategy": "use-capacity-reservations-first"
        }
    },
    "Type": "instant",
}
```

After you create the `instant` fleet using the preceding configuration, the following 16 instances are launched to meet the target capacity:

- 6 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is the lowest price, and there are 5 available unused m5.large Capacity Reservations. The Capacity Reservations are used first to launch 5 On-Demand Instances. After the remaining m4.xlarge and m4.2xlarge Capacity Reservations are used, to meet the target capacity an additional On-Demand Instance is launched according to the On-Demand allocation strategy, which is lowest-price in this example.
- 5 m4.xlarge On-Demand Instances in us-east-1a – m4.xlarge in us-east-1a is the next lowest price, and there are 5 available unused m4.xlarge Capacity Reservations
- 5 m4.2xlarge On-Demand Instances in us-east-1a – m4.2xlarge in us-east-1a is the third lowest price, and there are 5 available unused m4.2xlarge Capacity Reservations

After the fleet is launched, you can run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "AvailableInstanceCount": 0
}

{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "AvailableInstanceCount": 0
}

{
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "AvailableInstanceCount": 0
}
```

Example 6: Launch On-Demand Instances using targeted Capacity Reservations

You can configure a fleet to use targeted On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-

`reservations-first`. This example demonstrates how to launch On-Demand Instances into `targeted` Capacity Reservations, where the attributes of the Capacity Reservations are the same except for their Availability Zones (`us-east-1a` and `us-east-1b`). It also demonstrates how the fleet selects the instance pools in which to launch On-Demand Instances when the total target capacity exceeds the number of available unused Capacity Reservations.

In this example, the fleet configuration is as follows:

- Target capacity: 10 On-Demand Instances
- Total unused `targeted` Capacity Reservations: 6 (less than the fleet's On-Demand target capacity of 10 On-Demand Instances)
- Number of Capacity Reservation pools: 2 (`us-east-1a` and `us-east-1b`)
- Number of Capacity Reservations per pool: 3
- On-Demand allocation strategy: `lowest-price` (When the number of unused Capacity Reservations is less than the On-Demand target capacity, the fleet determines the pools in which to launch the remaining On-Demand capacity based on the On-Demand allocation strategy.)

  Note that you can also use the `prioritized` allocation strategy instead of the `lowest-price` allocation strategy.

For a walkthrough of the procedures that you must perform to accomplish this example, see [Tutorial: Configure EC2 Fleet to launch On-Demand Instances using targeted Capacity Reservations](#).

Capacity Reservations

The account has the following 6 unused Capacity Reservations in 2 different pools. In this example, the pools differ by their Availability Zones. The number of Capacity Reservations in each pool is indicated by `AvailableInstanceCount`.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "c5.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 3,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

```
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "c5.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1b",
    "AvailableInstanceCount": 3,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

Fleet configuration

The following fleet configuration shows only the pertinent configurations for this example. The total target capacity is 10, and the default target capacity type is `on-demand`. The On-Demand allocation strategy is `lowest-price`. The usage strategy for Capacity Reservations is `use-capacity-reservations-first`.

In this example, the On-Demand Instance price for `c5.xlarge` in `us-east-1` is $0.17 per hour.

> **Note**
>
> The fleet type must be `instant`. Other fleet types do not support `use-capacity-reservations-first`.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
            "Overrides": [
               {
                   "InstanceType": "c5.xlarge",
                   "AvailabilityZone": "us-east-1a"
               },
               {
                    "InstanceType": "c5.xlarge",
                    "AvailabilityZone": "us-east-1b"
               }
```

```
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 10,
        "DefaultTargetCapacityType": "on-demand"
    },
    "OnDemandOptions": {
        "AllocationStrategy": "lowest-price",
        "CapacityReservationOptions": {
             "UsageStrategy": "use-capacity-reservations-first"
         }
    },
    "Type": "instant"
}
```

After you create the `instant` fleet using the preceding configuration, the following 10 instances are launched to meet the target capacity:

- The Capacity Reservations are used first to launch 6 On-Demand Instances as follows:
  - 3 On-Demand Instances are launched into the 3 `c5.xlarge` `targeted` Capacity Reservations in `us-east-1a`
  - 3 On-Demand Instances are launched into the 3 `c5.xlarge` `targeted` Capacity Reservations in `us-east-1b`
- To meet the target capacity, 4 additional On-Demand Instances are launched into regular On-Demand capacity according to the On-Demand allocation strategy, which is `lowest-price` in this example. However, because the pools are the same price (because price is per Region and not per Availability Zone), the fleet launches the remaining 4 On-Demand Instances into either of the pools.

After the fleet is launched, you can run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "c5.xlarge",
    "AvailableInstanceCount": 0
}
```

```
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "c5.xlarge",
    "AvailableInstanceCount": 0
}
```

Example 7: Configure Capacity Rebalancing to launch replacement Spot Instances

The following example configures the EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation for a Spot Instance in the fleet. To configure the automatic replacement of Spot Instances, for `ReplacementStrategy`, specify `launch-before-terminate`. To configure the time delay from when the new replacement Spot Instances are launched to when the old Spot Instances are automatically deleted, for `termination-delay`, specify a value in seconds. For more information, see Configuration options.

Note

We recommend using `launch-before-terminate` only if you can predict how long your instance shutdown procedures will take to complete so that the old instances are only terminated after these procedures are completed. You are charged for all instances while they are running.

The effectiveness of the Capacity Rebalancing strategy depends on the number of Spot capacity pools specified in the EC2 Fleet request. We recommend that you configure the fleet with a diversified set of instance types and Availability Zones, and for `AllocationStrategy`, specify `capacity-optimized`. For more information about what you should consider when configuring an EC2 Fleet for Capacity Rebalancing, see Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances.

```
{
    "ExcessCapacityTerminationPolicy": "termination",
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "LaunchTemplate",
                "Version": "1"
```

```
            },
                 "Overrides": [
                       {
                           "InstanceType": "c3.large",
                           "WeightedCapacity": 1,
                            "Placement": {
                               "AvailabilityZone": "us-east-1a"
                           }
                       },
                       {
                           "InstanceType": "c4.large",
                           "WeightedCapacity": 1,
                            "Placement": {
                               "AvailabilityZone": "us-east-1a"
                           }
                       },
                       {
                           "InstanceType": "c5.large",
                           "WeightedCapacity": 1,
                            "Placement": {
                               "AvailabilityZone": "us-east-1a"
                           }
                       }
                ]
          }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 5,
        "DefaultTargetCapacityType": "spot"
    },
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "MaintenanceStrategies": {
            "CapacityRebalance": {
                "ReplacementStrategy": "launch-before-terminate",
                "TerminationDelay": "720"
            }
        }
    }
}
```

Example 8: Launch Spot Instances in a capacity-optimized fleet

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for capacity. To optimize for capacity, you must set `AllocationStrategy` to `capacity-optimized`.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
                 "Overrides": [
                       {
                           "InstanceType": "r4.2xlarge",
                           "Placement": {
                               "AvailabilityZone": "us-west-2a"
                           },
                      },
                       {
                           "InstanceType": "m4.2xlarge",
                           "Placement": {
                               "AvailabilityZone": "us-west-2b"
                           },
                       },
                       {
                           "InstanceType": "c5.2xlarge",
                           "Placement": {
                               "AvailabilityZone": "us-west-2b"
                           }
                       }
                 ]
           }
    ],
    "TargetCapacitySpecification": {
```

```
            "TotalTargetCapacity": 50,
            "DefaultTargetCapacityType": "spot"

    }
}
```

Example 9: Launch Spot Instances in a capacity-optimized fleet with priorities

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for capacity while using priority on a best-effort basis.

When using the `capacity-optimized-prioritized` allocation strategy, you can use the `Priority` parameter to specify the priorities of the Spot capacity pools, where the lower the number the higher priority. You can also set the same priority for several Spot capacity pools if you favor them equally. If you do not set a priority for a pool, the pool will be considered last in terms of priority.

To prioritize Spot capacity pools, you must set `AllocationStrategy` to `capacity-optimized-prioritized`. EC2 Fleet will optimize for capacity first, but will honor the priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect EC2 Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

In the following example, the three launch specifications specify three Spot capacity pools. Each pool is prioritized, where the lower the number the higher priority. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with the highest priority on a best-effort basis, but optimizes for capacity first.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized-prioritized"
        },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
             "Overrides": [
                    {
```

```
                            "InstanceType": "r4.2xlarge",
                            "Priority": 1,
                            "Placement": {
                                "AvailabilityZone": "us-west-2a"
                            },
                       },
                        {
                            "InstanceType": "m4.2xlarge",
                            "Priority": 2,
                            "Placement": {
                                "AvailabilityZone": "us-west-2b"
                            },
                        },
                        {
                            "InstanceType": "c5.2xlarge",
                            "Priority": 3,
                            "Placement": {
                                "AvailabilityZone": "us-west-2b"
                            }
                        }
                   ]
              }
    ],
    "TargetCapacitySpecification": {
            "TotalTargetCapacity": 50,
            "DefaultTargetCapacityType": "spot"
}
```

Example 10: Launch Spot Instances in a price-capacity-optimized fleet

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for both capacity and lowest price. To optimize for capacity while taking price into consideration, you must set the Spot `AllocationStrategy` to `price-capacity-optimized`.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching while also choosing the pool that is the lowest priced.

```
{
    "SpotOptions": {
        "AllocationStrategy": "price-capacity-optimized",
```

```
        "MinTargetCapacity": 2,
        "SingleInstanceType": true
    },
    "OnDemandOptions": {
        "AllocationStrategy": "lowest-price"
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
                 "Overrides": [
                       {
                           "InstanceType": "r4.2xlarge",
                           "Placement": {
                               "AvailabilityZone": "us-west-2a"
                           },
                      },
                       {
                           "InstanceType": "m4.2xlarge",
                           "Placement": {
                               "AvailabilityZone": "us-west-2b"
                           },
                       },
                       {
                           "InstanceType": "c5.2xlarge",
                           "Placement": {
                               "AvailabilityZone": "us-west-2b"
                           }
                       }
                 ]
           }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 50,
        "OnDemandTargetCapacity":0,
        "SpotTargetCapacity":50,
        "DefaultTargetCapacityType": "spot"
    },
    "Type": "instant"
}
```

Example 11: Configure attribute-based instance type selection

The following example demonstrates how to configure an EC2 Fleet to use attribute-based instance type selection for identifying instance types. To specify the required instance attributes, you specify the attributes in the `InstanceRequirements` structure.

In the following example, two instance attributes are specified:

- `VCpuCount` – A minimum of 2 vCPUs is specified. Because no maximum is specified, there is no maximum limit.
- `MemoryMiB` – A minimum of 4 MiB of memory is specified. Because no maximum is specified, there is no maximum limit.

Any instance types that have 2 or more vCPUs and 4 MiB or more of memory will be identified. However, price protection and the allocation strategy might exclude some instance types when EC2 Fleet provisions the fleet.

For a list and descriptions of all the possible attributes that you can specify, see InstanceRequirements in the *Amazon EC2 API Reference*.

```
{
 "SpotOptions": {
  "AllocationStrategy": "price-capacity-optimized"
 },
 "LaunchTemplateConfigs": [{
  "LaunchTemplateSpecification": {
   "LaunchTemplateName": "my-launch-template",
   "Version": "1"
  },
  "Overrides": [{
   "InstanceRequirements": {
    "VCpuCount": {
     "Min": 2
    },
    "MemoryMiB": {
     "Min": 4
    }
   }
  }]
 }],
 "TargetCapacitySpecification": {
```

```
    "TotalTargetCapacity": 20,
    "DefaultTargetCapacityType": "spot"
  },
  "Type": "instant"
}
```

Example CLI configurations Spot Fleet

You can define your Spot Fleet configuration in a JSON file, and then reference that file using the request-spot-fleet AWS CLI command to create your fleet, as follows:

```
aws ec2 request-spot-fleet --spot-fleet-request-config file://file_name.json
```

The following examples illustrate launch configurations for various Spot Fleet use cases. For more information about the configuration parameters, see request-spot-fleet. For more information about creating a Spot Fleet, see Create a Spot Fleet.

Note

For Spot Fleet, you can't specify a network interface ID in a launch template or launch specification. Make sure you omit the `NetworkInterfaceID` parameter in your launch template or launch specification.

Examples

- Example 1: Launch Spot Instances using the lowest-priced Availability Zone in the Region
- Example 2: Launch Spot Instances using the lowest-priced Availability Zone from a list
- Example 3: Launch Spot Instances using the lowest-priced instance type from a list
- Example 4. Override the price for the request
- Example 5: Launch a Spot Fleet using the diversified allocation strategy
- Example 6: Launch a Spot Fleet using instance weighting
- Example 7: Launch a Spot Fleet using On-Demand capacity
- Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances
- Example 9: Launch Spot Instances in a capacity-optimized fleet
- Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities

Example 1: Launch Spot Instances using the lowest-priced Availability Zone in the Region

The following example specifies a single launch specification without an Availability Zone or subnet. The Spot Fleet launches the instances in the lowest-priced Availability Zone that has a default subnet. The price you pay does not exceed the On-Demand price.

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "KeyName": "my-key-pair",
          "SecurityGroups": [
              {
                  "GroupId": "sg-1a2b3c4d"
              }
          ],
          "InstanceType": "m3.medium",
          "IamInstanceProfile": {
              "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
          }
      }
  ]
}
```

Example 2: Launch Spot Instances using the lowest-priced Availability Zone from a list

The following examples specify two launch specifications with different Availability Zones or subnets, but the same instance type and AMI.

Availability Zones

The Spot Fleet launches the instances in the default subnet of the lowest-priced Availability Zone that you specified.

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "KeyName": "my-key-pair",
          "SecurityGroups": [
              {
                  "GroupId": "sg-1a2b3c4d"
              }
          ],
          "InstanceType": "m3.medium",
          "Placement": {
              "AvailabilityZone": "us-west-2a, us-west-2b"
          },
          "IamInstanceProfile": {
              "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
          }
      }
  ]
}
```

Subnets

You can specify default subnets or nondefault subnets, and the nondefault subnets can be from a default VPC or a nondefault VPC. The Spot service launches the instances in whichever subnet is in the lowest-priced Availability Zone.

You can't specify different subnets from the same Availability Zone in a Spot Fleet request.

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "KeyName": "my-key-pair",
          "SecurityGroups": [
              {
                  "GroupId": "sg-1a2b3c4d"
              }
          ],
```

```
            "InstanceType": "m3.medium",
            "SubnetId": "subnet-a61dafcf, subnet-65ea5f08",
            "IamInstanceProfile": {
                "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
            }
        }
    ]
}
```

If the instances are launched in a default VPC, they receive a public IPv4 address by default. If the instances are launched in a nondefault VPC, they do not receive a public IPv4 address by default. Use a network interface in the launch specification to assign a public IPv4 address to instances launched in a nondefault VPC. When you specify a network interface, you must include the subnet ID and security group ID using the network interface.

```
    ...
        {
            "ImageId": "ami-1a2b3c4d",
            "KeyName": "my-key-pair",
            "InstanceType": "m3.medium",
            "NetworkInterfaces": [
                {
                    "DeviceIndex": 0,
                    "SubnetId": "subnet-1a2b3c4d",
                    "Groups": [ "sg-1a2b3c4d" ],
                    "AssociatePublicIpAddress": true
                }
            ],
            "IamInstanceProfile": {
                "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
            }
        }
    ...
```

Example 3: Launch Spot Instances using the lowest-priced instance type from a list

The following examples specify two launch configurations with different instance types, but the same AMI and Availability Zone or subnet. The Spot Fleet launches the instances using the specified instance type with the lowest price.

Availability Zone

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "SecurityGroups": [
              {
                  "GroupId": "sg-1a2b3c4d"
              }
          ],
          "InstanceType": "c5.4xlarge",
          "Placement": {
            "AvailabilityZone": "us-west-2b"
          }
      },
      {
          "ImageId": "ami-1a2b3c4d",
          "SecurityGroups": [
              {
                  "GroupId": "sg-1a2b3c4d"
              }
          ],
          "InstanceType": "r3.8xlarge",
          "Placement": {
              "AvailabilityZone": "us-west-2b"
          }
      }
  ]
}
```

Subnet

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "SecurityGroups": [
              {
```

```
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "InstanceType": "c5.4xlarge",
            "SubnetId": "subnet-1a2b3c4d"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "SecurityGroups": [
                {
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "InstanceType": "r3.8xlarge",
            "SubnetId": "subnet-1a2b3c4d"
        }
    ]
}
```

Example 4. Override the price for the request

We recommended that you use the default maximum price, which is the On-Demand price. If you prefer, you can specify a maximum price for the fleet request and maximum prices for individual launch specifications.

The following examples specify a maximum price for the fleet request and maximum prices for two of the three launch specifications. The maximum price for the fleet request is used for any launch specification that does not specify a maximum price. The Spot Fleet launches the instances using the instance type with the lowest price.

Availability Zone

```
{
  "SpotPrice": "1.00",
  "TargetCapacity": 30,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "c3.2xlarge",
          "Placement": {
              "AvailabilityZone": "us-west-2b"
```

```
            },
            "SpotPrice": "0.10"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "c3.4xlarge",
            "Placement": {
                "AvailabilityZone": "us-west-2b"
            },
            "SpotPrice": "0.20"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "c3.8xlarge",
            "Placement": {
                "AvailabilityZone": "us-west-2b"
            }
        }
      ]
}
```

Subnet

```
{
  "SpotPrice": "1.00",
  "TargetCapacity": 30,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "c3.2xlarge",
          "SubnetId": "subnet-1a2b3c4d",
          "SpotPrice": "0.10"
      },
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "c3.4xlarge",
          "SubnetId": "subnet-1a2b3c4d",
          "SpotPrice": "0.20"
      },
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "c3.8xlarge",
```

```
            "SubnetId": "subnet-1a2b3c4d"
        }
    ]
}
```

Example 5: Launch a Spot Fleet using the diversified allocation strategy

The following example uses the `diversified` allocation strategy. The launch specifications have different instance types but the same AMI and Availability Zone or subnet. The Spot Fleet distributes the 30 instances across the three launch specifications, such that there are 10 instances of each type. For more information, see [Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity](#).

Availability Zone

```
{
  "SpotPrice": "0.70",
  "TargetCapacity": 30,
  "AllocationStrategy": "diversified",
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "c4.2xlarge",
          "Placement": {
              "AvailabilityZone": "us-west-2b"
          }
      },
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "m3.2xlarge",
          "Placement": {
              "AvailabilityZone": "us-west-2b"
          }
      },
      {
          "ImageId": "ami-1a2b3c4d",
          "InstanceType": "r3.2xlarge",
          "Placement": {
              "AvailabilityZone": "us-west-2b"
          }
      }
```

```
  ]
}
```

Subnet

```
{
    "SpotPrice": "0.70",
    "TargetCapacity": 30,
    "AllocationStrategy": "diversified",
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "c4.2xlarge",
            "SubnetId": "subnet-1a2b3c4d"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "m3.2xlarge",
            "SubnetId": "subnet-1a2b3c4d"
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "r3.2xlarge",
            "SubnetId": "subnet-1a2b3c4d"
        }
    ]
}
```

A best practice to increase the chance that a spot request can be fulfilled by EC2 capacity in the event of an outage in one of the Availability Zones is to diversify across zones. For this scenario, include each Availability Zone available to you in the launch specification. And, instead of using the same subnet each time, use three unique subnets (each mapping to a different zone).

Availability Zone

```
{
  "SpotPrice": "0.70",
  "TargetCapacity": 30,
  "AllocationStrategy": "diversified",
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
```

```
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "c4.2xlarge",
            "Placement": {
                "AvailabilityZone": "us-west-2a"
            }
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "m3.2xlarge",
            "Placement": {
                "AvailabilityZone": "us-west-2b"
            }
        },
        {
            "ImageId": "ami-1a2b3c4d",

}
```

Example 6: Launch a Spot Fleet using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight. The Spot Fleet selects the instance type with the lowest price per unit hour. The Spot Fleet calculates the number of Spot Instances to launch by dividing the target capacity by the instance weight. If the result isn't an integer, the Spot Fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity.

If the `r3.2xlarge` request is successful, Spot provisions 4 of these instances. Divide 20 by 6 for a total of 3.33 instances, then round up to 4 instances.

If the `c3.xlarge` request is successful, Spot provisions 7 of these instances. Divide 20 by 3 for a total of 6.66 instances, then round up to 7 instances.

For more information, see Use instance weighting to manage cost and performance of your EC2 Fleet or Spot Fleet.

Availability Zone

```
{
  "SpotPrice": "0.70",
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [

          "SubnetId": "subnet-1a2b3c4d",
          "WeightedCapacity": 3
      }
  ]
}
```

Example 7: Launch a Spot Fleet using On-Demand capacity

To ensure that you always have instance capacity, you can include a request for On-Demand capacity in your Spot Fleet request. If there is capacity, the On-Demand request is always fulfilled. The balance of the target capacity is fulfilled as Spot if there is capacity and availability.

The following example specifies the desired target capacity as 10, of which 5 must be On-Demand capacity. Spot capacity is not specified; it is implied in the balance of the target capacity minus the On-Demand capacity. Amazon EC2 launches 5 capacity units as On-Demand, and 5 capacity units (10-5=5) as Spot if there is available Amazon EC2 capacity and availability.

```
{
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "AllocationStrategy": "lowestPrice",
  "TargetCapacity": 10,
  "SpotPrice": null,
  "ValidFrom": "2018-04-04T15:58:13Z",
  "ValidUntil": "2019-04-04T15:58:13Z",
  "TerminateInstancesWithExpiration": true,
  "LaunchSpecifications": [],
  "Type": "maintain",
  "OnDemandTargetCapacity": 5,
  "LaunchTemplateConfigs": [
    {

        "Version": "2"
      },
      "Overrides": [
        {
          "InstanceType": "t2.medium",
          "WeightedCapacity": 1,
          "SubnetId": "subnet-d0dc51fb"
        }
      ]
    }
  ]
}
```

Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances

The following example configures the Spot Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation for a Spot Instance in the fleet. To configure the automatic replacement of Spot Instances, for `ReplacementStrategy`, specify `launch-before-terminate`. To configure the time delay from the launch of the new replacement Spot Instances to the automatic deletion of the old Spot Instances, for `termination-delay`, specify a value in seconds. For more information, see Configuration options.

> **Note**
>
> We recommend using `launch-before-terminate` only if you can predict how long your instance shutdown procedures will take to complete. This ensures that the old instances are terminated only after the shutdown procedures are completed. You are charged for all instances while they are running.

The effectiveness of the Capacity Rebalancing strategy depends on the number of Spot capacity pools specified in the Spot Fleet request. We recommend that you configure the fleet with a diversified set of instance types and Availability Zones, and for `AllocationStrategy`, specify `capacityOptimized`. For more information about what you should consider when configuring a Spot Fleet for Capacity Rebalancing, see [Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances](#).

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "capacityOptimized",
        "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "LaunchTemplate",
                    "Version": "1"
                },
                 "Overrides": [
                       {
                           "InstanceType": "c3.large",
                           "WeightedCapacity": 1,
                           "Placement": {
                               "AvailabilityZone": "us-east-1a"
                           }
                       },
                       {
                           "InstanceType": "c4.large",
                           "WeightedCapacity": 1,
                           "Placement": {
                               "AvailabilityZone": "us-east-1a"
                           }
                       },
```

```
                        {
                            "InstanceType": "c5.large",
                            "WeightedCapacity": 1,
                            "Placement": {
                                "AvailabilityZone": "us-east-1a"
                            }
                        }
                 ]
          }
    ],
        "TargetCapacity": 5,
        "SpotMaintenanceStrategies": {
            "CapacityRebalance": {
                "ReplacementStrategy": "launch-before-terminate",
                "TerminationDelay": "720"
            }
        }
    }
}
```

Example 9: Launch Spot Instances in a capacity-optimized fleet

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for capacity. To optimize for capacity, you must set `AllocationStrategy` to `capacityOptimized`.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```
{
    "TargetCapacity": "50",
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "capacityOptimized",
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
            "Overrides": [
```

```
                {
                    "InstanceType": "r4.2xlarge",
                    "AvailabilityZone": "us-west-2a"
                },
                {
                    "InstanceType": "m4.2xlarge",
                    "AvailabilityZone": "us-west-2b"
                },
                {
                    "InstanceType": "c5.2xlarge",
                    "AvailabilityZone": "us-west-2b"
                }
            ]
        }
    ]
}
```

Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for capacity while using priority on a best-effort basis.

When using the `capacityOptimizedPrioritized` allocation strategy, you can use the `Priority` parameter to specify the priorities of the Spot capacity pools, where the lower the number the higher priority. You can also set the same priority for several Spot capacity pools if you favor them equally. If you do not set a priority for a pool, the pool will be considered last in terms of priority.

To prioritize Spot capacity pools, you must set `AllocationStrategy` to `capacityOptimizedPrioritized`. Spot Fleet will optimize for capacity first, but will honor the priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect Spot Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

In the following example, the three launch specifications specify three Spot capacity pools. Each pool is prioritized, where the lower the number the higher priority. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with the highest priority on a best-effort basis, but optimizes for capacity first.

```
{
```

```
    "TargetCapacity": "50",
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "capacityOptimizedPrioritized"
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "r4.2xlarge",
                   "Priority": 1,
                    "AvailabilityZone": "us-west-2a"
                },
                {
                           "InstanceType": "m4.2xlarge",
                           "Priority": 2,
                           "AvailabilityZone": "us-west-2b"
                },
                {
                           "InstanceType": "c5.2xlarge",
                           "Priority": 3,
                           "AvailabilityZone": "us-west-2b"
                }
            ]
        }
    ]
}
```

Example 11: Launch Spot Instances in a priceCapacityOptimized fleet

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for both capacity and lowest price. To optimize for capacity while taking price into consideration, you must set the Spot `AllocationStrategy` to `priceCapacityOptimized`.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching while also choosing the pool that is the lowest priced.

```
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "priceCapacityOptimized",
        "OnDemandAllocationStrategy": "lowestPrice",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::111111111111:role/aws-ec2-spot-fleet-tagging-
role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateId": "lt-0123456789example",
                    "Version": "1"
                },
                "Overrides": [
                     {
                           "InstanceType": "r4.2xlarge",
                           "AvailabilityZone": "us-west-2a"
                      },
                      {
                           "InstanceType": "m4.2xlarge",
                           "AvailabilityZone": "us-west-2b"
                      },
                      {
                           "InstanceType": "c5.2xlarge",
                           "AvailabilityZone": "us-west-2b"
                      }
                ]
            }
        ],
        "TargetCapacity": 50,
        "Type": "request"
    }
}
```

Example 12: Configure attribute-based instance type selection

The following example demonstrates how to configure a Spot Fleet to use attribute-based instance type selection for identifying instance types. To specify the required instance attributes, you specify the attributes in the `InstanceRequirements` structure.

In the following example, two instance attributes are specified:

- `VCpuCount` – A minimum of 2 vCPUs is specified. Because no maximum is specified, there is no maximum limit.
- `MemoryMiB` – A minimum of 4 MiB of memory is specified. Because no maximum is specified, there is no maximum limit.

Any instance types that have 2 or more vCPUs and 4 MiB or more of memory will be identified. However, price protection and the allocation strategy might exclude some instance types when Spot Fleet provisions the fleet.

For a list and descriptions of all the possible attributes that you can specify, see InstanceRequirements in the *Amazon EC2 API Reference*.

```
{
 "AllocationStrategy": "priceCapacityOptimized",
 "TargetCapacity": 20,
 "Type": "request",
 "LaunchTemplateConfigs": [{
  "LaunchTemplateSpecification": {
   "LaunchTemplateName": "my-launch-template",
   "Version": "1"
  },
  "Overrides": [{
   "InstanceRequirements": {
    "VCpuCount": {
     "Min": 2
    },
    "MemoryMiB": {
     "Min": 4
    }
   }
  }]
 }]
}
```

Quotas for EC2 Fleet and Spot Fleet

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Unless otherwise noted, each quota is Region-specific.

The usual Amazon EC2 quotas apply to instances launched by an EC2 Fleet or a Spot Fleet, such as Spot Instance limits and volume limits.

In addition, your AWS account has the following quotas related to EC2 Fleet and Spot Fleet:

Quota description	Quota
The number of EC2 Fleets and Spot Fleets per Region of type `maintain` and `request` in the `active`, `deleted_running` , and `cancelled_running` states	1,000 [1] [2] [3]
The number of EC2 Fleets of type `instant`	Unlimited
The number of Spot capacity pools (unique combination of instance type and subnet) for EC2 Fleets and Spot Fleets of type `maintain` and `request`	300 [1]
The number of Spot capacity pools (unique combination of instance type and subnet) for EC2 Fleets of type `instant`	Unlimited
The size of the user data in a launch specification	16 KB [2]
The target capacity per EC2 Fleet or Spot Fleet	10,000
The target capacity across all EC2 Fleets and Spot Fleets in a Region	100,000 [1]
An EC2 Fleet request or a Spot Fleet request can't span Regions.	
An EC2 Fleet request or a Spot Fleet request can't span different subnets from the same Availability Zone.	

[1] These quotas apply to both your EC2 Fleets and your Spot Fleets.

[2] These are hard quotas. You can't request an increase for these quotas.

[3] After you delete an EC2 Fleet or cancel a Spot Fleet request, and if you specified that the fleet should *not* terminate its Spot Instances when you deleted or canceled the request, the fleet request enters the `deleted_running` (EC2 Fleet) or `cancelled_running` (Spot Fleet) state and the instances continue to run until they are interrupted or you terminate them manually. If you terminate the instances, the fleet request enters the `deleted_terminating` (EC2 Fleet) or `cancelled_terminating` (Spot Fleet) state and does not count towards this quota. For more information, see Delete an EC2 Fleet request and the instances in the fleet and Cancel (delete) a Spot Fleet request.

Request a quota increase for target capacity

If you need more than the default quota for target capacity, you can request a quota increase.

To request a quota increase for target capacity

1. Open the Support Center Create case form.
2. Choose **Service limit increase**.
3. For **Limit type**, choose **EC2 Fleet**.
4. For **Region**, choose the AWS Region in which to request the quota increase.
5. For **Limit**, choose **Target Fleet Capacity per Fleet (in units)** or **Target Fleet Capacity per Region (in units)**, depending on which quota you want to increase.
6. For **New limit value**, enter the new quota value.
7. To request an increase for another quota, choose **Add another request**, and repeat Steps 4–6.
8. For **Use case description**, enter your reason for requesting a quota increase.
9. Under **Contact options**, specify your preferred contact language and contact method.
10. Choose **Submit**.

Networking in Amazon EC2

Amazon VPC enables you to launch AWS resources, such as Amazon EC2 instances, into a virtual network dedicated to your AWS account, known as a virtual private cloud (VPC). When you launch an instance, you can select a subnet from the VPC. The instance is configured with a primary network interface, which is a logical virtual network card. The instance receives a primary private IP address from the IPv4 address of the subnet, and it is assigned to the primary network interface.

You can control whether the instance receives a public IP address from Amazon's pool of public IP addresses. The public IP address of an instance is associated with your instance only until it is stopped or terminated. If you require a persistent public IP address, you can allocate an Elastic IP address for your AWS account and associate it with an instance or a network interface. An Elastic IP address remains associated with your AWS account until you release it, and you can move it from one instance to another as needed. You can bring your own IP address range to your AWS account, where it appears as an address pool, and then allocate Elastic IP addresses from your address pool.

To increase network performance and reduce latency, you can launch instances in a placement group. You can get significantly higher packet per second (PPS) performance using enhanced networking. You can accelerate high performance computing and machine learning applications using an Elastic Fabric Adapter (EFA), which is a network device that you can attach to a supported instance type.

Features

- Network maximum transmission unit (MTU) for your EC2 instance
- Virtual private clouds for your EC2 instances

Regions and Zones

Amazon EC2 is hosted in multiple locations world-wide. These locations are composed of AWS Regions, Availability Zones, Local Zones, AWS Outposts, and Wavelength Zones.

- **Regions** are separate geographic areas.
- **Availability Zones** are multiple, isolated locations within each Region.
- **Local Zones** provide you with the ability to place resources, such as compute and storage, in multiple locations closer to your end users.
- **Wavelength Zones** provide you with the ability to build applications that deliver ultra-low latencies to 5G devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks.
- **AWS Outposts** brings native AWS services, infrastructure, and operating models to virtually any data center, colocation space, or on-premises facility.

AWS operates state-of-the-art, highly available data centers. Although rare, failures can occur that affect the availability of instances that are in the same location. If you host all of your instances in a single location that is affected by a failure, none of your instances would be available.

For more information, see AWS Global Infrastructure.

Contents

Regions

Each Region is designed to be isolated from the other Regions. This achieves the greatest possible fault tolerance and stability.

When you launch an instance, select a Region that puts your instances close to specific customers, or that meets the legal or other requirements that you have. You can launch instances in multiple Regions.

When you view your resources, you see only the resources that are tied to the Region that you specified. This is because Regions are isolated from each other, and we don't automatically replicate resources across Regions.

Available Regions

For the list of available Regions, see AWS Regions.

Regional endpoints for Amazon EC2

When you work with an instance using the command line interface or API actions, you must specify its Regional endpoint. For more information about the Regions and endpoints for Amazon EC2, see Amazon EC2 service endpoints in the *Amazon EC2 Developer Guide*.

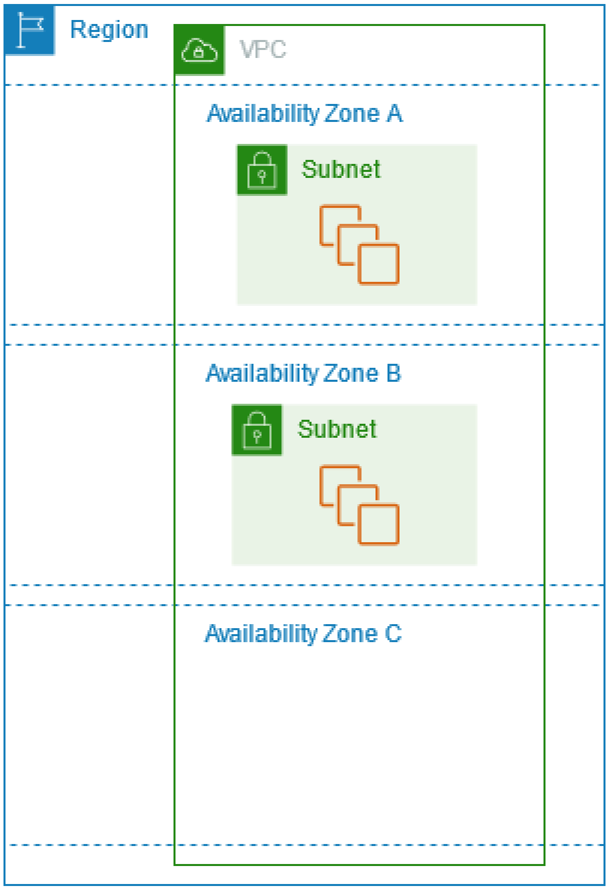
For more information, see AWS Regions in the *AWS Regions and Availability Zones User Guide*.

Availability Zones

Each Region has multiple, isolated locations known as *Availability Zones*. The code for an Availability Zone is its Region code followed by a letter identifier. For example, `us-east-1a`.

By launching EC2 instances in multiple Availability Zones, you can protect your applications from the failure of a single location in the Region.

The following diagram illustrates multiple Availability Zones in an AWS Region. Availability Zone A and Availability Zone B each have one subnet, and each subnet has EC2 instances. Availability Zone C has no subnets, therefore you can't launch instances into this Availability Zone.



For more information, see Virtual private clouds for your EC2 instances.

Availability Zones by Region

For the list of Availability Zones by Region, see AWS Availability Zones.

Instances in Availability Zones

When you launch an instance, you select a Region and a virtual private cloud (VPC). Then, you can either select a subnet from one of the Availability Zones or let us choose a subnet for you. When you launch your initial instances, we recommend that you let us select an Availability Zone for you based on system health and available capacity. If you launch additional instances, specify an Availability Zone only if your new instances must be close to, or separated from, your existing instances.

If you distribute instances across multiple Availability Zones and an instance fails, you can design your application so that an instance in another Availability Zone handles requests instead.

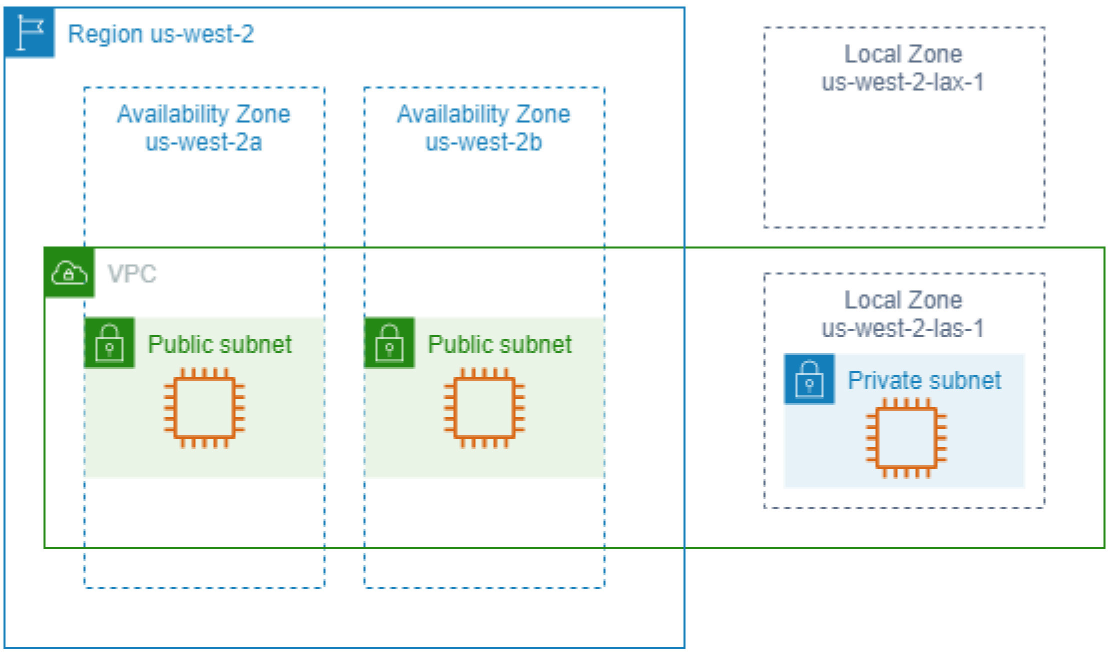
For more information, see AWS Availability Zones in the *AWS Regions and Availability Zones User Guide*.

Local Zones

A Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect, so that resources created in a Local Zone can serve local users with low-latency communications. For more information, see [What is AWS Local Zones?] in the *AWS Local Zones User Guide*.

The code for a Local Zone is its Region code followed by an identifier that indicates its physical location. For example, `us-west-2-lax-1` in Los Angeles.

The following diagram illustrates the AWS Region `us-west-2`, two of its Availability Zones, and two of its Local Zones. The VPC spans the Availability Zones and one of the Local Zones. Each zone in the VPC has one subnet, and each subnet has an instance.



Available Local Zones

For the list of available Local Zones, see [Available Local Zones] in the *AWS Local Zones User Guide*. For the list of announced Local Zones, see [AWS Local Zones locations].

Instances in Local Zones

To use a Local Zone, you must first enable it. Then, create a subnet in the Local Zone. You can specify the Local Zone subnet when you launch instances, which places it in the Local Zone subnet in the Local Zone.

When you launch an instance in a Local Zone, you also allocate an IP address from a network border group. A network border group is a unique set of Availability Zones, Local Zones, or Wavelength Zones from which AWS advertises IP addresses, for example, `us-west-2-lax-1a`. You can allocate the following IP addresses from a network border group:

- Amazon-provided Elastic IPv4 addresses
- Amazon-provided IPv6 VPC addresses (available only in the Los Angeles zones)

For more information about how to launch an instance in a Local Zone, see [Getting started with AWS Local Zones](#) in the *AWS Local Zones User Guide*.

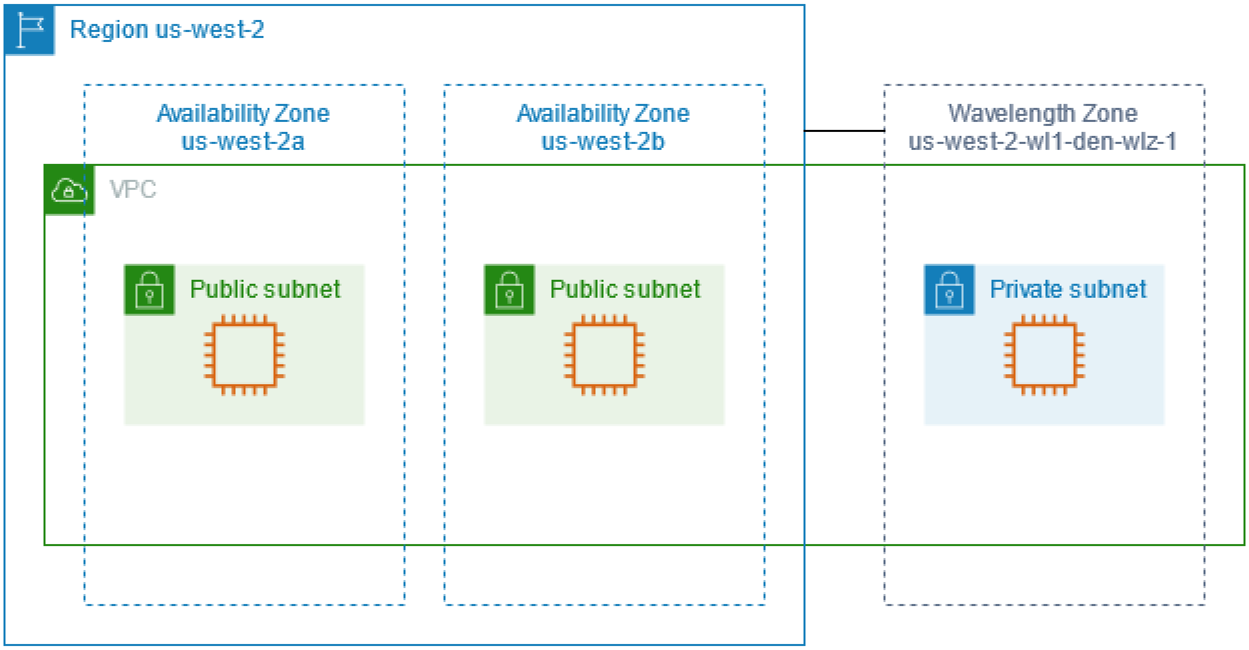
Wavelength Zones

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. Developers can extend a virtual private cloud (VPC) to one or more Wavelength Zones, and then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region.

A Wavelength Zone is an isolated zone in the carrier location where the Wavelength infrastructure is deployed. Wavelength Zones are tied to a Region. A Wavelength Zone is a logical extension of a Region, and is managed by the control plane in the Region.

The code for a Wavelength Zone is its Region code followed by an identifier that indicates the physical location. For example, `us-east-1-wl1-bos-wlz-1` in Boston.

The following diagram illustrates the AWS Region `us-west-2`, two of its Availability Zones, and a Wavelength Zone. The VPC spans the Availability Zones and the Wavelength Zone. Each zone in the VPC has one subnet, and each subnet has an instance.



Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see [Available Wavelength Zones](#) in the *AWS Wavelength Developer Guide*.

Available Wavelength Zones

For the list of available Wavelength Zones, see [Available Wavelength Zones](#) in the *AWS Wavelength Guide*.

Instances in Wavelength Zones

To use a Wavelength Zone, you must first opt in to the Zone. Then, create a subnet in the Wavelength Zone. You can specify the Wavelength subnet when you launch instances. You also allocate a carrier IP address from a network border group, which is a unique set of Availability Zones, Local Zones, or Wavelength Zones from which AWS advertises IP addresses, for example, `us-east-1-wl1-bos-wlz-1`.

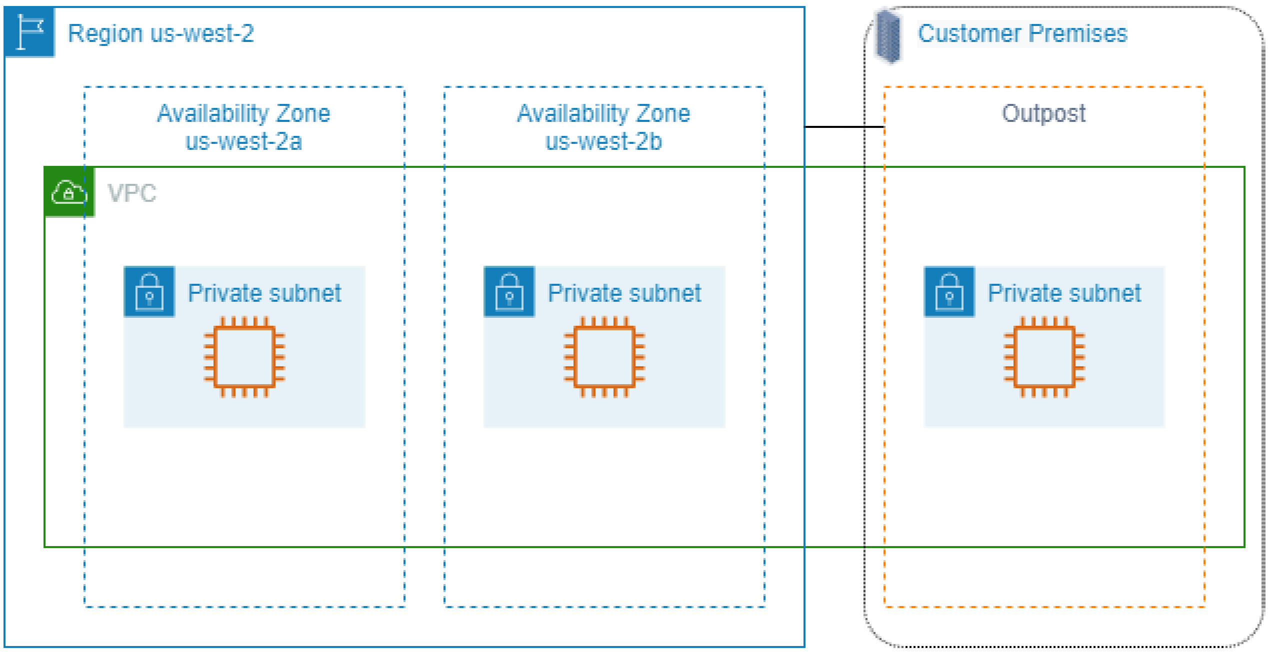
For step-by-step directions to launch an instance in a Wavelength Zone, see [Get started with AWS Wavelength](#) in the *AWS Wavelength Developer Guide*.

AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region. You can create subnets on your Outpost and specify them when you create AWS resources. Instances in Outpost subnets communicate with other instances in the AWS Region using private IP addresses, all within the same VPC.

The following diagram illustrates the AWS Region `us-west-2`, two of its Availability Zones, and an Outpost. The VPC spans the Availability Zones and the Outpost. The Outpost is in an on-premises customer data center. Each zone in the VPC has one subnet, and each subnet has an instance.



Instances on an Outpost

To begin using AWS Outposts, you must create an Outpost and order Outpost capacity. AWS Outposts offers two form factors, Outposts racks and Outposts servers. For more information about Outposts configurations, see [AWS Outposts Family](). After your Outpost equipment is installed, the compute and storage capacity is available for you when you launch EC2 instances on your Outpost.

To launch EC2 instances, you must create an Outpost subnet. Security groups control inbound and outbound traffic for instances in an Outpost subnet, just as they do for instances in an Availability Zone subnet. To connect to instances in Outpost subnets using SSH, specify a key pair when you launch them, just as you do for instances in Availability Zone subnets.

For more information, see Get started with Outposts racks or Get started with Outposts servers.

Volumes on an Outposts rack

If your Outposts compute capacity is on an Outpost rack, you can create EBS volumes in the Outpost subnet that you created. When you create the volume, specify the Amazon Resource Name (ARN) of the Outpost.

The following create-volume command creates an empty 50 GB volume on the specified Outpost.

```
aws ec2 create-volume --availability-zone us-east-2a --outpost-arn arn:aws:outposts:us-east-2:123456789012:outpost/op-03e6fecad652a6138 --size 50
```

You can dynamically modify the size of your Amazon EBS gp2 volumes without detaching them. For more information about modifying a volume without detaching it, see Request modifications to your EBS volumes in the *Amazon EBS User Guide*.

We recommend that you limit the root volume for an instance on an Outpost rack to 30 GiB or smaller. You can specify data volumes in the block device mapping of the AMI or the instance to provide additional storage. To trim unused blocks from the boot volume, see How to Build Sparse EBS Volumes in the *AWS Partner Network Blog*.

We recommend that you increase the NVMe timeout for the root volume. For more information, see I/O operation timeout in the *Amazon EBS User Guide*.

Volumes on an Outposts server

Instances on Outposts servers provide instance store volumes but do not support EBS volumes. Choose an Amazon EBS-backed AMI with only a single EBS snapshot. Choose an instance size with enough instance storage to meet the needs of your application. For more information, see Instance store volume limits.

Amazon EC2 instance IP addressing

Amazon EC2 and Amazon VPC support both the IPv4 and IPv6 addressing protocols. By default, Amazon VPC uses the IPv4 addressing protocol; you can't disable this behavior. When you create a VPC, you must specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and assign IPv6 addresses from that block to instances in your subnets.

When you launch an EC2 instance, you specify a VPC and a subnet. The instance receives a private IPv4 address from the CIDR range of the subnet. You can optionally configure your instances with public IPv4 addresses and IPv6 addresses. If EC2 instances in different VPCs communicate using public IP addresses, the traffic stays in the AWS private global network and does not traverse the public internet.

Contents

Private IPv4 addresses

A private IPv4 address is an IP address that's not reachable over the Internet. You can use private IPv4 addresses for communication between instances in the same VPC. For more information about the standards and specifications of private IPv4 addresses, see RFC 1918. We allocate private IPv4 addresses to instances using DHCP.

> **Note**
>
> You can create a VPC with a publicly routable CIDR block that falls outside of the private IPv4 address ranges specified in RFC 1918. However, for the purposes of this documentation, we refer to private IPv4 addresses (or 'private IP addresses') as the IP addresses that are within the IPv4 CIDR range of your VPC.

VPC subnets can be one of the following types:

- IPv4-only subnets – You can only create resources in these subnets with IPv4 addresses assigned to them.
- IPv6-only subnets – You can only create resources in these subnets with IPv6 addresses assigned to them.
- IPv4 and IPv6 subnets – You can create resources in these subnets with either IPv4 or IPv6 addresses assigned to them.

When you launch an EC2 instance into an IPv4-only or dual stack (IPv4 and IPv6) subnet, the instance receives a primary private IP address from the IPv4 address range of the subnet. For more information, see IP addressing in the *Amazon VPC User Guide*. If you don't specify a primary private IP address when you launch the instance, we select an available IP address in the subnet's IPv4 range for you. Each instance has a default network interface (index 0) that is assigned the primary private IPv4 address. You can also specify additional private IPv4 addresses, known as *secondary private IPv4 addresses*. Unlike primary private IP addresses, secondary private IP addresses can be reassigned from one instance to another. For more information, see Multiple IP addresses.

A private IPv4 address, regardless of whether it is a primary or secondary address, remains associated with the network interface when the instance is stopped and started, or hibernated and started, and is released when the instance is terminated.

Public IPv4 addresses

A public IP address is an IPv4 address that's reachable from the Internet. You can use public addresses for communication between your instances and the Internet.

When you launch an instance in a default VPC, we assign it a public IP address by default. When you launch an instance into a nondefault VPC, the subnet has an attribute that determines whether instances launched into that subnet receive a public IP address from the public IPv4 address pool. By default, we don't assign a public IP address to instances launched in a nondefault subnet.

You can control whether your instance receives a public IP address as follows:

- **Modify the public IP addressing attribute of your subnet.** For more information, see Modify the public IPv4 addressing attribute for your subnet in the *Amazon VPC User Guide*.
- **Enable or disable the public IP addressing feature during launch.** This overrides the subnet's public IP addressing attribute. For more information, see Assign a public IPv4 address at launch.
- **Unassign a public IP address from your instance after launch.** For more information, see the section called “Manage IP addresses”.

A public IP address is assigned to your instance from Amazon's pool of public IPv4 addresses, and is not associated with your AWS account. When a public IP address is disassociated from your instance, it is released back into the public IPv4 address pool, and you cannot reuse it.

We release the public IP address from your instance and assign a new one in the following cases:

- We release the public IP address when the instance is stopped, hibernated, or terminated. We assign a new public IP address when you start your stopped or hibernated instance.
- We release the public IP address when you associate an Elastic IP address with the instance. We assign a new public IP address when you disassociate the Elastic IP address from your instance.
- If we release the public IP address of your instance and it has a secondary network interface, we do not assign a new public IP address.
- If we release the public IP address of your instance and it has a secondary private IP address that is associated with an Elastic IP address, we do not assign a new public IP address.

If you require a persistent public IP address that can be associated to and from instances as you require, use an Elastic IP address instead.

If you use dynamic DNS to map an existing DNS name to a new instance's public IP address, it might take up to 24 hours for the IP address to propagate through the Internet. As a result, new instances might not receive traffic while terminated instances continue to receive requests. To solve this problem, use an Elastic IP address. You can allocate your own Elastic IP address, and associate it with your instance. For more information, see Elastic IP addresses.

If you are using Amazon VPC IP Address Manager (IPAM), you can get a contiguous block of public IPv4 addresses from AWS and use it to allocate Elastic IP addresses to AWS resources. Using contiguous IPv4 address blocks can significantly reduce management overhead for security access control lists and simplify IP address allocation and tracking for enterprises scaling on AWS. For more information, see Allocate sequential Elastic IP addresses from an IPAM pool in the *Amazon VPC IPAM User Guide*.

Considerations

- AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the **Public IPv4 Address** tab on the Amazon VPC pricing page.
- Instances that access other instances through their public NAT IP address are charged for regional or Internet data transfer, depending on whether the instances are in the same Region.

Public IPv4 address optimization

AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the **Public IPv4 Address** tab on the Amazon VPC pricing page.

The following list contains actions you can take to optimize the number of public IPv4 addresses you use:

- Use an elastic load balancer to load balance traffic to your EC2 instances and disable **Auto-assign public IP** on the primary ENI assigned to the instances. Load balancers use a single public IPv4 address, so this reduces your public IPv4 address count. You may also want consolidate existing load balancers to further reduce the public IPv4 address count.
- If the only reason for using a NAT gateway is to SSH into an EC2 instance in a private subnet for maintenance or emergencies, consider using EC2 Instance Connect Endpoint instead. With EC2 Instance Connect Endpoint, you can connect to an instance from the internet without requiring the instance to have a public IPv4 address.
- If your EC2 instances are in a public subnet with public IP addresses allocated to them, consider moving the instances to a private subnet, removing the public IP addresses, and using a public NAT gateway to allow access to and from your EC2 instances. There are cost considerations for using NAT gateways. Use this calculation method to decide if NAT gateways are cost effective. You can get the `Number of public IPv4 addresses` required for this calculation by creating an AWS Billing Cost and Usage Report.

  ```
  NAT gateway per hour + NAT gateway public IPs + NAT gateway transfer / Existing
   public IP cost
  ```

  Where:

  - `NAT gateway per hour = $0.045 * 730 hours in a month * Number of Availability Zones the NAT gateways are in`
  - `NAT gateway public IPs = $0.005 * 730 hours in a month * Number of IPs associated with your NAT gateways`
  - `NAT gateway transfer = $0.045 * Number of GBs that will go through the NAT gateway in a month`
  - `Existing public IP cost = $0.005 * 730 hours in a month * Number of public IPv4 addresses`

If the total is less than 1, NAT gateways are cheaper than public IPv4 addresses.

- Use AWS PrivateLink to connect privately to AWS services or services hosted by other AWS accounts rather than using public IPv4 addresses and internet gateways.
- Bring your own IP address range (BYOIP) to AWS and use the range for public IPv4 addresses rather than using Amazon-owned public IPv4 addresses.
- Turn off auto-assign public IPv4 address for instances launched into subnets. This option is generally disabled by default for VPCs when you create a subnet, but you should check your existing subnets to ensure it's disabled.
- If you have EC2 instances that do not need public IPv4 addresses, check that the network interfaces attached to your instances have **Auto-assign public IP** disabled.
- Configure accelerator endpoints in AWS Global Accelerator for EC2 instances in private subnets to enable internet traffic to flow directly to the endpoints in your VPCs without requiring public IP addresses. You can also bring your own addresses to AWS Global Accelerator and use your own IPv4 addresses for your accelerator's static IP addresses.

IPv6 addresses

IPv6 addresses are globally unique and can be configured to remain private or reachable over the Internet. Both public and private IPv6 addressing is available in AWS:

- **Private IPv6**: AWS considers private IPv6 addresses those that are not advertised and cannot be advertised on the Internet from AWS.
- **Public IPv6**: AWS considers public IPv6 addresses those that are advertised on the Internet from AWS.

For more information about public and private IPv6 addresses, see IPv6 addresses in the *Amazon VPC User Guide*.

All instance types support IPv6 addresses except for the following: C1, M1, M2, M3, and T1.

Your EC2 instances receive an IPv6 address if an IPv6 CIDR block is associated with your VPC and subnet, and if one of the following is true:

- Your subnet is configured to automatically assign an IPv6 address to an instance during launch. For more information, see Modify the IP addressing attributes of your subnet.

- You assign an IPv6 address to your instance during launch.
- You assign an IPv6 address to the primary network interface of your instance after launch.
- You assign an IPv6 address to a network interface in the same subnet, and attach the network interface to your instance after launch.

When your instance receives an IPv6 address during launch, the address is associated with the primary network interface (index 0) of the instance. You can manage the IPv6 addresses for your instances primary network interface as follows:

- Assign and unassign IPv6 addresses from the network interface. The number of IPv6 addresses you can assign to a network interface and the number of network interfaces you can attach to an instance varies per instance type. For more information, see Maximum IP addresses per network interface.
- Enable a primary IPv6 address. A primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. For more information, see Create a network interface for your EC2 instance or Manage the IP addresses for your network interface.

An IPv6 address persists when you stop and start, or hibernate and start, your instance, and is released when you terminate your instance. You cannot reassign an IPv6 address while it's assigned to another network interface—you must first unassign it.

You can control whether instances are reachable via their IPv6 addresses by controlling the routing for your subnet or by using security group and network ACL rules. For more information, see Internetwork traffic privacy in the *Amazon VPC User Guide*.

For more information about reserved IPv6 address ranges, see IANA IPv6 Special-Purpose Address Registry and RFC4291.

Multiple IP addresses

You can specify multiple private IPv4 and IPv6 addresses for your instances. The number of network interfaces and private IPv4 and IPv6 addresses that you can specify for an instance depends on the instance type. For more information, see Maximum IP addresses per network interface.

Use cases

- Host multiple websites on a single server by using multiple SSL certificates on a single server and associating each certificate with a specific IP address.
- Operate network appliances, such as firewalls or load balancers, that have multiple IP addresses for each network interface.
- Redirect internal traffic to a standby instance in case your instance fails, by reassigning the secondary IP address to the standby instance.

How multiple IP addresses work

- You can assign a secondary private IPv4 address to any network interface.
- You can assign multiple IPv6 addresses to a network interface that's in a subnet that has an associated IPv6 CIDR block.
- You must choose a secondary IPv4 address from the IPv4 CIDR block range of the subnet for the network interface.
- You must choose IPv6 addresses from the IPv6 CIDR block range of the subnet for the network interface.
- You associate security groups with network interfaces, not individual IP addresses. Therefore, each IP address you specify in a network interface is subject to the security group of its network interface.
- Multiple IP addresses can be assigned and unassigned to network interfaces attached to running or stopped instances.
- Secondary private IPv4 addresses that are assigned to a network interface can be reassigned to another one if you explicitly allow it.
- An IPv6 address cannot be reassigned to another network interface; you must first unassign the IPv6 address from the existing network interface.
- When assigning multiple IP addresses to a network interface using the command line tools or API, the entire operation fails if one of the IP addresses can't be assigned.
- Primary private IPv4 addresses, secondary private IPv4 addresses, Elastic IP addresses, and IPv6 addresses remain with a secondary network interface when it is detached from an instance or attached to an instance.
- Although you can't detach the primary network interface from an instance, you can reassign the secondary private IPv4 address of the primary network interface to another network interface.

For more information, see the section called “Secondary IP addresses”.

EC2 instance hostnames

When you create an EC2 instance, AWS creates a hostname for that instance. For more information on the types of hostnames and how they're provisioned by AWS, see EC2 instance hostnames and domains. Amazon provides a DNS server that resolves Amazon-provided hostnames to IPv4 and IPv6 addresses. The Amazon DNS server is located at the base of your VPC network range plus two. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.

Link-local addresses

Link-local addresses are well-known, non-routable IP addresses. Amazon EC2 uses addresses from the link-local address space to provide services that are accessible only from an EC2 instance. These services do not run on the instance, they run on the underlying host. When you access the link-local addresses for these services, you're communicating with either the Xen hypervisor or the Nitro controller.

Link-local address ranges

- IPv4 – 169.254.0.0/16 (169.254.0.0 to 169.254.255.255)
- IPv6 – fe80::/10

Services that you access using link-local addresses

- Instance Metadata Service
- Amazon Route 53 Resolver (also known as the Amazon DNS server)
- Amazon Time Sync Service
- AWS KMS servers

Manage the IPv4 addresses for your EC2 instances

You can assign a public IPv4 address to your instance when you launch it. You can view the IPv4 addresses for your instance in the console through either the **Instances** page or the **Network Interfaces** page.

Tasks

- Assign a public IPv4 address at launch

- Assign a private IPv4 address at launch
- View the primary IPv4 address
- View the IPv4 addresses using instance metadata

Assign a public IPv4 address at launch

Each subnet has an attribute that determines whether instances launched into that subnet are assigned a public IP address. By default, nondefault subnets have this attribute set to false, and default subnets have this attribute set to true. When you launch an instance, a public IPv4 addressing feature is also available for you to control whether your instance is assigned a public IPv4 address; you can override the default behavior of the subnet's IP addressing attribute. The public IPv4 address is assigned from Amazon's pool of public IPv4 addresses, and is assigned to the network interface with the device index of 0. This feature depends on certain conditions at the time you launch your instance.

Considerations

- You can unassign the public IP address from your instance after launch by managing the IP addresses associated with a network interface. For more information about public IPv4 addresses, see Public IPv4 addresses.
- You can't auto-assign a public IP address if you specify more than one network interface. Additionally, you cannot override the subnet setting using the auto-assign public IP feature if you specify an existing network interface for device index 0.
- Whether you assign a public IP address to your instance during launch or not, you can associate an Elastic IP address with your instance after it's launched. For more information, see Elastic IP addresses. You can also modify your subnet's public IPv4 addressing behavior. For more information, see Modify the public IPv4 addressing attribute for your subnet.

Console

To assign a public IPv4 address at launch

Follow the procedure to launch an instance, and when you configure Network Settings, choose the option to **Auto-assign Public IP**.

AWS CLI

To assign a public IPv4 address at launch

Use the run-instances command with the `--associate-public-ip-address` option.

```
--associate-public-ip-address
```

PowerShell

To assign a public IPv4 address at launch

Use the New-EC2Instance cmdlet with the `-AssociatePublicIp` parameter.

```
-AssociatePublicIp $true
```

Assign a private IPv4 address at launch

You can specify a private IPv4 address from the IPv4 address range of the subnet, or let Amazon EC2 chose one for you. This address is assigned to the primary network interface.

To assign IPv4 addresses after launch, see the section called “Assign secondary IP addresses to an instance”.

Console

To assign a private IPv4 address at launch

Follow the procedure to launch an instance. When you configure Network Settings, expand **Advanced network configuration** and enter a value for **Primary IP**.

AWS CLI

To assign a private IPv4 address at launch

Use the run-instances command with the `--private-ip-address` option.

```
--private-ip-addresses 10.251.50.12
```

To let Amazon EC2 choose the IP address, omit this option.

PowerShell

To assign a private IPv4 address at launch

Use the New-EC2Instance cmdlet with the `-PrivateIpAddress` parameter.

```
-PrivateIpAddress 10.251.50.12
```

To let Amazon EC2 choose the IP address, omit this parameter.

View the primary IPv4 address

The public IPv4 address is displayed as a property of the network interface in the console, but it's mapped to the primary private IPv4 address through NAT. Therefore, if you inspect the properties of your network interface on your instance, for example, through `ifconfig` (Linux) or `ipconfig` (Windows), the public IPv4 address is not displayed.

Console

To view the IPv4 addresses for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Networking** tab, find **Public IPv4 address** and **Private IPv4 addresses**.
5. (Optional) The **Networking** tab also contains the network interfaces and Elastic IP addresses for the instance.

AWS CLI

To view the primary IPv4 address for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[].Instances[].PrivateIpAddress" \
    --output text
```

The following is example output.

```
10.251.50.12
```

PowerShell

To view the primary IPv4 address for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances.PrivateIpAddress
```

The following is example output.

```
10.251.50.12
```

View the IPv4 addresses using instance metadata

You can get the IPv4 addresses for your instance by retrieving instance metadata. For more information, see Use instance metadata to manage your EC2 instance.

To view the IPv4 addresses using instance metadata

1. Connect to your instance. For more information, see Connect to your EC2 instance.
2. Run one of the following commands.

   IMDSv2

   Linux

   Run the following command from your Linux instance.

   ```
   TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-
   metadata-token-ttl-seconds: 21600"` \
   && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/
   meta-data/local-ipv4
   ```

   Windows

   Run the following command from your Windows instance.

   ```
   [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-
   seconds" = "21600"} `
   ```

```
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/local-ipv4
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/local-ipv4
```

Windows

Run the following command from your Windows instance.

```
Invoke-RestMethod http://169.254.169.254/latest/meta-data/local-ipv4
```

3. Use one of the following commands to access the public IP address. If there is an Elastic IP address associated with the instance, the command returns the Elastic IP address.

IMDSv2

Linux

Run the following command from your Linux instance.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H
 "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/
meta-data/public-ipv4
```

Windows

Run the following command from your Windows instance.

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-
seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/public-ipv4
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/public-ipv4
```

Windows

Run the following command from your Windows instance.

```
Invoke-RestMethod http://169.254.169.254/latest/meta-data/public-ipv4
```

Manage the IPv6 addresses for your EC2 instances

If your VPC and subnet have IPv6 CIDR blocks associated with them, you can assign an IPv6 address to your instance during or after launch. You can access the IPv6 addresses for your instances in the console on either the **Instances** page or the **Network Interfaces** page. The following tasks configure IP addresses for your instances. To configure IP addresses for your network interfaces instead, see the section called "Manage IP addresses".

Tasks

Assign an IPv6 address to an instance

You can specify an IPv6 address from the IPv6 address range of the subnet, or let Amazon EC2 choose one for you. This address is assigned to the primary network interface. Note that the following instance types do not support IPv6 addresses: C1, M1, M2, M3, and T1.

Console

To assign an IPv6 address at launch

Follow the procedure to launch an instance. When you configure Network Settings, choose the option to **Auto-assign IPv6 IP**. If you don't see this option, the selected subnet does not have an associated IPv6 CIDR block.

To assign an IPv6 address after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and choose **Actions**, **Networking**, **Manage IP addresses**.
4. Expand the network interface. Under **IPv6 addresses**, choose **Assign new IP address**.
5. Enter an IPv6 address from the range of the subnet, or leave the field blank to let Amazon EC2 choose the IPv6 address for you. If you don't see this option, the instance subnet does not have an associated IPv6 CIDR block.
6. Choose **Save**.

AWS CLI

To assign an IPv6 address at launch

Use the run-instances command with the `--ipv6-addresses` option. The following example assigns two IPv6 addresses.

```
--ipv6-addresses Ipv6Address=2001:db8::1234:5678:1.2.3.4
 Ipv6Address=2001:db8::1234:5678:5.6.7.8
```

To let Amazon EC2 choose the IPv6 addresses, use the `--ipv6-address-count` option instead. The following example assigns two IPv6 addresses.

```
--ipv6-address-count 2
```

To assign an IPv6 address after launch

Use the assign-ipv6-addresses command. The following example assigns two IPv6 addresses.

```
aws ec2 assign-ipv6-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --ipv6-addresses 2001:db8::1234:5678:1.2.3.4 2001:db8::1234:5678:5.6.7.8
```

To let Amazon EC2 choose the IPv6 addresses, use the `--ipv6-address-count` option instead. The following example assigns two IPv6 addresses.

```
aws ec2 assign-ipv6-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --ipv6-address-count 2
```

PowerShell

To assign an IPv6 address at launch

Use the New-EC2Instance cmdlet with the `-Ipv6Address` parameter. The following example assigns two IPv6 addresses.

```
-Ipv6Address $ipv6addr1,$ipv6addr2
```

Define the IPv6 addresses as follows.

```
$ipv6addr1 = New-Object Amazon.EC2.Model.InstanceIpv6Address
$ipv6addr1.Ipv6Address = "2001:db8::1234:5678:1.2.3.4"
$ipv6addr2 = New-Object Amazon.EC2.Model.InstanceIpv6Address
$ipv6addr2.Ipv6Address = "2001:db8::1234:5678:5.6.7.8"
```

To let Amazon EC2 choose the IPv6 addresses, use the `-Ipv6AddressCount` parameter instead. The following example assigns two IPv6 addresses.

```
-Ipv6AddressCount 2
```

To assign an IPv6 address after launch

Use the Register-EC2Ipv6AddressList cmdlet. The following example assigns two IPv6 addresses.

```
Register-EC2Ipv6AddressList `
```

```
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Ipv6Address "2001:db8::1234:5678:1.2.3.4","2001:db8::1234:5678:5.6.7.8"
```

To let Amazon EC2 choose the IPv6 addresses, use the `-Ipv6AddressCount` parameter instead. The following example assigns two IPv6 addresses.

```
Register-EC2Ipv6AddressList `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Ipv6AddressCount 2
```

View the IPv6 addresses for an instance

You can view the IPv6 addresses for your instances.

Console

To view the IPv6 addresses for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Networking** tab, locate **IPv6 addresses**.

AWS CLI

To view the IPv6 address for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[*].Instances[].Ipv6Address" \
    --output text
```

The following is example output.

```
2001:db8::1234:5678:1.2.3.4
```

PowerShell

To view the IPv6 address for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances.Ipv6Address
```

The following is example output.

```
2001:db8::1234:5678:1.2.3.4
```

View IPv6 addresses using instance metadata

After you connect to your instance, you can retrieve the IPv6 addresses using instance metadata. First, you must get the MAC address of the instance from `http://169.254.169.254/latest/meta-data/network/interfaces/macs/`.

IMDSv2

Linux

Run the following command from your Linux instance.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/network/interfaces/macs/mac-address/ipv6s
```

Windows

Run the following cmdlets from your Windows instance.

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} `
```

```
    -Method GET -Uri http://169.254.169.254/latest/meta-data/network/interfaces/
macs/mac-address/ipv6s
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/network/interfaces/macs/mac-address/
ipv6s
```

Windows

Run the following cmdlet from your Windows instance.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/network/interfaces/
macs/mac-address/ipv6s
```

Unassign an IPv6 address from an instance

You can unassign an IPv6 address from an instance at any time.

Console

To unassign an IPv6 address from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and choose **Actions**, **Networking**, **Manage IP addresses**.
4. Expand the network interface. Under **IPv6 addresses**, choose **Unassign** next to the IPv6 address.
5. Choose **Save**.

AWS CLI

To unassign an IPv6 address from an instance

Use the unassign-ipv6-addresses command.

```
aws ec2 unassign-ipv6-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --ipv6-addresses 2001:db8::1234:5678:1.2.3.4
```

PowerShell

To unassign an IPv6 address from an instance

Use the Unregister-EC2Ipv6AddressList cmdlet.

```
Unregister-EC2Ipv6AddressList `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Ipv6Address 2001:db8::1234:5678:1.2.3.4
```

Secondary IP addresses for your EC2 instances

The first IPv4 address assigned to a network interface is known as the primary IP address. Secondary IP addresses are additional IPv4 address assigned to a network interface. For more information, see the section called "Multiple IP addresses".

You can also assign multiple IPv6 addresses to an instance. For more information, see the section called "IPv6 addresses".

Tasks

Assign secondary IP addresses to an instance

You can assign secondary IP addresses to the network interface for an instance as you launch the instance, or after the instance is running.

Console

To assign a secondary IP address at launch

1. Follow the procedure to launch an instance. When you configure Network Settings, expand **Advanced network configuration**.

2. For **Secondary IP**, choose **Automatically assign** and enter the number of IP addresses for Amazon EC2 to assign. Alternatively, choose **Manually assign** and enter the IPv4 addresses.
3. Complete the remaining steps to launch the instance.

To assign a secondary IP address after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and choose **Actions**, **Networking**, **Manage IP addresses**.
4. Expand the network interface.
5. To add an IPv4 address, under **IPv4 addresses**, choose **Assign new IP address**. Enter an IPv4 address from the range of the subnet, or leave the field blank to let Amazon EC2 choose one for you.
6. Choose **Save**.

AWS CLI

To assign a secondary IP address at launch

Use the run-instances command with the `--secondary-private-ip-addresses` option.

```
--secondary-private-ip-addresses 10.251.50.12
```

To let Amazon EC2 choose the IP address, use the `--secondary-private-ip-address-count` option instead. The following example assigns one secondary IP address.

```
--secondary-private-ip-address-count 1
```

Alternatively, you can create a network interface. For more information, see the section called "Create a network interface".

To assign a secondary IP address after launch

Use the assign-private-ip-addresses command with the `--private-ip-addresses` option.

```
aws ec2 assign-private-ip-addresses \
    --network-interface-ids eni-1234567890abcdef0 \
```

```
    --private-ip-addresses 10.251.50.12
```

To let Amazon EC2 choose the IPv4 address, use the `--secondary-private-ip-address-count` parameter instead. The following example assigns one IPv4 address.

```
aws ec2 assign-private-ip-addresses \
    --network-interface-ids eni-1234567890abcdef0 \
    --secondary-private-ip-address-count 1
```

PowerShell

To assign a secondary IP address at launch

You must create a network interface. For more information, see the section called "Create a network interface".

To assign a secondary IP address after launch

Use the Register-EC2PrivateIpAddress cmdlet with the `-PrivateIpAddress` parameter.

```
Register-EC2PrivateIpAddress `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -PrivateIpAddress 10.251.50.12
```

To let Amazon EC2 choose the IPv4 addresses, use the `-SecondaryPrivateIpAddressCount` parameter instead. The following example assigns one IPv4 address.

```
Register-EC2PrivateIpAddress `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -SecondaryPrivateIpAddressCount 1
```

Configure the operating system to use secondary IP addresses

After you assign a secondary IP address to your instance, you must configure the operating system on your instance to recognize the additional private IPv4 address.

Linux instances

- If you are using Amazon Linux, the ec2-net-utils package can take care of this step for you. It configures additional network interfaces that you attach while the instance is running, refreshes secondary IPv4 addresses during DHCP lease renewal, and updates the related routing rules. You can immediately refresh the list of interfaces by using one of the following commands, depending on your system: `sudo systemctl restart systemd-networkd` (AL2023) or `sudo service network restart` (Amazon Linux 2). You can view the up-to-date list using the following command: `ip addr li`. If you require manual control over your network configuration, you can remove the ec2-net-utils package. For more information, see Configure your network interface using ec2-net-utils.

- If you are using another Linux distribution, see the documentation for your Linux distribution. Search for information about configuring additional network interfaces and secondary IPv4 addresses. If the instance has two or more interfaces on the same subnet, search for information about using routing rules to work around asymmetric routing.

Windows instances

For more information, see Configure secondary private IPv4 addresses for Windows instances.

Unassign a secondary IP address from an instance

If you no longer require a secondary IP address, you can unassign it from the instance or the network interface. When a secondary private IPv4 address is unassigned from a network interface, the Elastic IP address (if it exists) is also disassociated.

Console

To unassign a secondary private IPv4 address from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, choose **Actions**, **Networking**, **Manage IP addresses**.
4. Expand the network interface. For **IPv4 addresses**, choose **Unassign** for the IPv4 address to unassign.
5. Choose **Save**.

AWS CLI

To unassign a secondary private IP address

Use the unassign-private-ip-addresses command.

```
aws ec2 unassign-private-ip-addresses \
    --network-interface eni-1234567890abcdef0\
    --private-ip-addresses 10.251.50.12
```

PowerShell

To unassign a secondary private IP address

Use the Unregister-EC2PrivateIpAddress cmdlet.

```
Unregister-EC2PrivateIpAddress `
    -NetworkInterface eni-1234567890abcdef0 `
    -PrivateIpAddress 10.251.50.12
```

Configure secondary private IPv4 addresses for Windows instances

You can specify multiple private IPv4 addresses for your instances. After you assign a secondary private IPv4 address to an instance, you must configure the operating system on the instance to recognize the secondary private IPv4 address.

> **Note**
>
> These instructions are based on Windows Server 2022. The implementation of these steps might vary based on the operating system of the Windows instance.

Tasks

- Prerequisites
- Step 1: Configure static IP addressing in your instance
- Step 2: Configure a secondary private IP address for your instance
- Step 3: Configure applications to Use the secondary private IP address

Prerequisites

- Assign the secondary private IPv4 address to the network interface for the instance. You can assign the secondary private IPv4 address when you launch the instance, or after the instance is running. For more information, see Assign secondary IP addresses to an instance.

Step 1: Configure static IP addressing in your instance

To enable your Windows instance to use multiple IP addresses, you must configure your instance to use static IP addressing rather than a DHCP server.

> **Important**
>
> When you configure static IP addressing in your instance, the IP address must match exactly what is shown in the console, CLI, or API. If you enter these IP addresses incorrectly, the instance could become unreachable.

To configure static IP addressing on a Windows instance

1. Connect to your instance.
2. Find the IP address, subnet mask, and default gateway addresses for the instance by performing the following steps:
   - Run the following command in PowerShell:

     ```
     ipconfig /all
     ```

     Review the output and note the **IPv4 Address**, **Subnet Mask**, **Default Gateway**, and **DNS Servers** values for the network interface. Your output should resemble the following example:

     ```
     ...

     Ethernet adapter Ethernet 4:

        Connection-specific DNS Suffix  . : us-west-2.compute.internal
        Description . . . . . . . . . . . : Amazon Elastic Network Adapter #2
        Physical Address. . . . . . . . . : 02-9C-3B-FC-8E-67
        DHCP Enabled. . . . . . . . . . . : Yes
        Autoconfiguration Enabled . . . . : Yes
        Link-local IPv6 Address . . . . . : fe80::f4d1:a773:5afa:cd1%7(Preferred)
        IPv4 Address. . . . . . . . . . . : 10.200.0.128(Preferred)
        Subnet Mask . . . . . . . . . . . : 255.255.255.0
        Lease Obtained. . . . . . . . . . : Monday, April 8, 2024 12:19:29 PM
        Lease Expires . . . . . . . . . . : Monday, April 8, 2024 4:49:30 PM
     ```

```
   Default Gateway . . . . . . . . . : 10.200.0.1
   DHCP Server . . . . . . . . . . . : 10.200.0.1
   DHCPv6 IAID . . . . . . . . . . . : 151166011
   DHCPv6 Client DUID. . . . . . . . : 00-01-00-01-2D-67-AC-FC-12-34-9A-BE-A5-
E7
   DNS Servers . . . . . . . . . . . : 10.200.0.2
   NetBIOS over Tcpip. . . . . . . . : Enabled
```

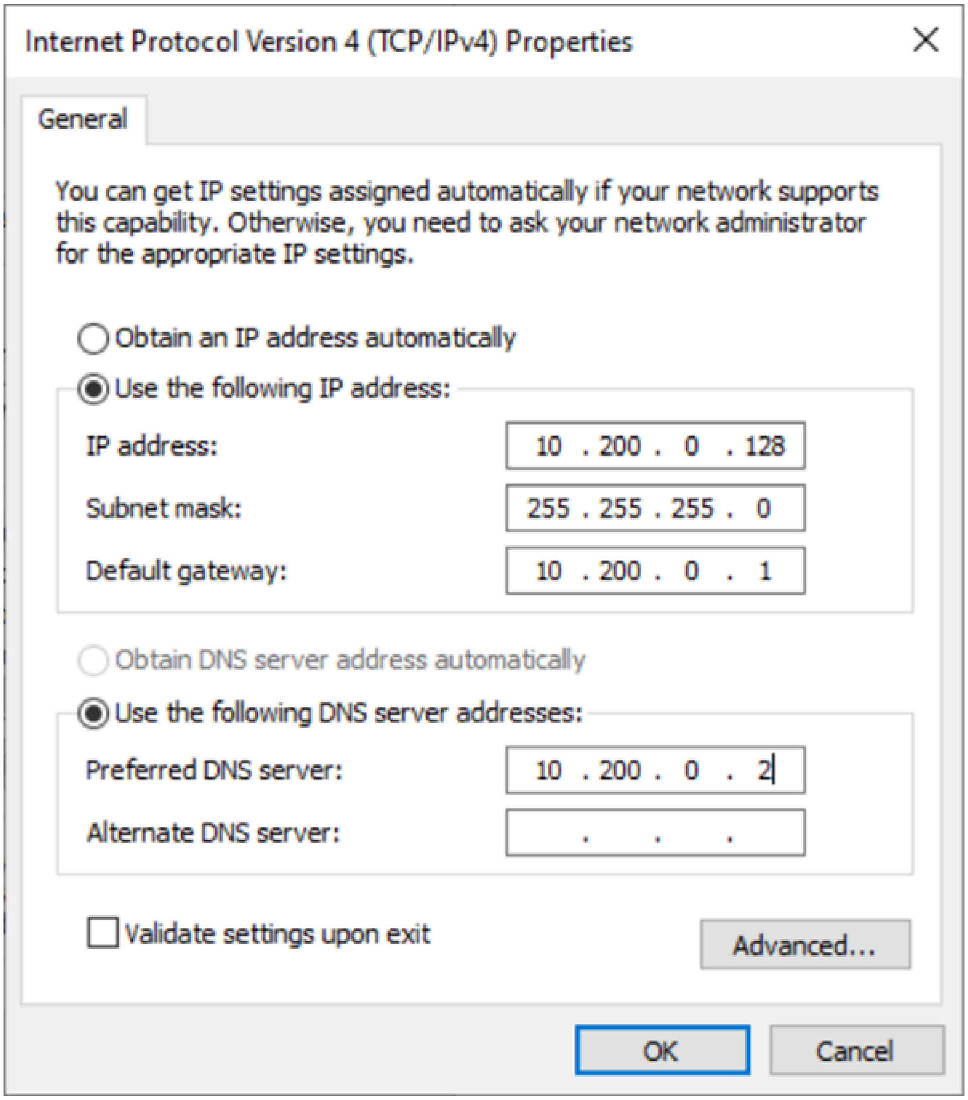
3. Open the **Network and Sharing Center** by running the following command in PowerShell:

```
& $env:SystemRoot\system32\control.exe ncpa.cpl
```

4. Open the context (right-click) menu for the network interface (Local Area Connection or Ethernet) and choose **Properties**.
5. Choose **Internet Protocol Version 4 (TCP/IPv4)**, **Properties**.
6. In the **Internet Protocol Version 4 (TCP/IPv4) Properties** dialog box, choose **Use the following IP address**, enter the following values, and then choose **OK**.

Field	Value
IP address	The IPv4 address obtained in step 2 above.
Subnet mask	The subnet mask obtained in step 2 above.
Default gateway	The default gateway address obtained in step 2 above.
Preferred DNS server	The DNS server obtained in step 2 above.
Alternate DNS server	The alternate DNS server obtained in step 2 above. If an alternate DNS server was not listed, leave this field blank.

> **Important**
>
> If you set the IP address to any value other than the current IP address, you will lose connectivity to the instance.



You will lose RDP connectivity to the Windows instance for a few seconds while the instance converts from using DHCP to static addressing. The instance retains the same IP address information as before, but now this information is static and not managed by DHCP.

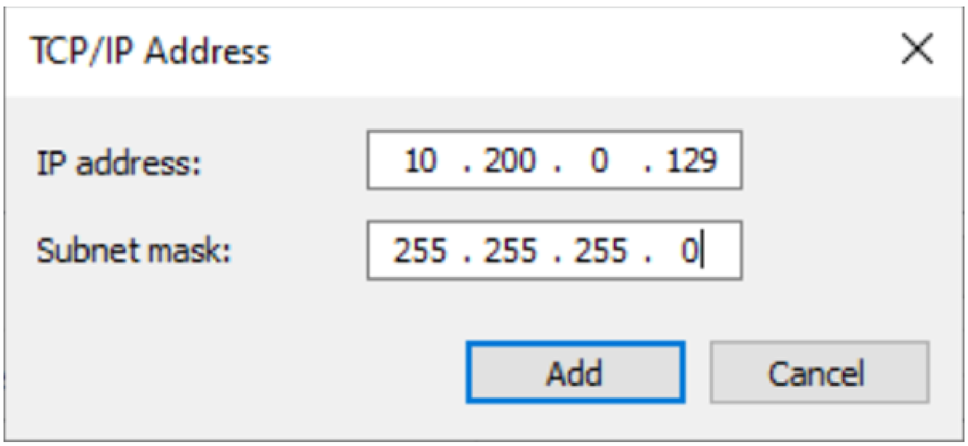
Step 2: Configure a secondary private IP address for your instance

After you have set up static IP addressing on your Windows instance, you are ready to prepare a second private IP address.

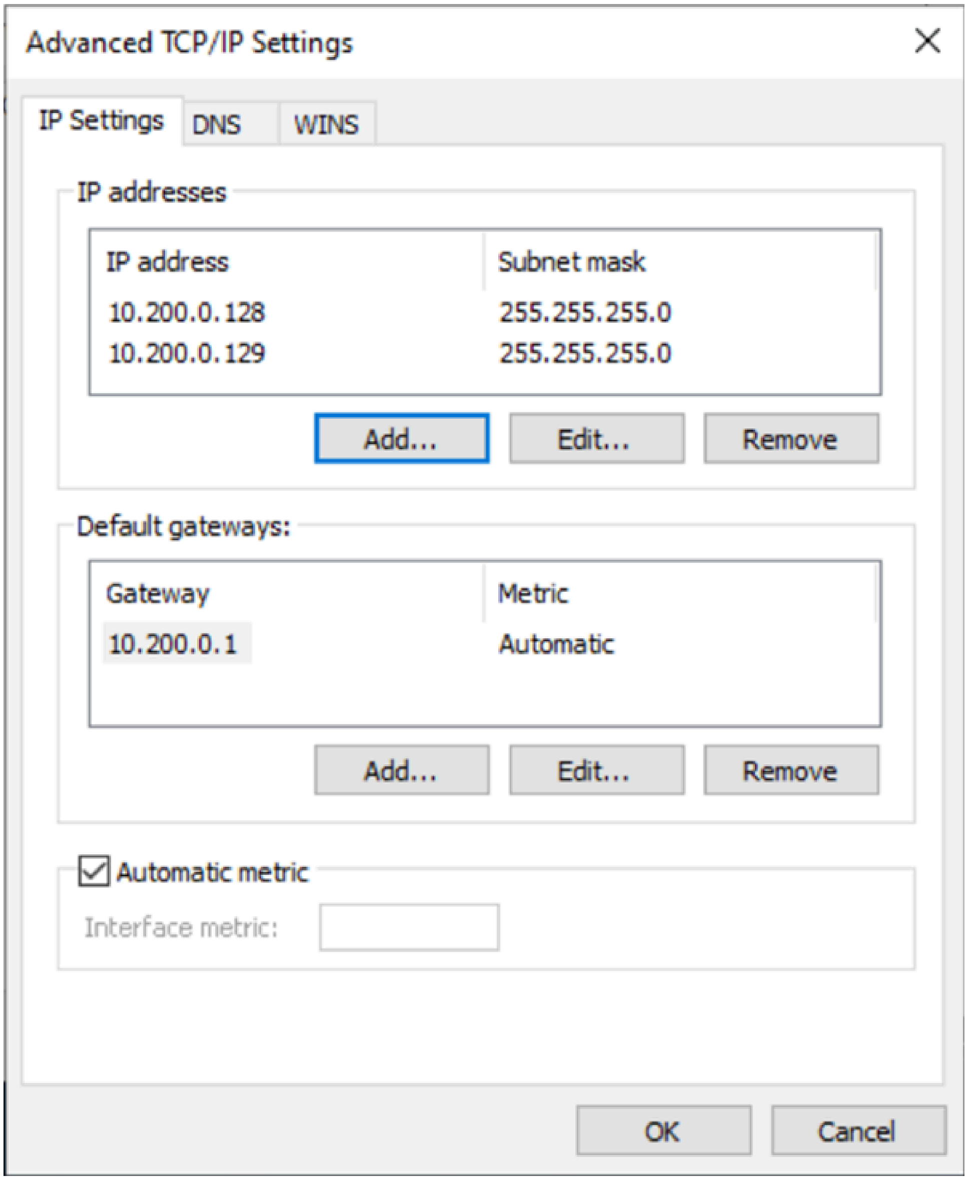
To configure a secondary IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Instances** and select your instance.
3. On the **Networking**, note the secondary IP address.
4. Connect to your instance.
5. On your Windows instance, choose **Start**, **Control Panel**.
6. Choose **Network and Internet**, **Network and Sharing Center**.
7. Select the network interface (Local Area Connection or Ethernet) and choose **Properties**.
8. On the **Local Area Connection Properties** page, choose **Internet Protocol Version 4 (TCP/IPv4)**, **Properties**, **Advanced**.
9. Choose **Add**.
10. In the **TCP/IP Address** dialog box, type the secondary private IP address for **IP address**. For **Subnet mask**, type the same subnet mask that you entered for the primary private IP address in [Step 1: Configure static IP addressing in your instance](), and then choose **Add**.



11. Verify the IP address settings and choose **OK**.



12. Choose **OK**, **Close**.
13. To confirm that the secondary IP address has been added to the operating system, run the `ipconfig /all` command in PowerShell. Your output should resemble the following:

```
Ethernet adapter Ethernet 4:

   Connection-specific DNS Suffix  . :
   Description . . . . . . . . . . . : Amazon Elastic Network Adapter #2
   Physical Address. . . . . . . . . : 02-9C-3B-FC-8E-67
   DHCP Enabled. . . . . . . . . . . : No
   Autoconfiguration Enabled . . . . : Yes
   Link-local IPv6 Address . . . . . : fe80::f4d1:a773:5afa:cd1%7(Preferred)
   IPv4 Address. . . . . . . . . . . : 10.200.0.128(Preferred)
```

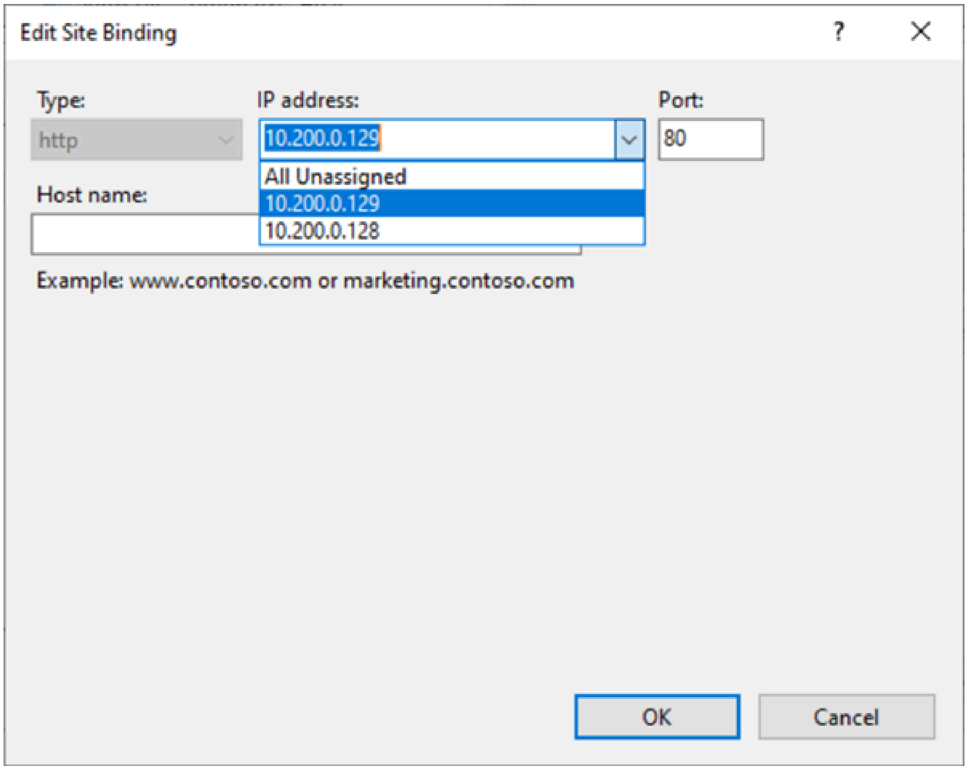
```
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   IPv4 Address. . . . . . . . . . . : 10.200.0.129(Preferred)
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   Default Gateway . . . . . . . . . : 10.200.0.1
   DHCPv6 IAID . . . . . . . . . . . : 151166011
   DHCPv6 Client DUID. . . . . . . . : 00-01-00-01-2D-67-AC-FC-12-34-9A-BE-A5-E7
   DNS Servers . . . . . . . . . . . : 10.200.0.2
   NetBIOS over Tcpip. . . . . . . . : Enabled
```

Step 3: Configure applications to Use the secondary private IP address

You can configure any applications to use the secondary private IP address. For example, if your instance is running a website on IIS, you can configure IIS to use the secondary private IP address.

To configure IIS to use the secondary private IP address

1. Connect to your instance.
2. Open Internet Information Services (IIS) Manager.
3. In the **Connections** pane, expand **Sites**.
4. Open the context (right-click) menu for your website and choose **Edit Bindings**.
5. In the **Site Bindings** dialog box, for **Type**, choose **http**, **Edit**.
6. In the **Edit Site Binding** dialog box, for **IP address**, select the secondary private IP address. (By default, each website accepts HTTP requests from all IP addresses.)



7. Choose **OK**, **Close**.

EC2 instance hostnames and domains

Understanding EC2 instance hostnames and domains is important for effectively managing and accessing your Amazon EC2 instances. Each EC2 instance can have different types of hostnames - private and public - that serve different purposes and follow specific naming conventions.

This topic explains the structure of EC2 instance hostnames, how they're constructed, and the different hostname types available. You'll learn how to view and modify hostname settings, understand when to use each type, and learn best practices for hostname management in your AWS environment.

Contents

Understanding EC2 instance hostnames and domains

A EC2 instance address is made up of different components. The following is an example of an EC2 instance address that uses the private IPv4 address of the instance:

```
   IP address         Domain name
   #--------# #-----------------------#
ip-10-24-34-0.us-west-2.compute.internal
#-----------#
  Hostname
#---------------------------------------#
    Fully qualified domain name (FQDN)
```

Where:

- **IP address**: The primary IPv4 address of the primary network interface associated with an instance.
- **Hostname**: The local name of a specific EC2 instance (used by the operating system and for local network identification)
- **Domain name**: The part of the FQDN that AWS provides
- **Fully qualified domain name (FQDN)**: The complete address that includes both the hostname and the domain name. This is the full, globally unique identifier used to reach your instance across networks.

Depending on the hostname type you choose for the instance or primary network interface attached to the instance, the hostname and domain name formats will be different from the example above. This section explains the hostname type options.

Hostname types

AWS provides two types of hostnames: **private** and **public**. The following table compares the key differences between private and public hostnames, including how they resolve, how they're configured, and when to use each type.

	Private hostnames	Public hostnames
DNS resolution	Private hostnames enable private FQDNs that are not accessible	Public hostnames enable public FQDNs that are accessible from the

	Private hostnames	Public hostnames
	from the public internet. Private hostnames only allow requests to resolve to private IPv4 and IPv6 GUA addresses within the VPC.	public internet. Public hostnames enable requests to resolve to private IPv4 and IPv6 GUA within the VPC and public IPs from the internet (split-horizon DNS).
Configuration	Private hostnames are configured at the instance level.	Public hostnames are configured at the network interface level.
When to use	• For hostnames that resolve only within your VPC, for internal communication • To keep your internal naming scheme private • To simplify internal resource management without external DNS considerations	• To access instances over both IPv4 and IPv6 from the internet • To enable smooth migration from IPv4 to IPv6 environments

Contents

Public hostnames

You can use *public hostnames* to access EC2 instances using hostnames that resolve to the public IPv4 or IPv6 address of the instance and ease your transition to IPv6.

Public hostnames allow you to:

- Access your EC2 instances over both IPv4 and IPv6, giving you more flexibility in how you connect to your resources.
- Migrate from IPv4 to IPv6 environments at your own pace. You can, for example, decouple your database and application migrations, reducing complexity and risk.

- Use multiple hostname options (IPv4-only, IPv6-only, and dual-stack) that automatically resolve to the appropriate IP addresses.
- Benefit from improved security with split-horizon DNS, which resolves hostnames to private IP addresses when queried from within your VPC.

Contents

Public hostname types and when to use them

To use public hostnames, you have to modify an existing network interface. This section describes the three public hostname type options and helps you decide which to use:

- **Dual-stack - IP based name**
  - This is the best option if you are migrating or planning to migrate from IPv4 to IPv6. This option allows for connectivity over both IPv4 and IPv6, giving flexibility to clients that may be using either protocol and enables clients to keep the same hostname throughout the migration to IPv6.
  - Requests from within the VPC resolve to both the private IPv4 address and the IPv6 Global Unicast Address (GUA) of the network interface. Requests from the internet resolve to both the public IPv4 and the IPv6 GUA address of the network interface.
  - **Example**
    - When you choose this option, a dual-stack FQDN will be generated for this network interface. This is an example of the FQDN that will be generated:
      - f5lnz-0khrm-nt2u3-gyqqt-nbdl5-q3cdpO.ap-southeast-2.ip.aws
    - Where:
      - f5lnz-0khrm-nt2u3-gyqqt-nbdl5-q3cdpO is the hostname that is a base36 representation of the primary public IPv6 address (f5lnz-0khrm-nt2u3-gyqqt-nbdl5) on the network interface along with a base36 representation of the primary public IPv4 address (q3cdpO) on the network interface.

        - f5lnz-0khrm-nt2u3-gyqqt-nbdl5 is resolved by the Amazon DNS resolver to the IPv6 GUA address FFFF:1407:4:f000:81d:2689:1066:4489. This is the first IPv6 GUA assigned to the network interface.
        - q3cdpO is resolved to the IPv4 address of 52.54.55.56. This is the public IPv4 address attached to the primary network interface.
        - ap-southeast-2 is the Region of the subnet that the network interface is in.
        - ip.aws is the domain provided by AWS.
- **IPv6 - IP based name**
    - This is a good option if you have already migrated to IPv6 and require connectivity only over IPv6.
    - Requests from within the VPC or from the internet resolve to the IPv6 GUA of the network interface.
    - **Example**
        - When you choose this option, a FQDN will be generated for this network interface. This is an example of the FQDN that will be generated:
            - f5lnz-0khrm-nt2u3-gyqqt-nbdl5.ap-southeast-2.ip.aws
        - Where:
            - f5lnz-0khrm-nt2u3-gyqqt-nbdl5 is a hostname that is a base36 representation of the primary public IPv6 address on the network interface.
            - f5lnz-0khrm-nt2u3-gyqqt-nbdl5 is resolved by the Amazon DNS resolver to the IPv6 GUA address FFFF:1407:4:f000:81d:2689:1066:4489. This is the first IPv6 GUA assigned to the network interface.
            - ap-southeast-2 is the Region of the subnet that the network interface is in.
            - ip.aws is the domain provided by AWS.
- **IPv4 - IP based name**
    - This is a good option if the instance using this network interface need to maintain IPv4 access during the transition to IPv6 or if applications or systems running on the instance only support IPv4. This is the best option if you only need to maintain IPv4 connectivity and your workloads don't require IPv6 support. For example, if you are migrating to IPv6, you may decide to keep some applications on IPv4 while others move to IPv6.
    - Requests from within the VPC resolve to the private primary IPv4 address of the network interface. Requests from the internet resolve to the public IPv4 address of the network interface.

- **Example**
  - If you choose this option, an IPv4-enabled public hostname will be generated for this network interface. This is an example of the DNS name that will be generated:
    - ec2-52-54-55-66.ap-southeast-2.compute.amazonaws.com
  - Where:
    - ec2-52-54-55-66 is a hostname that is a base36 representation of the primary public IPv4 address of a network interface.
    - ec2-52-54-55-66 resolves to the IPv4 address of 52.54.55.56. This is the public IPv4 address attached to the primary network interface.
    - ap-southeast-2 is the Region of the subnet that the network interface is in.
    - ip.aws is the domain provided by AWS.

> **Important**
>
> In the examples above, you can see that IP addresses are used to generate the hostname. If you change the primary private IPv4 address or the first IPv6 GUA assigned to the network interface, the portion of the hostname that translates to the IP address will change and **the previously-generated public hostname will no longer be valid**. In addition, changing the primary IPv4 public address forces a downstream refresh of Instance Metadata Service (IMDS) in the *Amazon EC2 User Guide*, so the EC2 instance IMDS metadata is automatically updated.

View public hostnames

If the VPC that the network interface is in does not have both EnableDnsHostnames and EnableDnsSupport enabled, there is no hostname type defined or generated.

Console

You can view the public hostnames for an instance or primary network interface.

To view the hostname type and DNS names of an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.

3. Select the checkbox for the instance.
4. On the **Network** tab, under **Hostname and DNS**, find the following:
   - **Public hostname type**
   - **Public DNS**
   - **IPv4-only IP based name**
   - **IPv6-only - IP based name**
   - **Dualstack - IP based name**

To view the hostname type and DNS names of a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. In the search field, enter the ID of the instance. Select the ID of the network interface to open its details page.
4. Under **Hostname and DNS**, find the following:
   - **Public hostname type**
   - **Public DNS name**
   - **Public IPv4 DNS name**
   - **Public IPv6 DNS name**
   - **Public Dualstack DNS name**

AWS CLI

To view the hostname type and DNS names of a network interface

Use the describe-network-interfaces command.

```
aws ec2 describe-network-interfaces \
    --network-interface-id eni-1234567890abcdef0 \
    --query NetworkInterfaces[].PublicIpDnsNameOptions
```

The following is example output. Because the hostname type is `public-dual-stack-dns-name`, the DNS hostname is the same as `PublicDualStackDnsName`.

```
[
     {
          "DnsHostnameType": "public-dual-stack-dns-name",
          "PublicIpv4DnsName": "ec2-52-54-55-66.ap-
southeast-2.compute.amazonaws.com",
          "PublicIpv6DnsName": "f5lnz-0khrm-nt2u3-gyqqt-nbdl5.ap-
southeast-2.ip.aws",
          "PublicDualStackDnsName": "f5lnz-0khrm-nt2u3-gyqqt-nbdl5-q3cdp0.ap-
southeast-2.ip.aws"
     }
]
```

PowerShell

To view the hostname type and DNS names of a network interface

Use the Get-EC2NetworkInterface cmdlet.

```
(Get-EC2NetworkInterface `
    -NetworkInterfaceId eni-1234567890abcdef0).PublicIpDnsNameOptions
```

The following is example output. Because the hostname type is `public-dual-stack-dns-name`, the DNS hostname is the same as `PublicDualStackDnsName`.

```
DnsHostnameType        : public-dual-stack-dns-name
PublicDualStackDnsName : f5lnz-0khrm-nt2u3-gyqqt-nbdl5-q3cdp0.ap-southeast-2.ip.aws
PublicIpv4DnsName      : ec2-52-54-55-66.ap-southeast-2.compute.amazonaws.com
PublicIpv6DnsName      : f5lnz-0khrm-nt2u3-gyqqt-nbdl5.ap-southeast-2.ip.aws
```

Modify public hostnames types

The public hostname type options depend on the IP addresses associated with the network interface:

- If the network interface has only a public IPv4 address, the hostname type must be **IPv4 - IP based name**.
- If the network interface has only an IPv6 address, the hostname type must be **IPv6 - IP based name**.
- If the network interface has both a public IPv4 address and an IPv6 address, the hostname type can be **Dual-stack - IP based name**.

Prerequisites

- The network interface must have an associated public IPv4 address or an IPv6 address.
- The VPC that the network interface is in must have EnableDnsHostnames and EnableDnsSupport enabled. See [View and update DNS attributes for your VPC](#) in the *Amazon VPC User Guide*.

Console

To modify the public hostname type

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. In the search field, enter the ID of the instance. Select the checkbox for the network interface.

   Alternatively, from the instance detail page, choose the **Networking** tab and select the ID of the network interface for device index 0.
4. Choose **Actions**, **Modify public hostname type**.
5. Choose an option:
   - **Dual-stack - IP based name**: A dual-stack public hostname for a network interface. Requests from within the VPC resolve to both the private IPv4 address and the IPv6 Global Unicast Address of the network interface. Requests from the internet resolve to both the public IPv4 and the IPv6 GUA address of the network interface.
   - **IPv4 - IP based name**: An IPv4-enabled public hostname for a network interface. Requests from within the VPC resolve to the private primary IPv4 address of the network interface. Requests from the internet resolve to the public IPv4 address of the network interface.
   - **IPv6 - IP based name**: An IPv6-enabled public hostname for a network interface. Requests from within the VPC or from the internet resolve to the IPv6 GUA of the network interface.
6. Choose **Modify**.

AWS CLI

To modify the public hostname type

Use the modify-public-ip-dns-name-options command.

```
aws ec2 modify-public-ip-dns-name-options \
    --network-interface-id eni-1234567890abcdef0 \
    --hostname-type public-dual-stack-dns-name
```

The following is example output.

```
{
    "Successful": true
}
```

PowerShell

To modify the public hostname type

Use the Edit-EC2PublicIpDnsNameOption cmdlet.

```
Edit-EC2PublicIpDnsNameOption `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -HostNameType public-dual-stack-dns-name
```

Private hostnames

This section describes the Amazon EC2 instance private hostnames available when you launch instances into your VPC subnets.

The private hostname distinguishes the EC2 instances on your network. You may use the private hostname of an instance if, for example, you want to run scripts to communicate with some or all of the instances on your network.

Contents

Private hostname types

There are two private hostname types for the guest OS hostname when EC2 instances are launched in a VPC:

- **IP name**: The legacy naming scheme where, when you launch an instance, the *private IPv4 address* of the instance is included in the hostname of the instance. The IP name exists for the life of the EC2 instance. When used as the Private DNS hostname, it will only return the private IPv4 address (A record).
- **Resource name**: When you launch an instance, the *EC2 instance ID* is included in the hostname of the instance. The resource name exists for the life of the EC2 instance. When used as the Private DNS hostname, it can return both the private IPv4 address (A record) and/or the IPv6 Global Unicast Address (AAAA record).

The EC2 instance guest OS hostname type depends on the subnet settings:

- If the instance is launched into an IPv4-only subnet, you can select either IP name or resource name.
- If the instance is launched into a dual-stack (IPv4+IPv6) subnet, you can select either IP name or resource name.
- If the instance is launched into an IPv6-only subnet, resource name is used automatically.

Contents

IP name

When you launch an EC2 instance with the **Hostname type** of **IP name**, the guest OS hostname is configured to use the private IPv4 address.

- Format for an instance in us-east-1: `*private-ipv4-address*.ec2.internal`
- Example: `*ip-10-24-34-0*.ec2.internal`
- Format for an instance in any other AWS Region: `*private-ipv4-address.region*.compute.internal`

- Example: *ip-10-24-34-0.us-west-2*.compute.internal

Resource name

When you launch EC2 instances in IPv6-only subnets, the **Hostname type** of **Resource name** is selected by default. When you launch an instance in IPv4-only or dual-stack (IPv4+IPv6) subnets, **Resource name** is an option that you can select. After you launch an instance, you can manage the hostname configuration. For more information, see Change resource based naming options for Amazon EC2.

When you launch an EC2 instance with a **Hostname type** of **Resource name**, the guest OS hostname is configured to use the EC2 instance ID.

- Format for an instance in us-east-1: *ec2-instance-id*.ec2.internal
- Example: *i-0123456789abcdef*.ec2.internal
- Format for an instance in any other AWS Region: *ec2-instance-id.region*.compute.internal
- Example: *i-0123456789abcdef.us-west-2*.compute.internal

The difference between IP name and Resource name

DNS queries for both IP names and resource names coexist to ensure backward compatibility and to allow you to migrate from IP based-naming for hostnames to resource-based naming. For private DNS hostnames based on IP names, you cannot configure whether a DNS A record query for the instance is responded to or not. DNS A record queries are always responded to irrespective of the guest OS hostname settings. In contrast, for private DNS hostnames based on resource name, you can configure whether DNS A and/or DNS AAAA queries for the instance are responded to or not. You configure the response behavior when you launch an instance or modify a subnet. For more information, see Change resource based naming options for Amazon EC2.

Where to find resource names and IP names

You can see the hostname types, resource name and IP name, in the Amazon EC2 console.

Contents

When creating an EC2 instance

When you create an EC2 instance, depending on which type of subnet you select, **Hostname type** of **Resource name** might be available or it might be selected and not be modifiable. This section explains the scenarios in which you see the hostname types resource name and IP name.

Scenario 1

You create an EC2 instance in the wizard (see Launch an EC2 instance using the launch instance wizard in the console) and, when you configure the details, you choose a subnet that you configured to be IPv6-only.

In this case, the **Hostname type** of **Resource name** is selected automatically and is not modifiable. **DNS Hostname** options of **Enable IP name IPv4 (A record) DNS requests** and **Enable resource-based IPv4 (A record) DNS requests** are deselected automatically and are not modifiable. **Enable resource-based IPv6 (AAAA record) DNS requests** is selected by default but is modifiable. If selected, DNS requests to the resource name will resolve to the IPv6 address (AAAA record) of this EC2 instance.

Scenario 2

You create an EC2 instance in the wizard (see Launch an EC2 instance using the launch instance wizard in the console) and, when you configure the details, you choose a subnet configured with an IPv4 CIDR block or both an IPv4 and IPv6 CIDR block ("dual stack").

In this case, **Enable IP name IPv4 (A record) DNS requests** is selected automatically and can't be changed. This means that requests to the IP name will resolve to the IPv4 address (A record) of this EC2 instance.

The options default to the configurations of the subnet, but you can modify the options for this instance depending on the subnet settings:

- **Hostname type**: Determines whether you want the guest OS hostname of the EC2 instance to be the resource name or IP name. The default value is **IP name**.
- **Enable resource-based IPv4 (A record) DNS requests**: Determines whether requests to your resource name resolve to the private IPv4 address (A record) of this EC2 instance. This option is not selected by default.
- **Enable resource-based IPv6 (AAAA record) DNS requests**: Determines whether requests to your resource name resolve to the IPv6 GUA address (AAAA record) of this EC2 instance. This option is not selected by default.

When viewing the details of an existing EC2 instance

You can see the hostname values for an existing EC2 instance in the **Details** tab for the EC2 instance:

- **Hostname type**: The hostname in IP name or resource name format.
- **Private IP DNS name (IPv4 only)**: The IP name that will always resolve to the private IPv4 address of the instance.
- **Private resource DNS name**: The resource name that resolves to the DNS records selected for this instance.
- **Answer private resource DNS name**: The resource name resolves to IPv4 (A), IPv6 (AAAA) or IPv4 and IPv6 (A and AAAA) DNS records.

In addition, if you connect to your EC2 instance directly over SSH and enter the `hostname` command, you'll see the hostname in either the IP name or resource name format.

Choosing between resource names and IP names

When you launch an EC2 instance (see [Launch an EC2 instance using the launch instance wizard in the console](#)), if you choose a **Hostname type** of **Resource name**, the EC2 instance launches with a hostname in the resource name format. In such cases, the DNS record for this EC2 instance can also point to the resource name. This gives you the flexibility to choose whether that hostname resolves to the IPv4 address, the IPv6 address, or both the IPv4 and IPv6 address of the instance. If you plan to use IPv6 in the future or if you are using dual-stack subnets today, it's best to use a **Hostname type** of **Resource name** so that you change DNS resolution for the hostnames of your instances without making any changes to the DNS records themselves. The resource name allows you to add and remove IPv4 and IPv6 DNS resolution on an EC2 instance.

If instead you choose a **Hostname type** of **IP name**, and use it as the DNS hostname, it can only resolve to the IPv4 address of the instance. It will not resolve to the IPv6 address of the instance even if the instance has both an IPv4 address and an IPv6 address associated with it.

Change resource based naming options for Amazon EC2

You can change the hostname type and DNS hostname configurations for subnets, which affects all subsequent instance launches in that subject, or you can change them for an EC2 instances after you launch it.

Resource based naming options

- **Hostname type**: Determines the default setting for the guest OS hostname of EC2 instances launched in the subnet. This is either the resource name or IP name.
- **Enable DNS hostname IPv4 (A record) requests**: Determines whether DNS requests/queries to the resource name resolve to the private IPv4 address (A record) of the EC2 instance.
- **Enable DNS hostname IPv6 (AAAA record) requests**: Determines whether DNS requests/queries to the resource name resolve to the IPv6 address (AAAA record) of the EC2 instance.

Subnets

Changing the subnet settings doesn't change the configuration of EC2 instances that are already launched in the subnet.

Console

To modify the options for a subnet

Open the Amazon VPC console and select the subnet. Choose **Actions**, **Edit subnet settings**. Modify the settings as needed and then save your changes.

AWS CLI

To modify the options for a subnet

Use the modify-subnet-attribute command.

```
aws ec2 modify-subnet-attribute \
    --subnet-id subnet-0abcdef1234567890 \
    --private-dns-hostname-type-on-launch resource-name \
    --enable-resource-name-dns-a-record-on-launch \
    --enable-resource-name-dns-aaaa-record-on-launch
```

PowerShell

To modify the options for a subnet

Use the Edit-EC2SubnetAttribute cmdlet.

```
Edit-EC2SubnetAttribute `
```

```
    -SubnetId subnet-0abcdef1234567890 `
    -PrivateDnsHostnameTypeOnLaunch ResourceName `
    -EnableResourceNameDnsAAAARecordOnLaunch $true `
    -EnableResourceNameDnsARecordOnLaunch $true
```

EC2 instances

Considerations

- To change the hostname type, you must first stop the instance. There is no need to stop an instance to change the other two options.
- Because you can't stop an instance store-backed instance, you can only configure the hostname type and DNS hostname options at instance launch. Only the following instance types support instance store volumes as root volumes: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

Console

To modify the hostname type and DNS hostname options for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. If you're going to change the **Use resource based naming as guest OS hostname** setting, first stop the EC2 instance. Otherwise, skip this step.

   To stop the instance, select the instance and choose **Instance state**, **Stop instance**.
3. Select the instance and choose **Actions**, **Instance settings**, **Change resource based naming options**.
   - **Use resource based naming as guest OS hostname**: Determines whether you want the guest OS hostname of the EC2 instance to be the resource name or IP name.
   - **Answer DNS hostname IPv4 (A record) requests**: Determines whether DNS requests/ queries to your resource name resolve to the private IPv4 address of this EC2 instance.
   - **Answer DNS hostname IPv6 (AAAA record) requests**: Determines whether DNS requests/queries to your resource name resolve to the IPv6 address (AAAA record) of this EC2 instance.
4. Choose **Save**.
5. If you stopped the instance, start it again.

AWS CLI

To modify the hostname type and DNS hostname options for an instance

Use the modify-private-dns-name-options command.

```
aws ec2 modify-private-dns-name-options \
    --instance-id i-1234567890abcdef0 \
    --private-dns-hostname-type resource-name \
    --enable-resource-name-dns-a-record \
    --enable-resource-name-dns-aaaa-record
```

PowerShell

To modify the hostname type and DNS hostname options for an instance

Use the Edit-EC2PrivateDnsNameOption cmdlet.

```
Edit-EC2PrivateDnsNameOption `
    -InstanceId i-1234567890abcdef0 `
    -PrivateDnsHostnameType ResourceName `
    -EnableResourceNameDnsAAAARecord $true`
    -EnableResourceNameDnsARecord $true
```

Bring your own IP addresses (BYOIP) to Amazon EC2

You can bring part or all of your publicly routable IPv4 or IPv6 address range from your on-premises network to your AWS account. You continue to control the address range and you can advertise the address range on the internet through AWS. After you bring the address range to Amazon EC2, it appears in your AWS account as an address pool.

> **Note**
>
> This documentation describes how to bring your own IP address range for use in Amazon EC2 only. To bring your own IP address range for use in AWS Global Accelerator, see Bring your own IP addresses (BYOIP) in the *AWS Global Accelerator Developer Guide*. To bring your own IP address range for use with Amazon VPC IP Address Manager, see Tutorial: Bring your IP addresses to IPAM in the *Amazon VPC IPAM User Guide*.

When you bring an IP address range to AWS, AWS validates that you control the IP address range. There are two methods that you can use to show that you control the range:

- If your IP address range is registered with an Internet Registry that supports RDAP (such as ARIN, RIPE and APNIC), you can verify control of your domain with an X.509 certificate by using the process on this page. The certificate must only be valid for the duration of the provisioning process. You can remove the certificate from your RIR's record after provisioning is complete.
- Regardless of whether your Internet Registry supports RDAP, you can use Amazon VPC IPAM to verify control of your domain with a DNS TXT record. That process is documented in Tutorial: Bring your IP addresses to IPAM in the *Amazon VPC IPAM User guide*.

For more information, see the AWS Online Tech talk Deep Dive on Bring Your Own IP.

Contents

BYOIP definitions

- **X.509 Self-sign certificate** — A certificate standard most commonly used to encrypt and authenticate data within a network. It is a certificate used by AWS to validate control over IP space from an RDAP record. For more information about X.509 certificates, see RFC 3280.
- **Autonomous System Number (ASN)** – A globally unique identifier that defines a group of IP prefixes run by one or more network operators that maintain a single, clearly-defined routing policy.
- **Regional Internet Registry (RIR)** – An organization that manages allocation and registration of IP addresses and ASNs within a region of the world.
- **Registry Data Access Protocol (RDAP)** — A read-only protocol to query current registration data within a RIR. Entries within the queried RIR database are referred to as "RDAP records". Certain

record types need to be updated by customers via a RIR-provided mechanism. These records are queried by AWS to verify control of an address space in the RIR.

- **Route Origin Authorization (ROA)** — An object created by RIRs for customers to authenticate IP advertisement in particular autonomous systems. For an overview, see Route Origin Authorizations (ROAs) on the ARIN website.
- **Local Internet Registry (LIR)** — Organizations such as internet service providers that allocate a block of IP addresses from an RIR for their customers.

Requirements and quotas

- The address range must be registered with your Regional Internet Registry (RIR). See your RIR for any policies regarding geographic regions. BYOIP currently supports registration in the American Registry for Internet Numbers (ARIN), Réseaux IP Européens Network Coordination Centre (RIPE), or Asia-Pacific Network Information Centre (APNIC). It must be registered to a business or institutional entity and cannot be registered to an individual person.
- The most specific IPv4 address range that you can bring is /24.
- The most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.
- ROAs are not required for CIDR ranges that are not publicly advertisable, but the RDAP records still need to be updated.
- You can bring each address range to one AWS Region at a time.
- You can bring a total of five BYOIP IPv4 and IPv6 address ranges per AWS Region to your AWS account. You cannot adjust the quotas for BYOIP CIDRs using the Service Quotas console, but you can request a quota increase by contacting the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
- You cannot share your IP address range with other accounts using AWS RAM unless you use Amazon VPC IP Address Manager (IPAM) and integrate IPAM with AWS Organizations. For more information, see Integrate IPAM with AWS Organizations in the *Amazon VPC IPAM User Guide*.
- The addresses in the IP address range must have a clean history. We might investigate the reputation of the IP address range and reserve the right to reject an IP address range if it contains an IP address that has a poor reputation or is associated with malicious behavior.
- Legacy address space, the IPv4 address space that was distributed by the Internet Assigned Numbers Authority's (IANA) central registry prior to the formation of the Regional Internet Registry (RIR) system, still requires a corresponding ROA object.

- For LIRs, it is common that they use a manual process to update their records. This can take days to deploy depending on the LIR.
- A single ROA object and RDAP record are needed for a large CIDR block. You can bring multiple smaller CIDR blocks from that range to AWS, even across multiple AWS Regions, using the single object and record.
- BYOIP is not supported for Wavelength Zones or on AWS Outposts.
- Do not make any manual changes for BYOIP in RADb or any other IRR. BYOIP will automatically update RADb. Any manual changes that include the BYOIP ASN will cause the BYOIP provision operation to fail.
- Once you bring an IPv4 address range to AWS, you can use all of the IP addresses in the range, including the first address (the network address) and the last address (the broadcast address).

Regional availability

The BYOIP feature is currently available in all commercial AWS Regions except for China Regions.

Local Zone availability

A Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones are grouped into "network border groups". In AWS, a network border group is a collection of Availability Zones (AZs), Local Zones, or Wavelength Zones from which AWS advertises a public IP address. Local Zones may have different network border groups than the AZs in an AWS Region to ensure minimum latency or physical distance between the AWS network and the customers accessing the resources in these Zones.

You can provision BYOIPv4 address ranges to and advertise them in the following Local Zone network border groups using the `--network-border-group` option:

- af-south-1-los-1
- ap-northeast-1-tpe-1
- ap-south-1-ccu-1
- ap-south-1-del-1
- ap-southeast-1-bkk-1
- ap-southeast-1-mnl-1
- ap-southeast-2-akl-1

- ap-southeast-2-per-1
- eu-central-1-ham-1
- eu-central-1-waw-1
- eu-north-1-cph-1
- eu-north-1-hel-1
- me-south-1-mct-1
- us-east-1-atl-2
- us-east-1-bos-1
- us-east-1-bue-1
- us-east-1-chi-2
- us-east-1-dfw-2
- us-east-1-iah-2
- us-east-1-lim-1
- us-east-1-mci-1
- us-east-1-mia-2
- us-east-1-msp-1
- us-east-1-nyc-1
- us-east-1-nyc-2
- us-east-1-phl-1
- us-east-1-qro-1
- us-east-1-scl-1
- us-west-2-den-1
- us-west-2-hnl-1
- us-west-2-las-1
- us-west-2-lax-1
- us-west-2-pdx-1
- us-west-2-phx-2
- us-west-2-sea-1

If you have Local Zones enabled (see Enable a Local Zone), you can choose a network border group for Local Zones when you provision and advertise a BYOIPv4 CIDR. Choose the network border group carefully as the EIP and the AWS resource it is associated with must reside in the same network border group.

> **Note**
>
> You cannot provision or advertise BYOIPv6 address ranges in Local Zones at this time.

Prerequisites for BYOIP in Amazon EC2

The onboarding process for BYOIP has two phases, for which you must perform three steps. These steps correspond to the steps depicted in the following diagram. We include manual steps in this documentation, but your RIR might offer managed services to help you with these steps.

> **Tip**
>
> The tasks in this section require a Linux terminal and may be performed using Linux, the AWS CloudShell, or the Windows Subsystem for Linux.

Contents

Overview

Preparation phase

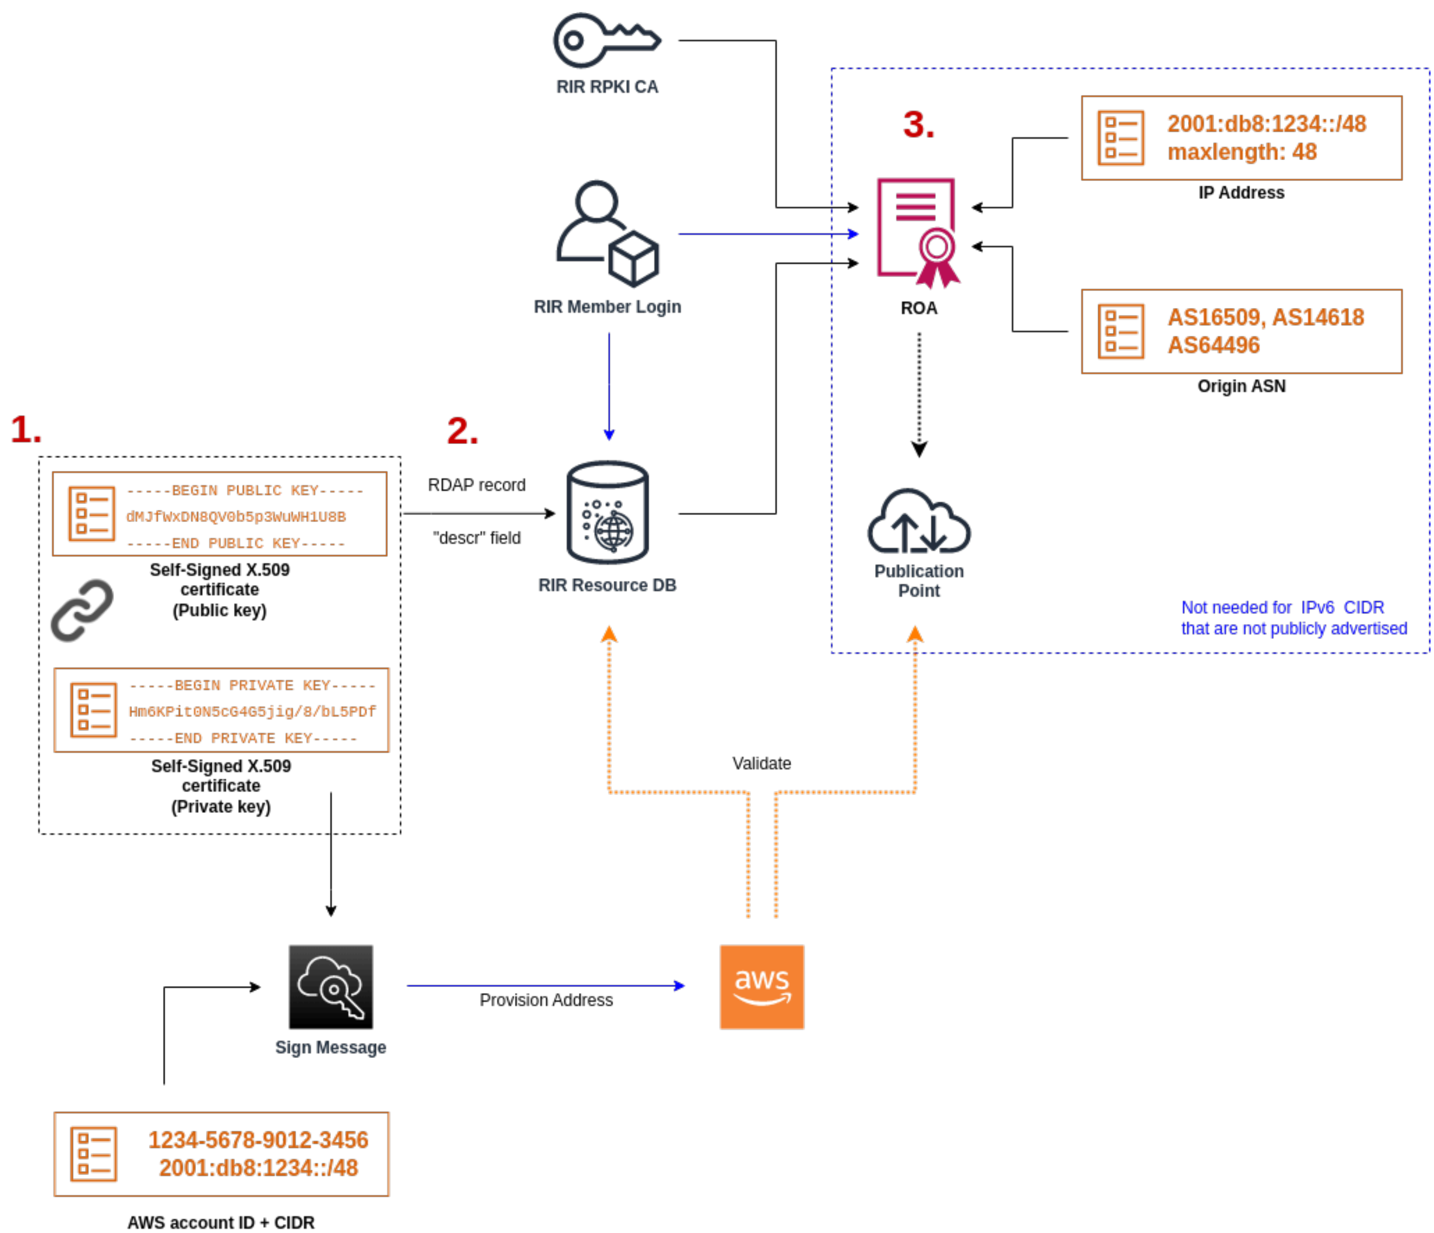
[1] Create a private key and use it to generate a self-signed X.509 certificate for authentication purposes. This certificate is only used during the provisioning phase. You can remove the certificate from your RIR's record after provisioning is complete

RIR configuration phase

[2] Upload the self-signed certificate to your RDAP record comments.

[3] Create a ROA object in your RIR. The ROA defines the desired address range, the Autonomous System Numbers (ASNs) allowed to advertise the address range, and an expiration date to register with the Resource Public Key Infrastructure (RPKI) of your RIR.

> **Note**
>
> A ROA is not required for non-publicly advertisable IPv6 address space.



To bring on multiple non-contiguous address ranges, you must repeat this process with each address range. However, the preparation and RIR configuration steps don't need to be repeated if splitting a contiguous block across several different AWS Regions.

Bringing on an address range has no effect on any address ranges that you brought on previously.

Create a private key and generate an X.509 certificate

Use the following procedure to create a self-signed X.509 certificate and add it to the RDAP record for your RIR. This key pair is used to authenticate the address range with the RIR. The **openssl** commands require OpenSSL version 1.0.2 or later.

Copy the following commands and replace only the placeholder values (in colored italic text).

This procedure follows the best practice of encrypting your private RSA key and requiring a passphrase to access it.

1. Generate an RSA 2048-bit private key as shown in the following.

   ```
   $ openssl genpkey -aes256 -algorithm RSA -pkeyopt rsa_keygen_bits:2048 -out
    private-key.pem
   ```

   The `-aes256` parameter specifies the algorithm used to encrypt the private key. The command returns the following output, including prompts to set a passphrase:

   ```
   ......+++
   .+++
   Enter PEM pass phrase: xxxxxxx
   Verifying - Enter PEM pass phrase: xxxxxxx
   ```

   You can inspect the key using the following command:

   ```
   $ openssl pkey -in private-key.pem -text
   ```

   This returns a passphrase prompt and the contents of the key, which should be similar to the following:

   ```
   Enter pass phrase for private-key.pem: xxxxxxx
   -----BEGIN PRIVATE KEY-----
   MIIEvgIBADANBgkqhkiG9w0BAQEFAASCBKgwggSkAgEAAoIBAQDFBXHRI4HVKAhh
   ```

```

```

Keep your private key in a secure location when it is not in use.

2. Generate an X.509 certificate using the private key created in the previous step. In this example, the certificate expires in 365 days, after which time it cannot be trusted. Be sure to set the expiration appropriately. The certificate must only be valid for the duration of the provisioning process. You can remove the certificate from your RIR's record after provisioning is complete. The `tr -d "\n"` command strips newline characters (line breaks) from the output. You need to provide a Common Name when prompted, but the other fields can be left blank.

```
$ openssl req -new -x509 -key private-key.pem -days 365 | tr -d "\n" >
 certificate.pem
```

This results in output similar to the following:

```
Enter pass phrase for private-key.pem: xxxxxxx
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) []:
State or Province Name (full name) []:
Locality Name (eg, city) []:
Organization Name (eg, company) []:
Organizational Unit Name (eg, section) []:
Common Name (eg, fully qualified host name) []:example.com
Email Address []:
```

Note

The Common Name is not needed for AWS provisioning. It can be any internal or public domain name.

You can inspect the certificate with the following command:

```
$ cat certificate.pem
```

The output should be a long, PEM-encoded string without line breaks, prefaced by `-----BEGIN CERTIFICATE-----` and followed by `-----END CERTIFICATE-----`.

Upload the X.509 certificate to the RDAP record in your RIR

Add the certificate that you previously created to the RDAP record for your RIR. Be sure to include the `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` strings before and after the encoded portion. All of this content must be on a single, long line. The procedure for updating RDAP depends on your RIR:

- For ARIN, use the Account Manager portal to add the certificate in the "Public Comments" section for the "Network Information" object representing your address range. Do not add it to the comments section for your organization.
- For RIPE, add the certificate as a new "descr" field to the "inetnum" or "inet6num" object representing your address range. These can usually be found in the "My Resources" section of the RIPE Database portal. Do not add it to the comments section for your organization or the "remarks" field of the above objects.
- For APNIC, add the certificate by editing remarks on the "inetnum" or "inet6num" record.

You can remove the certificate from your RIR's record after the provisioning stage below has been completed.

Create a ROA object in your RIR

Create a ROA object to authorize the Amazon ASNs 16509 and 14618 to advertise your address range, as well as the ASNs that are currently authorized to advertise the address range. For the AWS GovCloud (US) Regions, authorize ASN 8987 instead of 16509 and 14618. You must set the maximum length to the size of the CIDR that you are bringing in. The most specific IPv4 prefix you can bring is /24. The most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.

Important

If you are creating a ROA object for Amazon VPC IP Address Manager (IPAM), when you create the ROAs, for IPv4 CIDRs you must set the maximum length of an IP address prefix to /24. For IPv6 CIDRs, if you are adding them to an advertisable pool, the maximum length of an IP address prefix must be /48. This ensures that you have full flexibility to divide your public IP address across AWS Regions. IPAM enforces the maximum length you set. For more information about BYOIP addresses to IPAM, see Tutorial: BYOIP address CIDRs to IPAM in the *Amazon VPC IPAM User Guide*.

It might take up to 24 hours for the ROA to become available to Amazon. For more information, consult your RIR:

- ARIN — ROA Requests
- RIPE — Managing ROAs

- APNIC — Route Management

When you migrate advertisements from an on-premises workload to AWS, you must create a ROA for your existing ASN before creating the ROAs for Amazon's ASNs. Otherwise, you might see an impact to your existing routing and advertisements.

> **Important**
>
> For Amazon to advertise and continue advertising your IP address range, your ROAs with Amazon ASNs must be compliant with the above guidelines. If your ROAs are invalid or not compliant with the above guidelines, Amazon reserves the right to stop advertising your IP address range.

> **Note**
>
> This step is not required for non-publicly advertisable IPv6 address space.

Onboard your address range for use in Amazon EC2

The onboarding process for BYOIP includes the following tasks, depending on your needs.

Tasks

- Provision a publicly advertisable address range in AWS
- Provision an IPv6 address range that's not publicly advertisable
- Advertise the address range through AWS
- Deprovision the address range
- Validate your BYOIP

Provision a publicly advertisable address range in AWS

When you provision an address range for use with AWS, you are confirming that you control the address range and are authorizing Amazon to advertise it. We also verify that you control the address range through a signed authorization message. This message is signed with the self-signed X.509 key pair that you used when updating the RDAP record with the X.509 certificate.

AWS requires a cryptographically signed authorization message that it presents to the RIR. The RIR authenticates the signature against the certificate that you added to RDAP, and checks the authorization details against the ROA.

To provision the address range

1. **Compose message**

   Compose the plaintext authorization message. The format of the message is as follows, where the date is the expiry date of the message:

   ```
   1|aws|account|cidr|YYYYMMDD|SHA256|RSAPSS
   ```

   Replace the account number, address range, and expiry date with your own values to create a message resembling the following:

   ```
   text_message="1|aws|0123456789AB|198.51.100.0/24|20211231|SHA256|RSAPSS"
   ```

   This is not to be confused with a ROA message, which has a similar appearance.

2. **Sign message**

   Sign the plaintext message using the private key that you created previously. The signature returned by this command is a long string that you need to use in the next step.

   Important

   We recommend that you copy and paste this command. Except for the message content, do not modify or replace any of the values.

   ```
   signed_message=$( echo -n $text_message | openssl dgst -sha256 -sigopt
    rsa_padding_mode:pss -sigopt rsa_pss_saltlen:-1 -sign private-key.pem -keyform PEM
    | openssl base64 | tr -- '+=/' '-_~' | tr -d "\n")
   ```

3. **Provision address**

   Use the AWS CLI provision-byoip-cidr command to provision the address range. The `--cidr-authorization-context` option uses the message and signature strings that you created previously.

> **Important**
>
> You must specify the AWS Region where the BYOIP range should be provisioned if it differs from your [Configure the AWS CLI](#) `Default region name`.

```
aws ec2 provision-byoip-cidr --cidr address-range --cidr-authorization-context 
 Message="$text_message",Signature="$signed_message" --region us-east-1
```

Provisioning an address range is an asynchronous operation, so the call returns immediately, but the address range is not ready to use until its status changes from `pending-provision` to `provisioned`.

4. **Monitor progress**

   While most provisioning will be completed within two hours, it might take up to one week to complete the provisioning process for publicly advertisable ranges. Use the describe-byoip-cidrs command to monitor progress, as in this example:

```
aws ec2 describe-byoip-cidrs --max-results 5 --region us-east-1
```

   If there are issues during provisioning and the status goes to `failed-provision`, you must run the `provision-byoip-cidr` command again after the issues have been resolved.

Provision an IPv6 address range that's not publicly advertisable

By default, an address range is provisioned to be publicly advertisable to the internet. You can provision an IPv6 address range that will not be publicly advertisable. For routes that are not publicly advertisable, the provisioning process generally completes within minutes. When you associate an IPv6 CIDR block from a non-public address range with a VPC, the IPv6 CIDR can only be accessed through hybrid connectivity options that support IPv6, such as AWS Direct Connect, AWS Site-to-Site VPN, or Amazon VPC Transit Gateways.

A ROA is not required to provision a non-public address range.

Important

- You can only specify whether an address range is publicly advertisable during provisioning. You cannot change the advertisable status later on.
- Amazon VPC doesn't support unique local address (ULA) CIDRs. All VPCs must have unique IPv6 CIDRs. Two VPCs can’t have the same IPv6 CIDR range.

To provision an IPv6 address range that will not be publicly advertisable, use the following provision-byoip-cidr command.

```
aws ec2 provision-byoip-cidr --cidr address-range --cidr-authorization-context
 Message="$text_message",Signature="$signed_message" --no-publicly-advertisable --
region us-east-1
```

Advertise the address range through AWS

After the address range is provisioned, it is ready to be advertised. You must advertise the exact address range that you provisioned. You can't advertise only a portion of the provisioned address range.

If you provisioned an IPv6 address range that will not be publicly advertised, you do not need to complete this step.

We recommend that you stop advertising the address range or any portion of the range from other locations before you advertise it through AWS. If you keep advertising your IP address range or any portion of it from other locations, we can't reliably support it or troubleshoot issues. Specifically, we can't guarantee that traffic to the address range or a portion of the range will enter our network.

To minimize down time, you can configure your AWS resources to use an address from your address pool before it is advertised, and then simultaneously stop advertising it from the current location and start advertising it through AWS. For more information about allocating an Elastic IP address from your address pool, see Allocate an Elastic IP address.

Limitations

- You can run the **advertise-byoip-cidr** command at most once every 10 seconds, even if you specify different address ranges each time.

- You can run the **withdraw-byoip-cidr** command at most once every 10 seconds, even if you specify different address ranges each time.

To advertise the address range, use the following advertise-byoip-cidr command.

```
aws ec2 advertise-byoip-cidr --cidr address-range --region us-east-1
```

To stop advertising the address range, use the following withdraw-byoip-cidr command.

```
aws ec2 withdraw-byoip-cidr --cidr address-range --region us-east-1
```

Deprovision the address range

To stop using your address range with AWS, first release any Elastic IP addresses and disassociate any IPv6 CIDR blocks that are still allocated from the address pool. Then stop advertising the address range, and finally, deprovision the address range.

You cannot deprovision a portion of the address range. If you want to use a more specific address range with AWS, deprovision the entire address range and provision a more specific address range.

(IPv4) To release each Elastic IP address, use the following release-address command.

```
aws ec2 release-address --allocation-id eipalloc-12345678abcabcabc --region us-east-1
```

(IPv6) To disassociate an IPv6 CIDR block, use the following disassociate-vpc-cidr-block command.

```
aws ec2 disassociate-vpc-cidr-block --association-id vpc-cidr-assoc-12345abcd1234abc1
 --region us-east-1
```

To stop advertising the address range, use the following withdraw-byoip-cidr command.

```
aws ec2 withdraw-byoip-cidr --cidr address-range --region us-east-1
```

To deprovision the address range, use the following deprovision-byoip-cidr command.

```
aws ec2 deprovision-byoip-cidr --cidr address-range --region us-east-1
```

It can take up to a day to deprovision an address range.

Validate your BYOIP

1. Validate the self-signed x.509 key pair

   Validate that the certificate has been uploaded and is valid via the whois command.

   For ARIN, use `whois -h whois.arin.net r + 2001:0DB8:6172::/48` to look up the RDAP record for your address range. Check the `Public Comments` section for the `NetRange` (network range) in the command output. The certificate should be added in the `Public Comments` section for the address range.

   You can inspect the `Public Comments` containing the certificate using the following command:

   ```
   whois -h whois.arin.net r + 2001:0DB8:6172::/48 | grep Comments | grep BEGIN
   ```

   This returns output with the contents of the key, which should be similar to the following:

   ```
   Public Comments:

```

2. Validate the creation of a ROA object

   Validate the successful creation of the ROA objects using the RIPEstat Data API. Be sure to test your address range against the Amazon ASNs 16509 and 14618, plus the ASNs that are currently authorized to advertise the address range.

   You can inspect the ROA objects from different Amazon ASNs with your address range by using the following command:

```
curl --location --request GET "https://stat.ripe.net/data/rpki-validation/data.json?resource=ASN&prefix=CIDR
```

In this example output, the response has a result of `"status": "valid"` for the Amazon ASN 16509. This indicates the ROA object for the address range was created successfully:

```
{
    "messages": [],
    "see_also": [],
    "version": "0.3",
    "data_call_name": "rpki-validation",
    "data_call_status": "supported",
    "cached": false,
    "data": {
        "validating_roas": [
            {
                "origin": "16509",
                "prefix": "2001:0DB8::/32",
                "max_length": 48,
                "validity": "valid"
            },
            {
                "origin": "14618",
                "prefix": "2001:0DB8::/32",
                "max_length": 48,
                "validity": "invalid_asn"
            },
            {
                "origin": "64496",
                "prefix": "2001:0DB8::/32",
                "max_length": 48,
                "validity": "invalid_asn"
            }
        ],
        "status": "valid",
        "validator": "routinator",
        "resource": "16509",
        "prefix": "2001:0DB8::/32"
    },
    "query_id": "20230224152430-81e6384e-21ba-4a86-852a-31850787105f",
    "process_time": 58,
    "server_id": "app116",
```

```
    "build_version": "live.2023.2.1.142",
    "status": "ok",
    "status_code": 200,
    "time": "2023-02-24T15:24:30.773654"
}
```

A status of “unknown” indicates the ROA object for the address range has not been created. A status of “invalid_asn” indicates that the ROA object for the address range was not created successfully.

Use your BYOIP address range in Amazon EC2

You can view and use the IPv4 and IPv6 address ranges that you've provisioned in your account. For more information, see the section called “Onboard your address range”.

IPv4 address ranges

You can create an Elastic IP address from your IPv4 address pool and use it with your AWS resources, such as EC2 instances, NAT gateways, and Network Load Balancers.

To view information about the IPv4 address pools that you've provisioned in your account, use the following describe-public-ipv4-pools command.

```
aws ec2 describe-public-ipv4-pools --region us-east-1
```

To create an Elastic IP address from your IPv4 address pool, use the allocate-address command. You can use the `--public-ipv4-pool` option to specify the ID of the address pool returned by `describe-byoip-cidrs`. Or you can use the `--address` option to specify an address from the address range that you provisioned.

IPv6 address ranges

To view information about the IPv6 address pools that you've provisioned in your account, use the following describe-ipv6-pools command.

```
aws ec2 describe-ipv6-pools --region us-east-1
```

To create a VPC and specify an IPv6 CIDR from your IPv6 address pool, use the following create-vpc command. To let Amazon choose the IPv6 CIDR from your IPv6 address pool, omit the `--ipv6-cidr-block` option.

```
aws ec2 create-vpc --cidr-block 10.0.0.0/16 --ipv6-cidr-block ipv6-cidr --ipv6-pool pool-id --region us-east-1
```

To associate an IPv6 CIDR block from your IPv6 address pool with a VPC, use the following associate-vpc-cidr-block command. To let Amazon choose the IPv6 CIDR from your IPv6 address pool, omit the `--ipv6-cidr-block` option.

```
aws ec2 associate-vpc-cidr-block --vpc-id vpc-123456789abc123ab --ipv6-cidr-block ipv6-cidr --ipv6-pool pool-id --region us-east-1
```

To view your VPCs and the associated IPv6 address pool information, use the describe-vpcs command. To view information about associated IPv6 CIDR blocks from a specific IPv6 address pool, use the following get-associated-ipv6-pool-cidrs command.

```
aws ec2 get-associated-ipv6-pool-cidrs --pool-id pool-id --region us-east-1
```

If you disassociate the IPv6 CIDR block from your VPC, it's released back into your IPv6 address pool.

Elastic IP addresses

An *Elastic IP address* is a static IPv4 address designed for dynamic cloud computing. An Elastic IP address is allocated to your AWS account, and is yours until you release it. By using an Elastic IP address, you can mask the failure of an instance or software by rapidly remapping the address to another instance in your account. Alternatively, you can specify the Elastic IP address in a DNS record for your domain, so that your domain points to your instance. For more information, see the documentation for your domain registrar.

An Elastic IP address is a public IPv4 address, which is reachable from the internet. If you need to connect to an instance that does not have a public IPv4 address, you can associate an Elastic IP address with your instance to enable communication with the internet.

Contents

- Transfer an Elastic IP address between AWS accounts
- Release an Elastic IP address
- Create a reverse DNS record for email on Amazon EC2

Elastic IP address pricing

There is a charge for all Elastic IP addresses whether they are in use (allocated to a resource, like an EC2 instance) or idle (created in your account but unallocated).

AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the **Public IPv4 Address** tab on the Amazon VPC pricing page.

Elastic IP address basics

The following are the basic characteristics of an Elastic IP address:

- An Elastic IP address is static; it does not change over time.
- An Elastic IP address is for use in a specific Region only, and cannot be moved to a different Region.
- An Elastic IP address comes from Amazon's pool of IPv4 addresses, or from a custom IPv4 address pool that you have brought to your AWS account. We do not support Elastic IP addresses for IPv6.
- To use an Elastic IP address, you first allocate one to your account, and then associate it with your instance or a network interface.
- When you associate an Elastic IP address with an instance, it is also associated with the instance's primary network interface. When you associate an Elastic IP address with a network interface that is attached to an instance, it is also associated with the instance.
- When you associate an Elastic IP address with an instance or its primary network interface, if the instance already has a public IPv4 address associated with it, that public IPv4 address is released back into Amazon's pool of public IPv4 addresses and the Elastic IP address is associated with the instance instead. You cannot reuse the public IPv4 address previously associated with the instance and you cannot convert that public IPv4 address to an Elastic IP address. For more information, see Public IPv4 addresses.
- You can disassociate an Elastic IP address from a resource, and then associate it with a different resource. To avoid unexpected behavior, ensure that all active connections to the resource named

in the existing association are closed before you make the change. After you have associated your Elastic IP address to a different resource, you can reopen your connections to the newly associated resource.

- A disassociated Elastic IP address remains allocated to your account until you explicitly release it. You are charged for all Elastic IP addresses in your account, regardless of whether they are associated or disassociated with an instance. For more information, see the **Public IPv4 Address** tab on the Amazon VPC pricing page.
- When you associate an Elastic IP address with an instance that previously had a public IPv4 address, the public DNS host name of the instance changes to match the Elastic IP address.
- We resolve a public DNS host name to the public IPv4 address or the Elastic IP address of the instance outside the network of the instance, and to the private IPv4 address of the instance from within the network of the instance.
- When you allocate an Elastic IP address from an IP address pool that you have brought to your AWS account, it does not count toward your Elastic IP address limits. For more information, see Elastic IP address quota.
- When you allocate the Elastic IP addresses, you can associate the Elastic IP addresses with a network border group. This is the location from which we advertise the CIDR block. Setting the network border group limits the CIDR block to this group. If you do not specify the network border group, we set the border group containing all of the Availability Zones in the Region (for example, `us-west-2`).
- An Elastic IP address is for use in a specific network border group only.

Elastic IP address quota

By default, all AWS accounts have a quota of five (5) Elastic IP addresses per Region, because public (IPv4) internet addresses are a scarce public resource. We strongly recommend that you use Elastic IP addresses primarily for their ability to remap the address to another instance in the case of instance failure, and to use DNS hostnames for all other inter-node communication.

If you think your architecture warrants additional Elastic IP addresses, you can request a quota increase directly from the Service Quotas console. To request a quota increase, choose **Request increase at account-level**. For more information, see Amazon EC2 service quotas.

Associate an Elastic IP address with an instance

After you allocate an Elastic IP address, you can associate it with an AWS resource, such as an EC2 instance, NAT gateway, or Network Load Balancer. To associate an Elastic IP address with a different AWS resource later on, you can disassociate it from its current resource and then associated it with the new resource.

Tasks

- Allocate an Elastic IP address
- Associate an Elastic IP address
- Disassociate an Elastic IP address

Allocate an Elastic IP address

You can allocate an Elastic IP address for use in a Region. There is a charge for all Elastic IP addresses whether they are in use (associated with a resource, like an EC2 instance) or idle (created in your account but unassociated).

Console

To allocate an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network & Security**, **Elastic IPs**.
3. Choose **Allocate Elastic IP address**.
4. (Optional) When you allocate an Elastic IP address (EIP), you choose the **Network border group** in which to allocate the EIP. A network border group is a collection of Availability Zones (AZs), Local Zones, or Wavelength Zones from which AWS advertises a public IP address. Local Zones and Wavelength Zones may have different network border groups than the AZs in a Region to ensure minimum latency or physical distance between the AWS network and the customers accessing the resources in these Zones.

   Important

   You must allocate an EIP in the same network border group as the AWS resource that will be associated with the EIP. An EIP in one network border group can only be advertised in zones in that network border group and not in any other zones represented by other network border groups.

If you have Local Zones or Wavelength Zones enabled (for more information, see Enable a Local Zone or Enable Wavelength Zones), you can choose a network border group for AZs, Local Zones, or Wavelength Zones. Choose the network border group carefully as the EIP and the AWS resource it is associated with must reside in the same network border group. You can use the EC2 console to view the network border group that your Availability Zones, Local Zones, or Wavelength Zones are in. Typically, all Availability Zones in a Region belong to the same network border group, whereas Local Zones or Wavelength Zones belong to their own separate network border groups.

If you don't have Local Zones or Wavelength Zones enabled, when you allocate an EIP, the network border group that represents all of the AZs for the Region (such as `us-west-2`) is predefined for you and you cannot change it. This means that the EIP that you allocate to this network border group will be advertised in all AZs in the Region you're in.

5. For **Public IPv4 address pool**, choose one of the following:

   - **Amazon's pool of IPv4 addresses**—If you want an IPv4 address to be allocated from Amazon's pool of IPv4 addresses.
   - **Public IPv4 address that you bring to your AWS account**—If you want to allocate a non-contiguous (non-sequential) public IPv4 address from an IP address pool that you have brought to your AWS account. This option is disabled if you do not have any IP address pools. For more information about bringing your own IP address range to your AWS account, see Bring your own IP addresses (BYOIP) to Amazon EC2.
   - **Customer owned pool of IPv4 addresses**—If you want to allocate an IPv4 address from a pool created from your on-premises network for use with an AWS Outpost. This option is disabled if you do not have an AWS Outpost.
   - **Allocate using an IPAM IPv4 pool**: If you want to allocate sequential Elastic IP addresses from a contiguous public IPv4 block in an IPAM pool. Allocating sequential Elastic IP addresses can significantly reduce management overhead for security access control lists and simplify IP address allocation and tracking for enterprises scaling on AWS. For more information, see Allocate sequential Elastic IP addresses from an IPAM pool in the *Amazon VPC IPAM User Guide*.

6. (Optional) To add a tag, choose **Add new tag** and enter a tag key and a tag value.

AWS CLI

To allocate an Elastic IP address

Use the allocate-address AWS CLI command.

```
aws ec2 allocate-address
```

PowerShell

To allocate an Elastic IP address

Use the New-EC2Address cmdlet.

```
New-EC2Address -Domain Vpc
```

Associate an Elastic IP address

If you're associating an Elastic IP address with your instance to enable communication with the internet, you must also ensure that your instance is in a public subnet. For more information, see Enable internet access using an internet gateway in the *Amazon VPC User Guide*.

Console

To associate an Elastic IP address with an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to associate and choose **Actions**, **Associate Elastic IP address**.
4. For **Resource type**, choose **Instance**.
5. For instance, choose the instance with which to associate the Elastic IP address. You can also enter text to search for a specific instance.
6. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
7. Choose **Associate**.

To associate an Elastic IP address with a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to associate and choose **Actions**, **Associate Elastic IP address**.
4. For **Resource type**, choose **Network interface**.
5. For **Network interface**, choose the network interface with which to associate the Elastic IP address. You can also enter text to search for a specific network interface.
6. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
7. Choose **Associate**.

AWS CLI

To associate an Elastic IP address

Use the associate-address AWS CLI command.

```
aws ec2 associate-address --instance-id i-0b263919b6498b123 --allocation-
id eipalloc-64d5890a
```

PowerShell

To associate an Elastic IP address

Use the Register-EC2Address cmdlet.

```
Register-EC2Address `
    -InstanceId i-0b263919b6498b123 `
    -AllocationId eipalloc-64d5890a
```

Disassociate an Elastic IP address

You can disassociate an Elastic IP address from an instance or network interface at any time. After you disassociate the Elastic IP address, you can associate it with another resource.

Console

To disassociate and reassociate an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to disassociate, choose **Actions**, **Disassociate Elastic IP address**.
4. Choose **Disassociate**.

AWS CLI

To disassociate an Elastic IP address

Use the disassociate-address AWS CLI command.

```
aws ec2 disassociate-address --association-id eipassoc-12345678
```

PowerShell

To disassociate an Elastic IP address

Use the Unregister-EC2Address cmdlet.

```
Unregister-EC2Address -AssociationId eipassoc-12345678
```

Transfer an Elastic IP address between AWS accounts

You can transfer an Elastic IP address from one AWS account to another. This can be helpful in the following situations:

- **Disaster recovery** – Quickly remap the IP addresses for public-facing internet workloads during emergency events.
- **Organizational restructuring** – Quickly move a workload from one AWS account to another. An address transfer avoids the need to wait for new Elastic IP addresses to be allowed by your security groups and network ACLs.
- **Centralized security administration** – Use a centralized AWS security account to track and transfer Elastic IP addresses that have been vetted for security compliance.

Pricing

There is no charge for transferring Elastic IP addresses.

Tasks

- Enable Elastic IP address transfer
- Accept a transferred Elastic IP address
- Disable Elastic IP address transfer

Enable Elastic IP address transfer

This section describes how to accept a transferred Elastic IP address. Note the following limitations related to enabling Elastic IP addresses for transfer:

- You can transfer Elastic IP addresses from any AWS account (source account) to any other AWS account in the same AWS Region (transfer account). You cannot transfer Elastic IP addresses to a different Region.
- When you transfer an Elastic IP address, there is a two-step handshake between the AWS accounts. When the source account starts the transfer, the transfer accounts have seven days to accept the Elastic IP address transfer. During those seven days, the source account can view the pending transfer (for example in the AWS console or by using the describe-address-transfers command). After seven days, the transfer expires and ownership of the Elastic IP address returns to the source account.
- Accepted transfers are visible to the source account (for example in the AWS console or by using the describe-address-transfers command) for 14 days after the transfers have been accepted.
- AWS does not notify transfer accounts about pending Elastic IP address transfer requests. The owner of the source account must notify the owner of the transfer account that there is an Elastic IP address transfer request that they must accept.
- Any tags that are associated with an Elastic IP address being transferred are reset when the transfer is complete.
- You cannot transfer Elastic IP addresses allocated from public IPv4 address pools that you bring to your AWS account – commonly referred to as Bring Your Own IP (BYOIP) address pools.
- You cannot transfer Elastic IP addresses allocated from an Amazon-provided contiguous public IPv4 Amazon VPC IP Address Manager (IPAM) pool. Instead, IPAM allows you to share IPAM pools across AWS accounts by integrating IPAM with AWS Organizations and using AWS RAM. For more

information, see Allocate sequential Elastic IP addresses from an IPAM pool in the *Amazon VPC IPAM User Guide*.

- If you attempt to transfer an Elastic IP address that has a reverse DNS record associated with it, you can begin the transfer process, but the transfer account will not be able to accept the transfer until the associated DNS record is removed.
- If you have enabled and configured AWS Outposts, you might have allocated Elastic IP addresses from a customer-owned IP address pool (CoIP). You cannot transfer Elastic IP addresses allocated from a CoIP. However, you can use AWS RAM to share a CoIP with another account. For more information, see Customer-owned IP addresses in the *AWS Outposts User Guide*.
- You can use Amazon VPC IPAM to track the transfer of Elastic IP addresses to accounts in an organization from AWS Organizations. For more information, see View IP address history. If an Elastic IP address is transferred to an AWS account outside of the organization, the IPAM audit history of the Elastic IP address is lost.

These steps must be completed by the source account.

Console

To enable Elastic IP address transfer

1. Ensure that you're using the source AWS account.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose **Elastic IPs**.
4. Select one or more Elastic IP address to enable for transfer and choose **Actions**, **Enable transfer**.
5. If you are transferring multiple Elastic IP addresses, you’ll see the **Transfer type** option. Choose one of the following options:
   - Choose **Single account** if you are transferring the Elastic IP addresses to a single AWS account.
   - Choose **Multiple accounts** if you are transferring the Elastic IP addresses to multiple AWS accounts.
6. Under **Transfer account ID**, enter the IDs of the AWS accounts that you want to transfer the Elastic IP addresses to.
7. Confirm the transfer by entering `enable` in the text box.

8. Choose **Submit**.
9. To accept the transfer, see Accept a transferred Elastic IP address. To disable the transfer, see Disable Elastic IP address transfer.

AWS CLI

To enable Elastic IP address transfer

Use the enable-address-transfer command.

```
aws ec2 enable-address-transfer \
    --allocation-id eipalloc-09ad461b0d03f6aaf \
    --transfer-account-id 123456789012
```

PowerShell

To enable Elastic IP address transfer

Use the Enable-EC2AddressTransfer cmdlet.

```
Enable-EC2AddressTransfer `
    -AllocationId eipalloc-09ad461b0d03f6aaf `
    -TransferAccountId 123456789012
```

Accept a transferred Elastic IP address

This section describes how to accept a transferred Elastic IP address.

When you transfer an Elastic IP address, there is a two-step handshake between the AWS accounts. When the source account starts the transfer, the transfer accounts have seven days to accept the Elastic IP address transfer. During those seven days, the source account can view the pending transfer (for example in the AWS console or by using the describe-address-transfers command). After seven days, the transfer expires and ownership of the Elastic IP address returns to the source account.

When accepting transfers, note the following exceptions that might occur and how to resolve them:

- **AddressLimitExceeded**: If your transfer account has exceeded the Elastic IP address quota, the source account can enable Elastic IP address transfer, but this exception occurs when the transfer account tries to accept the transfer. By default, all AWS accounts are limited to 5 Elastic IP addresses per Region. See Elastic IP address quota for instructions on increasing the limit.

- **InvalidTransfer.AddressCustomPtrSet**: If you or someone in your organization has configured the Elastic IP address that you are attempting to transfer to use reverse DNS lookup, the source account can enable transfer for the Elastic IP address, but this exception occurs when the transfer account tries to accept the transfer. To resolve this issue, the source account must remove the DNS record for the Elastic IP address. For more information, see Create a reverse DNS record for email on Amazon EC2.
- **InvalidTransfer.AddressAssociated**: If an Elastic IP address is associated with an ENI or EC2 instance, the source account can enable transfer for the Elastic IP address, but this exception occurs when the transfer account tries to accept the transfer. To resolve this issue, the source account must disassociate the Elastic IP address. For more information, see Disassociate an Elastic IP address.

For any other exceptions, contact Support.

These steps must be completed by the transfer account.

Console

To accept an Elastic IP address transfer

1. Ensure that you're using the transfer account.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose **Elastic IPs**.
4. Choose **Actions**, **Accept transfer**.
5. No tags that are associated with the Elastic IP address being transferred are transferred with the Elastic IP address when you accept the transfer. If you want to define a **Name** tag for the Elastic IP address that you are accepting, select **Create a tag with a key of 'Name' and a value that you specify**.
6. Enter the Elastic IP address that you want to transfer.
7. If you are accepting multiple transferred Elastic IP addresses, choose **Add address** to enter an additional Elastic IP address.
8. Choose **Submit**.

AWS CLI

To accept an Elastic IP address transfer

Use the accept-address-transfer command.

```
aws ec2 accept-address-transfer --address 100.21.184.216
```

PowerShell

To accept an Elastic IP address transfer

Use the Approve-EC2AddressTransfer cmdlet.

```
Approve-EC2AddressTransfer -Address 100.21.184.216
```

Disable Elastic IP address transfer

This section describes how to disable an Elastic IP transfer after the transfer has been enabled.

These steps must be completed by the source account that enabled the transfer.

Console

To disable an Elastic IP address transfer

1. Ensure that you're using the source AWS account.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose **Elastic IPs**.
4. In the resource list of Elastic IPs, ensure that you have the property enabled that shows the column **Transfer status**.
5. Select one or more Elastic IP address that have a **Transfer status** of **Pending**, and choose **Actions**, **Disable transfer**.
6. Confirm by entering **`disable`** in the text box.
7. Choose **Submit**.

AWS CLI

To disable Elastic IP address transfer

Use the disable-address-transfer command.

```
aws ec2 disable-address-transfer --allocation-id eipalloc-09ad461b0d03f6aaf
```

PowerShell

To disable Elastic IP address transfer

Use the Disable-EC2AddressTransfer cmdlet.

```
Disable-EC2AddressTransfer -AllocationId eipalloc-09ad461b0d03f6aaf
```

Release an Elastic IP address

If you no longer need an Elastic IP address, we recommend that you release it. The Elastic IP address to release must not be currently associated with an AWS resource.

Console

To release an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to release and choose **Actions**, **Release Elastic IP addresses**.
4. Choose **Release**.

AWS CLI

To release an Elastic IP address

Use the release-address AWS CLI command.

```
aws ec2 release-address --allocation-id eipalloc-64d5890a
```

PowerShell

To release an Elastic IP address

Use the Remove-EC2Address cmdlet.

```
Remove-EC2Address -AllocationId eipalloc-64d5890a
```

After you release your Elastic IP address, you might be able to recover. The following rules apply:

- You can't recover an Elastic IP address if it has been allocated to another AWS account, or if it will result in your exceeding your Elastic IP address limit.
- You can't recover tags associated with an Elastic IP address.

AWS CLI

To recover an Elastic IP address

Use the allocate-address command.

```
aws ec2 allocate-address \
    --domain vpc \
    --address 203.0.113.3
```

PowerShell

To recover an Elastic IP address

Use the New-EC2Address cmdlet.

```
New-EC2Address `
    -Address 203.0.113.3 `
    -Domain vpc `
    -Region us-east-1
```

Create a reverse DNS record for email on Amazon EC2

If you intend to send email to third parties from an EC2 instance, we recommend that you provision one or more Elastic IP addresses and assign static reverse DNS records to the Elastic IP addresses that you use to send email. This can help you avoid having your email flagged as spam by some anti-spam organizations. AWS works with ISPs and internet anti-spam organizations to reduce the chance that your email sent from these addresses will be flagged as spam.

Considerations

- Before you create a reverse DNS record, you must set a corresponding forward DNS record (record type A) that points to your Elastic IP address.
- If a reverse DNS record is associated with an Elastic IP address, the Elastic IP address is locked to your account and cannot be released from your account until the record is removed.
- If you contacted Support to set up reverse DNS for an Elastic IP address, you can remove the reverse DNS, but you can't release the Elastic IP address because it is locked by Support. To unlock the Elastic IP address, contact AWS Support. After the Elastic IP address is unlocked, you can release it.
- [AWS GovCloud (US) Region] You can't create a reverse DNS record. AWS must assign the static reverse DNS records for you. Open a support case to remove reverse DNS and email sending limitations. You must provide your Elastic IP addresses and reverse DNS records.

Create a reverse DNS record

You can create a reverse DNS record for your Elastic IP address as follows.

Console

To create a reverse DNS record

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address and choose **Actions**, **Update reverse DNS**.
4. For **Reverse DNS domain name**, enter the domain name.
5. Enter **`update`** to confirm.
6. Choose **Update**.

AWS CLI

To create a reverse DNS record

Use the modify-address-attribute command.

```
aws ec2 modify-address-attribute \
    --allocation-id eipalloc-abcdef01234567890 \
```

```
    --domain-name example.com
```

The following is example output.

```
{
    "Addresses": [
        {
            "PublicIp": "192.0.2.0",
            "AllocationId": "eipalloc-abcdef01234567890",
            "PtrRecord": "example.net.",
            "PtrRecordUpdate": {
                "Value": "example.com.",
                "Status": "PENDING"
            }
        }
    ]
}
```

PowerShell

To create a reverse DNS record

Use the Edit-EC2AddressAttribute cmdlet.

```
Edit-EC2AddressAttribute `
    -AllocationId 'eipalloc-abcdef01234567890' `
    -DomainName 'example.com' |
Format-List `
    AllocationId, PtrRecord, PublicIp,
    @{Name='PtrRecordUpdate';Expression={$_.PtrRecordUpdate | Format-List | Out-
String}}
```

The following is example output.

```
AllocationId    : eipalloc-abcdef01234567890
PtrRecord       : example.net.
PublicIp        : 192.0.2.0
PtrRecordUpdate :
                  Reason :
                  Status : PENDING
                  Value  : example.com.
```

Remove a reverse DNS record

You can remove a reverse DNS record from your Elastic IP address as follows.

If you receive the following error, you can submit a Request to remove email sending restrictions to Support for assistance.

```
The address cannot be released because it is locked to your account.
```

Console

To remove a reverse DNS record

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address and choose **Actions**, **Update reverse DNS**.
4. For **Reverse DNS domain name**, clear the domain name.
5. Enter **`update`** to confirm.
6. Choose **Update**.

AWS CLI

To remove a reverse DNS record

Use the reset-address-attribute command.

```
aws ec2 reset-address-attribute \
    --allocation-id eipalloc-abcdef01234567890 \
    --attribute domain-name
```

The following is example output.

```
{
    "Addresses": [
        {
            "PublicIp": "192.0.2.0",
            "AllocationId": "eipalloc-abcdef01234567890",
            "PtrRecord": "example.com.",
            "PtrRecordUpdate": {
                "Value": "example.net.",
```

```
                "Status": "PENDING"
            }
        }
    ]
}
```

PowerShell

To remove a reverse DNS record

Use the Reset-EC2AddressAttribute cmdlet.

```
Reset-EC2AddressAttribute `
    -AllocationId 'eipalloc-abcdef01234567890' `
    -Attribute domain-name |
Format-List `
    AllocationId, PtrRecord, PublicIp,
    @{Name='PtrRecordUpdate';Expression={$_.PtrRecordUpdate | Format-List | Out-
String}}
```

The following is example output.

```
AllocationId    : eipalloc-abcdef01234567890
PtrRecord       : example.com.
PublicIp        : 192.0.2.0
PtrRecordUpdate :
                  Reason :
                  Status : PENDING
                  Value  : example.net.
```

Elastic network interfaces

An *elastic network interface* is a logical networking component in a VPC that represents a virtual network card. You can create and configure network interfaces and attach them to instances that you launch in the same Availability Zone. The attributes of a network interface follow it as it's attached or detached from an instance and reattached to another instance. When you move a network interface from one instance to another, network traffic is redirected from the original instance to the new instance.

Note that this AWS resource is referred to as a *network interface* in the AWS Management Console and the Amazon EC2 API. Therefore, we use "network interface" in this documentation instead of "elastic network interface". The term "network interface" in this documentation always means "elastic network interface".

Network interface attributes

A network interface can include the following attributes:

- A primary private IPv4 address from the IPv4 address range of your subnet
- A primary IPv6 address from the IPv6 address range of your subnet
- Secondary private IPv4 addresses from the IPv4 address range of your subnet
- One Elastic IP address (IPv4) for each private IPv4 address
- One public IPv4 address
- Secondary IPv6 addresses
- Security groups
- A MAC address
- A source/destination check flag
- A description

Monitoring traffic

You can enable a VPC flow log on your network interface to capture information about the traffic going to and from a network interface. After you've created a flow log, you can view and retrieve its data in Amazon CloudWatch Logs. For more information, see VPC Flow Logs in the *Amazon VPC User Guide*.

Contents

- Prefix delegation for Amazon EC2 network interfaces
- Delete a network interface

Network interface concepts

The following are important concepts to understand as you get started using network interfaces.

Primary network interface

Each instance has a default network interface, called the *primary network interface*. You can't detach a primary network interface from an instance.

Secondary network interfaces

You can create and attach secondary network interfaces to your instance. The maximum number of network interfaces varies by instance type. For more information, see Maximum IP addresses per network interface.

IPv4 addresses for network interfaces

When you launch an EC2 instance into an IPv4-only or dual stack subnet, the instance receives a primary private IP address from the IPv4 address range of the subnet. You can also specify additional private IPv4 addresses, known as secondary private IPv4 addresses. Unlike primary private IP addresses, secondary private IP addresses can be reassigned from one instance to another.

Public IPv4 addresses for network interfaces

All subnets have a modifiable attribute that determines whether network interfaces created in that subnet (and therefore instances launched into that subnet) are assigned a public IPv4 address. For more information, see Subnet settings in the *Amazon VPC User Guide*. When you launch an instance, the IP address is assigned to the primary network interface. If you specify an existing network interface as the primary network interface when you launch an instance, the public IPv4 address is determined by this network interface.

When you create a network interface, it inherits the public IPv4 addressing attribute from the subnet. If you later modify the public IPv4 addressing attribute of the subnet, the network interface keeps the setting that was in effect when it was created.

We release the public IP address when the instance is stopped, hibernated, or terminated. We assign a new public IP address when you start your stopped or hibernated instance, unless it has a secondary network interface or a secondary private IPv4 address that is associated with an Elastic IP address.

IPv6 addresses for network interfaces

If you associate IPv6 CIDR blocks with your VPC and subnet, you can assign IPv6 addresses from the subnet range to a network interface. Each IPv6 address can be assigned to one network interface.

All subnets have a modifiable attribute that determines whether network interfaces created in that subnet (and therefore instances launched into that subnet) are automatically assigned an IPv6 address from the range of the subnet. When you launch an instance, the IPv6 address is assigned to the primary network interface.

Elastic IP addresses for network interfaces

You can associate an Elastic IP address with one of the private IPv4 addresses for the network interface. You can associate one Elastic IP address with each private IPv4 address. If you disassociate an Elastic IP address from a network interface, you can release it or associate it with a different instance.

Termination behavior

You can set the termination behavior for a network interface that's attached to an instance. You can specify whether the network interface should be automatically deleted when you terminate the instance to which it's attached.

Source/destination checking

You can enable or disable source/destination checks, which ensure that the instance is either the source or the destination of any traffic that it receives. Source/destination checks are enabled by default. You must disable source/destination checks if the instance runs services such as network address translation, routing, or firewalls.

Requester-managed network interfaces

These network interfaces are created and managed by AWS services to enable you to use some resources and services. You can't manage these network interfaces yourself. For more information, see Requester-managed network interfaces.

Prefix delegation

A prefix is a reserved private IPv4 or IPv6 CIDR range that you allocate for automatic or manual assignment to network interfaces that are associated with an instance. By using Delegated Prefixes, you can launch services faster by assigning a range of IP addresses as a single prefix.

Managed network interfaces

A *managed network interface* is managed by a service provider, such as Amazon EKS Auto Mode. You can't directly modify the settings of a managed network interface. Managed network interface are identified by a **true** value in the **Managed** field. For more information, see Amazon EC2 managed instances.

Network cards

Most instance types support one network card. Instance types that support multiple network cards provide higher network performance, including bandwidth capabilities above 100 Gbps and improved packet rate performance. When you attach a network interface to an instance that supports multiple network cards, you can select the network card for the network interface. The primary network interface must be assigned to network card index 0.

EFA and EFA-only network interfaces count as a network interface. You can assign only one EFA or EFA-only network interface per network card. The primary network interface can't be an EFA-only network interface.

The following instance types support multiple network cards. For information about the number of network interfaces that an instance type supports, see Maximum IP addresses per network interface.

Instance type	Number of network cards
c6in.32xlarge	2
c6in.metal	2
c8gn.48xlarge	2
c8gn.metal-48xl	2
dl1.24xlarge	4
g6e.24xlarge	2
g6e.48xlarge	4
hpc6id.32xlarge	2

Instance type	Number of network cards
hpc7a.12xlarge	2
hpc7a.24xlarge	2
hpc7a.48xlarge	2
hpc7a.96xlarge	2
m6idn.32xlarge	2
m6idn.metal	2
m6in.32xlarge	2
m6in.metal	2
p4d.24xlarge	4
p4de.24xlarge	4
p5.48xlarge	32
p5e.48xlarge	32
p5en.48xlarge	16
p6-b200.48xlarge	8
p6e-gb200.36xlarge	17
r6idn.32xlarge	2
r6idn.metal	2
r6in.32xlarge	2
r6in.metal	2
trn1.32xlarge	8

Instance type	Number of network cards
trn1n.32xlarge	16
trn2.48xlarge	16
trn2u.48xlarge	16
u7in-16tb.224xlarge	2
u7in-24tb.224xlarge	2
u7in-32tb.224xlarge	2
u7inh-32tb.480xlarge	2

Maximum IP addresses per network interface

Each instance type supports a maximum number of network interfaces, maximum number of private IPv4 addresses per network interface, and maximum number of IPv6 addresses per network interface. The limit for IPv6 addresses is separate from the limit for private IPv4 addresses per network interface. Note that all instance types support IPv6 addressing except for the following: C1, M1, M2, M3, and T1.

Available network interfaces

The *Amazon EC2 Instance Types Guide* provides the information about the network interfaces available for each instance type. For more information, see the following:

- Network specifications – General purpose
- Network specifications – Compute optimized
- Network specifications – Memory optimized
- Network specifications – Storage optimized
- Network specifications – Accelerated computing
- Network specifications – High-performance computing
- Network specifications – Previous generation

Console

To retrieve the maximum network interfaces

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instance Types**.
3. Add a filter to specify the instance type (**Instance type=c5.12xlarge**) or instance family (**Instance family=c5**).
4. (Optional) Click the **Preferences** icon and then turn on **Maximum number of network interfaces**. This column indicates the maximum number of network interfaces for each instance type.
5. (Optional) Select the instance type. On the **Networking** tab, find **Maximum number of network interfaces**.

AWS CLI

To retrieve the maximum network interfaces

You can use the [describe-instance-types](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instance-types.html) command to display information about an instance type, such as its supported network interfaces and IP addresses per interface. The following example displays this information for all C5 instances.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=c5.*" \
    --query "InstanceTypes[].{ \
        Type: InstanceType, \
        MaxENI: NetworkInfo.MaximumNetworkInterfaces, \
        IPv4addr: NetworkInfo.Ipv4AddressesPerInterface}" \
    --output table
```

The following is example output.

```
---------------------------------------
|        DescribeInstanceTypes        |
+----------+----------+---------------+
| IPv4addr | MaxENI   |     Type      |
+----------+----------+---------------+
|  30      |  8       |  c5.4xlarge   |
|  50      |  15      |  c5.24xlarge  |
```

```
|  15       |  4        |  c5.xlarge    |
|  30       |  8        |  c5.12xlarge  |
|  10       |  3        |  c5.large     |
|  15       |  4        |  c5.2xlarge   |
|  50       |  15       |  c5.metal     |
|  30       |  8        |  c5.9xlarge   |
|  50       |  15       |  c5.18xlarge  |
+----------+----------+---------------+
```

PowerShell

To retrieve the maximum network interfaces

You can use the Get-EC2InstanceType PowerShell command to display information about an instance type, such as its supported network interfaces and IP addresses per interface. The following example displays this information for all C5 instances.

```
Get-EC2InstanceType -Filter @{Name="instance-type"; Values="c5.*"} | `
Select-Object `
    @{Name='Ipv4AddressesPerInterface';
 Expression={($_.Networkinfo.Ipv4AddressesPerInterface)}},
    @{Name='MaximumNetworkInterfaces';
 Expression={($_.Networkinfo.MaximumNetworkInterfaces)}},
    InstanceType | `
Format-Table -AutoSize
```

The following is example output.

```
Ipv4AddressesPerInterface MaximumNetworkInterfaces InstanceType
------------------------- ------------------------ ------------
                       30                        8 c5.4xlarge
                       15                        4 c5.xlarge
                       30                        8 c5.12xlarge
                       50                       15 c5.24xlarge
                       30                        8 c5.9xlarge
                       50                       15 c5.metal
                       15                        4 c5.2xlarge
                       10                        3 c5.large
                       50                       15 c5.18xlarge
```

Create a network interface for your EC2 instance

You can create a network interface for use by your EC2 instances. When you create a network interface, you specify the subnet for which it is created. You can't move a network interface to another subnet after it's created. You must attach a network interface to an instance in the same Availability Zone. You can detach a secondary network interface from an instance and then attach it to a different instance in the same Availability Zone. You can't detach a primary network interface from an instance. For more information, see the section called “Network interface attachments”.

Console

To create a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Choose **Create network interface**.
4. (Optional) For **Description**, enter a descriptive name.
5. For **Subnet**, select a subnet. The options available in the subsequent steps change depending on the type of subnet you select (IPv4-only, IPv6-only, or dual-stack (IPv4 and IPv6)).
6. For **Interface type**, choose one of the following:
   - **ENA**: A high-performance network interface designed to handle high throughput and packet-per-second rates for TCP/IP protocols while minimizing CPU usage. This is the default value. For more information about ENA, see Elastic Network Adapter.
   - **EFA with ENA**: A network interface that supports both ENA and EFA devices for traditional TCP/IP based transport along with SRD based transport. If you choose EFA with ENA, the instance you are attaching it to must support EFA. For more information about EFA, see Elastic Fabric Adapter.
   - **EFA-only**: A high-performance network interface designed to handle high throughput, low latency inter-node communication for SRD based transport while bypassing the operating system stack. If you choose this option, the instance you are attaching it to must support EFA. EFA-only network interfaces do not support IP addresses. For more information about EFA, see Elastic Fabric Adapter.
7. For **Private IPv4 address**, do one of the following:

- Choose **Auto-assign** to allow Amazon EC2 to select an IPv4 address from the subnet.
- Choose **Custom** and enter an IPv4 address that you select from the subnet.

8. (Subnets with IPv6 addresses only) For **IPv6 address**, do one of the following:
   - Choose **None** if you do not want to assign an IPv6 address to the network interface.
   - Choose **Auto-assign** to allow Amazon EC2 to select an IPv6 address from the subnet.
   - Choose **Custom** and enter an IPv6 address that you select from the subnet.
9. (Optional) If you're creating a network interface in a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. This assigns a primary IPv6 global unicast address (GUA) to the network interface. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if the instance that this ENI will be attached to relies on its IPv6 address not changing. AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you can't disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
10. (Optional) To create an Elastic Fabric Adapter, choose **Elastic Fabric Adapter**, **Enable**.
11. (Optional) Under **Advanced settings**, you can optionally set IP prefix delegation. For more information, see [Prefix delegation](#).

    - **Auto-assign** — AWS chooses the prefix from the IPv4 or IPv6 CIDR blocks for the subnet, and assigns it to the network interface.
    - **Custom** — You specify the prefix from the IPv4 or IPv6 CIDR blocks for the subnet, and AWS verifies that the prefix is not already assigned to other resources before assigning it to the network interface.
12. (Optional) Under **Advanced settings**, for **Idle connection tracking timeout**, modify the default idle connection timeouts. For more information, see [Idle connection tracking timeout](#).

    - **TCP established timeout**: Timeout (in seconds) for idle TCP connections in an established state.
      - Min: `60` seconds
      - Max: `432000` seconds

    - Default: `350` seconds for [Nitrov6](#) instance types, excluding P6e-GB200. And `432000` seconds for other instance types, including P6e-GB200.
    - Recommended: Less than `432000` seconds
  - **UDP timeout**: Timeout (in seconds) for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction.
    - Min: `30` seconds
    - Max: `60` seconds
    - Default: `30` seconds
  - **UDP stream timeout**: Timeout (in seconds) for idle UDP flows classified as streams which have seen more than one request-response transaction.
    - Min: `60` seconds
    - Max: `180` seconds
    - Default: `180` seconds

13. For **Security groups**, select one or more security groups.
14. (Optional) For each tag, choose **Add new tag** and enter a tag key and an optional tag value.
15. Choose **Create network interface**.

AWS CLI

Example 1: To create a network interface with IP addresses chosen by Amazon EC2

Use the following create-network-interface command. This example creates a network interface with a public IPv4 address and an IPv6 address chosen by Amazon EC2.

```
aws ec2 create-network-interface \
    --subnet-id subnet-0abcdef1234567890 \
    --description "my dual-stack network interface" \
    --ipv6-address-count 1 \
    --groups sg-1234567890abcdef0
```

Example 2: To create a network interface with specific IP addresses

Use the following create-network-interface command.

```
aws ec2 create-network-interface \
    --subnet-id subnet-0abcdef1234567890 \
```

```
    --description "my dual-stack network interface" \
    --private-ip-address 10.251.50.12 \
    --ipv6-addresses 2001:db8::1234:5678:1.2.3.4 \
    --groups sg-1234567890abcdef0
```

Example 3: To create a network interface with a count of secondary IP addresses

Use the following create-network-interface command. In this example, Amazon EC2 chooses both the primary IP address and the secondary IP addresses.

```
aws ec2 create-network-interface \
    --subnet-id subnet-0abcdef1234567890 \
    --description "my network interface" \
    --secondary-private-ip-address-count 2 \
    --groups sg-1234567890abcdef0
```

Example 4: To create a network interface with a specific secondary IP address

Use the following create-network-interface command. This example specifies a primary IP address and a secondary IP address.

```
aws ec2 create-network-interface \
    --subnet-id subnet-0abcdef1234567890 \
    --description "my network interface" \
    --private-ip-addresses PrivateIpAddress=10.0.1.30,Primary=true \
                           PrivateIpAddress=10.0.1.31,Primary=false
    --groups sg-1234567890abcdef0
```

PowerShell

Example 1: To create a network interface with IP addresses chosen by Amazon EC2

Use the New-EC2NetworkInterface cmdlet. This example creates a network interface with a public IPv4 address and an IPv6 address chosen by Amazon EC2.

```
New-EC2NetworkInterface `
    -SubnetId subnet-0abcdef1234567890 `
    -Description "my dual-stack network interface" `
    -Ipv6AddresCount 1 `
    -Group sg-1234567890abcdef0
```

Example 2: To create a network interface with specific IP addresses

Use the New-EC2NetworkInterface cmdlet.

```
New-EC2NetworkInterface `
    -SubnetId subnet-0abcdef1234567890 `
    -Description "my dual-stack network interface" `
    -PrivateIpAddress 10.251.50.12 `
    -Ipv6Address $ipv6addr `
    -Group sg-1234567890abcdef0
```

Define the IPv6 addresses as follows.

```
$ipv6addr = New-Object Amazon.EC2.Model.InstanceIpv6Address
$ipv6addr1.Ipv6Address = "2001:db8::1234:5678:1.2.3.4"
```

Example 3: To create a network interface with a count of secondary IP addresses

Use the New-EC2NetworkInterface cmdlet. In this example, Amazon EC2 chooses both the primary IP address and the secondary IP addresses.

```
New-EC2NetworkInterface `
    -SubnetId subnet-0abcdef1234567890 `
    -Description "my network interface" `
    -SecondaryPrivateIpAddressCount 2 `
    -Group sg-1234567890abcdef0
```

Example 4: To create a network interface with a specific secondary IP address

Use the New-EC2NetworkInterface cmdlet. This example specifies a primary IP address and a secondary IP address.

```
New-EC2NetworkInterface `
    -SubnetId subnet-0abcdef1234567890 `
    -Description "my network interface" `
    -PrivateIpAddresses @($primary, $secondary) `
    -Group sg-1234567890abcdef0
```

Define the secondary addresses as follows.

```
$primary = New-Object Amazon.EC2.Model.PrivateIpAddressSpecification
$primary.PrivateIpAddress = "10.0.1.30"
```

```
$primary.Primary = $true
$secondary = New-Object Amazon.EC2.Model.PrivateIpAddressSpecification
$secondary.PrivateIpAddress = "10.0.1.31"
$secondary.Primary = $false
```

Network interface attachments for your EC2 instance

You can create network interfaces to be used by your EC2 instances as primary or secondary network interfaces. You must attach a network interface to an EC2 instance if it is in the same Availability Zone as the network interface. The instance type of an instance determines how many network interfaces you can attach to the instance. For more information, see the section called "IP addresses per network interface".

Considerations

- You can attach a network interface to an instance when it's running (hot attach), when it's stopped (warm attach), or when the instance is being launched (cold attach).
- You can detach secondary network interfaces when the instance is running or stopped. However, you can't detach the primary network interface.
- You can detach a secondary network interface from one instance and attach it to another instance.
- When launching an instance using the CLI, API, or an SDK, you can specify the primary network interface and additional network interfaces. Note that you can't enable the auto-assignment of public IPv4 addresses if you add a secondary network interface during launch.
- Launching an Amazon Linux or Windows Server instance with multiple network interfaces automatically configures interfaces, private IPv4 addresses, and route tables on the operating system of the instance.
- A warm or hot attach of an additional network interface might require you to manually bring up the second interface, configure the private IPv4 address, and modify the route table accordingly. Instances running Amazon Linux or Windows Server automatically recognize the warm or hot attach and configure themselves.
- You can't attach another network interface to an instance (for example, a NIC teaming configuration) to increase or double the network bandwidth to or from the dual-homed instance.
- If you attach multiple network interfaces from the same subnet to an instance, you might encounter networking issues such as asymmetric routing. If possible, add a secondary private IPv4 address on the primary network interface instead.

- For EC2 instances in an IPv6-only subnet, if you attach a secondary network interface, the private DNS hostname of the secondary network interface resolves to the primary IPv6 address for the primary network interface.
- [Windows instances] – If you add multiple network interfaces to an instance, you must configure the network interfaces to use static routing.

Attach a network interface

You can attach a network interface to any instance in the same Availability Zone as the network interface, using either the **Instances** or **Network Interfaces** page of the Amazon EC2 console. Alternatively, you can specify existing network interfaces when you launch instances.

If the public IPv4 address on your instance is released, it does not receive a new one if there is more than one network interface attached to the instance. For more information about the behavior of public IPv4 addresses, see Public IPv4 addresses.

Console

To attach a network interface using the Instances page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the checkbox for the instance.
4. Choose **Actions**, **Networking**, **Attach network interface**.
5. Choose a VPC. The network interface can reside in the same VPC as your instance or in a different VPC that you own, as long as the network interface is in the same Availability Zone as the instance. This enables you to create multi-homed instances across VPCs with different networking and security configurations.
6. Select a network interface. If the instance supports multiple network cards, you can choose a network card.
7. Choose **Attach**.

To attach a network interface using the Network Interfaces page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.

3. Select the checkbox for the network interface.
4. Choose **Actions**, **Attach**.
5. Choose an instance. If the instance supports multiple network cards, you can choose a network card.
6. Choose **Attach**.

AWS CLI

To attach a network interface

Use the following attach-network-interface command.

```
aws ec2 attach-network-interface \
    --network-interface-id eni-1234567890abcdef0 \
    --instance-id i-1234567890abcdef0 \
    --device-index 1
```

PowerShell

To attach a network interface

Use the Add-EC2NetworkInterface cmdlet.

```
Add-EC2NetworkInterface `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -InstanceId i-1234567890abcdef0 `
    -DeviceIndex 1
```

Detach a network interface

You can detach a secondary network interface that is attached to an EC2 instance at any time, using either the **Instances** or **Network Interfaces** page of the Amazon EC2 console.

If you try to detach a network interface that is attached to a resource from another service, such as an Elastic Load Balancing load balancer, a Lambda function, a WorkSpace, or a NAT gateway, you get an error that you do not have permission to access the resource. To find which service created the resource attached to a network interface, check the description of the network interface. If you delete the resource, then its network interface is deleted.

Console

To detach a network interface using the Instances page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the checkbox for the instance. Check the **Network interfaces** section of the **Networking** tab to verify that the network interface is attached to an instance as a secondary network interface.
4. Choose **Actions**, **Networking**, **Detach network interface**.
5. Select the network interface and choose **Detach**.

To detach a network interface using the Network Interfaces page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface. Check the **Instance details** section of the **Details** tab to verify that the network interface is attached to an instance as a secondary network interface.
4. Choose **Actions**, **Detach**.
5. When prompted for confirmation, choose **Detach**.
6. If the network interface fails to detach from the instance, choose **Force detachment**, **Enable** and then try again. We recommend that force detachment only as a last resort. Forcing a detachment can prevent you from attaching a different network interface on the same index until you restart the instance. It can also prevent the instance metadata from reflecting that the network interface was detached until you restart the instance.

AWS CLI

To detach a network interface

Use the following detach-network-interface command.

```
aws ec2 detach-network-interface --attachment-id eni-attach-016c93267131892c9
```

PowerShell

To detach a network interface

Use the Dismount-EC2NetworkInterface cmdlet.

```
Dismount-EC2NetworkInterface -AttachmentId eni-attach-016c93267131892c9
```

Manage the IP addresses for your network interface

You can manage the following IP addresses for your network interfaces:

- Elastic IP addresses (one per private IPv4 address)
- IPv4 addresses
- IPv6 addresses

Console

To manage the IP addresses of a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface.
4. To manage the IPv4 and IPv6 addresses, do the following:

   a. Choose **Actions**, **Manage IP addresses**.
   b. Expand the network interface.
   c. For **IPv4 addresses**, edit the IP addresses as needed. To assign an additional IPv4 address, choose **Assign new IP address** and then specify an IPv4 address from the subnet range or let AWS choose one for you.
   d. (Dual stack or IPv6 only) For **IPv6 addresses**, edit the IP addresses as needed. To assign an additional IPv6 address, choose **Assign new IP address** and then specify an IPv6 address from the subnet range or let AWS choose one for you.
   e. To assign or unassign a public IPv4 address to a network interface, choose **Auto-assign public IP**. You can enable or disable this for any network interface, but it only affects the primary network interface.

f. (Dual stack or IPv6-only) For **Assign primary IPv6 IP**, choose **Enable** to assign a primary IPv6 address. The first GUA associated with the network interface is chosen as the primary IPv6 address. After you assign a primary IPv6 address, you can't change it. This address is the primary IPv6 address until the instance is terminated or the network interface is detached.

g. Choose **Save**.

5. To associate an Elastic IP address, do the following:

   a. Choose **Actions**, **Associate address**.
   b. For **Elastic IP address**, select the Elastic IP address.
   c. For **Private IPv4 address**, select the private IPv4 address to associate with the Elastic IP address.
   d. (Optional) Choose **Allow the Elastic IP address to be reassociated** if the network interface is currently associated with another instance or network interface.
   e. Choose **Associate**.

6. To disassociate an Elastic IP address, do the following:

   a. Choose **Actions**, **Disassociate address**.
   b. For **Public IP address**, select the Elastic IP address.
   c. Choose **Disassociate**.

AWS CLI

To manage the IPv4 addresses

Use the following assign-private-ip-addresses command to assign an IPv4 address.

```
aws ec2 assign-private-ip-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --private-ip-addresses 10.0.0.82
```

Use the following unassign-private-ip-addresses command to unassign an IPv4 address.

```
aws ec2 unassign-private-ip-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --private-ip-addresses 10.0.0.82
```

To manage the IPv6 addresses

Use the following assign-ipv6-addresses command to assign an IPv6 address.

```
aws ec2 assign-ipv6-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --ipv6-addresses 2001:db8:1234:1a00:9691:9503:25ad:1761
```

Use the following unassign-ipv6-addresses command to unassign an IPv6 address.

```
aws ec2 unassign-ipv6-addresses \
    --network-interface-id eni-1234567890abcdef0 \
    --ipv6-addresses 2001:db8:1234:1a00:9691:9503:25ad:1761
```

To manage the Elastic IP address for the primary private IPv4 address

Use the following associate-address command to associate an Elastic IP address with the primary private IPv4 address.

```
aws ec2 associate-address \
    --allocation-id eipalloc-0b263919b6EXAMPLE \
    --network-interface-id eni-1234567890abcdef0
```

Use the following disassociate-address command to disassociate an Elastic IP address from the primary private IPv4 address.

```
aws ec2 disassociate-address --association-id eipassoc-2bebb745a1EXAMPLE
```

PowerShell

To manage the IPv4 addresses

Use the Register-EC2PrivateIpAddress cmdlet to assign an IPv4 address.

```
Register-EC2PrivateIpAddress `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -PrivateIpAddress 10.0.0.82
```

Use the Unregister-EC2PrivateIpAddress cmdlet to unassign an IPv4 address.

```
Unregister-EC2PrivateIpAddress `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -PrivateIpAddress 10.0.0.82
```

To manage the IPv6 addresses

Use the Register-EC2Ipv6AddressList cmdlet to assign an IPv6 address.

```
Register-EC2Ipv6AddressList `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Ipv6Address 2001:db8:1234:1a00:9691:9503:25ad:1761
```

Use the Unregister-EC2Ipv6AddressList cmdlet to unassign an IPv6 address.

```
Unregister-EC2Ipv6AddressList `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Ipv6Address 2001:db8:1234:1a00:9691:9503:25ad:1761
```

To manage the Elastic IP address for the primary private IPv4 address

Use the Register-EC2Address cmdlet to associate an Elastic IP address with the primary private IPv4 address.

```
Register-EC2Address `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -AllocationId eipalloc-0b263919b6EXAMPLE
```

Use the Unregister-EC2Address cmdlet to disassociate an Elastic IP address from the primary private IPv4 address.

```
Unregister-EC2Address -AssociationId eipassoc-2bebb745a1EXAMPLE
```

Modify network interface attributes

You can change the following network interface attributes:

- Description

- Security groups
- Delete on termination
- Source/destination check
- Idle connection tracking timeout

Considerations

You can't change the attributes of a requester-managed network interface.

Console

To modify network interface attributes

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface.
4. To change the description, do the following
   a. Choose **Actions**, **Change description**.
   b. For **Description**, enter a description.
   c. Choose **Save**.
5. To change the security groups, do the following:
   a. Choose **Actions**, **Change security groups**.
   b. For **Associated security groups**, add and remove security groups as needed. The security group and network interface must be created for the same VPC.
   c. Choose **Save**.
6. To change the termination behavior, do the following:
   a. Choose **Actions**, **Change termination behavior**.
   b. Select or clear **Delete on termination**, **Enable**.
   c. Choose **Save**.
7. To change source/destination checking, do the following:
   a. Choose **Actions**, **Change source/dest check**.
   b. Select or clear **Source/destination check**, **Enable**.

c. Choose **Save**.

8. To change idle connection tracking timeouts, do the following:

   a. Choose **Actions**, **Modify idle connection tracking timeout**.

   b. Modify timeout values as needed. For more information, see Idle connection tracking timeout.

      - **TCP established timeout**: Timeout (in seconds) for idle TCP connections in an established state.
        - Min: `60` seconds
        - Max: `432000` seconds
        - Default: `350` seconds for Nitrov6 instance types, excluding P6e-GB200. And `432000` seconds for other instance types, including P6e-GB200.
        - Recommended: Less than `432000` seconds
      - **UDP timeout**: Timeout (in seconds) for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction.
        - Min: `30` seconds
        - Max: `60` seconds
        - Default: `30` seconds
      - **UDP stream timeout**: Timeout (in seconds) for idle UDP flows classified as streams which have seen more than one request-response transaction.
        - Min: `60` seconds
        - Max: `180` seconds
        - Default: `180` seconds

   c. Choose **Save**.

AWS CLI

Example Example: To modify the description

Use the following modify-network-interface-attribute command.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --description "my updated description"
```

Example Example: To modify the security groups

Use the following modify-network-interface-attribute command.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --groups sg-1234567890abcdef0
```

Example Example: To modify the termination behavior

Use the following modify-network-interface-attribute command.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --attachment AttachmentId=eni-attach-43348162abEXAMPLE,DeleteOnTermination=false
```

Example Example: To enable source/destination checking

Use the following modify-network-interface-attribute command.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --source-dest-check
```

Example Example: To modify idle connection tracking timout

Use the following modify-network-interface-attribute command. For more information, see Idle connection tracking timeout.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --connection-tracking-specification
 TcpEstablishedTimeout=172800,UdpStreamTimeout=90,UdpTimeout=60
```

PowerShell

Example Example: To modify the description

Use the Edit-EC2NetworkInterfaceAttribute cmdlet.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-1234567890abcdef0 `
```

```
    -Description "my updated description"
```

Example Example: To modify the security groups

Use the Edit-EC2NetworkInterfaceAttribute cmdlet.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Group sg-1234567890abcdef0
```

Example Example: To modify the termination behavior

Use the Edit-EC2NetworkInterfaceAttribute cmdlet.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -Attachment_AttachmentId eni-attach-43348162abEXAMPLE `
    -Attachment_DeleteOnTermination $false
```

Example Example: To enable source/destination checking

Use the Edit-EC2NetworkInterfaceAttribute cmdlet.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -SourceDestCheck $true
```

Example Example: To modify idle connection tracking timeouts

Use the Edit-EC2NetworkInterfaceAttribute cmdlet. For more information, see Idle connection tracking timeout.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -ConnectionTrackingSpecification_TcpEstablishedTimeout 172800 `
    -ConnectionTrackingSpecification_UdpStreamTimeout 90 `
    -ConnectionTrackingSpecification_UdpTimeout 60
```

Multiple network interfaces for your Amazon EC2 instances

Attaching multiple network interfaces to an instance is useful when you need the following:

- A management network.
- Network and security appliances.
- Dual-homed instances with workloads in different subnets or VPCs.
- A low-budget, high-availability solution.

Management network

The following overview describes a management network created using multiple network interfaces.

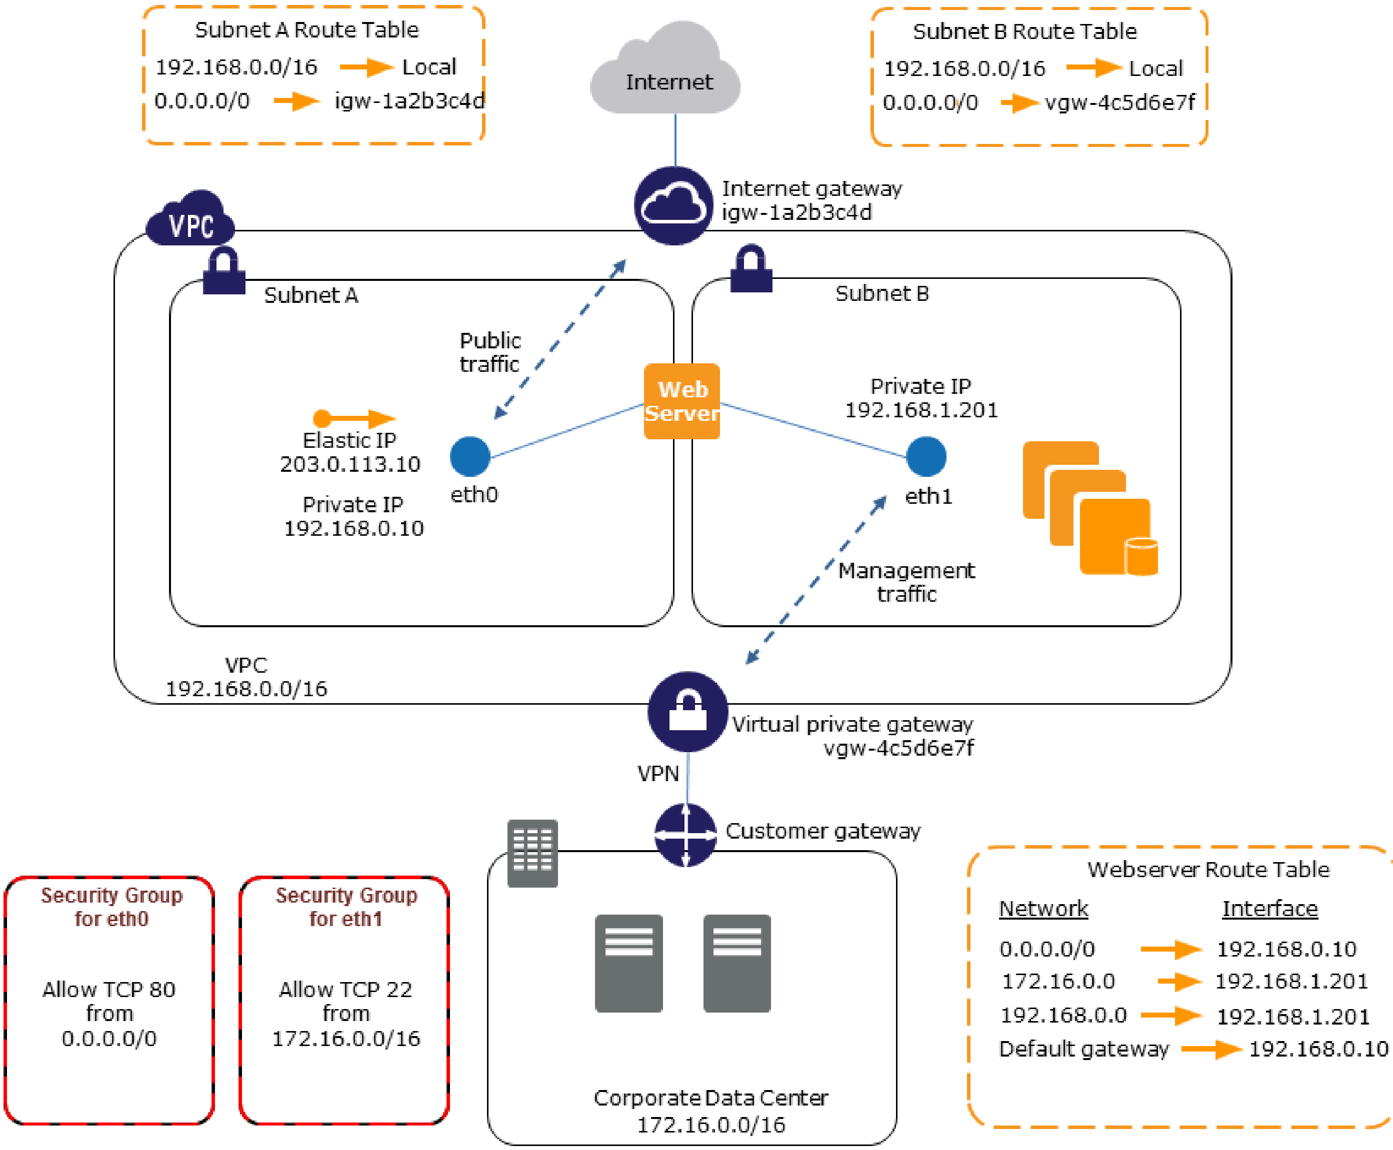
Criteria

- The primary network interface on the instance (for example, eth0) handles public traffic.
- The secondary network interface on the instance (for example, eth1) handles backend management traffic. It's connected to a separate subnet that has more restrictive access controls, and is located within the same Availability Zone as the primary network interface.

Settings

- The primary network interface, which may or may not be behind a load balancer, has an associated security group that allows access to the server from the internet. For example, allow TCP port 80 and 443 from 0.0.0.0/0 or from the load balancer.
- The secondary network interface has an associated security group that allows SSH access only, initiated from one of the following locations:
  - An allowed range of IP addresses, either within the VPC, or from the internet.
  - A private subnet within the same Availability Zone as the primary network interface.
  - A virtual private gateway.

> **Note**
>
> To ensure failover capabilities, consider using a secondary private IPv4 for incoming traffic on a network interface. In the event of an instance failure, you can move the interface and/or secondary private IPv4 address to a standby instance.



Network and security appliances

Some network and security appliances, such as load balancers, network address translation (NAT) servers, and proxy servers prefer to be configured with multiple network interfaces. You can create and attach secondary network interfaces to instances that are running these types of applications and configure the additional interfaces with their own public and private IP addresses, security groups, and source/destination checking.

Dual-homed instances with workloads in different subnets

You can place a network interface on each of your web servers that connects to a mid-tier network where an application server resides. The application server can also be dual-homed to a backend network (subnet) where the database server resides. Instead of routing network packets through the dual-homed instances, each dual-homed instance receives and processes requests on the front end, initiates a connection to the backend, and then sends requests to the servers on the backend network.

Dual-homed instances with workloads in different VPCs in the same account

You can launch an EC2 instance in one VPC and attach a secondary ENI from a different VPC, as long as the network interface is in the same Availability Zone as the instance. This enables you to create multi-homed instances across VPCs with different networking and security configurations. You can't create multi-homed instances across VPCs in different AWS accounts.

You can use dual-homed instances across VPCs in the following use cases:

- **Overcome CIDR overlaps between two VPCs that can’t be peered together**: You can leverage a secondary CIDR in a VPC and allow an instance to communicate across two non-overlapping IP ranges.
- **Connect multiple VPCs within a single account**: Enable communication between individual resources that would normally be separated by VPC boundaries.

Low-budget, high-availability solution

If one of your instances serving a particular function fails, its network interface can be attached to a replacement or hot standby instance pre-configured for the same role in order to rapidly recover the service. For example, you can use a network interface as your primary or secondary network interface to a critical service such as a database instance or a NAT instance. If the instance fails, you (or more likely, the code running on your behalf) can attach the network interface to a hot standby instance. Because the interface maintains its private IP addresses, Elastic IP addresses, and MAC address, network traffic begins flowing to the standby instance as soon as you attach the network interface to the replacement instance. Users experience a brief loss of connectivity between the time the instance fails and the time that the network interface is attached to the standby instance, but no changes to the route table or your DNS server are required.

Requester-managed network interfaces

A requester-managed network interface is a network interface that an AWS service creates in your VPC on your behalf. The network interface is associated with a resource for another service, such as a DB instance from Amazon RDS, a NAT gateway, or an interface VPC endpoint from AWS PrivateLink.

Considerations

- You can view the requester-managed network interfaces in your account. You can add or remove tags, but you can't change other properties of a requester-managed network interface.
- You can't detach a requester-managed network interface.
- When you delete the resource associated with a requester-managed network interface, the AWS service detaches the network interface and deletes it. If the service detached a network interface but didn't delete it, you can delete the detached network interface.

Console

To view requester-managed network interfaces

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network & Security**, **Network Interfaces**.
3. Select the ID of the network interface to open its details page.
4. The following are the key fields that you can use to determine the purpose of the network interface:

   - **Description**: A description provided by the AWS service that created the interface. For example, "VPC Endpoint Interface vpce 089f2123488812123".
   - **Requester-managed**: Indicates whether the network interface is managed by AWS.
   - **Requester ID**: The alias or AWS account ID of the principal or service that created the network interface. If you created the network interface, this is your AWS account ID. Otherwise, another principal or service created it.

AWS CLI

To view requester-managed network interfaces

Use the describe-network-interfaces command as follows.

```
aws ec2 describe-network-interfaces \
    --filters "Name=requester-managed,Values=true" \
    --query "NetworkInterfaces[*].[Description, InterfaceType]" \
    --output table
```

The following is example output that shows the key fields that you can use to determine the purpose of the network interface: `Description` and `InterfaceType`.

```
-------------------------------------------------------------------------------
|                          DescribeNetworkInterfaces                          |
+---------------------------------------------------+-------------------------+
|  VPC Endpoint Interface: vpce-0f00567fa8477a1e6   |  interface              |
|  VPC Endpoint Interface vpce-0d8ddce4be80e4474    |  interface              |
|  VPC Endpoint Interface vpce-078221a1e27d1ea5b    |  vpc_endpoint           |
|  Resource Gateway Interface rgw-0bba03f3d56060135 |  interface              |
|  VPC Endpoint Interface: vpce-0cc199f605eaeace7   |  interface              |
|  VPC Endpoint Interface vpce-019b90d6f16d4f958    |  interface              |
+---------------------------------------------------+-------------------------+
```

PowerShell

To view requester-managed network interfaces

Use the Get-EC2NetworkInterface cmdlet as follows.

```
Get-EC2NetworkInterface -Filter @{Name="requester-managed"; Values="true"} | Select
 Description, InterfaceType
```

The following is example output that shows the key fields that you can use to determine the purpose of a network interface: `Description` and `InterfaceType`.

```
Description                                        InterfaceType
-----------                                        -------------
VPC Endpoint Interface: vpce-0f00567fa8477a1e6   interface
VPC Endpoint Interface vpce-0d8ddce4be80e4474    interface
VPC Endpoint Interface vpce-078221a1e27d1ea5b    vpc_endpoint
Resource Gateway Interface rgw-0bba03f3d56060135 interface
VPC Endpoint Interface: vpce-0cc199f605eaeace7   interface
VPC Endpoint Interface vpce-019b90d6f16d4f958    interface
```

Prefix delegation for Amazon EC2 network interfaces

You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces. By assigning prefixes, you scale and simplify the management of applications, including container and networking applications that require multiple IP addresses on an instance. For more information about IPv4 and IPv6 addresses, see Amazon EC2 instance IP addressing.

The following assignment options are available:

- **Automatic assignment** — AWS chooses the prefix and assigns it to your network interface. If the subnet for the network interface has a subnet CIDR reservation of type `prefix`, we select the prefixes from the subnet CIDR reservation. Otherwise, we select them from the subnet CIDR range.
- **Manual assignment** — You specify the prefix and AWS verifies that it is not already assigned to other resources before assigning it to your network interface.

Assigning prefixes has the following benefits:

- Increased IP addresses on a network interface — When you use a prefix, you assign a block of IP addresses as opposed to individual IP addresses. This increases the number of IP addresses for a network interface.
- Simplified VPC management for containers — In container applications, each container requires a unique IP address. Assigning prefixes to your instance simplifies the management of your VPCs, as you can launch and terminate containers without having to call Amazon EC2 APIs for individual IP assignments.

Contents

Basics

- You can assign a prefix to new or existing network interfaces.
- To use prefixes, you assign a prefix to your network interface, attach the network interface to your instance, and then configure your operating system.
- When you choose the option to specify a prefix, the prefix must meet the following requirements:
  - The IPv4 prefix that you can specify is `/28`.
  - The IPv6 prefix that you can specify is `/80`.
  - The prefix is in the subnet CIDR of the network interface, and does not overlap with other prefixes or IP addresses assigned to existing resources in the subnet.
- You can assign a prefix to the primary or secondary network interface.
- You can assign an Elastic IP address to a network interface that has a prefix assigned to it.
- You can also assign an Elastic IP address to the IP address part of the assigned prefix.
- We resolve the private DNS host name of an instance to the primary private IPv4 address.
- We assign each private IPv4 address for a network interface, including those from prefixes, using the following format:
  - `us-east-1` Region

    ```
    ip-private-ipv4-address.ec2.internal
    ```

  - All other Regions

    ```
    ip-private-ipv4-address.region.compute.internal
    ```

Considerations

Take the following into consideration when you use prefixes:

- Network interfaces with prefixes are supported with Nitro-based instances.
- Prefixes for network interfaces must use IPv6 addresses or private IPv4 addresses.
- The maximum number of IP addresses that you can assign to a network interface depends on the instance type. Each prefix that you assign to a network interface counts as one IP address. For example, a `c5.large` instance has a limit of `10` IPv4 addresses per network interface. Each

network interface for this instance has a primary IPv4 address. If a network interface has no secondary IPv4 addresses, you can assign up to 9 prefixes to the network interface. For each additional IPv4 address that you assign to a network interface, you can assign one less prefix to the network interface. For more information, see Maximum IP addresses per network interface.

- Prefixes are included in source/destination checks.
- You must configure your operating system to work with network interfaces with prefixes. Note the following:
  - Some Amazon Linux AMIs contain additional scripts installed by AWS, known as `ec2-net-utils`. These scripts optionally automate the configuration of your network interfaces. They are for use only on Amazon Linux.
  - For containers, you can use a Container Network Interface (CNI) for the Kubernetes plug-in, or `dockerd` if you use Docker to manage your containers.

Manage prefixes for your network interfaces

When you assign prefixes to a network interface, you can choose whether to let us automatically assign the prefixes or you can specify custom prefixes. If you let us automatically assign prefixes and the subnet for the network interface has a subnet CIDR reservation of type `prefix`, we select the prefixes from the subnet CIDR reservation. Otherwise, we select them from the subnet CIDR range.

Tasks

- Assign prefixes during network interface creation
- Assign prefixes to an existing network interface
- Remove prefixes from your network interfaces

Assign prefixes during network interface creation

You can assign automatic or custom prefixes when you create a network interface.

Console

To assign automatic prefixes during network interface creation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.

3. Choose **Create network interface**.
4. Enter a description for the network interface, select the subnet in which to create the network interface, and configure the private IPv4 and IPv6 addresses.
5. Expand **Advanced settings**.
6. For **IPv4 prefix delegation** do one of the following:
   - To automatically assign an IPv4 prefix, choose **Auto-assign**. For **Number of IPv4 prefixes**, enter the number of prefixes to assign.
   - To assign a specific IPv4 prefix, choose **Custom**. Choose **Add new prefix** and enter the prefix.
7. For **IPv6 prefix delegation** do one of the following:
   - To automatically assign an IPv6 prefix, choose **Auto-assign**. For **Number of IPv6 prefixes**, enter the number of prefixes to assign.
   - To assign a specific IPv6 prefix, choose **Custom**. Choose **Add new prefix** and enter the prefix.

   > **Note**
   >
   > **IPv6 prefix delegation** appears only if the selected subnet is enabled for IPv6.

8. Select the security groups to associate with the network interface and assign resource tags if needed.
9. Choose **Create network interface**.

AWS CLI

To assign automatic IPv4 prefixes during network interface creation

Use the create-network-interface command and set `--ipv4-prefix-count` to the number of IPv4 prefixes for AWS to assign. In the following example, AWS assigns one IPv4 prefix.

```
aws ec2 create-network-interface \
--subnet-id subnet-047cfed18eEXAMPLE \
--description "IPv4 automatic example" \
--ipv4-prefix-count 1
```

To assign specific IPv4 prefixes during network interface creation

Use the create-network-interface command and set `--ipv4-prefixes` to the prefixes. AWS selects IPv4 addresses from this range. In the following example, the prefix CIDR is 10.0.0.208/28.

```
aws ec2 create-network-interface \
    --subnet-id subnet-047cfed18eEXAMPLE \
    --description "IPv4 manual example" \
    --ipv4-prefixes Ipv4Prefix=10.0.0.208/28
```

To assign automatic IPv6 prefixes during network interface creation

Use the create-network-interface command and set `--ipv6-prefix-count` to the number of IPv6 prefixes for AWS to assign. In the following example, AWS assigns one IPv6 prefix.

```
aws ec2 create-network-interface \
--subnet-id subnet-047cfed18eEXAMPLE \
--description "IPv6 automatic example" \
--ipv6-prefix-count 1
```

To assign specific IPv6 prefixes during network interface creation

Use the create-network-interface command and set `--ipv6-prefixes` to the prefixes. AWS selects IPv6 addresses from this range. In the following example, the prefix CIDR is 2600:1f13:fc2:a700:1768::/80.

```
aws ec2 create-network-interface \
    --subnet-id subnet-047cfed18eEXAMPLE \
    --description "IPv6 manual example" \
    --ipv6-prefixes Ipv6Prefix=2600:1f13:fc2:a700:1768::/80
```

PowerShell

To assign automatic IPv4 prefixes during network interface creation

Use the New-EC2NetworkInterface cmdlet and set `Ipv4PrefixCount` to the number of IPv4 prefixes for AWS to assign. In the following example, AWS assigns one IPv4 prefix.

```
New-EC2NetworkInterface `
    -SubnetId 'subnet-047cfed18eEXAMPLE' `
    -Description 'IPv4 automatic example' `
    -Ipv4PrefixCount 1
```

To assign specific IPv4 prefixes during network interface creation

Use the [New-EC2NetworkInterface] cmdlet and set `Ipv4Prefix` to the prefixes. AWS selects IPv4 addresses from this range. In the following example, the prefix CIDR is 10.0.0.208/28.

```
Import-Module AWS.Tools.EC2
New-EC2NetworkInterface `
    -SubnetId 'subnet-047cfed18eEXAMPLE' `
    -Description 'IPv4 manual example' `
    -Ipv4Prefix (New-Object `
        -TypeName Amazon.EC2.Model.Ipv4PrefixSpecificationRequest `
        -Property @{Ipv4Prefix = '10.0.0.208/28'})
```

To assign automatic IPv6 prefixes during network interface creation

Use the [New-EC2NetworkInterface] cmdlet and set `Ipv6PrefixCount` to the number of IPv6 prefixes for AWS to assign. In the following example, AWS assigns one IPv6 prefix.

```
New-EC2NetworkInterface `
    -SubnetId 'subnet-047cfed18eEXAMPLE' `
    -Description 'IPv6 automatic example' `
    -Ipv6PrefixCount 1
```

To assign specific IPv6 prefixes during network interface creation

Use the [New-EC2NetworkInterface] cmdlet and set `Ipv6Prefixes` to the prefixes. AWS selects IPv6 addresses from this range. In the following example, the prefix CIDR is 2600:1f13:fc2:a700:1768::/80.

```
Import-Module AWS.Tools.EC2
New-EC2NetworkInterface `
    -SubnetId 'subnet-047cfed18eEXAMPLE' `
    -Description 'IPv6 manual example' `
    -Ipv6Prefix (New-Object `
        -TypeName Amazon.EC2.Model.Ipv6PrefixSpecificationRequest `
        -Property @{Ipv6Prefix = '2600:1f13:fc2:a700:1768::/80'})
```

Assign prefixes to an existing network interface

You can assign automatic or custom prefixes to an existing network interface.

Console

To assign automatic prefixes to an existing network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface to which to assign the prefixes, and choose **Actions**, **Manage prefixes**.
4. For **IPv4 prefix delegation** do one of the following:
   - To automatically assign an IPv4 prefix, choose **Auto-assign**. For **Number of IPv4 prefixes**, enter the number of prefixes to assign.
   - To assign a specific IPv4 prefix, choose **Custom**. Choose **Add new prefix** and enter the prefix.
5. For **IPv6 prefix delegation** do one of the following:
   - To automatically assign an IPv6 prefix, choose **Auto-assign**. For **Number of IPv6 prefixes**, enter the number of prefixes to assign.
   - To assign a specific IPv6 prefix, choose **Custom**. Choose **Add new prefix** and enter the prefix.

   > **Note**
   >
   > **IPv6 prefix delegation** appears only if the selected subnet is enabled for IPv6.

6. Choose **Save**.

AWS CLI

Use the assign-ipv6-addresses command to assign IPv6 prefixes and the assign-private-ip-addresses command to assign IPv4 prefixes to existing network interfaces.

To assign automatic IPv4 prefixes to an existing network interface

Use the assign-private-ip-addresses command and set `--ipv4-prefix-count` to the number of IPv4 prefixes for AWS to assign. In the following example, AWS assigns one IPv4 prefix.

```
aws ec2 assign-private-ip-addresses \
--network-interface-id eni-081fbb4095EXAMPLE \
```

```
--ipv4-prefix-count 1
```

To assign specific IPv4 prefixes to an existing network interface

Use the assign-private-ip-addresses command and set `--ipv4-prefixes` to the prefix. AWS selects IPv4 addresses from this range. In the following example, the prefix CIDR is 10.0.0.208/28.

```
aws ec2 assign-private-ip-addresses \
--network-interface-id eni-081fbb4095EXAMPLE \
--ipv4-prefixes 10.0.0.208/28
```

To assign automatic IPv6 prefixes to an existing network interface

Use the assign-ipv6-addresses command and set `--ipv6-prefix-count` to the number of IPv6 prefixes for AWS to assign. In the following example, AWS assigns one IPv6 prefix.

```
aws ec2 assign-ipv6-addresses \
--network-interface-id eni-00d577338cEXAMPLE \
--ipv6-prefix-count 1
```

To assign specific IPv6 prefixes to an existing network interface

Use the assign-ipv6-addresses command and set `--ipv6-prefixes` to the prefix. AWS selects IPv6 addresses from this range. In the following example, the prefix CIDR is 2600:1f13:fc2:a700:18bb::/80.

```
aws ec2 assign-ipv6-addresses \
--network-interface-id eni-00d577338cEXAMPLE \
--ipv6-prefixes 2600:1f13:fc2:a700:18bb::/80
```

PowerShell

To assign automatic IPv4 prefixes to an existing network interface

Use the Register-EC2PrivateIpAddress cmdlet and set `Ipv4PrefixCount` to the number of IPv4 prefixes for AWS to assign. In the following example, AWS assigns one IPv4 prefix.

```
Register-EC2PrivateIpAddress `
    -NetworkInterfaceId 'eni-00d577338cEXAMPLE' `
```

```
    -Ipv4PrefixCount 1
```

To assign specific IPv4 prefixes to an existing network interface

Use the Register-EC2PrivateIpAddress cmdlet and set `Ipv4Prefix` to the prefix. AWS selects IPv4 addresses from this range. In the following example, the prefix CIDR is 10.0.0.208/28.

```
Register-EC2PrivateIpAddress `
    -NetworkInterfaceId 'eni-00d577338cEXAMPLE' `
    -Ipv4Prefix '10.0.0.208/28'
```

To assign automatic IPv6 prefixes to an existing network interface

Use the Register-EC2Ipv6AddressList cmdlet and set `Ipv6PrefixCount` to the number of IPv4 prefixes for AWS to assign. In the following example, AWS assigns one IPv6 prefix.

```
Register-EC2Ipv6AddressList `
    -NetworkInterfaceId 'eni-00d577338cEXAMPLE' `
    -Ipv6PrefixCount 1
```

To assign specific IPv6 prefixes to an existing network interface

Use the Register-EC2Ipv6AddressList cmdlet and set `Ipv6Prefix` to the prefix. AWS selects IPv6 addresses from this range. In the following example, the prefix CIDR is 2600:1f13:fc2:a700:18bb::/80.

```
Register-EC2Ipv6AddressList `
    -NetworkInterfaceId 'eni-00d577338cEXAMPLE' `
    -Ipv6Prefix '2600:1f13:fc2:a700:18bb::/80'
```

Remove prefixes from your network interfaces

You can remove prefixes from an existing network interface.

Console

To remove the prefixes from a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.

3. Select the network interface.
4. Choose **Actions**, **Manage prefixes**.
5. For **IPv4 prefix delegation**, to remove specific prefixes, choose **Unassign** next to the prefixes to remove. To remove all prefixes, choose **Do not assign**.
6. For **IPv6 prefix delegation**, to remove specific prefixes, choose **Unassign** next to the prefixes to remove. To remove all prefixes, choose **Do not assign**.

> **Note**
>
> **IPv6 prefix delegation** appears only if the selected subnet is enabled for IPv6.

7. Choose **Save**.

AWS CLI

You can use the unassign-ipv6-addresses command to remove IPv6 prefixes and the unassign-private-ip-addresses commands to remove IPv4 prefixes from your existing network interfaces.

To remove IPv4 prefixes from a network interface

Use the unassign-private-ip-addresses command and set `--ipv4-prefix` to the prefix CIDR to remove.

```
aws ec2 unassign-private-ip-addresses \
--network-interface-id eni-081fbb4095EXAMPLE \
--ipv4-prefixes 10.0.0.176/28
```

To remove IPv6 prefixes from a network interface

Use the unassign-ipv6-addresses command and set `--ipv6-prefix` to the prefix CIDR to remove.

```
aws ec2 unassign-ipv6-addresses \
--network-interface-id eni-00d577338cEXAMPLE \
--ipv6-prefix 2600:1f13:fc2:a700:18bb::/80
```

PowerShell

To remove IPv4 prefixes from a network interface

Use the Unregister-EC2PrivateIpAddress cmdlet and set Ipv4Prefix to the prefix CIDR to remove.

```
Unregister-EC2PrivateIpAddress `
    -NetworkInterfaceId 'eni-00d577338cEXAMPLE' `
    -Ipv4Prefix '10.0.0.208/28'
```

To remove IPv6 prefixes from a network interface

Use the Unregister-EC2Ipv6AddressList cmdlet and set Ipv6Prefix to the prefix CIDR to remove.

```
Unregister-EC2Ipv6AddressList `
    -NetworkInterfaceId 'eni-00d577338cEXAMPLE' `
    -Ipv6Prefix '2600:1f13:fc2:a700:18bb::/80'
```

Delete a network interface

Deleting a network interface releases all attributes associated with the interface and releases any private IP addresses or Elastic IP addresses to be used by another instance.

You can't delete a network interface that is in use. First, you must detach the network interface.

Console

To delete a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface, and then choose **Actions**, **Delete**.
4. When prompted for confirmation, choose **Delete**.

AWS CLI

To delete a network interface

Use the following delete-network-interface command.

```
aws ec2 delete-network-interface --network-interface-id eni-1234567890abcdef0
```

PowerShell

To delete a network interface

Use the Remove-EC2NetworkInterface cmdlet.

```
Remove-EC2NetworkInterface -NetworkInterfaceId eni-1234567890abcdef0
```

Amazon EC2 instance network bandwidth

Instance bandwidth specifications apply to both inbound and outbound traffic for the instance. For example, if an instance specifies up to 10 Gbps of bandwidth, that means it has up to 10 Gbps of bandwidth for inbound traffic and, simultaneously, up to 10 Gbps for outbound traffic. The network bandwidth that's available to an EC2 instance depends on several factors, as follows.

Multi-flow traffic

Bandwidth for multi-flow traffic is limited to 50% of the available bandwidth for traffic that goes through an internet gateway or a local gateway for instances with 32 or more vCPUs, or 5 Gbps, whichever is larger. For instances with fewer than 32 vCPUs, bandwidth is limited to 5 Gbps.

Single-flow traffic

Bandwidth for single-flow traffic is limited to 5 Gbps when instances are not in the same cluster placement group. To reduce latency and increase single-flow bandwidth, try one of the following:

- Use a cluster placement group to achieve up to 10 Gbps bandwidth for instances within the same placement group.
- Set up multiple paths between two endpoints to achieve higher bandwidth with Multipath TCP (MPTCP).
- Configure ENA Express for eligible instances within the same Availability Zone to achieve up to 25 Gbps between those instances.

> **Note**
>
> A single-flow is considered a unique 5-tuple TCP or UDP flow. For other protocols following the IP header, such as `GRE` or `IPsec`, the 3 tuple of source IP, destination IP, and next protocol is used to define a flow.

Available instance bandwidth

The available network bandwidth of an instance depends on the number of vCPUs that it has. For example, an `m5.8xlarge` instance has 32 vCPUs and 10 Gbps network bandwidth, and an `m5.16xlarge` instance has 64 vCPUs and 20 Gbps network bandwidth. However, instances might not achieve this bandwidth; for example, if they exceed network allowances at the instance level, such as packet per second or number of tracked connections. How much of the available bandwidth the traffic can utilize depends on the number of vCPUs and the destination. For example, an `m5.16xlarge` instance has 64 vCPUs, so traffic to another instance in the Region can utilize the full bandwidth available (20 Gbps). However, traffic that goes through an internet gateway or a local gateway can utilize only 50% of the bandwidth available (10 Gbps).

Typically, instances with 16 vCPUs or fewer (size `4xlarge` and smaller) are documented as having "up to" a specified bandwidth; for example, "up to 10 Gbps". These instances have a baseline bandwidth. To meet additional demand, they can use a network I/O credit mechanism to burst beyond their baseline bandwidth. Instances can use burst bandwidth for a limited time, typically from 5 to 60 minutes, depending on the instance size.

An instance receives the maximum number of network I/O credits at launch. If the instance exhausts its network I/O credits, it returns to its baseline bandwidth. A running instance earns network I/O credits whenever it uses less network bandwidth than its baseline bandwidth. A stopped instance does not earn network I/O credits. Instance burst is on a best effort basis, even when the instance has credits available, as burst bandwidth is a shared resource.

There are separate network I/O credit buckets for inbound and outbound traffic.

Base and burst network performance

The *Amazon EC2 Instance Types Guide* describes the network performance for each instance type, plus the baseline network bandwidth available for instances that can use burst bandwidth. For more information, see the following:

- Network specifications – General purpose
- Network specifications – Compute optimized
- Network specifications – Memory optimized
- Network specifications – Storage optimized
- Network specifications – Accelerated computing
- Network specifications – High-performance computing

- Network specifications – Previous generation

Alternatively, you can use a command line tool to get this information. The Amazon EC2 console does not display the baseline network bandwidth of an instance type.

AWS CLI

You can use the describe-instance-types command to display information about an instance type. The following example displays network performance information for all C5 instances.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=c5.*" \
    --query "InstanceTypes[].[InstanceType, NetworkInfo.NetworkPerformance,
 NetworkInfo.NetworkCards[0].BaselineBandwidthInGbps] | sort_by(@,&[2])" \
    --output table
```

The following is example output. If your output is missing the baseline bandwidth, update to the latest version of the AWS CLI.

```
--------------------------------------------
|           DescribeInstanceTypes          |
+--------------+--------------------+-------+
|  c5.large    |  Up to 10 Gigabit  |  0.75 |
|  c5.xlarge   |  Up to 10 Gigabit  |  1.25 |
|  c5.2xlarge  |  Up to 10 Gigabit  |  2.5  |
|  c5.4xlarge  |  Up to 10 Gigabit  |  5.0  |
|  c5.9xlarge  |  12 Gigabit        |  12.0 |
|  c5.12xlarge |  12 Gigabit        |  12.0 |
|  c5.18xlarge |  25 Gigabit        |  25.0 |
|  c5.24xlarge |  25 Gigabit        |  25.0 |
|  c5.metal    |  25 Gigabit        |  25.0 |
+--------------+--------------------+-------+
```

PowerShell

You can use the Get-EC2InstanceType PowerShell command to display information about an instance type. The following example displays network performance information for all C5 instances.

```
Get-EC2InstanceType -Filter @{Name = "instance-type"; Values = "c5.*" } | `
```

```
    Select-Object `
    InstanceType,
    @{Name = 'NetworkPerformance'; Expression =
 {($_.Networkinfo.NetworkCards.NetworkPerformance)}},
    @{Name = 'BaselineBandwidthInGbps'; Expression =
 {($_.Networkinfo.NetworkCards.BaselineBandwidthInGbps)}} | `
Format-Table -AutoSize
```

The following is example output.

```
InstanceType NetworkPerformance BaselineBandwidthInGbps
------------ ------------------ -----------------------
c5.4xlarge   Up to 10 Gigabit                      5.00
c5.xlarge    Up to 10 Gigabit                      1.25
c5.12xlarge  12 Gigabit                           12.00
c5.9xlarge   12 Gigabit                           12.00
c5.24xlarge  25 Gigabit                           25.00
c5.metal     25 Gigabit                           25.00
c5.2xlarge   Up to 10 Gigabit                      2.50
c5.large     Up to 10 Gigabit                      0.75
c5.18xlarge  25 Gigabit                           25.00
```

EC2 instance bandwidth weighting configuration

Some instance types support configurable bandwidth weighting, where you can select baseline bandwidth weighting that favors either network processing or EBS operations. Default settings for baseline bandwidth are determined by your instance type. You can configure the bandwidth weighting during launch, or modify your instance settings with the following weighting preferences:

- **default** – This option uses the standard bandwidth configuration for your instance type.
- **vpc-1** – This option increases the baseline bandwidth available for networking and decreases the baseline bandwidth for EBS operations.
- **ebs-1** – This option increases the baseline bandwidth available for EBS operations, and decreases the baseline bandwidth for networking.

Bandwidth weighting considerations

The following are some considerations that might affect your bandwidth weighting strategy.

- Setting bandwidth weighting preferences only affects bandwidth specifications. The network packets per second (PPS) and EBS input/output operations per second (IOPS) specifications don't change.
- The combined bandwidth specification between networking and EBS does not change. When you select a bandwidth weighting configuration, the baseline bandwidth available for the selected option increases, and the baseline bandwidth for the remaining option is reduced by the same absolute amount. For all instances except Flex instances, the available burst bandwidth remains the same for your selected option, and is reduced for the remaining option. For Flex instances up to 4xlarge, burst bandwidth remains unchanged. For Flex instances 8xlarge and larger, burst bandwidth increases by the same amount as the baseline bandwidth.
- It's important to understand how changes in bandwidth allocation can affect I/O performance for EBS. For EC2 instances that have `vpc-1` configuration (increased networking bandwidth), you might experience lower IOPS for EBS volumes if you reach the EBS bandwidth limit before you've reached the IOPS limit. This is more noticeable with larger I/O sizes.

  For example, on an instance type that normally supports 240,000 IOPS with 16 KiB I/O size, if you select `vpc-1` weighting, that might reduce the achievable IOPS due to the adjusted EBS baseline bandwidth limit.

  When planning your workload, consider your I/O size and patterns. Smaller I/O sizes are less likely to be affected by bandwidth limitations, while larger I/O sizes or sequential workloads might see more impact from bandwidth changes. Always test your specific workload to ensure optimal performance with your chosen configuration.
- The networking multi-flow bandwidth specification for traffic that goes through an internet gateway or a local gateway is adjusted to 50% of the baseline bandwidth of the configured option or 5 Gbps, where applicable. For more information, see [Amazon EC2 instance network bandwidth](#).

  The following example is based on an instance type that has a default baseline bandwidth of 40 Gbps, and a default border bandwidth of 20 Gbps. If you choose `vpc-1` bandwidth weighting for this instance, the weighted baseline bandwidth changes to 50 Gbps, and the border bandwidth changes to 25 Gbps.
- This feature is available in all commercial regions, aligned with EC2 instance availablilty and support.
- This feature adds no additional cost to your EC2 instance.

Supported instance types for bandwidth weighting

Instance types in the following instance families support configurable bandwidth weighting.

- **General purpose:** M8g, M8gd, M8i, M8i-flex
- **Compute optimized:** C8g, C8gd
- **Memory optimized:** R8g, R8gd, R8i, R8i-flex, X8g

Check current bandwidth settings

To see the current bandwidth settings for your instance, select one of the tabs for instructions.

Console

To get the bandwidth setting for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you want to check from the list, and navigate to the **Networking** tab. Your current setting is shown in the **Configured bandwidth** field. Amazon EC2 uses default settings for your instance type if the bandwidth is not set to a specific value.

AWS CLI

To get the bandwidth setting for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].NetworkPerformanceOptions.BandwidthWeighting
 \
    --output text
```

The following is example output.

```
default
```

This example lists all of your instances that have the bandwidth weighting preference set to vpc-1, for higher networking bandwidth.

```
aws ec2 describe-instances \
    --filters "Name=network-performance-options.bandwidth-weighting,Values=vpc-1" \
    --query Reservations[].Instances[].InstanceId \
    --output text
```

PowerShell

To get the bandwidth setting for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
    -
InstanceId i-1234567890abcdef0).Instances.NetworkPerformanceOptions.BandwidthWeighting.Value
```

The following is example output.

```
default
```

This example lists all of your instances that have the bandwidth weighting preference set to vpc-1, for higher networking bandwidth.

```
(Get-EC2Instance `
    -Filter @{Name="network-performance-options.bandwidth-
weighting";Values="vpc-1"}).Instances.InstanceId
```

Configure bandwidth weighting for your instance

You can configure bandwidth weighting either at launch or by modifying existing instances from the EC2 console, API/SDKs or CLI.

Configure bandwidth weighting when you launch an instance

To configure bandwidth settings when you launch an instance, select one of the tabs for instructions.

You can also specify bandwidth weighting in a launch template. To create a launch template, see Create an Amazon EC2 launch template. The parameter to set is in the same location as it is for launching an instance directly from the console. Expand the **Advanced details** section, and set the **Instance bandwidth configuration**.

To launch an instance with your launch template, see [Launch EC2 instances using a launch template](#).

Console

To launch an instance with configurable bandwidth weighting

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Choose **Launch instances**. This opens the **Launch an instance** dialog. There are several additional ways that you can get to the the launch dialog, depending on your preference. For example, you can launch an instance directly from an AMI or from the Amazon EC2 dashboard itself.
4. The Amazon Machine Image (AMI) that you launch from must be based on `Arm` architecture. Many **Quick Start** images support both `x86` and `Arm` architectures, After you choose the operating system for your instance, select the `Arm` option from the **Architecture** list.
5. The instance type must be one of the [Supported instance types](#) for this feature.
6. When you expand the **Advanced details** section, you can scroll down to find the **Instance bandwidth configuration** settings. Select the bandwidth configuration option for your instance.
7. Configure all of the other settings for your instance as you normally would, and choose **Launch instance**.

AWS CLI

To launch an instance with configurable bandwidth weighting

Use the [run-instances](#) command with the following option to launch instances that are configured for higher network bandwidth weighting.

```
--network-performance-options BandwidthWeighting=vpc-1
```

Use the [run-instances](#) command with the following option to launch instances that are configured for higher EBS bandwidth weighting.

```
--network-performance-options BandwidthWeighting=ebs-1
```

PowerShell

To launch an instance with configurable bandwidth weighting

Use the New-EC2Instance cmdlet with the following parameter to launch instances that are configured for higher network bandwidth weighting.

```
-NetworkPerformanceOptions_BandwidthWeighting vpc-1
```

Use the New-EC2Instance cmdlet with the following parameter to launch instances that are configured for higher EBS bandwidth weighting.

```
-NetworkPerformanceOptions_BandwidthWeighting ebs-1
```

Update bandwidth weighting for an existing instance

To update bandwidth weighting for an existing instance, your instance must be in the `Stopped` state.

Console

To update bandwidth weighting

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you want to update from the list.
4. Before you change the bandwidth configuration, your instance must be in a `Stopped` state. If your instance is running, select **Stop instance** from the **Instance state** menu.
5. Choose **Manage bandwidth** from the **Actions > Networking** menu. This opens the **Manage bandwidth** dialog.

> **Note**
>
> If your instance type doesn't support configuration for bandwidth weighting, that menu item is disabled.

6. Select the option to update your instance, and choose **Change** to save your settings.

AWS CLI

To update bandwidth weighting

Use the modify-instance-network-performance-options command to configure higher network bandwidth weighting for the specified instance.

```
aws ec2 modify-instance-network-performance-options \
    --instance-id i-1234567890abcdef0 \
    --bandwidth-weighting=vpc-1
```

The following example configures higher EBS bandwidth weighting for the specified instance.

```
aws ec2 modify-instance-network-performance-options \
    --instance-id i-1234567890abcdef0 \
    --bandwidth-weighting=ebs-1
```

PowerShell

To update bandwidth weighting

Use the Edit-EC2InstanceNetworkPerformanceOption cmdlet to configure higher network bandwidth weighting for the specified instance.

```
Edit-EC2InstanceNetworkPerformanceOption `
    -InstanceId i-1234567890abcdef0 `
    -BandwidthWeighting vpc-1
```

The following example configures higher EBS bandwidth weighting for the specified instance.

```
Edit-EC2InstanceNetworkPerformanceOption `
    -InstanceId i-1234567890abcdef0 `
    -BandwidthWeighting ebs-1
```

Bandwidth weighting impact for networking

The following table shows the impact of bandwidth weighting on networking bandwidth, in Gbps, for the supported instance types.

Instance type	Default Baseline / Burst	vpc-1 Baseline / Burst	ebs-1 Baseline / Burst
c8g.medium	0.52 / 12.5	0.65 / 12.5	0.441 / 10.0
c8g.large	0.937 / 12.5	1.171 / 12.5	0.779 / 10.0
c8g.xlarge	1.875 / 12.5	2.344 / 12.5	1.562 / 10.0
c8g.2xlarge	3.75 / 15.0	4.688 / 15.0	3.125 / 12.5

Monitor instance bandwidth

You can use CloudWatch metrics to monitor instance network bandwidth and the packets sent and received. You can use the network performance metrics provided by the Elastic Network Adapter (ENA) driver to monitor when traffic exceeds the network allowances that Amazon EC2 defines at the instance level.

You can configure whether Amazon EC2 sends metric data for the instance to CloudWatch using one-minute periods or five-minute periods. It is possible that the network performance metrics would show that an allowance was exceeded and packets were dropped while the CloudWatch instance metrics do not. This can happen when the instance has a short spike in demand for network resources (known as a microburst), but the CloudWatch metrics are not granular enough to reflect these microsecond spikes.

- Instance metrics
- Monitor network performance

Enhanced networking on Amazon EC2 instances

Enhanced networking uses single root I/O virtualization (SR-IOV) to provide high-performance networking capabilities on supported instance types. SR-IOV is a method of device virtualization that provides higher I/O performance and lower CPU utilization when compared to traditional virtualized network interfaces. Enhanced networking provides higher bandwidth, higher packet per second (PPS) performance, and consistently lower latency between instances. There is no additional charge for using enhanced networking.

For information about the supported network speed for each instance type, see Amazon EC2 Instance Types.

You can enable enhanced networking using one of the following mechanisms:

Elastic Network Adapter (ENA)

The Elastic Network Adapter (ENA) supports network speeds of up to 100 Gbps for supported instance types.

All Nitro-based instances use ENA for enhanced networking. In addition, the following Xen-based instances use ENA: H1, I3, G3, `m4.16xlarge`, P2, P3, P3dn, and R4.

For more information, see Enable enhanced networking with ENA on your EC2 instances.

Intel 82599 Virtual Function (VF) interface

The Intel 82599 Virtual Function interface supports network speeds of up to 10 Gbps for supported instance types.

The following instance types use the Intel 82599 VF interface for enhanced networking: C3, C4, D2, I2, M4 (excluding m4.16xlarge), and R3.

For more information, see Enhanced networking with the Intel 82599 VF interface.

Contents

- Nitro system considerations for performance tuning
- Optimize network performance on EC2 Windows instances

Enable enhanced networking with ENA on your EC2 instances

Amazon EC2 provides enhanced networking capabilities through the Elastic Network Adapter (ENA). To use enhanced networking, you must use an AMI that includes the required ENA driver or manually install it. Then you can enable ENA support on your instance.

To review release notes or install instructions for an ENA driver, see the tab that matches your instance operating system platform.

Linux

You can review the following documentation on GitHub:

- Review ENA Linux kernel driver release notes on GitHub.
- For an overview of the ENA Linux kernel driver that includes install instructions see Linux kernel driver for Elastic Network Adapter (ENA) family on GitHub.

Windows

You can review the following documentation from the **Manage device drivers** section of this guide:

- Track ENA Windows driver version releases.
- Install the ENA driver on EC2 Windows instances.

For Nitro-based instances, enhanced networking capabilities vary by the Nitro version that the instance type implements.

To review network specifications for your instance, choose the instance family link for your instance type. If you're not sure which instance family applies, see Naming conventions in the *Amazon EC2 Instance Types* guide.

- Network specifications for accelerated computing instances

Contents

Prerequisites for enhanced networking with ENA

To prepare for enhanced networking using the ENA, set up your instance as follows:

- Launch a Nitro-based instance.
- Ensure that the instance has internet connectivity.
- If you have important data on the instance that you want to preserve, you should back that data up now by creating an AMI from your instance. Updating the ENA kernel driver and enabling the `enaSupport` attribute might render incompatible instances or operating systems unreachable. If you have a recent backup, your data will still be retained if this happens.
- **Linux instances** – Launch the instance using a supported version of the Linux kernel and a supported distribution, so that ENA enhanced networking is enabled for your instance automatically. For more information, see ENA Linux Kernel Driver Release Notes.
- **Windows instances** – If the instance is running Windows Server 2008 R2 SP1, ensure that is has the SHA-2 code signing support update.
- Use AWS CloudShell from the AWS Management Console, or install and configure the AWS CLI or the AWS Tools for Windows PowerShell on any computer you choose, preferably your local desktop or laptop. For more information, see Access Amazon EC2 or the AWS CloudShell User Guide. Enhanced networking cannot be managed from the Amazon EC2 console.

Test whether enhanced networking is enabled

You can test whether enhanced networking is enabled in your instances or your AMIs.

Instance attribute

Check the value of the `enaSupport` instance attribute.

AWS CLI

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[].Instances[].EnaSupport"
```

If enhanced networking is enabled, the output is as follows.

```
[
    true
]
```

PowerShell

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances.EnaSupport
```

If enhanced networking is enabled, the output is as follows.

```
True
```

Image attribute

Check the value of the `enaSupport` image attribute.

AWS CLI

Use the describe-images command.

```
aws ec2 describe-images \
```

```
    --image-id ami-0abcdef1234567890 \
    --query "Images[].EnaSupport"
```

If enhanced networking is enabled, the output is as follows.

```
[
    true
]
```

PowerShell

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).EnaSupport
```

If enhanced networking is enabled, the output is as follows.

```
True
```

Linux network interface driver

Use the following command to verify that the `ena` kernel driver is being used on a particular interface, substituting the interface name that you want to check. If you are using a single interface (default), this is `eth0`. If your Linux distribution supports predictable network names, this could be a name like `ens5`. For more information, expand the section for RHEL, SUSE, and CentOS in Enable enhanced networking on your instance.

In the following example, the `ena` kernel driver is not loaded, because the listed driver is `vif`.

```
[ec2-user ~]$ ethtool -i eth0
driver: vif
version:
firmware-version:
bus-info: vif-0
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

In this example, the ena kernel driver is loaded and at the minimum recommended version. This instance has enhanced networking properly configured.

```
[ec2-user ~]$ ethtool -i eth0
driver: ena
version: 1.5.0g
firmware-version:
expansion-rom-version:
bus-info: 0000:00:05.0
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

Enable enhanced networking on your instance

The procedure that you use depends on the operating system of the instance.

Amazon Linux

The AMIs for Amazon Linux include the kernel driver required for enhanced networking with ENA installed and have ENA support enabled. Therefore, if you launch an instance with an HVM version of Amazon Linux on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled.

Ubuntu

The latest Ubuntu HVM AMIs include the kernel driver required for enhanced networking with ENA installed and have ENA support enabled. Therefore, if you launch an instance with the latest Ubuntu HVM AMI on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled.

If you launched your instance using an older AMI and it does not have enhanced networking enabled already, you can install the `linux-aws` kernel package to get the latest enhanced networking drivers and update the required attribute.

To install the `linux-aws` kernel package (Ubuntu 16.04 or later)

Ubuntu 16.04 and 18.04 ship with the Ubuntu custom kernel (`linux-aws` kernel package). To use a different kernel, contact Support.

To install the `linux-aws` kernel package (Ubuntu Trusty 14.04)

1. Connect to your instance.
2. Update the package cache and packages.

```
ubuntu:~$ sudo apt-get update && sudo apt-get upgrade -y linux-aws
```

> **Important**
>
> If during the update process you are prompted to install `grub`, use `/dev/xvda` to install `grub` onto, and then choose to keep the current version of `/boot/grub/menu.lst`.

3. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI) or Stop-EC2Instance (AWS Tools for Windows PowerShell).

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Ubuntu (instance store-backed instances).

4. From your local computer, enable the enhanced networking attribute using one of the following commands:

   - modify-instance-attribute (AWS CLI)

   ```
   aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --ena-support
   ```

   - Edit-EC2InstanceAttribute (Tools for Windows PowerShell)

   ```
   Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -EnaSupport $true
   ```

5. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed AMI. The AMI inherits the enhanced networking `enaSupport` attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

6. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI) or Start-EC2Instance (AWS Tools for Windows PowerShell).

To enable enhanced networking on Ubuntu (instance store-backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed AMI, making sure to enable the enhanced networking attribute when you register the AMI.

- register-image (AWS CLI)

```
aws ec2 register-image --ena-support ...
```

- Register-EC2Image (AWS Tools for Windows PowerShell)

```
Register-EC2Image -EnaSupport $true ...
```

RHEL, SUSE, CentOS

The latest AMIs for Red Hat Enterprise Linux, SUSE Linux Enterprise Server, and CentOS include the kernel driver required for enhanced networking with ENA and have ENA support enabled. Therefore, if you launch an instance with the latest AMI on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled.

The following procedure provides the general steps for enabling enhanced networking on a Linux distribution other than Amazon Linux AMI or Ubuntu. For more information, such as detailed syntax for commands, file locations, or package and tool support, see the documentation for your Linux distribution.

To enable enhanced networking on Linux

1. Connect to your instance.
2. Clone the source code for the `ena` kernel driver on your instance from GitHub at https://github.com/amzn/amzn-drivers. (SUSE Linux Enterprise Server 12 SP2 and later include ENA 2.02 by default, so you are not required to download and compile the ENA driver. For SUSE Linux Enterprise Server 12 SP2 and later, you should file a request to add the driver version you want to the stock kernel).

   ```
   git clone https://github.com/amzn/amzn-drivers
   ```

3. Compile and install the `ena` kernel driver on your instance. These steps depend on the Linux distribution. For more information about compiling the kernel driver on Red Hat Enterprise Linux, see [How do I install the latest ENS driver for enhanced network support on an Amazon EC2 instance that runs RHEL?]

4. Run the **sudo depmod** command to update kernel driver dependencies.

5. Update `initramfs` on your instance to ensure that the new kernel driver loads at boot time. For example, if your distribution supports **dracut**, you can use the following command.

```
dracut -f -v
```

6. Determine if your system uses predictable network interface names by default. Systems that use **systemd** or **udev** versions 197 or greater can rename Ethernet devices and they do not guarantee that a single network interface will be named `eth0`. This behavior can cause problems connecting to your instance. For more information and to see other configuration options, see [Predictable Network Interface Names] on the freedesktop.org website.

   a. You can check the **systemd** or **udev** versions on RPM-based systems with the following command.

   ```
   rpm -qa | grep -e '^systemd-[0-9]\+\|^udev-[0-9]\+'
   systemd-208-11.el7_0.2.x86_64
   ```

   In the above Red Hat Enterprise Linux 7 example, the **systemd** version is 208, so predictable network interface names must be disabled.

   b. Disable predictable network interface names by adding the `net.ifnames=0` option to the `GRUB_CMDLINE_LINUX` line in `/etc/default/grub`.

   ```
   sudo sed -i '/^GRUB\_CMDLINE\_LINUX/s/\"$/\ net\.ifnames\=0\"/' /etc/default/
   grub
   ```

   c. Rebuild the grub configuration file.

   ```
   sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

7. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: [stop-instances] (AWS CLI), [Stop-EC2Instance] (AWS Tools for Windows PowerShell).

[Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Linux (instance store–backed instances).

8. From your local computer, enable the enhanced networking `enaSupport` attribute using one of the following commands:

   - modify-instance-attribute (AWS CLI)

   ```
   aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --ena-support
   ```

   - Edit-EC2InstanceAttribute (Tools for Windows PowerShell)

   ```
   Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -EnaSupport $true
   ```

9. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed AMI. The AMI inherits the enhanced networking `enaSupport` attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

   If your instance operating system contains an `/etc/udev/rules.d/70-persistent-net.rules` file, you must delete it before creating the AMI. This file contains the MAC address for the Ethernet adapter of the original instance. If another instance boots with this file, the operating system will be unable to find the device and `eth0` might fail, causing boot issues. This file is regenerated at the next boot cycle, and any instances launched from the AMI create their own version of the file.

10. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI) or Start-EC2Instance (AWS Tools for Windows PowerShell).

11. (Optional) Connect to your instance and verify that the kernel driver is installed.

    If you are unable to connect to your instance after enabling enhanced networking, see Troubleshoot the ENA kernel driver on Linux.

To enable enhanced networking on Linux (instance store–backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed AMI, making sure to enable the enhanced networking attribute when you register the AMI.

- register-image (AWS CLI)

```
aws ec2 register-image --ena-support ...
```

- Register-EC2Image (AWS Tools for Windows PowerShell)

```
Register-EC2Image -EnaSupport ...
```

Ubuntu with DKMS

This method is for testing and feedback purposes only. It is not intended for use with production deployments. For production deployments, see Ubuntu.

> **Important**
>
> Using DKMS voids the support agreement for your subscription. It should not be used for production deployments.

To enable enhanced networking with ENA on Ubuntu (EBS-backed instances)

1. Follow steps 1 and 2 in Ubuntu.
2. Install the `build-essential` packages to compile the kernel driver and the `dkms` package so that your `ena` kernel driver is rebuilt every time your kernel is updated.

   ```
   ubuntu:~$ sudo apt-get install -y build-essential dkms
   ```

3. Clone the source for the `ena` kernel driver on your instance from GitHub at https://github.com/amzn/amzn-drivers.

   ```
   ubuntu:~$ git clone https://github.com/amzn/amzn-drivers
   ```

4. Move the `amzn-drivers` package to the `/usr/src/` directory so DKMS can find it and build it for each kernel update. Append the version number (you can find the current version number in the release notes) of the source code to the directory name. For example, version `1.0.0` is shown in the following example.

   ```
   ubuntu:~$ sudo mv amzn-drivers /usr/src/amzn-drivers-1.0.0
   ```

5. Create the DKMS configuration file with the following values, substituting your version of `ena`.

   Create the file.

   ```
   ubuntu:~$ sudo touch /usr/src/amzn-drivers-1.0.0/dkms.conf
   ```

   Edit the file and add the following values.

   ```
   ubuntu:~$ sudo vim /usr/src/amzn-drivers-1.0.0/dkms.conf
   PACKAGE_NAME="ena"
   PACKAGE_VERSION="1.0.0"
   CLEAN="make -C kernel/linux/ena clean"
   MAKE="make -C kernel/linux/ena/ BUILD_KERNEL=${kernelver}"
   BUILT_MODULE_NAME[0]="ena"
   BUILT_MODULE_LOCATION="kernel/linux/ena"
   DEST_MODULE_LOCATION[0]="/updates"
   DEST_MODULE_NAME[0]="ena"
   AUTOINSTALL="yes"
   ```

6. Add, build, and install the `ena` kernel driver on your instance using DKMS.

   Add the kernel driver to DKMS.

   ```
   ubuntu:~$ sudo dkms add -m amzn-drivers -v 1.0.0
   ```

   Build the kernel driver using the **dkms** command.

   ```
   ubuntu:~$ sudo dkms build -m amzn-drivers -v 1.0.0
   ```

   Install the kernel driver using **dkms**.

   ```
   ubuntu:~$ sudo dkms install -m amzn-drivers -v 1.0.0
   ```

7. Rebuild `initramfs` so the correct kernel driver is loaded at boot time.

```
ubuntu:~$ sudo update-initramfs -u -k all
```

8. Verify that the ena kernel driver is installed using the modinfo ena command from [Test whether enhanced networking is enabled](#).

```
ubuntu:~$ modinfo ena
filename:    /lib/modules/3.13.0-74-generic/updates/dkms/ena.ko
version:  1.0.0

9. Continue with Step 3 in [Ubuntu](#).

Enable enhanced networking on Windows

If you launched your instance and it does not have enhanced networking enabled already, you must download and install the required network adapter driver on your instance, and then set the `enaSupport` instance attribute to activate enhanced networking.

To enable enhanced networking

1. Connect to your instance and log in as the local administrator.
2. [Windows Server 2016 and 2019 only] Run the following EC2Launch PowerShell script to configure the instance after the driver is installed.

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -
Schedule
```

3. From the instance, install the driver as follows:

    a. Download the latest driver to the instance.

    b. Extract the zip archive.

    c. Install the driver by running the `install.ps1` PowerShell script.

    > **Note**
    >
    > If you get an execution policy error, set the policy to `Unrestricted` (by default it is set to `Restricted` or `RemoteSigned`). In a command line, run `Set-ExecutionPolicy -ExecutionPolicy Unrestricted`, and then run the `install.ps1` PowerShell script again.

4. From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI) or Stop-EC2Instance (AWS Tools for Windows PowerShell).
5. Enable ENA support on your instance as follows:

    a. From your local computer, check the EC2 instance ENA support attribute on your instance by running one of the following commands. If the attribute is not enabled, the output will be "[]" or blank. `EnaSupport` is set to `false` by default.

    - describe-instances (AWS CLI)

    ```
    aws ec2 describe-instances --instance-ids i-1234567890abcdef0 --query
     "Reservations[].Instances[].EnaSupport"
    ```

    - Get-EC2Instance (Tools for Windows PowerShell)

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances.EnaSupport
```

b. To enable ENA support, run one of the following commands:

- modify-instance-attribute (AWS CLI)

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --ena-support
```

- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)

```
Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -EnaSupport $true
```

If you encounter problems when you restart the instance, you can also disable ENA support using one of the following commands:

- modify-instance-attribute (AWS CLI)

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --no-ena-support
```

- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)

```
Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -EnaSupport $false
```

c. Verify that the attribute has been set to `true` using **describe-instances** or **Get-EC2Instance** as shown previously. You should now see the following output:

```
[
 true
]
```

6. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI) or Start-EC2Instance (AWS Tools for Windows PowerShell).

7. On the instance, validate that the ENA driver is installed and enabled as follows:

   a. Right-click the network icon and choose **Open Network and Sharing Center**.

   b. Choose the Ethernet adapter (for example, **Ethernet 2**).

c. Choose **Details**. For **Network Connection Details**, check that **Description** is **Amazon Elastic Network Adapter**.

8. (Optional) Create an AMI from the instance. The AMI inherits the `enaSupport` attribute from the instance. Therefore, you can use this AMI to launch another instance with ENA enabled by default.

ENA queues

ENA queues are allocated to network interfaces with default static limits based on the instance type and size. On supported instance types, you can dynamically allocate these queues across Elastic Network Interfaces (ENIs). While the total queue count per instance depends on its type and size, you can configure multiple ENIs with ENA queues until you meet the maximum queue count for the ENI and the instance.

Flexible ENA queue allocation optimizes resource distribution, enabling maximum vCPU utilization. High network performance workloads typically require multiple ENA queues. You can fine-tune network performance and packets per second (PPS) by adjusting queue counts according to your specific workload needs. For example, network-intensive applications may require more queues compared to CPU-intensive applications.

Topics

Supported instances

The following instances support dynamic allocation of multiple ENA queues.

General purpose

Instance type	Default ENA queues per interface	Maximum ENA queues per interface	Maximum ENA queues per instance
	M6i		
`m6i.large`	2	2	6

Instance type	Default ENA queues per interface	Maximum ENA queues per interface	Maximum ENA queues per instance

Modify the number of queues

You can modify the number of ENA queues using AWS Management Console or AWS CLI. In the AWS Management Console, the ENA queues configuration is available under each **Network interface** setting.

To modify the number of ENA queues using the AWS CLI, use either one of the following commands. Before modifying the queue count, use the following command to check your current queue count.

```
aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

> **Note**
>
> - Your instance must be stopped before modifying the number of ENA queues.
> - The value for ENA queues must be a power of 2, such as, 1, 2, 4, 8, 16, 32, etc.
> - The number of queues allocated to any single ENI cannot exceed the number of vCPUs available on your instance.

attach-network-interface

In the following example, 32 ENA queues are configured on an ENI.

```
aws ec2 attach-network-interface \
  --network-interface-id eni-001aa1bb223cdd4e4 \
  --instance-id i-1234567890abcdef0 \
  --device-index 1 \
  --ena-queue-count 32
```

run-instances

In the following example, 2 ENA queues each are configured on 3 ENIs.

```
aws ec2 run-instances \
  --image-id ami-12ab3c30 \
  --instance-type c6i.large \
  --min-count 1 \
  --max-count 1 \
  --network-interfaces \
    "[{\"DeviceIndex\":0,\"SubnetId\":\"subnet-123456789012a345a\",\"EnaQueueCount
\":2},
     {\"DeviceIndex\":1,\"SubnetId\":\"subnet-123456789012a345a\",\"EnaQueueCount
\":2},
     {\"DeviceIndex\":2,\"SubnetId\":\"subnet-123456789012a345a\",\"EnaQueueCount
\":2}]"
```

modify-network-interface-attribute

In the following example, 32 ENA queues are configured on an ENI.

```
aws ec2 modify-network-interface-attribute \
--network-interface-id eni-1234567890abcdef0 \
--attachment AttachmentId=eni-attach-12345678,EnaQueueCount=32
```

In the following example, the ENA count is reset to the default value.

```
aws ec2 modify-network-interface-attribute \
--network-interface-id eni-1234567890abcdef0 \
--attachment AttachmentId=eni-attach-12345678,DefaultEnaQueueCount=true
```

Troubleshoot the ENA kernel driver on Linux

The Elastic Network Adapter (ENA) is designed to improve operating system health and reduce the chances of long-term disruption because of unexpected hardware behavior and or failures. The ENA architecture keeps device or driver failures as transparent to the system as possible. This topic provides troubleshooting information for ENA.

If you are unable to connect to your instance, start with the Troubleshoot connectivity issues section.

If you experience performance degradation after migrating to a sixth generation instance type, see the article What do I need to do before I migrate my EC2 instance to a sixth generation instance to make sure that I get maximum network performance?

If you are able to connect to your instance, you can gather diagnostic information by using the failure detection and recovery mechanisms that are covered in the later sections of this topic.

Contents

- Sub-optimal configuration notifications

Troubleshoot connectivity issues

If you lose connectivity while enabling enhanced networking, the `ena` module might be incompatible with your instance's current running kernel. This can happen if you install the module for a specific kernel version (without **dkms**, or with an improperly configured **dkms.conf** file) and then your instance kernel is updated. If the instance kernel that is loaded at boot time does not have the `ena` module properly installed, your instance will not recognize the network adapter and your instance becomes unreachable.

If you enable enhanced networking for a PV instance or AMI, this can also make your instance unreachable.

If your instance becomes unreachable after enabling enhanced networking with ENA, you can disable the `enaSupport` attribute for your instance and it will fall back to the stock network adapter.

To disable enhanced networking with ENA (EBS-backed instances)

1. From your local computer, stop the instance by using the Amazon EC2 console, the stop-instances command (AWS CLI), or the Stop-EC2Instance cmdlet (AWS Tools for PowerShell).
2. From your local computer, disable the enhanced networking attribute by using the modify-instance-attribute command with the `--no-ena-support` option or the Edit-EC2InstanceAttribute cmdlet with the `-EnaSupport $false` parameter.
3. From your local computer, start the instance using the Amazon EC2 console, the start-instances command, or the Start-EC2Instance cmdlet.
4. (Optional) Connect to your instance and try reinstalling the `ena` module with your current kernel version by following the steps in Enable enhanced networking with ENA on your EC2 instances.

To disable enhanced networking with ENA (instance store-backed instances)

1. Create a new AMI as described in Create an instance store-backed AMI.
2. When you register the AMI, be sure to include the `--no-ena-support` option in the stop-instances command (AWS CLI) or the `-EnaSupport $false` parameter in the Register-EC2Image cmdlet.

Keep-alive mechanism

The ENA device posts keep-alive events at a fixed rate (usually once every second). The ENA driver implements a watchdog mechanism, which checks for the presence of these keep-alive messages. If a message or messages are present, the watchdog is rearmed, otherwise the driver concludes that the device experienced a failure and then does the following:

- Dumps its current statistics to syslog
- Resets the ENA device
- Resets the ENA driver state

The above reset procedure may result in some traffic loss for a short period of time (TCP connections should be able to recover), but should not otherwise affect the user.

The ENA device may also indirectly request a device reset procedure, by not sending a keep-alive notification, for example, if the ENA device reaches an unknown state after loading an irrecoverable configuration.

The following is an example of the reset procedure:

```
[18509.800135] ena 0000:00:07.0 eth1: Keep alive watchdog timeout. // The watchdog process initiates a reset
[18509.815244] ena 0000:00:07.0 eth1: Trigger reset is on

 process is complete
```

Register read timeout

The ENA architecture suggests a limited usage of memory mapped I/O (MMIO) read operations. MMIO registers are accessed by the ENA device driver only during its initialization procedure.

If the driver logs (available in **dmesg** output) indicate failures of read operations, this may be caused by an incompatible or incorrectly compiled driver, a busy hardware device, or hardware failure.

Intermittent log entries that indicate failures on read operations should not be considered an issue; the driver will retry them in this case. However, a sequence of log entries containing read failures indicate a driver or hardware problem.

Below is an example of driver log entry indicating a read operation failure due to a timeout:

```
[ 47.113698] [ENA_COM: ena_com_reg_bar_read32] reading reg failed for timeout.
 expected: req id[1] offset[88] actual: req id[57006] offset[0]
[ 47.333715] [ENA_COM: ena_com_reg_bar_read32] reading reg failed for timeout.
 expected: req id[2] offset[8] actual: req id[57007] offset[0]
[ 47.346221] [ENA_COM: ena_com_dev_reset] Reg read32 timeout occurred
```

Statistics

If you experience insufficient network performance or latency issues, you should retrieve the device statistics and examine them. These statistics can be obtained using **ethtool** as follows.

```
[ec2-user ~]$ ethtool -S ethN
NIC statistics:
 tx_timeout: 0
 suspend: 0
 resume: 0
 wd_expired: 0
 interface_up: 1
 interface_down: 0
 admin_q_pause: 0
 bw_in_allowance_exceeded: 0
 bw_out_allowance_exceeded: 0
 pps_allowance_exceeded: 0
 conntrack_allowance_available: 450878
 conntrack_allowance_exceeded: 0
 linklocal_allowance_exceeded: 0
 queue_0_tx_cnt: 4329
 queue_0_tx_bytes: 1075749
 queue_0_tx_queue_stop: 0
 ...
```

The following command output parameters are described below:

`tx_timeout`: *N*

The number of times that the Netdev watchdog was activated.

`suspend`: *N*

The number of times the driver performed a suspend operation.

`resume`: *N*

The number of times the driver performed a resume operation.

`wd_expired`: *N*

The number of times that the driver did not receive the keep-alive event in the preceding three seconds.

`interface_up`: *N*

The number of times that the ENA interface was brought up.

`interface_down`: *N*

The number of times that the ENA interface was brought down.

`admin_q_pause`: *N*

The number of times the admin queue was not found in a running state.

`bw_in_allowance_exceeded`: *N*

The number of packets queued or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance.

`bw_out_allowance_exceeded`: *N*

The number of packets queued or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance.

`pps_allowance_exceeded`: *N*

The number of packets queued or dropped because the bidirectional PPS exceeded the maximum for the instance. *

`conntrack_allowance_available`: *N*

The number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type. Only available for Nitro-based instances. Not supported with FreeBSD instances or DPDK environments.

`conntrack_allowance_exceeded`: *N*

The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance.

`linklocal_allowance_exceeded`: *N*

The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the Amazon DNS service, the Instance Metadata Service, and the Amazon Time Sync Service, but does not impact traffic to custom DNS resolvers.

`queue_N_tx_cnt`: *N*

The number of transmitted packets for this queue.

`queue_N_tx_bytes`: *N*

The number of transmitted bytes for this queue.

`queue_N_tx_queue_stop`: *N*

The number of times that queue *N* was full and stopped.

`queue_N_tx_queue_wakeup`: *N*

The number of times that queue *N* resumed after being stopped.

`queue_N_tx_dma_mapping_err`: *N*

Direct memory access error count. If this value is not 0, it indicates low system resources.

`queue_N_tx_linearize`: *N*

The number of times SKB linearization was attempted for this queue.

`queue_N_tx_linearize_failed`: *N*

The number of times SKB linearization failed for this queue.

`queue_N_tx_napi_comp`: *N*

The number of times the `napi` handler called `napi_complete` for this queue.

`queue_N_tx_tx_poll`: *N*

The number of times the `napi` handler was scheduled for this queue.

`queue_N_tx_doorbells`: *N*

The number of transmission doorbells for this queue.

`queue_N_tx_prepare_ctx_err`: *N*

The number of times `ena_com_prepare_tx` failed for this queue.

`queue_N_tx_bad_req_id`: *N*

Invalid `req_id` for this queue. The valid `req_id` is zero, minus the `queue_size`, minus 1.

`queue_N_tx_llq_buffer_copy`: *N*

The number of packets whose headers size are larger than llq entry for this queue.

`queue_N_tx_missed_tx`: *N*

The number of packets that were left uncompleted for this queue.

`queue_N_tx_unmask_interrupt`: *N*

The number of times the tx interrupt was unmasked for this queue.

`queue_N_rx_cnt`: *N*

The number of received packets for this queue.

`queue_N_rx_bytes`: *N*

The number of received bytes for this queue.

`queue_N_rx_rx_copybreak_pkt`: *N*

The number of times the rx queue received a packet that is less than the rx_copybreak packet size for this queue.

`queue_N_rx_csum_good`: *N*

The number of times the rx queue received a packet where the checksum was checked and was correct for this queue.

`queue_N_rx_refil_partial`: *N*

The number of times the driver did not succeed in refilling the empty portion of the rx queue with the buffers for this queue. If this value is not zero, it indicates low memory resources.

`queue_N_rx_bad_csum`: *N*

The number of times the `rx` queue had a bad checksum for this queue (only if rx checksum offload is supported).

`queue_N_rx_page_alloc_fail`: *N*

The number of time that page allocation failed for this queue. If this value is not zero, it indicates low memory resources.

`queue_N_rx_skb_alloc_fail`: *N*

The number of time that SKB allocation failed for this queue. If this value is not zero, it indicates low system resources.

`queue_N_rx_dma_mapping_err`: *N*

Direct memory access error count. If this value is not 0, it indicates low system resources.

`queue_N_rx_bad_desc_num`: *N*

Too many buffers per packet. If this value is not 0, it indicates the use of very small buffers.

`queue_N_rx_bad_req_id`: *N*

The req_id for this queue is not valid. The valid req_id is from [0, queue_size - 1].

`queue_N_rx_empty_rx_ring`: *N*

The number of times the rx queue was empty for this queue.

`queue_N_rx_csum_unchecked`: *N*

The number of times the rx queue received a packet whose checksum wasn't checked for this queue.

`queue_N_rx_xdp_aborted`: *N*

The number of times that an XDP packet was classified as XDP_ABORT.

`queue_N_rx_xdp_drop`: *N*

The number of times that an XDP packet was classified as XDP_DROP.

`queue_N_rx_xdp_pass`: *N*

The number of times that an XDP packet was classified as XDP_PASS.

`queue_N_rx_xdp_tx`: *N*

The number of times that an XDP packet was classified as XDP_TX.

`queue_N_rx_xdp_invalid`: *N*

The number of times that the XDP return code for the packet was not valid.

`queue_N_rx_xdp_redirect`: *N*

The number of times that an XDP packet was classified as XDP_REDIRECT.

`queue_N_xdp_tx_cnt`: *N*

The number of transmitted packets for this queue.

`queue_N_xdp_tx_bytes`: *N*

The number of transmitted bytes for this queue.

`queue_N_xdp_tx_queue_stop`: *N*

The number of times that this queue was full and stopped.

`queue_N_xdp_tx_queue_wakeup`: *N*

The number of times that this queue resumed after being stopped.

`queue_N_xdp_tx_dma_mapping_err`: *N*

Direct memory access error count. If this value is not 0, it indicates low system resources.

`queue_N_xdp_tx_linearize`: *N*

The number of times XDP buffer linearization was attempted for this queue.

`queue_N_xdp_tx_linearize_failed`: *N*

The number of times XDP buffer linearization failed for this queue.

`queue_N_xdp_tx_napi_comp`: *N*

The number of times the napi handler called napi_complete for this queue.

`queue_N_xdp_tx_tx_poll`: *N*

The number of times the napi handler was scheduled for this queue.

`queue_N_xdp_tx_doorbells`: *N*

The number of transmission doorbells for this queue.

`queue_N_xdp_tx_prepare_ctx_err`: *N*

The number of times ena_com_prepare_tx failed for this queue. This value should always be zero; if not, see the driver logs.

`queue_N_xdp_tx_bad_req_id`: *N*

The req_id for this queue is not valid. The valid req_id is from [0, queue_size - 1].

`queue_N_xdp_tx_llq_buffer_copy`: *N*

The number of packets that had their headers copied using llq buffer copy for this queue.

`queue_N_xdp_tx_missed_tx`: *N*

The number of times a tx queue entry missed a completion timeout for this queue.

`queue_N_xdp_tx_unmask_interrupt`: *N*

The number of times the tx interrupt was unmasked for this queue.

`ena_admin_q_aborted_cmd`: *N*

The number of admin commands that were aborted. This usually happens during the auto-recovery procedure.

`ena_admin_q_submitted_cmd`: *N*

The number of admin queue doorbells.

`ena_admin_q_completed_cmd`: *N*

The number of admin queue completions.

`ena_admin_q_out_of_space`: *N*

The number of times that the driver tried to submit new admin command, but the queue was full.

`ena_admin_q_no_completion`: *N*

The number of times that the driver did not get an admin completion for a command.

Driver error logs in syslog

The ENA driver writes log messages to **syslog** during system boot. You can examine these logs to look for errors if you are experiencing issues. Below is an example of information logged by the ENA driver in **syslog** during system boot, along with some annotations for select messages.

```
Jun  3 22:37:46 ip-172-31-2-186 kernel: [  478.416939] [ENA_COM:

Which errors can I ignore?

The following warnings that may appear in your system's error logs can be ignored for the Elastic Network Adapter:

Set host attribute isn't supported

Host attributes are not supported for this device.

failed to alloc buffer for rx queue

This is a recoverable error, and it indicates that there may have been a memory pressure issue when the error was thrown.

Feature *X* isn't supported

The referenced feature is not supported by the Elastic Network Adapter. Possible values for *X* include:

- 10: RSS Hash function configuration is not supported for this device.
- 12: RSS Indirection table configuration is not supported for this device.
- 18: RSS Hash Input configuration is not supported for this device.
- 20: Interrupt moderation is not supported for this device.
- 27: The Elastic Network Adapter driver does not support polling the Ethernet capabilities from snmpd.

Failed to config AENQ

The Elastic Network Adapter does not support AENQ configuration.

Trying to set unsupported AENQ events

This error indicates an attempt to set an AENQ events group that is not supported by the Elastic Network Adapter.

Sub-optimal configuration notifications

The ENA device detects sub-optimal configuration settings in the driver that you can change. The device notifies the ENA driver and logs a warning to the console. The following example shows the format of the warning message.

```
Sub-optimal configuration notification code: 1. Refer to AWS ENA documentation for
 additional details and mitigation options.
```

The following list shows notification code details and recommended actions for sub-optimal configuration findings.

- **Code 1: ENA Express with wide LLQ configuration is not recommended**

  ENA Express ENI is configured with wide LLQ. This configuration is sub-optimal and could impact performance for ENA Express. We recommend that you disable wide LLQ settings when you use ENA Express ENIs as follows.

  ```
  sudo rmmod ena && sudo modprobe ena force_large_llq_header=0
  ```

  For more information about optimal configuration for ENA Express, see Improve network performance between EC2 instances with ENA Express.
- **Code 2: ENA Express ENI with sub-optimal Tx queue depth is not recommended**

  ENA Express ENI is configured with sub-optimal Tx queue depth. This configuration could impact performance for ENA Express. We recommend that you enlarge all Tx queues to the maximum value for the network interface when you use ENA Express ENIs as follows.

  You can run the following **ethtool** commands to adjust LLQ size. To learn more about how to control, query, and enable wide-LLQ, see the Large Low-Latency Queue (Large LLQ) topic of the Linux kernel driver for ENA documentation in the *Amazon Drivers GitHub repository*.

  ```
  ethtool -g interface
  ```

Set your Tx queues to the maximum depth:

```
ethtool -G interface tx depth
```

For more information about optimal configuration for ENA Express, see [Improve network performance between EC2 instances with ENA Express].

- **Code 3: ENA with regular LLQ size and Tx packet traffic exceeds the maximum header supported size**

  By default, ENA LLQ supports Tx packet header size up to 96 bytes. If the packet header size is larger than 96 bytes, the packet is dropped. To mitigate this issue, we recommend that you enable wide-LLQ, which increases the supported Tx packet header size to a maximum of 224 bytes.

  However, when you enable wide-LLQ, the maximum Tx ring size is reduced from 1000 to 512 entries. Wide-LLQ is enabled by default for all Nitro v4 and later instance types.

  - Nitro v4 instance types have a default maximum wide-LLQ Tx ring size of 512 entries, which can't be changed.
  - Nitro v5 instance types have a default wide-LLQ Tx ring size of 512 entries, which you can increase up to 1000 entries.

  You can run the following **ethtool** commands to adjust LLQ size. To learn more about how to control, query, and enable wide-LLQ, see the [Large Low-Latency Queue (Large LLQ)] topic of the Linux kernel driver for ENA documentation in the *Amazon Drivers GitHub repository*.

  Find the maximum depth for your Tx queues:

```
ethtool -g interface
```

  Set your Tx queues to the maximum depth:

```
ethtool -G interface tx depth
```

Troubleshoot the Elastic Network Adapter Windows driver

The Elastic Network Adapter (ENA) is designed to improve operating system health and to reduce unexpected hardware behavior or failures that can disrupt the operation of your Windows instance. The ENA architecture keeps device or driver failures as transparent to the operating system as possible.

Collect diagnostic information on the instance

The steps to open Windows operating system (OS) tools vary, depending on what version of the OS is installed on your instance. In the following sections, we use the **Run** dialog to open the tools, which works the same across all OS versions. However, you can access these tools using any method that you prefer.

Access the Run dialog

- Using the Windows logo key combination: `Windows` + `R`
- Using the search bar:
  - Enter `run` in the search bar.
  - Select the **Run** application from the search results.

Some steps require the context menu to access properties or context-sensitive actions. There are several ways to do this, depending on your OS version and hardware.

Access the context menu

- Using your mouse: right-click an item to bring up its context menu.
- Using your keyboard:
  - Depending on your OS version, use `Shift` + `F10`, or `Ctrl` + `Shift` + `F10`.
  - If you have the context key on your keyboard (three horizontal lines in a box), select the item you want and then press the context key.

If you can connect to your instance, use the following techniques to gather diagnostic information for troubleshooting.

Check ENA device status

To check the status of your ENA Windows driver using the Windows Device Manager, follow these steps:

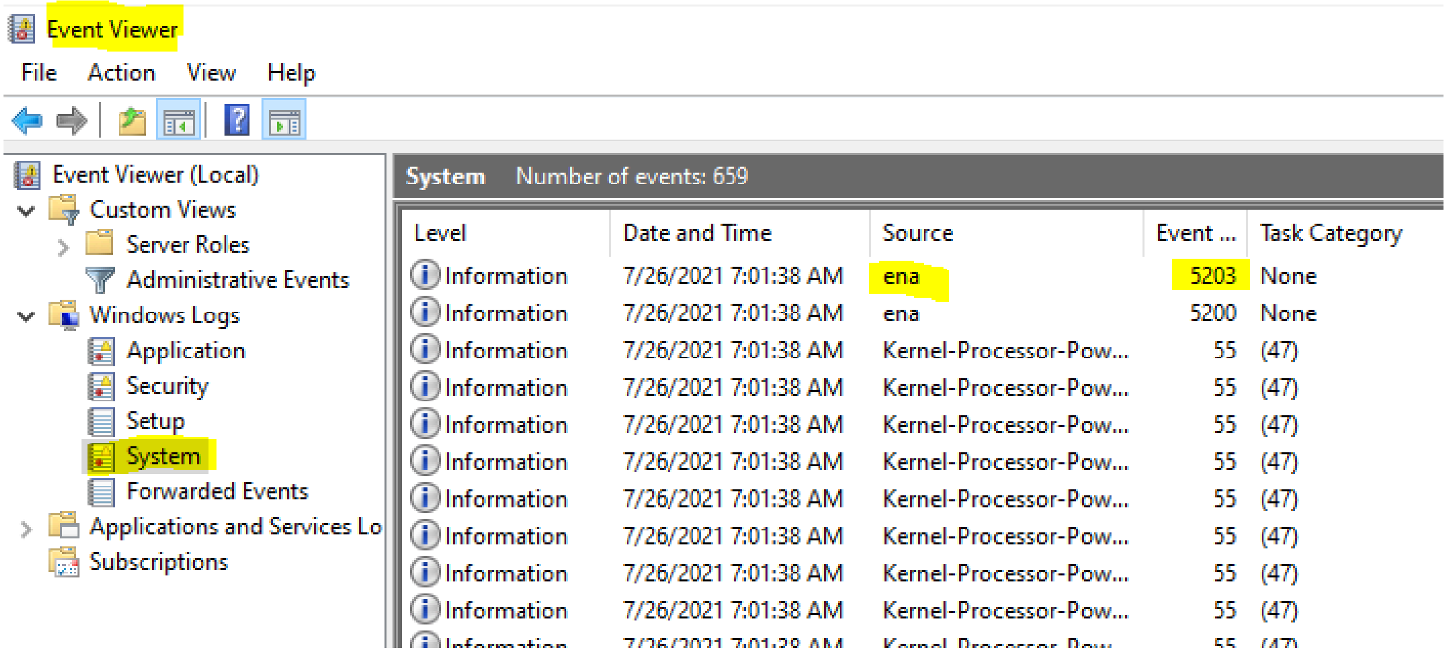
1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.
6. Verify that the message in the **General** tab says "This device is working properly."

Investigate driver event messages

To review ENA Windows driver event logs using the Windows Event Viewer, follow these steps:

1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Event Viewer, enter `eventvwr.msc` in the **Run** box.
3. Choose **OK**. This opens the Event Viewer window.
4. Expand the **Windows Logs** menu, and then choose **System**.
5. Under **Actions**, in the top-right panel, choose **Filter Current Log**. This displays the filtering dialog.
6. In the **Event sources** box, enter `ena`. This limits results to events that were generated by the ENA Windows driver.
7. Choose **OK**. This shows filtered event log results in the detail sections of the window.
8. To drill down into the details, select an event message from the list.

The following example shows an ENA driver event in the Windows Event Viewer system events list:



Event message summary

The following table shows event messages that the ENA Windows driver generates.

Input

Event ID	ENA driver event description	Type
5001	Hardware is out of resources	Error
5002	Adapter has detected a hardware error	Error
5005	Adapter has timed out on NDIS operation that did not complete in a timely manner	Error
5032	Adapter has failed to reset the device	Error
5200	Adapter has been initialized	Informational
5201	Adapter has been halted	Informational
5202	Adapter has been paused	Informational

Event ID	ENA driver event description	Type
5203	Adapter has been restarted	Informational
5204	Adapter has been shut down	Informational
5205	Adapter has been reset	Error
5206	Adapter has been surprise removed	Error
5208	Adapter initialization routine has failed	Error
5210	Adapter has encountered and successfully recovered an internal issue	Error

Review performance metrics

The ENA Windows driver publishes network performance metrics from the instances where metrics are enabled. You can view and enable metrics on the instance using the native Performance Monitor application. For more information about the metrics that the ENA Windows driver produces, see Monitor network performance for ENA settings on your EC2 instance.

On instances where ENA metrics are enabled, and the Amazon CloudWatch agent is installed, CloudWatch collects the metrics that are associated with the counters in Windows Performance Monitor, as well as some advanced metrics for ENA. These metrics are collected in addition to the metrics enabled by default on EC2 instances. For more information about the metrics, see Metrics collected by the CloudWatch agent in the *Amazon CloudWatch User Guide*.

Note

Performance metrics are available for ENA driver versions 2.4.0 and later (also for version 2.2.3). ENA driver version 2.2.4 was rolled back due to potential performance degradation on the sixth generation EC2 instances. We recommend that you upgrade to the current version of the driver to ensure that you have the latest updates.

Some of the ways that you can use performance metrics include:

- Troubleshoot instance performance issues.
- Choose the right instance size for a workload.
- Proactively plan scaling activities.
- Benchmark applications to determine if they maximize the performance available on an instance.

Refresh rate

By default, the driver refreshes metrics using a 1-second interval. However, the application that retrieves the metrics might use a different interval for polling. You can change the refresh interval in Device Manager, using the advanced properties for the driver.

To change the metrics refresh interval for the ENA Windows driver, follow these steps:

1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.
6. Open the **Advanced** tab in the pop-up window.
7. From the **Property** list, choose **Metrics Refresh Interval** to change the value.
8. When you are done, choose **OK**.

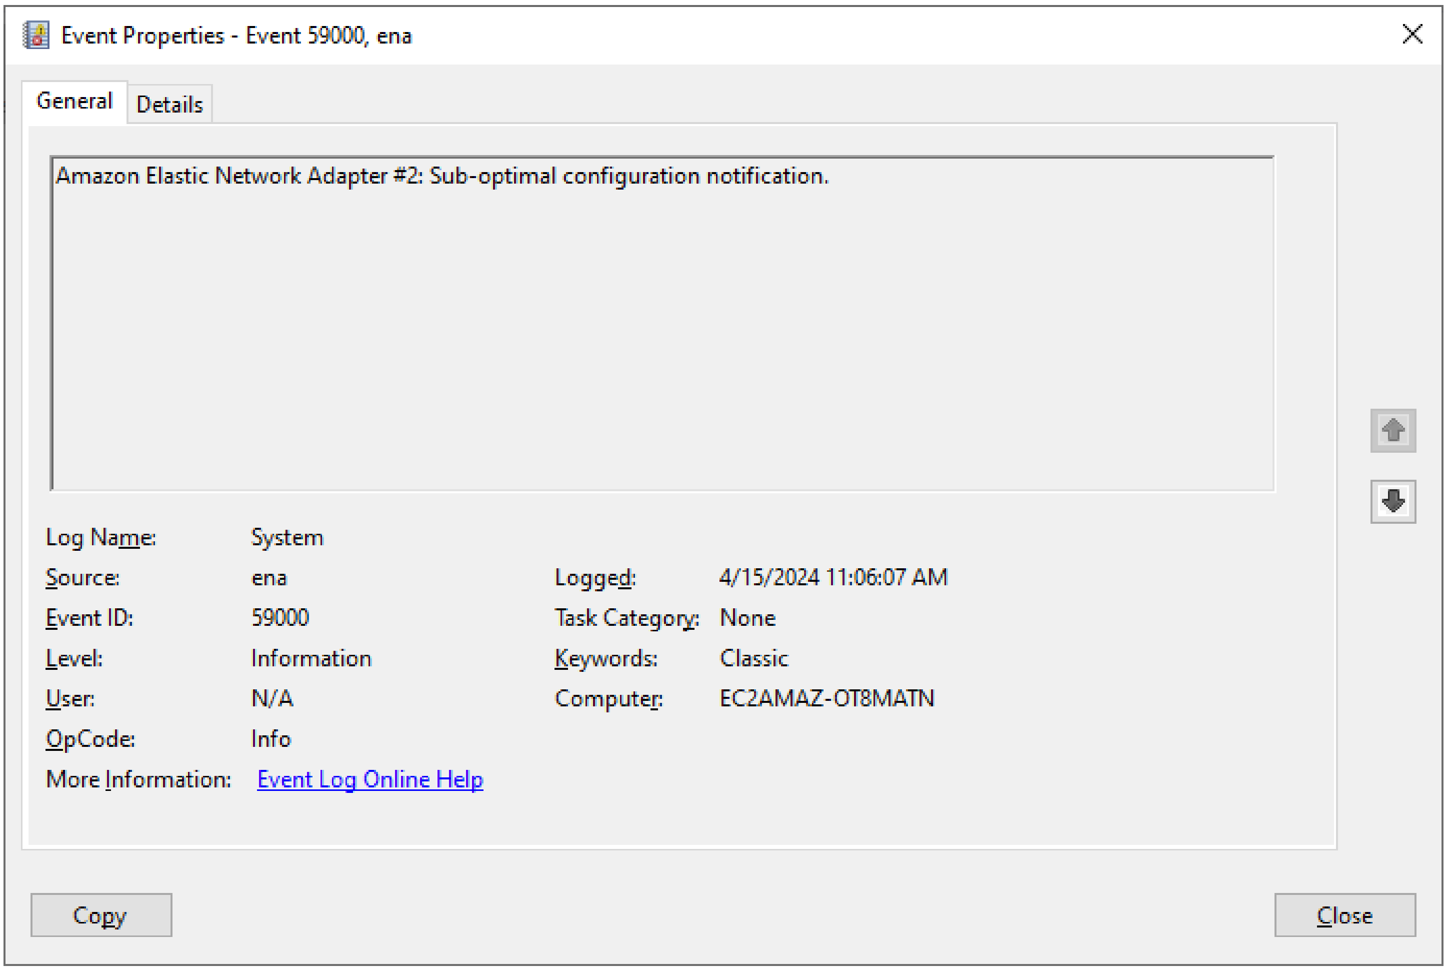
Investigate sub-optimal configuration notifications

The ENA device detects sub-optimal configuration settings in the driver that you can change. The device notifies the ENA driver and logs an event notification. To review sub-optimal events in the Windows Event Viewer

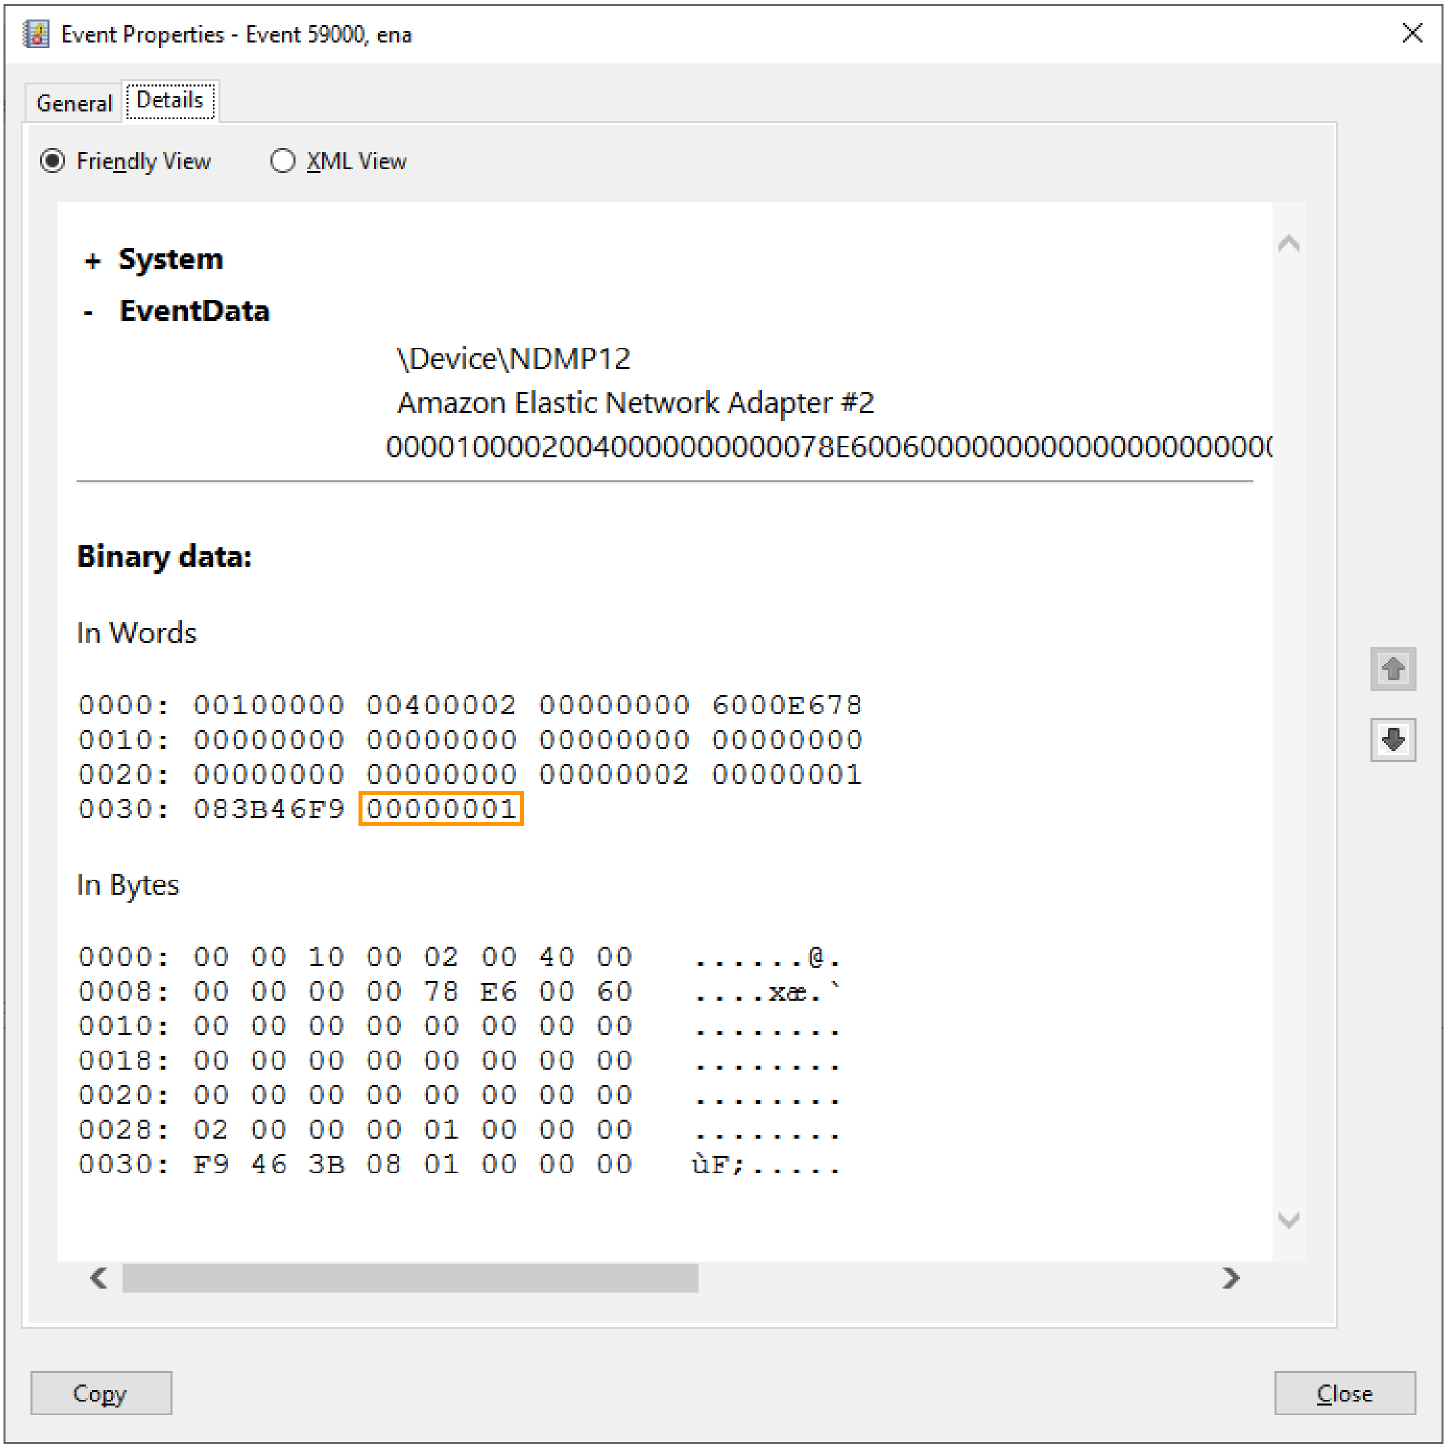
1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Event Viewer, enter `eventvwr.msc` in the **Run** box.
3. Choose **OK**. This opens the Event Viewer window.
4. Expand the **Windows Logs** menu, and then choose **System**.

5. Under **Actions**, in the top-right panel, choose **Filter Current Log**. This displays the filtering dialog.
6. In the **Event sources** box, enter `ena`. This limits results to events that were generated by the ENA Windows driver.
7. Choose **OK**. This shows filtered event log results in the detail sections of the window.

Events with ID `59000` notify you of sub-optimal configuration findings. Right-click an event and choose **Event Properties** to open a detailed view, or select **Preview Pane** from the **View** menu to see the same detail.



Open the **Details** tab to see the event code. In the **Binary Data: In words** section, the last word is the code.



The following list shows notification code details and recommended actions for sub-optimal configuration findings.

- **Code 1: ENA Express with wide LLQ configuration is not recommended**

ENA Express ENI is configured with wide LLQ. This configuration is sub-optimal and could impact performance for ENA Express. We recommend that you disable wide LLQ settings when you use ENA Express ENIs as follows.

1. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
2. Choose **OK**. This opens the Device Manager window.
3. Select the arrow to the left of **Network adapters** to expand the list.
4. Open the device properties for the `Amazon Elastic Network Adapter`.
5. From there, open the **Advanced** tab to make your changes.
6. Select the **LLQ Header Size Policy** property, and set its value to `Normal (128 Bytes)`.
7. Choose **OK** to save your changes.

- **Code 2: ENA Express ENI with sub-optimal Tx queue depth is not recommended**

  ENA Express ENI is configured with sub-optimal Tx queue depth. This configuration could impact performance for ENA Express. We recommend that you enlarge all Tx queues to the maximum value for the network interface when you use ENA Express ENIs as follows.

  Follow these steps to enlarge the Tx queues to the maximum depth:

1. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
2. Choose **OK**. This opens the Device Manager window.
3. Select the arrow to the left of **Network adapters** to expand the list.
4. Open the device properties for the `Amazon Elastic Network Adapter`.
5. From there, open the **Advanced** tab to make your changes.
6. Select the **Transmit Buffers** property, and set its value to the maximum supported.
7. Choose **OK** to save your changes.

ENA adapter reset

The reset process starts when the ENA Windows driver detects an error on an adapter, and marks the adapter as unhealthy. The driver cannot reset itself, so it depends on the operating system to check the adapter health status, and call the reset handle for the ENA Windows driver. The reset process might result in a brief period of time where traffic loss occurs. However, TCP connections should be able to recover.

The ENA adapter might also indirectly request a device reset procedure, by failing to send a keep-alive notification. For example, if the ENA adapter reaches an unknown state after loading an irrecoverable configuration, it might stop sending keep-alive notifications.

Common causes for ENA adapter reset

- Keep-alive messages are missing

  The ENA adapter posts keep-alive events at a fixed rate (usually once every second). The ENA Windows driver implements a watchdog mechanism, which periodically checks for the presence of these keep-alive messages. If it detects one or more new messages since the last time it checked, it records a successful outcome. Otherwise, the driver concludes that the device experienced a failure, and initiates a reset sequence.
- Packets are stuck in transmit queues

  The ENA adapter verifies that packets are flowing through the transmit queues as expected. The ENA Windows driver detects if packets are getting stuck, and initiates a reset sequence if they are.
- Read timeout for Memory Mapped I/O (MMIO) registers

  To limit memory mapped I/O (MMIO) read operations, the ENA Windows driver accesses MMIO registers only during initialization and reset processes. If the driver detects a timeout, it takes one of the following actions, depending on what process was running:
  - If a timeout is detected during initialization, it fails the flow, which results in the driver displaying a yellow exclamation mark by the ENA adapter in Windows Device Manager.
  - If a timeout is detected during reset, it fails the flow. The OS then initiates a surprise removal of the ENA adapter, and recovers it by stopping and starting the adapter that was removed. For more information about surprise removal of a network interface card (NIC), see Handling the Surprise Removal of a NIC in the *Microsoft Windows Hardware Developer* documentation.

Troubleshooting scenarios

The following scenarios can help you troubleshoot issues that you might experience with the ENA Windows driver. We recommend that you start with upgrading your ENA driver, if you don't have the latest version. To find the latest driver for your Windows OS version, see Track ENA Windows driver version releases.

Unexpected ENA driver version installed

Description

After you go through the steps to install a specific version of the ENA driver, the Windows Device Manager shows that Windows installed a different version of the ENA driver.

Cause

When you run the install for a driver package, Windows ranks all of the driver packages that are valid for the given device in the local Driver Store before it begins. Then it selects the package with the lowest rank value as the best match. This can be different from the package that you intended to install. For more information about the device driver package selection process, see How Windows selects a driver package for a device on the *Microsoft documentation website*.

Solution

To ensure that Windows installs your chosen driver package version, you can remove lower ranked driver packages from the Driver Store with the PnPUtil command line tool.

Follow these steps to update the ENA driver:

1. Connect to your instance and log in as the local administrator.
2. Open the Device Manager properties window, as described in the Check ENA device status section. This opens the **General** tab of the **Amazon Elastic Network Adapter Properties** window.
3. Open the **Driver** tab.
4. Choose **Update Driver**. This opens the **Update Driver Software – Amazon Elastic Network Adapter** dialog box.

    a. On the **How do you want to search for driver software?** page, choose **Browse my computer for driver software**.

    b. On the **Browse for driver software on your computer** page, choose **Let me pick from a list of device drivers on my computer**, located below the search bar.

    c. On the **Select the device driver you want to install for this hardware** page, choose **Have Disk...**.

    d. In the **Install from Disk** window, choose **Browse...**, next to the file location from the dropdown list.

   e. Navigate to the location where you downloaded the target ENA driver package. Select the file named `ena.inf` and choose **Open**.

   f. To start the install, choose **OK**, and then choose **Next**.

5. If the installer doesn't automatically reboot your instance, run the **Restart-Computer** PowerShell cmdlet.

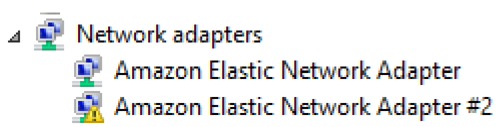
```
PS C:\> Restart-Computer
```

Device warning for ENA driver

Description

The ENA adapter icon in the Device Manager **Network adapters** section displays a warning sign (a yellow triangle with an exclamation mark inside).

The following example shows an ENA adapter with the warning icon in Windows Device Manager:



Cause

This device warning is commonly caused by environment issues, which might require more research, and often require a process of elimination to determine the underlying cause. For a full list of device errors, see Device Manager Error Messages in the Microsoft documentation.

Solution

The solution for this device warning depends on the root cause. The process of elimination described here includes a few basic steps to help identify and resolve the most common issues that might have a simple solution. Additional root cause analysis is required when these steps do not resolve the issue.

Follow these steps to help identify and resolve common issues:

1. **Stop and start the device**

   Open the Device Manager properties window, as described in the Check ENA device status section. This opens the **General** tab of the **Amazon Elastic Network Adapter Properties** window, where the **Device status** displays the error code and a short message.

   a. Open the **Driver** tab.
   b. Choose **Disable Device**, and respond **Yes** to the warning message that displays.
   c. Choose **Enable Device**.

2. **Stop and start the EC2 instance**

   If the adapter still shows the warning icon in Device Manager, the next step is to stop and start the EC2 instance. This relaunches the instance on different hardware in most cases.

3. **Investigate possible instance resource issue**

   If you have stopped and started your EC2 instance, and the problem persists, this might indicate a resource issue on your instance, such as insufficient memory.

Connection timeout with adapter reset (error codes 5007, 5205)

Description

The Windows Event Viewer shows adapter timeout and reset events occurring in combination for ENA adapters. Messages resemble the following examples:

- **Event ID 5007**: Amazon Elastic Network Adapter : Timed out during an operation.
- **Event ID 5205**: Amazon Elastic Network Adapter : Adapter reset has been started.

Adapter resets cause minimal traffic disruption. Even when there are multiple resets, it would be unusual for them to cause any severe network disruption.

Cause

This sequence of events indicates that the ENA Windows driver initiated a reset for an ENA adapter that was unresponsive. However, the mechanism that the device driver uses to detect this issue is subject to false positives resulting from CPU 0 starvation.

Solution

If this combination of errors happens frequently, check your resource allocations to see where adjustments might be helpful.

1. Open the **Run** dialog using one of the methods described in the preceding section.

2. To open the Windows Resource Monitor, enter `resmon` in the **Run** box.
3. Choose **OK**. This opens the Resource Monitor window.
4. Open the **CPU** tab. Per-CPU usage graphs are shown along the right side of the Resource Monitor window.
5. Check the usage levels for CPU 0 to see if they are too high.

We recommend that you configure RSS to exclude CPU 0 for the ENA adapter on larger instance types (more than 16 vCPU). For smaller instance types, configuring RSS might improve the experience, but due to the lower number of available cores, testing is necessary to ensure that constraining CPU cores does not negatively impact performance.

Use the **Set-NetAdapterRss** command to configure RSS for your ENA adapter, as shown in the following example.

```
Set-NetAdapterRss -name (Get-NetAdapter | Where-Object {$_.InterfaceDescription -like
 "*Elastic*"}).Name -Baseprocessorgroup 0 -BaseProcessorNumber 1
```

Migrating to a sixth generation instance infrastructure impacts performance or attachment

Description

If you migrate to a sixth generation EC2 instance, you might experience reduced performance or ENA attachment failures if you haven't updated your ENA Windows driver version.

Cause

The sixth generation EC2 instance types require the following minimum version of the ENA Windows driver, based on the instance operating system (OS).

Minimum version

Windows Server version	ENA driver version
Windows Server 2008 R2	2.2.3 or 2.4.0
Windows Server 2012 and later	2.2.3 and later

Windows Server version	ENA driver version
Windows Workstation	2.2.3 and later

Solution

Before you upgrade to a sixth generation EC2 instance, make sure that the AMI you launch from has compatible drivers based on the instance OS as shown in the previous table. For more information, see [What do I need to do before migrating my EC2 instance to a sixth generation instance to make sure that I get maximum network performance?] in the *AWS re:Post Knowledge Center*.

Suboptimal performance for the elastic network interface

Description

The ENA interface is not performing as expected.

Cause

Root cause analysis for performance issues is a process of elimination. There are too many variables involved to name a common cause.

Solution

The first step in your root cause analysis is to review the diagnostic information for the instance that is not performing as expected, to determine if there are errors that might be causing the issue. For more information, see the [Collect diagnostic information on the instance] section.

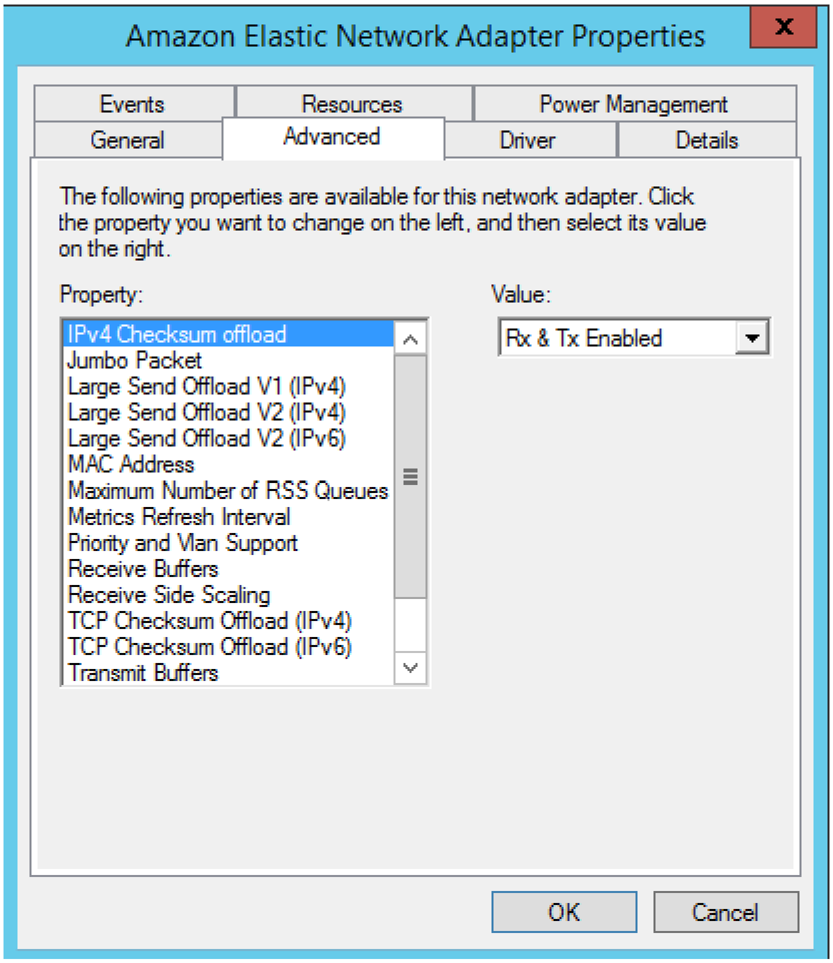
You might need to modify the default operating system configuration to achieve maximum network performance on instances with enhanced networking. Some optimizations, such as turning on checksum offloading and enabling RSS, are configured by default in official Windows AMIs. For other optimizations that you can apply to the ENA adapter, see the performance adjustments shown in [ENA adapter performance adjustments].

We recommend that you proceed with caution, and limit device property adjustments to those that are listed in this section, or to specific changes that are recommended by the AWS support team.

To change ENA adapter properties, follow these steps:

1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.
6. To make your changes, open the **Advanced** tab.
7. When you're done, choose **OK** to save your changes.

The following example shows an ENA adapter property in the Windows Device Manager:



ENA adapter performance adjustments

The following table includes properties that can be adjusted to improve performance for the ENA interface.

Input

Property	Description	Default value	Adjustment
Receive Buffers	Controls the number of entries in the software receive queues.	1024	Can be increased up to a maximum of 8192.
Receive Side Scaling (RSS)	Enables the efficient distribution of network receive processing across multiple CPUs in multiprocessor systems.	Enabled	You can spread the load across multiple processors. To learn more, see [Optimize network performance on EC2 Windows instances](#).
Maximum Number of RSS Queues	Sets the maximum number of RSS queues allowed when RSS is enabled.	32	The number of RSS queues is determined during driver initialization, and includes the following limitations (among others): • RSS queue limit set by this property • Instance limits (vCPU count) • Hardware generation limits (up to 8 RSS queues in ENAv1,

Property	Description	Default value	Adjustment
			and up to 32 RSS queues in ENAv2) You can set the value from 1-32, depending on your instance and hardware generation limits. To learn more, see Optimize network performance on EC2 Windows instances.
Jumbo packet	Enables the use of jumbo ethernet frames (more than 1500 bytes of payload).	Disabled (this limits payload to 1500 bytes or less)	Value can be set up to `9015`, which translates to 9001 bytes of payload. This is the maximum payload for jumbo ethernet frames. See Considerations for using jumbo ethernet frames.

Considerations for using jumbo ethernet frames

Jumbo frames allow more than 1500 bytes of data by increasing the payload size per packet, which increases the percentage of the packet that is not packet overhead. Fewer packets are needed to send the same amount of usable data. However, traffic is limited to a maximum MTU of 1500 in the following cases:

- Traffic outside of a given AWS Region for EC2 Classic.
- Traffic outside of a single VPC.

- Traffic over an inter-Region VPC peering connection.
- Traffic over VPN connections.
- Traffic over an internet gateway.

> **Note**
>
> Packets over 1500 bytes are fragmented. If you have the `Don't Fragment` flag set in the IP header, these packets are dropped.
> Jumbo frames should be used with caution for internet-bound traffic, or any traffic that leaves a VPC. Packets are fragmented by intermediate systems, which slows down this traffic. To use jumbo frames inside of a VPC without impacting outbound traffic that's leaving the VPC, try one of the following options:
>
> - Configure the MTU size by route.
> - Use multiple network interfaces with different MTU sizes and different routes.

Recommended use cases for jumbo frames

Jumbo frames can be useful for traffic inside of and between VPCs. We recommend using jumbo frames for the following use cases:

- For instances that are collocated inside of a cluster placement group, jumbo frames help to achieve the maximum network throughput possible. For more information, see Placement groups for your Amazon EC2 instances.
- You can use jumbo frames for traffic between your VPCs and your on-premises networks over AWS Direct Connect. For more information about using AWS Direct Connect, and verifying jumbo frame capability, see MTU for private virtual interfaces or transit virtual interfaces in the *AWS Direct Connect User Guide*.
- For more information about supported MTU sizes for transit gateways, see Quotas for your transit gateways in the *Amazon VPC Transit Gateways*.

Improve network performance between EC2 instances with ENA Express

ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD is a high performance network transport protocol that uses dynamic routing to increase throughput and minimize tail latency. With ENA Express, you can communicate between two EC2 instances in the same Availability Zone.

Benefits of ENA Express

- Increases the maximum bandwidth a single flow can use from 5 Gbps up to 25 Gbps within the Availability Zone, up to the aggregate instance limit.
- Reduces tail latency of network traffic between EC2 instances, especially during periods of high network load.
- Detects and avoids congested network paths.
- Handles some tasks directly in the network layer, such as packet reordering on the receiving end, and most retransmits that are needed. This frees up the application layer for other work.

> **Note**
>
> - If your application sends or receives a high volume of packets per second, and needs to optimize for latency most of the time, especially during periods when there is no congestion on the network, Enhanced networking might be a better fit for your network.
> - ENA Express traffic can't be sent in a Local Zone.

After you've enabled ENA Express for the network interface attachment on an instance, the sending instance initiates communication with the receiving instance, and SRD detects if ENA Express is operating on both the sending instance and the receiving instance. If ENA Express is operating, the communication can use SRD transmission. If ENA Express is not operating, the communication falls back to standard ENA transmission.

During periods of time when network traffic is light, you might notice a slight increase in packet latency (tens of microseconds) when the packet uses ENA Express. During those times, applications that prioritize specific network performance characteristics can benefit from ENA Express as follows:

- Processes can benefit from increased maximum single flow bandwidth from 5 Gbps up to 25 Gbps within the same Availability Zone, up to the aggregate instance limit. For example, if a specific instance type supports up to 12.5 Gbps, the single flow bandwidth is also limited to 12.5 Gbps.
- Longer running processes should experience reduced tail latency during periods of network congestion.
- Processes can benefit from a smoother and more standard distribution for network response times.

Topics

How ENA Express works

ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. It distributes packets for each network flow across different AWS network paths, and dynamically adjusts distribution when it detects signs of congestion. It also manages packet reordering on the receiving end.

To ensure that ENA Express can manage network traffic as intended, sending and receiving instances and the communication between them must meet all of the following requirements:

- Both sending and receiving instance types are supported. See the Supported instance types for ENA Express table for more information.
- Both sending and receiving instances must have ENA Express configured. If there are differences in the configuration, you can run into situations where traffic defaults to standard ENA transmission. The following scenario shows what can happen.

  Scenario: Differences in configuration

Instance	ENA Express Enabled	UDP uses ENA Express
Instance 1	Yes	Yes
Instance 2	Yes	No

In this case, TCP traffic between the two instances can use ENA Express, as both instances have enabled it. However, since one of the instances does not use ENA Express for UDP traffic, communication between these two instances over UDP uses standard ENA transmission.

- The sending and receiving instances must run in the same Availability Zone.
- The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.
- (Linux instances only) To utilize full bandwidth potential, use driver version 2.2.9 or higher.
- (Linux instances only) To produce metrics, use driver version 2.8 or higher.

If any requirement is unmet, the instances use the standard TCP/UDP protocol but without SRD to communicate.

To ensure that your instance network driver is configured for optimum performance, review the recommended best practices for ENA drivers. These best practices apply to ENA Express, as well. For more information, see the ENA Linux Driver Best Practices and Performance Optimization Guide on the GitHub website.

Note

Amazon EC2 refers to the relationship between an instance and a network interface that's attached to it as an *attachment*. ENA Express settings apply to the attachment. If the network interface is detached from the instance, the attachment no longer exists, and the ENA Express settings that applied to it are no longer in force. The same is true when an instance is terminated, even if the network interface remains.

After you've enabled ENA Express for the network interface attachments on both the sending instance and the receiving instance, you can use ENA Express metrics to help ensure that your instances take full advantage of the performance improvements that SRD technology provides. For more information about ENA Express metrics, see Metrics for ENA Express.

Supported instance types for ENA Express

The following instance types support ENA Express.

General purpose

Instance type	Architecture
m6a.12xlarge	x86_64

im4gn.16xlarge	arm64

Prerequisites for Linux instances

To ensure that ENA Express can operate effectively, update the settings for your Linux instance as follows.

- If your instance uses jumbo frames, run the following command to set your maximum transmission unit (MTU) to `8900`.

```
[ec2-user ~]$ sudo ip link set dev eth0 mtu 8900
```

- Increase the receiver (Rx) ring size, as follows:

```
[ec2-user ~]$ ethtool -G device rx 8192
```

- To maximize ENA Express bandwidth, configure your TCP queue limits as follows:

  1. Set the TCP small queue limit to 1MB or higher. This increases the amount of data that's queued for transmission on a socket.

  ```
  sudo sh -c 'echo 1048576 > /proc/sys/net/ipv4/tcp_limit_output_bytes'
  ```

  2. Disable byte queue limits on the eth device if they're enabled for your Linux distribution. This increases data queued for transmission for the device queue.

  ```
  sudo sh -c 'for txq in /sys/class/net/eth0/queues/tx-*; do echo max > ${txq}/
  byte_queue_limits/limit_min; done'
  ```

> **Note**
>
> The ENA driver for the Amazon Linux distribution disables byte queue limits by default.

Tune performance for ENA Express settings on Linux instances

To check your Linux instance configuration for optimal ENA Express performance, you can run the following script that's available on the Amazon GitHub repository:

https://github.com/amzn/amzn-ec2-ena-utilities/blob/main/ena-express/check-ena-express-settings.sh

The script runs a series of tests and suggests both recommended and required configuration changes.

Review ENA Express settings for your EC2 instance

You can verify the ENA Express settings by instance or by network interface. To update the ENA Express settings, see the section called “Configure instance settings”.

Console

To view ENA Express settings for a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Network interfaces**.
3. Select a network interface to see the details for that instance. You can choose the **Network interface ID** link to open the detail page, or you can select the checkbox on the left side of the list to view details in the detail pane at the bottom of the page.
4. In the **Network interface attachment** section on the the **Details** tab or detail page, review settings for **ENA Express** and **ENA Express UDP**.

To view ENA Express settings for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.

3. Select an instance to see the details for that instance. You can choose the **Instance ID** link to open the detail page, or you can select the checkbox on the left side of the list to view details in the detail pane at the bottom of the page.
4. In the **Network interfaces** section on the **Networking** tab, scroll right to review settings for **ENA Express** and **ENA Express UDP**.

AWS CLI

To get the ENA Express settings for an instance

Use the describe-instances command. This command example returns a list of ENA Express configurations for the network interfaces attached to each of the running instances that are specified by the `--instance-ids` parameter.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 i-0598c7d356eba48d7 \
    --query 'Reservations[*].Instances[*].[InstanceId,
 NetworkInterfaces[*].Attachment.EnaSrdSpecification]'
```

The following is example output.

```
[
    [
        [
            "i-1234567890abcdef0",
            [
                {
                    "EnaSrdEnabled": true,
                    "EnaSrdUdpSpecification": {
                        "EnaSrdUdpEnabled": false
                    }
                }
            ]
        ]
    ],
    [
        [
            "i-0598c7d356eba48d7",
            [
            {
                    "EnaSrdEnabled": true,
```

```
                    "EnaSrdUdpSpecification": {
                        "EnaSrdUdpEnabled": false
                    }
                }
            ]
        ]
    ]
]
```

To get the ENA Express settings for a network interface

Use the describe-network-interfaces command.

```
aws ec2 describe-network-interfaces \
    --network-interface-ids eni-1234567890abcdef0 \
    --query NetworkInterfaces[].[NetworkInterfaceId,Attachment.EnaSrdSpecification]
```

The following is example output.

```
[
    [
        "eni-1234567890abcdef0",
        {
            "EnaSrdEnabled": true,
            "EnaSrdUdpSpecification": {
                "EnaSrdUdpEnabled": false
            }
        }
    ]
]
```

PowerShell

To get the ENA Express settings for a network interface

Use the Get-EC2NetworkInterface cmdlet.

```
Get-EC2NetworkInterface `
    -NetworkInterfaceId eni-1234567890abcdef0 | `
Select-Object `
    Association,
    NetworkInterfaceId,
```

```
    OwnerId,
    @{Name = 'AttachTime'; Expression = { $_.Attachment.AttachTime } },
    @{Name = 'AttachmentId'; Expression = { $_.Attachment.AttachmentId } },
    @{Name = 'DeleteOnTermination'; Expression = 
{ $_.Attachment.DeleteOnTermination } },
    @{Name = 'NetworkCardIndex'; Expression = { $_.Attachment.NetworkCardIndex } },
    @{Name = 'InstanceId'; Expression = { $_.Attachment.InstanceId } },
    @{Name = 'InstanceOwnerId'; Expression = { $_.Attachment.InstanceOwnerId } },
    @{Name = 'Status'; Expression = { $_.Attachment.Status } },
    @{Name = 'EnaSrdEnabled'; Expression = 
{ $_.Attachment.EnaSrdSpecification.EnaSrdEnabled } },
    @{Name = 'EnaSrdUdpEnabled'; Expression = 
{ $_.Attachment.EnaSrdSpecification.EnaSrdUdpSpecification.EnaSrdUdpEnabled } }
```

The following is example output.

```
Association         : 
NetworkInterfaceId  : eni-0d1234e5f6a78901b
OwnerId             : 111122223333
AttachTime          : 6/11/2022 1:13:11 AM
AttachmentId        : eni-attach-0d1234e5f6a78901b
DeleteOnTermination : True
NetworkCardIndex    : 0
InstanceId          : i-1234567890abcdef0
InstanceOwnerId     : 111122223333
Status              : attached
EnaSrdEnabled       : True
EnaSrdUdpEnabled    : False
```

Configure ENA Express settings for your EC2 instance

You can configure ENA Express for supported EC2 instance types without needing to install any additional software. For more information, see the section called “Supported instance types for ENA Express”.

Console

To manage ENA Express for a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Network interfaces**.

3. Select a network interface that is attached to an instance. You can choose the **Network interface ID** link to open the detail page, or you can select the checkbox on the left side of the list.
4. Choose **Manage ENA Express** from the **Action** menu at the top right side of the page. This opens the **Manage ENA Express** dialog, with the selected network interface ID and current settings displayed.

   If the network interface you selected is not attached to an instance, this action does not appear in the menu.
5. To use **ENA Express**, select the **Enable** checkbox.
6. When ENA Express is enabled, you can configure UDP settings. To use **ENA Express UDP**, select the **Enable** checkbox.
7. To save your settings, choose **Save**.

To manage ENA Express for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance that you want to manage. You can choose the **Instance ID** to open the detail page, or you can select the checkbox on the left side of the list.
4. Select the **Network interface** to configure for your instance.
5. Choose **Manage ENA Express** from the **Action** menu at the top right side of the page.
6. To configure ENA Express for a network interface that's attached to your instance, select it from the **Network interface** list.
7. To use **ENA Express** for the selected network interface attachment, select the **Enable** checkbox.
8. When ENA Express is enabled, you can configure UDP settings. To use **ENA Express UDP**, select the **Enable** checkbox.
9. To save your settings, choose **Save**.

To configure ENA Express when you attach a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Network interfaces**.

3. Select a network interface that is not attached to an instance (**Status** is **Available**). You can choose the **Network interface ID** link to open the detail page, or you can select the checkbox on the left side of the list.
4. Select the **Instance** that you'll attach to.
5. To use **ENA Express** after you attach the network interface to the instance, select the **Enable** checkbox.
6. When ENA Express is enabled, you can configure UDP settings. To use **ENA Express UDP**, select the **Enable** checkbox.
7. To attach the network interface to the instance and save your ENA Express settings, choose **Attach**.

AWS CLI

To configure ENA Express when you attach a network interface

Use the attach-network-interface command, as shown in the following examples.

Example 1: Use ENA Express for TCP traffic, but not UDP traffic

This example configures `EnaSrdEnabled` as `true`, and allows `EnaSrdUdpEnabled` to default to `false`.

```
aws ec2 attach-network-interface \
    --network-interface-id eni-1234567890abcdef0 \
    --instance-id i-1234567890abcdef0 \
    --device-index 1 \
    --ena-srd-specification 'EnaSrdEnabled=true'
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

This example configures both `EnaSrdEnabled` and `EnaSrdUdpEnabled` as `true`.

```
aws ec2 attach-network-interface \
    --network-interface-id eni-1234567890abcdef0 \
    --instance-id i-1234567890abcdef0 \
    --device-index 1 \
    --ena-srd-specification
 'EnaSrdEnabled=true,EnaSrdUdpSpecification={EnaSrdUdpEnabled=true}'
```

To update ENA Express settings for a network interface attachment

Use the modify-network-interface-attribute command as shown in the following examples.

Example 1: Use ENA Express for TCP traffic, but not UDP traffic

This example configures `EnaSrdEnabled` as `true`, and allows `EnaSrdUdpEnabled` to default to `false` if it has never been set previously.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --ena-srd-specification 'EnaSrdEnabled=true'
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

This example configures both `EnaSrdEnabled` and `EnaSrdUdpEnabled` as `true`.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --ena-srd-specification
 'EnaSrdEnabled=true,EnaSrdUdpSpecification={EnaSrdUdpEnabled=true}'
```

Example 3: Stop using ENA Express for UDP traffic

This example configures `EnaSrdUdpEnabled` as `false`.

```
aws ec2 modify-network-interface-attribute \
    --network-interface-id eni-1234567890abcdef0 \
    --ena-srd-specification 'EnaSrdUdpSpecification={EnaSrdUdpEnabled=false}'
```

PowerShell

To configure ENA Express when you attach a network interface

Use the Add-EC2NetworkInterface cmdlet as shown in the following examples.

Example 1: Use ENA Express for TCP traffic, but not UDP traffic

This example configures `EnaSrdEnabled` as `true`, and allows `EnaSrdUdpEnabled` to default to `false`.

```
Add-EC2NetworkInterface `
```

```
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -InstanceId i-1234567890abcdef0 `
    -DeviceIndex 1 `
    -EnaSrdSpecification_EnaSrdEnabled $true
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

This example configures both `EnaSrdEnabled` and `EnaSrdUdpEnabled` as `true`.

```
Add-EC2NetworkInterface `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -InstanceId i-1234567890abcdef0 `
    -DeviceIndex 1 `
    -EnaSrdSpecification_EnaSrdEnabled $true `
    -EnaSrdUdpSpecification_EnaSrdUdpEnabled $true
```

To configure ENA Express settings for your network interface attachment

Use the Edit-EC2NetworkInterfaceAttribute cmdlet as shown in the following examples.

Example 1: Use ENA Express for TCP traffic, but not UDP traffic

This example configures `EnaSrdEnabled` as `true`, and allows `EnaSrdUdpEnabled` to default to `false` if it has never been set previously.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -EnaSrdSpecification_EnaSrdEnabled $true ;
Get-EC2NetworkInterface -NetworkInterfaceId eni-0123f4567890a1b23 | `
Select-Object `
    NetworkInterfaceId,
    @{Name = 'EnaSrdEnabled'; Expression =
 { $_.Attachment.EnaSrdSpecification.EnaSrdEnabled }},
    @{Name = 'EnaSrdUdpEnabled'; Expression =
 { $_.Attachment.EnaSrdSpecification.EnaSrdUdpSpecification.EnaSrdUdpEnabled }} | `
Format-List
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

This example configures both `EnaSrdEnabled` and `EnaSrdUdpEnabled` as `true`.

```
Edit-EC2NetworkInterfaceAttribute `
```

```
    -NetworkInterfaceId eni-1234567890abcdef0 `
    -EnaSrdSpecification_EnaSrdEnabled $true `
    -EnaSrdSpecification_EnaSrdUdpSpecification_EnaSrdUdpEnabled $true ;
Get-EC2NetworkInterface -NetworkInterfaceId eni-1234567890abcdef0 | `
Select-Object `
    NetworkInterfaceId,
    @{Name = 'EnaSrdEnabled'; Expression =
 { $_.Attachment.EnaSrdSpecification.EnaSrdEnabled }},
    @{Name = 'EnaSrdUdpEnabled'; Expression =
 { $_.Attachment.EnaSrdSpecification.EnaSrdUdpSpecification.EnaSrdUdpEnabled }} | `
Format-List
```

Example 3: Stop using ENA Express for UDP traffic

This example configures `EnaSrdUdpEnabled` as `false`.

```
Edit-EC2NetworkInterfaceAttribute `
    -NetworkInterfaceId eni-0123f4567890a1b23 `
    -EnaSrdSpecification_EnaSrdUdpSpecification_EnaSrdUdpEnabled $false ;
Get-EC2NetworkInterface -NetworkInterfaceId eni-0123f4567890a1b23 | `
Select-Object `
    NetworkInterfaceId,
    @{Name = 'EnaSrdEnabled'; Expression =
 { $_.Attachment.EnaSrdSpecification.EnaSrdEnabled }},
    @{Name = 'EnaSrdUdpEnabled'; Expression =
 { $_.Attachment.EnaSrdSpecification.EnaSrdUdpSpecification.EnaSrdUdpEnabled }} | `
Format-List
```

Configure ENA Express at launch

You can use one of the following methods to configure ENA Express directly when you launch an instance. The specified links refer you to the AWS Management Console instructions for these methods.

- **Launch instance wizard** – You can configure ENA Express at launch with the launch instance wizard. For more information, see **Advanced network configuration** in the Network settings for the launch instance wizard.
- **Launch template** – You can configure ENA Express at launch when you use a launch template. For more information, see the Create an Amazon EC2 launch template page, then expand the **Network settings** section and review the **Advanced network configuration**.

Enhanced networking with the Intel 82599 VF interface

For Xen-based instances, the Intel 82599 Virtual Function (VF) interface provides enhanced networking capabilities. The interface uses the Intel `ixgbevf` driver.

The following tabs show how to verify the network adapter driver that's installed for your instance operating system.

Linux

Linux network interface driver

Use the following command to verify that the module is being used on a particular interface, substituting the interface name that you want to check. If you are using a single interface (default), this is `eth0`. If the operating system supports predictable network names, this could be a name like `ens5`.

In the following example, the `ixgbevf` module is not loaded, because the listed driver is `vif`.

```
[ec2-user ~]$ ethtool -i eth0
driver: vif
version:
firmware-version:
bus-info: vif-0
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

In this example, the `ixgbevf` module is loaded. This instance has enhanced networking properly configured.

```
[ec2-user ~]$ ethtool -i eth0
driver: ixgbevf
version: 4.0.3
firmware-version: N/A
bus-info: 0000:00:03.0
supports-statistics: yes
supports-test: yes
supports-eeprom-access: no
```

```
supports-register-dump: yes
supports-priv-flags: no
```

Windows

Windows network adapter

To verify that the driver is installed, connect to your instance and open Device Manager. You should see `Intel(R) 82599 Virtual Function` listed under **Network adapters**.

Contents

Prepare your instance for enhanced networking

To prepare for enhanced networking using the Intel 82599 VF interface, set up your instance as follows:

- Verify that the instance type is one of the following: C3, C4, D2, I2, M4 (excluding `m4.16xlarge`), and R3.
- Ensure that the instance has internet connectivity.
- If you have important data on the instance that you want to preserve, you should back that data up now by creating an AMI from your instance. Updating kernels and kernel modules, as well as enabling the `sriovNetSupport` attribute, might render incompatible instances or operating systems unreachable. If you have a recent backup, your data will still be retained if this happens.
- **Linux instances** – Launch the instance from an HVM AMI using Linux kernel version of 2.6.32 or later. The latest Amazon Linux HVM AMIs have the modules required for enhanced networking installed and have the required attributes set. Therefore, if you launch an Amazon EBS–backed, enhanced networking–supported instance using a current Amazon Linux HVM AMI, enhanced networking is already enabled for your instance.

> **Warning**
>
> Enhanced networking is supported only for HVM instances. Enabling enhanced networking with a PV instance can make it unreachable. Setting this attribute without the proper module or module version can also make your instance unreachable.

- **Windows instances –** Launch the instance from a 64-bit HVM AMI. You can't enable enhanced networking on Windows Server 2008. Enhanced networking is already enabled for Windows Server 2012 R2 and Windows Server 2016 and later AMIs. Windows Server 2012 R2 includes Intel driver 1.0.15.3 and we recommend that you upgrade that driver to the latest version using the Pnputil.exe utility.
- Use AWS CloudShell from the AWS Management Console, or install and configure the AWS CLI or the AWS Tools for Windows PowerShell on any computer you choose, preferably your local desktop or laptop. For more information, see Access Amazon EC2 or the AWS CloudShell User Guide. Enhanced networking cannot be managed from the Amazon EC2 console.

Test whether enhanced networking is enabled

Verify that the `sriovNetSupport` attribute is set on the instance or the image.

AWS CLI

To check the instance attribute (sriovNetSupport)

Use the following describe-instance-attribute command. If the attribute is set, the value is `simple`.

```
aws ec2 describe-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --attribute sriovNetSupport
```

To check the image attribute (sriovNetSupport)

Use the following describe-images command. If the attribute is set, the value is `simple`.

```
aws ec2 describe-images \
    --image-id ami-0abcdef1234567890 \
```

```
    --query "Images[].SriovNetSupport"
```

PowerShell

To check the instance attribute (sriovNetSupport)

Use the Get-EC2InstanceAttribute cmdlet. If the attribute is set, the value is `simple`.

```
Get-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -Attribute sriovNetSupport
```

To check the image attribute (sriovNetSupport)

Use the following describe-images command. If the attribute is set, the value is `simple`.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).SriovNetSupport
```

Enable enhanced networking on your instance

The procedure that you use depends on the operating system of the instance.

> **Warning**
>
> There is no way to disable the enhanced networking attribute after you've enabled it.

Amazon Linux

The latest Amazon Linux HVM AMIs have the `ixgbevf` module required for enhanced networking installed and have the required `sriovNetSupport` attribute set. Therefore, if you launch an instance type using a current Amazon Linux HVM AMI, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled.

If you launched your instance using an older Amazon Linux AMI and it does not have enhanced networking enabled already, use the following procedure to enable enhanced networking.

To enable enhanced networking

1. Connect to your instance.

2. From the instance, run the following command to update your instance with the newest kernel and kernel modules, including `ixgbevf`:

```
[ec2-user ~]$ sudo yum update
```

3. From your local computer, reboot your instance using the Amazon EC2 console or one of the following commands: reboot-instances (AWS CLI) or Restart-EC2Instance (AWS Tools for Windows PowerShell).

4. Connect to your instance again and verify that the `ixgbevf` module is installed and at the minimum recommended version using the **modinfo ixgbevf** command from Test whether enhanced networking is enabled.

5. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI) or Stop-EC2Instance (AWS Tools for Windows PowerShell).

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, skip to the next procedure.

6. From your local computer, enable the enhanced networking attribute using one of the following commands:

   AWS CLI

   Use the modify-instance-attribute command as follows.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --sriov-net-support simple
```

   PowerShell

   Use the Edit-EC2InstanceAttribute cmdlet as follows.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -SriovNetSupport "simple"
```

7. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed AMI. The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

8. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI) or Start-EC2Instance (AWS Tools for Windows PowerShell).
9. Connect to your instance and verify that the `ixgbevf` module is installed and loaded on your network interface using the **ethtool -i eth*n*** command from Test whether enhanced networking is enabled.

To enable enhanced networking (instance store-backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed AMI, making sure to enable the enhanced networking attribute when you register the AMI.

AWS CLI

Use the register-image command as follows.

```
aws ec2 register-image --sriov-net-support simple ...
```

PowerShell

Use Register-EC2Image as follows.

```
Register-EC2Image -SriovNetSupport "simple" ...
```

Ubuntu

Before you begin, check if enhanced networking is already enabled on your instance.

The Quick Start Ubuntu HVM AMIs include the necessary drivers for enhanced networking. If you have a version of `ixgbevf` earlier than 2.16.4, you can install the `linux-aws` kernel package to get the latest enhanced networking drivers.

The following procedure provides the general steps for compiling the `ixgbevf` module on an Ubuntu instance.

To install the `linux-aws` kernel package

1. Connect to your instance.

2. Update the package cache and packages.

```
ubuntu:~$ sudo apt-get update && sudo apt-get upgrade -y linux-aws
```

> **Important**
>
> If during the update process, you are prompted to install `grub`, use `/dev/xvda` to install `grub`, and then choose to keep the current version of `/boot/grub/menu.lst`.

Other Linux distributions

Before you begin, check if enhanced networking is already enabled on your instance. The latest Quick Start HVM AMIs include the necessary drivers for enhanced networking, therefore you do not need to perform additional steps.

The following procedure provides the general steps if you need to enable enhanced networking with the Intel 82599 VF interface on a Linux distribution other than Amazon Linux or Ubuntu. For more information, such as detailed syntax for commands, file locations, or package and tool support, see the specific documentation for your Linux distribution.

To enable enhanced networking on Linux

1. Connect to your instance.
2. Download the source for the `ixgbevf` module on your instance from Sourceforge at https://sourceforge.net/projects/e1000/files/ixgbevf%20stable/.

   Versions of `ixgbevf` earlier than 2.16.4, including version 2.14.2, do not build properly on some Linux distributions, including certain versions of Ubuntu.
3. Compile and install the `ixgbevf` module on your instance.

> **Warning**
>
> If you compile the `ixgbevf` module for your current kernel and then upgrade your kernel without rebuilding the driver for the new kernel, your system might revert to the distribution-specific `ixgbevf` module at the next reboot. This could make your system unreachable if the distribution-specific version is incompatible with enhanced networking.

4. Run the **sudo depmod** command to update module dependencies.
5. Update `initramfs` on your instance to ensure that the new module loads at boot time.
6. Determine if your system uses predictable network interface names by default. Systems that use **systemd** or **udev** versions 197 or greater can rename Ethernet devices and they do not guarantee that a single network interface will be named `eth0`. This behavior can cause problems connecting to your instance. For more information and to see other configuration options, see Predictable Network Interface Names on the freedesktop.org website.

   a. You can check the **systemd** or **udev** versions on RPM-based systems with the following command:

   ```
   [ec2-user ~]$ rpm -qa | grep -e '^systemd-[0-9]\+\|^udev-[0-9]\+'
       systemd-208-11.el7_0.2.x86_64
   ```

   In the above Red Hat Enterprise Linux 7 example, the **systemd** version is 208, so predictable network interface names must be disabled.

   b. Disable predictable network interface names by adding the `net.ifnames=0` option to the `GRUB_CMDLINE_LINUX` line in `/etc/default/grub`.

   ```
   [ec2-user ~]$ sudo sed -i '/^GRUB\_CMDLINE\_LINUX/s/\"$/\ net\.ifnames\=0\"/' /
   etc/default/grub
   ```

   c. Rebuild the grub configuration file.

   ```
   [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

7. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI) or Stop-EC2Instance (AWS Tools for Windows PowerShell).

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, skip to the next procedure.

8. From your local computer, enable the enhanced networking attribute using one of the following commands:

   AWS CLI

   Use the modify-instance-attribute command as follows.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 -\
    -sriov-net-support simple
```

PowerShell

Use the Edit-EC2InstanceAttribute cmdlet as follows.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -SriovNetSupport "simple"
```

9. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed AMI. The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

   If your instance operating system contains an `/etc/udev/rules.d/70-persistent-net.rules` file, you must delete it before creating the AMI. This file contains the MAC address for the Ethernet adapter of the original instance. If another instance boots with this file, the operating system will be unable to find the device and `eth0` might fail, causing boot issues. This file is regenerated at the next boot cycle, and any instances launched from the AMI create their own version of the file.
10. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI) or Start-EC2Instance (AWS Tools for Windows PowerShell).
11. (Optional) Connect to your instance and verify that the module is installed.

To enable enhanced networking (instance store–backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed AMI, making sure to enable the enhanced networking attribute when you register the AMI.

AWS CLI

Use the register-image command as follows.

```
aws ec2 register-image --sriov-net-support simple ...
```

PowerShell

Use Register-EC2Image as follows.

```
Register-EC2Image -SriovNetSupport "simple" ...
```

Windows

If you launched your instance and it does not have enhanced networking enabled already, you must download and install the required network adapter driver on your instance, and then set the `sriovNetSupport` instance attribute to activate enhanced networking. You can only enable this attribute on supported instance types. For more information, see Enhanced networking on Amazon EC2 instances.

> **Important**
>
> To view the latest driver updates in the Windows AMIs, see Windows AMI version history in the *AWS Windows AMI Reference*.

To enable enhanced networking

1. Connect to your instance and log in as the local administrator.
2. [Windows Server 2016 and later] Run the following EC2 Launch PowerShell script to configure the instance after the driver is installed.

   ```
   PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -
   Schedule
   ```

   > **Important**
   >
   > The administrator password will reset when you enable the initialize instance EC2 Launch script. You can modify the configuration file to disable the administrator password reset by specifying it in the settings for the initialization tasks.

3. From the instance, download the Intel network adapter driver for your operating system:

   - **Windows Server 2022**

Visit the [download page] and download `Wired_driver_*version*_x64.zip`.

- **Windows Server 2019** including for Server version 1809 and later*

  Visit the download page and download Wired_driver_*version*_x64.zip.

- **Windows Server 2016** including for Server version 1803 and earlier*

  Visit the download page and download Wired_driver_*version*_x64.zip.

- **Windows Server 2012 R2**

  Visit the download page and download Wired_driver_*version*_x64.zip.

- **Windows Server 2012**

  Visit the download page and download Wired_driver_*version*_x64.zip.

- **Windows Server 2008 R2**

  Visit the download page and download PROWinx64Legacy.exe.

*Server versions 1803 and earlier as well as 1809 and later are not specifically addressed on the Intel Drivers and Software pages.

4. Install the Intel network adapter driver for your operating system.

   - **Windows Server 2008 R2**

     1. In the **Downloads** folder, locate the PROWinx64Legacy.exe file and rename it to PROWinx64Legacy.zip.
     2. Extract the contents of the PROWinx64Legacy.zip file.
     3. Open the command line, navigate to the extracted folder, and run the following command to use the pnputil utility to add and install the INF file in the driver store.

        ```
        C:\> pnputil -a PROXGB\Winx64\NDIS62\vxn62x64.inf
        ```

   - **Windows Server 2022, Windows Server 2019, Windows Server 2016, Windows Server 2012 R2, and Windows Server 2012**

     1. In the **Downloads** folder, extract the contents of the Wired_driver_*version*_x64.zip file.
     2. Open the command line, navigate to the extracted folder, and run one of the following commands to use the pnputil utility to add and install the INF file in the driver store.

- Windows Server 2022

```
pnputil -i -a PROXGB\Winx64\NDIS68\vxn68x64.inf
```

- Windows Server 2019

```
pnputil -i -a PROXGB\Winx64\NDIS68\vxn68x64.inf
```

- Windows Server 2016

```
pnputil -i -a PROXGB\Winx64\NDIS65\vxn65x64.inf
```

- Windows Server 2012 R2

```
pnputil -i -a PROXGB\Winx64\NDIS64\vxn64x64.inf
```

- Windows Server 2012

```
pnputil -i -a PROXGB\Winx64\NDIS63\vxn63x64.inf
```

5. From your local computer, enable the enhanced networking attribute using one of the following commands:

   AWS CLI

   Use the modify-instance-attribute command as follows.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --sriov-net-support simple
```

   PowerShell

   Use the Edit-EC2InstanceAttribute cmdlet as follows.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -SriovNetSupport "simple"
```

6. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed AMI. The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.
7. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI) or Start-EC2Instance (AWS Tools for Windows PowerShell).

Troubleshoot connectivity issues

If you lose connectivity while enabling enhanced networking, the `ixgbevf` module might be incompatible with the kernel. Try installing the version of the `ixgbevf` module included with the distribution of Linux for your instance.

If you enable enhanced networking for a PV instance or AMI, this can make your instance unreachable.

For more information, see How do I turn on and configure enhanced networking on my EC2 instances?

Monitor network performance for ENA settings on your EC2 instance

The Elastic Network Adapter (ENA) driver publishes network performance metrics from the instances where they are enabled. You can use these metrics to troubleshoot instance performance issues, choose the right instance size for a workload, plan scaling activities proactively, and benchmark applications to determine whether they maximize the performance available on an instance.

Amazon EC2 defines network maximums at the instance level to ensure a high-quality networking experience, including consistent network performance across instance sizes. AWS provides maximums for the following for each instance:

- **Bandwidth capability** – Each EC2 instance has a maximum bandwidth for aggregate inbound and outbound traffic, based on instance type and size. Some instances use a network I/O credit mechanism to allocate network bandwidth based on average bandwidth utilization. Amazon EC2 also has maximum bandwidth for traffic to AWS Direct Connect and the internet. For more information, see Amazon EC2 instance network bandwidth.
- **Packet-per-second (PPS) performance** – Each EC2 instance has a maximum PPS performance, based on instance type and size.

- **Connections tracked** – The security group tracks each connection established to ensure that return packets are delivered as expected. There is a maximum number of connections that can be tracked per instance. For more information, see [Amazon EC2 security group connection tracking](#)
- **Link-local service access** – Amazon EC2 provides a maximum PPS per network interface for traffic to local proxy services such as the Amazon DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.

When the network traffic for an instance exceeds a maximum, AWS shapes the traffic that exceeds the maximum by queueing and then dropping network packets. You can monitor when traffic exceeds a maximum using the network performance metrics. These metrics inform you, in real time, of impact to network traffic and possible network performance issues.

Contents

Requirements

Linux instances

- Install ENA driver version 2.2.10 or later. To verify the installed version, use the **ethtool** command. In the following example, the version meets the minimum requirement.

```
[ec2-user ~]$ ethtool -i eth0 | grep version
version: 2.2.10
```

  To upgrade your ENA driver, see Enhanced networking.

- To import these metrics to Amazon CloudWatch, install the CloudWatch agent. For more information, see Collect network performance metrics in the *Amazon CloudWatch User Guide*.
- To support the `conntrack_allowance_available` metric, install ENA driver version 2.8.1 or later.

- To override the egress fragment PPS limit of 1024, install ENA driver version 2.13.3 or later.

Windows instances

- Install ENA driver version 2.2.2 or later. To verify the installed version, use Device Manager as follows.
  1. Open Device Manager by running `devmgmt.msc`.
  2. Expand **Network Adapters**.
  3. Choose **Amazon Elastic Network Adapter**, **Properties**.
  4. On the **Driver** tab, locate **Driver Version**.

  To upgrade your ENA driver, see Enhanced networking.
- To import these metrics to Amazon CloudWatch, install the CloudWatch agent. For more information, see Collect advanced network metrics in the *Amazon CloudWatch User Guide*.

Metrics for the ENA driver

The ENA driver delivers the following metrics to the instance in real time. They provide the cumulative number of packets queued or dropped on each network interface since the last driver reset.

Metric	Description	Supported on
`bw_in_allowance_exceeded`	The number of packets queued or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance.	All instance types
`bw_out_allowance_exceeded`	The number of packets queued or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance.	All instance types
`conntrack_allowance_exceeded`	The number of packets dropped because connection tracking exceeded the maximum for the	All instance types

Metric	Description	Supported on
	instance and new connections could not be established. This can result in packet loss for traffic to or from the instance.	
`conntrack_allowance_available`	The number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type.	Nitro-based instances only
`linklocal_allowance_exceeded`	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the Amazon DNS service, the Instance Metadata Service, and the Amazon Time Sync Service, but does not impact traffic to custom DNS resolvers.	All instance types
`pps_allowance_exceeded`	The number of packets queued or dropped because the bidirectional PPS exceeded the maximum for the instance. *	All instance types

* Depending on the fragment proxy mode setting for ENA Linux driver v2.13.3 or later, this limit can also include egress fragment drops that exceed 1024 PPS for the network interface. If fragment proxy mode is enabled for the Linux driver, egress fragment drops bypass the 1024 PPS limit that usually applies and are counted within standard PPS allowances. Fragment proxy mode is disabled by default.

View the network performance metrics for your instance

The procedure that you use depends on the operating system of the instance.

Linux instances

You can publish metrics to your favorite tools to visualize the metric data. For example, you can publish the metrics to Amazon CloudWatch using the CloudWatch agent. The agent enables you to select individual metrics and control publication.

You can also use the **ethtool** to retrieve the metrics for each network interface, such as eth0, as follows.

```
[ec2-user ~]$ ethtool -S eth0
     bw_in_allowance_exceeded: 0
     bw_out_allowance_exceeded: 0
     pps_allowance_exceeded: 0
     conntrack_allowance_exceeded: 0
     linklocal_allowance_exceeded: 0
     conntrack_allowance_available: 136812
```

Windows instances

You can view the metrics using any consumer of Windows performance counters. The data can be parsed according to the EnaPerfCounters manifest. This is an XML file that defines the performance counter provider and its countersets.

To install the manifest

If you launched the instance using an AMI that contains ENA driver 2.2.2 or later, or used the install script in the driver package for ENA driver 2.2.2, the manifest is already installed. To install the manifest manually, use the following steps:

1. Remove the existing manifest using the following command:

   ```
   unlodctr /m:EnaPerfCounters.man
   ```

2. Copy the manifest file `EnaPerfCounters.man` from the driver installation package to `%SystemRoot%\System32\drivers`.
3. Install the new manifest using the following command:

```
lodctr /m:EnaPerfCounters.man
```

To view metrics using Performance Monitor

1. Open Performance Monitor.
2. Press Ctrl+N to add new counters.
3. Choose **ENA Packets Shaping** from the list.
4. Select the instances to monitor and choose **Add**.
5. Choose **OK**.

Metrics for ENA Express

ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD is a high performance network transport protocol that uses dynamic routing to increase throughput and minimize tail latency. If you've enabled ENA Express for the network interface attachments on both the sending instance and receiving instance, you can use ENA Express metrics to help ensure that your instances take full advantage of the performance improvements that SRD technology provides. For example:

- Evaluate your resources to ensure that they have sufficient capacity to establish more SRD connections.
- Identify where there are potential issues that prevent eligible outgoing packets from using SRD.
- Calculate the percentage of outgoing traffic that uses SRD for the instance.
- Calculate the percentage of incoming traffic that uses SRD for the instance.

> **Note**
>
> To produce metrics, use driver version 2.8 or higher.

To see a list of metrics for your Linux instance that's filtered for ENA Express, run the following **ethtool** command for your network interface (shown here as `eth0`). Take note of the value of the `ena_srd_mode` metric.

```
[ec2-user ~]$ ethtool -S eth0 | grep ena_srd
NIC statistics:
 ena_srd_mode: 1
 ena_srd_tx_pkts: 0
 ena_srd_eligible_tx_pkts: 0
 ena_srd_rx_pkts: 0
 ena_srd_resource_utilization: 0
```

The following metrics are available for all instances that have ENA Express enabled.

ena_srd_mode

Describes which ENA Express features are enabled. Values are as follows:

- `0` = ENA Express off, UDP off
- `1` = ENA Express on, UDP off
- `2` = ENA Express off, UDP on

> **Note**
>
> This only happens when ENA Express was originally enabled, and UDP was configured to use it. The prior value is retained for UDP traffic.

- `3` = ENA Express on, UDP on

ena_srd_eligible_tx_pkts

The number of network as follows:

- Both sending and receiving instance types are supported. See the Supported instance types for ENA Express table for more information.
- Both sending and receiving instances must have ENA Express configured.
- The sending and receiving instances must run in the same Availability Zone.
- The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.

> **Note**
>
> The ENA Express eligibility metric covers source and destination requirements, and the network between the two endpoints. Eligible packets can still be disqualified after

they've already been counted. For example, if an eligible packet is over the maximum transmission unit (MTU) limit, it falls back to standard ENA transmission, though the packet is still reflected as eligible in the counter.

ena_srd_tx_pkts

The number of SRD packets transmitted within a given time period.

ena_srd_rx_pkts

The number of SRD packets received within a given time period.

ena_srd_resource_utilization

The percentage of the maximum allowed memory utilization for concurrent SRD connections that the instance has consumed.

To confirm if packet transmission is using SRD, you can compare the number of eligible packets (`ena_srd_eligible_tx_pkts` metric) to the number of SRD packets transmitted (`ena_srd_tx_pkts` metric) during a given time period.

Egress traffic (outgoing packets)

To ensure that your egress traffic uses SRD as expected, compare the number of SRD eligible packets (`ena_srd_eligible_tx_pkts`) with the number of SRD packets sent (`ena_srd_tx_pkts`) over a given time period.

Significant differences between the number of eligible packets and the number of SRD packets sent are often caused by resource utilization issues. When the network card attached to the instance has used up its maximum resources, or if packets are over the MTU limit, eligible packets are not able to transmit via SRD, and must fall back to standard ENA transmission. Packets can also fall into this gap during live migrations or live server updates. Additional troubleshooting is required to determine the root cause.

> **Note**
>
> You can ignore occasional minor differences between the number of eligible packets and the number of SRD packets. This can happen when your instance establishes a connection to another instance for SRD traffic, for example.

To find out what percentage of your total egress traffic over a given time period uses SRD, compare the number of SRD packets sent (`ena_srd_tx_pkts`) to the total number of packets sent for the instance (`NetworkPacketOut`) during that time.

Ingress traffic (incoming packets)

To find out what percentage of your ingress traffic uses SRD, compare the number of SRD packets received (`ena_srd_rx_pkts`) over a given time period to the total number of packets received for the instance (`NetworkPacketIn`) during that time.

Resource utilization

Resource utilization is based on the number of concurrent SRD connections a single instance can hold at a given time. The resource utilization metric (`ena_srd_resource_utilization`) keeps track of your current utilization for the instance. As utilization approaches 100%, you can expect to see performance issues. ENA Express falls back from SRD to standard ENA transmission, and the possibility of dropped packets increases. High resource utilization is a sign that it's time to scale the instance out to improve network performance.

> **Note**
>
> When the network traffic for an instance exceeds a maximum, AWS shapes the traffic that exceeds the maximum by queueing and then dropping network packets.

Persistence

Egress and ingress metrics accrue while ENA Express is enabled for the instance. Metrics stop accruing if ENA Express is deactivated, but persist as long as the instance is still running. Metrics reset if the instance reboots or is terminated, or if the network interface is detached from the instance.

Network performance metrics with the DPDK driver for ENA

The ENA driver version 2.2.0 and later supports network metrics reporting. DPDK 20.11 includes the ENA driver 2.2.0 and is the first DPDK version to support this feature.

DPDK driver v25.03 or later supports fragment proxy mode. If fragment proxy mode is enabled for the DPDK driver, egress fragment drops bypass the 1024 PPS limit that usually applies and are counted within standard PPS allowances. Fragment proxy mode is disabled by default.

You can use an example application to view DPDK statistics. To start an interactive version of the example application, run the following command.

```
./app/dpdk-testpmd -- -i
```

Within this interactive session, you can enter a command to retrieve extended statistics for a port. The following example command retrieves the statistics for port 0.

```
show port xstats 0
```

The following is an example of an interactive session with the DPDK example application.

```
[root@ip-192.0.2.0 build]# ./app/dpdk-testpmd -- -i
        EAL: Detected 4 lcore(s)
        EAL: Detected 1 NUMA nodes

```

For more information about the example application and using it to retrieve extended statistics. see Testpmd Application User Guide in the DPDK documentation.

Metrics on instances running FreeBSD

Starting with version 2.3.0, the ENA FreeBSD driver supports collecting network performance metrics on instances running FreeBSD. To enable the collection of FreeBSD metrics, enter the following command and set *interval* to a value between 1 and 3600. This specifies how often, in seconds, to collect FreeBSD metrics.

```
sysctl dev.ena.network_interface.eni_metrics.sample_interval=interval
```

For example, the following command sets the driver to collect FreeBSD metrics on network interface 1 every 10 seconds:

```
sysctl dev.ena.1.eni_metrics.sample_interval=10
```

To turn off the collection of FreeBSD metrics, you can run the preceding command and specify `0` as the *interval*.

After you enable collecting FreeBSD metrics, you can retrieve the latest set of collected metrics by running the following command.

```
sysctl dev.ena.network_interface.eni_metrics
```

Improve network latency for Linux based EC2 instances

Network latency is the amount of time it takes for a packet of data to travel from its source to its destination. Applications that send data across the network depend on timely responses to provide a positive user experience. High network latency can lead to various issues, such as the following:

- Slow load times for web pages
- Video stream lag
- Difficulty accessing online resources

This section outlines steps that you can take to improve the network latency on Amazon EC2 instances that run on Linux. To achieve optimal latency, follow these steps to configure your instance, kernel, and ENA driver settings. For additional configuration guidance, see the [ENA Linux Driver Best Practices and Performance Optimization Guide] on GitHub.

> **Note**
>
> Steps and settings may vary slightly, depending on your specific network hardware, the AMI that you launched your instance from, and your application use case. Before you make any changes, thoroughly test and monitor your network performance to ensure that you're getting the desired results.

Reduce the number of network hops for data packets

Each hop that a data packet takes as it moves from router to router increases network latency. Typically, traffic must take multiple hops to reach your destination. There are two ways to reduce network hops for your Amazon EC2 instances, as follows:

- **Cluster placement group** – When you specify a cluster placement group, Amazon EC2 launches instances that are in close proximity to each other, physically within the same Availability Zone (AZ) with tighter packing. The physical proximity of the instances in the group allows them to take advantage of high-speed connectivity, resulting in low latency and high single flow throughput.
- **Dedicated Host** – A Dedicated Host is a physical server that's dedicated for your use. With a Dedicated Host, you can launch your instances to run on the same physical server. Communication between instances that run on the same Dedicated Host can happen without extra network hops.

How Linux kernel configuration affects latency

Linux kernel configuration can increase or decrease network latency. To achieve your latency optimization goals, it's important to fine-tune the Linux kernel configuration according to the specific requirements of your workload.

There are many configuration options for the Linux kernel that might help decrease network latency. The most impactful options are as follows.

- **Enable busy poll mode** – Busy poll mode reduces latency on the network receive path. When you enable busy poll mode, the socket layer code can directly poll the receive queue of a network device. The downside of busy polling is higher CPU usage in the host that comes from polling for new data in a tight loop. There are two global settings that control the number of microseconds to wait for packets for all interfaces.

`busy_read`

A low latency busy poll timeout for socket reads. This controls the number of microseconds to wait for the socket layer to read packets on the device queue. To enable the feature globally with the **sysctl** command, the Linux Kernel organization recommends a value of 50 microseconds. For more information, see [busy_read](https://) in the *Linux kernel user's and administrator's guide*.

```
[ec2-user ~]$ sudo sysctl -w net.core.busy_read=50
```

`busy_poll`

A low latency busy poll timeout for poll and select. This controls the number of microseconds to wait for events. The recommended value is between 50-100 microseconds, depending on the number of sockets you're polling. The more sockets you add, the higher the number should be.

```
[ec2-user ~]$ sudo sysctl -w net.core.busy_poll=50
```

- **Configure CPU power states (C-states) –** C-states control the sleep levels that a core may enter when it's inactive. You might want to control C-states to tune your system for latency versus performance. In deeper C-states, the CPU is essentially "asleep" and can't respond to requests until it wakes up and transitions back to an active state. Putting cores to sleep takes time, and although a sleeping core allows more headroom for another core to boost to a higher frequency, it takes time for that sleeping core to wake back up and perform work.

  For example, if a core that's assigned to handle network packet interrupts is asleep, there might be a delay in servicing that interrupt. You can configure the system so that it doesn't use deeper C-states. However, while this configuration reduces the processor reaction latency, it also reduces the headroom available to other cores for Turbo Boost.

  To reduce the processor reaction latency, you can limit deeper C-states. For more information, see High performance and low latency by limiting deeper C-states in the *Amazon Linux 2 User Guide*.

Interrupt moderation

The ENA network driver enables communication between an instance and a network. The driver processes network packets and passes them on to the network stack or to the Nitro card. When a network packet comes in, the Nitro card generates an interrupt for the CPU to notify the software of an event.

Interrupt

An interrupt is a signal that a device or application sends to the processor. The interrupt tells the processor that an event has occurred or a condition has been met that requires immediate attention. Interrupts can handle time-sensitive tasks such as receiving data from a network interface, handling hardware events, or servicing requests from other devices.

Interrupt moderation

Interrupt moderation is a technique that reduces the number of interrupts a device generates by aggregating or delaying them. The purpose of interrupt moderation is to improve system performance by reducing the overhead associated with handling a large number of interrupts. Too many interrupts increase CPU usage, impacting the throughput adversely, while too few interrupts increase the latency.

Dynamic interrupt moderation

Dynamic interrupt moderation is an enhanced form of interrupt moderation that dynamically adjusts the interrupt rate based on the current system load and traffic patterns. It aims to strike a balance between reducing interrupt overhead and packets per second, or bandwidth.

> **Note**
>
> Dynamic interrupt moderation is enabled by default in some AMIs (but can be enabled or disabled in all AMIs).

To minimize network latency, it might be necessary to disable interrupt moderation. However, this can also increase the overhead of interrupt processing. It's important to find the right balance between reducing latency and minimizing overhead. `ethtool` commands can help you configure interrupt moderation. By default, `rx-usecs` is set to `20`, and `tx-usecs` is set to `64`.

To get the current interrupt modification configuration, use the following command.

```
[ec2-user ~]$ ethtool -c interface | egrep "rx-usecs:|tx-usecs:|Adaptive RX"
Adaptive RX: on  TX: off
rx-usecs: 20
tx-usecs: 64
```

To disable interrupt modification and dynamic interrupt moderation, use the following command.

```
[ec2-user ~]$ sudo ethtool -C interface adaptive-rx off rx-usecs 0 tx-usecs 0
```

Nitro system considerations for performance tuning

The Nitro System is a collection of hardware and software components built by AWS that enable high performance, high availability, and high security. The Nitro System provides bare metal-like capabilities that eliminate virtualization overhead and support workloads that require full access to host hardware. For more detailed information, see AWS Nitro System.

All current generation EC2 instance types perform network packet processing on EC2 Nitro Cards. This topic covers high level packet handling on the Nitro card, common aspects of network architecture and configuration that impact packet handling performance, and what actions you can take to achieve peak performance for your Nitro based instances.

Nitro Cards handle all input and output (I/O) interfaces, such as those needed for Virtual Private Clouds (VPCs). For all of the components that send or receive information over the network, the Nitro cards act as a self-contained computing device for I/O traffic that's physically separate from the system main board on which customer workloads run.

Network packet flow on Nitro cards

EC2 instances built on the Nitro system have hardware acceleration capabilities that enable faster packet processing, as measured by packets per second (PPS) throughput rates. When a Nitro card performs the initial evaluation for a new flow, it saves information that's the same for all packets in the flow, such as security groups, access control lists, and route table entries. When it processes additional packets for the same flow, it can use the saved information to reduce overhead for those packets.

Your connection rate is measured by the connections per second (CPS) metric. Each new connection requires additional processing overhead that must be factored into workload capability estimates. It's important to consider both the CPS and PPS metrics when you design your workloads.

How a connection is established

When a connection is established between a Nitro based instance and another endpoint, the Nitro card evaluates the full flow for the first packet that's sent or received between the two endpoints. For subsequent packets of the same flow, full reevaluation is usually not necessary. However, there are exceptions. For more information about the exceptions, see Packets that don't use hardware acceleration.

The following properties define the two endpoints and the packet flow between them. These five properties together are known as a 5-tuple flow.

- Source IP
- Source port
- Destination IP
- Destination port
- Communication protocol

The direction of the packet flow is known as *ingress* (inbound) and *egress* (outbound). The following high level descriptions summarize end to end network packet flow.

- **Ingress –** When a Nitro card handles an inbound network packet, it evaluates the packet against stateful firewall rules and access control lists. It tracks the connection, meters it, and performs other actions as applicable. Then it forwards the packet to its destination on the host CPU.
- **Egress –** When a Nitro card handles an outbound network packet, it looks up the remote interface destination, evaluates various VPC functions, applies rate limits, and performs other actions that apply. Then it forwards the packet to its next hop destination on the network.

Design your network for optimal performance

To take advantage of your Nitro system's performance capabilities, you must understand what your network processing needs are and how those needs affect the workload for your Nitro resources. Then you can design for optimal performance for your network landscape. Your infrastructure settings and application workload design and configuration can impact both the packet processing and connection rates. For example, if your application has a high rate of connection establishment, such as a DNS service, firewall, or virtual router, it will have less opportunity to take advantage of the hardware acceleration that only occurs after the connection is established.

You can configure application and infrastructure settings to streamline workloads and improve network performance. However, not all packets are eligible for acceleration. The Nitro system uses the full network flow for new connections and for packets that aren't eligible for acceleration.

The remainder of this section will focus on application and infrastructure design considerations to help ensure that packets flow within the accelerated path as much as possible.

Network design considerations for the Nitro system

When you configure network traffic for your instance, there are many aspects to consider that can affect PPS performance. After a flow is established, the majority of packets that regularly come in or go out are eligible for acceleration. However, exceptions exist to ensure that infrastructure designs and packet flows continue to meet protocol standards.

To get the best performance from your Nitro card, you should carefully consider the pros and cons of the following configuration details for your infrastructure and applications.

Infrastructure considerations

Your infrastructure configuration can affect your packet flow and processing efficiency. The following list includes some important considerations.

Network interface configuration with asymmetry

Security groups use connection tracking to track information about traffic that flows to and from the instance. Asymmetric routing, where traffic comes into an instance through one network interface and leaves through a different network interface, can reduce the peak performance that an instance can achieve if flows are tracked. For more information about security group connection tracking, untracked connections, and automatically tracked connections, see [Amazon EC2 security group connection tracking](#).

Network drivers

Network drivers are updated and released on a regular basis. If your drivers are out of date, that can significantly impair performance. Keep your drivers up to date to ensure that you have the latest patches and can take advantage of performance improvements, such as the accelerated path feature that's only available for the latest generation of drivers. Earlier drivers don't support the accelerated path feature.

To take advantage of the accelerated path feature, we recommend that you install the latest ENA driver on your instances.

Linux instances – ENA Linux driver 2.2.9 or later. To install or update the ENA Linux driver from the Amazon Drivers GitHub repository, see the Driver compilation section of the readme file.

Windows instances – ENA Windows driver 2.0.0 or later. To install or update the ENA Windows driver, see Install the ENA driver on EC2 Windows instances.

Distance between endpoints

A connection between two instances in the same Availability Zone can process more packets per second than a connection across Regions as a result of TCP windowing at the application layer, which determines how much data can be in flight at any given time. Long distances between instances increase latency and decrease the number of packets that the endpoints can process.

Byte queue limit (BQL)

BQL is a feature that limits the number of bytes passed to the Nitro card to reduce queuing. BQL is disabled by default in ENA drivers, in Amazon Linux operating systems, and in most Linux distributions. If BQL and the fragment proxy override are both enabled, it can result in performance limitations by restricting the number of bytes passed to Nitro before all fragments are processed.

Application design considerations

There are aspects of application design and configuration that can affect your processing efficiency. The following list includes some important considerations.

Packet size

Larger packet sizes can increase throughput for the data that an instance can send and receive on the network. Amazon EC2 supports jumbo frames of 9001 bytes, however other services may enforce different limits. Smaller packet sizes can increase the packet process rate, but this can reduce the maximum achieved bandwidth when the number of packets exceed PPS allowances.

If the size of a packet exceeds the Maximum Transmission Unit (MTU) of a network hop, a router along the path might fragment it. The resulting packet fragments are considered exceptions, and are normally processed at the standard rate (not accelerated). This can cause variations in your performance. However, you can override the standard behavior for outbound fragmented packets with the fragment proxy mode setting. For more information, see Maximize network performance on your Nitro system. We recommended that you evaluate your topology when you configure MTU.

Protocol trade-offs

Reliable protocols like TCP have more overhead than unreliable protocols like UDP. The lower overhead and simplified network processing for the UDP transport protocol can result in a higher PPS rate, but at the expense of reliable packet delivery. If reliable packet delivery isn't critical for your application, UDP might be a good option.

Micro-bursting

Micro-bursting occurs when traffic exceeds allowances during brief periods of time rather than being evenly distributed. This typically happens on a microsecond scale.

For example, say that you have an instance that can send up to 10 Gbps, and your application sends the full 10 Gb in half a second. This micro-burst exceeds the allowance during the first half second and leaves nothing for the remainder of the second. Even though you sent 10Gb in the 1 second timeframe, allowances in the first half second can result in packets being queued or dropped.

You can use a network scheduler such as Linux Traffic Control to help pace your throughput and avoid causing queued or dropped packets as a result of micro-bursting.

Number of flows

A single flow is limited to 5 Gbps unless it's inside of a cluster placement group that supports up to 10 Gbps, or if it uses ENA Express, which supports up to 25 Gbps.

Similarly, a Nitro card can process more packets across multiple flows as opposed to using a single flow. To achieve the peak packet processing rate per instance, we recommend at least 100 flows on instances with 100 Gbps or higher aggregate bandwidth. As aggregate bandwidth capabilities increase, the number of flows needed to achieve peak processing rates also increases. Benchmarking will help you determine what configuration you need to achieve peak rates on your network.

Elastic Network Adapter (ENA) queues

ENA (Elastic Network Adapter) uses multiple receive (Rx) and transmit (Tx) queues (ENA queues) to improve network performance and scalability on EC2 instances. These queues efficiently manage network traffic by load-balancing sent and received data across available queues.

For more information, see the section called "ENA queues".

Feature process overhead

Features like Traffic Mirroring and ENA Express can add more processing overhead, which can reduce absolute packet processing performance. You can limit feature use or disable features to increase packet processing rates.

Connection tracking to maintain state

Your security groups use connection tracking to store information about traffic to and from the instance. Connection tracking applies rules against each individual flow of network traffic to determine if the traffic is allowed or denied. The Nitro card uses flow tracking to maintain state for the flow. As more security group rules are applied, more work is required to evaluate the flow.

> **Note**
>
> Not all network traffic flows are tracked. If a security group rule is configured with [Untracked connections](), no additional work is required except for connections that are automatically tracked to ensure symmetric routing when there are multiple valid reply paths.

Packets that don't use hardware acceleration

Not all packets can take advantage of hardware acceleration. Handling these exceptions involves some processing overhead which is necessary to ensure the health of your network flows. Network flows must reliably meet protocol standards, conform to changes in the VPC design, and route packets only to allowed destinations. However, the overhead reduces your performance.

Packet fragments

As mentioned under **Application considerations**, packet fragments that result from packets that exceed network MTU are normally handled as exceptions, and can't take advantage of hardware acceleration. However, you can bypass egress fragment limitations with the fragment proxy mode, depending on your driver version. For more information, see actions you can take in the Maximize network performance on your Nitro system section.

Idle connections

When a connection has no activity for a while, even if the connection hasn't reached its timeout limit, the system can de-prioritize it. Then, if data comes in after the connection is de-prioritized, the system needs to handle it as an exception in order to reconnect.

To manage your connections, you can use connection tracking timeouts to close idle connections. You can also use TCP keepalives to keep idle connections open. For more information, see Idle connection tracking timeout.

VPC mutation

Updates to security groups, route tables, and access control lists all need to be reevaluated in the processing path to ensure that route entries and security group rules still apply as expected.

ICMP flows

Internet Control Message Protocol (ICMP) is a network layer protocol that network devices use to diagnose network communication issues. These packets always use the full flow.

Asymmetric L2 flows

NitroV3 and earlier platforms do not use hardware acceleration for traffic between two ENIs in the same subnet where one ENI is using the default gateway router and the other is not. NitroV4 and later platforms utilize hardware acceleration in this scenario. For better performance on NitroV3 or earlier platforms, ensure that either the default gateway router used matches between both ENIs, or those ENIs are in different subnets.

Maximize network performance on your Nitro system

You can maximize your network performance on Nitro system by adjusting network settings.

Topics

Considerations

Before you make any design decisions or adjust any network settings on your instance, we recommend that you take the following steps to help ensure that you have the best outcome:

1. Understand the pros and cons of the actions that you can take to improve performance by reviewing Network design considerations for the Nitro system.

   For more considerations and best practices for your instance configuration on Linux, see ENA Linux Driver Best Practices and Performance Optimization Guide on GitHub.
2. Benchmark your workloads with peak active flow count to determine a baseline for your application performance. With a performance baseline, you can test variations in your settings or application design to understand which considerations will have the most impact, especially if you plan to scale up or scale out.

Tune PPS performance

The following list contains actions that you can take to tune your PPS performance, depending on your system needs.

- Reduce the physical distance between two instances. When sending and receiving instances are located in same Availability Zone or use cluster placement groups, you can reduce the number of hops a packet needs to take to travel from one endpoint to another.
- Use Untracked connections.
- Use the UDP protocol for network traffic.
- For EC2 instances with aggregate bandwidth of 100 Gbps or more, distribute the workload over 100 or more individual flows to spread the work evenly across the Nitro card.
- To overcome the egress fragment PPS limit on EC2 instances, you can enable fragment proxy mode (depending on your driver version). This setting allows fragmented packets to be evaluated in the processing path, thereby overcoming the egress PPS limit of 1024. When loading the driver, run one of the following commands to enable or disable fragment proxy mode:

  Enable fragment proxy mode

  ```
  sudo insmod ena.ko enable_frag_bypass=1
  ```

  Disable fragment proxy mode

```
sudo insmod ena.ko enable_frag_bypass=0
```

Configure ENA queue allocation

On supported instance types, you can dynamically allocate these queues across Elastic Network Interfaces (ENIs). Flexible ENA queue allocation optimizes resource distribution, enabling maximum vCPU utilization. High network performance workloads typically require multiple ENA queues. For more information, see [ENA queues](#).

Monitor performance on Linux instances

You can use Ethtool metrics on Linux instances to monitor instance networking performance indicators such as bandwidth, packet rate, and connection tracking. For more information, see [Monitor network performance for ENA settings on your EC2 instance](#).

Optimize network performance on EC2 Windows instances

To achieve the maximum network performance on your Windows instances with enhanced networking, you might need to modify the default operating system configuration. We recommend the following configuration changes for applications that require high network performance. Other optimizations (such as turning on checksum offloading and enabling RSS, for example) are already configured on official Windows AMIs.

> **Note**
>
> TCP chimney offloading should be disabled in most use cases, and has been deprecated as of Windows Server 2016.

In addition to these operating system optimizations, you should also consider the maximum transmission unit (MTU) of your network traffic, and adjust according to your workload and network architecture. For more information, see [Network maximum transmission unit (MTU) for your EC2 instance](#).

AWS regularly measures average round trip latencies between instances launched in a cluster placement group of 50us and tail latencies of 200us at the 99.9 percentile. If your applications require consistently low latencies, we recommend using the latest version of the ENA drivers on fixed performance instances built on the Nitro System.

Configure Receive side scaling CPU affinity

Receive side scaling (RSS) is used to distribute network traffic CPU load across multiple processors. By default, the official Amazon Windows AMIs are configured with RSS enabled. ENA elastic network interfaces provide up to eight RSS queues. By defining CPU affinity for RSS queues, as well as for other system processes, it is possible to spread the CPU load out over multi-core systems, enabling more network traffic to be processed. On instance types with more than 16 vCPUs, we recommend that you use the `Set-NetAdapterRSS` PowerShell cmdlet, which manually excludes the boot processor (logical processor 0 and 1 when hyper-threading is enabled) from the RSS configuration for all elastic network interfaces, in order to prevent contention with various system components.

Windows is hyper-thread aware and ensures that the RSS queues of a single network interface card (NIC) are always placed on different physical cores. Therefore, unless hyper-threading is disabled, in order to completely prevent contention with other NICs, spread the RSS configuration of each NIC among a range of 16 logical processors. The `Set-NetAdapterRss` cmdlet allows you to define the per-NIC range of valid logical processors by defining the values of BaseProcessorGroup, BaseProcessorNumber, MaxProcessingGroup, MaxProcessorNumber, and NumaNode (optional). If there are not enough physical cores to completely eliminate inter-NIC contention, minimize the overlapping ranges or reduce the number of logical processors in the elastic network interface ranges depending on the expected workload of the interface (in other words, a low volume administrative network interface may not need as many RSS queues assigned). Also, as previously noted, various components must run on CPU 0, and therefore we recommend excluding it from all RSS configurations when sufficient vCPUs are available.

For example, when there are three elastic network interfaces on a 72 vCPU instance with 2 NUMA nodes with hyper-threading enabled, the following commands spread the network load between the two CPUs without overlap and prevent the use of core 0 completely.

```
Set-NetAdapterRss -Name NIC1 -BaseProcessorGroup 0 -BaseProcessorNumber 2 -
MaxProcessorNumber 16
Set-NetAdapterRss -Name NIC2 -BaseProcessorGroup 1 -BaseProcessorNumber 0 -
MaxProcessorNumber 14
Set-NetAdapterRss -Name NIC3 -BaseProcessorGroup 1 -BaseProcessorNumber 16 -
MaxProcessorNumber 30
```

Note that these settings are persistent for each network adapter. If an instance is resized to one with a different number of vCPUs, you should reevaluate the RSS configuration for each enabled elastic network interface. The complete Microsoft documentation for the cmdlet can be found here: Set-NetAdapterRss.

Special note for SQL workloads: We also recommend that you review your I/O thread affinity settings along with your elastic network interface RSS configuration to minimize I/O and network contention for the same CPUs. See Server configuration: affinity mask.

Elastic Fabric Adapter for AI/ML and HPC workloads on Amazon EC2

An Elastic Fabric Adapter (EFA) is a network device that you can attach to your Amazon EC2 instance to accelerate Artificial Intelligence (AI), Machine Learning (ML), and High Performance Computing (HPC) applications. EFA enables you to achieve the application performance of an on-premises AI/ML or HPC cluster, with the scalability, flexibility, and elasticity provided by the AWS Cloud.

EFA provides lower and more consistent latency and higher throughput than the TCP transport traditionally used in cloud-based HPC systems. It enhances the performance of inter-instance communication that is critical for scaling AI/ML and HPC applications. It is optimized to work on the existing AWS network infrastructure and it can scale depending on application requirements.

EFA integrates with Libfabric 1.7.0 and later, and it supports Nvidia Collective Communications Library (NCCL) for AI and ML applications, and Open MPI 4.1 and later and Intel MPI 2019 Update 5 and later for HPC applications.

EFA supports RDMA (Remote Direct Memory Access) write on most supported instance types that have Nitro version 4 and later. RDMA read is supported on all instances with Nitro version 4 and later. For more information, see Supported instance types.

Contents

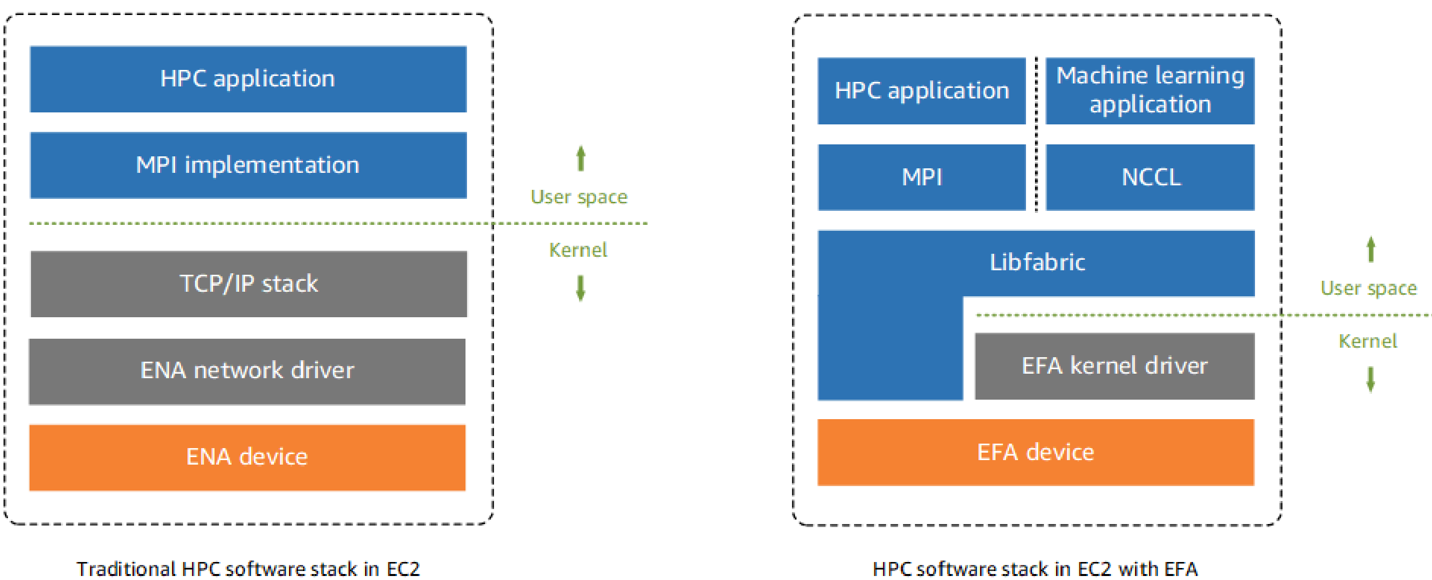
- Get started with EFA and NCCL for ML workloads on Amazon EC2
- Maximize network bandwidth on Amazon EC2 instances with multiple network cards
- Create and attach an Elastic Fabric Adapter to an Amazon EC2 instance
- Detach and delete an EFA from an Amazon EC2 instance
- Monitor an Elastic Fabric Adapter on Amazon EC2
- Verify the EFA installer using a checksum
- Elastic Fabric Adapter release notes

EFA basics

An EFA device can be attached to an EC2 instance in two ways:

1. Using a traditional EFA interface, also called EFA with ENA, which creates both an EFA device and an ENA device.
2. Using an EFA-only interface, which creates just the EFA device.

The EFA device provides capabilities like built-in OS-bypass and congestion control through the Scalable Reliable Datagram (SRD) protocol. The EFA device features enable low-latency, reliable transport functionality that allows EFA interface to provide better application performance for HPC and ML applications on Amazon EC2. While the ENA device offers traditional IP networking.



Traditionally, AI/ML applications use NCCL and HPC applications use the Message Passing Interface (MPI) to interface with the system's network transport. In the AWS cloud, this has meant that applications interface with NCCL or MPI, which then uses the operating system's TCP/IP stack and the ENA device driver to enable network communication between instances.

With a traditional EFA (EFA with ENA) or EFA-only interface, AI/ML applications use NCCL and HPC applications use MPI, to interface directly with the Libfabric API. The Libfabric API bypasses the operating system kernel and communicates directly with the EFA device to put packets on the network. This reduces overhead and enables AI/ML and HPC applications to run more efficiently.

Note

Libfabric is a core component of the OpenFabrics Interfaces (OFI) framework, which defines and exports the user-space API of OFI. For more information, see the Libfabric OpenFabrics website.

Differences between ENA, EFA, and EFA-only network interfaces

Amazon EC2 provides two types of network interfaces:

- **ENA** interfaces provide all of the traditional IP networking and routing features that are required to support IP networking for a VPC. For more information, see Enable enhanced networking with ENA on your EC2 instances.
- **EFA** (EFA with ENA) interfaces provide both the ENA device for IP networking and the EFA device for low-latency, high-throughput communication.
- **EFA-only** interfaces support only the EFA device capabilities, without the ENA device for traditional IP networking.

The following table provides a comparison of ENA, EFA, and EFA-only network interfaces.

	ENA	EFA (EFA with ENA)	EFA-only
Supports IP networking functionality	Yes	Yes	No
Can be assigned	Yes	Yes	No

	ENA	EFA (EFA with ENA)	EFA-only
IPv4 or IPv6 addresses			
Can be used as primary network interface for instance	Yes	Yes	No
Counts towards ENI attacheme nt limit for instance	Yes	Yes	Yes
Instance type support	Supported on all Nitro-based instances types	Supported instance types	Supported instance types
Parameter naming in EC2 APIs	`interface`	`efa`	`efa-only`
Field naming in EC2 console	No selection	EFA with ENA	EFA-only

Supported interfaces and libraries

EFAs support the following interfaces and libraries:

- Open MPI 4.1 and later
- Intel MPI 2019 Update 5 and later
- NVIDIA Collective Communications Library (NCCL) 2.4.2 and later
- AWS Neuron SDK version 2.3 and later

Supported instance types

All of the following instance types support EFA. Additionally, the tables indicate RDMA read and RDMA write support for the instance types.

Nitro v6

To see the available instance types that support EFAs in a specific Region

The available instance types vary by Region. To see the available instance types that support EFAs in a Region, use the describe-instance-types command with the `--region` parameter. Include the `--filters` parameter to scope the results to the instance types that support EFA and the `--query` parameter to scope the output to the value of `InstanceType`.

```
aws ec2 describe-instance-types \
    --region us-east-1  \
    --filters Name=network-info.efa-supported,Values=true \
    --query "InstanceTypes[*].[InstanceType]"  \
    --output text | sort
```

Supported operating systems

Operating system support differs depending on the processor type. The following table shows the supported operating systems.

Operating system	Intel/AMD (x86_64) instance types	AWS Graviton (arm64) instance types
Amazon Linux 2023	✓	✓
Amazon Linux 2	✓	✓
RHEL 8 and 9	✓	✓
Debian 11 and 12	✓	✓
Rocky Linux 8 and 9	✓	✓
Ubuntu 22.04 and 24.04	✓	✓
SUSE Linux Enterprise 15 SP2 and later	✓	✓
OpenSUSE Leap 15.5 and later	✓	

Note

Some of the listed operating systems might not be supported with Intel MPI. If you are using Intel MPI, refer to the Intel MPI documentation to verify support for your operating system.

EFA limitations

EFAs have the following limitations:

- RDMA write is not supported with all instance types. For more information, see Supported instance types.
- EFA traffic[1] between P4d/P4de/DL1 instances and other instance types is currently not supported.
- Instance types that support multiple network cards can be configured with one EFA per network card. All other supported instance types support only one EFA per instance.
- `c7g.16xlarge`, `m7g.16xlarge`, and `r7g.16xlarge` Dedicated Instances and Dedicated Hosts are not supported when an EFA is attached.
- EFA traffic[1] can't cross Availability Zones or VPCs. This does not apply to normal IP traffic from the ENA device of an EFA interface.
- EFA traffic[1] is not routable. Normal IP traffic from the ENA device of an EFA interface remains routable.
- EFA is not supported on AWS Outposts.
- The EFA device of an EFA (EFA with ENA) interface is supported on Windows instances only for AWS Cloud Digital Interface Software Development Kit (AWS CDI SDK) based applications. If you attach an EFA (EFA with ENA) interface to a Windows instance for non-CDI SDK based applications, it functions as an ENA interface, without the added EFA device capabilities. The EFA-only interface is not supported by AWS CDI based applications on Windows or Linux. For more information, see the AWS Cloud Digital Interface Software Development Kit (AWS CDI SDK) User Guide.

[1]*EFA traffic* refers to the traffic transmitted through the EFA device of either an EFA (EFA with ENA) or EFA-only interface.

EFA pricing

EFA is available as an optional Amazon EC2 networking feature that you can enable on any supported instance at no additional cost.

Get started with EFA and MPI for HPC workloads on Amazon EC2

This tutorial helps you to launch an EFA and MPI-enabled instance cluster for HPC workloads.

Note

The `u7i-12tb.224xlarge`, `u7in-16tb.224xlarge`, `u7in-24tb.224xlarge`, and `u7in-32tb.224xlarge` instances can run up to 128 parallel MPI processes with Open MPI or up to 256 parallel MPI processes with Intel MPI.

Tasks

Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure creates a security group that allows all inbound and outbound traffic to and from itself, and that allows inbound SSH traffic from any IPv4 address for SSH connectivity.

Important

This security group is intended for testing purposes only. For your production environments, we recommend that you create an inbound SSH rule that allows traffic only from the IP address from which you are connecting, such as the IP address of your computer, or a range of IP addresses in your local network.

For other scenarios, see [Security group rules for different use cases](#).

To create an EFA-enabled security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups** and then choose **Create security group**.
3. In the **Create security group** window, do the following:
   a. For **Security group name**, enter a descriptive name for the security group, such as `EFA-enabled security group`.
   b. (Optional) For **Description**, enter a brief description of the security group.
   c. For **VPC**, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose **Create security group**.
4. Select the security group that you created, and on the **Details** tab, copy the **Security group ID**.
5. With the security group still selected, choose **Actions**, **Edit inbound rules**, and then do the following:
   a. Choose **Add rule**.
   b. For **Type**, choose **All traffic**.
   c. For **Source type**, choose **Custom** and paste the security group ID that you copied into the field.
   d. Choose **Add rule**.
   e. For **Type**, choose **SSH**.
   f. For **Source type**, choose **Anywhere-IPv4**.
   g. Choose **Save rules**.
6. With the security group still selected, choose **Actions**, **Edit outbound rules**, and then do the following:
   a. Choose **Add rule**.
   b. For **Type**, choose **All traffic**.
   c. For **Destination type**, choose **Custom** and paste the security group ID that you copied into the field.
   d. Choose **Save rules**.

Step 2: Launch a temporary instance

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.
3. (*Optional*) In the **Name and tags** section, provide a name for the instance, such as `EFA-instance`. The name is assigned to the instance as a resource tag (`Name=`*`EFA-instance`*).
4. In the **Application and OS Images** section, select an AMI for one of the supported operating systems.
5. In the **Instance type** section, select a supported instance type.
6. In the **Key pair** section, select the key pair to use for the instance.
7. In the **Network settings** section, choose **Edit**, and then do the following:

   a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.

   b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.

   c. Expand the **Advanced network configuration** section.

      For **Network interface 1**, select **Network card index = 0**, **Device index = 0**, and **Interface type = EFA with ENA**.

      (Optional) If you are using a multi-card instance type, such as `p4d.24xlarge` or `p5.48xlarge`, for each additional network interface required, choose **Add network interface**, for **Network card index** select the next unused index, and then select **Device index = 1** and **Interface type = EFA with ENA** or **EFA-only**.
8. In the **Storage** section, configure the volumes as needed.
9. In the **Summary** panel on the right, choose **Launch instance**.

Note

Consider requiring the use of IMDSv2 for the temporary instance as well as the AMI that you will create in Step 9 unless you have already set IMDSv2 as the default for the account. For more information about IMDSv2 configuration steps, see Configure instance metadata options for new instances.

Step 3: Install the EFA software

Install the EFA-enabled kernel, EFA drivers, Libfabric, and Open MPI stack that is required to support EFA on your temporary instance.

The steps differ depending on whether you intend to use EFA with Open MPI, with Intel MPI, or with Open MPI and Intel MPI.

Note

Some operating systems might not be supported with Intel MPI. If you are using Intel MPI, refer to the Intel MPI documentation to verify support for your operating system.

To install the EFA software

1. Connect to the instance you launched. For more information, see Connect to your Linux instance using SSH.
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes.
   - Amazon Linux 2023, Amazon Linux 2, RHEL 8/9, Rocky Linux 8/9

     ```
     $ sudo yum update -y
     ```
   - Ubuntu and Debian

     ```
     $ sudo apt-get update && sudo apt-get upgrade -y
     ```
   - SUSE Linux Enterprise

```
$ sudo zypper update -y
```

3. Reboot the instance and reconnect to it.

4. Download the EFA software installation files. The software installation files are packaged into a compressed tarball (`.tar.gz`) file. To download the latest *stable* version, use the following command.

   You can also get the latest version by replacing the version number with `latest` in the preceding command.

   ```
   $ curl -O https://efa-installer.amazonaws.com/aws-efa-installer-1.43.2.tar.gz
   ```

5. (*Optional*) Verify the authenticity and integrity of the EFA tarball (`.tar.gz`) file.

   We recommend that you do this to verify the identity of the software publisher and to check that the file has not been altered or corrupted since it was published. If you do not want to verify the tarball file, skip this step.

   > **Note**
   >
   > Alternatively, if you prefer to verify the tarball file by using an MD5 or SHA256 checksum instead, see Verify the EFA installer using a checksum.

   a. Download the public GPG key and import it into your keyring.

      ```
      $ wget https://efa-installer.amazonaws.com/aws-efa-installer.key && gpg --
      import aws-efa-installer.key
      ```

      The command should return a key value. Make a note of the key value, because you need it in the next step.

   b. Verify the GPG key's fingerprint. Run the following command and specify the key value from the previous step.

      ```
      $ gpg --fingerprint key_value
      ```

The command should return a fingerprint that is identical to `4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC`. If the fingerprint does not match, don't run the EFA installation script, and contact Support.

c. Download the signature file and verify the signature of the EFA tarball file.

```
$ wget https://efa-installer.amazonaws.com/aws-efa-installer-1.43.2.tar.gz.sig
 && gpg --verify ./aws-efa-installer-1.43.2.tar.gz.sig
```

The following shows example output.

```
gpg: Signature made Wed 29 Jul 2020 12:50:13 AM UTC using RSA key ID DD2D3CCC
gpg: Good signature from "Amazon EC2 EFA <ec2-efa-maintainers@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 4E90 91BC BB97 A96B 26B1  5E59 A054 80B1 DD2D 3CCC
```

If the result includes `Good signature`, and the fingerprint matches the fingerprint returned in the previous step, proceed to the next step. If not, don't run the EFA installation script, and contact Support.

6. Extract the files from the compressed `.tar.gz` file and navigate into the extracted directory.

```
$ tar -xf aws-efa-installer-1.43.2.tar.gz && cd aws-efa-installer
```

7. Install the EFA software. Do one of the following depending on your use case.

> **Note**
>
> **EFA does not support NVIDIA GPUDirect with SUSE Linux**. If you are using SUSE Linux, you must additionally specify the `--skip-kmod` option to prevent kmod installation. By default, SUSE Linux does not allow out-of-tree kernel modules.

Open MPI and Intel MPI

If you intend to use EFA with Open MPI and Intel MPI, you must install the EFA software with Libfabric and Open MPI, and you **must complete Step 5: Install Intel MPI**.

To install the EFA software with Libfabric and Open MPI, run the following command.

Note

From EFA 1.30.0, both Open MPI 4.1 and Open MPI 5 are installed by default. You can optionally specify the version of Open MPI that you want to install. To install only Open MPI 4.1, include `--mpi=openmpi4`. To install only Open MPI 5, include `--mpi=openmpi5`. To install both, omit the `--mpi` option.

```
$ sudo ./efa_installer.sh -y
```

Libfabric is installed to `/opt/amazon/efa`. Open MPI 4.1 is installed to `/opt/amazon/openmpi`. Open MPI 5 is installed to `/opt/amazon/openmpi5`.

Open MPI only

If you intend to use EFA with Open MPI only, you must install the EFA software with Libfabric and Open MPI, and you can **skip Step 5: Install Intel MPI**. To install the EFA software with Libfabric and Open MPI, run the following command.

Note

From EFA 1.30.0, both Open MPI 4.1 and Open MPI 5 are installed by default. You can optionally specify the version of Open MPI that you want to install. To install only Open MPI 4.1, include `--mpi=openmpi4`. To install only Open MPI 5, include `--mpi=openmpi5`. To install both, omit the `--mpi` option.

```
$ sudo ./efa_installer.sh -y
```

Libfabric is installed to `/opt/amazon/efa`. Open MPI 4.1 is installed to `/opt/amazon/openmpi`. Open MPI 5 is installed to `/opt/amazon/openmpi5`.

Intel MPI only

If you intend to use EFA with Intel MPI only, you can install the EFA software without Libfabric and Open MPI. In this case, Intel MPI uses its embedded Libfabric. If you choose to do this, you **must complete Step 5: Install Intel MPI**.

To install the EFA software without Libfabric and Open MPI, run the following command.

```
$ sudo ./efa_installer.sh -y --minimal
```

8. If the EFA installer prompts you to reboot the instance, do so and then reconnect to the instance. Otherwise, log out of the instance and then log back in to complete the installation.
9. Delete the uncompressed tarball and the tarball itself. Otherwise, these will be included in the EFA-enabled AMI that you create, increasing its size.

Step 4: (*Optional*) Enable Open MPI 5

> **Note**
>
> Perform this step only if you intend to use Open MPI 5.

From EFA 1.30.0, both Open MPI 4.1 and Open MPI 5 are installed by default. Alternatively, you can choose to install only Open MPI 4.1 or Open MPI 5.

If you chose to install Open MPI 5 in **Step 3: Install the EFA software**, and you intend to use it, you must perform the following steps to enable it.

To enable Open MPI 5

1. Add Open MPI 5 to the PATH environment variable.

```
$ module load openmpi5
```

2. Verify that Open MPI 5 is enabled for use.

```
$ which mpicc
```

The command should return the Open MPI 5 installation directory - `/opt/amazon/openmpi5`.

3. (*Optional*) To ensure that Open MPI 5 is added to PATH environment variable each time the instance starts, do the following:

bash shell

Add `module load openmpi5` to `/home/username/.bashrc` and `/home/username/.bash_profile`.

csh and tcsh shells

Add `module load openmpi5` to `/home/username/.cshrc`.

If you need to remove Open MPI 5 from the PATH environment variable, run the following command and remove the command from the shell startup scripts.

```
$ module unload openmpi5
```

Step 5: (*Optional*) Install Intel MPI

Important

Perform this step only if you intend to use Intel MPI. If you intend to only use Open MPI, skip this step.

Intel MPI requires an additional installation and environment variable configuration.

Prerequisite

Ensure that the user performing the following steps has sudo permissions.

To install Intel MPI

1. To download the Intel MPI installation script, do the following

   a. Visit the Intel website.

   b. In the **Intel MPI Library** section of the webpage, choose the link for the **Intel MPI Library for Linux Offline** installer.

2. Run the installation script that you downloaded in the previous step.

   ```
   $ sudo bash installation_script_name.sh
   ```

3. In the installer, choose **Accept & install**.

4. Read the Intel Improvement Program, choose the appropriate option, and then choose **Begin Installation**.

5. When the installation completes, choose **Close**.

6. By default, Intel MPI uses its embedded (internal) Libfabric. You can configure Intel MPI to use the Libfabric that ships with the EFA installer instead. Typically, the EFA installer ships with a later version of Libfabric than Intel MPI. In some cases, the Libfabric that ships with the EFA installer is more performant than that of Intel MPI. To configure Intel MPI to use the Libfabric that ships with the EFA installer, do one of the following depending on your shell.

   bash shells

   Add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

   ```
   export I_MPI_OFI_LIBRARY_INTERNAL=0
   ```

   csh and tcsh shells

   Add the following statement to `/home/username/.cshrc`.

   ```
   setenv I_MPI_OFI_LIBRARY_INTERNAL 0
   ```

7. Add the following **source** command to your shell script to source the `vars.sh` script from the installation directory to set up the compiler environment each time the instance starts. Do one of the following depending on your shell.

   bash shells

   Add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

   ```
   source /opt/intel/oneapi/mpi/latest/env/vars.sh
   ```

   csh and tcsh shells

   Add the following statement to `/home/username/.cshrc`.

   ```
   source /opt/intel/oneapi/mpi/latest/env/vars.csh
   ```

8. By default, if EFA is not available due to a misconfiguration, Intel MPI defaults to the TCP/IP network stack, which might result in slower application performance. You can prevent this by setting `I_MPI_OFI_PROVIDER` to `efa`. This causes Intel MPI to fail with the following error if EFA is not available:

    ```
    Abort (XXXXXX) on node 0 (rank 0 in comm 0): Fatal error in PMPI_Init: OtherMPI
     error,
    MPIR_Init_thread (XXX)........:
    MPID_Init (XXXX)..............:
    MPIDI_OFI_mpi_init_hook (XXXX):
    open_fabric (XXXX)............:
    find_provider (XXXX)..........:
    OFI fi_getinfo() failed (ofi_init.c:2684:find_provider:
    ```

    Do one of the following depending on your shell.

    bash shells

    Add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

    ```
    export I_MPI_OFI_PROVIDER=efa
    ```

    csh and tcsh shells

    Add the following statement to `/home/username/.cshrc`.

    ```
    setenv I_MPI_OFI_PROVIDER efa
    ```

9. By default, Intel MPI doesn't print debugging information. You can specify different verbosity levels to control the debugging information. Possible values (in order of the amount of detail they provide) are: `0` (default), 1, 2, 3, 4, 5. Level 1 and higher prints the `libfabric version` and `libfabric provider`. Use `libfabric version` to check whether Intel MPI is using the internal Libfabric or the Libfabric that ships with the EFA installer. If it's using the internal Libfabric, the version is suffixed with `impi`. Use `libfabric provider` to check with Intel MPI is using EFA or the TCP/IP network. If it's using EFA, the value is `efa`. If it's using TCP/IP, the value is `tcp;ofi_rxm`.

    To enable debugging information, do one of the following depending on your shell.

bash shells

Add the following statement to /home/*username*/.bashrc and /home/*username*/.bash_profile.

```
export I_MPI_DEBUG=value
```

csh and tcsh shells

Add the following statement to /home/*username*/.cshrc.

```
setenv I_MPI_DEBUG value
```

10. By default, Intel MPI uses the operating system's shared memory (shm) for intra-node communication, and it uses Libfabric (ofi) only for inter-node communication. Generally, this configuration provides the best performance. However, in some cases the Intel MPI shm fabric can cause certain applications to hang indefinitely.

    To resolve this issue, you can force Intel MPI to use Libfabric for both intra-node and inter-node communication. To do this, do one of the following depending on your shell.

    bash shells

    Add the following statement to /home/*username*/.bashrc and /home/*username*/.bash_profile.

    ```
    export I_MPI_FABRICS=ofi
    ```

    csh and tcsh shells

    Add the following statement to /home/*username*/.cshrc.

    ```
    setenv I_MPI_FABRICS ofi
    ```

Note

The EFA Libfabric provider uses the operating system's shared memory for intra-node communication. This means that setting `I_MPI_FABRICS` to `ofi` yields similar performance to the default `shm:ofi` configuration.

11. Log out of the instance and then log back in.

If you no longer want to use Intel MPI, remove the environment variables from the shell startup scripts.

Step 6: Disable ptrace protection

To improve your HPC application's performance, Libfabric uses the instance's local memory for interprocess communications when the processes are running on the same instance.

The shared memory feature uses Cross Memory Attach (CMA), which is not supported with *ptrace protection*. If you are using a Linux distribution that has ptrace protection enabled by default, such as Ubuntu, you must disable it. If your Linux distribution does not have ptrace protection enabled by default, skip this step.

To disable ptrace protection

Do one of the following:

- To temporarily disable ptrace protection for testing purposes, run the following command.

```
$ sudo sysctl -w kernel.yama.ptrace_scope=0
```

- To permanently disable ptrace protection, add `kernel.yama.ptrace_scope = 0` to `/etc/sysctl.d/10-ptrace.conf` and reboot the instance.

Step 7. Confirm installation

To confirm successful installation

1. To confirm that MPI was successfully installed, run the following command:

```
$ which mpicc
```

- For Open MPI, the returned path should include `/opt/amazon/`
- For Intel MPI, the returned path should include `/opt/intel/`. If you do not get the expected output, ensure that you have sourced the Intel MPI `vars.sh` script.

2. To confirm that the EFA software components and Libfabric were successfully installed, run the following command.

```
$ fi_info -p efa -t FI_EP_RDM
```

The command should return information about the Libfabric EFA interfaces. The following example shows the command output.

```
provider: efa
    fabric: EFA-fe80::94:3dff:fe89:1b70
    domain: efa_0-rdm
    version: 2.0
    type: FI_EP_RDM
    protocol: FI_PROTO_EFA
```

Step 8: Install your HPC application

Install the HPC application on the temporary instance. The installation procedure varies depending on the specific HPC application. For more information, see [Manage software on your AL2 instance] in the *Amazon Linux 2 User Guide*.

> **Note**
>
> Refer to your HPC application's documentation for installation instructions.

Step 9: Create an EFA-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

To create an AMI from your temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and choose **Actions**, **Image**, **Create image**.
4. For **Create image**, do the following:

   a. For **Image name**, enter a descriptive name for the AMI.

   b. (Optional) For **Image description**, enter a brief description of the purpose of the AMI.

   c. Choose **Create image**.
5. In the navigation pane, choose **AMIs**.
6. Locate the AMI tht you created in the list. Wait for the status to change from `pending` to `available` before continuing to the next step.

Step 10: Launch EFA-enabled instances into a cluster placement group

Launch your EFA-enabled instances into a cluster placement group using the EFA-enabled AMI that you created in **Step 7**, and the EFA-enabled security group that you created in **Step 1**.

> **Note**
>
> - It is not an absolute requirement to launch your EFA-enabled instances into a cluster placementgroup. However, we do recommend running your EFA-enabled instances in a cluster placement group as it launches the instances into a low-latency group in a single Availability Zone.
> - To ensure that capacity is available as you scale your cluster's instances, you can create a Capacity Reservation for your cluster placement group. For more information, see Use Capacity Reservations with cluster placement groups.

To launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.

3. (*Optional*) In the **Name and tags** section, provide a name for the instance, such as `EFA-instance`. The name is assigned to the instance as a resource tag (`Name=EFA-instance`).
4. In the **Application and OS Images** section, choose **My AMIs**, and then select the AMI that you created in the previous step.
5. In the **Instance type** section, select a supported instance type.
6. In the **Key pair** section, select the key pair to use for the instance.
7. In the **Network settings** section, choose **Edit**, and then do the following:

    a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.

    b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.

    c. Expand the **Advanced network configuration** section.

    For **Network interface 1**, select **Network card index = 0**, **Device index = 0**, and **Interface type = EFA with ENA**.

    (*Optional*) If you are using a multi-card instance type, such as `p4d.24xlarge` or `p5.48xlarge`, for each additional network interface required, choose **Add network interface**, for **Network card index** select the next unused index, and then select **Device index = 1** and **Interface type = EFA with ENA** or **EFA-only**.
8. (*Optional*) In the **Storage** section, configure the volumes as needed.
9. In the **Advanced details** section, for **Placement group name**, select the cluster placement group into which to launch the instances. If you need to create a new cluster placement group, choose **Create new placement group**.
10. In the **Summary** panel on the right, for **Number of instances**, enter the number of EFA-enabled instances that you want to launch, and then choose **Launch instance**.

Step 11: Terminate the temporary instance

At this point, you no longer need the instance that you launched in Step 2. You can terminate the instance to stop incurring charges for it.

To terminate the temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and then choose **Actions**, **Instance state**, **Terminate (delete) instance**.
4. When prompted for confirmation, choose **Terminate (delete)**.

Step 12: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

To enable passwordless SSH between the instances in the cluster

1. Select one instance in the cluster as the leader node, and connect to it.
2. Disable `strictHostKeyChecking` and enable `ForwardAgent` on the leader node. Open `~/.ssh/config` using your preferred text editor and add the following.

```
Host *
    ForwardAgent yes
Host *
    StrictHostKeyChecking no
```

3. Generate an RSA key pair.

```
$ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
```

   The key pair is created in the `$HOME/.ssh/` directory.
4. Change the permissions of the private key on the leader node.

```
$ chmod 600 ~/.ssh/id_rsa
chmod 600 ~/.ssh/config
```

5. Open `~/.ssh/id_rsa.pub` using your preferred text editor and copy the key.
6. For each member node in the cluster, do the following:

   a. Connect to the instance.

b. Open `~/.ssh/authorized_keys` using your preferred text editor and add the public key that you copied earlier.

7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

```
$ ssh member_node_private_ip
```

You should connect to the member node without being prompted for a key or password.

Get started with EFA and NCCL for ML workloads on Amazon EC2

The NVIDIA Collective Communications Library (NCCL) is a library of standard collective communication routines for multiple GPUs across a single node or multiple nodes. NCCL can be used together with EFA, Libfabric, and MPI to support various machine learning workloads. For more information, see the NCCL website.

Requirements

- Only accelerated computing P series instance types are supported. For more information, see Amazon EC2 accelerated computing instances.
- Only Amazon Linux 2023, Amazon Linux 2, Ubuntu 24.04, and Ubuntu 22.04 base AMIs are supported.
- Only NCCL 2.4.2 and later is supported with EFA.

For more information about running machine learning workloads with EFA and NCCL using an AWS Deep Learning AMIs, see Using EFA on the DLAMI in the *AWS Deep Learning AMIs Developer Guide*.

Steps

- Step 1: Prepare an EFA-enabled security group
- Step 2: Launch a temporary instance
- Step 3: Install Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN
- Step 4: Install GDRCopy
- Step 5: Install the EFA software
- Step 6: Install NCCL
- Step 7: Install the NCCL tests

Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure creates a security group that allows all inbound and outbound traffic to and from itself, and that allows inbound SSH traffic from any IPv4 address for SSH connectivity.

> **Important**
>
> This security group is intended for testing purposes only. For your production environments, we recommend that you create an inbound SSH rule that allows traffic only from the IP address from which you are connecting, such as the IP address of your computer, or a range of IP addresses in your local network.

For other scenarios, see Security group rules for different use cases.

To create an EFA-enabled security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups** and then choose **Create security group**.
3. In the **Create security group** window, do the following:

   a. For **Security group name**, enter a descriptive name for the security group, such as `EFA-enabled security group`.
   b. (Optional) For **Description**, enter a brief description of the security group.
   c. For **VPC**, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose **Create security group**.
4. Select the security group that you created, and on the **Details** tab, copy the **Security group ID**.

5. With the security group still selected, choose **Actions**, **Edit inbound rules**, and then do the following:

   a. Choose **Add rule**.
   b. For **Type**, choose **All traffic**.
   c. For **Source type**, choose **Custom** and paste the security group ID that you copied into the field.
   d. Choose **Add rule**.
   e. For **Type**, choose **SSH**.
   f. For **Source type**, choose **Anywhere-IPv4**.
   g. Choose **Save rules**.

6. With the security group still selected, choose **Actions**, **Edit outbound rules**, and then do the following:

   a. Choose **Add rule**.
   b. For **Type**, choose **All traffic**.
   c. For **Destination type**, choose **Custom** and paste the security group ID that you copied into the field.
   d. Choose **Save rules**.

Step 2: Launch a temporary instance

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.
3. (*Optional*) In the **Name and tags** section, provide a name for the instance, such as `EFA-instance`. The name is assigned to the instance as a resource tag (`Name=`*`EFA-instance`*).
4. In the **Application and OS Images** section, select an AMI for one of the supported operating systems.

5. In the **Instance type** section, select a supported instance type.
6. In the **Key pair** section, select the key pair to use for the instance.
7. In the **Network settings** section, choose **Edit**, and then do the following:

    a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.

    b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.

    c. Expand the **Advanced network configuration** section.

    For **Network interface 1**, select **Network card index = 0**, **Device index = 0**, and **Interface type = EFA with ENA**.

    (*Optional*) If you are using a multi-card instance type, such as `p4d.24xlarge` or `p5.48xlarge`, for each additional network interface required, choose **Add network interface**, for **Network card index** select the next unused index, and then select **Device index = 1** and **Interface type = EFA with ENA** or **EFA-only**.

8. In the **Storage** section, configure the volumes as needed.

> **Note**
>
> You must provision an additional 10 to 20 GiB of storage for the Nvidia CUDA Toolkit. If you do not provision enough storage, you will receive an `insufficient disk space` error when attempting to install the Nvidia drivers and CUDA toolkit.

9. In the **Summary** panel on the right, choose **Launch instance**.

Step 3: Install Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

Amazon Linux 2023 and Amazon Linux 2

To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

```
$ sudo yum upgrade -y && sudo reboot
```

After the instance has rebooted, reconnect to it.

2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

```
$ sudo yum groupinstall 'Development Tools' -y
```

3. Disable the nouveau open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   ```
   $ sudo yum install -y wget kernel-devel-$(uname -r) kernel-headers-$(uname -
   r)
   ```

   b. Add nouveau to the /etc/modprobe.d/blacklist.conf deny list file.

   ```
   $ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   blacklist vga16fb
   blacklist nouveau
   blacklist rivafb
   blacklist nvidiafb
   blacklist rivatv
   EOF
   ```

   c. Append GRUB_CMDLINE_LINUX="rdblacklist=nouveau" to the grub file and rebuild the Grub configuration.

   ```
   $ echo 'GRUB_CMDLINE_LINUX="rdblacklist=nouveau"' | sudo tee -a /etc/
   default/grub \
   && sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

4. Reboot the instance and reconnect to it.

5. Prepare the required repositories

   a. Enable the EPEL repository and set the distribution to rhel7.

   ```
   $ sudo amazon-linux-extras install epel \
   && distribution='rhel7'
   ```

   b. Set up the CUDA network repository and update the repository cache.

```
$ ARCH=$( /bin/arch ) \
&& sudo yum-config-manager --add-repo http://developer.download.nvidia.com/
compute/cuda/repos/$distribution/${ARCH}/cuda-$distribution.repo \
&& sudo yum clean expire-cache
```

c. (*Kernel version 5.10 only*) Perform these steps only if you are using Amazon Linux 2 with kernel version 5.10. If you are using Amazon Linux 2 with kernel version 4.12, skip these steps. To check your kernel version, run **uname -r**.

   i. Create the Nvidia driver configuration file named `/etc/dkms/nvidia.conf`.

```
$ sudo mkdir -p /etc/dkms \
&& echo "MAKE[0]=\"'make' -j2 module SYSSRC=\${kernel_source_dir}
 IGNORE_XEN_PRESENCE=1 IGNORE_PREEMPT_RT_PRESENCE=1 IGNORE_CC_MISMATCH=1
 CC=/usr/bin/gcc10-gcc\"" | sudo tee /etc/dkms/nvidia.conf
```

   ii. (`p4d.24xlarge` and `p5.48xlarge` only) Copy the Nvidia driver configuration file.

```
$ sudo cp /etc/dkms/nvidia.conf /etc/dkms/nvidia-open.conf
```

6. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

```
$ sudo yum clean all \
&& sudo yum -y install nvidia-driver-latest-dkms \
&& sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel
```

7. Reboot the instance and reconnect to it.

8. (`p4d.24xlarge` and `p5.48xlarge` only) Start the Nvidia Fabric Manager service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```
$ sudo systemctl enable nvidia-fabricmanager && sudo systemctl start nvidia-
fabricmanager
```

9. Ensure that the CUDA paths are set each time that the instance starts.

   - For *bash* shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

```
export PATH=/usr/local/cuda/bin:$PATH
```

```
export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/
lib64:$LD_LIBRARY_PATH
```

- For *tcsh* shells, add the following statements to `/home/username/.cshrc`.

```
setenv PATH=/usr/local/cuda/bin:$PATH
setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/
lib64:$LD_LIBRARY_PATH
```

10. To confirm that the Nvidia GPU drivers are functional, run the following command.

```
$ nvidia-smi -q | head
```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

Ubuntu 24.04 and Ubuntu 22.04

To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

```
$ sudo apt-get update && sudo apt-get upgrade -y
```

2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

```
$ sudo apt-get update && sudo apt-get install build-essential -y
```

3. To use the Nvidia GPU driver, you must first disable the `nouveau` open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   ```
   $ sudo apt-get install -y gcc make linux-headers-$(uname -r)
   ```

   b. Add nouveau to the `/etc/modprobe.d/blacklist.conf` deny list file.

   ```
   $ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   ```

```
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

c. Open `/etc/default/grub` using your preferred text editor and add the following.

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

d. Rebuild the Grub configuration.

```
$ sudo update-grub
```

4. Reboot the instance and reconnect to it.

5. Add the CUDA repository and install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

- `p3dn.24xlarge`

```
$ sudo apt-key adv --fetch-keys http://developer.download.nvidia.com/compute/
machine-learning/repos/ubuntu2004/x86_64/7fa2af80.pub \
&& wget -O /tmp/deeplearning.deb http://developer.download.nvidia.com/compute/
machine-learning/repos/ubuntu2004/x86_64/nvidia-machine-learning-repo-
ubuntu2004_1.0.0-1_amd64.deb \
&& sudo dpkg -i /tmp/deeplearning.deb \
&& wget -O /tmp/cuda.pin https://developer.download.nvidia.com/compute/cuda/
repos/ubuntu2004/x86_64/cuda-ubuntu2004.pin \
&& sudo mv /tmp/cuda.pin /etc/apt/preferences.d/cuda-repository-pin-600 \
&& sudo apt-key adv --fetch-keys https://developer.download.nvidia.com/
compute/cuda/repos/ubuntu2004/x86_64/3bf863cc.pub \
&& sudo add-apt-repository 'deb http://developer.download.nvidia.com/compute/
cuda/repos/ubuntu2004/x86_64/ /' \
&& sudo apt update \
&& sudo apt install nvidia-dkms-535 \
&& sudo apt install -o Dpkg::Options::='--force-overwrite' cuda-drivers-535
 cuda-toolkit-12-3 libcudnn8 libcudnn8-dev -y
```

- `p4d.24xlarge` and `p5.48xlarge`

```
$ sudo apt-key adv --fetch-keys http://developer.download.nvidia.com/compute/
machine-learning/repos/ubuntu2004/x86_64/7fa2af80.pub \
&& wget -O /tmp/deeplearning.deb http://developer.download.nvidia.com/compute/
machine-learning/repos/ubuntu2004/x86_64/nvidia-machine-learning-repo-
ubuntu2004_1.0.0-1_amd64.deb \
&& sudo dpkg -i /tmp/deeplearning.deb \
&& wget -O /tmp/cuda.pin https://developer.download.nvidia.com/compute/cuda/
repos/ubuntu2004/x86_64/cuda-ubuntu2004.pin \
&& sudo mv /tmp/cuda.pin /etc/apt/preferences.d/cuda-repository-pin-600 \
&& sudo apt-key adv --fetch-keys https://developer.download.nvidia.com/
compute/cuda/repos/ubuntu2004/x86_64/3bf863cc.pub \
&& sudo add-apt-repository 'deb http://developer.download.nvidia.com/compute/
cuda/repos/ubuntu2004/x86_64/ /' \
&& sudo apt update \
&& sudo apt install nvidia-kernel-open-535 \
&& sudo apt install -o Dpkg::Options::='--force-overwrite' cuda-drivers-535
 cuda-toolkit-12-3 libcudnn8 libcudnn8-dev -y
```

6. Reboot the instance and reconnect to it.

7. (`p4d.24xlarge` and `p5.48xlarge` only) Install the Nvidia Fabric Manager.

   a. You must install the version of the Nvidia Fabric Manager that matches the version of the Nvidia kernel module that you installed in the previous step.

      Run the following command to determine the version of the Nvidia kernel module.

      ```
      $ cat /proc/driver/nvidia/version | grep "Kernel Module"
      ```

      The following is example output.

      ```
      NVRM version: NVIDIA UNIX x86_64 Kernel Module  450.42.01  Tue Jun 15
       21:26:37 UTC 2021
      ```

      In the example above, major version `450` of the kernel module was installed. This means that you need to install Nvidia Fabric Manager version `450`.

   b. Install the Nvidia Fabric Manager. Run the following command and specify the major version identified in the previous step.

```
$ sudo apt install -o Dpkg::Options::='--force-overwrite' nvidia-
fabricmanager-major_version_number
```

For example, if major version 450 of the kernel module was installed, use the following command to install the matching version of Nvidia Fabric Manager.

```
$ sudo apt install -o Dpkg::Options::='--force-overwrite' nvidia-
fabricmanager-450
```

c. Start the service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```
$ sudo systemctl start nvidia-fabricmanager && sudo systemctl enable nvidia-
fabricmanager
```

8. Ensure that the CUDA paths are set each time that the instance starts.

   - For *bash* shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

   ```
   export PATH=/usr/local/cuda/bin:$PATH
   export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/
   lib64:$LD_LIBRARY_PATH
   ```

   - For *tcsh* shells, add the following statements to `/home/username/.cshrc`.

   ```
   setenv PATH=/usr/local/cuda/bin:$PATH
   setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/
   lib64:$LD_LIBRARY_PATH
   ```

9. To confirm that the Nvidia GPU drivers are functional, run the following command.

   ```
   $ nvidia-smi -q | head
   ```

   The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

Step 4: Install GDRCopy

Install GDRCopy to improve the performance of Libfabric. For more information about GDRCopy, see the GDRCopy repository.

Amazon Linux 2023 and Amazon Linux 2

To install GDRCopy

1. Install the required dependencies.

```
$ sudo yum -y install dkms rpm-build make check check-devel subunit subunit-devel
```

2. Download and extract the GDRCopy package.

```
$ wget https://github.com/NVIDIA/gdrcopy/archive/refs/tags/v2.4.tar.gz \
&& tar xf v2.4.tar.gz ; cd gdrcopy-2.4/packages
```

3. Build the GDRCopy RPM package.

```
$ CUDA=/usr/local/cuda ./build-rpm-packages.sh
```

4. Install the GDRCopy RPM package.

```
$ sudo rpm -Uvh gdrcopy-kmod-2.4-1dkms.noarch*.rpm \
&& sudo rpm -Uvh gdrcopy-2.4-1.x86_64*.rpm \
&& sudo rpm -Uvh gdrcopy-devel-2.4-1.noarch*.rpm
```

Ubuntu 24.04 and Ubuntu 22.04

To install GDRCopy

1. Install the required dependencies.

```
$ sudo apt -y install build-essential devscripts debhelper check libsubunit-dev
 fakeroot pkg-config dkms
```

2. Download and extract the GDRCopy package.

```
$ wget https://github.com/NVIDIA/gdrcopy/archive/refs/tags/v2.4.tar.gz \
```

```
&& tar xf v2.4.tar.gz \
&& cd gdrcopy-2.4/packages
```

3. Build the GDRCopy RPM package.

```
$ CUDA=/usr/local/cuda ./build-deb-packages.sh
```

4. Install the GDRCopy RPM package.

```
$ sudo dpkg -i gdrdrv-dkms_2.4-1_amd64.*.deb \
&& sudo dpkg -i libgdrapi_2.4-1_amd64.*.deb \
&& sudo dpkg -i gdrcopy-tests_2.4-1_amd64.*.deb \
&& sudo dpkg -i gdrcopy_2.4-1_amd64.*.deb
```

Step 5: Install the EFA software

Install the EFA-enabled kernel, EFA drivers, Libfabric, aws-ofi-nccl plugin, and Open MPI stack that is required to support EFA on your instance.

To install the EFA software

1. Connect to the instance you launched. For more information, see Connect to your Linux instance using SSH.
2. Download the EFA software installation files. The software installation files are packaged into a compressed tarball (`.tar.gz`) file. To download the latest *stable* version, use the following command.

   You can also get the latest version by replacing the version number with `latest` in the preceding command.

   ```
   $ curl -O https://efa-installer.amazonaws.com/aws-efa-installer-1.43.2.tar.gz
   ```
3. (*Optional*) Verify the authenticity and integrity of the EFA tarball (`.tar.gz`) file.

   We recommend that you do this to verify the identity of the software publisher and to check that the file has not been altered or corrupted since it was published. If you do not want to verify the tarball file, skip this step.

> **Note**
>
> Alternatively, if you prefer to verify the tarball file by using an MD5 or SHA256 checksum instead, see Verify the EFA installer using a checksum.

a. Download the public GPG key and import it into your keyring.

```
$ wget https://efa-installer.amazonaws.com/aws-efa-installer.key && gpg --
import aws-efa-installer.key
```

The command should return a key value. Make a note of the key value, because you need it in the next step.

b. Verify the GPG key's fingerprint. Run the following command and specify the key value from the previous step.

```
$ gpg --fingerprint key_value
```

The command should return a fingerprint that is identical to `4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC`. If the fingerprint does not match, don't run the EFA installation script, and contact Support.

c. Download the signature file and verify the signature of the EFA tarball file.

```
$ wget https://efa-installer.amazonaws.com/aws-efa-installer-1.43.2.tar.gz.sig
 && gpg --verify ./aws-efa-installer-1.43.2.tar.gz.sig
```

The following shows example output.

```
gpg: Signature made Wed 29 Jul 2020 12:50:13 AM UTC using RSA key ID DD2D3CCC
gpg: Good signature from "Amazon EC2 EFA <ec2-efa-maintainers@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 4E90 91BC BB97 A96B 26B1  5E59 A054 80B1 DD2D 3CCC
```

If the result includes `Good signature`, and the fingerprint matches the fingerprint returned in the previous step, proceed to the next step. If not, don't run the EFA installation script, and contact Support.

4. Extract the files from the compressed `.tar.gz` file and navigate into the extracted directory.

```
$ tar -xf aws-efa-installer-1.43.2.tar.gz && cd aws-efa-installer
```

5. Run the EFA software installation script.

> **Note**
>
> From EFA 1.30.0, both Open MPI 4.1 and Open MPI 5 are installed by default. Unless you need Open MPI 5, we recommend that you install only Open MPI 4.1. The following command installs Open MPI 4.1 only. If you want to install Open MPI 4.1 and Open MPI 5, remove `--mpi=openmpi4`.

```
$ sudo ./efa_installer.sh -y --mpi=openmpi4
```

Libfabric is installed in the `/opt/amazon/efa` directory. The **aws-ofi-nccl plugin** is installed in the `/opt/amazon/ofi-nccl` directory. **Open MPI** is installed in the `/opt/amazon/openmpi` directory.

6. If the EFA installer prompts you to reboot the instance, do so and then reconnect to the instance. Otherwise, log out of the instance and then log back in to complete the installation.

7. Confirm that the EFA software components were successfully installed.

```
$ fi_info -p efa -t FI_EP_RDM
```

The command should return information about the Libfabric EFA interfaces. The following example shows the command output.

- `p3dn.24xlarge` with single network interface

```
provider: efa
fabric: EFA-fe80::94:3dff:fe89:1b70
domain: efa_0-rdm
version: 2.0
```

```
type: FI_EP_RDM
protocol: FI_PROTO_EFA
```

- `p4d.24xlarge` and `p5.48xlarge` with multiple network interfaces

```
provider: efa
fabric: EFA-fe80::c6e:8fff:fef6:e7ff
domain: efa_0-rdm
version: 111.0
type: FI_EP_RDM
protocol: FI_PROTO_EFA
provider: efa
fabric: EFA-fe80::c34:3eff:feb2:3c35
domain: efa_1-rdm
version: 111.0
type: FI_EP_RDM
protocol: FI_PROTO_EFA
provider: efa
fabric: EFA-fe80::c0f:7bff:fe68:a775
domain: efa_2-rdm
version: 111.0
type: FI_EP_RDM
protocol: FI_PROTO_EFA
provider: efa
fabric: EFA-fe80::ca7:b0ff:fea6:5e99
domain: efa_3-rdm
version: 111.0
type: FI_EP_RDM
protocol: FI_PROTO_EFA
```

Step 6: Install NCCL

Install NCCL. For more information about NCCL, see the NCCL repository.

To install NCCL

1. Navigate to the `/opt` directory.

```
$ cd /opt
```

2. Clone the official NCCL repository to the instance and navigate into the local cloned repository.

```
$ sudo git clone https://github.com/NVIDIA/nccl.git -b v2.23.4-1 && cd nccl
```

3. Build and install NCCL and specify the CUDA installation directory.

```
$ sudo make -j src.build CUDA_HOME=/usr/local/cuda
```

Step 7: Install the NCCL tests

Install the NCCL tests. The NCCL tests enable you to confirm that NCCL is properly installed and that it is operating as expected. For more information about the NCCL tests, see the nccl-tests repository.

To install the NCCL tests

1. Navigate to your home directory.

```
$ cd $HOME
```

2. Clone the official nccl-tests repository to the instance and navigate into the local cloned repository.

```
$ git clone https://github.com/NVIDIA/nccl-tests.git && cd nccl-tests
```

3. Add the Libfabric directory to the LD_LIBRARY_PATH variable.

   - Amazon Linux 2023 and Amazon Linux 2

   ```
   $ export LD_LIBRARY_PATH=/opt/amazon/efa/lib64:$LD_LIBRARY_PATH
   ```

   - Ubuntu 24.04 and Ubuntu 22.04

   ```
   $ export LD_LIBRARY_PATH=/opt/amazon/efa/lib:$LD_LIBRARY_PATH
   ```

4. Install the NCCL tests and specify the MPI, NCCL, and CUDA installation directories.

```
$ make MPI=1 MPI_HOME=/opt/amazon/openmpi NCCL_HOME=/opt/nccl/build CUDA_HOME=/usr/
local/cuda
```

Step 8: Test your EFA and NCCL configuration

Run a test to ensure that your temporary instance is properly configured for EFA and NCCL.

To test your EFA and NCCL configuration

1. Create a host file that specifies the hosts on which to run the tests. The following command creates a host file named `my-hosts` that includes a reference to the instance itself.

   IMDSv2

   ```
   [ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H
    "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
   && curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/
   meta-data/local-ipv4 >> my-hosts
   ```

   IMDSv1

   ```
   [ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/local-ipv4 >> my-
   hosts
   ```

2. Run the test and specify the host file (`--hostfile`) and the number of GPUs to use (`-n`). The following command runs the `all_reduce_perf` test on 8 GPUs on the instance itself, and specifies the following environment variables.

   - `FI_EFA_USE_DEVICE_RDMA=1`—(`p4d.24xlarge` only) uses the device's RDMA functionality for one-sided and two-sided transfer.
   - `NCCL_DEBUG=INFO`—enables detailed debugging output. You can also specify `VERSION` to print only the NCCL version at the start of the test, or `WARN` to receive only error messages.

   For more information about the NCCL test arguments, see the NCCL Tests README in the official nccl-tests repository.

   - `p3dn.24xlarge`

   ```
   $ /opt/amazon/openmpi/bin/mpirun \
   -x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/
   lib:/opt/amazon/openmpi/lib:/opt/amazon/ofi-nccl/lib:$LD_LIBRARY_PATH \
   -x NCCL_DEBUG=INFO \
   --hostfile my-hosts -n 8 -N 8 \
   ```

```
--mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to
 none \
$HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
```

- `p4d.24xlarge` and `p5.48xlarge`

```
$ /opt/amazon/openmpi/bin/mpirun \
-x FI_EFA_USE_DEVICE_RDMA=1 \
-x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/
lib:/opt/amazon/openmpi/lib:/opt/amazon/ofi-nccl/lib:$LD_LIBRARY_PATH \
-x NCCL_DEBUG=INFO \
--hostfile my-hosts -n 8 -N 8 \
--mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to
 none \
$HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
```

3. You can confirm that EFA is active as the underlying provider for NCCL when the `NCCL_DEBUG` log is printed.

```
ip-192-168-2-54:14:14 [0] NCCL INFO NET/OFI Selected Provider is efa*
```

The following additional information is displayed when using a `p4d.24xlarge` instance.

```
ip-192-168-2-54:14:14 [0] NCCL INFO NET/OFI Running on P4d platform, Setting
 NCCL_TOPO_FILE environment variable to /home/ec2-user/install/plugin/share/aws-
ofi-nccl/xml/p4d-24xl-topo.xml
```

Step 9: Install your machine learning applications

Install the machine learning applications on the temporary instance. The installation procedure varies depending on the specific machine learning application. For more information about installing software on your Linux instance, see Manage software on your Amazon Linux 2 instance.

Note

Refer to your machine learning application's documentation for installation instructions.

Step 10: Create an EFA and NCCL-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

To create an AMI from your temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and choose **Actions**, **Image**, **Create image**.
4. For **Create image**, do the following:
   a. For **Image name**, enter a descriptive name for the AMI.
   b. (Optional) For **Image description**, enter a brief description of the purpose of the AMI.
   c. Choose **Create image**.
5. In the navigation pane, choose **AMIs**.
6. Locate the AMI tht you created in the list. Wait for the status to change from `pending` to `available` before continuing to the next step.

Step 11: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.

To terminate the temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and then choose **Actions**, **Instance state**, **Terminate instance**.
4. When prompted for confirmation, choose **Terminate**.

Step 12: Launch EFA and NCCL-enabled instances into a cluster placement group

Launch your EFA and NCCL-enabled instances into a cluster placement group using the EFA-enabled AMI and the EFA-enabled security group that you created earlier.

Note

- It is not an absolute requirement to launch your EFA-enabled instances into a cluster placement group. However, we do recommend running your EFA-enabled instances in a cluster placement group as it launches the instances into a low-latency group in a single Availability Zone.
- To ensure that capacity is available as you scale your cluster's instances, you can create a Capacity Reservation for your cluster placement group. For more information, see Use Capacity Reservations with cluster placement groups.

New console

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.
3. (*Optional*) In the **Name and tags** section, provide a name for the instance, such as `EFA-instance`. The name is assigned to the instance as a resource tag (`Name=`*`EFA-instance`*).
4. In the **Application and OS Images** section, choose **My AMIs**, and then select the AMI that you created in the previous step.
5. In the **Instance type** section, select either `p3dn.24xlarge` or `p4d.24xlarge`.
6. In the **Key pair** section, select the key pair to use for the instance.
7. In the **Network settings** section, choose **Edit**, and then do the following:

    a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.

    b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.

    c. Expand the **Advanced network configuration** section.

       For **Network interface 1**, select **Network card index = 0**, **Device index = 0**, and **Interface type = EFA with ENA**.

(Optional) If you are using a multi-card instance type, such as `p4d.24xlarge` or `p5.48xlarge`, for each additional network interface required, choose **Add network interface**, for **Network card index** select the next unused index, and then select **Device index = 1** and **Interface type = EFA eith ENA** or **EFA-only**.

8. (*Optional*) In the **Storage** section, configure the volumes as needed.
9. In the **Advanced details** section, for **Placement group name**, select the cluster placement group into which to launch the instance. If you need to create a new cluster placement group, choose **Create new placement group**.
10. In the **Summary** panel on the right, for **Number of instances**, enter the number of EFA-enabled instances that you want to launch, and then choose **Launch instance**.

Old console

To launch your EFA and NCCL-enabled instances into a cluster placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance**.
3. On the **Choose an AMI** page, choose **My AMIs**, find the AMI that you created earlier, and then choose **Select**.
4. On the **Choose an Instance Type** page, select **p3dn.24xlarge** and then choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, do the following:

   a. For **Number of instances**, enter the number of EFA and NCCL-enabled instances that you want to launch.

   b. For **Network** and **Subnet**, select the VPC and subnet into which to launch the instances.

   c. For **Placement group**, select **Add instance to placement group**.

   d. For **Placement group name**, select **Add to a new placement group**, and then enter a descriptive name for the placement group. Then for **Placement group strategy**, select **cluster**.

   e. For **EFA**, choose **Enable**.

   f. In the **Network Interfaces** section, for device **eth0**, choose **New network interface**. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you are launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.

g. Choose **Next: Add Storage**.

6. On the **Add Storage** page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume). Then choose **Next: Add Tags**.
7. On the **Add Tags** page, specify tags for the instances, such as a user-friendly name, and then choose **Next: Configure Security Group**.
8. On the **Configure Security Group** page, for **Assign a security group**, select **Select an existing security group**, and then select the security group that you created earlier.
9. Choose **Review and Launch**.
10. On the **Review Instance Launch** page, review the settings, and then choose **Launch** to choose a key pair and to launch your instances.

Step 13: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

To enable passwordless SSH between the instances in the cluster

1. Select one instance in the cluster as the leader node, and connect to it.
2. Disable `strictHostKeyChecking` and enable `ForwardAgent` on the leader node. Open `~/.ssh/config` using your preferred text editor and add the following.

```
Host *
    ForwardAgent yes
Host *
    StrictHostKeyChecking no
```

3. Generate an RSA key pair.

```
$ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
```

The key pair is created in the `$HOME/.ssh/` directory.

4. Change the permissions of the private key on the leader node.

```
$ chmod 600 ~/.ssh/id_rsa
chmod 600 ~/.ssh/config
```

5. Open `~/.ssh/id_rsa.pub` using your preferred text editor and copy the key.
6. For each member node in the cluster, do the following:

   a. Connect to the instance.

   b. Open `~/.ssh/authorized_keys` using your preferred text editor and add the public key that you copied earlier.

7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

```
$ ssh member_node_private_ip
```

You should connect to the member node without being prompted for a key or password.

Maximize network bandwidth on Amazon EC2 instances with multiple network cards

Many instances types that support EFA also have multiple network cards. For more information, see Network cards. If you plan to use EFA with one of these instance types, we recommend the following basic configuration:

- For the primary network interface (network card index `0`, device index `0`), create an EFA (EFA with ENA) interface. You can't use an EFA-only network interface as the primary network interface.
- For each additional network interface, use the next unused network card index, device index 1, and either an EFA (EFA with ENA) or EFA-only network interface, depending on your usecase, such as ENA bandwidth requirements or IP address space. For example use cases, see EFA configuration for a P5 instances.

Note

P5 instances require network interfaces to be configured in a specific manner to enable maximum network bandwidth. For more information, see [EFA configuration for a P5 instances](#).

The following examples show how to launch an instance based on these recommendations.

Instance launch

To specify EFAs during instance launch using the launch instance wizard

1. In the **Network settings** section, choose **Edit**.
2. Expand **Advanced network configuration**.
3. For the primary network interface (**Network interface 1**), select **Network card index = 0**, **Device index = 0**, and **Interface type = EFA with ENA**.
4. For each additional network interface required, choose **Add network interface**. For **Network card index** select the next unused index, and then select **Device index = 1**, and **Interface type = EFA with ENA** or **EFA-only**.

To specify EFAs during instance launch using the run-instances command

For `--network-interfaces`, specify the required number of network interfaces. For the primary network interface, specify `NetworkCardIndex=0`, `DeviceIndex=0`, and `InterfaceType=efa`. For any additional network interfaces, for `NetworkCardIndex` specify the next unused index, `DeviceIndex=1`, and `InterfaceType=efa` or `efa-only`.

The following example command snippet shows a request with 32 EFA devices and one ENA device.

```
$ aws --region $REGION ec2 run-instances \
 --instance-type p5.48xlarge \
 --count 1 \
 --key-name key_pair_name \
 --image-id ami-0abcdef1234567890 \
 --network-interfaces
 "NetworkCardIndex=0,DeviceIndex=0,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
 \
```

```
"NetworkCardIndex=1,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=2,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=3,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=4,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=5,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=6,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=7,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=8,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=9,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=
efa-only" \
"NetworkCardIndex=10,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=11,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=12,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=13,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=14,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=15,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=16,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=17,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=18,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=19,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=20,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=21,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=22,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
```

```
"NetworkCardIndex=23,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=24,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=25,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=26,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=27,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=28,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=29,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=30,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only" \
"NetworkCardIndex=31,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType
efa-only"
...
```

Launch templates

To add EFAs to a launch template using the Amazon EC2 console

1. In the **Network settings** section, expand **Advanced network configuration**.
2. To add the primary network interface (Network interface 1), choose **Add network interface** and then select **Network card index = 0**, **Device index = 0**, and **Interface type = EFA with ENA**.
3. To add additional network interfaces, choose **Add network interface**. For **Network card index**, select the next unused index, and then select **Device index = 1**, and **Interface type = EFA with ENA** or **EFA-only**.

To add EFAs to a launch template using the create-launch-template command

For `NetworkInterfaces`, specify the required number of network interfaces. For the primary network interface, specify `NetworkCardIndex=0`, `DeviceIndex=0`, and `InterfaceType=efa`. For any additional network interfaces, for `NetworkCardIndex` specify the next unused index, `DeviceIndex=1`, and `InterfaceType=efa` or `efa-only`.

The following snippet shows an example with 3 network interfaces out of the possible 32 network interfaces.

```
"NetworkInterfaces":[
{
  "NetworkCardIndex":0,
  "DeviceIndex":0,
  "InterfaceType": "efa",
  "AssociatePublicIpAddress":false,
  "Groups":[
    "security_group_id"
  ],
  "DeleteOnTermination":true
},
{
  "NetworkCardIndex": 1,
  "DeviceIndex": 1,
  "InterfaceType": "efa|efa-only",
  "AssociatePublicIpAddress":false,
  "Groups":[
    "security_group_id"
  ],
  "DeleteOnTermination":true
},
{
  "NetworkCardIndex": 2,
  "DeviceIndex": 1,
  "InterfaceType": "efa|efa-only",
  "AssociatePublicIpAddress":false,
  "Groups":[
    "security_group_id"
  ],
  "DeleteOnTermination":true
},
{
  "NetworkCardIndex": 3,
  "DeviceIndex": 1,
  "InterfaceType": "efa|efa-only",
  "AssociatePublicIpAddress":false,
  "Groups":[
    "security_group_id"
  ],
  "DeleteOnTermination":true
}
...
```

EFA configuration for a P5 instances

P5 instances have a total network bandwidth capacity of 3,200 Gbps, of which up to 800 Gbps can be utilized for IP network traffic. Because EFA and IP network traffic share the same underlying resources, bandwidth used by one will reduce the bandwidth that is available to the other. This means that you can distribute the network bandwidth between EFA traffic and IP traffic in any combination, as long as the total bandwidth does not exceed 3,200 Gbps and IP bandwidth does not exceed 800 Gbps. For example, if you use 400 Gbps for IP bandwidth, you can achieve up to 2,800 Gbps of EFA bandwidth at the same time.

Use case 1: Save IP addresses and avoid potential Linux IP issues

This configuration provides up to 3200 Gbps of EFA networking bandwidth and up to 100 Gbps of IP networking bandwidth with one private IP address. This configuration also helps to avoid potential Linux IP issues, such as disallowed auto-assignment of public IP addresses and IP routing challenges (hostname to IP address mapping issues and source IP address mismatches), that can arise if an instance has multiple network interfaces.

- For the primary network interface (network card index 0, device index 0), use an EFA (EFA with ENA) network interface.
- For the remaining network interfaces (network card indexes 1-31, device index 1), use EFA-only network interfaces.

Use case 2: Maximum EFA and IP network bandwidth

This configuration provides up to 3200 Gbps of EFA networking bandwidth and up to 800 Gbps of IP networking bandwidth with 8 private IP address. You can't auto-assign public IP addresses with this configuration. However, you can attach an Elastic IP address to the primary network interface (network card index 0, device index 0) after launch for internet connectivity.

- For the primary network interface (network card index 0, device index 0), use an EFA (EFA with ENA) network interface.
- For the remaining interfaces, do the following:
  - Specify EFA-only network interfaces on network card indexes 1, 2, and 3, and use device index 1.
  - Specify one EFA (EFA with ENA) network interface and three EFA-only network interfaces **in each** of the following network card index subsets, and use device index 1 for all of them:

- [4,5,6,7]
- [8,9,10,11]
- [12,13,14,15]
- [16,17,18,19]
- [20,21,22,23]
- [24,25,26,27]
- [28,29,30,31]

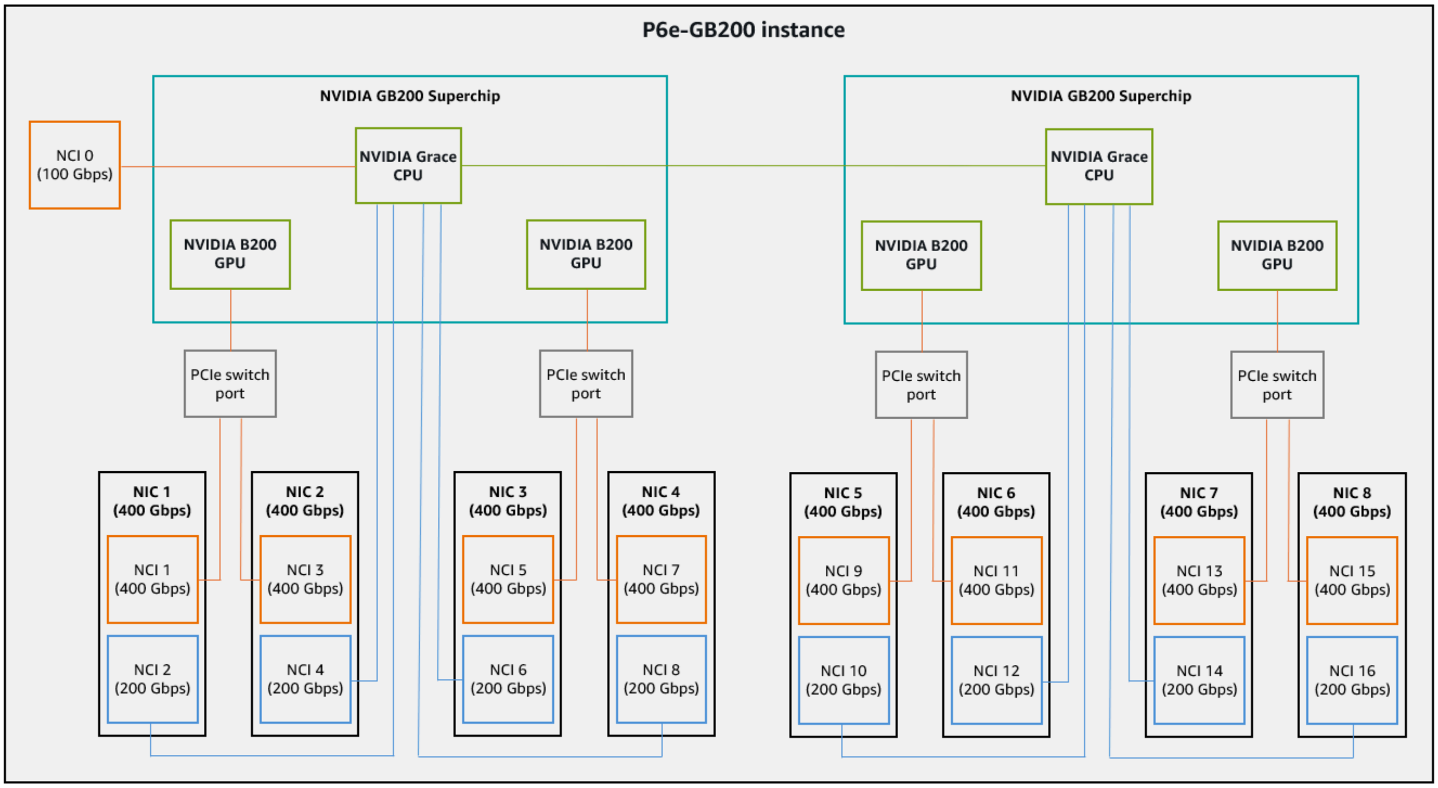
The following example illustrates this configuration:

```
$ aws --region $REGION ec2 run-instances \
 --instance-type p5.48xlarge \
 --count 1 \
 --key-name key_pair_name \
 --image-id ami_id \
 --network-interfaces
 "NetworkCardIndex=0,DeviceIndex=0,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
 \
"NetworkCardIndex=1,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=2,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=3,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=4,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
 \
"NetworkCardIndex=5,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=6,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=7,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=8,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
 \
"NetworkCardIndex=9,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa
only" \
"NetworkCardIndex=10,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=11,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
```

```
"NetworkCardIndex=12,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
 \
"NetworkCardIndex=13,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=14,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=15,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=16,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
 \
"NetworkCardIndex=17,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=18,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=19,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=20,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
 \
"NetworkCardIndex=21,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=22,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=23,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=24,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
 \
"NetworkCardIndex=25,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=26,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=27,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=28,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
 \
"NetworkCardIndex=29,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=30,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only" \
"NetworkCardIndex=31,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=ef
only"
...
```

EFA configuration for a P6e-GB200 instances

P6e-GB200 instances can be configured with up to 17 network cards. The following image shows the physical network interface card (NIC) layout for P6e-GB200 instances, along with the mapping of network card indexes (NCIs).



The primary NCI (index 0) supports up to 100 Gbps of ENA bandwidth. NCIs with the following indexes support EFA-only network interfaces and 400 Gbps EFA bandwidth: [1, 3, 5, 7, 9, 11, 13, 15]. NCIs with the following indexes support up to 200 Gbps ENA or EFA bandwidth: [2, 4, 6, 8, 10, 12, 14, 16].

The NCIs in the following groups share an underlying physical NIC on the host:

- [1 and 2]
- [3 and 4]
- [5 and 6]
- [7 and 8]
- [9 and 10]
- [11 and 12]
- [13 and 14]

- [15 and 16]

Each physical NIC supports up 400 Gbps of bandwidth. Because the NCIs in these groups share the same underlying physical NIC, bandwidth used by one will reduce the bandwidth that is available to the other. For example, if NCI 2 uses 200 Gbps of ENA bandwidth, NCI 1 can use up to 200 Gbps of EFA bandwidth at the same time.

Each underlying GPU on the host can send traffic directly over the following pairs of NCIs:

- [1 and 3]
- [5 and 7]
- [9 and 11]
- [13 and 15]

Each GPU supports up to 400 Gbps of EFA bandwidth. Because the network cards in these groups share the same GPU, bandwidth used by one will reduce the bandwidth that is available to the other. For example, if NCI 1 uses 200 Gbps of EFA bandwidth, NCI 3 can use up to 200 Gbps of EFA bandwidth at the same time. Therefore, to achieve maximum EFA performance, we recommend that you do **one of the following** to achieve a total of 1,600 Gbps EFA bandwidth:

- Add an EFA-only network interface to only one NCI in each group to achieve 400 Gbps per network interface (*4 EFA network interfaces x 400 Gbps*).
- Add an EFA-only network interface to each NCI in each group to achieve 200 Gbps per network interface (*8 EFA network interfaces x 200 Gbps*).

For example, the following configuration provides up to 1,600 Gbps of EFA bandwidth using a single EFA-only network interface in each NCI group, and up to 100 Gbps of ENA networking bandwidth using only the primary NCI (index 0).

- For the primary NCI (network card index 0, device index 0), use an ENA network interface.
- Add EFA-only network interfaces to the following:
  - NCI 1, device index 0
  - NCI 5, device index 0
  - NCI 9, device index 0
  - NCI 13, device index 0

Create and attach an Elastic Fabric Adapter to an Amazon EC2 instance

You can create an EFA and attach it to an Amazon EC2 instance much like any other elastic network interface in Amazon EC2. However, unlike elastic network interfaces, EFAs can't be attached to or detached from an instance in a `running` state.

Considerations

- You can change the security group that is associated with an EFA. To enable OS-bypass functionality, the EFA must be a member of a security group that allows all inbound and outbound traffic to and from the security group itself. For more information, see Step 1: Prepare an EFA-enabled security group.

  You change the security group that is associated with an EFA in the same way that you change the security group that is associated with an elastic network interface. For more information, see the section called "Modify network interface attributes".
- You assign an Elastic IP (IPv4) and IPv6 address to an EFA (EFA with ENA) network interface in the same way that you assign an IP address to an elastic network interface. For more information, see Managing IP addresses.

  You can't assign an IP address to an EFA-only network interface.

Tasks

- Create an EFA
- Attach an EFA to a stopped instance
- Attach an EFA when launching an instance
- Add an EFA to a launch template

Create an EFA

You can create an EFA in a subnet in a VPC. You can't move the EFA to another subnet after it's created, and you can only attach it to stopped instances in the same Availability Zone.

Console

To create an EFA (EFA with ENA or ENA-only) network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Network Interfaces** and then choose **Create network interface**.
3. For **Description**, enter a descriptive name for the EFA.
4. For **Subnet**, select the subnet in which to create the EFA.
5. **Interface type**, choose one of the following options:
   - **EFA with ENA** — To create a network interface that supports both ENA and EFA devices.
   - **EFA-only** — To create a network interface with an EFA device only.
6. (For EFA with ENA only) Configure the IP address and prefix assignment for the network interface. The type of IP addresses and prefixes you can assign depend on the selected subnet. For IPv4-only subnets, you can assign IPv4 IP addresses and prefixes only. For IPv6-only subnets, you can assign IPv6 IP addresses and prefixes only. For dual-stack subnets, you can assign both IPv4 and IPv6 IP addresses and prefixes.

   > **Note**
   >
   > You can't assign IP addresses to an EFA-only network interface.

   a. For **Private IPv4 address** and/or **IPv6 address**, choose **Auto-assign** to have Amazon EC2 automatically assign an IP address from the selected subnet, or choose **Custom** to manually specify the IP address to assign.
   b. If you assign an IPv6 address, you can optionally enable **Assign primary IPv6 IP**. Doing this assigns a primary IPv6 global unicast address (GUA) to the network interface. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. For more information, see IPv6 addresses.
   c. For **IPv4 prefix delegation** and/or **IPv6 prefix delegation**, choose **Auto-assign** to have Amazon EC2 automatically assign a prefix from the subnet's CIDR block, or choose **Custom** to manually specify a prefix from the subnet's CIDR block. If you specify a prefix, AWS verifies that it is not already assigned to another resource. For more information, see Prefix delegation for Amazon EC2 network interfaces
   d. (Optional) Configure the **Idle connection tracking timeout** settings. For more information, see Idle connection tracking timeout

- **TCP established timeout** — The timeout period, in seconds, for idle TCP connections in an established state. Min: 60 seconds. Max: 432000 seconds (5 days). Default: 432000 seconds. Recommended: Less than 432000 seconds.
- **UDP timeout** — The timeout period, in seconds, for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction. Min: 30 seconds. Max: 60 seconds. Default: 30 seconds.
- **UDP stream timeout** — The timeout period, in seconds, for idle UDP flows classified as streams that have seen more than one request-response transaction. Min: 60 seconds. Max: 180 seconds (3 minutes). Default: 180 seconds.

7. For **Security groups**, select one or more security groups.
8. Choose **Create network interface**.

AWS CLI

To create an EFA

Use the create-network-interface command. For `--interface-type`, specify `efa` for an EFA network interface or `efa-only` for an EFA-only network interface.

```
aws ec2 create-network-interface \
    --subnet-id subnet-0abcdef1234567890 \
    --interface-type efa \
    --description "my efa"
```

PowerShell

To create an EFA

Use the New-EC2NetworkInterface cmdlet. For `-InterfaceType`, specify `efa` for an EFA network interface or `efa-only` for an EFA-only network interface

```
New-EC2NetworkInterface `
    -SubnetId subnet-0abcdef1234567890 `
    -InterfaceType efa `
    -Description "my efa"
```

Attach an EFA to a stopped instance

You can attach an EFA to any supported instance that is in the `stopped` state. You cannot attach an EFA to an instance that is in the `running` state. For more information about the supported instance types, see Supported instance types.

You attach an EFA to an instance in the same way that you attach a network interface to an instance. For more information, see Attach a network interface.

Attach an EFA when launching an instance

AWS CLI

To attach an existing EFA when launching an instance

Use the run-instances command with the `--network-interfaces` option. For the primary network interface, specify an EFA network interface and `NetworkCardIndex=0`, `DeviceIndex=0`. To attach multiple EFA network interfaces, see Maximize network bandwidth.

```
--network-interfaces "NetworkCardIndex=0, \
    DeviceIndex=0, \
    NetworkInterfaceId=eni-1234567890abcdef0, \
    Groups=sg-1234567890abcdef0, \
    SubnetId=subnet-0abcdef1234567890"
```

To attach a new EFA when launching an instance

Use the run-instances command with the `--network-interfaces` option. For the primary network interface, use `NetworkCardIndex=0`, `DeviceIndex=0`, and `InterfaceType=efa`. If you are attaching multiple EFA network interfaces, see Maximize network bandwidth.

```
--network-interfaces "NetworkCardIndex=0, \
    DeviceIndex=0, \
    InterfaceType=efa, \
    Groups=sg-1234567890abcdef0, \
    SubnetId=subnet-0abcdef1234567890"
```

PowerShell

To attach an existing EFA when launching an instance

Use the New-EC2Instance cmdlet with the `-NetworkInterfaces` parameter.

```
-NetworkInterface $networkInterface
```

Define the network interface as follows.

```
$networkInterface = New-Object
 Amazon.EC2.Model.InstanceNetworkInterfaceSpecification
$networkInterface.DeviceIndex = 0
$networkInterface.NetworkInterfaceId = "eni-1234567890abcdef0"
$networkInterface.Groups = @("sg-1234567890abcdef0")
$networkInterface.SubnetId = "subnet-0abcdef1234567890"
```

To attach a new EFA when launching an instance

Use the New-EC2Instance cmdlet with the `-NetworkInterfaces` parameter.

```
-NetworkInterface $networkInterface
```

Define the network interface as follows.

```
$networkInterface = New-Object
 Amazon.EC2.Model.InstanceNetworkInterfaceSpecification
$networkInterface.DeviceIndex = 0
$networkInterface.InterfaceType = "efa"
$networkInterface.Groups = @("sg-1234567890abcdef0")
$networkInterface.SubnetId = "subnet-0abcdef1234567890"
```

Add an EFA to a launch template

You can create a launch template that contains the configuration information needed to launch EFA-enabled instances. You can specify both EFA and EFA-only network interfaces in the launch template. To create an EFA-enabled launch template, create a new launch template and specify a supported instance type, your EFA-enabled AMI, and an EFA-enabled security group. For `NetworkInterfaces`, specify the EFA network interfaces to attach. For the primary network interface, use `NetworkCardIndex=0`, `DeviceIndex=0`, and `InterfaceType=efa`. If you are attaching multiple EFA network interfaces, see Maximize network bandwidth on Amazon EC2 instances with multiple network cards.

You can leverage launch templates to launch EFA-enabled instances with other AWS services, such as AWS Batch or AWS ParallelCluster.

For more information about creating launch templates, see Create an Amazon EC2 launch template.

Detach and delete an EFA from an Amazon EC2 instance

You can detach an EFA from an Amazon EC2 instance and delete it in the same way as any other elastic network interface in Amazon EC2.

Detach an EFA

To detach an EFA from an instance, you must first stop the instance. You cannot detach an EFA from an instance that is in the running state.

You detach an EFA from an instance in the same way that you detach an elastic network interface from an instance. For more information, see Detach a network interface.

Delete an EFA

To delete an EFA, you must first detach it from the instance. You cannot delete an EFA while it is attached to an instance.

You delete EFAs in the same way that you delete elastic network interfaces. For more information, see Delete a network interface.

Monitor an Elastic Fabric Adapter on Amazon EC2

You can use the following features to monitor the performance of your Elastic Fabric Adapters.

Topics

EFA driver metrics for an Amazon EC2 instance

The Elastic Fabric Adapter (EFA) driver publishes multiple metrics from the instances that have EFA interfaces attached. You can use these metrics to troubleshoot application performance issues, choose the right cluster size for a workload, plan scaling activities proactively, and benchmark applications to determine whether they maximize the EFA performance available on an instance.

Topics

Available EFA driver metrics

The EFA driver publishes the following metrics to the instance in real time. They provide the cumulative number of errors and packets or bytes sent, received, or dropped by the attached EFA devices since instance launch or the last driver reset.

Metric	Description
`tx_bytes`	The number of bytes transmitted. Unit: bytes
`rx_bytes`	The number of bytes received. Unit: bytes
`tx_pkts`	The number of packets transmitted. Unit: count
`rx_pkts`	The number of packets received. Unit: count
`rx_drops`	The number of packets that were received and then dropped. Unit: count
`send_bytes`	The number of bytes sent using send operations. Unit: bytes

Metric	Description
recv_bytes	The number of bytes received by send operations. Unit: bytes
send_wrs	The number of packets sent using send operations. Unit: count
recv_wrs	The number of packets received by send operations. Unit: count
rdma_write_wrs	The number of completed rdma write operations. Unit: count
rdma_read_wrs	The number of completed rdma read operations. Unit: count
rdma_write_bytes	The number of bytes written to it by other instances using rdma write operations. Unit: bytes
rdma_read_bytes	The number of bytes received using rdma read operations. Unit: bytes
rdma_write_wr_err	The number of rdma write operations that had local or remote errors. Unit: count

Metric	Description
rdma_read_wr_err	The number of rdma read operations that had local or remote errors. Unit: count
rdma_read_resp_bytes	The number of bytes sent in response to rdma read operations. Unit: bytes
rdma_write_recv_bytes	The number of bytes received by rdma write operations. Unit: bytes

Retrieve EFA driver metrics for your instance

You can use the rdma-tool command line tool to retrieve the metrics for all EFA interfaces attached to an instance as follows:

```
$ rdma -p statistic show
link rdmap0s31/1
    tx_bytes 0
    tx_pkts 0
    rx_bytes 0
    rx_pkts 0
    rx_drops 0
    send_bytes 0
    send_wrs 0
    recv_bytes 0
    recv_wrs 0
    rdma_read_wrs 0
    rdma_read_bytes 0
    rdma_read_wr_err 0
    rdma_read_resp_bytes 0
    rdma_write_wrs 0
    rdma_write_bytes 0
    rdma_write_wr_err 0
```

Alternatively, you can retrieve the metrics for each EFA interface attached to an instance from the sys files using the following command.

```
$ more /sys/class/infiniband/device_number/ports/port_number/hw_counters/* | cat
```

For example

```
$ more /sys/class/infiniband/rdmap0s31/ports/1/hw_counters/* | cat
::::::::::::::
/sys/class/infiniband/rdmap0s31/ports/1/hw_counters/lifespan
::::::::::::::
12
::::::::::::::
/sys/class/infiniband/rdmap0s31/ports/1/hw_counters/rdma_read_bytes
::::::::::::::
0
::::::::::::::
/sys/class/infiniband/rdmap0s31/ports/1/hw_counters/rdma_read_resp_bytes
::::::::::::::
0
::::::::::::::
/sys/class/infiniband/rdmap0s31/ports/1/hw_counters/rdma_read_wr_err
::::::::::::::

```

Amazon VPC flow logs

You can create an Amazon VPC Flow Log to capture information about the traffic going to and from an EFA. Flow log data can be published to Amazon CloudWatch Logs and Amazon S3. After you create a flow log, you can retrieve and view its data in the chosen destination. For more information, see VPC Flow Logs in the *Amazon VPC User Guide*.

You create a flow log for an EFA in the same way that you create a flow log for an elastic network interface. For more information, see Create a flow log in the *Amazon VPC User Guide*.

In the flow log entries, EFA traffic is identified by the `srcAddress` and `destAddress`, which are both formatted as MAC addresses, as shown in the following example.

```
version accountId  eniId        srcAddress        destAddress       sourcePort destPort
 protocol packets bytes start      end        action log-status
2       3794735123 eni-10000001 01:23:45:67:89:ab 05:23:45:67:89:ab -          -
 -        9       5689  1521232534 1524512343 ACCEPT OK
```

Amazon CloudWatch

If you are using EFA in an Amazon EKS cluster, you can monitor your EFAs using CloudWatch Container Insights. For more information, see Amazon EKS and Kubernetes Container Insights metrics in the *Amazon CloudWatch User Guide*.

Verify the EFA installer using a checksum

You can optionally verify the EFA tarball (`.tar.gz` file) using an MD5 or SHA256 checksum. We recommend that you do this to verify the identity of the software publisher and to check that the application has not been altered or corrupted since it was published.

To verify the tarball

Use the **md5sum** utility for the MD5 checksum, or the **sha256sum** utility for the SHA256 checksum, and specify the tarball filename. You must run the command from the directory in which you saved the tarball file.

- MD5

  ```
  $  md5sum tarball_filename.tar.gz
  ```

- SHA256

  ```
  $  sha256sum tarball_filename.tar.gz
  ```

The commands should return a checksum value in the following format.

```
checksum_value tarball_filename.tar.gz
```

Compare the checksum value returned by the command with the checksum value provided in the table below. If the checksums match, then it is safe to run the installation script. If the checksums do not match, do not run the installation script, and contact Support.

For example, the following command verifies the EFA 1.9.4 tarball using the SHA256 checksum.

```
$  sha256sum aws-efa-installer-1.9.4.tar.gz
```

Example output:

```
1009b5182693490d908ef0ed2c1dd4f813cc310a5d2062ce9619c4c12b5a7f14 aws-efa-
installer-1.9.4.tar.gz
```

The following table lists the checksums for recent versions of EFA.

Version	Checksums
EFA 1.43.2	**MD5:** `7287b25a07c9747c0d4001e8fc5f59b2` **SHA256:** `de15c5bdbc83b952afbde876110830c604ad0796680e5157c05f7c1979a41069`

Elastic Fabric Adapter release notes

The following table describes the version history and changelog for the Elastic Fabric Adapter software.

Version	Changes	Release date
1.43.2	• Upgrade to libnccl-ofi 1.16.3	Aug 15 2025
1.43.1	• Upgrade to libfabric 2.1.0amzn5.0 • Upgrade to libnccl-ofi 1.16.2	July 31, 2025
1.43.0	• Deprecate support for Ubuntu 20.04 • Upgrade to libnccl-ofi 1.16.1 • Upgrade to rdma-core 58.amzn0 • Upgrade to libfabric 2.1.0amzn4.0 • Enable optimizations for Graviton platforms • Upgrade to efa driver 2.17.2 • Upgrade to efa-nv-peermem 1.2.2	July 25, 2025

Version	Changes	Release date
1.42.0	• Upgrade to efa driver 2.15.3 • Upgrade to efa-nv-peermem 1.2.1 • Upgrade to rdma-core 57.amzn1 • Upgrade to libfabric 2.1.0amzn3.0 • Upgrade to libnccl-ofi 1.15.0	June 6, 2025
1.41.0	• Upgrade to rdma-core 57.amzn0	May 16, 2025
1.40.0	• Upgrade to libfabric 2.1.0amzn2.0 • Upgrade to rdma-core 56.0 • Upgrade to efa-config 1.18. • Deprecate support for Debian 10 • Upgrade to libnccl-ofi 1.14.2 • Enable CUDA support in Libfabric on ARM for Ubuntu and Amazon Linux 2023 • Add libnccl-ofi on ARM for Ubuntu and Amazon Linux 2023	May 2, 2025
1.39.0	• Upgrade to libfabric 2.1.0 • Upgrade to Open MPI 5.0.6 • Upgrade to libnccl-ofi 1.14.1 • Upgrade to efa driver 2.15.0	April 16, 2025
1.38.1	• Update to `Libfabric 1.22.0amzn5.0`	March 3, 2025
1.38.0	• Add `libnccl-ofi 1.13.2-1`	January 8, 2025
1.37.0	• Upgrade to `libfabric 1.22.0amzn4.0` • Upgrade to `rdma-core 54.amzn0`	November 18, 2024

Version	Changes	Release date
1.36.0	• Add support for Debian 12 • Distribute `efa_test.sh` as a utility script at `/opt/amazon/efa/bin` • Upgrade to efa driver 2.13.0 • Upgrade to `libfabric 1.22.0amzn3.0` • Upgrade to `rdma-core 54.0` • Upgrade to open mpi 4.1.7	November 7, 2024
1.35.0	• Upgrade to Open MPI 5.0.5 • Upgrade to PRRTE 3.0.6 and rename the RPM package to prrte-aws • Rename the OpenPMIx RPM package to pmix-aws • Configure build options for dpkg and RPM builds • Upgrade to `Libfabric 1.22.0amzn2.0` • Upgrade to efa driver 2.12.1	October 14, 2024
1.34.0	• Drop support for CentOS 7 and RHEL 7 • Ingest `Libfabric 1.22.0amzn1.0` • Update efa-config package to 1.17	August 6, 2024
1.33.0	• Upgrade to efa driver 2.10.0 • Upgrade to `rdma-core 52.0` • Upgrade to PRRTE 3.0.5 • Upgrade to Open MPI 5.0.3 • Add support for Ubuntu 24.04 LTS • Remove OpenPMIx, PRRTE and Open MPI HTML documentation. Users should refer to the official website. • Drop support for openSUSE 15.4 or older	June 20, 2024

Version	Changes	Release date
1.32.0	• Upgrade to efa driver 2.8.0 • Upgrade to efa-nv-peermem driver 1.1.1 • Upgrade efa-config package to 1.16 • Upgrade efa-profile package to 1.7 • Upgrade to `rdma-core 50.0` • Upgrade to `libfabric 1.21.0amzn1.0` • Enhance `efa_test.sh` with `fi_pingpong` port selection • Install newer rdma-core from system when required	April 18, 2024
1.31.0	• Upgrade to OpenPMIx 4.2.8 • Upgrade to PRRTE 3.0.3 • Upgrade to Open MPI 5.0.2, and convert MCA components to DSO. • Upgrade to `Libfabric 1.20.1amzn1.0`	March 7, 2024
1.30.0	• Include OpenPMIx 4.2.7, installed at `/opt/amazon/pmix` by default • Include PRRTE 3.0.2, installed at `/opt/amazon/prrte` by default • Include Open MPI 5.0.0, installed at `/opt/amazon/openmpi5` by default • Update efa-profile to 1.6	December 2023
1.29.1	• Ingest `libfabric 1.19.0amzn4.0`	December 2023
1.29.0	• Ingest efa kernel driver 2.6.0 • Ingest `libfabric 1.19.0amzn3.0`	November 2023
1.28.0	• Upgrade Open MPI to 4.1.6 • Ingest `libfabric 1.19.0amzn2.0`	October 2023

Version	Changes	Release date
1.27.0	• Add `Libfabric 1.19.0amzn1.0` to installer • Enable GCC builtin atomics for Open MPI 4	September 2023
1.26.1	• `efa_test.sh` : fix infinite retry bug	September 2023
1.26.0	• Add support for RHEL 9 • Fix debug build on multiple distributions • Ingest `libfabric 1.18.2amzn1.0` • `efa_test.sh` : Add retry for `fi_pingpong`	September 2023
1.25.1	• Ingest `libfabric 1.18.1amzn1.0` • Update timeouts in EFA installer scripts	September 2023
1.25.0	• Add support for Amazon Linux 2023 • Bugfix in post-installation test	July 2023
1.24.1	• Upgrade libfabric to 1.18.1 • Upgrade efa driver to 2.5.0	July 2023
1.24.0	• Ingest `rdma-core 46.0` • Ingest efa driver 2.4.1 • Support Debian 11	June 2023
1.23.1	• Ingest `libfabric 1.18.0amzn2.0`	June 2023
1.23.0	• Add support for Debian 10 • Drop support for Ubuntu 18.04 LTS • Upgrade efa-config package to 1.14 • Ingest `libfabric 1.18.0amzn1.0`	May 2023
1.22.1	• Upgrade libfabric to 1.17.1	March 2023

Version	Changes	Release date
1.22.0	• Upgrade Open MPI to 4.1.5 • Upgrade libfabric to 1.17.0 • Upgrade efa-config package to 1.13	February 2023
1.21.0	• Add support for Rocky Linux 9 OS • Ingest efa driver 2.1.1 • Ingest `libfabric 1.16.1amzn3.0` • Upgrade efa-config package to 1.12	December 2022
1.20.0	• Add support for Rocky Linux 8 OS. • Ingest efa driver 2.1.0. • Ingest `rdma-core 43.0`. • Ingest `libfabric 1.16.1amzn1.0`	November 2022
1.19.0	• Ingest `libfabric 1.16.0` • Build Open MPI with `--enable-orterun-prefix-by-default`	October 2022
1.18.0	• Add support for Ubuntu22.04	August 2022
1.17.3	• Update libfabric to `1.16.0~amzn4.0` . The ~ indicates it is a pre-release version of libfabric 1.16.0. • Extend post-installation pingpong test timeout to 20 seconds	August 2022
1.17.2	• Update libfabric to `1.16.0~amzn3.0` . The ~ indicates it is a pre-release version of libfabric 1.16.0.	July 2022
1.17.1	• Update libfabric to `1.16.0~amzn2.0` . The ~ indicates it is a pre-release version of libfabric 1.16.0. • Disable the experimental net provider when building libfabric	July 2022

Version	Changes	Release date
1.17.0	• Update `rdma-core` to v41.0 • Update Open MPI to 4.1.4 • Update libfabric to `1.16.0~amzn1.0` . The ~ indicates it is a pre-release version of libfabric 1.16.0.	July 2022
1.16.0	• Update libfabric to `1.15.1amzn1.0` , contains neuron library name change • Upgrade efa-config to 1.10 • Exclude opx and rxd providers in the libfabric build	June 2022
1.15.2	• Update libfabric to 1.14.1	May 2022
1.15.1	• Update libfabric to `1.14.0amzn1.0`	March 2022
1.15.0	• Fix a bug that cause installation fail on Open SuSE 15.3 • Drop support of Open SuSE 15.2 (as Open SuSE 15.2 reached end of life) • Drop Support of CentOS 8 (as CentOS 8 reached end of life) • Update libfabric to 1.14.0 • Update efa kernel driver to 1.16.0 • Update `rdma-core` to v39.0 • Update Open MPI to version 4.1.2.	Feburary 2022
1.14.1	• Update libfabric to `1.13.2amzn1.0` .	October 2021

Version	Changes	Release date
1.14.0	• Ingest efa kernel driver 1.14.2. • Make `-g, --enable-gdr` in `efa_installer.sh` as a no-op option as the latest efa kernel driver enables GDR support by default. • Ingest `rdma-core v37.0`. • Ingest `libfabric 1.13.2`. • Add packages list and compare RPM/DEB to list during installation to prevent unknown package installations. • Add sleep in installer script to wait for udev rule to apply after EFA driver reload.	October 2021
1.13.0	• Update `rdma-core` to v35.0. • Update `libfabric` to v1.13.0amzn1.0. • Add EFA support for CentOS/RHEL 8 on Gravition2 platform. • Add version comparison logic in installer script to skip the local package installation when there is one installed in system with higher version.	August 2021
1.12.3	• Update EFA kernel module to 1.13.0. • Update efa-config package to version 1.9. Improve the calculation of huge page reservation to handle large defaulted huge page size.	July 2021
1.12.2	• Update EFA kernel module to 1.12.3. • Build Open MPI debian packages with `--with-libevent=external` and `--with-hwloc=external` . • Bump Open MPI rpm build ID to 2 to fix backward compatibility issue of HWLOC on CentOS 8. • Remove the installation of kernel-devel and kernel-source packages on SLES15SP2 and openSUSE 15.2.	June 2021
1.12.1	• Update Libfabric to version 1.11.2amzon1.1. • Update EFA kernel module to version 1.12.1.	May 2021

Version	Changes	Release date
1.12.0	• Update Open MPI to version 4.1.1. • Update Libfabric to version 1.11.2amzn1.0. • Build rdma-core for Amazon Linux 2 using the same packaging configuration as the AL2 rdma-core. • Do not force `-Wl,--enable-new-dtags` when building Open MPI RPMs. • Build Open MPI with system libraries for hwloc and libevent. • Update EFA kernel module to version 1.12.0 • Update efa-config package to version 1.8. Improve the calculation of huge page reservation for long-lived instances. • Update efa-profile package to version 1.5. Remove the open mpi collective tuning file that worked as a workaround to fix Open MPI 4.1.0 hang on P4d. • Update `rdma-core` to v32.1. • Drop support for Amazon Linux 1 and Ubuntu 16.04.	May 2021
1.11.2	• Fix Open MPI hang when using Open MPI on P4d by changing the default algorithm used to implement MPI_BARRIER via a configuration file. • Disable use of builtin atomics in Open MPI on ARM via `--disable-builtin-atomics` to work around compiler issue.	February 2021
1.11.1	• Update Open MPI to version 4.1.0. • Update efa-config package to version 1.7. Improve calculati on of huge page reservation count. • Update efa-profile package to version 1.3. Removes unneeded collectives decision file now that Open MPI 4.1.0 is used.	December 2020

Version	Changes	Release date
1.11.0	• Add support for Gravition2 platform. • Update `rdma-core` to version 31.2amzn. • Update Libfabric to version 1.11.1amzn1.0. • Update efa-config to version 1.6. • Update efa-profile to version 1.2.	December 2020
1.10.1	• Add support for CentOS / RHEL 8. • Add support for Ubuntu 20.04. • Add support for SUSE Linux Enterprise 15.	November 2020
1.10.0	• Add GPUDirect RDMA support for P4d platform. Use `--enable-gdr` installer option to instal GDR-aware kernel module and userspace. • Update EFA kernel module to version 1.10.2. • Update `rdma-core` to version 31.amzn0. • Update Libfabric to version 1.11.1. • Update Open MPI to version 4.0.5. • Update efa-config to version 1.5. • Update efa-profile to version 1.1. Includes improved Open MPI collectives decision file.	October 2020
1.9.5	• Update efa-config to version 1.4. Fixes bug in Open MPI collective decision file.	September 2020
1.9.4	• Update Open MPI to version 4.0.3. • Update Libfabric to version 1.10.1amazon1.1. • Update `rdma-core` to version 28.amzn0.	July 2020

Version	Changes	Release date
1.9.3	• Update EFA kernel module to version 1.6.0. • Update `rdma-core` to version 28.amzn0. • Update Libfabric to version 1.10.1amzn1.1. • Update efa-config to version 1.3. Adds collectives tuning file for Open MPI. • Skip dkms installation if it is already installed. • Fix `--skip-kmod` installation mode to actually work.	June 2020
1.8.4	• Move configuration files into efa-config and efa-profile packages so that they are tracked by the operating system package manager. • Update Open MPI to version 4.0.3.	April 2020
1.8.3	• Update EFA kernel module to version 1.5.1. • Distributed DKMS on some platforms rather than relying on EPEL repositories for added installation reliability. • On RHEL 7, install RPMs built on CentOS 7 instead of RPMs built on Amazon Linux 2.	February 2020
1.8.2	• Revert `rdma-core` to version 25 due to a mismatch in device naming between kernel module and `rdma-core` .	January 2020
1.8.1	• Update Libfabric to version 1.9.0amzn1.1.	January 2020
1.8.0	• Update `rdma-core` to version 27.0. • Update EFA kernel module to version 1.5.0. • Update Libfabric to version 1.9.0amzn1.0. • Add option `--minimal` to install just the EFA kernel module and `rdma-core` .	December 2019
1.7.1	• Update Libfabric to version 1.8.1amzn1.3.	December 2019

Version	Changes	Release date
1.7.0	• Add Libfabric module file. • Update Libfabric to version 1.8.1amzn1.1.	November 2019
1.6.2	• Update Open MPI to version 1.6.2.	October 2019
1.6.1	• Update Libfabric to version 1.8.1amzn1.0. • Update Open MPI to version 4.0.1. • Update `rdma-core` to version 26.0.	October 2019
1.5.4	• Update EFA kernel module to version 1.4.1.	September 2019
1.5.3	• Update EFA kernel module to version 1.3.1. • Avoid installing `kernel-devel` or `linux-headers` packages unless installing the kernel driver.	September 2019
1.5.1	• Only configure huge pages when EFA device is present.	August 2019
1.5.0	• Update Libfabric to version 1.8.0amzn1.1. • Update `rmda-core` to version 25.0.	August 2019
1.4.1	• Add Libfabric and Open MPI library paths (`/opt/amazon/efa/lib64` and `/opt/amazon/efa/openmpi/lib`) to `/etc/ld.so.conf.d/efa.conf` to ensure the Open MPI and Libfabric shared libraries are properly located.	July 2019
1.4.0	• Update EFA kernel module to version 1.3.0. • Update Libfabric to version 1.8.0amzn1.0 • First release to support Intel MPI 2019 Update 4.	July 2019

Amazon EC2 instance topology

Describing your instance topology provides a hierarchical view of the relative proximity between your Amazon EC2 instances. You can use this information to manage high performance computing

(HPC) and machine learning (ML) compute infrastructure at scale, while optimizing job placement. HPC and ML jobs are sensitive to latency and throughput. You can use the instance topology to detect the location of your instances, and then use this information to optimize HPC and ML jobs by running them on instances that are physically closer to each other.

You can use instance topology to detect the location of your existing instances, but you can't use it to choose to launch a new instance physically close to an existing instance. To influence instance placement, you can create Capacity Reservations in cluster placement groups.

Considerations

- Instance topology views are only available for instances in the `running` state.
- Each instance topology view is unique per account.
- The AWS Management Console does not support viewing the instance topology.

Pricing

There is no additional cost to describe your instance topology.

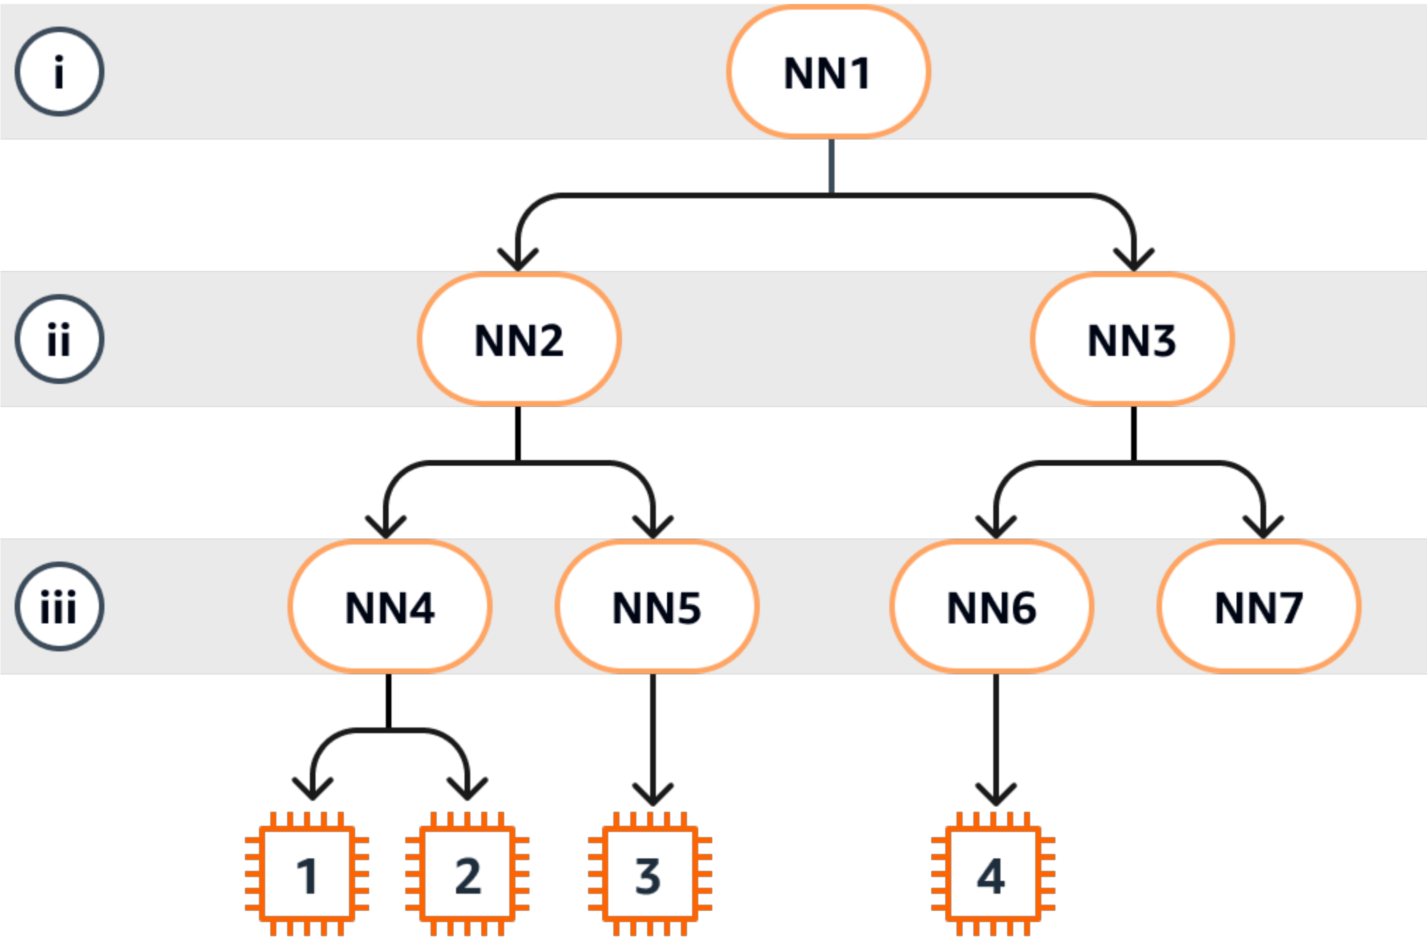
Contents

How Amazon EC2 instance topology works

The AWS network is arranged in a hierarchy of layers. EC2 instances connect into the network at or below the third layer, depending on the instance type. An instance's topology is described by a set of nodes, with one node in each layer of the network. The node set in the DescribeInstanceTopology API response provides a top-down view of the network hierarchy, with the bottom node connected to the instance.

> **Note**
>
> Some instance types comprise 4 network nodes in a node set representing 4 layers in the network, while others comprise 3 network nodes representing 3 layers in the network. For the supported instance types, see Instance types.

The following diagram provides a visual representation that you can use to understand the instance topology. The network nodes are identified as **NN1 – NN7**. The numerals **i**, **ii**, and **iii** identify the network layers. The numbers **1**, **2**, **3**, and **4** identify the EC2 instances. Instances connect to a node in the bottom layer, identified by **iii** in the following diagram. More than one instance can connect to the same node.



In this example:

- Instance 1 connects to network node 4 (NN4) in layer iii. NN4 connects to network node 2 (NN2) in layer ii, and NN2 connects to network node 1 (NN1) in layer i, which is the top of the network hierarchy in this example. The network node set comprises NN1, NN2, and NN4, expressed hierarchically from the upper layers to the bottom layer.
- Instance 2 also connects to network node 4 (NN4). Instance 1 and instance 2 share the same network node set: NN1, NN2, and NN4.
- Instance 3 connects to network node 5 (NN5). NN5 connects to NN2, and NN2 connects to NN1. The network node set for instance 3 is NN1, NN2, and NN5.
- Instance 4 connects to network node 6 (NN6). Its network node set is NN1, NN3, and NN6.

When considering the proximity of instances 1, 2, and 3, instances 1 and 2 are closer to each other because they connect to the same network node (NN4), while instance 3 is further away because it connects to a different network node (NN5).

When considering the proximity of all the instances in this diagram, instances 1, 2, and 3 are closer to each other than they are to instance 4 because they share NN2 in their network node set.

As a general rule, if the network node connected to any two instances is the same, these instances are physically close to each other, as is the case with instances 1 and 2. Furthermore, the fewer the number of hops between network nodes, the closer the instances are to each other. For example, instances 1 and 3 have fewer hops to a common network node (NN2) than they have to the network node (NN1) they have in common with instance 4, and are therefore closer to each other than they are to instance 4.

There are no instances running under network node 7 (NN7) in this example, and therefore the API output won't include NN7.

How to interpret the output

You get the instance topology information using the DescribeInstanceTopology API. The output provides a hierarchical view of the underlying network topology for an instance.

The following example output corresponds to the network topology information of the four instances in the preceding diagram. Comments are included in the example output for the purposes of this example.

The following information in the output is important to note:

- `NetworkNodes` describes the network node set of an instance.
- In each network node set, the network nodes are listed in hierarchical order from top to bottom.
- The network node that is connected to the instance is the last network node in the list (the bottom layer).
- To work out which instances are close to each other, first find common network nodes in the bottom layer. If there are no common network nodes in the bottom layer, then find common network nodes in the upper layers.

In the following example output, `i-1111111111example` and `i-2222222222example` are located closest to each other compared to the other instances in this example because they have the network node `nn-4444444444example` in common in the bottom layer.

> **Note**
>
> The response contains 3 or more network nodes. For information about the number of network nodes in the response for each supported instance type, see [Instance types](#).

Prerequisites for Amazon EC2 instance topology

Before you describe the instance topology for your instances, ensure that your instances meet the following requirements.

Requirements to describe the topology of your instances

- AWS Regions
- Instance types
- Instance state
- IAM permission

AWS Regions

Supported AWS Regions:

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)

- Asia Pacific (Melbourne), Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Spain), Europe (Stockholm)
- Israel (Tel Aviv)
- South America (São Paulo)
- AWS GovCloud (US-West)

Instance types

Supported instance types:

- Returns 3 network nodes in the response
  - `hpc6a.48xlarge` | `hpc6id.32xlarge` | `hpc7a.12xlarge` | `hpc7a.24xlarge` | `hpc7a.48xlarge` | `hpc7a.96xlarge` | `hpc7g.4xlarge` | `hpc7g.8xlarge` | `hpc7g.16xlarge`
  - `p3dn.24xlarge` | `p4d.24xlarge` | `p4de.24xlarge` | `p5.48xlarge` | `p5e.48xlarge` | `p5en.48xlarge` | `p6e-gb200.36xlarge`
  - `trn1.2xlarge` | `trn1.32xlarge` | `trn1n.32xlarge` | `trn2.48xlarge` | `trn2u.48xlarge`
- Returns 4 network nodes in the response
  - `p6-b200.48xlarge`

The available instance types vary by Region. For more information, see [Amazon EC2 instance types by Region](#).

Instance state

Instances must be in the `running` state. You can't get instance topology information for instances that are in another state.

IAM permission

Your IAM identity (user, user group, or role) requires the following IAM permission:

- `ec2:DescribeInstanceTopology`

Examples for Amazon EC2 instance topology

You can use the describe-instance-topology command to describe the instance topology for your EC2 instances.

When you use the `describe-instance-topology` command without parameters or filters, the response includes all your instances that match the supported instance types for this command in the specified Region. You can specify the Region by including the `--region` parameter, or by setting a default Region. For more information about setting a default Region, see Select a Region for your Amazon EC2 resources.

You can include parameters to return instances that match specified instance IDs or placement group names. You can also include filters to return instances that match a specified instance type or instance family, or instances in a specified Availability Zone or Local Zone. You can include a single parameter or filter, or a combination of parameters and filters.

The output is paginated, with up to 20 instances per page by default. You can specify up to 100 instances per page using the `--max-results` parameter.

For more information, see describe-instance-topology.

Required permissions

The following permission is required to describe instance topology:

- `ec2:DescribeInstanceTopology`

Examples

- Example 1 – Instance IDs
- Example 2 – Placement group name parameter
- Example 3 – Instance type filter
  - Example 3a – Exact match filter for a specified instance type
  - Example 3b – Wild card filter for an instance family
  - Example 3c – Combined instance family and exact match filters
- Example 4 – Zone ID filter
  - Example 4a – Availability Zone filter
  - Example 4b – Local Zone filter

Example 1 – Instance IDs

AWS CLI

To describe the topology of specific instances

Use the describe-instance-topology command with the `--instance-ids` parameter. The output includes only the instances that match the specified instance IDs.

```
aws ec2 describe-instance-topology \
    --region us-west-2 \
    --instance-ids i-1111111111example i-2222222222example
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-1111111111example",
            "InstanceType": "p4d.24xlarge",
            "GroupName": "ML-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        },
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "GroupName": "HPC-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3214313214example"
```

```
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of specific instances

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -InstanceId i-1111111111example, i-2222222222example
```

Example 2 – Placement group name parameter

AWS CLI

To describe the topology of instances in a specific placement group

Use the describe-instance-topology command with the `group-names` parameter. The output includes only the instances that are in either of the specified placement groups.

```
aws ec2 describe-instance-topology \
    --region us-west-2 \
    --group-names ML-group HPC-group
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-1111111111example",
            "InstanceType": "p4d.24xlarge",
            "GroupName": "ML-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
```

```
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        },
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "GroupName": "HPC-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3214313214example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances in a specific placement group

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -GroupName ML-group, HPC-group
```

Example 3 – Instance type filter

You can filter by a specified instance type (exact match) or filter by an instance family (using a wildcard). You can also combine a specified instance type filter and instance family filter.

Example 3a – Exact match filter for a specified instance type

AWS CLI

To describe the topology of instances with a specific instance type

Use the describe-instance-topology command with the `instance-type` filter. The output includes only the instances with the specified instance type.

```
aws ec2 describe-instance-topology \
    --region us-west-2 \
    --filters Name=instance-type,Values=trn1n.32xlarge
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances with a specific instance type

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="instance-type"; Values="trn1n.32xlarge"}
```

Example 3b – Wild card filter for an instance family

AWS CLI

To describe the topology of instances with a specific instance family

Use the describe-instance-topology command with the `instance-type` filter. The output includes only the instances with the specified instance family.

```
aws ec2 describe-instance-topology \
    --region us-west-2 \
    --filters Name=instance-type,Values=trn1*
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        },
        {
            "InstanceId": "i-3333333333example",
            "InstanceType": "trn1.32xlarge",
            "NetworkNodes": [
                "nn-1212121212example",
                "nn-1211122211example",
                "nn-1311133311example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az4",
            "AvailabilityZone": "us-west-2d"
        },
        {
            "InstanceId": "i-444444444example",
            "InstanceType": "trn1.2xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-5434334334example",
                "nn-1235301234example"
            ],
```

```
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances with a specific instance family

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="instance-type"; Values="trn1*"}
```

Example 3c – Combined instance family and exact match filters

AWS CLI

To describe the topology of instances with an instance family or instance type

Use the describe-instance-topology command with the `instance-type` filter. The output includes only the instances that meet the specified criteria.

```
aws ec2 describe-instance-topology \
    --region us-west-2 \
    --filters "Name=instance-type,Values=p4d*,trn1n.32xlarge"
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-1111111111example",
            "InstanceType": "p4d.24xlarge",
            "GroupName": "ML-group",
            "NetworkNodes": [
                "nn-1111111111example",
```

```
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        },
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-4343434343example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "usw2-az2",
            "AvailabilityZone": "us-west-2a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances with an instance family or instance type

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="instance-type"; Values="p4d*", "trn1n.32xlarge"}
```

Example 4 – Zone ID filter

You can use the `zone-id` filter to filter by an Availability Zone or Local Zone. You can also combine an Availability Zone filter and Local Zone filter.

Example 4a – Availability Zone filter

AWS CLI

To describe the topology of instances in a specific Availability Zone

Use the describe-instance-topology command with the zone-id filter. The output includes only the instances in the specified Availability Zone.

```
aws ec2 describe-instance-topology \
    --region us-east-1 \
    --filters Name=zone-id,Values=use1-az1
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3214313214example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "use1-az1",
            "AvailabilityZone": "us-east-1a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances in a specific Availability Zone

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="zone-id"; Values="use1-az1"}
```

Example 4b – Local Zone filter

AWS CLI

To describe the topology of instances in a specific Local Zone

Use the describe-instance-topology command with the zone-id filter. The output includes only the instances in the specified Local Zone.

```
aws ec2 describe-instance-topology \
    --region us-east-1 \
    --filters Name=zone-id,Values=use1-atl2-az1
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-1111111111example",
            "InstanceType": "p4d.24xlarge",
            "GroupName": "ML-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "use1-atl2-az1",
            "AvailabilityZone": "us-east-1-atl-2a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances in a specific Local Zone

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="zone-id"; Values="use1-atl2-az1"}
```

Example 4c – Combined Availability Zone and Local Zone filters

AWS CLI

To describe the topology of instances in a specific zone

Use the describe-instance-topology command with the `zone-id` filter. The output includes only the instances that are in either of the specified zones.

```
aws ec2 describe-instance-topology \
    --region us-east-1 \
    --filters Name=zone-id,Values=use1-az1,use1-atl2-az1
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-1111111111example",
            "InstanceType": "p4d.24xlarge",
            "GroupName": "ML-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "use1-atl2-az1",
            "AvailabilityZone": "us-east-1-atl-2a"
        },
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3214313214example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "use1-az1",
            "AvailabilityZone": "us-east-1a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances in a specific zone

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="zone-id"; Values="use1-az1", "use1-atl2-az1"}
```

Example 5 – Instance type and zone ID filters

You can combine filters in a single command.

AWS CLI

To describe the topology of instances with specific instance types, instance families, and zones

Use the describe-instance-topology command with the `instance-type` and `zone-id` filters. The response contains any instances with either of the specified instance types and are in either of the specified zones.

```
aws ec2 describe-instance-topology \
    --region us-east-1 \
    --filters "Name=instance-type,Values=p4d*,trn1n.32xlarge" \
              "Name=zone-id,Values=use1-az1,use1-atl2-az1"
```

The following is example output.

```
{
    "Instances": [
        {
            "InstanceId": "i-1111111111example",
            "InstanceType": "p4d.24xlarge",
            "GroupName": "ML-group",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3333333333example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "use1-atl2-az1",
            "AvailabilityZone": "us-east-1-atl-2a"
        },
```

```
        {
            "InstanceId": "i-2222222222example",
            "InstanceType": "trn1n.32xlarge",
            "NetworkNodes": [
                "nn-1111111111example",
                "nn-2222222222example",
                "nn-3214313214example"
            ],
            "CapacityBlockId": "null",
            "ZoneId": "use1-az1",
            "AvailabilityZone": "us-east-1a"
        }
    ],
    "NextToken": "SomeEncryptedToken"
}
```

PowerShell

To describe the topology of instances with specific instance types, instance families, and zones

Use the Get-EC2InstanceTopology cmdlet.

```
Get-EC2InstanceTopology `
    -Filter @{Name="instance-type"; Values="p4d*", "trn1n.32xlarge"} `
            @{Name="zone-id"; Values="use1-az1", "use1-atl2-az1"}
```

Placement groups for your Amazon EC2 instances

To meet the needs of your workload, you can launch a group of *interdependent* EC2 instances into a *placement group* to influence their placement.

Depending on the type of workload, you can create a placement group using one of the following placement strategies:

- **Cluster** – Packs instances close together inside an Availability Zone. This strategy enables workloads to achieve the low-latency network performance necessary for tightly-coupled node-to-node communication that is typical of high-performance computing (HPC) applications.
- **Partition** – Spreads your instances across logical partitions such that groups of instances in one partition do not share the underlying hardware with groups of instances in different partitions.

This strategy is typically used by large distributed and replicated workloads, such as Hadoop, Cassandra, and Kafka.

- **Spread** – Strictly places a small group of instances across distinct underlying hardware to reduce correlated failures.

Placement groups are optional. If you don't launch your instances into a placement group, EC2 tries to place the instances in such a way that all of your instances are spread out across the underlying hardware to minimize correlated failures.

Pricing

There is no charge for creating a placement group.

Rules and limitations

Before you use placement groups, be aware of the following rules:

- An instance can be placed in one placement group at a time; you can't place an instance in multiple placement groups.
- You can't merge placement groups.
- On-Demand Capacity Reservations and zonal Reserved Instances allow you to reserve capacity for EC2 instances in Availability Zones. When you launch an instance, if the instance attributes match those specified by an On-Demand Capacity Reservation or a zonal Reserved Instance, then the reserved capacity is automatically used by the instance. This is also true if you launch the instance into a placement group.
- You can't launch Dedicated Hosts in placement groups.
- You can't launch a Spot Instance that is configured to stop or hibernate on interruption in a placement group.

Contents

Placement strategies for your placement groups

You can create a placement group for your EC2 instances using one of the following placement strategies.

Placement strategies

- Cluster placement groups
- Partition placement groups
- Spread placement groups

Cluster placement groups

A cluster placement group is a logical grouping of instances within a single Availability Zone. Instances are not isolated to a single rack. A cluster placement group can span peered virtual private networks (VPCs) in the same Region. Instances in the same cluster placement group enjoy a higher per-flow throughput limit for TCP/IP traffic and are placed in the same high-bisection bandwidth segment of the network.

The following image shows instances that are placed into a cluster placement group.

Cluster placement groups are recommended for applications that benefit from low network latency, high network throughput, or both. They are also recommended when the majority of the network traffic is between the instances in the group. To provide the lowest latency and the highest packet-per-second network performance for your placement group, choose an instance type that supports enhanced networking. For more information, see Enhanced Networking.

We recommend that you launch your instances in the following way:

- Use a single launch request to launch the number of instances that you need in the placement group.
- Use the same instance type for all instances in the placement group.

If you try to add more instances to the placement group later, or if you try to launch more than one instance type in the placement group, you increase your chances of getting an insufficient capacity error.

If you stop an instance in a placement group and then start it again, it still runs in the placement group. However, the start fails if there isn't enough capacity for the instance.

If you receive a capacity error when launching an instance in a placement group that already has running instances, stop and start all of the instances in the placement group, and try the launch again. Starting the instances may migrate them to hardware that has capacity for all of the requested instances.

Rules and limitations

The following rules apply to cluster placement groups:

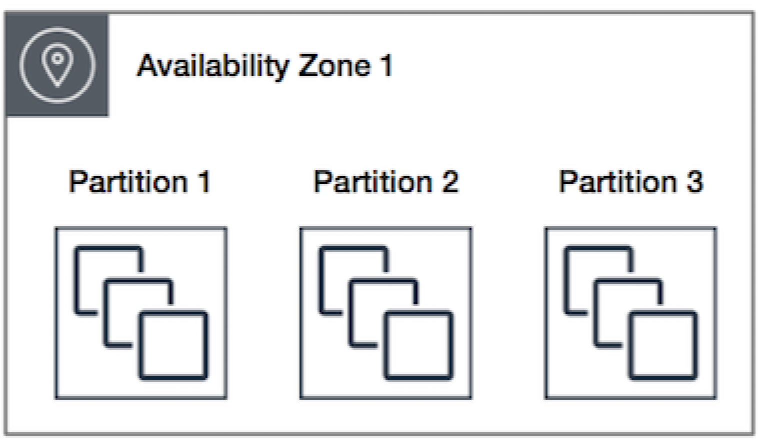
- The following instance types are supported:
  - Current generation instances, except for burstable performance instances (for example, T2), Mac1 instances, and M7i-flex instances.
  - The following previous generation instances: A1, C3, C4, I2, M4, R3, and R4.
- A cluster placement group can't span multiple Availability Zones.
- The maximum network throughput speed of traffic between two instances in a cluster placement group is limited by the slower of the two instances. For applications with high-throughput requirements, choose an instance type with network connectivity that meets your requirements.
- For instances that are enabled for enhanced networking, the following rules apply:
  - Instances within a cluster placement group can use up to 10 Gbps for single-flow traffic. Instances that are not within a cluster placement group can use up to 5 Gbps for single-flow traffic.
  - Traffic to and from Amazon S3 buckets within the same Region over the public IP address space or through a VPC endpoint can use all available instance aggregate bandwidth.
- You can launch multiple instance types into a cluster placement group. However, this reduces the likelihood that the required capacity will be available for your launch to succeed. We recommend using the same instance type for all instances in a cluster placement group.

- We recommend that you reserve capacity explicitly in the cluster placement group by creating an On-Demand Capacity Reservation in the cluster placement group. Note that you can't reserve capacity using zonal Reserved Instances, as they can't reserve capacity explicitly in a placement group.
- Network traffic to the internet and over an AWS Direct Connect connection to on-premises resources is limited to 5 Gbps for cluster placement groups.

Partition placement groups

Partition placement groups help reduce the likelihood of correlated hardware failures for your application. When using partition placement groups, Amazon EC2 divides each group into logical segments called partitions. Amazon EC2 ensures that each partition within a placement group has its own set of racks. Each rack has its own network and power source. No two partitions within a placement group share the same racks, allowing you to isolate the impact of hardware failure within your application.

The following image is a simple visual representation of a partition placement group in a single Availability Zone. It shows instances that are placed into a partition placement group with three partitions—**Partition 1**, **Partition 2**, and **Partition 3**. Each partition comprises multiple instances. The instances in a partition do not share racks with the instances in the other partitions, allowing you to contain the impact of a single hardware failure to only the associated partition.



Partition placement groups can be used to deploy large distributed and replicated workloads, such as HDFS, HBase, and Cassandra, across distinct racks. When you launch instances into a partition placement group, Amazon EC2 tries to distribute the instances evenly across the number of partitions that you specify. You can also launch instances into a specific partition to have more control over where the instances are placed.

A partition placement group can have partitions in multiple Availability Zones in the same Region. A partition placement group can have a maximum of seven partitions per Availability Zone. The number of instances that can be launched into a partition placement group is limited only by the limits of your account.

In addition, partition placement groups offer visibility into the partitions — you can see which instances are in which partitions. You can share this information with topology-aware applications, such as HDFS, HBase, and Cassandra. These applications use this information to make intelligent data replication decisions for increasing data availability and durability.

If you start or launch an instance in a partition placement group and there is insufficient unique hardware to fulfill the request, the request fails. Amazon EC2 makes more distinct hardware available over time, so you can try your request again later.

Rules and limitations

The following rules apply to partition placement groups:

- A partition placement group supports a maximum of seven partitions per Availability Zone. The number of instances that you can launch in a partition placement group is limited only by your account limits.
- When instances are launched into a partition placement group, Amazon EC2 tries to evenly distribute the instances across all partitions. Amazon EC2 doesn’t guarantee an even distribution of instances across all partitions.
- A partition placement group with Dedicated Instances can have a maximum of two partitions.
- Capacity Reservations do not reserve capacity in a partition placement group.

Spread placement groups

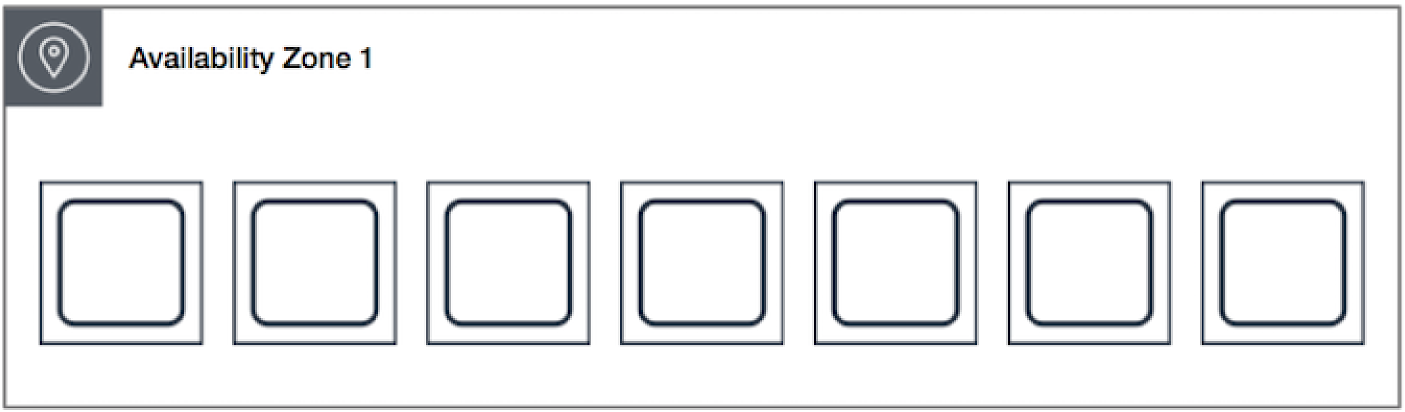
A spread placement group is a group of instances that are each placed on distinct hardware.

Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. Launching instances in a spread level placement group reduces the risk of simultaneous failures that might occur when instances share the same equipment. Spread level placement groups provide access to distinct hardware, and are therefore suitable for mixing instance types or launching instances over time.

If you start or launch an instance in a spread placement group and there is insufficient unique hardware to fulfill the request, the request fails. Amazon EC2 makes more distinct hardware available over time, so you can try your request again later. Placement groups can spread instances across racks or hosts. Rack level spread placement groups can be used in AWS Regions and on AWS Outposts. Host level spread placement groups can be used with AWS Outposts only.

Rack level spread placement groups

The following image shows seven instances in a single Availability Zone that are placed into a spread placement group. The seven instances are placed on seven different racks, each rack has its own network and power source.



A rack level spread placement group can span multiple Availability Zones in the same Region. In a Region, a rack level spread placement group can have a maximum of seven running instances per Availability Zone per group. With Outposts, a rack level spread placement group can hold as many instances as you have racks in your Outpost deployment.

Host level spread placement groups

Host level spread placement groups are only available with AWS Outposts. A host spread level placement group can hold as many instances as you have hosts in your Outpost deployment. For more information, see the section called “Placement groups on AWS Outposts”.

Rules and limitations

The following rules apply to spread placement groups:

- A rack spread placement group supports a maximum of seven running instances per Availability Zone. For example, in a Region with three Availability Zones, you can run a total of 21 instances in the group, with seven instances in each Availability Zone. If you try to start an eighth instance in the same Availability Zone and in the same spread placement group, the instance will not launch. If you need more than seven instances in an Availability Zone, we recommend that you use multiple spread placement groups. Using multiple spread placement groups does not provide guarantees about the spread of instances between groups, but it does help ensure the spread for each group, thus limiting the impact from certain classes of failures.

- Spread placement groups are not supported for Dedicated Instances.
- Host level spread placement groups are only supported for placement groups on AWS Outposts. A host level spread placement group can hold as many instances as you have hosts in your Outpost deployment.
- In a Region, a rack level spread placement group can have a maximum of seven running instances per Availability Zone per group. With AWS Outposts, a rack level spread placement group can hold as many instances as you have racks in your Outpost deployment.
- Capacity Reservations do not reserve capacity in a spread placement group.

Create a placement group for your EC2 instances

You can use a placement group to control the placement of instances relative to each other. After you create a placement group, you can launch instances in the placement group.

Limitation

You can create a maximum of 500 placement groups per Region.

Console

To create a placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**.
3. Choose **Create placement group**.
4. Specify a name for the group.
5. Choose the placement strategy for the group: **Cluster**, **Spread**, or **Partition**.

   If you chose **Spread**, you must choose the spread level: **Rack** or **Host**.

   If you chose **Partition**, you must enter the number of partitions for the group.
6. (Optional) To add a tag, choose **Add new tag**, and then enter a key and value.
7. Choose **Create group**.

AWS CLI

Use the [create-placement-group](#) command.

To create a cluster placement group

The following example creates a placement group that uses the `cluster` placement strategy, and it applies a tag with a key of `purpose` and a value of `production`.

```
aws ec2 create-placement-group \
    --group-name my-cluster \
    --strategy cluster \
    --tag-specifications 'ResourceType=placement-
group,Tags={Key=purpose,Value=production}'
```

To create a partition placement group

The following example creates a placement group that uses the `partition` placement strategy, and specifies the five partitions using the `--partition-count` parameter.

```
aws ec2 create-placement-group \
    --group-name HDFS-Group-A \
    --strategy partition \
    --partition-count 5
```

PowerShell

Use the [New-EC2PlacementGroup](#) cmdlet.

To create a cluster placement group

The following example creates a cluster placement group.

```
New-EC2PlacementGroup `
    -GroupName my-placement-group `
    -Strategy cluster
```

To create a partition placement group

The following example creates a partition placement group.

```
New-EC2PlacementGroup `
```

```
    -GroupName my-placement-group `
    -Strategy partition `
    -PartitionCount 5
```

Change the placement for an EC2 instance

You can change the placement group for an instance as follows:

- Add an instance to a placement group
- Move an instance from one placement group to another
- Remove an instance from a placement group

Requirement

Before you can change the placement group for an instance, the instance must be in the `stopped` state.

Console

To change the instance placement

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Instance settings**, **Modify instance placement**.
5. For **Placement group**, do one of the following:
   - To add the instance to a placement group, choose the placement group.
   - To move the instance from one placement group to another, choose the placement group.
   - To remove the instance from the placement group, choose **None**.
6. Choose **Save**.

AWS CLI

To move an instance to a placement group

Use the following modify-instance-placement command.

```
aws ec2 modify-instance-placement \
    --instance-id i-0123a456700123456 \
    --group-name MySpreadGroup
```

To remove an instance from a placement group

Use the following modify-instance-placement command. When you specify an empty string for the placement group name, this removes the instance from its current placement group.

```
aws ec2 modify-instance-placement \
    --instance-id i-0123a456700123456 \
    --group-name ""
```

PowerShell

To move an instance to a placement group

Use the Edit-EC2InstancePlacement cmdlet with the name of the placement group.

```
Edit-EC2InstancePlacement `
    -InstanceId i-0123a456700123456 `
    -GroupName MySpreadGroup
```

To remove an instance from a placement group

Use the Edit-EC2InstancePlacement cmdlet with an empty string for the name of the placement group.

```
Edit-EC2InstancePlacement `
    -InstanceId i-0123a456700123456 `
    -GroupName ""
```

Delete a placement group

If you need to replace a placement group or no longer need one, you can delete it. Before you can delete a placement group, it must contain no instances. You can terminate the instances, move them to another placement group, or remove them from the placement group.

Console

To delete a placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**.
3. Select the placement group and choose **Actions**, **Delete**.
4. When prompted for confirmation, enter **`Delete`** and then choose **Delete**.

AWS CLI

To delete a placement group

Use the delete-placement-group command.

```
aws ec2 delete-placement-group --group-name my-cluster
```

PowerShell

To delete a placement group

Use the Remove-EC2PlacementGroup cmdlet.

```
Remove-EC2PlacementGroup -GroupName my-cluster
```

Shared placement groups

Placement group sharing allows you to influence the placement of interdependent instances that are owned by separate AWS accounts. An owner can share a placement group across multiple AWS accounts or within their organization. A participant can launch instances in a placement group that is shared with their account.

A placement group owner can share a placement group with:

- Specific AWS accounts inside or outside of its organization
- An organizational unit inside its organization
- Its entire organization

You can use VPC peering to connect instances owned by separate AWS accounts and get the full latency benefits offered by shared cluster placement groups.

Contents

Rules and limitations

The following rules and limitations apply when you share a placement group or when a placement group is shared with you.

- To share a placement group, you must own it in your AWS account. You can't share a placement group that has been shared with you.
- When you share a partition or spread placement group, the placement group limits do not change. A shared partition placement group supports a maximum of seven partitions per Availability Zone, and a shared spread placement group supports a maximum of seven running instances per Availability Zone.
- To share a placement group with your organization or an organizational unit in your organization, you must enable sharing with AWS Organizations. For more information, see Sharing your AWS resources.
- When using the AWS Management Console to launch an instance, you can select any placement groups that were shared with you. When using the AWS CLI to launch an instance, you must specify a shared placement group by ID, not by name. You can use the name of a placement group only if you're the owner of the shared placement group.
- You are responsible for managing the instances owned by you in a shared placement group.
- You can't view or modify instances and capacity reservations that are associated with a shared placement group but not owned by you.
- The Amazon Resource Name (ARN) of a placement group contains the ID of the account that owns the placement group. You can use the account ID portion of a placement group ARN to identify the owner of a placement group that is shared with you.

Required permissions

To share a placement group, users must have permissions for following actions:

- `ec2:PutResourcePolicy`
- `ec2:DeleteResourcePolicy`

Sharing across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To specify the location of your Dedicated Hosts relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an Availability Zone ID for the `us-east-1` Region and it is the same location in every AWS account. For more information, see AZ IDs.

Placement group sharing

To share a placement group, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared.

If you are part of an organization in AWS Organizations sharing within your organization is enabled, consumers in your organization are granted access to the shared placement group.

If the placement group is shared with an AWS account outside of your organization, the AWS account owner will receive an invitation to join the resource share. They can access the shared placement group after accepting the invitation.

You can share a placement group across AWS accounts using AWS Resource Access Manager. For more information, see Creating a resource share in the *AWS RAM User Guide*.

Placement group unsharing

The placement group owner can unshare a shared placement group at any time. When you unshare a shared placement group, the following changes occur:

- The AWS accounts with which a placement group was shared are no longer able to launch instances or reserve capacity.
- Any instances running in a shared placement group are disassociated from the placement group, but they continue to run in your AWS account.
- Any capacity reservations in a shared placement group are disassociated from the placement group, but remain available to you in your AWS account.

For more information, see Deleting a resource share in the *AWS RAM User Guide*.

Placement groups on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create placement groups on Outposts that you have created in your account. This allows you to spread out instances across underlying hardware on an Outpost at your site. You create and use placement groups on Outposts in the same way that you create and use placement groups in regular Availability Zones. When you create a placement group with a spread strategy on an Outpost, you can choose to have the placement group spread instances across hosts or racks. Spreading instances across hosts allows you to use a spread strategy with a single rack Outpost.

Considerations

- A rack level spread placement group can hold as many instances as you have racks in your Outpost deployment.
- A host level spread placement group can hold as many instances as you have hosts in your Outpost deployment.

Prerequisite

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the *AWS Outposts User Guide*.

To use a placement group on an Outpost

1. Create a subnet on the Outpost. For more information, see Create a subnet in the *AWS Outposts User Guide*.
2. Create a placement group in the associated Region of the Outpost. If you create a placement group with a spread strategy, you can choose host or rack level spread to determine how the group will spread instances across the underlying hardware on your Outpost. For more information, see the section called “Create a placement group”.
3. Launch an instance into the placement group. For **Subnet** choose the subnet that you created in Step 1, and for **Placement group name**, select the placement group that you created in Step 2. For more information, see Launch an instance on the Outpost in the *AWS Outposts User Guide*.

Network maximum transmission unit (MTU) for your EC2 instance

The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed over the connection. The larger the MTU of a connection, the more data that can be passed in a single packet. Ethernet frames consist of the packet, or the actual data you are sending, and the network overhead information that surrounds it.

Ethernet frames can come in different formats, and the most common format is the standard Ethernet v2 frame format. It supports 1500 MTU, which is the largest Ethernet packet size supported over most of the internet. The maximum supported MTU for an instance depends on its instance type.

All EC2 instance types support 1500 MTU.

Contents

Jumbo frames (9001 MTU)

With jumbo frames, you can increase the payload size per packet, thereby increasing the percentage of the packet that is not packet overhead. With jumbo frames, fewer packets are needed to send the same amount of usable data. However, certain types of traffic are subject to the following maximum payloads:

MTU limit 1500 bytes

- Traffic over an internet gateway
- Traffic over VPN connections
- Traffic between AWS Regions, unless a transit gateway is used

MTU limit 8500 bytes

- Traffic over an inter-region VPC peering connection

If packets are over their MTU limit, they are fragmented, or they are dropped if the `Don't Fragment` flag is set in the IP header.

Jumbo frames should be used with caution for internet-bound traffic or any traffic that leaves a VPC. Packets are fragmented by intermediate systems, which slows down this traffic. To use jumbo frames inside a VPC and not slow traffic that's bound for outside the VPC, you can configure the MTU size by route, or use multiple elastic network interfaces with different MTU sizes and different routes.

For instances that are collocated inside a cluster placement group, jumbo frames help to achieve the maximum network throughput possible, and they are recommended in this case. For more information, see Placement groups for your Amazon EC2 instances.

You can use jumbo frames for traffic between your VPCs and your on-premises networks over AWS Direct Connect. For more information, and for how to verify Jumbo Frame capability, see MTU for private virtual interfaces or transit virtual interfaces in the *AWS Direct Connect User Guide*.

All current generation instance types support jumbo frames. The following previous generation instance types support jumbo frames: A1, C3, I2, M3, and R3.

Related resources

- For NAT gateways, see NAT gateway basics in the *Amazon VPC User Guide*.
- For transit gateways, see Maximum transmission unit in the *Amazon VPC Transit Gateways User Guide*.
- For Local Zones, see Considerations in the *AWS Local Zones User Guide*.
- For AWS Wavelength, see Maximum transmission unit in the *AWS Wavelength User Guide*.
- For Outposts see Service link maximum transmission unit requirements in the *AWS Outposts User Guide*.

Path MTU Discovery

Path MTU Discovery (PMTUD) is used to determine the path MTU between two devices. The path MTU is the maximum packet size that's supported on the path between the originating host and the receiving host. When there is a difference in the MTU size in the network between two hosts, PMTUD enables the receiving host to respond to the originating host with an ICMP message. This ICMP message instructs the originating host to use the lowest MTU size along the network path and to resend the request. Without this negotiation, packet drop can occur because the request is too large for the receiving host to accept.

For IPv4, when a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: `Destination Unreachable: Fragmentation Needed and Don't Fragment was Set` (Type 3, Code 4). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

The IPv6 protocol does not support fragmentation in the network. When a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: `ICMPv6 Packet Too Big (PTB)` (Type 2). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

Connections made through some components, like NAT gateways and load balancers, are automatically tracked. This means that security group tracking is automatically enabled for your outbound connection attempts. If connections are automatically tracked or if your security group rules allow inbound ICMP traffic, you can receive PMTUD responses.

Note that ICMP traffic can be blocked even if the traffic is allowed at the security group level, such as if you have a network access control list entry that denies ICMP traffic to the subnet.

> **Important**
>
> Path MTU Discovery does not guarantee that jumbo frames will not be dropped by some routers. An internet gateway in your VPC will forward packets up to 1500 bytes only. 1500 MTU packets are recommended for internet traffic.

For MTU rules over NAT gateways, see Maximum transmission unit (MTU) in the *Amazon VPC User Guide*. For MTU rules over Transit gateways, see Maximum transmission unit (MTU) in the *AWS Transit Gateway User Guide*.

Set the MTU for your Amazon EC2 instances

The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed over the connection. All Amazon EC2 instances support standard frames (1500 MTU) and all current generation instance types support jumbo frames (9001 MTU).

You can view the MTU for your Amazon EC2 instances, view the path MTU between your instance and another host, and configure your instances to use either standard or jumbo frames.

Tasks

- Check the path MTU between two hosts
- Check the MTU for your instance
- Set the MTU for your instance

Check the path MTU between two hosts

You can check the path MTU between your EC2 instance and another host. You can specify a DNS name or an IP address as the destination. If the destination is another EC2 instance, verify that its security group allows inbound UDP traffic.

The procedure that you use depends on the operating system of the instance.

Linux instances

Run the **tracepath** command on your instance to check the path MTU between your EC2 instance and the specified destination. This command is part of the `iputils` package, which is available by default in many Linux distributions.

This example checks the path MTU between the EC2 instance and `amazon.com`.

```
[ec2-user ~]$ tracepath amazon.com
```

In this example output, the path MTU is 1500.

```
 1?: [LOCALHOST]     pmtu 9001
 1:  ip-172-31-16-1.us-west-1.compute.internal (172.31.16.1)   0.187ms pmtu 1500
 1:  no reply
 2:  no reply
 3:  no reply
 4:  100.64.16.241 (100.64.16.241)                              0.574ms
 5:  72.21.222.221 (72.21.222.221)                             84.447ms asymm 21
 6:  205.251.229.97 (205.251.229.97)                           79.970ms asymm 19
 7:  72.21.222.194 (72.21.222.194)                             96.546ms asymm 16
 8:  72.21.222.239 (72.21.222.239)                             79.244ms asymm 15
 9:  205.251.225.73 (205.251.225.73)                           91.867ms asymm 16
...
31:  no reply
     Too many hops: pmtu 1500
     Resume: pmtu 1500
```

Windows instances

To check path MTU using mturoute

1. Download **mturoute.exe** to your EC2 instance from https://elifulkerson.com/projects/mturoute.php.
2. Open a Command Prompt window and change to the directory where you downloaded **mturoute.exe**.
3. Use the following command to check the path MTU between your EC2 instance and the specified destination. This example checks the path MTU between the EC2 instance and `www.elifulkerson.com`.

```
.\mturoute.exe www.elifulkerson.com
```

In this example output, the path MTU is 1500.

```
* ICMP Fragmentation is not permitted. *
* Speed optimization is enabled. *
* Maximum payload is 10000 bytes. *
+ ICMP payload of 1472 bytes succeeded.
- ICMP payload of 1473 bytes is too big.
Path MTU: 1500 bytes.
```

Check the MTU for your instance

You can check the MTU value for your instance. Some instances are configured to use jumbo frames, and others are configured to use standard frame sizes.

The procedure that you use depends on the operating system of the instance.

Linux instances

To check the MTU setting on a Linux instance

Run the following **ip** command on your EC2 instance. If the primary network interface is not `eth0`, replace `eth0` with your network interface.

```
[ec2-user ~]$ ip link show eth0
```

In this example output, *`mtu 9001`* indicates that the instance uses jumbo frames.

```
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9001 qdisc pfifo_fast state UP mode
 DEFAULT group default qlen 1000
    link/ether 02:90:c0:b7:9e:d1 brd ff:ff:ff:ff:ff:ff
```

Windows instances

The procedure that you use depends on the driver on your instance.

ENA driver

Version 2.1.0 and later

To get the MTU value, use the following **Get-NetAdapterAdvancedProperty** command on your EC2 instance. Use the wildcard (asterisk) to get all Ethernet names. Check the output for the interface name `*JumboPacket`. A value of 9015 indicates that Jumbo frames are enabled. Jumbo frames are disabled by default.

```
Get-NetAdapterAdvancedProperty -Name "Ethernet*"
```

Version 1.5 and earlier

To get the MTU value, use the following **Get-NetAdapterAdvancedProperty** command on your EC2 instance. Check the output for the interface name `MTU`. A value of 9001 indicates that Jumbo frames are enabled. Jumbo frames are disabled by default.

```
Get-NetAdapterAdvancedProperty -Name "Ethernet"
```

Intel SRIOV 82599 driver

To get the MTU value, use the following **Get-NetAdapterAdvancedProperty** command on your EC2 instance. Check the entry for the interface name `*JumboPacket`. A value of 9014 indicates that Jumbo frames are enabled. (Note that the MTU size includes the header and the payload.) Jumbo frames are disabled by default.

```
Get-NetAdapterAdvancedProperty -Name "Ethernet"
```

AWS PV driver

To get the MTU value, use the following command on your EC2 instance. The name of the interface can vary. In the output, look for an entry with the name "Ethernet," "Ethernet 2," or "Local Area Connection". You'll need the interface name to enable or disable jumbo frames. A value of 9001 indicates that Jumbo frames are enabled.

```
netsh interface ipv4 show subinterface
```

Set the MTU for your instance

You might want to use jumbo frames for network traffic within your VPC and standard frames for internet traffic. Whatever your use case, we recommend that you verify that your instance behaves as expected.

The procedure that you use depends on the operating system of the instance.

Linux instances

To set the MTU value on a Linux instance

1. Run the following **ip** command on your instance. It sets the desired MTU value to 1500, but you could use 9001 instead. If the primary network interface is not `eth0`, replace `eth0` with the actual network interface.

   ```
   [ec2-user ~]$ sudo ip link set dev eth0 mtu 1500
   ```

2. (Optional) To persist your network MTU setting after a reboot, modify the following configuration files, based on your operating system type.

   - **Amazon Linux 2023** – Modify the `[Link]` section of the config file. The default config file is `/usr/lib/systemd/network/80-ec2.network`, or you can update any custom config file created in /run/systemd/network/, where the file name is *`priority`*-*`interface`*.network. For more information, see [Networking service](#) in the Amazon Linux documentation.

     ```
     MTUBytes=1500
     ```

   - **Amazon Linux 2** – Add the following line to the `/etc/sysconfig/network-scripts/ifcfg-eth0` file:

     ```
     MTU=1500
     ```

     Add the following line to the `/etc/dhcp/dhclient.conf` file:

     ```
     request subnet-mask, broadcast-address, time-offset, routers, domain-name,
      domain-search, domain-name-servers, host-name, nis-domain, nis-servers, ntp-
     servers;
     ```

   - **Other Linux distributions** – Consult their specific documentation.

3. (Optional) Reboot your instance and verify that the MTU setting is correct.

Windows instances

The procedure that you use depends on the driver on your instance.

ENA driver

You can change the MTU using Device Manager or the **Set-NetAdapterAdvancedProperty** command on your instance.

Version 2.1.0 and later

Use the following command to enable jumbo frames.

```
Set-NetAdapterAdvancedProperty -Name "Ethernet" -RegistryKeyword "*JumboPacket" -
RegistryValue 9015
```

Use the following command to disable jumbo frames.

```
Set-NetAdapterAdvancedProperty -Name "Ethernet" -RegistryKeyword "*JumboPacket" -
RegistryValue 1514
```

Version 1.5 and earlier

Use the following command to enable jumbo frames.

```
Set-NetAdapterAdvancedProperty -Name "Ethernet" -RegistryKeyword "MTU" -
RegistryValue 9001
```

Use the following command to disable jumbo frames.

```
Set-NetAdapterAdvancedProperty -Name "Ethernet" -RegistryKeyword "MTU" -
RegistryValue 1500
```

Intel SRIOV 82599 driver

You can change the MTU using Device Manager or the **Set-NetAdapterAdvancedProperty** command on your instance.

Use the following command to enable jumbo frames.

```
Set-NetAdapterAdvancedProperty -Name "Ethernet" -RegistryKeyword "*JumboPacket" -
RegistryValue 9014
```

Use the following command to disable jumbo frames.

```
Set-NetAdapterAdvancedProperty -Name "Ethernet" -RegistryKeyword "*JumboPacket" -
RegistryValue 1514
```

AWS PV driver

You can change the MTU using the **netsh** command on your instance. You can't change the MTU using Device Manager.

Use the following command to enable jumbo frames.

```
netsh interface ipv4 set subinterface "Ethernet" mtu=9001
```

Use the following command to disable jumbo frames.

```
netsh interface ipv4 set subinterface "Ethernet" mtu=1500
```

Troubleshoot

If you experience connectivity issues between your EC2 instance and an Amazon Redshift cluster when using jumbo frames, see Queries appear to hang and sometimes fail to reach the cluster in the *Amazon Redshift Management Guide*.

Virtual private clouds for your EC2 instances

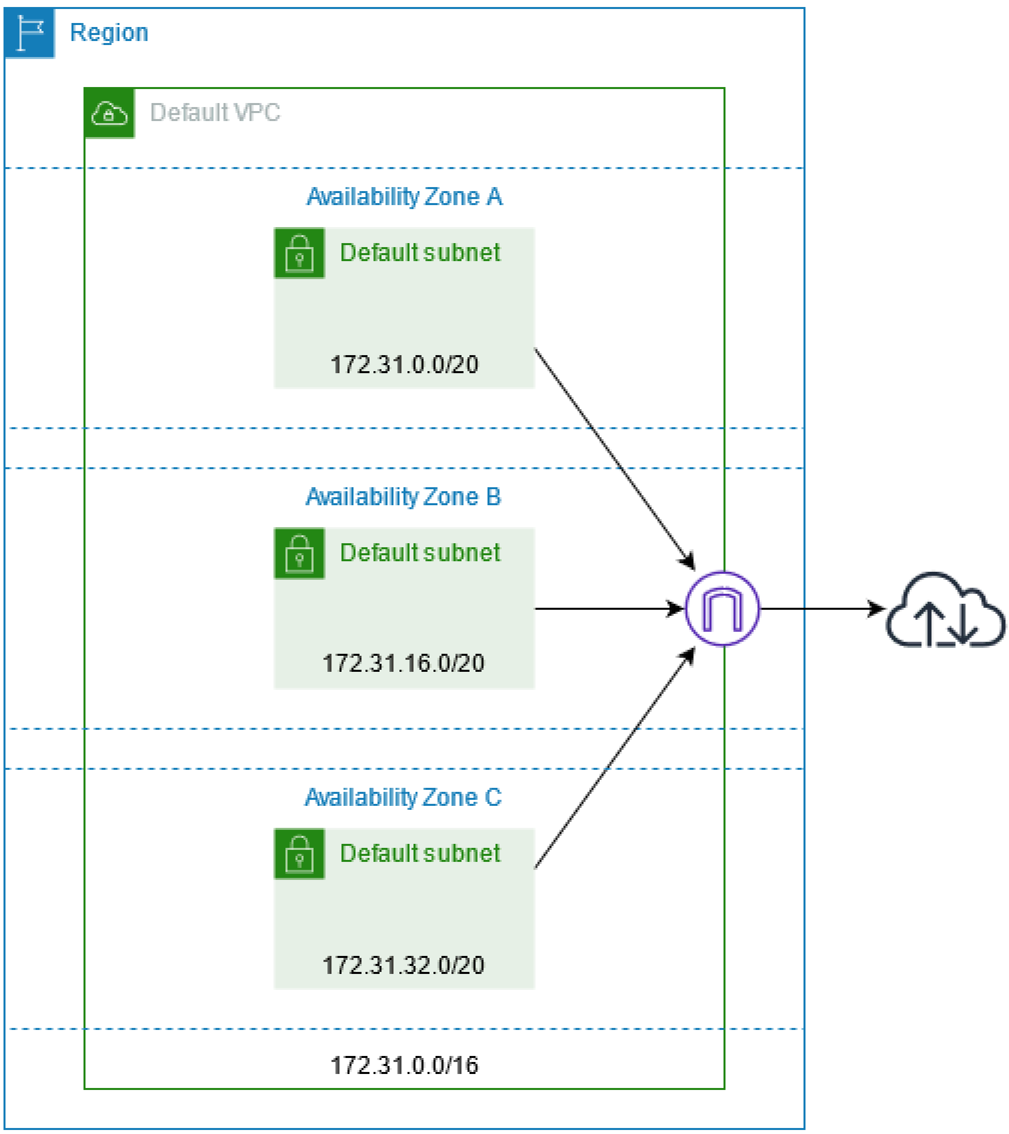
Amazon Virtual Private Cloud (Amazon VPC) enables you to define a virtual network in your own logically isolated area within the AWS cloud, known as a *virtual private cloud* or *VPC*. You can create AWS resources, such as Amazon EC2 instances, into the subnets of your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using scalable infrastructure from AWS. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet or to your own data center.

Contents

- Nondefault VPCs
- Internet access
- Shared subnets
- IPv6-only subnets

Your default VPCs

When you create your AWS account, we create a *default VPC* in each Region. A default VPC is a VPC that is already configured and ready for you to use. For example, there is a default subnet for each Availability Zone in each default VPC, an internet gateway attached to the VPC, and there's a route in the main route table that sends all traffic (0.0.0.0/0) to the internet gateway. You can modify the configuration of your default VPCs as needed. For example, you can add subnets and route tables.



Nondefault VPCs

Instead of using a default VPC for your resources, you can create your own VPC, as described in Create a VPC in the *Amazon VPC User Guide*.

Here are some things to consider when creating a VPC for your EC2 instances.

- You can use the default suggestion for the IPv4 CIDR block or enter the CIDR block required by your application or network.
- To ensure high availability, create subnets in multiple Availability Zones.
- If your instances must be accessible from the internet, do one of the following:
  - If your instances can be in a public subnet, add public subnets. Keep both DNS options enabled. You can optionally add private subnets now or later on.
  - If your instances must be in a private subnet, add only private subnets. You can add a NAT gateway to provide internet access to instances in the private subnets. If your instances send or receive a significant volume of traffic across Availability Zones, create a NAT gateway in each Availability Zone. Otherwise, you can create a NAT gateway in just one of the Availability Zones and launch instances that send or receive cross-zone traffic in the same Availability Zone as the NAT gateway.

Internet access

Instances launched into a default subnet in a default VPC have access to the internet, as default VPCs are configured to assign public IP addresses and DNS hostnames, and the main route table is configured with a route to an internet gateway attached to the VPC.

For instances that you launch in nondefault subnets and VPCs, you can use one of the following options to ensure that the instances that you launch in these subnets have access to the internet:

- Configure an internet gateway. For more information, see Connect to the internet using an internet gateway in the *Amazon VPC User Guide*.
- Configure a public NAT gateway. For more information, see Access the internet from a private subnet in the *Amazon VPC User Guide*.

Shared subnets

When launching EC2 instances into shared VPC subnets, note the following:

- Participants can run instances in a shared subnet by specifying the ID of the shared subnet. Participants must own any network interfaces that they specify.
- Participants can start, stop, terminate, and describe instances that they've created in a shared subnet. Participants can't start, stop, terminate, or describe instances that the VPC owner created in the shared subnet.
- VPC owners can't start, stop, terminate, or describe instances created by participants in a shared subnet.
- Participants can connect to an instance in a shared subnet using EC2 Instance Connect Endpoint. The participant must create the EC2 Instance Connect Endpoint in the shared subnet. Participants can't use an EC2 Instance Connect Endpoint that the VPC owner created in the shared subnet.

For information about shared Amazon EC2 resources, see the following:

- the section called "Manage AMI sharing with an organization or OU"
- the section called "Shared Capacity Reservations"
- the section called "Shared placement groups"
- Cross-account Amazon EC2 Dedicated Host sharing

For more information about shared subnets, see Share your VPC with other accounts in the *Amazon VPC User Guide*.

IPv6-only subnets

An EC2 instance launched in an IPv6-only subnet receives an IPv6 address but not an IPv4 address. Any instances that you launch into an IPv6-only subnet must be Nitro-based instances.

Security in Amazon EC2

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Amazon EC2, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility includes the following areas:
  - Controlling network access to your instances, for example, through configuring your VPC and security groups. For more information, see Controlling network traffic.
  - Managing the credentials used to connect to your instances.
  - Managing the guest operating system and software deployed to the guest operating system, including updates and security patches. For more information, see Update management for Amazon EC2 instances.
  - Configuring the IAM roles that are attached to the instance and the permissions associated with those roles. For more information, see IAM roles for Amazon EC2.

This documentation helps you understand how to apply the shared responsibility model when using Amazon EC2. It shows you how to configure Amazon EC2 to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EC2 resources.

Contents

- Update management for Amazon EC2 instances
- Security best practices for Windows instances
- Amazon EC2 key pairs and Amazon EC2 instances
- Amazon EC2 security groups for your EC2 instances
- NitroTPM for Amazon EC2 instances
- Credential Guard for Windows instances
- Access Amazon EC2 using an interface VPC endpoint

Data protection in Amazon EC2

The AWS shared responsibility model applies to data protection in Amazon Elastic Compute Cloud. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon EC2 or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Contents

Amazon EBS data security

Amazon EBS volumes are presented to you as raw, unformatted block devices. These devices are logical devices that are created on the EBS infrastructure and the Amazon EBS service ensures that the devices are logically empty (that is, the raw blocks are zeroed or they contain cryptographically pseudorandom data) prior to any use or re-use by a customer.

If you have procedures that require that all data be erased using a specific method, either after or before use (or both), such as those detailed in **DoD 5220.22-M** (National Industrial Security Program Operating Manual) or **NIST 800-88** (Guidelines for Media Sanitization), you have the ability to do so on Amazon EBS. That block-level activity will be reflected down to the underlying storage media within the Amazon EBS service.

Encryption at rest

EBS volumes

Amazon EBS encryption is an encryption solution for your EBS volumes and snapshots. It uses AWS KMS keys. For more information, see Amazon EBS encryption in the *Amazon EBS User Guide*.

[Windows instances] You can also use Microsoft EFS and NTFS permissions for folder- and file-level encryption.

Instance store volumes

The data on NVMe instance store volumes is encrypted using an XTS-AES-256 cipher, implemented on a hardware module on the instance. The keys used to encrypt data that's written to locally-attached NVMe storage devices are per-customer, and per volume. The keys are generated by, and only reside within, the hardware module, which is inaccessible to AWS personnel. The encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

The data on HDD instance store volumes on H1, D3, and D3en instances is encrypted using XTS-AES-256 and one-time keys.

When you stop, hibernate, or terminate an instance, every block of storage in the instance store volume is reset. Therefore, your data cannot be accessed through the instance store of another instance.

Memory

Memory encryption is enabled on the following instances:

- Instances with AWS Graviton2 or later AWS Graviton processors support always-on memory encryption. The encryption keys are securely generated within the host system, do not leave the host system, and are destroyed when the host is rebooted or powered down. For more information, see AWS Graviton Processors.
- Instances with 3rd generation Intel Xeon Scalable processors (Ice Lake), such as M6i instances, and 4th generation Intel Xeon Scalable processors (Sapphire Rapids), such as M7i instances. These processors support always-on memory encryption using Intel Total Memory Encryption (TME).
- Instances with 3rd generation AMD EPYC processors (Milan), such as M6a instances, and 4th generation AMD EPYC processors (Genoa), such as M7a instances. These processors support always-on memory encryption using AMD Secure Memory Encryption (SME).
- AMD Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP) is supported for some AMD-based instance types. For more information, see Find EC2 instance types that support AMD SEV-SNP.

Encryption in transit

Encryption at the physical layer

All data flowing across AWS Regions over the AWS global network is automatically encrypted at the physical layer before it leaves AWS secured facilities. All traffic between AZs is encrypted.

Additional layers of encryption, including those listed in this section, may provide additional protections.

Encryption provided by Amazon VPC peering and Transit Gateway cross-Region peering

All cross-Region traffic that uses Amazon VPC peering and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves AWS secured facilities, as previously noted in this section.

Encryption between instances

AWS provides secure and private connectivity between EC2 instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose**: M5dn, M5n, M5zn, M6a, M6i, M6id, M6idn, M6in, M7a, M7g, M7gd, M7i, M7i-flex, M8g, M8gd, M8i, M8i-flex
  - **Compute optimized:** C5n, C6a, C6gn, C6i, C6id, C6in, C7a, C7g, C7gd, C7gn, C7i, C7i-flex, C8g, C8gd, C8gn
  - **Memory optimized:** R5dn, R5n, R6a, R6i, R6idn, R6in, R6id, R7a, R7g, R7gd, R7i, R7iz, R8g, R8gd, R8i, R8i-flex, U-3tb1, U-6tb1, U-9tb1, U-12tb1, U-18tb1, U-24tb1, U7i-6tb, U7i-8tb, U7i-12tb, U7in-16tb, U7in-24tb, U7in-32tb, U7inh-32tb, X2idn, X2iedn, X2iezn, X8g
  - **Storage optimized:** D3, D3en, I3en, I4g, I4i, I7i, I7ie, I8g, I8ge, Im4gn, Is4gen
  - **Accelerated computing:** DL1, DL2q, F2, G4ad, G4dn, G5, G6, G6e, G6f, Gr6, Gr6f, Inf1, Inf2, P3dn, P4d, P4de, P5, P5e, P5en, P6-B200, P6e-GB200, Trn1, Trn1n, Trn2, Trn2u, VT1
  - **High-performance computing:** Hpc6a, Hpc6id, Hpc7a, Hpc7g
- The instances are in the same Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves AWS secured facilities, as previously noted in this section.

To view the instance types that encrypt in-transit traffic between instances using the AWS CLI

Use the following describe-instance-types command.

```
aws ec2 describe-instance-types \
    --filters Name=network-info.encryption-in-transit-supported,Values=true \
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

Encryption to and from AWS Outposts

An Outpost creates special network connections called *service links* to its AWS home Region and, optionally, private connectivity to a VPC subnet that you specify. All traffic over those connection is fully encrypted. For more information, see Connectivity through service links and Encryption in transit in the *AWS Outposts User Guide*.

Remote access encryption

The SSH and RDP protocols provides secure communications channels for remote access to your instances, whether directly or through EC2 Instance Connect. Remote access to your instances using AWS Systems Manager Session Manager or the Run Command is encrypted using TLS 1.2, and requests to create a connection are signed using SigV4, and authenticated and authorized by AWS Identity and Access Management.

It is your responsibility to use an encryption protocol, such as Transport Layer Security (TLS), to encrypt sensitive data in transit between clients and your Amazon EC2 instances.

(Windows instances) Make sure to allow only encrypted connections between EC2 instances and the AWS API endpoints or other sensitive remote network services. You can enforce this through an outbound security group or Windows Firewall rules.

Infrastructure security in Amazon EC2

As a managed service, Amazon Elastic Compute Cloud is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well‐Architected Framework*.

You use AWS published API calls to access Amazon EC2 through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

For more information, see Infrastructure Protection in the *Security Pillar – AWS Well-Architected Framework*.

Network isolation

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the AWS Cloud. Use separate VPCs to isolate infrastructure by workload or organizational entity.

A subnet is a range of IP addresses in a VPC. When you launch an instance, you launch it into a subnet in your VPC. Use subnets to isolate the tiers of your application (for example, web, application, and database) within a single VPC. Use private subnets for your instances if they should not be accessed directly from the internet.

To call the Amazon EC2 API from your VPC using private IP addresses, use AWS PrivateLink. For more information, see Access Amazon EC2 using an interface VPC endpoint.

Isolation on physical hosts

Different EC2 instances on the same physical host are isolated from each other as though they are on separate physical hosts. The hypervisor isolates CPU and memory, and the instances are provided virtualized disks instead of access to the raw disk devices.

When you stop or terminate an instance, the memory allocated to it is scrubbed (set to zero) by the hypervisor before it is allocated to a new instance, and every block of storage is reset. This ensures that your data is not unintentionally exposed to another instance.

Network MAC addresses are dynamically assigned to instances by the AWS network infrastructure. IP addresses are either dynamically assigned to instances by the AWS network infrastructure, or assigned by an EC2 administrator through authenticated API requests. The AWS network allows instances to send traffic only from the MAC and IP addresses assigned to them. Otherwise, the traffic is dropped.

By default, an instance cannot receive traffic that is not specifically addressed to it. If you need to run network address translation (NAT), routing, or firewall services on your instance, you can disable source/destination checking for the network interface.

Controlling network traffic

Consider the following options for controlling network traffic to your EC2 instances:

- Restrict access to your instances using security groups. Configure rules that allow the minimum required network traffic. For example, you can allow traffic only from the address ranges for your corporate network or only for specific protocols, such as HTTPS. For Windows instances, allow Windows management traffic and minimal outbound connections.
- Leverage security groups as the primary mechanism for controlling network access to Amazon EC2 instances. When necessary, use network ACLs sparingly to provide stateless, coarse-grain network control. Security groups are more versatile than network ACLs due to their ability to perform stateful packet filtering and create rules that reference other security groups. However, network ACLs can be effective as a secondary control for denying a specific subset of traffic or providing high-level subnet guard rails. Also, because network ACLs apply to an entire subnet, they can be used as defense-in-depth in case an instance is ever launched unintentionally without a correct security group.
- [Windows instances] Centrally manage Windows Firewall settings with Group Policy Objects (GPO) to further enhance network controls. Customers often use the Windows Firewall for further visibility into network traffic and to complement security group filters, creating advanced rules to block specific applications from accessing the network or to filter traffic from a subset IP addresses. For example, the Windows Firewall can limit access to the EC2 metadata service IP address to specific users or applications. Alternatively, a public-facing service might use security groups to restrict traffic to specific ports and the Windows Firewall to maintain a list of explicitly blocked IP addresses.
- Use private subnets for your instances if they should not be accessed directly from the internet. Use a bastion host or NAT gateway for internet access from an instance in a private subnet.
- [Windows instances] Use secure administration protocols like RDP encapsulation over SSL/TLS. The Remote Desktop Gateway Quick Start provides best practices for deploying remote desktop gateway, including configuring RDP to use SSL/TLS.

- [Windows instances] Use Active Directory or AWS Directory Service to tightly and centrally control and monitor interactive user and group access to Windows instances, and avoid local user permissions. Also avoid using Domain Administrators and instead create more granular, application-specific role-based accounts. Just Enough Administration (JEA) allows changes to Windows instances to be managed without interactive or administrator access. In addition, JEA enables organizations to lock down administrative access to the subset of Windows PowerShell commands required for instance administration. For additional information, see the section on "Managing OS-level Access to Amazon EC2" in the AWS Security Best Practices whitepaper.
- [Windows instances] System Administrators should use Windows accounts with limited access to perform daily activities, and only elevate access when necessary to perform specific configuration changes. Additionally, only access Windows instances directly when absolutely necessary. Instead, leverage central configuration management systems such as EC2 Run Command, Systems Center Configuration Manager (SCCM), Windows PowerShell DSC, or Amazon EC2 Systems Manager (SSM) to push changes to Windows servers.
- Configure Amazon VPC subnet route tables with the minimal required network routes. For example, place only Amazon EC2 instances that require direct Internet access into subnets with routes to an internet gateway, and place only Amazon EC2 instances that need direct access to internal networks into subnets with routes to a virtual private gateway.
- Consider using additional security groups or network interfaces to control and audit Amazon EC2 instance management traffic separately from regular application traffic. This approach allows customers to implement special IAM policies for change control, making it easier to audit changes to security group rules or automated rule-verification scripts. Using multiple network interfaces also provides additional options for controlling network traffic, including the ability to create host-based routing policies or leverage different VPC subnet routing rules based on the assigned subnet of the network interface.
- Use AWS Virtual Private Network or AWS Direct Connect to establish private connections from your remote networks to your VPCs. For more information, see Network-to-Amazon VPC Connectivity Options.
- Use VPC Flow Logs to monitor the traffic that reaches your instances.
- Use GuardDuty Malware Protection to identify suspicious behavior indicative of malicious software on your instances that might compromise your workload, repurpose resources for malicious use, and gain unauthorized access to your data.
- Use GuardDuty Runtime Monitoring to identify and respond to potential threats to your instances. For more information, see How Runtime Monitoring works with Amazon EC2 instances.

- Use AWS Security Hub, Reachability Analyzer, or Network Access Analyzer to check for unintended network accessibility from your instances.
- Use EC2 Instance Connect to connect to your instances using Secure Shell (SSH) without the need to share and manage SSH keys.
- Use AWS Systems Manager Session Manager to access your instances remotely instead of opening inbound SSH or RDP ports and managing key pairs.
- Use AWS Systems Manager Run Command to automate common administrative tasks instead of connecting to your instances.
- [Windows instances] Many of the Windows OS roles and Microsoft business applications also provide enhanced functionality such as IP Address Range restrictions within IIS, TCP/IP filtering policies in Microsoft SQL Server, and connection filter policies in Microsoft Exchange. Network restriction functionality within the application layer can provide additional layers of defense for critical business application servers.

Amazon VPC supports additional network security controls, such as gateways, proxy servers, and network monitoring options. For more information, see Control network traffic in the *Amazon VPC User Guide*.

Resilience in Amazon EC2

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

If you need to replicate your data or applications over greater geographic distances, use AWS Local Zones. An AWS Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Like all AWS Regions, AWS Local Zones are completely isolated from other AWS Zones.

If you need to replicate your data or applications in an AWS Local Zone, AWS recommends that you use one of the following zones as the failover zone:

- Another Local Zone

- An Availability Zone in the Region that is not the parent zone. You can use the describe-availability-zones command to view the parent zone.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon EC2 offers the following features to support your data resiliency:

- Copying AMIs across Regions
- Copying EBS snapshots across Regions
- Automating EBS-backed AMIs using Amazon Data Lifecycle Manager
- Automating EBS snapshots using Amazon Data Lifecycle Manager
- Maintaining the health and availability of your fleet using Amazon EC2 Auto Scaling
- Distributing incoming traffic across multiple instances in a single Availability Zone or multiple Availability Zones using Elastic Load Balancing

Compliance validation for Amazon EC2

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security Compliance & Governance – These solution implementation guides discuss architectural considerations and provide steps for deploying security and compliance features.
- HIPAA Eligible Services Reference – Lists HIPAA eligible services. Not all AWS services are HIPAA eligible.
- AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.

- AWS Customer Compliance Guides – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- Evaluating Resources with Rules in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- Amazon GuardDuty – This AWS service detects potential threats to your AWS accounts, workloads, containers, and data by monitoring your environment for suspicious and malicious activities. GuardDuty can help you address various compliance requirements, like PCI DSS, by meeting intrusion detection requirements mandated by certain compliance frameworks.
- AWS Audit Manager – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Identity and access management for Amazon EC2

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon EC2 resources. IAM is an AWS service that you can use with no additional charge.

Your security credentials identify you to services in AWS and grant you access to AWS resources, such as your Amazon EC2 resources. You can use features of Amazon EC2 and IAM to allow other users, services, and applications to use your Amazon EC2 resources without sharing your security credentials. You can use IAM to control how other users use resources in your AWS account, and you can use security groups to control access to your Amazon EC2 instances. You can choose to allow full or limited use of your Amazon EC2 resources.

If you are a developer, you can use IAM roles to manage the security credentials needed by the applications that you run on your EC2 instances. After you attach an IAM role to your instance, your applications running on the instance can retrieve the credentials from the Instance Metadata Service (IMDS).

For best practices for securing your AWS resources using IAM, see Security best practices in IAM in the *IAM User Guide*.

Contents

Identity-based policies for Amazon EC2

By default, users don't have permission to create or modify Amazon EC2 resources, or perform tasks using the Amazon EC2 API, Amazon EC2 console, or CLI. To allow users to create or modify resources and perform tasks, you must create IAM policies that grant users permission to use the specific resources and API actions they'll need, and then attach those policies to the users, groups, or IAM roles that require those permissions.

When you attach a policy to a user, group of users, or role it allows or denies the users permission to perform the specified tasks on the specified resources. For more general information about IAM policies, see Policies and permissions in IAM in the *IAM User Guide*. For more information about managing and creating IAM policies, see Manage IAM policies.

An IAM policy must grant or deny permissions to use one or more Amazon EC2 actions. It must also specify the resources that can be used with the action, which can be all resources, or in some cases, specific resources. The policy can also include conditions that you apply to the resource.

To get started, you can check whether the AWS managed policies for Amazon EC2 meet your needs. Otherwise, you can create your own custom policies. For more information, see the section called “AWS managed policies”.

Contents

- Actions for Amazon EC2
- Supported resource-level permissions for Amazon EC2 API actions
- Amazon Resource Names (ARNs) for Amazon EC2
- Condition keys for Amazon EC2
- Control access using attribute-based access
- Grant permissions to users, groups, and roles
- Check that users have the required permissions

Policy syntax

An IAM policy is a JSON document that consists of one or more statements. Each statement is structured as follows.

```
{
  "Statement":[{
    "Effect":"effect",
    "Action":"action",
    "Resource":"arn",
    "Condition":{
      "condition":{
        "key":"value"
        }
      }
    }
  ]
}
```

There are various elements that make up a statement:

- **Effect:** The *effect* can be `Allow` or `Deny`. By default, users don't have permission to use resources and API actions, so all requests are denied. An explicit allow overrides the default. An explicit deny overrides any allows.
- **Action**: The *action* is the specific API action for which you are granting or denying permission. To learn about specifying *action*, see Actions for Amazon EC2.
- **Resource**: The resource that's affected by the action. Some Amazon EC2 API actions allow you to include specific resources in your policy that can be created or modified by the action. You specify a resource using an Amazon Resource Name (ARN) or using the wildcard (*) to indicate

that the statement applies to all resources. For more information, see Supported resource-level permissions for Amazon EC2 API actions.

- **Condition**: Conditions are optional. They can be used to control when your policy is in effect. For more information about specifying conditions for Amazon EC2, see Condition keys for Amazon EC2.

For more information about policy requirements, see the IAM JSON policy reference in the *IAM User Guide*. For example IAM policy statements for Amazon EC2, see Example policies to control access the Amazon EC2 API.

Actions for Amazon EC2

In an IAM policy statement, you can specify any API action from any service that supports IAM. For Amazon EC2, use the following prefix with the name of the API action: `ec2:`. For example: `ec2:RunInstances` and `ec2:CreateImage`.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["ec2:action1", "ec2:action2"]
```

You can also specify multiple actions using wildcards. For example, you can specify all actions whose name begins with the word "Describe" as follows:

```
"Action": "ec2:Describe*"
```

Note

Currently, the Amazon EC2 Describe* API actions do not support resource-level permissions. For more information about resource-level permissions for Amazon EC2, see Identity-based policies for Amazon EC2.

To specify all Amazon EC2 API actions, use the * wildcard as follows:

```
"Action": "ec2:*"
```

For a list of Amazon EC2 actions, see Actions defined by Amazon EC2 in the *Service Authorization Reference*.

Supported resource-level permissions for Amazon EC2 API actions

Resource-level permissions refers to the ability to specify which resources users are allowed to perform actions on. Amazon EC2 has partial support for resource-level permissions. This means that for certain Amazon EC2 actions, you can control when users are allowed to use those actions based on conditions that have to be fulfilled, or specific resources that users are allowed to use. For example, you can grant users permissions to launch instances, but only of a specific type, and only using a specific AMI.

To specify a resource in an IAM policy statement, use its Amazon Resource Name (ARN). For more information about specifying the ARN value, see [Amazon Resource Names (ARNs) for Amazon EC2](). If an API action does not support individual ARNs, you must use a wildcard (*) to specify that all resources can be affected by the action.

To see tables that identify which Amazon EC2 API actions support resource-level permissions, and the ARNs and condition keys that you can use in a policy, see [Actions, resources, and condition keys for Amazon EC2]().

Keep in mind that you can apply tag-based resource-level permissions in the IAM policies you use for Amazon EC2 API actions. This gives you better control over which resources a user can create, modify, or use. For more information, see [Grant permission to tag Amazon EC2 resources during creation]().

Amazon Resource Names (ARNs) for Amazon EC2

Each IAM policy statement applies to the resources that you specify using their ARNs.

An ARN has the following general syntax:

```
arn:aws:[service]:[region]:[account-id]:resourceType/resourcePath
```

service

The service (for example, `ec2`).

region

The Region for the resource (for example, `us-east-1`).

account-id

The AWS account ID, with no hyphens (for example, `123456789012`).

resourceType

The type of resource (for example, `instance`).

resourcePath

A path that identifies the resource. You can use the * wildcard in your paths.

For example, you can indicate a specific instance (`i-1234567890abcdef0`) in your statement using its ARN as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"
```

You can specify all instances that belong to a specific account by using the * wildcard as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*"
```

You can also specify all Amazon EC2 resources that belong to a specific account by using the * wildcard as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:*"
```

To specify all resources, or if a specific API action does not support ARNs, use the * wildcard in the `Resource` element as follows.

```
"Resource": "*"
```

Many Amazon EC2 API actions involve multiple resources. For example, `AttachVolume` attaches an Amazon EBS volume to an instance, so a user must have permissions to use the volume and the instance. To specify multiple resources in a single statement, separate their ARNs with commas, as follows.

```
"Resource": ["arn1", "arn2"]
```

For a list of ARNs for Amazon EC2 resources, see [Resource types defined by Amazon EC2](#).

Condition keys for Amazon EC2

In a policy statement, you can optionally specify conditions that control when it is in effect. Each condition contains one or more key-value pairs. Condition keys are not case-sensitive. We've defined AWS global condition keys, plus additional service-specific condition keys.

For a list of service-specific condition keys for Amazon EC2, see Condition keys for Amazon EC2. Amazon EC2 also implements the AWS global condition keys. For more information, see Information available in all requests in the *IAM User Guide*.

All Amazon EC2 actions support the `aws:RequestedRegion` and `ec2:Region` condition keys. For more information, see Example: Restrict access to a specific Region.

To use a condition key in your IAM policy, use the `Condition` statement. For example, the following policy grants users permission to add and remove inbound and outbound rules for any security group. It uses the `ec2:Vpc` condition key to specify that these actions can only be performed on security groups in a specific VPC.

JSON

```
{
"Version": "2012-10-17",
  "Statement":[{
    "Effect":"Allow",
    "Action": [
       "ec2:AuthorizeSecurityGroupIngress",
       "ec2:AuthorizeSecurityGroupEgress",
       "ec2:RevokeSecurityGroupIngress",
       "ec2:RevokeSecurityGroupEgress"],
     "Resource": "arn:aws:ec2:us-east-1:111122223333:security-group/*",
      "Condition": {
        "StringEquals": {
          "ec2:Vpc": "arn:aws:ec2:us-east-1:111122223333:vpc/
vpc-11223344556677889"
        }
      }
    }
  ]
}
```

If you specify multiple conditions, or multiple keys in a single condition, we evaluate them using a logical AND operation. If you specify a single condition with multiple values for one key, we evaluate the condition using a logical OR operation. For permissions to be granted, all conditions must be met.

You can also use placeholders when you specify conditions. For more information, see IAM policy elements: Variables and tags in the *IAM User Guide*.

> **Important**
>
> Many condition keys are specific to a resource, and some API actions use multiple resources. If you write a policy with a condition key, use the `Resource` element of the statement to specify the resource to which the condition key applies. If not, the policy may prevent users from performing the action at all, because the condition check fails for the resources to which the condition key does not apply. If you do not want to specify a resource, or if you've written the `Action` element of your policy to include multiple API actions, then you must use the `...IfExists` condition type to ensure that the condition key is ignored for resources that do not use it. For more information, see ...IfExists Conditions in the *IAM User Guide*.

Condition keys

- ec2:Attribute condition key
- ec2:ResourceID condition keys
- ec2:SourceInstanceARN condition key

ec2:Attribute condition key

The `ec2:Attribute` condition key can be used for conditions that filter access by an attribute of a resource.

This condition key supports only properties that are of a primitive data type (such as strings or integers), or complex **AttributeValue** objects that contain only a **Value** property (such as the **Description** or **ImdsSupport** objects of the ModifyImageAttribute API action). The condition key can't be used with complex objects that contain multiple properties, such as the **LaunchPermission** object of ModifyImageAttribute.

For example, the following policy uses the `ec2:Attribute/Description` condition key to filter access by the complex **Description** object of the **ModifyImageAttribute** API action. The condition key allows only requests that modify an image's description to either `Production` or `Development`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:ModifyImageAttribute",
      "Resource": "arn:aws:ec2:us-east-1::image/ami-*",
      "Condition": {
        "StringEquals": {
          "ec2:Attribute/Description": [
            "Production",
            "Development"
          ]
        }
      }
    }
  ]
}
```

The following example policy uses the `ec2:Attribute` condition key to filter access by the primitive **Attribute** property of the **ModifyImageAttribute** API action. The condition key denies all requests that attempt to modify an image's description.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:ModifyImageAttribute",
      "Resource": "arn:aws:ec2:us-east-1::image/ami-*",
```

```
        "Condition": {
          "StringEquals": {
            "ec2:Attribute": "Description"
          }
        }
      }
    ]
}
```

ec2:ResourceID condition keys

When using the following `ec2:`*`Resource`*`ID` condition keys with the specified API actions, the condition key value is used to specify the resulting resource that is created by the API action. `ec2:`*`Resource`*`ID` condition keys can't be used to specify a source resource that is specified in the API request. If you use one of the following `ec2:`*`Resource`*`ID` condition keys with a specified API, then you must always specify the wildcard (`*`). If you specify a different value, the condition always resolves to `*` during runtime. For example, to use the `ec2:ImageId` condition key with the **CopyImage** API, then you must specify the condition key as follows:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CopyImage",
      "Resource": "arn:aws:ec2:us-east-1::image/ami-*",
      "Condition": {
        "StringEquals": {
          "ec2:ImageID": "*"
        }
      }
    }
  ]
}
```

We recommend that you avoid using these condition keys with these API actions:

- `ec2:DhcpOptionsID` – `CreateDhcpOptions`
- `ec2:ImageID` – `CopyImage`, `CreateImage`, `ImportImage`, and `RegisterImage`
- `ec2:InstanceID` – `RunInstances` and `ImportInstance`
- `ec2:InternetGatewayID` – `CreateInternetGateway`
- `ec2:NetworkAclID` – `CreateNetworkAcl`
- `ec2:NetworkInterfaceID` – `CreateNetworkInterface`
- `ec2:PlacementGroupName` – `CreatePlacementGroup`
- `ec2:RouteTableID` – `CreateRouteTable`
- `ec2:SecurityGroupID` – `CreateSecurityGroup`
- `ec2:SnapshotID` – `CopySnapshot`, `CreateSnapshot`, `CreateSnapshots`, and `ImportSnapshots`
- `ec2:SubnetID` – `CreateSubnet`
- `ec2:VolumeID` – `CreateVolume` and `ImportVolume`
- `ec2:VpcID` – `CreateVpc`
- `ec2:VpcPeeringConnectionID` – `CreateVpcPeeringConnection`

To filter access based on specific resource IDs, we recommend that you use the `Resource` policy element as follows.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CopyImage",
      "Resource": "arn:aws:ec2:us-east-1::image/ami-01234567890abcdef"
    }
  ]
}
```

ec2:SourceInstanceARN condition key

Use `ec2:SourceInstanceARN` to specify the ARN of the instance from which a request is made. This is an AWS global condition key, which means that you can use it with services other than Amazon EC2. For a policy example, see Example: Allow a specific instance to view resources in other AWS services.

Control access using attribute-based access

When you create an IAM policy that grants users permission to use EC2 resources, you can include tag information in the `Condition` element of the policy to control access based on tags. This is known as attribute-based access control (ABAC). ABAC provides better control over which resources a user can modify, use, or delete. For more information, see What is ABAC for AWS?

For example, you can create a policy that allows users to terminate an instance, but denies the action if the instance has the tag `environment=production`. To do this, you use the `aws:ResourceTag` condition key to allow or deny access to the resource based on the tags that are attached to the resource.

```
"StringEquals": { "aws:ResourceTag/environment": "production" }
```

To learn whether an Amazon EC2 API action supports controlling access using the `aws:ResourceTag` condition key, see Actions, resources, and condition keys for Amazon EC2. Note that the `Describe` actions do not support resource-level permissions, so you must specify them in a separate statement without conditions.

For example IAM policies, see Example policies to control access the Amazon EC2 API.

If you allow or deny users access to resources based on tags, you must consider explicitly denying users the ability to add those tags to or remove them from the same resources. Otherwise, it's possible for a user to circumvent your restrictions and gain access to a resource by modifying its tags.

Grant permissions to users, groups, and roles

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Check that users have the required permissions

After you've created an IAM policy, we recommend that you check whether it grants users the permissions to use the particular API actions and resources they need before you put the policy into production.

First, create a user for testing purposes, and then attach the IAM policy that you created to the test user. Then, make a request as the test user.

If the Amazon EC2 action that you are testing creates or modifies a resource, you should make the request using the `DryRun` parameter (or run the AWS CLI command with the `--dry-run` option). In this case, the call completes the authorization check, but does not complete the operation. For example, you can check whether the user can terminate a particular instance without actually terminating it. If the test user has the required permissions, the request returns `DryRunOperation`; otherwise, it returns `UnauthorizedOperation`.

If the policy doesn't grant the user the permissions that you expected, or is overly permissive, you can adjust the policy as needed and retest until you get the desired results.

> **Important**
>
> It can take several minutes for policy changes to propagate before they take effect. Therefore, we recommend that you allow five minutes to pass before you test your policy updates.

If an authorization check fails, the request returns an encoded message with diagnostic information. You can decode the message using the `DecodeAuthorizationMessage` action.

For more information, see DecodeAuthorizationMessage in the *AWS Security Token Service API Reference*, and decode-authorization-message.

Example policies to control access the Amazon EC2 API

You can use IAM policies to grant users the permissions required to work with Amazon EC2. For step-by-step directions, see Creating IAM policies in the *IAM User Guide*.

The following examples show policy statements that you could use to grant users permissions to use Amazon EC2. These policies are designed for requests that are made using the AWS CLI or an AWS SDK. In the following examples, replace each *`user input placeholder`* with your own information.

Examples

- Example: Read-only access
- Example: Restrict access to a specific Region
- Work with instances
- Launch instances (RunInstances)
- Work with Spot Instances
- Example: Work with Reserved Instances
- Example: Tag resources
- Example: Work with IAM roles
- Example: Work with route tables
- Example: Allow a specific instance to view resources in other AWS services
- Example: Work with launch templates
- Work with instance metadata
- Work with Amazon EBS volumes and snapshots

For example policies for working in the Amazon EC2 console, see Example policies to control access to the Amazon EC2 console.

Example: Read-only access

The following policy grants users permissions to use all Amazon EC2 API actions whose names begin with `Describe`. The `Resource` element uses a wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see [Actions, resources, and condition keys for Amazon EC2](#).

Users don't have permission to perform any actions on the resources (unless another statement grants them permission to do so) because they're denied permission to use API actions by default.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:Describe*",
      "Resource": "*"
    }
   ]
}
```

Example: Restrict access to a specific Region

The following policy denies users permission to use all Amazon EC2 API actions unless the Region is Europe (Frankfurt). It uses the global condition key `aws:RequestedRegion`, which is supported by all Amazon EC2 API actions.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
       {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:RequestedRegion": "eu-central-1"
        }
      }
    }
```

```
  ]
}
```

Alternatively, you can use the condition key `ec2:Region`, which is specific to Amazon EC2 and is supported by all Amazon EC2 API actions.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
       {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "ec2:Region": "eu-central-1"
        }
      }
    }
  ]
}
```

Work with instances

Examples

- Example: Describe, launch, stop, start, and terminate all instances
- Example: Describe all instances, and stop, start, and terminate only particular instances

Example: Describe, launch, stop, start, and terminate all instances

The following policy grants users permissions to use the API actions specified in the `Action` element. The `Resource` element uses a * wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The users don't have permission to use any other API actions (unless another statement grants them permission to do so) because users are denied permission to use API actions by default.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeImages",
        "ec2:DescribeKeyPairs",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeAvailabilityZones",
        "ec2:RunInstances",
        "ec2:TerminateInstances",
        "ec2:StopInstances",
        "ec2:StartInstances"
      ],
      "Resource": "*"
    }
   ]
}
```

Example: Describe all instances, and stop, start, and terminate only particular instances

The following policy allows users to describe all instances, to start and stop only instances i-1234567890abcdef0 and i-0598c7d356eba48d7, and to terminate only instances in the `us-east-1` Region, with the resource tag "`purpose=test`".

The first statement uses a * wildcard for the `Resource` element to indicate that users can specify all resources with the action; in this case, they can list all instances. The * wildcard is also necessary in cases where the API action does not support resource-level permissions (in this case, `ec2:DescribeInstances`). For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The second statement uses resource-level permissions for the `StopInstances` and `StartInstances` actions. The specific instances are indicated by their ARNs in the `Resource` element.

The third statement allows users to terminate all instances in the `us-east-1` Region that belong to the specified AWS account, but only where the instance has the tag `"purpose=test"`. The `Condition` element qualifies when the policy statement is in effect.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
      "Action": "ec2:DescribeInstances",
      "Resource": "*"
   },
   {
      "Effect": "Allow",
      "Action": [
        "ec2:StopInstances",
        "ec2:StartInstances"
      ],
      "Resource": [
        "arn:aws:ec2:us-east-1:111122223333:instance/i-1234567890abcdef0",
        "arn:aws:ec2:us-east-1:111122223333:instance/i-0598c7d356eba48d7"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "ec2:TerminateInstances",
      "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
      "Condition": {
         "StringEquals": {
            "aws:ResourceTag/purpose": "test"
         }
      }
   }

   ]
}
```

Launch instances (RunInstances)

The RunInstances API action launches one or more On-Demand Instances or one or more Spot Instances. `RunInstances` requires an AMI and creates an instance. Users can specify a key pair and security group in the request. Launching into a VPC requires a subnet, and creates a network interface. Launching from an Amazon EBS-backed AMI creates a volume. Therefore, the user must have permissions to use these Amazon EC2 resources. You can create a policy statement that requires users to specify an optional parameter on `RunInstances`, or restricts users to particular values for a parameter.

For more information about the resource-level permissions that are required to launch an instance, see Actions, resources, and condition keys for Amazon EC2.

By default, users don't have permissions to describe, start, stop, or terminate the resulting instances. One way to grant the users permission to manage the resulting instances is to create a specific tag for each instance, and then create a statement that enables them to manage instances with that tag. For more information, see Work with instances.

Resources

- AMIs
- Instance types
- Subnets
- EBS volumes
- Tags
- Tags in a launch template
- Elastic GPUs
- Launch templates

AMIs

The following policy allows users to launch instances using only the specified AMIs, `ami-9e1670f7` and `ami-45cf5c3c`. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:us-east-1::image/ami-9e1670f7",
        "arn:aws:ec2:us-east-1::image/ami-45cf5c3c",
        "arn:aws:ec2:us-east-1:111122223333:instance/*",
        "arn:aws:ec2:us-east-1:111122223333:volume/*",
        "arn:aws:ec2:us-east-1:111122223333:key-pair/*",
        "arn:aws:ec2:us-east-1:111122223333:security-group/*",
        "arn:aws:ec2:us-east-1:111122223333:subnet/*",
        "arn:aws:ec2:us-east-1:111122223333:network-interface/*"
      ]
    }
   ]
}
```

Alternatively, the following policy allows users to launch instances from all AMIs owned by Amazon, or certain trusted and verified partners. The `Condition` element of the first statement tests whether `ec2:Owner` is `amazon`. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
         {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws:ec2:us-east-1::image/ami-*"
      ],
      "Condition": {
         "StringEquals": {
```

```
                "ec2:Owner": "amazon"
            }
        }
    },
    {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2:us-east-1:111122223333:instance/*",
            "arn:aws:ec2:us-east-1:111122223333:subnet/*",
            "arn:aws:ec2:us-east-1:111122223333:volume/*",
            "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
            "arn:aws:ec2:us-east-1:111122223333:key-pair/*",
            "arn:aws:ec2:us-east-1:111122223333:security-group/*"
            ]
        }
    ]
}
```

Instance types

The following policy allows users to launch instances using only the `t2.micro` or `t2.small` instance type, which you might do to control costs. The users can't launch larger instances because the `Condition` element of the first statement tests whether `ec2:InstanceType` is either `t2.micro` or `t2.small`.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws:ec2:us-east-1:111122223333:instance/*"
      ],
      "Condition": {
         "StringEquals": {
            "ec2:InstanceType": ["t2.micro", "t2.small"]
         }
```

```
        }
    },
    {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2:us-east-1::image/ami-*",
            "arn:aws:ec2:us-east-1:111122223333:subnet/*",
            "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
            "arn:aws:ec2:us-east-1:111122223333:volume/*",
            "arn:aws:ec2:us-east-1:111122223333:key-pair/*",
            "arn:aws:ec2:us-east-1:111122223333:security-group/*"
            ]
        }
    ]
}
```

Alternatively, you can create a policy that denies users permissions to launch any instances except `t2.micro` and `t2.small` instance types.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
        "Effect": "Deny",
        "Action": "ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2:us-east-1:111122223333:instance/*"
        ],
        "Condition": {
            "StringNotEquals": {
                "ec2:InstanceType": ["t2.micro", "t2.small"]
            }
        }
    },
    {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
```

```
            "arn:aws:ec2:us-east-1::image/ami-*",
            "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
            "arn:aws:ec2:us-east-1:111122223333:instance/*",
            "arn:aws:ec2:us-east-1:111122223333:subnet/*",
            "arn:aws:ec2:us-east-1:111122223333:volume/*",
            "arn:aws:ec2:us-east-1:111122223333:key-pair/*",
            "arn:aws:ec2:us-east-1:111122223333:security-group/*"
            ]
        }
    ]
}
```

Subnets

The following policy allows users to launch instances using only the specified subnet, `subnet-12345678`. The group can't launch instances into any another subnet (unless another statement grants the users permission to do so).

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:us-east-1:111122223333:subnet/subnet-12345678",
        "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
        "arn:aws:ec2:us-east-1:111122223333:instance/*",
        "arn:aws:ec2:us-east-1:111122223333:volume/*",
        "arn:aws:ec2:us-east-1::image/ami-*",
        "arn:aws:ec2:us-east-1:111122223333:key-pair/*",
        "arn:aws:ec2:us-east-1:111122223333:security-group/*"
      ]
    }
   ]
}
```

Alternatively, you could create a policy that denies users permissions to launch an instance into any other subnet. The statement does this by denying permission to create a network interface, except where subnet `subnet-12345678` is specified. This denial overrides any other policies that are created to allow launching instances into other subnets.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
         {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws:ec2:us-east-1:111122223333:network-interface/*"
      ],
      "Condition": {
         "ArnNotEquals": {
            "ec2:Subnet": "arn:aws:ec2:us-east-1:111122223333:subnet/
subnet-12345678"
         }
      }
   },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
         "arn:aws:ec2:us-east-1::image/ami-*",
         "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
         "arn:aws:ec2:us-east-1:111122223333:instance/*",
         "arn:aws:ec2:us-east-1:111122223333:subnet/*",
         "arn:aws:ec2:us-east-1:111122223333:volume/*",
         "arn:aws:ec2:us-east-1:111122223333:key-pair/*",
         "arn:aws:ec2:us-east-1:111122223333:security-group/*"
         ]
      }
   ]
}
```

EBS volumes

The following policy allows users to launch instances only if the EBS volumes for the instance are encrypted. The user must launch an instance from an AMI that was created with encrypted snapshots, to ensure that the root volume is encrypted. Any additional volume that the user attaches to the instance during launch must also be encrypted.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
                {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2:*:*:volume/*"
            ],
            "Condition": {
                "Bool": {
                    "ec2:Encrypted": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2:*::image/ami-*",
                "arn:aws:ec2:*:*:network-interface/*",
                "arn:aws:ec2:*:*:instance/*",
                "arn:aws:ec2:*:*:subnet/*",
                "arn:aws:ec2:*:*:key-pair/*",
                "arn:aws:ec2:*:*:security-group/*"
            ]
        }
    ]
}
```

Tags

Tag instances on creation

The following policy allows users to launch instances and tag the instances during creation. For resource-creating actions that apply tags, users must have permissions to use the `CreateTags` action. The second statement uses the `ec2:CreateAction` condition key to allow users to create tags only in the context of `RunInstances`, and only for instances. Users cannot tag existing resources, and users cannot tag volumes using the `RunInstances` request.

For more information, see Grant permission to tag Amazon EC2 resources during creation.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
      "Condition": {
         "StringEquals": {
             "ec2:CreateAction" : "RunInstances"
          }
       }
    }
  ]
}
```

Tag instances and volumes on creation with specific tags

The following policy includes the `aws:RequestTag` condition key that requires users to tag any instances and volumes that are created by `RunInstances` with the tags `environment=production` and `purpose=webserver`. If users don't pass these specific tags, or if they don't specify tags at all, the request fails.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": [
         "arn:aws:ec2:us-east-1::image/*",
         "arn:aws:ec2:us-east-1:111122223333:subnet/*",
         "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
         "arn:aws:ec2:us-east-1:111122223333:security-group/*",
         "arn:aws:ec2:us-east-1:111122223333:key-pair/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": [
          "arn:aws:ec2:us-east-1:111122223333:volume/*",
          "arn:aws:ec2:us-east-1:111122223333:instance/*"
      ],
      "Condition": {
         "StringEquals": {
             "aws:RequestTag/environment": "production" ,
             "aws:RequestTag/purpose": "webserver"
          }
       }
    },
    {
      "Effect": "Allow",
      "Action": [
```

```
            "ec2:CreateTags"
         ],
         "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
         "Condition": {
            "StringEquals": {
                "ec2:CreateAction" : "RunInstances"
             }
          }
      }
    ]
}
```

Tag instances and volumes on creation with at least one specific tag

The following policy uses the `ForAnyValue` modifier on the `aws:TagKeys` condition to indicate that at least one tag must be specified in the request, and it must contain the key `environment` or `webserver`. The tag must be applied to both instances and volumes. Any tag values can be specified in the request.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": [
         "arn:aws:ec2:us-east-1::image/*",
         "arn:aws:ec2:us-east-1:111122223333:subnet/*",
         "arn:aws:ec2:us-east-1:111122223333:network-interface/*",
         "arn:aws:ec2:us-east-1:111122223333:security-group/*",
         "arn:aws:ec2:us-east-1:111122223333:key-pair/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
          "ec2:RunInstances"
```

```
        ],
        "Resource": [
            "arn:aws:ec2:us-east-1:111122223333:volume/*",
            "arn:aws:ec2:us-east-1:111122223333:instance/*"
        ],
        "Condition": {
            "ForAnyValue:StringEquals": {
                "aws:TagKeys": ["environment","webserver"]
            }
         }
      },
      {
        "Effect": "Allow",
        "Action": [
            "ec2:CreateTags"
        ],
        "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
        "Condition": {
            "StringEquals": {
                "ec2:CreateAction" : "RunInstances"
            }
         }
      }
    ]
}
```

If instances are tagged on creation, they must be tagged with a specific tag

In the following policy, users do not have to specify tags in the request, but if they do, the tag must be `purpose=test`. No other tags are allowed. Users can apply the tags to any taggable resource in the `RunInstances` request.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
```

```
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
      "Condition": {
         "StringEquals": {
             "aws:RequestTag/purpose": "test",
             "ec2:CreateAction" : "RunInstances"
          },
          "ForAllValues:StringEquals": {
              "aws:TagKeys": "purpose"
          }
       }
    }
  ]
}
```

To disallow anyone called tag on create for RunInstances

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
```

```
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*",
                "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Only allow specific tags for spot-instances-request. Surprise inconsistency number 2 comes into play here. Under normal circumstances, specifying no tags will result in Unauthenticated. In the case of spot-instances-request, this policy will not be evaluated if there are no spot-instances-request tags, so a non-tag Spot on Run request will succeed.

Tags in a launch template

In the following example, users can launch instances, but only if they use a specific launch template (`lt-09477bcd97b0d310e`). The `ec2:IsLaunchTemplateResource` condition key prevents users from overriding any of the resources specified in the launch template. The second part of the statement allows users to tag instances on creation—this part of the statement is necessary if tags are specified for the instance in the launch template.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws:ec2:us-east-1:111122223333:launch-
template/lt-09477bcd97b0d310e"
          },
          "Bool": {
```

```
                "ec2:IsLaunchTemplateResource": "true"
             }
          }
       },
       {
         "Effect": "Allow",
         "Action": [
            "ec2:CreateTags"
         ],
         "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
         "Condition": {
            "StringEquals": {
                "ec2:CreateAction" : "RunInstances"
             }
          }
       }
    ]
}
```

Elastic GPUs

In the following policy, users can launch an instance and specify an elastic GPU to attach to the instance. Users can launch instances in any Region, but they can only attach an elastic GPU during a launch in the `us-east-2` Region.

The `ec2:ElasticGpuType` condition key ensures that instances use either the `eg1.medium` or `eg1.large` elastic GPU type.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
             {
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:*:111122223333:elastic-gpu/*"
            ],
```

```
            "Condition": {
                "StringEquals": {
                    "ec2:Region": "us-east-2",
                    "ec2:ElasticGpuType": [
                        "eg1.medium",
                        "eg1.large"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2:*::image/ami-*",
                "arn:aws:ec2:*:111122223333:network-interface/*",
                "arn:aws:ec2:*:111122223333:instance/*",
                "arn:aws:ec2:*:111122223333:subnet/*",
                "arn:aws:ec2:*:111122223333:volume/*",
                "arn:aws:ec2:*:111122223333:key-pair/*",
                "arn:aws:ec2:*:111122223333:security-group/*"
            ]
        }
    ]
}
```

Launch templates

In the following example, users can launch instances, but only if they use a specific launch template (`lt-09477bcd97b0d310e`). Users can override any parameters in the launch template by specifying the parameters in the `RunInstances` action.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
         {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
```

```
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws:ec2:us-east-1:111122223333:launch-
template/lt-09477bcd97b0d310e"
          }
       }
    }
  ]
}
```

In this example, users can launch instances only if they use a launch template. The policy uses the `ec2:IsLaunchTemplateResource` condition key to prevent users from overriding any pre-existing ARNs in the launch template.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
         {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws:ec2:us-east-1:111122223333:launch-
template/*"
          },
          "Bool": {
             "ec2:IsLaunchTemplateResource": "true"
          }
       }
    }
  ]
}
```

The following example policy allows user to launch instances, but only if they use a launch template. Users cannot override the subnet and network interface parameters in the request; these parameters can only be specified in the launch template. The first part of the statement uses the

NotResource element to allow all other resources except subnets and network interfaces. The second part of the statement allows the subnet and network interface resources, but only if they are sourced from the launch template.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "NotResource": ["arn:aws:ec2:us-east-1:111122223333:subnet/*",
                      "arn:aws:ec2:us-east-1:111122223333:network-interface/*" ],
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws:ec2:us-east-1:111122223333:launch-
template/*"
          }
       }
    },
   {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": ["arn:aws:ec2:us-east-1:111122223333:subnet/*",
                   "arn:aws:ec2:us-east-1:111122223333:network-interface/*" ],
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws:ec2:us-east-1:111122223333:launch-
template/*"
          },
          "Bool": {
             "ec2:IsLaunchTemplateResource": "true"
          }
       }
    }
  ]
}
```

The following example allows users to launch instances only if they use a launch template, and only if the launch template has the tag `Purpose=Webservers`. Users cannot override any of the launch template parameters in the `RunInstances` action.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
        {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "NotResource": "arn:aws:ec2:us-east-1:111122223333:launch-template/*",
      "Condition": {
         "ArnLike": {
             "ec2:LaunchTemplate": "arn:aws:ec2:us-east-1:111122223333:launch-
template/*"
          },
         "Bool": {
             "ec2:IsLaunchTemplateResource": "true"
          }
       }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "arn:aws:ec2:us-east-1:111122223333:launch-template/*",
      "Condition": {
       "StringEquals": {
           "aws:ResourceTag/Purpose": "Webservers"
        }
       }
     }
  ]
}
```

Work with Spot Instances

You can use the RunInstances action to create Spot Instance requests, and tag the Spot Instance requests on create. The resource to specify for RunInstances is `spot-instances-request`.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don’t need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or `*` wildcard in the CreateTags allow statement, otherwise the call will fail.

You can request Spot Instances using RunInstances or RequestSpotInstances. The following example IAM policies apply only when requesting Spot Instances using RunInstances.

Example: Request Spot Instances using RunInstances

The following policy allows users to request Spot Instances by using the RunInstances action. The `spot-instances-request` resource, which is created by RunInstances, requests Spot Instances.

> **Note**
>
> To use RunInstances to create Spot Instance requests, you can omit `spot-instances-request` from the `Resource` list if you do not intend to tag the Spot Instance requests on create. This is because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*",
                "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        }
    ]
}
```

Warning

NOT SUPPORTED – Example: Deny users permission to request Spot Instances using RunInstances

The following policy is not supported for the `spot-instances-request` resource.

The following policy is meant to give users the permission to launch On-Demand Instances, but deny users the permission to request Spot Instances. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement is meant to deny the RunInstances action for the `spot-instances-request` resource. However, this condition is not supported because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*"
            ]
        },
        {
            "Sid": "DenySpotInstancesRequestsNOTSUPPORTEDDONOTUSE",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
        }
    ]
}
```

Example: Tag Spot Instance requests on create

The following policy allows users to tag all resources that are created during instance launch. The first statement allows RunInstances to create the listed resources. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement provides a `*` wildcard to allow all resources to be tagged when they are created at instance launch.

Note

If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement. Therefore, you must explicitly allow the `spot-instances-request` resource for the RunInstances action, otherwise the call will fail.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*",
                "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Sid": "TagResources",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Example: Deny tag on create for Spot Instance requests

The following policy denies users the permission to tag the resources that are created during instance launch.

The first statement allows RunInstances to create the listed resources. The `spot-instances-request` resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement provides a `*` wildcard to deny all resources being tagged when they are created at instance launch. If `spot-instances-request` or any other resource is tagged on create, the RunInstances call will fail.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*",

            ]
        },
        {
            "Sid": "DenyTagResources",
            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Warning

NOT SUPPORTED – Example: Allow creating a Spot Instance request only if it is assigned a specific tag

The following policy is not supported for the `spot-instances-request` resource.

The following policy is meant to grant RunInstances the permission to create a Spot Instance request only if the request is tagged with a specific tag.

The first statement allows RunInstances to create the listed resources.

The second statement is meant to grant users the permission to create a Spot Instance request only if the request has the tag `environment=production`. If this condition is applied to other resources created by RunInstances, specifying no tags results in an `Unauthenticated` error. However, if no tags are specified for the Spot Instance request, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement, which results in non-tagged Spot Instance requests being created by RunInstances.

Note that specifying another tag other than `environment=production` results in an `Unauthenticated` error, because if a user tags a Spot Instance request, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*"
            ]
```

```
        },
        {
            "Sid":
 "RequestSpotInstancesOnlyIfTagIsEnvironmentProductionNOTSUPPORTEDDONOTUSE",
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws:ec2:us-east-1:*:spot-instances-request/
*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        },
        {
            "Sid": "TagResources",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }

    ]
}
```

Example: Deny creating a Spot Instance request if it is assigned a specific tag

The following policy denies RunInstances the permission to create a Spot Instance request if the request is tagged with `environment=production`.

The first statement allows RunInstances to create the listed resources.

The second statement denies users the permission to create a Spot Instance request if the request has the tag `environment=production`. Specifying `environment=production` as a tag results in an `Unauthenticated` error. Specifying other tags or specifying no tags will result in the creation of a Spot Instance request.

JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*",
                "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Sid": "DenySpotInstancesRequests",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws:ec2:us-east-1:*:spot-instances-request/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        },
        {
            "Sid": "TagResources",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

Example: Work with Reserved Instances

The following policy gives users permission to view, modify, and purchase Reserved Instances in your account.

It is not possible to set resource-level permissions for individual Reserved Instances. This policy means that users have access to all the Reserved Instances in the account.

The `Resource` element uses a * wildcard to indicate that users can specify all resources with the action; in this case, they can list and modify all Reserved Instances in the account. They can also purchase Reserved Instances using the account credentials. The * wildcard is also necessary in cases where the API action does not support resource-level permissions.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeReservedInstances",
        "ec2:ModifyReservedInstances",
        "ec2:PurchaseReservedInstancesOffering",
        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeReservedInstancesOfferings"
      ],
      "Resource": "*"
    }
   ]
}
```

To allow users to view and modify the Reserved Instances in your account, but not purchase new Reserved Instances.

JSON

```
{
  "Version": "2012-10-17",
   "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeReservedInstances",
        "ec2:ModifyReservedInstances",
```

```
                "ec2:DescribeAvailabilityZones"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Tag resources

The following policy allows users to use the `CreateTags` action to apply tags to an instance only if the tag contains the key`environment` and the value `production`. No other tags are allowed and the user cannot tag any other resource types.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
             {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        }
    ]
}
```

The following policy allows users to tag any taggable resource that already has a tag with a key of `owner` and a value of the username. In addition, users must specify a tag with a key of `anycompany:environment-type` and a value of either `test` or `prod` in the request. Users can specify additional tags in the request.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
              {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/anycompany:environment-type":
 ["test","prod"],
                    "aws:ResourceTag/owner": "${aws:username}"
                }
            }
        }
    ]
}
```

You can create an IAM policy that allows users to delete specific tags for a resource. For example, the following policy allows users to delete tags for a volume if the tag keys specified in the request are `environment` or `cost-center`. Any value can be specified for the tag but the tag key must match either of the specified keys.

> **Note**
>
> If you delete a resource, all tags associated with the resource are also deleted. Users do not need permissions to use the `ec2:DeleteTags` action to delete a resource that has tags; they only need permissions to perform the deleting action.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
      {
        "Effect": "Allow",
        "Action": "ec2:DeleteTags",
        "Resource": "arn:aws:ec2:us-east-1:111122223333:volume/*",
        "Condition": {
          "ForAllValues:StringEquals": {
            "aws:TagKeys": ["environment","cost-center"]
          }
        }
      }
    ]
}
```

This policy allows users to delete only the `environment=prod` tag on any resource, and only if the resource is already tagged with a key of `owner` and a value of the username. Users can't delete any other tags for a resource.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
      {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteTags"
      ],
      "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/environment": "prod",
          "aws:ResourceTag/owner": "${aws:username}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": ["environment"]
        }
      }
    }
  ]
}
```

Example: Work with IAM roles

The following policy allows users to attach, replace, and detach an IAM role to instances that have the tag `department=test`. Replacing or detaching an IAM role requires an association ID, therefore the policy also grants users permission to use the `ec2:DescribeIamInstanceProfileAssociations` action.

Users must have permission to use the `iam:PassRole` action in order to pass the role to the instance.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation",
        "ec2:DisassociateIamInstanceProfile"
      ],
      "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/department":"test"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeIamInstanceProfileAssociations",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::111122223333:role/DevTeam*"
    }
  ]
}
```

The following policy allows users to attach or replace an IAM role for any instance. Users can only attach or replace IAM roles with names that begin with `TestRole-`. For the `iam:PassRole` action, ensure that you specify the name of the IAM role and not the instance profile (if the names are different). For more information, see Instance profiles.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:AssociateIamInstanceProfile",
                "ec2:ReplaceIamInstanceProfileAssociation"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeIamInstanceProfileAssociations",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::111122223333:role/TestRole-*"
        }
    ]
}
```

Example: Work with route tables

The following policy allows users to add, remove, and replace routes for route tables that are associated with VPC `vpc-ec43eb89` only. To specify a VPC for the `ec2:Vpc` condition key, you must specify the full ARN of the VPC.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
              {
            "Effect": "Allow",
            "Action": [
                "ec2:DeleteRoute",
                "ec2:CreateRoute",
                "ec2:ReplaceRoute"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1:111122223333:route-table/*"
            ],
            "Condition": {
                "StringEquals": {
                    "ec2:Vpc": "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-
ec43eb89"
                }
            }
        }
    ]
}
```

Example: Allow a specific instance to view resources in other AWS services

The following is an example of a policy that you might attach to an IAM role. The policy allows an instance to view resources in various AWS services. It uses the `ec2:SourceInstanceARN` global condition key to specify that the instance from which the request is made must be instance `i-093452212644b0dd6`. If the same IAM role is associated with another instance, the other instance cannot perform any of these actions.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
              {
            "Effect": "Allow",
```

```
            "Action": [
                "ec2:DescribeVolumes",
                "s3:ListAllMyBuckets",
                "dynamodb:ListTables",
                "rds:DescribeDBInstances"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "ArnEquals": {
                    "ec2:SourceInstanceARN": "arn:aws:ec2:us-
east-1:111122223333:instance/i-093452212644b0dd6"
                }
            }
        }
    ]
}
```

Example: Work with launch templates

The following policy allows users to create a launch template version and modify a launch template, but only for a specific launch template (`lt-09477bcd97b0d3abc`). Users cannot work with other launch templates.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
   {
      "Action": [
        "ec2:CreateLaunchTemplateVersion",
        "ec2:ModifyLaunchTemplate"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:ec2:us-east-1:111122223333:launch-template/
lt-09477bcd97b0d3abc"
    }
  ]
}
```

The following policy allows users to delete any launch template and launch template version, provided that the launch template has the tag `Purpose=Testing`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
       {
      "Action": [
        "ec2:DeleteLaunchTemplate",
        "ec2:DeleteLaunchTemplateVersions"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:ec2:us-east-1:111122223333:launch-template/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Purpose": "Testing"
        }
      }
    }
  ]
}
```

Work with instance metadata

The following policies ensure that users can only retrieve instance metadata using Instance Metadata Service Version 2 (IMDSv2). You can combine the following four policies into one policy with four statements. When combined as one policy, you can use the policy as a service control policy (SCP). It can work equally well as a *deny* policy that you apply to an existing IAM policy (taking away and limiting existing permission), or as an SCP that is applied globally across an account, an organizational unit (OU), or an entire organization.

> **Note**
>
> The following RunInstances metadata options policies must be used in conjunction with a policy that gives the principal permissions to launch an instance with RunInstances. If the principal does not also have RunInstances permissions, it will not be able to launch

an instance. For more information, see the policies in [Work with instances]() and [Launch instances (RunInstances)]().

Important

If you use Auto Scaling groups and you need to require the use of IMDSv2 on all new instances, your Auto Scaling groups must use *launch templates*.

When an Auto Scaling group uses a launch template, the `ec2:RunInstances` permissions of the IAM principal are checked when a new Auto Scaling group is created. They are also checked when an existing Auto Scaling group is updated to use a new launch template or a new version of a launch template.

Restrictions on the use of IMDSv1 on IAM principals for `RunInstances` are only checked when an Auto Scaling group that is using a launch template, is created or updated. For an Auto Scaling group that is configured to use the `Latest` or `Default` launch template, the permissions are not checked when a new version of the launch template is created. For permissions to be checked, you must configure the Auto Scaling group to use a *specific version* of the launch template.

To enforce the use of IMDSv2 on instances launched by Auto Scaling groups, the following additional steps are required:

1. Disable the use of launch configurations for all accounts in your organization by using either service control policies (SCPs) or IAM permissions boundaries for new principals that are created. For existing IAM principals with Auto Scaling group permissions, update their associated policies with this condition key. To disable the use of launch configurations, create or modify the relevant SCP, permissions boundary, or IAM policy with the `"autoscaling:LaunchConfigurationName"` condition key with the value specified as `null`.
2. For new launch templates, configure the instance metadata options in the launch template. For existing launch templates, create a new version of the launch template and configure the instance metadata options in the new version.
3. In the policy that gives any principal the permission to use a launch template, restrict association of `$latest` and `$default` by specifying `"autoscaling:LaunchTemplateVersionSpecified": "true"`. By restricting the use to a specific version of a launch template, you can ensure that new instances will be launched using the version in which the instance metadata options are configured. For

more information, see LaunchTemplateSpecification in the *Amazon EC2 Auto Scaling API Reference*, specifically the `Version` parameter.

4. For an Auto Scaling group that uses a launch configuration, replace the launch configuration with a launch template. For more information, see Migrate your Auto Scaling groups to launch templates in the *Amazon EC2 Auto Scaling User Guide*.
5. For an Auto Scaling group that uses a launch template, make sure that it uses a new launch template with the instance metadata options configured, or uses a new version of the current launch template with the instance metadata options configured. For more information, see update-auto-scaling-group.

Examples

- Require the use of IMDSv2
- Deny opt-out of IMDSv2
- Specify maximum hop limit
- Limit who can modify the instance metadata options
- Require role credentials to be retrieved from IMDSv2

Require the use of IMDSv2

The following policy specifies that you can't call the RunInstances API unless the instance is also opted in to require the use of IMDSv2 (indicated by `"ec2:MetadataHttpTokens": "required"`). If you do not specify that the instance requires IMDSv2, you get an `UnauthorizedOperation` error when you call the RunInstances API.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
               {
            "Sid": "RequireImdsV2",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws:ec2:*:*:instance/*",
            "Condition": {
```

```
                "StringNotEquals": {
                    "ec2:MetadataHttpTokens": "required"
                }
            }
        }
    ]
}
```

Deny opt-out of IMDSv2

The following policy specifies that you cannot call the `ModifyInstanceMetadataOptions` API and allow the option of IMDSv1 or IMDSv2. If you call the `ModifyInstanceMetadataOptions` API, the `HttpTokens` attribute must be set to `required`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "DenyIMDSv1HttpTokensModification",
        "Effect": "Deny",
        "Action": "ec2:ModifyInstanceMetadataOptions",
        "Resource": "arn:aws:ec2:*:*:instance/*",
        "Condition": {
            "StringNotEquals": {
                "ec2:Attribute/HttpTokens": "required"
            },
            "Null": {
                "ec2:Attribute/HttpTokens": false
            }
        }
    }]
}
```

Specify maximum hop limit

The following policy specifies that you can't call the RunInstances API unless you also specify a hop limit, and the hop limit can't be more than 3. If you fail to do that, you get an `UnauthorizedOperation` error when you call the RunInstances API.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
               {
            "Sid": "MaxImdsHopLimit",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws:ec2:*:*:instance/*",
            "Condition": {
                "NumericGreaterThan": {
                    "ec2:MetadataHttpPutResponseHopLimit": "3"
                }
            }
        }
    ]
}
```

Limit who can modify the instance metadata options

The following policy permits only users with the role `ec2-imds-admins` to make changes to the instance metadata options. If any principal other than the `ec2-imds-admins` role tries to call the ModifyInstanceMetadataOptions API, it will get an `UnauthorizedOperation` error. This statement could be used to control the use of the ModifyInstanceMetadataOptions API; there are currently no fine-grained access controls (conditions) for the ModifyInstanceMetadataOptions API.

Require role credentials to be retrieved from IMDSv2

The following policy specifies that if this policy is applied to a role, and the role is assumed by the EC2 service and the resulting credentials are used to sign a request, then the request must be signed by EC2 role credentials retrieved from IMDSv2. Otherwise, all of its API calls will get an `UnauthorizedOperation` error. This statement/policy can be applied generally because, if the request is not signed by EC2 role credentials, it has no effect.

JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
            {
        "Sid": "RequireAllEc2RolesToUseV2",
        "Effect": "Deny",
        "Action": "*",
        "Resource": "*",
        "Condition": {
            "NumericLessThan": {
                "ec2:RoleDelivery": "2.0"
            }
        }
      }
    ]
}
```

Work with Amazon EBS volumes and snapshots

For example policies for working with Amazon EBS volumes and snapshots, see Identity-based policy examples for Amazon EBS.

Example policies to control access to the Amazon EC2 console

You can use IAM policies to grant users the permissions required to work with Amazon EC2. For step-by-step directions, see Creating IAM policies in the *IAM User Guide*.

The console uses additional API actions for its features, so these policies may not work as expected. For example, a user that has permission to use only the `DescribeVolumes` API action will encounter errors when trying to view volumes in the console. This section demonstrates policies that enable users to work with specific parts of the console. For additional information about creating policies for the Amazon EC2 console, see the following AWS Security Blog post: Granting Users Permission to Work in the Amazon EC2 Console.

The following examples show policy statements that you could use to grant users permissions to use Amazon EC2. Replace each *`user input placeholder`* with your own information. These policies are designed for requests that are made using the AWS Management Console. The Amazon EC2 console might call multiple API actions to display a single resource, and it might not be obvious until the user attempts a task and the console displays an error. For more information, see the following AWS Security Blog post: Granting Users Permission to Work in the Amazon EC2 Console.

Examples

- Example: Read-only access
- Example: Use the EC2 launch instance wizard
- Example: Work with security groups
- Example: Work with Elastic IP addresses
- Example: Work with Reserved Instances

To help you work out which API actions are required to perform tasks in the console, you can use a service that logs calls, such as AWS CloudTrail. If your policy does not grant permission to create or modify a specific resource, the console displays an encoded message with diagnostic information. You can decode the message using the DecodeAuthorizationMessage API action for AWS STS, or the decode-authorization-message command in the AWS CLI.

Example: Read-only access

To allow users to view all resources in the Amazon EC2 console, you can use the same policy as the following example: Example: Read-only access. Users cannot perform any actions on those resources or create new resources, unless another statement grants them permission to do so.

View instances, AMIs, and snapshots

Alternatively, you can provide read-only access to a subset of resources. To do this, replace the * wildcard in the `ec2:Describe` API action with specific `ec2:Describe` actions for each resource. The following policy allows users to view all instances, AMIs, and snapshots in the Amazon EC2 console. The `ec2:DescribeTags` action allows users to view public AMIs. The console requires the tagging information to display public AMIs; however, you can remove this action to allow users to view only private AMIs.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeInstances",
         "ec2:DescribeImages",
         "ec2:DescribeTags",
```

```
            "ec2:DescribeSnapshots"
        ],
        "Resource": "*"
    }
    ]
}
```

Note

The Amazon EC2 `ec2:Describe*` API actions do not support resource-level permissions, so you cannot control which individual resources users can view in the console. Therefore, the * wildcard is necessary in the `Resource` element of the above statement. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

View instances and CloudWatch metrics

The following policy allows users to view instances in the Amazon EC2 console, as well as CloudWatch alarms and metrics in the **Monitoring** tab of the **Instances** page. The Amazon EC2 console uses the CloudWatch API to display the alarms and metrics, so you must grant users permission to use the `cloudwatch:DescribeAlarms`, `cloudwatch:DescribeAlarmsForMetric`, `cloudwatch:ListMetrics`, `cloudwatch:GetMetricStatistics`, and `cloudwatch:GetMetricData` actions.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeInstanceTypes",
            "cloudwatch:DescribeAlarms",
            "cloudwatch:DescribeAlarmsForMetric",
            "cloudwatch:ListMetrics",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:GetMetricData"
```

```
        ],
        "Resource": "*"
    }
    ]
}
```

Example: Use the EC2 launch instance wizard

The Amazon EC2 launch instance wizard is a screen with options to configure and launch an instance. Your policy must include permission to use the API actions that allow users to work with the wizard's options. If your policy does not include permission to use those actions, some items in the wizard cannot load properly, and users cannot complete a launch.

Basic launch instance wizard access

To complete a launch successfully, users must be given permission to use the `ec2:RunInstances` API action, and at least the following API actions:

- `ec2:DescribeImages`: To view and select an AMI.
- `ec2:DescribeInstanceTypes`: To view and select an instance type.
- `ec2:DescribeVpcs`: To view the available network options.
- `ec2:DescribeSubnets`: To view all available subnets for the chosen VPC.
- `ec2:DescribeSecurityGroups` or `ec2:CreateSecurityGroup`: To view and select an existing security group, or to create a new one.
- `ec2:DescribeKeyPairs` or `ec2:CreateKeyPair`: To select an existing key pair, or to create a new one.
- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
```

```
                "ec2:DescribeImages",
                "ec2:DescribeInstanceTypes",
                "ec2:DescribeKeyPairs",
                "ec2:DescribeVpcs",
                "ec2:DescribeSubnets",
                "ec2:DescribeSecurityGroups",
                "ec2:CreateSecurityGroup",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:CreateKeyPair"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": "*"
        }
    ]
}
```

You can add API actions to your policy to provide more options for users, for example:

- `ec2:DescribeAvailabilityZones`: To view and select a specific Availability Zone.
- `ec2:DescribeNetworkInterfaces`: To view and select existing network interfaces for the selected subnet.
- To add outbound rules to VPC security groups, users must be granted permission to use the `ec2:AuthorizeSecurityGroupEgress` API action. To modify or delete existing rules, users must be granted permission to use the relevant `ec2:RevokeSecurityGroup*` API action.
- `ec2:CreateTags`: To tag the resources that are created by `RunInstances`. For more information, see Grant permission to tag Amazon EC2 resources during creation. If users do not have permission to use this action and they attempt to apply tags on the tagging page of the launch instance wizard, the launch fails.

Important

Specifying a **Name** while launching an instance creates a tag and requires the `ec2:CreateTags` action. Be careful about granting users permission to use the `ec2:CreateTags` action, because doing so limits your ability to use the `aws:ResourceTag` condition key to restrict their use of other resources. If you grant users permission to use the `ec2:CreateTags` action, they can change a resource's tag in order to bypass those restrictions. For more information, see Control access using attribute-based access.

- To use Systems Manager parameters when selecting an AMI, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your policy. `ssm:DescribeParameters` grants your users the permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your users the permission to get the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see **Restrict access to specific Systems Manager parameters** later in this section.

Currently, the Amazon EC2 `Describe*` API actions do not support resource-level permissions, so you cannot restrict which individual resources users can view in the launch instance wizard. However, you can apply resource-level permissions on the `ec2:RunInstances` API action to restrict which resources users can use to launch an instance. The launch fails if users select options that they are not authorized to use.

Restrict access to a specific instance type, subnet, and Region

The following policy allows users to launch `t2.micro` instances using AMIs owned by Amazon, and only into a specific subnet (`subnet-1a2b3c4d`). Users can only launch in the specified Region. If users select a different Region, or select a different instance type, AMI, or subnet in the launch instance wizard, the launch fails.

The first statement grants users permission to view the options in the launch instance wizard or to create new ones, as explained in the example above. The second statement grants users permission to use the network interface, volume, key pair, security group, and subnet resources for the `ec2:RunInstances` action, which are required to launch an instance into a VPC. For more information about using the `ec2:RunInstances` action, see Launch instances (RunInstances). The third and fourth statements grant users permission to use the instance and AMI resources respectively, but only if the instance is a `t2.micro` instance, and only if the AMI is owned by Amazon, or certain trusted and verified partners.

JSON

```
{
   "Version": "2012-10-17",
```

```
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeImages",
            "ec2:DescribeInstanceTypes",
            "ec2:DescribeKeyPairs",
            "ec2:CreateKeyPair",
            "ec2:DescribeVpcs",
            "ec2:DescribeSubnets", "ec2:DescribeSecurityGroups",
            "ec2:CreateSecurityGroup",
            "ec2:AuthorizeSecurityGroupIngress"
    ],
    "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action":"ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2:us-east-2:111122223333:network-interface/*",
            "arn:aws:ec2:us-east-2:111122223333:volume/*",
            "arn:aws:ec2:us-east-2:111122223333:key-pair/*",
            "arn:aws:ec2:us-east-2:111122223333:security-group/*",
            "arn:aws:ec2:us-east-2:111122223333:subnet/subnet-1a2b3c4d"
        ]
    },
    {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2:us-east-2:111122223333:instance/*"
        ],
        "Condition": {
            "StringEquals": {
                "ec2:InstanceType": "t2.micro"
            }
        }
    },
    {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
                "arn:aws:ec2:us-east-2::image/ami-*"
        ],
```

```
            "Condition": {
                "StringEquals": {
                    "ec2:Owner": "amazon"
                }
            }
        }
        ]
}
```

Restrict access to specific Systems Manager parameters

The following policy grants access to use Systems Manager parameters with a specific name.

The first statement grants users the permission to view Systems Manager parameters when selecting an AMI in the launch instance wizard. The second statement grants users the permission to only use parameters that are named `prod-*`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ssm:DescribeParameters"
        ],
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": [
            "ssm:GetParameters"
        ],
       "Resource": "arn:aws:ssm:us-east-2:123456123456:parameter/prod-*"
    }
    ]
}
```

Example: Work with security groups

View security groups and add and remove rules

The following policy grants users permission to view security groups in the Amazon EC2 console, to add and remove inbound and outbound rules, and to list and modify rule descriptions for existing security groups that have the tag `Department=Test`.

In the first statement, the `ec2:DescribeTags` action allows users to view tags in the console, which makes it easier for users to identify the security groups that they are allowed to modify.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeSecurityGroups",
         "ec2:DescribeSecurityGroupRules",
         "ec2:DescribeTags"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:AuthorizeSecurityGroupIngress",
         "ec2:RevokeSecurityGroupIngress",
         "ec2:AuthorizeSecurityGroupEgress",
         "ec2:RevokeSecurityGroupEgress",
         "ec2:ModifySecurityGroupRules",
         "ec2:UpdateSecurityGroupRuleDescriptionsIngress",
         "ec2:UpdateSecurityGroupRuleDescriptionsEgress"
      ],
      "Resource": [
         "arn:aws:ec2:us-east-2:111122223333:security-group/*"
      ],
      "Condition": {
         "StringEquals": {
            "aws:ResourceTag/Department": "Test"
         }
```

```
        }
      },
      {
        "Effect": "Allow",
        "Action": [
          "ec2:ModifySecurityGroupRules"
        ],
        "Resource": [
          "arn:aws:ec2:us-east-2:111122223333:security-group-rule/*"
        ]
      }
]}
```

Work with the Create Security Group dialog box

You can create a policy that allows users to work with the **Create Security Group** dialog box in the Amazon EC2 console. To use this dialog box, users must be granted permission to use at the least the following API actions:

- `ec2:CreateSecurityGroup`: To create a new security group.
- `ec2:DescribeVpcs`: To view a list of existing VPCs in the **VPC** list.

With these permissions, users can create a new security group successfully, but they cannot add any rules to it. To work with rules in the **Create Security Group** dialog box, you can add the following API actions to your policy:

- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.
- `ec2:AuthorizeSecurityGroupEgress`: To add outbound rules to VPC security groups.
- `ec2:RevokeSecurityGroupIngress`: To modify or delete existing inbound rules. This is useful to allow users to use the **Copy to new** feature in the console. This feature opens the **Create Security Group** dialog box and populates it with the same rules as the security group that was selected.
- `ec2:RevokeSecurityGroupEgress`: To modify or delete outbound rules for VPC security groups. This is useful to allow users to modify or delete the default outbound rule that allows all outbound traffic.
- `ec2:DeleteSecurityGroup`: To cater for when invalid rules cannot be saved. The console first creates the security group, and then adds the specified rules. If the rules are invalid, the action

fails, and the console attempts to delete the security group. The user remains in the **Create Security Group** dialog box so that they can correct the invalid rule and try to create the security group again. This API action is not required, but if a user is not granted permission to use it and attempts to create a security group with invalid rules, the security group is created without any rules, and the user must add them afterward.

- `ec2:UpdateSecurityGroupRuleDescriptionsIngress`: To add or update descriptions of ingress (inbound) security group rules.
- `ec2:UpdateSecurityGroupRuleDescriptionsEgress`: To add or update descriptions of egress (outbound) security group rules.
- `ec2:ModifySecurityGroupRules`: To modify security group rules.
- `ec2:DescribeSecurityGroupRules`: To list security group rules.

The following policy grants users permission to use the **Create Security Group** dialog box, and to create inbound and outbound rules for security groups that are associated with a specific VPC (`vpc-1a2b3c4d`). Users can create security groups for a VPC, but they cannot add any rules to them. Similarly, users cannot add any rules to any existing security group that's not associated with VPC `vpc-1a2b3c4d`. Users are also granted permission to view all security groups in the console. This makes it easier for users to identify the security groups to which they can add inbound rules. This policy also grants users permission to delete security groups that are associated with VPC `vpc-1a2b3c4d`.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeSecurityGroups",
        "ec2:CreateSecurityGroup",
        "ec2:DescribeVpcs"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteSecurityGroup",
```

```
            "ec2:AuthorizeSecurityGroupIngress",
            "ec2:AuthorizeSecurityGroupEgress"
          ],
          "Resource": "arn:aws:ec2:us-east-2:111122223333:security-group/*",
          "Condition":{
             "ArnEquals": {
                "ec2:Vpc": "arn:aws:ec2:us-east-2:111122223333:vpc/vpc-1a2b3c4d"
             }
          }
       }
    ]
}
```

Example: Work with Elastic IP addresses

To allow users to view Elastic IP addresses in the Amazon EC2 console, you must grant users permission to use the `ec2:DescribeAddresses` action.

To allow users to work with Elastic IP addresses, you can add the following actions to your policy.

- `ec2:AllocateAddress`: To allocate an Elastic IP address.
- `ec2:ReleaseAddress`: To release an Elastic IP address.
- `ec2:AssociateAddress`: To associate an Elastic IP address with an instance or a network interface.
- `ec2:DescribeNetworkInterfaces` and `ec2:DescribeInstances`: To work with the **Associate address** screen. The screen displays the available instances or network interfaces to which you can associate an Elastic IP address.
- `ec2:DisassociateAddress`: To disassociate an Elastic IP address from an instance or a network interface.

The following policy allows users to view, allocate, and associate Elastic IP addresses with instances. Users cannot associate Elastic IP addresses with network interfaces, disassociate Elastic IP addresses, or release them.

JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeAddresses",
                "ec2:AllocateAddress",
                "ec2:DescribeInstances",
                "ec2:AssociateAddress"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Work with Reserved Instances

The following policy allows users to view and modify Reserved Instances in your account, as well as purchase new Reserved Instances in the AWS Management Console.

This policy allows users to view all the Reserved Instances, as well as On-Demand Instances, in the account. It's not possible to set resource-level permissions for individual Reserved Instances.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeReservedInstances",
         "ec2:ModifyReservedInstances",
         "ec2:PurchaseReservedInstancesOffering",
         "ec2:DescribeInstances",
         "ec2:DescribeInstanceTypes",
         "ec2:DescribeAvailabilityZones",
         "ec2:DescribeReservedInstancesOfferings"
      ],
      "Resource": "*"
   }
   ]
}
```

The `ec2:DescribeAvailabilityZones` action is necessary to ensure that the Amazon EC2 console can display information about the Availability Zones in which you can purchase Reserved Instances. The `ec2:DescribeInstances` action is not required, but ensures that the user can view the instances in the account and purchase reservations to match the correct specifications.

You can adjust the API actions to limit user access, for example removing `ec2:DescribeInstances` and `ec2:DescribeAvailabilityZones` means the user has read-only access.

AWS managed policies for Amazon EC2

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies] that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see [AWS managed policies] in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the **ReadOnlyAccess** AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [AWS managed policies for job functions] in the *IAM User Guide*.

AWS managed policy: AmazonEC2FullAccess

You can attach the `AmazonEC2FullAccess` policy to your IAM identities. This policy grants permissions that allow full access to Amazon EC2.

To view the permissions for this policy, see [AmazonEC2FullAccess] in the *AWS Managed Policy Reference*.

AWS managed policy: AmazonEC2ReadOnlyAccess

You can attach the `AmazonEC2ReadOnlyAccess` policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon EC2.

To view the permissions for this policy, see AmazonEC2ReadOnlyAccess in the *AWS Managed Policy Reference*.

AWS managed policy: AmazonEC2ImageReferencesAccessPolicy

You can attach the `AmazonEC2ImageReferencesAccessPolicy` policy to your IAM identities. This policy grants the permissions needed to use the EC2 DescribeImageReferences API, including permission to view EC2 instances, launch templates, Systems Manager parameters, and Image Builder recipes. The policy supports the `IncludeAllResourceTypes` flag and will continue to work when AWS adds support for new resource types, removing the need for future policy updates.

To view the permissions for this policy, see AmazonEC2ImageReferencesAccessPolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2CapacityReservationFleetRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2CapacityReservationFleet** to allow the service to create, modify, and cancel Capacity Reservations in a Capacity Reservation Fleet on your behalf. For more information, see Using service-linked roles for Capacity Reservation Fleet.

To view the permissions for this policy, see AWSEC2CapacityReservationFleetRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2FleetServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2Fleet** to allow EC2 Fleet to request, launch, terminate, and tag instances on your behalf. For more information, see Service-linked role for EC2 Fleet.

To view the permissions for this policy, see AWSEC2FleetServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2SpotFleetServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2SpotFleet** to allow Spot Fleet to launch and manage instances on your behalf. For more information, see Service-linked role for Spot Fleet.

To view the permissions for this policy, see AWSEC2SpotFleetServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2SpotServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2Spot** to allow Amazon EC2 to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests.

To view the permissions for this policy, see AWSEC2SpotServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: AWSEC2VssSnapshotPolicy

You can attach this managed policy to the IAM instance profile role that you use for your Amazon EC2 Windows instances. The policy grants permissions to allow Amazon EC2 to create and manage VSS snapshots on your behalf.

To view the permissions for this policy, see AWSEC2VssSnapshotPolicy in the *AWS Managed Policy Reference*.

AWS managed policy: DeclarativePoliciesEC2Report

This policy is attached to the service-linked role named `AWSServiceRoleForDeclarativePoliciesEC2Report` to provide access to read-only APIs needed to generate the account status report for declarative policies.

To view the permissions for this policy, see DeclarativePoliciesEC2Report in the *AWS Managed Policy Reference*.

AWS managed policy: EC2FastLaunchFullAccess

You can attach the `EC2FastLaunchFullAccess` policy to your instance profile or other IAM role. This policy grants full access to EC2 Fast Launch actions, and targeted permissions as follows.

Permissions details

- **EC2 Fast Launch** – Administrative access is granted, so that the role can enable or disable EC2 Fast Launch, and describe EC2 Fast Launch images.
- **Amazon EC2** – Access is granted for Amazon EC2 RunInstances, CreateTags, Describe, and Create and Modify Launch Template operations. Access is also granted to create network and security group resources, authorize ingress rules, and delete resources that EC2 Fast Launch created.
- **IAM** – Access is granted to get and use instance profiles whose name contains `ec2fastlaunch` to create the EC2FastLaunchServiceRolePolicy service-linked role.
- **AWS CloudFormation** – Access is granted for EC2 Fast Launch to describe and create CloudFormation stacks, and to delete stacks that it created.

To view the permissions for this policy, see EC2FastLaunchFullAccess in the *AWS Managed Policy Reference*.

AWS managed policy: EC2FastLaunchServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForEC2FastLaunch** to allow Amazon EC2 to create and manage a set of pre-provisioned snapshots that reduce the time it takes to launch instances from your EC2 Fast Launch-enabled AMI. For more information, see the section called "Service-linked role".

To view the permissions for this policy, see EC2FastLaunchServiceRolePolicy in the *AWS Managed Policy Reference*.

AWS managed policy: Ec2InstanceConnect

You can attach the `Ec2InstanceConnect` policy to your IAM identities. This policy grants permissions that allows customers to call EC2 Instance Connect to publish ephemeral keys to their EC2 instances and connect via ssh or the EC2 Instance Connect CLI.

To view the permissions for this policy, see Ec2InstanceConnect in the *AWS Managed Policy Reference*.

AWS managed policy: Ec2InstanceConnectEndpoint

This policy is attached to a service-linked role named **AWSServiceRoleForEC2InstanceConnect** to allow EC2 Instance Connect Endpoint to perform actions on your behalf. For more information, see Service-linked role for EC2 Instance Connect Endpoint.

To view the permissions for this policy, see [Ec2InstanceConnectEndpoint]() in the *AWS Managed Policy Reference*. For a description of the updates to this policy, see [Amazon EC2 updates to AWS managed policies]().

Amazon EC2 updates to AWS managed policies

View details about updates to AWS managed policies for Amazon EC2 since this service began tracking these changes.

Change	Description	Date
[AmazonEC2ImageReferencesAccessPolicy]() – New policy	Amazon EC2 added this policy to provide permission to scan all resources types supported by the EC2 DescribeImageReferences API.	August 26, 2025
[Ec2InstanceConnectEndpoint]() – Updated policy	To support the modification of existing Instance Connect Endpoints, Amazon EC2 updated this policy to add permissions to assign and unassign IPv6 addresses and modify security groups on network interfaces created by EC2 Instance Connect Endpoint. Amazon EC2 also updated this policy to replace the `Null` condition operator with the `StringLike` condition operator.	July 31, 2025
[EC2FastLaunchServiceRolePolicy]() – Updated policy	To help prevent orphaned resources, Amazon EC2 updated this policy to add permission to describe volumes, volume attributes and network interfaces,	July 17, 2025

Change	Description	Date
	and to delete volumes and network interfaces that EC2 Fast Launch created.	
[EC2FastLaunchFullAccess]() – Updated policy	Amazon EC2 updated this policy to include Create and Modify Launch Template operations, to create network and security group resources , authorize ingress rules, and delete resources that EC2 Fast Launch created. It can additionally describe and create CloudFormation stacks, and delete stacks that EC2 Fast Launch created.	May 14, 2025
[EC2FastLaunchServiceRolePolicy]() – Updated policy	Amazon EC2 updated this policy to add Amazon EventBridge access to create and manage event rules for EC2 Fast Launch. Additionally, EC2 Fast Launch can now describe AWS CloudFormation stacks, launch an instance from an AMI that's associated with AWS License Manager, get a list of AWS KMS grants it created that can be retired, and delete launch templates that it created.	May 14, 2025

Change	Description	Date
AWSEC2CapacityReservationFleetRolePolicy – Updated permissions	Amazon EC2 updated the `AWSEC2CapacityReservationFleetRolePolicy` managed policy to use the `ArnLike` condition operator instead of the `StringLike` condition operator.	March 03, 2025
AmazonEC2ReadOnlyAccess – Added permissions	Amazon EC2 added a permission that allows you to retrieve security groups using the `GetSecurityGroupsForVpc` operation.	December 27, 2024
EC2FastLaunchFullAccess – New policy	Amazon EC2 added this policy to perform API actions related to the EC2 Fast Launch feature from an instance. The policy can be attached to the instance profile for an instance that's launched from a EC2 Fast Launch enabled AMI.	May 14, 2024
AWSEC2VssSnapshotPolicy – New policy	Amazon EC2 added the `AWSEC2VssSnapshotPolicy` policy that contains permissions to create and add tags to Amazon Machine Images (AMIs) and EBS snapshots.	March 28, 2024

Change	Description	Date
Ec2InstanceConnectEndpoint – New policy	Amazon EC2 added the `Ec2InstanceConnectEndpoint` policy. This policy is attached to the **AWSServiceRoleForEC2InstanceConnect** service-linked role, to allow Amazon EC2 to perform actions on your behalf when you create an EC2 Instance Connect Endpoint.	January 24, 2023
EC2FastLaunchServiceRolePolicy – New policy	Amazon EC2 added the EC2 Fast Launch feature to enable Windows AMIs to launch instances faster by creating a set of pre-provisioned snapshots.	November 26, 2021
Amazon EC2 started tracking changes	Amazon EC2 started tracking changes to its AWS managed policies	March 1, 2021

IAM roles for Amazon EC2

Applications must sign their API requests with AWS credentials. Therefore, if you are an application developer, you need a strategy for managing credentials for your applications that run on EC2 instances. For example, you can securely distribute your AWS credentials to the instances, enabling the applications on those instances to use your credentials to sign requests, while protecting your credentials from other users. However, it's challenging to securely distribute credentials to each instance, especially those that AWS creates on your behalf, such as Spot Instances or instances in Auto Scaling groups. You must also be able to update the credentials on each instance when you rotate your AWS credentials.

We designed IAM roles so that your applications can securely make API requests from your instances, without requiring you to manage the security credentials that the applications use. Instead of creating and distributing your AWS credentials, you can delegate permission to make API requests using IAM roles as follows:

1. Create an IAM role.
2. Define which accounts or AWS services can assume the role.
3. Define which API actions and resources the application can use after assuming the role.
4. Specify the role when you launch your instance, or attach the role to an existing instance.
5. Have the application retrieve a set of temporary credentials and use them.

For example, you can use IAM roles to grant permissions to applications running on your instances that need to use a bucket in Amazon S3. You can specify permissions for IAM roles by creating a policy in JSON format. These are similar to the policies that you create for users. If you change a role, the change is propagated to all instances.

> **Note**
>
> Amazon EC2 IAM role credentials are not subject to maximum session durations configured in the role. For more information, see Methods to assume a role in the *IAM User Guide*.

When creating IAM roles, associate least privilege IAM policies that restrict access to the specific API calls the application requires. For Windows-to-Windows communication, use well-defined and well-documented Windows groups and roles to grant application-level access between Windows instances. Groups and roles allow customers to define least privilege application and NTFS folder-level permissions to limit access to application-specific requirements.

You can only attach one IAM role to an instance, but you can attach the same role to many instances. For more information about creating and using IAM roles, see Roles in the *IAM User Guide*.

You can apply resource-level permissions to your IAM policies to control the users' ability to attach, replace, or detach IAM roles for an instance. For more information, see Supported resource-level permissions for Amazon EC2 API actions and the following example: Example: Work with IAM roles.

Contents

Instance profiles

Amazon EC2 uses an *instance profile* as a container for an IAM role. When you create an IAM role using the IAM console, the console creates an instance profile automatically and gives it the same name as the role to which it corresponds. If you use the Amazon EC2 console to launch an instance with an IAM role or to attach an IAM role to an instance, you choose the role based on a list of instance profile names.

If you use the AWS CLI, API, or an AWS SDK to create a role, you create the role and instance profile as separate actions, with potentially different names. If you then use the AWS CLI, API, or an AWS SDK to launch an instance with an IAM role or to attach an IAM role to an instance, specify the instance profile name.

An instance profile can contain only one IAM role. You can include an IAM role in multiple instance profiles.

To update permissions for an instance, replace its instance profile. We do not recommend removing a role from an instance profile, because there is a delay of up to one hour before this change takes effect.

For more information, see Use instance profiles in the *IAM User Guide*.

Permissions for your use case

When you first create an IAM role for your applications, you might sometimes grant permissions beyond what is required. Before launching your application in your production environment, you can generate an IAM policy that is based on the access activity for an IAM role. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the role in your specified date range. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM role. That way, you grant only the permissions that the role needs to interact with AWS resources for your specific use case. This helps you adhere to the best practice of granting least privilege. For more information, see IAM Access Analyzer policy generation in the *IAM User Guide*.

Retrieve security credentials from instance metadata

An application on the instance retrieves the security credentials provided by the role from the instance metadata item `iam/security-credentials/`*role-name*. The application is granted the permissions for the actions and resources that you've defined for the role through the security credentials associated with the role. These security credentials are temporary and we rotate them automatically. We make new credentials available at least five minutes before the expiration of the old credentials.

For more information about instance metadata, see Use instance metadata to manage your EC2 instance.

> **Warning**
>
> If you use services that use instance metadata with IAM roles, ensure that you don't expose your credentials when the services make HTTP calls on your behalf. The types of services that could expose your credentials include HTTP proxies, HTML/CSS validator services, and XML processors that support XML inclusion.

For your Amazon EC2 workloads, we recommend that you retrieve session credentials using the method described below. These credentials should enable your workload to make AWS API requests, without needing to use `sts:AssumeRole` to assume the same role that is already associated with the instance. Unless you need to pass session tags for attribute-based access control (ABAC) or pass a session policy to further restrict permissions of the role, such role assumption calls are unnecessary as they create a new set of the same temporary role session credentials.

If your workload uses a role to assume itself, you must create a trust policy that explicitly allows that role to assume itself. If you do not create the trust policy, you get an `AccessDenied` error. For more information, see Update a role trust policy in the *IAM User Guide*.

IMDSv2

Linux

Run the following command from your Linux instance to retrieve the security credentials for an IAM role.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/iam/security-credentials/role-name
```

Windows

Run the following cmdlet from your Windows instance to retrieve the security credentials for an IAM role.

```
[string]$token = Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/iam/security-credentials/role-name
```

IMDSv1

Linux

Run the following command from your Linux instance to retrieve the security credentials for an IAM role.

```
curl http://169.254.169.254/latest/meta-data/iam/security-credentials/role-name
```

Windows

Run the following cmdlet from your Windows instance to retrieve the security credentials for an IAM role.

```
Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/iam/security-credentials/role-name
```

The following is example output. If you are not able to retrieve the security credentials, see I can't access the temporary security credentials on my EC2 instance in the *IAM User Guide*.

```
{
  "Code" : "Success",
  "LastUpdated" : "2012-04-26T16:39:16Z",
  "Type" : "AWS-HMAC",
  "AccessKeyId" : "ASIAIOSFODNN7EXAMPLE",
  "SecretAccessKey" : "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
  "Token" : "token",
  "Expiration" : "2017-05-17T15:09:54Z"
}
```

For applications, AWS CLI, and Tools for Windows PowerShell commands that run on the instance, you do not have to explicitly get the temporary security credentials—the AWS SDKs, AWS CLI, and Tools for Windows PowerShell automatically get the credentials from the EC2 instance metadata service and use them. To make a call outside of the instance using temporary security credentials (for example, to test IAM policies), you must provide the access key, secret key, and the session token. For more information, see Using Temporary Security Credentials to Request Access to AWS Resources in the *IAM User Guide*.

Grant permissions to attach an IAM role to an instance

The identities in your AWS account, such as IAM users, must have specific permissions to launch an Amazon EC2 instance with an IAM role, attach an IAM role to an instance, replace the IAM role for an instance, or detach an IAM role from an instance. You must grant permission to use the following API actions as required:

- `iam:PassRole`
- `ec2:AssociateIamInstanceProfile`
- `ec2:DisassociateIamInstanceProfile`
- `ec2:ReplaceIamInstanceProfileAssociation`

Note

If you specify the resource for `iam:PassRole` as `*`, this would grant access to pass any of your IAM roles to an instance. To follow the best practice of least privilege, specify the ARNs of specific IAM roles with `iam:PassRole`, as shown in the example policy below.

Example policy for programmatic access

The following IAM policy grants permissions to launch instances with an IAM role, attach an IAM role to an instance, or replace the IAM role for an instance using the AWS CLI or the Amazon EC2 API.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances",
         "ec2:AssociateIamInstanceProfile",
         "ec2:DisassociateIamInstanceProfile",
         "ec2:ReplaceIamInstanceProfileAssociation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::123456789012:role/DevTeam*"
    }
  ]
}
```

Additional requirement for console access

To grant permissions to complete the same tasks using the Amazon EC2 console, you must also include the `iam:ListInstanceProfiles` API action.

Attach an IAM role to an instance

You can create an IAM role and attach it to an instance during or after launch. You can also replace or detach IAM roles.

To attach an IAM role to an instance at launch using the Amazon EC2 console, expand **Advanced details**. For **IAM instance profile**, select the IAM role.

> **Note**
>
> If you created your IAM role using the IAM console, the instance profile was created for you and given the same name as the role. If you created your IAM role using the AWS CLI, API, or an AWS SDK, you might have given your instance profile a different name than the role.

You can attach an IAM role to an instance that is running or stopped. If the instance already has an IAM role attached, you must replace it with the new IAM role.

Console

To attach an IAM role to an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Security**, **Modify IAM role**.
5. For **IAM role**, select the IAM instance profile.
6. Choose **Update IAM role**.

AWS CLI

To attach an IAM role to an instance

Use the associate-iam-instance-profile command to attach the IAM role to the instance. When you specify the instance profile, you can use either the Amazon Resource Name (ARN) of the instance profile, or you can use its name.

```
aws ec2 associate-iam-instance-profile \
    --instance-id i-1234567890abcdef0 \
    --iam-instance-profile Name="TestRole-1"
```

PowerShell

To attach an IAM role to an instance

Use the Register-EC2IamInstanceProfile cmdlet.

```
Register-EC2IamInstanceProfile `
    -InstanceId i-1234567890abcdef0 `
    -IamInstanceProfile_Name TestRole-1
```

To replace the IAM role on an instance that already has an attached IAM role, the instance must be running. You can do this if you want to change the IAM role for an instance without detaching the existing one first. For example, you can do this to ensure that API actions performed by applications running on the instance are not interrupted.

Console

To replace an IAM role for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Security**, **Modify IAM role**.
5. For **IAM role**, select the IAM instance profile.
6. Choose **Update IAM role**.

AWS CLI

To replace an IAM role for an instance

1. If required, use the describe-iam-instance-profile-associations command to get the association ID.

   ```
   aws ec2 describe-iam-instance-profile-associations \
       --filters Name=instance-id,Values=i-1234567890abcdef0 \
       --query IamInstanceProfileAssociations.AssociationId
   ```

2. Use the replace-iam-instance-profile-association command. Specify the association ID for the existing instance profile and the ARN or name of the new instance profile.

   ```
   aws ec2 replace-iam-instance-profile-association \
       --association-id iip-assoc-0044d817db6c0a4ba \
       --iam-instance-profile Name="TestRole-2"
   ```

PowerShell

To replace an IAM role for an instance

1. If required, use the Get-EC2IamInstanceProfileAssociation cmdlet to get the association ID.

```
(Get-EC2IamInstanceProfileAssociation -Filter @{Name="instance-id";
 Values="i-0636508011d8e966a"}).AssociationId
```

2. Use the Set-EC2IamInstanceProfileAssociation cmdlet. Specify the association ID for the existing instance profile and the ARN or name of the new instance profile.

```
Set-EC2IamInstanceProfileAssociation `
    -AssociationId iip-assoc-0044d817db6c0a4ba `
    -IamInstanceProfile_Name TestRole-2
```

You can detach an IAM role from an instance that is running or stopped.

Console

To detach an IAM role from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Security**, **Modify IAM role**.
5. For **IAM role**, choose **No IAM Role**.
6. Choose **Update IAM role**.
7. When promoted for confirmation, enter **Detach**, and then choose **Detach**.

AWS CLI

To detach an IAM role from an instance

1. If required, use describe-iam-instance-profile-associations to get the association ID for the IAM instance profile to detach.

```
aws ec2 describe-iam-instance-profile-associations \
```

```
    --filters Name=instance-id,Values=i-1234567890abcdef0 \
    --query IamInstanceProfileAssociations.AssociationId
```

2. Use the disassociate-iam-instance-profile command.

```
aws ec2 disassociate-iam-instance-profile --association-id iip-
assoc-0044d817db6c0a4ba
```

PowerShell

To detach an IAM role from an instance

1. If required, use Get-EC2IamInstanceProfileAssociation to get the association ID for the IAM instance profile to detach.

```
(Get-EC2IamInstanceProfileAssociation -Filter @{Name="instance-id";
 Values="i-0636508011d8e966a"}).AssociationId
```

2. Use the Unregister-EC2IamInstanceProfile cmdlet.

```
Unregister-EC2IamInstanceProfile -AssociationId iip-assoc-0044d817db6c0a4ba
```

Instance identity roles for Amazon EC2 instances

Each Amazon EC2 instance that you launch has an *instance identity role* that represents its identity. An instance identity role is a type of IAM role. AWS services and features that are integrated to use the instance identity role can use it to identify the instance to the service.

The instance identity role credentials are accessible from the Instance Metadata Service (IMDS) at `/identity-credentials/ec2/security-credentials/ec2-instance`. The credentials consist of an AWS temporary access key pair and a session token. They are used to sign AWS Sigv4 requests to the AWS services that use the instance identity role. The credentials are present in the instance metadata regardless of whether a service or feature that makes use of instance identity roles is enabled on the instance.

Instance identity roles are automatically created when an instance is launched, have no role-trust policy document, and are not subject to any identity or resource policy.

Supported services

The following AWS services use the instance identity role:

- **Amazon EC2 –** EC2 Instance Connect uses the instance identity role to update the host keys for a Linux instance.
- **Amazon GuardDuty –** GuardDuty Runtime Monitoring uses the instance identity role to allow the runtime agent to send security telemetry to the GuardDuty VPC endpoint.
- **AWS Security Token Service (AWS STS) –** Instance identity role credentials can be used with the AWS STS `GetCallerIdentity` action.
- **AWS Systems Manager –** When using Default Host Management Configuration, AWS Systems Manager uses the identity provided by the instance identity role to register EC2 instances. After identifying your instance, Systems Manager can pass your `AWSSystemsManagerDefaultEC2InstanceManagementRole` IAM role to your instance.

Instance identity roles can't be used with other AWS services or features because they do not have an integration with instance identity roles.

Instance identity role ARN

The instance identity role ARN takes the following format:

```
arn:aws-partition:iam::account-number:assumed-role/aws:ec2-instance/instance-id
```

For example:

```
arn:aws:iam::0123456789012:assumed-role/aws:ec2-instance/i-1234567890abcdef0
```

For more information about ARNs, see Amazon Resource Names (ARNs) in the *IAM User Guide*.

Update management for Amazon EC2 instances

We recommend that you regularly patch, update, and secure the operating system and applications on your EC2 instances. You can use AWS Systems Manager Patch Manager to automate the process of installing security-related updates for both the operating system and applications.

For EC2 instances in an Auto Scaling group, you can use the AWS-PatchAsgInstance runbook to help avoid instances that are undergoing patching from being replaced. Alternatively, you can use any automatic update services or recommended processes for installing updates that are provided by the application vendor.

Resources

- **AL2023 –** Updating AL2023 in the *Amazon Linux 2023 User Guide*
- **AL2 –** Manage software on your Amazon Linux 2 instance in the *Amazon Linux 2 User Guide*
- **Windows instances –** the section called "Update management"

Security best practices for Windows instances

We recommend that you follow these security best practices for your Windows instances.

Contents

High-level security best practices

You should adhere to the following high-level security best practices for your Windows instances:

- **Least access –** Grant access only to systems and locations that are trusted and expected. This applies to all Microsoft products such as Active Directory, Microsoft business productivity servers, and infrastructure services such as Remote Desktop Services, reverse proxy servers, IIS web servers,and more. Use AWS capabilities such as Amazon EC2 instance security groups, network access control lists (ACLs), and Amazon VPC public/private subnets to layer security across multiple locations in an architecture. Within a Windows instance, customers can use Windows Firewall to further layer a defense-in-depth strategy within their deployment. Install only the OS components and applications that are necessary for the system to function as designed. Configure infrastructure services such as IIS to run under service accounts, or to use features such as application pool identities to access resources locally and remotely across your infrastructure.
- **Least privilege –** Determine the minimum set of privileges that instances and accounts need in order to perform their functions. Restrict these servers and users to only allow these defined

permissions. Use techniques such as Role Based Access Controls to reduce the surface area of administrative accounts, and create the most limited roles to accomplish a task. Use OS features such as Encrypting File System (EFS) within NTFS to encrypt sensitive data at rest, and control application and user access to it.

- **Configuration management –** Create a baseline server configuration that incorporates up-to-date security patches and host-based protection suites that include anti-virus, anti-malware, intrusion detection/prevention, and file integrity monitoring. Assess each server against the current recorded baseline to identify and flag any deviations. Ensure each server is configured to generate and securely store appropriate log and audit data.
- **Change management –** Create processes to control changes to server configuration baselines and work toward fully automated change processes. Also, leverage Just Enough Administration (JEA) with Windows PowerShell DSC to limit administrative access to the minimum required functions.
- **Patch management –** Implement processes that regularly patch, update, and secure the operating system and applications on your EC2 instances.
- **Audit logs –** Audit access and all changes to Amazon EC2 instances to verify server integrity and ensure only authorized changes are made. Leverage features such as Enhanced Logging for IIS to enhance default logging capabilities. AWS capabilities such as VPC Flow Logs and AWS CloudTrail are also available to audit network access, including allowed/denied requests and API calls, respectively.

Update management

To ensure the best results when you run Windows Server on Amazon EC2, we recommend that you implement the following best practices:

- Configure Windows Update
- Update drivers
- Use the latest Windows AMIs
- Test performance before migration
- Update launch agents
- Reboot your Windows instance after you install updates. For more information, see Reboot your Amazon EC2 instance.

For information about how to upgrade or migrate a Windows instance to a newer version of Windows Server, see Upgrade an EC2 Windows instance to a newer version of Windows Server.

Configure Windows Update

By default, instances that are launched from AWS Windows Server AMIs don't receive updates through Windows Update.

Update Windows drivers

Maintain the latest drivers on all Windows EC2 instances to ensure that the latest issue fixes and performance enhancements are applied across your fleet. Depending on your instance type, you should update the AWS PV, Amazon ENA, and AWS NVMe drivers.

- Use SNS topics to receive updates for new driver releases.
- Use the AWS Systems Manager Automation runbook AWSSupport-UpgradeWindowsAWSDrivers to easily apply the updates across your instances.

Launch instances using the latest Windows AMIs

AWS releases new Windows AMIs each month, which contain the latest OS patches, drivers, and launch agents. You should leverage the latest AMI when you launch new instances or when you build your own custom images.

- To view updates to each release of the AWS Windows AMIs, see AWS Windows AMI version history.
- To build with the latest available AMIs, see Query for the Latest Windows AMI Using Systems Manager Parameter Store.
- For more information about specialized Windows AMIs that you can use to launch instances for your database and compliance hardening use cases, see Specialized Windows AMIs in the *AWS Windows AMI Reference*.

Test system/application performance before migration

Migrating enterprise applications to AWS can involve many variables and configurations. Always performance test the EC2 solution to ensure that:

- Instance types are properly configured, including instance size, enhanced networking, and tenancy (shared or dedicated).

- Instance topology is appropriate for the workload and leverages high-performance features when necessary, such as dedicated tenancy, placement groups, instance store volumes, and bare metal.

Install the latest version of EC2Launch v2

Install the latest EC2Launch v2 agent to ensure that the latest enhancements are applied across your fleet. For more information, see Install EC2Launch v2.

If you have a mixed fleet, or if you want to continue to use the EC2Launch (Windows Server 2016 and 2019) or EC2 Config (legacy OS only) agents, update to the latest versions of the respective agents.

Automatic updates are supported on the following combinations of Windows Server version and launch agents. You can opt in to automatic updates in the SSM Quick Setup Host Management console under **Amazon EC2 Launch Agents**.

Windows Version	EC2Launch v1	EC2Launch v2
2016	✓	✓
2019	✓	✓
2022		✓

- For more information about updating to EC2Launch v2, see the section called “Install EC2Launch v2”.
- For information to manually update EC2Config, see the section called “Install EC2Config”.
- For information to manually update EC2Launch, see the section called “Install EC2Launch”.

Configuration management

Amazon Machine Images (AMIs) provide an initial configuration for an Amazon EC2 instance, which includes the Windows OS and optional customer-specific customizations, such as applications and security controls. Create an AMI catalog containing customized security configuration baselines to ensure that all Windows instances are launched with standard security controls. Security baselines can be baked into an AMI, bootstrapped dynamically when an EC2 instance is launched, or packaged as a product for uniform distribution through AWS Service Catalog portfolios. For more information on securing an AMI, see Best Practices for Building an AMI.

Each Amazon EC2 instance should adhere to organizational security standards. Do not install any Windows roles and features that are not required, and do install software to protect against malicious code (antivirus, antimalware, exploit mitigation), monitor host-integrity, and perform intrusion detection. Configure security software to monitor and maintain OS security settings, protect the integrity of critical OS files, and alert on deviations from the security baseline. Consider implementing recommended security configuration benchmarks published by Microsoft, the Center for Internet Security (CIS), or the National Institute of Standards and Technology (NIST). Consider using other Microsoft tools for particular application servers, such as the Best Practice Analyzer for SQL Server.

AWS customers can also run Amazon Inspector assessments to improve the security and compliance of applications deployed on Amazon EC2 instances. Amazon Inspector automatically assesses applications for vulnerabilities or deviations from best practices and includes a knowledge base of hundreds of rules mapped to common security compliance standards (for example, PCI DSS) and vulnerability definitions. Examples of built-in rules include checking if remote root login is enabled, or if vulnerable software versions are installed. These rules are regularly updated by AWS security researchers.

When securing Windows instances, we recommend that you implement Active Directory Domain Services to enable a scalable, secure, and manageable infrastructure for distributed locations. Additionally, after launching instances from the Amazon EC2 console or by using an Amazon EC2 provisioning tool, such as AWS CloudFormation, it is good practice to utilize native OS features, such as Microsoft Windows PowerShell DSC to maintain configuration state in the event that configuration drift occurs.

Change management

After initial security baselines are applied to Amazon EC2 instances at launch, control ongoing Amazon EC2 changes to maintain the security of your virtual machines. Establish a change management process to authorize and incorporate changes to AWS resources (such as security groups, route tables, and network ACLs) as well as to OS and application configurations (such as Windows or application patching, software upgrades, or configuration file updates).

AWS provides several tools to help manage changes to AWS resources, including AWS CloudTrail, AWS Config, AWS CloudFormation, and AWS Elastic Beanstalk, and management packs for Systems

Center Operations Manager and System Center Virtual Machine Manager. Note that Microsoft releases Windows patches the second Tuesday of each month (or as needed) and AWS updates all Windows AMIs managed by AWS within five days after Microsoft releases a patch. Therefore it is important to continually patch all baseline AMIs, update AWS CloudFormation templates and Auto Scaling group configurations with the latest AMI IDs, and implement tools to automate running instance patch management.

Microsoft provides several options for managing Windows OS and application changes. SCCM, for example, provides full lifecycle coverage of environment modifications. Select tools that address business requirements and control how changes will affect application SLAs, capacity, security, and disaster recovery procedures. Avoid manual changes and instead leverage automated configuration management software or command line tools such as the EC2 Run Command or Windows PowerShell to implement scripted, repeatable change processes. To assist with this requirement, use bastion hosts with enhanced logging for all interactions with your Windows instances to ensure that all events and tasks are automatically recorded.

Audit and accountability for Amazon EC2 Windows instances

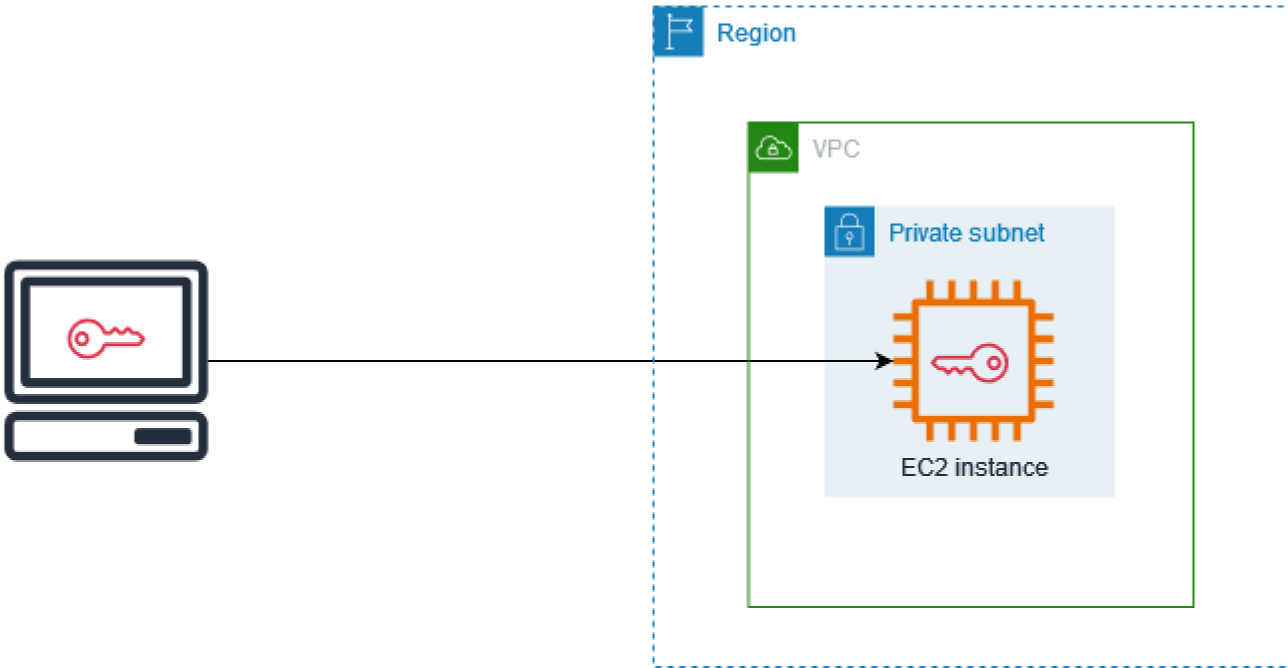
AWS CloudTrail, AWS Config, and AWS Config Rules provide audit and change tracking features for auditing AWS resource changes. Configure Windows event logs to send local log files to a centralized log management system to preserve log data for security and operational behavior analysis. Microsoft System Center Operations Manager (SCOM) aggregates information about Microsoft applications deployed to Windows instances and applies preconfigured and custom rulesets based on application roles and services. System Center Management Packs build on SCOM to provide application-specific monitoring and configuration guidance. These Management Packs support Windows Server Active Directory, SharePoint Server 2013, Exchange Server 2013, Lync Server 2013, SQL Server 2014, and many more servers and technologies.

In addition to Microsoft systems management tools, customers can use Amazon CloudWatch to monitor instance CPU utilization, disk performance, network I/O, and perform host and instance status checks. The EC2Config, EC2Launch, and EC2Launch v2 launch agents provide access to additional, advanced features for Windows instances. For example, they can export Windows system, security, application, and Internet Information Services (IIS) logs to CloudWatch Logs which can then be integrated with Amazon CloudWatch metrics and alarms. Customers can also create scripts that export Windows performance counters to Amazon CloudWatch custom metrics.

Amazon EC2 key pairs and Amazon EC2 instances

A key pair, consisting of a public key and a private key, is a set of security credentials that you use to prove your identity when connecting to an Amazon EC2 instance. For Linux instances, the private key allows you to securely SSH into your instance. For Windows instances, the private key is required to decrypt the administrator password, which you then use to connect to your instance.

Amazon EC2 stores the public key on your instance, and you store the private key, as shown in the following diagram. It's important that you store your private key in a secure place because anyone who possesses your private key can connect to your instances that use the key pair.



When you launch an instance, you can specify a key pair, so that you can connect to your instance using a method that requires a key pair. Depending on how you manage your security, you can specify the same key pair for all your instances or you can specify different key pairs.

For Linux instances, when your instance boots for the first time, the public key that you specified at launch is placed on your Linux instance in an entry within `~/.ssh/authorized_keys`. When you connect to your Linux instance using SSH, to log in you must specify the private key that corresponds to the public key.

For more information about connecting to your EC2 instance, see Connect to your EC2 instance.

Important

Because Amazon EC2 doesn't keep a copy of your private key, there is no way to recover a private key if you lose it. However, there can still be a way to connect to instances for which you've lost the private key. For more information, see I've lost my private key. How can I connect to my instance?

As an alternative to key pairs, you can use AWS Systems Manager Session Manager to connect to your instance with an interactive one-click browser-based shell or the AWS Command Line Interface (AWS CLI).

Contents

Create a key pair for your Amazon EC2 instance

You can use Amazon EC2 to create your key pairs, or you can use a third-party tool to create your key pairs, and then import them to Amazon EC2.

Amazon EC2 supports 2048-bit SSH-2 RSA keys for Linux and Windows instances. Amazon EC2 also supports ED25519 keys for Linux instances.

For instructions on how to connect to your instance after you have created a key pair, see the section called “Connect to your Linux instance using SSH” and the section called “Connect to your Windows instance using RDP”.

Contents

Create a key pair using Amazon EC2

When you create a key pair using Amazon EC2, the public key is stored in Amazon EC2, and you store the private key.

You can create up to 5,000 key pairs per Region. To request an increase, create a support case. For more information, see Creating a support case in the *Support User Guide*.

Console

To create a key pair using Amazon EC2

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under **Network & Security**, choose **Key Pairs**.
3. Choose **Create key pair**.
4. For **Name**, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can’t include leading or trailing spaces.
5. Select a key pair type appropriate for your operating system:

   (Linux instances) For **Key pair type**, choose either **RSA** or **ED25519**.

   (Windows instances) For **Key pair type**, choose **RSA**. **ED25519** keys are not supported for Windows instances.
6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.
7. To add a tag to the public key, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
8. Choose **Create key pair**.
9. The private key file is automatically downloaded by your browser. The base file name is the name that you specified as the name of your key pair, and the file name extension is determined by the file format that you chose. Save the private key file in a safe place.

   > **Important**
   >
   > This is the only chance for you to save the private key file.

10. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

    ```
    chmod 400 key-pair-name.pem
    ```

    If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.

AWS CLI

To create a key pair using Amazon EC2

1. Use the create-key-pair command as follows to generate the key pair and to save the private key to a `.pem` file. The `--query` option prints the private key material to the output. The `--output` option saves the private key material in the specified file. The extension should be either `.pem` or `.ppk`, depending on the key format. The private key name can be different from the public key name, but for ease of use, use the same name.

    ```
    aws ec2 create-key-pair \
        --key-name my-key-pair \
        --key-type rsa \
        --key-format pem \
        --query "KeyMaterial" \
        --output text > my-key-pair.pem
    ```

2. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

    ```
    chmod 400 key-pair-name.pem
    ```

    If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.

PowerShell

To create a key pair using Amazon EC2

Use the New-EC2KeyPair cmdlet as follows to generate the key and save it to a .pem or .ppk file. The **Out-File** cmdlet saves the private key material in a file with the specified extension. The extension should be either .pem or .ppk, depending on the key format. The private key name can be different from the public key name, but for ease of use, use the same name.

```
(New-EC2KeyPair `
    -KeyName "my-key-pair" `
    -KeyType "rsa" `
    -KeyFormat "pem").KeyMaterial | Out-File -Encoding ascii -FilePath C:\path\my-
key-pair.pem
```

Create a key pair using AWS CloudFormation

When you create a new key pair using AWS CloudFormation, the private key is saved to AWS Systems Manager Parameter Store. The parameter name has the following format:

```
/ec2/keypair/key_pair_id
```

For more information, see AWS Systems Manager Parameter Store in the *AWS Systems Manager User Guide*.

To create a key pair using AWS CloudFormation

1. Specify the AWS::EC2::KeyPair resource in your template.

```
Resources:
  NewKeyPair:
    Type: 'AWS::EC2::KeyPair'
    Properties:
      KeyName: new-key-pair
```

2. Use the describe-key-pairs command as follows to get the ID of the key pair.

```
aws ec2 describe-key-pairs --filters Name=key-name,Values=new-key-pair --query
 KeyPairs[*].KeyPairId --output text
```

The following is example output.

```
key-05abb699beEXAMPLE
```

3. Use the get-parameter command as follows to get the parameter for your key and save the key material in a `.pem` file.

```
aws ssm get-parameter --name /ec2/keypair/key-05abb699beEXAMPLE --with-decryption
 --query Parameter.Value --output text > new-key-pair.pem
```

Required IAM permissions

To enable AWS CloudFormation to manage Parameter Store parameters on your behalf, the IAM role assumed by AWS CloudFormation or your user must have the following permissions:

- `ssm:PutParameter` – Grants permission to create a parameter for the private key material.
- `ssm:DeleteParameter` – Grants permission to delete the parameter that stored the private key material. This permission is required whether the key pair was imported or created by AWS CloudFormation.

When AWS CloudFormation deletes a key pair that was created or imported by a stack, it performs a permissions check to determine whether you have permission to delete parameters, even though AWS CloudFormation creates a parameter only when it creates a key pair, not when it imports a key pair. AWS CloudFormation tests for the required permission using a fabricated parameter name that does not match any parameter in your account. Therefore, you might see a fabricated parameter name in the `AccessDeniedException` error message.

Create a key pair using a third-party tool and import the public key to Amazon EC2

Instead of using Amazon EC2 to create a key pair, you can create an RSA or ED25519 key pair by using a third-party tool and then import the public key to Amazon EC2.

Requirements for key pairs

- Supported types:
  - (Linux and Windows) RSA
  - (Linux only) ED25519

> **Note**
>
> ED25519 keys are not supported for Windows instances.

  - Amazon EC2 does not accept DSA keys.
- Supported formats:
  - OpenSSH public key format (for Linux, the format in `~/.ssh/authorized_keys`)
  - (Linux only) If you connect using SSH while using the EC2 Instance Connect API, the SSH2 format is also supported.
  - SSH private key file format must be PEM or PPK
  - (RSA only) Base64 encoded DER format
  - (RSA only) SSH public key file format as specified in RFC 4716
- Supported lengths:
  - 1024, 2048, and 4096.
  - (Linux only) If you connect using SSH while using the EC2 Instance Connect API, the supported lengths are 2048 and 4096.

To create a key pair using a third-party tool

1. Generate a key pair with a third-party tool of your choice. For example, you can use **ssh-keygen** (a tool provided with the standard OpenSSH installation). Alternatively, Java, Ruby, Python, and many other programming languages provide standard libraries that you can use to create a key pair.

   > **Important**
   >
   > The private key must be in the PEM or PPK format. For example, use `ssh-keygen -m PEM` to generate the OpenSSH key in the PEM format.

2. Save the public key to a local file. For example, `~/.ssh/my-key-pair.pub` (Linux, macOS) or `C:\keys\my-key-pair.pub` (Windows). The file name extension for this file is not important.
3. Save the private key to a local file that has the `.pem` or `.ppk` extension. For example, `~/.ssh/my-key-pair.pem` or `~/.ssh/my-key-pair.ppk` (Linux, macOS) or `C:\keys\my-key-`

`pair.pem` or `C:\keys\my-key-pair.ppk` (Windows). The file extension is important because, depending on the tool you use to connect to your instance, you'll need a specific file format. OpenSSH requires a `.pem` file, while PuTTY requires a `.ppk` file.

> **Important**
>
> Save the private key file in a safe place. You'll need to provide the name of your public key when you launch an instance, and the corresponding private key each time you connect to the instance.

After you have created the key pair, use one of the following methods to import your public key to Amazon EC2.

Console

To import the public key to Amazon EC2

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Key Pairs**.
3. Choose **Import key pair**.
4. For **Name**, enter a descriptive name for the public key. The name can include up to 255 ASCII characters. It can’t include leading or trailing spaces.

   > **Note**
   >
   > When you connect to your instance from the EC2 console, the console suggests this name for the name of your private key file.

5. Either choose **Browse** to navigate to and select your public key, or paste the contents of your public key into the **Public key contents** field.
6. Choose **Import key pair**.
7. Verify that the public key that you imported appears in the list of key pairs.

AWS CLI

To import the public key to Amazon EC2

Use the import-key-pair command.

```
aws ec2 import-key-pair \
    --key-name my-key-pair \
    --public-key-material fileb://path/my-key-pair.pub
```

To verify that the key pair was imported successfully

Use the describe-key-pairs command.

```
aws ec2 describe-key-pairs --key-names my-key-pair
```

PowerShell

To import the public key to Amazon EC2

Use the Import-EC2KeyPair cmdlet.

```
$publickey=[Io.File]::ReadAllText("C:\Users\TestUser\.ssh\id_rsa.pub")
Import-EC2KeyPair `
    -KeyName my-key-pair `
    -PublicKey $publickey
```

To verify that the key pair was imported successfully

Use the Get-EC2KeyPair cmdlet.

```
Get-EC2KeyPair -KeyName my-key-pair
```

Describe your key pairs

You can describe the key pairs that you stored in Amazon EC2. You can also retrieve the public key material and identify the public key that was specified at launch.

Tasks

- Describe your key pairs
- Retrieve the public key material
- Identify the public key specified at launch

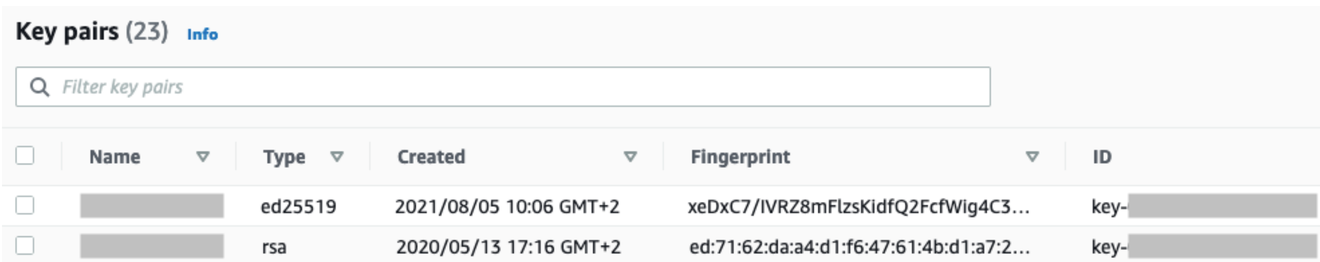
Describe your key pairs

You can view the following information about your public keys that are stored in Amazon EC2: public key name, ID, key type, fingerprint, public key material, the date and time (in the UTC time zone) the key was created by Amazon EC2 (if the key was created by a third-party tool, then it's the date and time the key was imported to Amazon EC2), and any tags that are associated with the public key.

Console

To view information about your key pairs

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose **Key Pairs**.
3. You can view the information about each public key in the **Key pairs** table.



4. To view a public key's tags, select the checkbox next to the key, and then choose **Actions**, **Manage tags**.

AWS CLI

To view information about a key pair

Use the describe-key-pairs command.

```
aws ec2 describe-key-pairs --key-names key-pair-name
```

PowerShell

To view information about a key pair

Use the Get-EC2KeyPair cmdlet.

```
Get-EC2KeyPair -KeyName key-pair-name
```

Retrieve the public key material

You can get the public key material for your key pairs. The following is an example public key. Note that there are line breaks added for readability.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6V
hz2ItxCih+PnDSUaw+WNQn/mZphTk/a/gU8jEzoOWbkM4yxyb/wB96xbiFveSFJuOp/d6RJhJOI0iBXr
lsLnBItntckiJ7FbtxJMXLvvwJryDUilBMTjYtwB+QhYXUMOzce5Pjz5/i8SeJtjnV3iAoG/cQk+0FzZ
qaeJAAHco+CY/5WrUBkrHmFJr6HcXkvJdWPkYQS3xqC0+FmUZofz221CBt5IMucxXPkX4rWi+z7wB3Rb
BQoQzd8v7yeb7OzlPnWOyN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
```

Private key

To retrieve the public key material using ssh-keygen (Linux)

On your local Linux or macOS computer, use the **ssh-keygen** command. Specify the path where you downloaded your private key (the `.pem` file).

```
ssh-keygen -y -f /path_to_key_pair/my-key-pair.pem
```

If this **ssh-keygen** command fails, run the following **chmod** command to ensure that the private key file has the required permissions.

```
chmod 400 key-pair-name.pem
```

To retrieve the public key material using PuTTYgen (Windows)

On your local Windows computer, start PuTTYgen. Choose **Load**. Select the `.ppk` or `.pem` private key file. PuTTYgen displays the public key under **Public key for pasting into OpenSSH authorized_keys file**. You can also view the public key by choosing **Save public key**, specifying a name for the file, saving the file, and then opening the file.

AWS CLI

To retrieve the public key material

Use the following describe-key-pairs command and specify the `--include-public-key` option.

```
aws ec2 describe-key-pairs \
    --key-names key-pair-name \
    --include-public-key \
```

```
    --query "KeyPairs[].PublicKey"
```

PowerShell

To retrieve the public key material

Use the Get-EC2KeyPair cmdlet.

```
(Get-EC2KeyPair -KeyName key-pair-name -IncludePublicKey $true).PublicKey
```

IMDSv2

Linux

Run the following commands from your Linux instance.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key
```

Windows

Run the following cmdlets from your Windows instance.

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key
```

Windows

Run the following cmdlet from your Windows instance.

```
Invoke-RestMethod -uri  http://169.254.169.254/latest/meta-data/public-keys/0/
openssh-key
```

Identify the public key specified at launch

If you specify a public key when you launch an instance, the public key name is recorded by the instance. The public key name reported for an instance does not change, even if you change the public key on the instance or add public keys.

Console

To identify the public key specified at instance launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Instance details**, find **Key pair assigned at launch**.

AWS CLI

To identify the public key specified at instance launch

Use the following describe-instances command.

```
aws ec2 describe-instances \
    --instance-id i-1234567890abcdef0 \
    --query "Reservations[].Instances[].KeyName" \
    --output text
```

The following is example output.

```
key-pair-name
```

PowerShell

To identify the public key specified at instance launch

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances | Select KeyName
```

The following is example output.

```
KeyName
-------
key-pair-name
```

Delete your key pair

You can delete a key pair, which removes the public key that is stored in Amazon EC2. Deleting a key pair does not delete the matching private key.

When you delete a public key using the following methods, you're only deleting the public key that you stored in Amazon EC2 when you created or imported the key pair. Deleting a public key doesn't remove the public key from any instances to which you've added it, either when you launched the instance or later. It also doesn't delete the private key on your local computer. You can continue to connect to instances that you launched using a public key that you've deleted from Amazon EC2 as long as you still have the private key (`.pem`) file.

Important

If you're using an Auto Scaling group (for example, in an Elastic Beanstalk environment), ensure that the public key you're deleting is not specified in an associated launch template or launch configuration. If Amazon EC2 Auto Scaling detects an unhealthy instance, it launches a replacement instance. However, the instance launch fails if the public key cannot be found. For more information, see Launch templates in the *Amazon EC2 Auto Scaling User Guide*.

Console

To delete your public key on Amazon EC2

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Key Pairs**.
3. Select the key pair to delete and choose **Actions**, **Delete**.

4. In the confirmation field, enter `Delete` and then choose **Delete**.

AWS CLI

To delete your public key on Amazon EC2

Use the delete-key-pair command.

```
aws ec2 delete-key-pair --key-name my-key-pair
```

PowerShell

To delete your public key on Amazon EC2

Use the Remove-EC2KeyPair cmdlet.

```
Remove-EC2KeyPair -KeyName my-key-pair
```

Add or replace a public key on your Linux instance

If you lose a private key, you lose access to any instances that use the key pair. For more information about connecting to an instance using a different key pair than the one that you specified at launch, see I've lost my private key.

When you launch an instance, you can specify a key pair. If you specify a key pair at launch, when your instance boots for the first time, the public key material is placed on your Linux instance in an entry within `~/.ssh/authorized_keys`.

You can change the key pair that is used to access the default system account of your instance by adding a new public key on the instance, or by replacing the public key (deleting the existing public key and adding a new one) on the instance. You can also remove all public keys from an instance. To add or replace a key pair, you must be able to connect to your instance.

You might add or replace a key pair for the following reasons:

- If a user in your organization requires access to the system user using a separate key pair, you can add the public key to your instance.

- If someone has a copy of the private key (`.pem` file) and you want to prevent them from connecting to your instance (for example, if they've left your organization), you can delete the public key on the instance and replace it with a new one.
- If you create a Linux AMI from an instance, the public key material is copied from the instance to the AMI. If you launch an instance from the AMI, the new instance includes the public key from the original instance. To prevent someone who has the private key from connecting to the new instance, you can remove the public key from the original instance *before* creating the AMI.

Use the following procedures to modify the key pair for the default user, such as `ec2-user`. For information about adding users to your instance, see the documentation for the operating system on your instance.

To add or replace a key pair

1. Create a new key pair using the Amazon EC2 console or a third-party tool.
2. Retrieve the public key from your new key pair. For more information, see Retrieve the public key material.
3. Connect to your instance using your existing private key.
4. Using a text editor of your choice, open the `.ssh/authorized_keys` file on the instance. Paste the public key information from your new key pair underneath the existing public key information. Save the file.
5. Disconnect from your instance, and test that you can connect to your instance using the new private key file.
6. (Optional) If you're replacing an existing key pair, connect to your instance and delete the public key information for the original key pair from the `.ssh/authorized_keys` file.

Important

If you're using an Auto Scaling group, ensure that the key pair you're replacing is not specified in your launch template or launch configuration. If Amazon EC2 Auto Scaling detects an unhealthy instance, it launches a replacement instance. However, the instance launch fails if the key pair cannot be found. For more information, see Launch templates in the *Amazon EC2 Auto Scaling User Guide*.

To remove a public key from an instance

1. Connect to your instance.
2. Using a text editor of your choice, open the `.ssh/authorized_keys` file on the instance. Delete the public key information, and then save the file.

> **Warning**
>
> After you remove all the public keys from an instance and disconnect from the instance, you can't connect to it again unless the AMI provides another way of logging in.

Verify the fingerprint of your key pair

To verify the fingerprint of your key pair, compare the fingerprint displayed on the **Key pairs** page in the Amazon EC2 console, or returned by the describe-key-pairs command, with the fingerprint that you generate using the private key on your local computer. These fingerprints should match.

When Amazon EC2 calculates a fingerprint, Amazon EC2 might append padding to the fingerprint with = characters. Other tools, such as **ssh-keygen**, might omit this padding.

If you're trying to verify the fingerprint of your Linux EC2 instance, not the fingerprint of your key pair, see Get the instance fingerprint.

How the fingerprints are calculated

Amazon EC2 uses different hash functions to calculate the fingerprints for RSA and ED25519 key pairs. Furthermore, for RSA key pairs, Amazon EC2 calculates the fingerprints differently using different hash functions depending on whether the key pair was created by Amazon EC2 or imported to Amazon EC2.

The following table lists the hash functions that are used to calculate the fingerprints for RSA and ED25519 key pairs that are created by Amazon EC2 and imported to Amazon EC2.

(Linux instances) Hash functions used to calculate fingerprints

Key pair source	RSA key pairs (Windows and Linux)	ED25519 key pairs (Linux)
Created by Amazon EC2	SHA-1	SHA-256
Imported to Amazon EC2	MD5[1]	SHA-256

[1] If you import a public RSA key to Amazon EC2, the fingerprint is calculated using an MD5 hash function. This is true regardless of how you created the key pair, for example, by using a third-party tool or by generating a new public key from an existing private key created using Amazon EC2.

When using the same key pair in different Regions

If you plan to use the same key pair to connect to instances in different AWS Regions, you must import the public key to all of the Regions in which you'll use it. If you use Amazon EC2 to create the key pair, you can Retrieve the public key material so that you can import the public key to the other Regions.

Note

- If you create an RSA key pair using Amazon EC2, and then you generate a public key from the Amazon EC2 private key, the imported public keys will have a different fingerprint than the original public key. This is because the fingerprint of the original RSA key created using Amazon EC2 is calculated using a SHA-1 hash function, while the fingerprint of the imported RSA keys is calculated using an MD5 hash function.
- For ED25519 key pairs, the fingerprints will be same regardless of whether they’re created by Amazon EC2 or imported to Amazon EC2, because the same SHA-256 hash function is used to calculate the fingerprint.

Generate a fingerprint from the private key

Use one of the following commands to generate a fingerprint from the private key on your local machine.

If you're using a Windows local machine, you can run the following commands using the Windows Subsystem for Linux (WSL). Install the WSL and a Linux distribution using the instructions in the [How to install Linux on Windows with WSL](). The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

- **If you created the key pair using Amazon EC2**

  Use the OpenSSL tools to generate a fingerprint as shown in the following examples.

  For RSA key pairs:

  ```
  openssl pkcs8 -in path_to_private_key -inform PEM -outform DER -topk8 -nocrypt |
   openssl sha1 -c
  ```

  (Linux instances) For ED25519 key pairs:

  ```
  ssh-keygen -l -f path_to_private_key
  ```

- **(RSA key pairs only) If you imported the public key to Amazon EC2**

  You can follow this procedure regardless of how you created the key pair, for example, by using a third-party tool or by generating a new public key from an existing private key created using Amazon EC2

  Use the OpenSSL tools to generate the fingerprint as shown in the following example.

  ```
  openssl rsa -in path_to_private_key -pubout -outform DER | openssl md5 -c
  ```

- **If you created an OpenSSH key pair using OpenSSH 7.8 or later and imported the public key to Amazon EC2**

  Use **ssh-keygen** to generate the fingerprint as shown in the following examples.

  For RSA key pairs:

  ```
  ssh-keygen -ef path_to_private_key -m PEM | openssl rsa -RSAPublicKey_in -outform DER
   | openssl md5 -c
  ```

  (Linux instances) For ED25519 key pairs:

```
ssh-keygen -l -f path_to_private_key
```

Amazon EC2 security groups for your EC2 instances

A *security group* acts as a virtual firewall for your EC2 instances to control incoming and outgoing traffic. Inbound rules control the incoming traffic to your instance, and outbound rules control the outgoing traffic from your instance. When you launch an instance, you can specify one or more security groups. If you don't specify a security group, Amazon EC2 uses the default security group for the VPC. After you launch an instance, you can change its security groups.

Security is a shared responsibility between AWS and you. For more information, see Security in Amazon EC2. AWS provides security groups as one of the tools for securing your instances, and you need to configure them to meet your security needs. If you have requirements that aren't fully met by security groups, you can maintain your own firewall on any of your instances in addition to using security groups.

Pricing

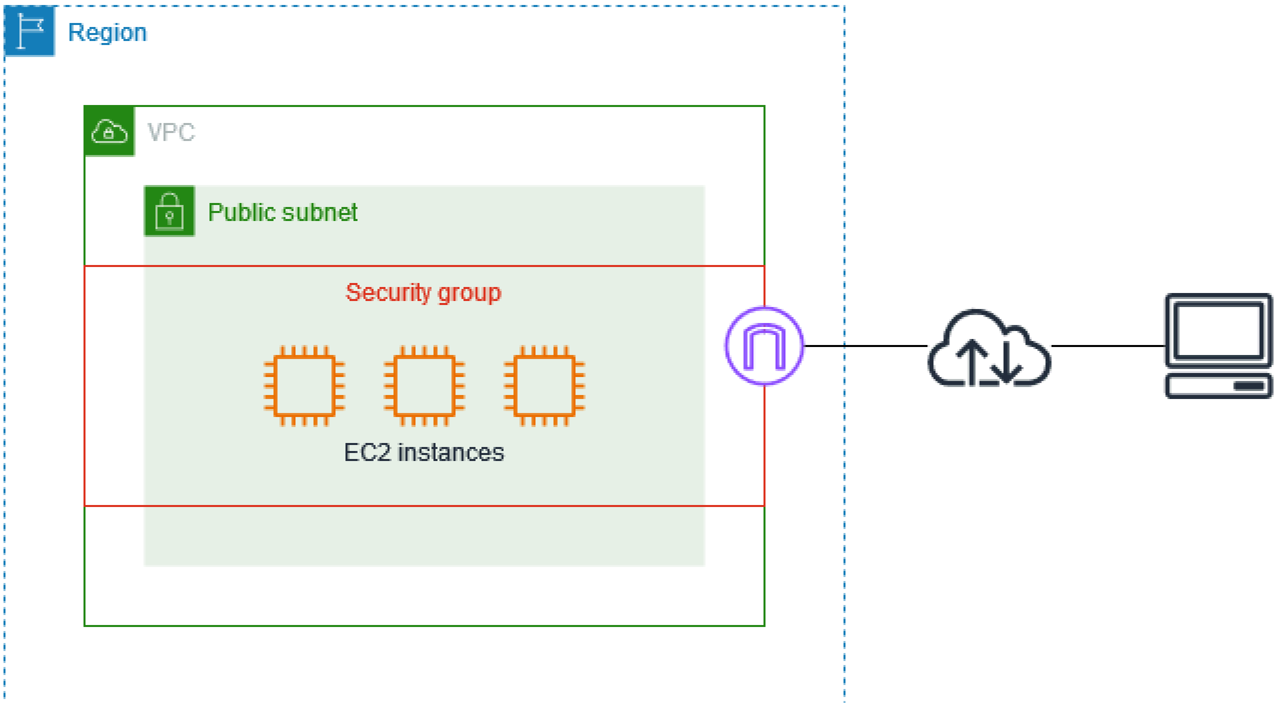
There is no additional charge for using security groups.

Contents

Overview

You can associate each instance with multiple security groups, and you can associate each security group with multiple instances. You add rules to each security group that allow traffic to or from its associated instances. You can modify the rules for a security group at any time. New and modified rules are automatically applied to all instances that are associated with the security group. When Amazon EC2 decides whether to allow traffic to reach an instance, it evaluates all rules from all security groups that are associated with the instance. For more information, see Security group rules in the *Amazon VPC User Guide*.

The following diagram shows a VPC with a subnet, an internet gateway, and a security group. The subnet contains EC2 instances. The security group is associated with the instances. The only traffic that reaches the instance is the traffic allowed by the security group rules. For example, if the security group contains a rule that allows SSH traffic from your network, then you can connect to your instance from your computer using SSH. If the security group contains a rule that allows all traffic from the resources associated with it, then each instance can receive any traffic sent from the other instances.



Security groups are stateful—if you send a request from your instance, the response traffic for that request is allowed to flow in regardless of inbound security group rules. Also, responses to allowed inbound traffic are allowed to flow out, regardless of outbound rules. For more information, see Connection tracking.

Create a security group for your Amazon EC2 instance

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You can add rules to a security group that enable you to connect to your instance using SSH (Linux instances) or RDP (Windows instances). You can also add rules that allow client traffic, for example, HTTP and HTTPS traffic destined to a web server.

You can associate a security group with an instance when you launch the instance. When you add or remove rules from associated security groups, those changes are automatically applied to all instances to which you've associated the security group.

After you launch an instance, you can associate additional security groups. For more information, see Change the security groups for your Amazon EC2 instance.

You can add inbound and outbound security group rules when you create a security group or you can add them later on. For more information, see Configure security group rules. For examples of rules that you can add to a security group, see Security group rules for different use cases.

Considerations

- New security groups start with only an outbound rule that allows all traffic to leave the resource. You must add rules to enable any inbound traffic or to restrict the outbound traffic.
- When configuring a source for a rule that allows SSH or RDP access to your instances, do not allow access from anywhere, because it would allow this access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.
- If there is more than one rule for a specific port, Amazon EC2 applies the most permissive rule. For example, if you have a rule that allows access to TCP port 22 (SSH) from IP address 203.0.113.1, and another rule that allows access to TCP port 22 from anywhere, then everyone has access to TCP port 22.
- You can associate multiple security groups with an instance. Therefore, an instance can have hundreds of rules that apply. This might cause problems when you access the instance. We recommend that you condense your rules as much as possible.
- When you specify a security group as the source or destination for a rule, the rule affects all instances that are associated with the security group. Incoming traffic is allowed based on the private IP addresses of the instances that are associated with the source security group (and not the public IP or Elastic IP addresses). For more information about IP addresses, see Amazon EC2 instance IP addressing.
- Amazon EC2 blocks traffic on port 25 by default. For more information, see Restriction on email sent using port 25.

Console

To create a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create security group**.
4. Enter a descriptive name and brief description for the security group. You can't change the name and description of a security group after it is created.
5. For **VPC**, choose the VPC in which you'll run your Amazon EC2 instances.
6. (Optional) To add inbound rules, choose **Inbound rules**. For each rule, choose **Add rule** and specify the protocol, port, and source. For example, to allow SSH traffic, choose **SSH** for **Type** and specify the public IPv4 address of your computer or network for **Source**.
7. (Optional) To add outbound rules, choose **Outbound rules**. For each rule, choose **Add rule** and specify the protocol, port, and destination. Otherwise, you can keep the default rule, which allows all outbound traffic.
8. (Optional) To add a tag, choose **Add new tag** and enter the tag key and value.
9. Choose **Create security group**.

AWS CLI

To create a security group

Use the following create-security-group command.

```
aws ec2 create-security-group \
    --group-name my-security-group \
    --description "my security group" \
    --vpc-id vpc-1234567890abcdef0
```

For examples that add rules, see the section called “Configure security group rules”.

PowerShell

To create a security group

Use the New-EC2SecurityGroup cmdlet.

```
New-EC2SecurityGroup `
```

```
    -GroupName my-security-group `
    -Description "my security group" `
    -VpcId vpc-1234567890abcdef0
```

For examples that add rules, see the section called “Configure security group rules”.

Change the security groups for your Amazon EC2 instance

You can specify security groups for your Amazon EC2 instances when you launch them. After you launch an instance, you can add or remove security groups. You can also add, remove, or edit security group rules for associated security groups at any time.

Security groups are associated with network interfaces. Adding or removing security groups changes the security groups associated with the primary network interface. You can also change the security groups associated with any secondary network interfaces. For more information, see Modify network interface attributes.

Tasks

- Add or remove security groups
- Configure security group rules

Add or remove security groups

After you launch an instance, you can add or remove security groups from the list of associated security groups. When you associate multiple security groups with an instance, the rules from each security group are effectively aggregated to create one set of rules. Amazon EC2 uses this set of rules to determine whether to allow traffic.

Requirements

- The instance must be in the `running` or `stopped` state.

Console

To change the security groups for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.

3. Select your instance, and then choose **Actions**, **Security**, **Change security groups**.
4. For **Associated security groups**, select a security group from the list and choose **Add security group**.

   To remove an already associated security group, choose **Remove** for that security group.
5. Choose **Save**.

AWS CLI

To change the security groups for an instance

Use the following modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --groups sg-1234567890abcdef0
```

PowerShell

To change the security groups for an instance

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -Group sg-1234567890abcdef0
```

Configure security group rules

After you create a security group, you can add, update, and delete its security group rules. When you add, update, or delete a rule, the change is automatically applied to the resources that are associated with the security group.

For examples of rules that you can add to a security group, see Security group rules for different use cases.

Sources and destinations

You can specify the following as sources for inbound rules or destinations for outbound rules.

- **Custom –** A IPv4 CIDR block, and IPv6 CIDR block, another security group, or a prefix list.
- **Anywhere-IPv4** – The 0.0.0.0/0 IPv4 CIDR block.
- **Anywhere-IPv6** – The ::/0 IPv6 CIDR block.
- **My IP –** The public IPv4 address of your local computer.

> **Warning**
>
> If you add inbound rules for ports 22 (SSH) or 3389 (RDP), we strongly recommend that you authorize only the specific IP address or range of addresses that need access to your instances. If you choose **Anywhere-IPv4**, you allow traffic from all IPv4 addresses to access your instances using the specified protocol. If you choose **Anywhere-IPv6**, you allow traffic from all IPv6 addresses to access your instances using the specified protocol.

Console

To configure security group rules

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Select the security group.
4. To edit the inbound rules, choose **Edit inbound rules** from **Actions** or the **Inbound rules** tab.

    a. To add a rule, choose **Add rule** and enter the type, protocol, port, and source for the rule.

       If the type is TCP or UDP, you must enter the port range to allow. For custom ICMP, you must choose the ICMP type name from **Protocol**, and, if applicable, the code name from **Port range**. For any other type, the protocol and port range are configured for you.

    b. To update a rule, change its protocol, description, and source as needed. However, you can't change the source type. For example, if the source is an IPv4 CIDR block, you can't specify an IPv6 CIDR block, a prefix list, or a security group.

    c. To delete a rule, choose its **Delete** button.

5. To edit the outbound rules, choose **Edit outbound rules** from **Actions** or the **Outbound rules** tab.

    a. To add a rule, choose **Add rule** and enter the type, protocol, port, and destination for the rule. You can also enter an optional description.

       If the type is TCP or UDP, you must enter the port range to allow. For custom ICMP, you must choose the ICMP type name from **Protocol**, and, if applicable, the code name from **Port range**. For any other type, the protocol and port range are configured for you.

    b. To update a rule, change its protocol, description, and source as needed. However, you can't change the source type. For example, if the source is an IPv4 CIDR block, you can't specify an IPv6 CIDR block, a prefix list, or a security group.

    c. To delete a rule, choose its **Delete** button.

6. Choose **Save rules**.

AWS CLI

To add security group rules

Use the authorize-security-group-ingress command to add inbound rules. The following example allows inbound SSH traffic from the CIDR blocks in the specified prefix list.

```
aws ec2 authorize-security-group-ingress \
    --group-id sg-1234567890abcdef0 \
    --ip-permissions
 'IpProtocol=tcp,FromPort=22,ToPort=22,PrefixListIds=[{PrefixListId=pl-
f8a6439156EXAMPLE}]'
```

Use the authorize-security-group-egress command to add outbound rules. The following example allows outbound TCP traffic on port 80 to instances with the specified security group.

```
aws ec2 authorize-security-group-egress \
    --group-id sg-1234567890abcdef0 \
    --ip-permissions
 'IpProtocol=tcp,FromPort=80,ToPort=80,UserIdGroupPairs=[{GroupId=sg-0aad1c26bb6EXAMPLE}]'
```

To remove security group rules

Use the following [revoke-security-group-ingress] command to remove an inbound rule.

```
aws ec2 revoke-security-group-egress \
    --group id sg-1234567890abcdef0 \
    --security-group-rule-ids sgr-09ed298024EXAMPLE
```

Use the following [revoke-security-group-egress] command to remove an outbound rule.

```
aws ec2 revoke-security-group-ingress \
    --group id sg-1234567890abcdef0 \
    --security-group-rule-ids sgr-0352250c1aEXAMPLE
```

To modify security group rules

Use the [modify-security-group-rules] command. The following example changes the IPv4 CIDR block of the specified security group rule.

```
aws ec2 modify-security-group-rules \
    --group id sg-1234567890abcdef0 \
    --security-group-rules
 'SecurityGroupRuleId=sgr-09ed298024EXAMPLE,SecurityGroupRule={IpProtocol=tcp,FromPort=80,To
```

PowerShell

To add security group rules

Use the [Grant-EC2SecurityGroupIngress] cmdlet to add inbound rules. The following example allows inbound SSH traffic from the CIDR blocks in the specified prefix list.

```
$plid = New-Object -TypeName Amazon.EC2.Model.PrefixListId
$plid.Id = "pl-f8a6439156EXAMPLE"
Grant-EC2SecurityGroupIngress `
    -GroupId sg-1234567890abcdef0 `
    -IpPermission @{IpProtocol="tcp"; FromPort=22; ToPort=22; PrefixListIds=$plid}
```

Use the [Grant-EC2SecurityGroupEgress] cmdlet to add outbound rules. The following example allows outbound TCP traffic on port 80 to instances with the specified security group.

```
$uigp = New-Object -TypeName Amazon.EC2.Model.UserIdGroupPair
$uigp.GroupId = "sg-0aad1c26bb6EXAMPLE"
```

```
Grant-EC2SecurityGroupEgress `
    -GroupId sg-1234567890abcdef0 `
    -IpPermission @{IpProtocol="tcp"; FromPort=80; ToPort=80; UserIdGroupPairs=
$uigp}
```

To remove security group rules

Use the Revoke-EC2SecurityGroupIngress cmdlet to remove inbound rules.

```
Revoke-EC2SecurityGroupIngress `
    -GroupId sg-1234567890abcdef0 `
    -SecurityGroupRuleId sgr-09ed298024EXAMPLE
```

Use the Revoke-EC2SecurityGroupEgress cmdlet to remove outbound rules.

```
Revoke-EC2SecurityGroupEgress `
    -GroupId sg-1234567890abcdef0 `
    -SecurityGroupRuleId sgr-0352250c1aEXAMPLE
```

To modify security group rules

Use the Edit-EC2SecurityGroupRule cmdlet. The following example changes the IPv4 CIDR block of the specified security group rule.

```
$sgrr = New-Object -TypeName Amazon.EC2.Model.SecurityGroupRuleRequest
$sgrr.IpProtocol = "tcp"
$sgrr.FromPort = 80
$sgrr.ToPort = 80
$sgrr.CidrIpv4 = "0.0.0.0/0"
$sgr = New-Object -TypeName Amazon.EC2.Model.SecurityGroupRuleUpdate
$sgr.SecurityGroupRuleId = "sgr-09ed298024EXAMPLE"
$sgr.SecurityGroupRule = $sgrr
Edit-EC2SecurityGroupRule  `
    -GroupId sg-1234567890abcdef0 `
    -SecurityGroupRule $sgr
```

Delete an Amazon EC2 security group

When you are finished with a security group that you created for use with your Amazon EC2 instances, you can delete it.

Requirements

- The security group can't be associated with an instance or network interface.
- The security group can't be referenced by a rule in another security group.

Console

To delete a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. (Optional) To verify that your security group is not associated with an instance, do the following:
   a. In the navigation pane, choose **Security Groups**.
   b. Copy the ID of the security group to delete.
   c. In the navigation pane, choose **Instances**.
   d. In the search bar, add **Security group IDs equals** filter and paste the ID of the security group. If there are no results, then the security group is not associated with an instance. Otherwise, you must disassociate the security group before you can delete it.
3. In the navigation pane, choose **Security Groups**.
4. Select the security group and choose **Actions**, **Delete security groups**.
5. If you selected more than one security group, you are prompted for confirmation. If some of the security groups can't be deleted, we display the status of each security group, which indicates whether it will be deleted. To confirm deletion, enter **Delete**.
6. Choose **Delete**.

AWS CLI

To delete a security group

Use the following delete-security-group command.

```
aws ec2 delete-security-group --group-id sg-1234567890abcdef0
```

PowerShell

To delete a security group

Use the Remove-EC2SecurityGroup cmdlet.

```
Remove-EC2SecurityGroup -GroupId sg-1234567890abcdef0
```

Amazon EC2 security group connection tracking

Your security groups use connection tracking to track information about traffic to and from the instance. Rules are applied based on the connection state of the traffic to determine if the traffic is allowed or denied. With this approach, security groups are stateful. This means that responses to inbound traffic are allowed to flow out of the instance regardless of outbound security group rules, and vice versa.

As an example, suppose that you initiate a command such as netcat or similar to your instances from your home computer, and your inbound security group rules allow ICMP traffic. Information about the connection (including the port information) is tracked. Response traffic from the instance for the command is not tracked as a new request, but rather as an established connection, and is allowed to flow out of the instance, even if your outbound security group rules restrict outbound ICMP traffic.

For protocols other than TCP, UDP, or ICMP, only the IP address and protocol number is tracked. If your instance sends traffic to another host, and the host sends the same type of traffic to your instance within 600 seconds, the security group for your instance accepts it regardless of inbound security group rules. The security group accepts it because it’s regarded as response traffic for the original traffic.

When you change a security group rule, its tracked connections are not immediately interrupted. The security group continues to allow packets until existing connections time out. To ensure that traffic is immediately interrupted, or that all traffic is subject to firewall rules regardless of the tracking state, you can use a network ACL for your subnet. Network ACLs are stateless and therefore do not automatically allow response traffic. Adding a network ACL that blocks traffic in either direction breaks existing connections. For more information, see Network ACLs in the *Amazon VPC User Guide*.

Note

Security groups have no effect on DNS traffic to or from the Route 53 Resolver, sometimes referred to as the 'VPC+2 IP address' (see What is Amazon Route 53 Resolver? in the

Amazon Route 53 Developer Guide), or the 'AmazonProvidedDNS' (see Work with DHCP option sets in the *Amazon Virtual Private Cloud User Guide*). If you wish to filter DNS requests through the Route 53 Resolver, you can enable Route 53 Resolver DNS Firewall (see Route 53 Resolver DNS Firewall in the *Amazon Route 53 Developer Guide*).

Untracked connections

Not all flows of traffic are tracked. If a security group rule permits TCP or UDP flows for all traffic (0.0.0.0/0 or ::/0) and there is a corresponding rule in the other direction that permits all response traffic (0.0.0.0/0 or ::/0) for any port (0-65535), then that flow of traffic is not tracked, unless it is part of an automatically tracked connection. The response traffic for an untracked flow is allowed based on the inbound or outbound rule that permits the response traffic, not based on tracking information.

An untracked flow of traffic is immediately interrupted if the rule that enables the flow is removed or modified. For example, if you have an open (0.0.0.0/0) outbound rule, and you remove a rule that allows all (0.0.0.0/0) inbound SSH (TCP port 22) traffic to the instance (or modify it such that the connection would no longer be permitted), your existing SSH connections to the instance are immediately dropped. The connection was not previously being tracked, so the change will break the connection. On the other hand, if you have a narrower inbound rule that initially allows an SSH connection (meaning that the connection was tracked), but change that rule to no longer allow new connections from the address of the current SSH client, the existing SSH connection is not interrupted because it is tracked.

Automatically tracked connections

Connections made through the following are automatically tracked, even if the security group configuration does not otherwise require tracking:

- Egress-only internet gateways
- Global Accelerator accelerators
- NAT gateways
- Network Firewall firewall endpoints
- Network Load Balancers
- AWS PrivateLink (interface VPC endpoints)

- AWS Lambda (Hyperplane elastic network interfaces)

Connection tracking allowances

Amazon EC2 defines the maximum number of connections that can be tracked per instance. After the maximum is reached, any packets that are sent or received are dropped because a new connection cannot be established. When this happens, applications that send and receive packets cannot communicate properly. Use the `conntrack_allowance_available` network performance metric to determine the number of tracked connections still available for that instance type.

To determine whether packets were dropped because the network traffic for your instance exceeded the maximum number of connections that can be tracked, use the `conntrack_allowance_exceeded` network performance metric. For more information, see [Monitor network performance for ENA settings on your EC2 instance](#).

With Elastic Load Balancing, if you exceed the maximum number of connections that can be tracked per instance, we recommend that you scale either the number of instances registered with the load balancer or the size of the instances registered with the load balancer.

Connection tracking performance considerations

Asymmetric routing, where traffic comes into an instance through one network interface and leaves through a different network interface, can reduce the peak performance that an instance can achieve if flows are tracked.

To maintain peak performance when connection tracking is enabled for your security groups, we recommend the following configuration:

- Avoid asymmetric routing topologies, if possible.
- Instead of using security groups for filtering, use network ACLs.
- If you must use security groups with connection tracking, configure the shortest idle connection tracking timeout possible. For more details on idle connection tracking timeout, see the following section.

For more information about performance tuning on the Nitro system, see [Nitro system considerations for performance tuning](#).

Idle connection tracking timeout

The security group tracks each connection established to ensure that return packets are delivered as expected. There is a maximum number of connections that can be tracked per instance. Connections that remain idle can lead to connection tracking exhaustion and cause connections not to be tracked and packets to be dropped. You can set the timeout for idle connection tracking on an Elastic network interface.

> **Note**
>
> This feature is available only with Nitro-based instances.

There are three configurable timeouts:

- **TCP established timeout**: Timeout (in seconds) for idle TCP connections in an established state.
  - Min: `60` seconds
  - Max: `432000` seconds
  - Default: `350` seconds for Nitrov6 instance types, excluding P6e-GB200. And `432000` seconds for other instance types, including P6e-GB200.
  - Recommended: Less than `432000` seconds
- **UDP timeout**: Timeout (in seconds) for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction.
  - Min: `30` seconds
  - Max: `60` seconds
  - Default: `30` seconds
- **UDP stream timeout**: Timeout (in seconds) for idle UDP flows classified as streams which have seen more than one request-response transaction.
  - Min: `60` seconds
  - Max: `180` seconds
  - Default: `180` seconds

You may want to modify the default timeouts for any of the following cases:

- If you are monitoring tracked connections using Amazon EC2 network performance metrics, the *conntrack_allowance_exceeded* and *conntrack_allowance_available* metrics enable you to monitor dropped packets and tracked connection utilization to proactively manage EC2 instance capacity with scale up or out actions to help meet network connections demand before dropping packets. If you are observing *conntrack_allowance_exceeded* drops on your EC2 instances, you may benefit from setting a lower TCP established timeout to account for stale TCP/UDP sessions resulting from improper clients or network middle boxes.
- Typically, load balancers or firewalls have TCP Established idle timeout in the range of 60 to 90 minutes. If you are running workloads that are expected to handle a very high number of connections (greater than 100k) from appliances like network firewalls, configuring a similar timeout on an EC2 network interface is advised.
- If you are running a workload that utilizes an asymmetric routing topology, we recommend that you configure a TCP Established idle timeout of 60 seconds.
- If you are running workloads with high numbers of connections like DNS, SIP, SNMP, Syslog, Radius and other services that primarily use UDP to serve requests, setting the 'UDP-stream' timeout to 60s provides higher scale/performance for existing capacity and to prevent gray failures.
- For TCP/UDP connections through network load balancers (NLBs) and elastic load balancers (ELB), all connections are tracked. Idle timeout value for TCP flows is 350secs and UDP flows is 120 secs, and varies from interface level timeout values. You may want to configure timeouts at the network interface level to allow for more flexibility for timeout than the defaults for ELB/NLB.

You have the option to configure the connection tracking timeouts when you do the following:

- Create a network interface
- Modify network interface attributes
- Launch an EC2 instance
- Create an EC2 instance launch template

Example

In the following example, the security group has inbound rules that allow TCP and ICMP traffic, and outbound rules that allow all outbound traffic.

Inbound

Protocol type	Port number	Source
TCP	22 (SSH)	203.0.113.1/32
TCP	80 (HTTP)	0.0.0.0/0
TCP	80 (HTTP)	::/0
ICMP	All	0.0.0.0/0

Outbound

Protocol type	Port number	Destination
All	All	0.0.0.0/0
All	All	::/0

With a direct network connection to the instance or network interface, the tracking behavior is as follows:

- Inbound and outbound TCP traffic on port 22 (SSH) is tracked, because the inbound rule allows traffic from 203.0.113.1/32 only, and not all IP addresses (0.0.0.0/0).
- Inbound and outbound TCP traffic on port 80 (HTTP) is not tracked, because the inbound and outbound rules allow traffic from all IP addresses.
- ICMP traffic is always tracked.

If you remove the outbound rule for IPv4 traffic, all inbound and outbound IPv4 traffic is tracked, including traffic on port 80 (HTTP). The same applies for IPv6 traffic if you remove the outbound rule for IPv6 traffic.

Security group rules for different use cases

You can create a security group and add rules that reflect the role of the instance that's associated with the security group. For example, an instance that's configured as a web server needs security group rules that allow inbound HTTP and HTTPS access. Likewise, a database instance needs rules that allow access for the type of database, such as access over port 3306 for MySQL.

The following are examples of the kinds of rules that you can add to security groups for specific kinds of access.

Examples

- Web server rules
- Database server rules
- Rules to connect to instances from your computer
- Rules to connect to instances from an instance with the same security group
- Rules for ping/ICMP
- DNS server rules
- Amazon EFS rules
- Elastic Load Balancing rules

For instructions, see Create a security group and the section called "Configure security group rules".

Web server rules

The following inbound rules allow HTTP and HTTPS access from any IP address. If your VPC is enabled for IPv6, you can add rules to control inbound HTTP and HTTPS traffic from IPv6 addresses.

Protocol type	Protocol number	Port	Source IP	Notes
TCP	6	80 (HTTP)	0.0.0.0/0	Allows inbound HTTP access from any IPv4 address
TCP	6	443 (HTTPS)	0.0.0.0/0	Allows inbound HTTPS access from any IPv4 address
TCP	6	80 (HTTP)	::/0	Allows inbound HTTP access from any IPv6 address

Protocol type	Protocol number	Port	Source IP	Notes
TCP	6	443 (HTTPS)	::/0	Allows inbound HTTPS access from any IPv6 address

Database server rules

The following inbound rules are examples of rules you might add for database access, depending on what type of database you're running on your instance. For more information about Amazon RDS instances, see the Amazon RDS User Guide.

For the source IP, specify one of the following:

- A specific IP address or range of IP addresses (in CIDR block notation) in your local network
- A security group ID for a group of instances that access the database

Protocol type	Protocol number	Port	Notes
TCP	6	1433 (MS SQL)	The default port to access a Microsoft SQL Server database, for example, on an Amazon RDS instance
TCP	6	3306 (MYSQL/Aurora)	The default port to access a MySQL or Aurora database, for example, on an Amazon RDS instance
TCP	6	5439 (Redshift)	The default port to access an Amazon Redshift cluster database.
TCP	6	5432 (PostgreSQL)	The default port to access a PostgreSQL database, for example, on an Amazon RDS instance

Protocol type	Protocol number	Port	Notes
TCP	6	1521 (Oracle)	The default port to access an Oracle database, for example, on an Amazon RDS instance

You can optionally restrict outbound traffic from your database servers. For example, you might want to allow access to the internet for software updates, but restrict all other kinds of traffic. You must first remove the default outbound rule that allows all outbound traffic.

Protocol type	Protocol number	Port	Destination IP	Notes
TCP	6	80 (HTTP)	0.0.0.0/0	Allows outbound HTTP access to any IPv4 address
TCP	6	443 (HTTPS)	0.0.0.0/0	Allows outbound HTTPS access to any IPv4 address
TCP	6	80 (HTTP)	::/0	(IPv6-enabled VPC only) Allows outbound HTTP access to any IPv6 address
TCP	6	443 (HTTPS)	::/0	(IPv6-enabled VPC only) Allows outbound HTTPS access to any IPv6 address

Rules to connect to instances from your computer

To connect to your instance, your security group must have inbound rules that allow SSH access (for Linux instances) or RDP access (for Windows instances).

Protocol type	Protocol number	Port	Source IP
TCP	6	22 (SSH)	The public IPv4 address of your computer, or a range of IP addresses in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.
TCP	6	3389 (RDP)	The public IPv4 address of your computer, or a range of IP addresses in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.

Rules to connect to instances from an instance with the same security group

To allow instances that are associated with the same security group to communicate with each other, you must explicitly add rules for this.

Note

If you configure routes to forward the traffic between two instances in different subnets through a middlebox appliance, you must ensure that the security groups for both instances allow traffic to flow between the instances. The security group for each instance must reference the private IP address of the other instance, or the CIDR range of the subnet that contains the other instance, as the source. If you reference the security group of the other instance as the source, this does not allow traffic to flow between the instances.

The following table describes the inbound rule for a security group that enables associated instances to communicate with each other. The rule allows all types of traffic.

Protocol type	Protocol number	Ports	Source IP
-1 (All)	-1 (All)	-1 (All)	The ID of the security group, or the CIDR range of the subnet that contains the other instance (see note).

Rules for ping/ICMP

The **ping** command is a type of ICMP traffic. To ping your instance, you must add one of the following inbound ICMP rules.

Type	Protocol	Source		
Custom ICMP - IPv4	Echo request	The public IPv4 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.		
All ICMP - IPv4	IPv4 ICMP (1)	The public IPv4 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.		

To use the **ping6** command to ping the IPv6 address for your instance, you must add the following inbound ICMPv6 rule.

Type	Protocol	Source		
All ICMP - IPv6	IPv6 ICMP (58)	The IPv6 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.		

DNS server rules

If you've set up your EC2 instance as a DNS server, you must ensure that TCP and UDP traffic can reach your DNS server over port 53.

For the source IP, specify one of the following:

- An IP address or range of IP addresses (in CIDR block notation) in a network
- The ID of a security group for the set of instances in your network that require access to the DNS server

Protocol type	Protocol number	Port
TCP	6	53
UDP	17	53

Amazon EFS rules

If you're using an Amazon EFS file system with your Amazon EC2 instances, the security group that you associate with your Amazon EFS mount targets must allow traffic over the NFS protocol.

Protocol type	Protocol number	Ports	Source IP	Notes
TCP	6	2049 (NFS)	The ID of the security group	Allows inbound NFS access from resources (including the mount tar get) associated with this security group

To mount an Amazon EFS file system on your Amazon EC2 instance, you must connect to your instance. Therefore, the security group associated with your instance must have rules that allow inbound SSH from your local computer or local network.

Protocol type	Protocol number	Ports	Source IP	Notes
TCP	6	22 (SSH)	The IP address range of your local computer, or the range of IP addresses (in CIDR block notation) for your network.	Allows inbound SSH access from your local computer.

Elastic Load Balancing rules

If you register your EC2 instances with a load balancer, the security group associated with your load balancer must allow communication with the instances. For more information, see the following in the Elastic Load Balancing documentation.

- Security groups for your Application Load Balancer
- Security groups for your Network Load Balancer
- Configure security groups for your Classic Load Balancer

NitroTPM for Amazon EC2 instances

Nitro Trusted Platform Module (NitroTPM) is a virtual device that is provided by the AWS Nitro System and conforms to the TPM 2.0 specification. It securely stores artifacts (such as passwords, certificates, or encryption keys) that are used to authenticate the instance. NitroTPM can generate keys and use them for cryptographic functions (such as hashing, signing, encryption, and decryption).

NitroTPM provides *measured boot*, a process where the bootloader and operating system create cryptographic hashes of every boot binary and combine them with the previous values in NitroTPM internal Platform Configuration Registers (PCRs). With measured boot, you can obtain signed PCR values from NitroTPM and use them to prove to remote entities the integrity of the instance's boot software. This is known as remote *attestation*.

With NitroTPM, keys and secrets can be tagged with a specific PCR value so that they can never be accessed if the value of the PCR, and thus the instance integrity, changes. This special form of conditional access is referred to as *sealing and unsealing*. Operating system technologies, like BitLocker, can use NitroTPM to seal a drive decryption key so that the drive can only be decrypted when the operating system has booted correctly and is in a known good state.

To use NitroTPM, you must select an Amazon Machine Image (AMI) that has been configured for NitroTPM support, and then use the AMI to launch Nitro-based instances. You can select one of Amazon's prebuilt AMIs or create one yourself.

Pricing

There is no additional cost for using NitroTPM. You pay only for the underlying resources that you use.

Contents

Requirements for using NitroTPM with Amazon EC2 instances

To launch an instance with NitroTPM enabled, you must meet the following requirements.

Topics

- AMIs
- Instance types
- Considerations

AMIs

The AMI must have NitroTPM enabled.

Linux AMIs

There are no preconfigured AMIs. You must configure your own AMI. For more information, see Enable a Linux AMI for NitroTPM.

Windows AMIs

To find an AWS Windows AMI that's preconfigured for NitroTPM and UEFI Secure Boot with Microsoft keys, see Find Windows Server AMIs configured with NitroTPM and UEFI Secure Boot in the *AWS Windows AMIs Reference*.

> **Note**
>
> **Operating system** — The AMI must include an operating system with a TPM 2.0 Command Response Buffer (CRB) driver. Most current operating systems include a TPM 2.0 CRB driver.
> **UEFI boot mode** — The AMI must be configured for UEFI boot mode. For more information, see UEFI Secure Boot for Amazon EC2 instances.

Instance types

You must use one of the following virtualized instance types:

- **General purpose**: M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6a, M6g, M6gd, M6i, M6id, M6idn, M6in, M7a, M7g, M7gd, M7i, M7i-flex, M8g, M8gd, M8i, M8i-flex, T3, T3a, T4g

- **Compute optimized**: C5, C5a, C5ad, C5d, C5n, C6a, C6g, C6gd, C6gn, C6i, C6id, C6in, C7a, C7g, C7gd, C7gn, C7i, C7i-flex, C8g, C8gd, C8gn
- **Memory optimized**: R5, R5a, R5ad, R5b, R5d, R5dn, R5n, R6a, R6g, R6gd, R6i, R6idn, R6in, R6id, R7a, R7g, R7gd, R7i, R7iz, R8g, R8gd, R8i, R8i-flex, U7i-6tb, U7i-8tb, U7i-12tb, U7in-16tb, U7in-24tb, U7in-32tb, X2idn, X2iedn, X2iezn, X8g, z1d
- **Storage optimized**: D3, D3en, I3en, I4i, I7i, I7ie, I8g, I8ge
- **Accelerated computing**: F2, G4dn, G5, G6, G6e, G6f, Gr6, Gr6f, Inf1, Inf2, P5, P5e, P5en, P6-B200, Trn2, Trn2u
- **High-performance computing**: Hpc6a, Hpc6id

Considerations

The following considerations apply when using NitroTPM:

- After you launch an instance using an AMI with NitroTPM enabled, if you want to change the instance type, the new instance type that you choose must also support NitroTPM.
- BitLocker volumes that are encrypted with NitroTPM-based keys can only be used on the original instance.
- The NitroTPM state is not displayed in the Amazon EC2 console.
- The NitroTPM state is not included in Amazon EBS snapshots.
- The NitroTPM state is not included in VM Import/Export images.
- NitroTPM is not supported on AWS Outposts., Local Zones, or Wavelength Zones.

Enable a Linux AMI for NitroTPM

To enable NitroTPM for an instance, you must launch the instance using an AMI with NitroTPM enabled. You must configure your Linux AMI with NitroTPM support when you register it. You can't configure NitroTPM support later on.

For the list of Windows AMIs that are preconfigured for NitroTPM support, see Requirements for using NitroTPM with Amazon EC2 instances.

You must create an AMI with NitroTPM configured by using the RegisterImage API. You can't use the Amazon EC2 console or VM Import/Export.

To enable a Linux AMI for NitroTPM

1. Launch a temporary instance with your required Linux AMI. Note the ID of its root volume, which you can find in the console on the **Storage** tab for the instance.
2. After the instance reaches the `running` state, create a snapshot of the instance's root volume. For more information, see Create a snapshot of an EBS volume.
3. Register the snapshot you created as an AMI. In the block device mapping, specify the snapshot that you created for the root volume.

   The following is an example register-image command. For `--tpm-support`, specify `v2.0`. For `--boot-mode`, specify `uefi`.

```
aws ec2 register-image \
    --name my-image \
    --boot-mode uefi \
    --architecture x86_64 \
    --root-device-name /dev/xvda \
    --block-device-mappings DeviceName=/dev/
xvda,Ebs={SnapshotId=snap-0abcdef1234567890} \
    --tpm-support v2.0
```

   The following is an example for the Register-EC2Image cmdlet.

```
$block = @{SnapshotId=snap-0abcdef1234567890}
Register-EC2Image `
    -Name my-image `
    -Architecture "x86_64" `
    -RootDeviceName /dev/xvda `
    -BlockDeviceMapping @{DeviceName="/dev/xvda";Ebs=$block} `
    -BootMode Uefi `
    -TpmSupport V20
```

4. Terminate the temporary instance that you launched in step 1.

Verify that an AMI is enabled for NitroTPM

To enable NitroTPM for an instance, you must launch the instance using an AMI with NitroTPM enabled. You can describe an image to verify that it is enabled for NitroTPM. If you are the AMI owner, you can describe the `tpmSupport` image attribute.

The Amazon EC2 console does not display `TpmSupport`.

AWS CLI

To verify that NitroTPM is enabled

Use the describe-images command.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[*].TpmSupport
```

If NitroTPM is enabled for the AMI, the output is as follows. If TPM is not enabled, the output is empty.

```
[
    "v2.0"
]
```

Alternatively, if you are the AMI owner, you can use the describe-image-attribute command with the `tpmSupport` attribute.

```
aws ec2 describe-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute tpmSupport
```

The following is example output.

```
{
    "ImageId": "ami-0abcdef1234567890",
    "TpmSupport": {
        "Value": "v2.0"
    }
}
```

To find AMIs with NitroTPM enabled

The following example lists the IDs of the AMIs that you own with NitroTPM enabled.

```
aws ec2 describe-images \
    --owners self \
```

```
    --filters Name=tpm-support,Values=v2.0 \
    --query Images[].ImageId
```

PowerShell

To verify that NitroTPM is enabled

Use the Get-EC2Image cmdlet.

```
Get-EC2Image `
    -ImageId ami-0abcdef1234567890 | Select TpmSupport
```

If NitroTPM is enabled for the AMI, the output is as follows. If TPM is not enabled, the output is empty.

```
TpmSupport
----------
v2.0
```

Alternatively, if you are the AMI owner, you can use the Get-EC2ImageAttribute cmdlet with the `tpmSupport` attribute.

```
Get-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute tpmSupport
```

To find AMIs with NitroTPM enabled

The following example lists the IDs of the AMIs that you own with NitroTPM enabled.

```
Get-EC2Image `
    -Owner self `
    -Filter @{Name="tpm-support; Values="v2.0"} | Select ImageId
```

Enable or stop using NitroTPM on an Amazon EC2 instance

You can enable an Amazon EC2 instance for NitroTPM only at launch. Once an instance is enabled for NitroTPM, you can't disable it. If you no longer need to use NitroTPM, you must configure the operating system to stop using it.

Topics

Launch an instance with NitroTPM enabled

When you launch an instance with the prerequisites, NitroTPM is automatically enabled on the instance. You can enable NitroTPM on an instance only at launch. For information about launching an instance, see Launch an Amazon EC2 instance.

Stop using NitroTPM on an instance

After launching an instance with NitroTPM enabled, you can't disable NitroTPM for the instance. However, you can configure the operating system to stop using NitroTPM by disabling the TPM 2.0 device driver on the instance by using the following tools:

- For **Linux instances**, use tpm-tools.
- For **Windows instances**, use the TPM management console (tpm.msc).

For more information about disabling the device driver, see the documentation for your operating system.

Verify that an Amazon EC2 instance is enabled for NitroTPM

You can verify whether an Amazon EC2 instance is enabled for NitroTPM. If NitroTPM support is enabled on the instance, the command returns `"v2.0"`. Otherwise, the `TpmSupport` field is not present in the output.

The Amazon EC2 console does not display the `TpmSupport` field.

AWS CLI

To verify whether an instance is enabled for NitroTPM

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].TpmSupport
```

PowerShell

To verify whether an instance is enabled for NitroTPM

Use the Get-EC2Instance cmdlet.

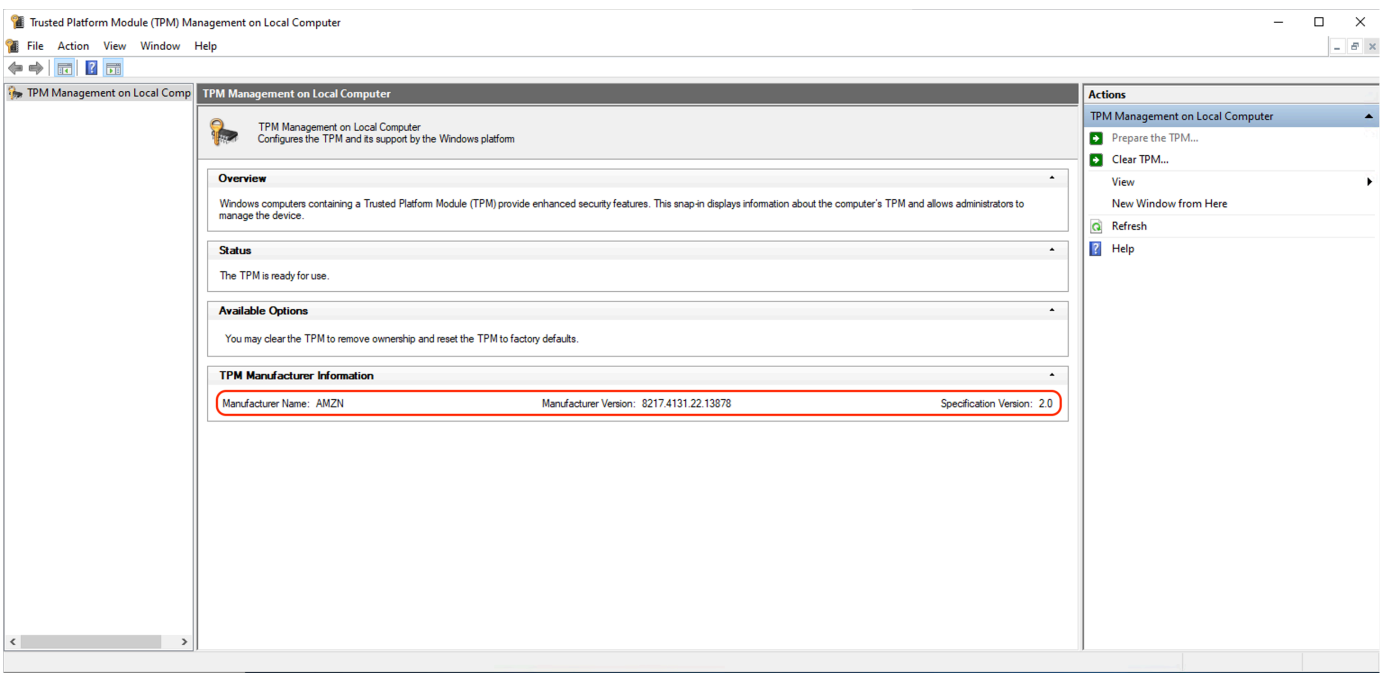
```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances.TpmSupport
```

Verify NitroTPM access on your Windows instance

(Windows instances only) To verify whether the NitroTPM is accessible to Windows

1. Connect to your EC2 Windows instance.
2. On the instance, run the tpm.msc program.

   The **TPM Management on Local Computer** window opens.
3. Check the **TPM Manufacturer Information** field. It contains the manufacturer's name and the version of the NitroTPM on the instance.



Retrieve the public endorsement key for an EC2 instance

You can securely retrieve the public endorsement key for an instance at any time.

AWS CLI

To retrieve the public endorsement key for an instance

Use the get-instance-tpm-ek-pub command.

Example 1

The following example gets the `rsa-2048` public endorsement key in `tpmt` format for the specified instance.

```
aws ec2 get-instance-tpm-ek-pub \
    --instance-id i-1234567890abcdef0 \
    --key-format tpmt \
    --key-type rsa-2048
```

The following is the example output.

```
{
    "InstanceId": "i-01234567890abcdef",
    "KeyFormat": "tpmt",
    "KeyType": "rsa-2048",
    "KeyValue": "AAEACwADALIAIINxl2dEhLEXAMPLEUal1yT9UtduBlILZPKh2hszFGmqAAYAgABDA
    EXAMPLEAAABAOiRd7WmgtdGNoV1h/AxmW+CXExblG8pEUfNm0LOLiYnEXAMPLERqApiFa/UhvEYqN4
    Z7jKMD/usbhsQaAB1gKA5RmzuhSazHQkax7EXAMPLEzDthlS7HNGuYn5eG7qnJndRcakS+iNxT8Hvf
    0S1ZtNuItMs+Yp4SO6aU28MT/JZkOKsXIdMerY3GdWbNQz9AvYbMEXAMPLEPyHfzgVO0QTTJVGdDxh
    vxtXCOu9GYf0crbjEXAMPLEd4YTbWdDdgOKWF9fjzDytJSDhrLAOUctNzHPCd/92l5zEXAMPLEOIFA
    Ss50C0/802c17W2pMSVHvCCa9lYCiAfxH/vYKovAAE="
}
```

Example 2

The following example gets the `rsa-2048` public endorsement key in `der` format for the specified instance.

```
aws ec2 get-instance-tpm-ek-pub \
    --instance-id i-1234567890abcdef0 \
    --key-format der \
    --key-type rsa-2048
```

The following is the example output.

```
{
```

```
    "InstanceId": "i-1234567890abcdef0",
    "KeyFormat": "der",
    "KeyType": "rsa-2048",
    "KeyValue": "MIIBIjANBgEXAMPLEw0BAQEFAAOCAQ8AMIIBCgKCAQEA6JF3taEXAMPLEXWH8DGZb4
    JcTFuUbykRR82bQs4uJifaKSOv5NGoEXAMPLEG8Rio3hnuMowP+6xuGxBoAHWAoDlGbO6FJrMdEXAMP
    LEnYUHvMO2GVLsc0a5ifl4buqcmd1FxqRL6I3FPwe9/REXAMPLE0yz5inhI7ppTbwxP8lmQ4qxch0x6
    tjcZ1Zs1DP0EXAMPLERUYLQ/Id/OBU7RBNMlUZ0PGG/G1cI670Zh/RytuOdx9iEXAMPLEtZ0N2A4pYX
    1+PMPK0lIOGssA5Ry03Mc8J3/3aXnOD2/ASRQ4gUBKznQLT/zTZEXAMPLEJUe8IJr2VgKIB/Ef+9gqi
    8AAQIDAQAB"
}
```

PowerShell

To retrieve the public endorsement key for an instance

Use the Get-EC2InstanceTpmEkPub cmdlet.

Example 1

The following example gets the `rsa-2048` public endorsement key in `tpmt` format for the specified instance.

```
Get-EC2InstanceTpmEkPub `
    -InstanceId i-1234567890abcdef0 `
    -KeyFormat tpmt `
    -KeyType rsa-2048
```

Example 2

The following example gets the `rsa-2048` public endorsement key in `der` format for the specified instance.

```
Get-EC2InstanceTpmEkPub `
    -InstanceId i-1234567890abcdef0 `
    -KeyFormat der `
    -KeyType rsa-2048
```

Credential Guard for Windows instances

The AWS Nitro System supports Credential Guard for Amazon Elastic Compute Cloud (Amazon EC2) Windows instances. Credential Guard is a Windows virtualization-based security (VBS) feature that enables the creation of isolated environments to protect security assets, such as Windows user credentials and code integrity enforcement, beyond Windows kernel protections. When you run EC2 Windows instances, Credential Guard uses the AWS Nitro System to protect Windows login credentials from being extracted from the operating system's memory.

Contents

Prerequisites

Your Windows instance must meet the following prerequisites to utilize Credential Guard.

Amazon Machine Images (AMIs)

The AMI must be preconfigured to enable NitroTPM and UEFI Secure Boot. For more information on supported AMIs, see the section called “Requirements”.

Memory integrity

Memory integrity, also known as *hypervisor-protected code integrity (HVCI)* or *hypervisor enforced code integrity*, isn't supported. Before you turn on Credential Guard, you must ensure this feature is disabled. For more information, see Disable memory integrity.

Instance types

The following instance types support Credential Guard across all sizes unless noted otherwise: `C5`, `C5d`, `C5n`, `C6i`, `C6id`, `C6in`, `C7i`, `C7i-flex`, `M5`, `M5d`, `M5dn`, `M5n`, `M5zn`, `M6i`, `M6id`, `M6idn`, `M6in`, `M7i`, `M7i-flex`, `R5`, `R5b`, `R5d`, `R5dn`, `R5n`, `R6i`, `R6id`, `R6idn`, `R6in` `R7i`, `R7iz`, `T3`.

> **Note**
>
> - Though NitroTPM has some required instance types in common, the instance type must be one of the preceding instance types to support Credential Guard.
> - Credential Guard isn't supported for:
>   - Bare metal instances.

- The following instance types: C7i.48xlarge, M7i.48xlarge, and R7i.48xlarge.

For more information about instance types, see the Amazon EC2 Instance Types Guide.

Launch a supported instance

You can use the Amazon EC2 console or AWS Command Line Interface (AWS CLI) to launch an instance which can support Credential Guard. You will need a compatible AMI ID for launching your instance which is unique for each AWS Region.

> **Tip**
>
> You can use the following link to discover and launch instances with compatible Amazon provided AMIs in the Amazon EC2 console: https://console.aws.amazon.com/ec2/v2/home?#Images:visibility=public-images;v=3;search=:TPM-Windows_Server;ownerAlias=amazon

Console

To launch an instance

Follow the steps to launch an instance, specifying a supported instance type and a preconfigured Windows AMI.

AWS CLI

To launch an instance

Use the run-instances command to launch an instance using a supported instance type and preconfigured Windows AMI.

```
aws ec2 run-instances \
    --image-id resolve:ssm:/aws/service/ami-windows-latest/TPM-Windows_Server-2022-
English-Full-Base \
    --instance-type c6i.large \
    --region us-east-1 \
    --subnet-id subnet-0abcdef1234567890
```

```
    --key-name key-name
```

PowerShell

To launch an instance

Use the New-EC2Instance command to launch an instance using a supported instance type and preconfigured Windows AMI.

```
New-EC2Instance `
    -ImageId resolve:ssm:/aws/service/ami-windows-latest/TPM-Windows_Server-2022-
English-Full-Base `
    -InstanceType c6i.large `
    -Region us-east-1 `
    -SubnetId subnet-0abcdef1234567890 `
    -KeyName key-name
```

Disable memory integrity

You can use the Local Group Policy Editor to disable memory integrity in supported scenarios. The following guidance can be applied for each configuration setting under **Virtualization Based Protection of Code Integrity**:

- **Enabled without lock** – Modify the setting to **Disabled** to disable memory integrity.
- **Enabled with UEFI lock** – Memory integrity has been enabled with UEFI lock. Memory integrity can't be disabled once it has been enabled with UEFI lock. We recommend creating a new instance with memory integrity disabled and terminating the unsupported instance if it's not in use.

To disable memory integrity with the Local Group Policy Editor

1. Connect to your instance as a user account with administrator privileges using the Remote Desktop Protocol (RDP). For more information, see the section called "Connect using an RDP client".
2. Open the Start menu and search for **cmd** to start a command prompt.
3. Run the following command to open the Local Group Policy Editor: `gpedit.msc`
4. In the Local Group Policy Editor, choose **Computer Configuration**, **Administrative Templates**, **System**, **Device Guard**.

5. Select **Turn On Virtualization Based Security**, then select **Edit policy setting**.
6. Open the settings drop-down for **Virtualization Based Protection of Code Integrity**, choose **Disabled**, then choose **Apply**.
7. Reboot the instance to apply the changes.

Turn on Credential Guard

After you have launched a Windows instance with a supported instance type and compatible AMI, and confirmed that memory integrity is disabled, you can turn on Credential Guard.

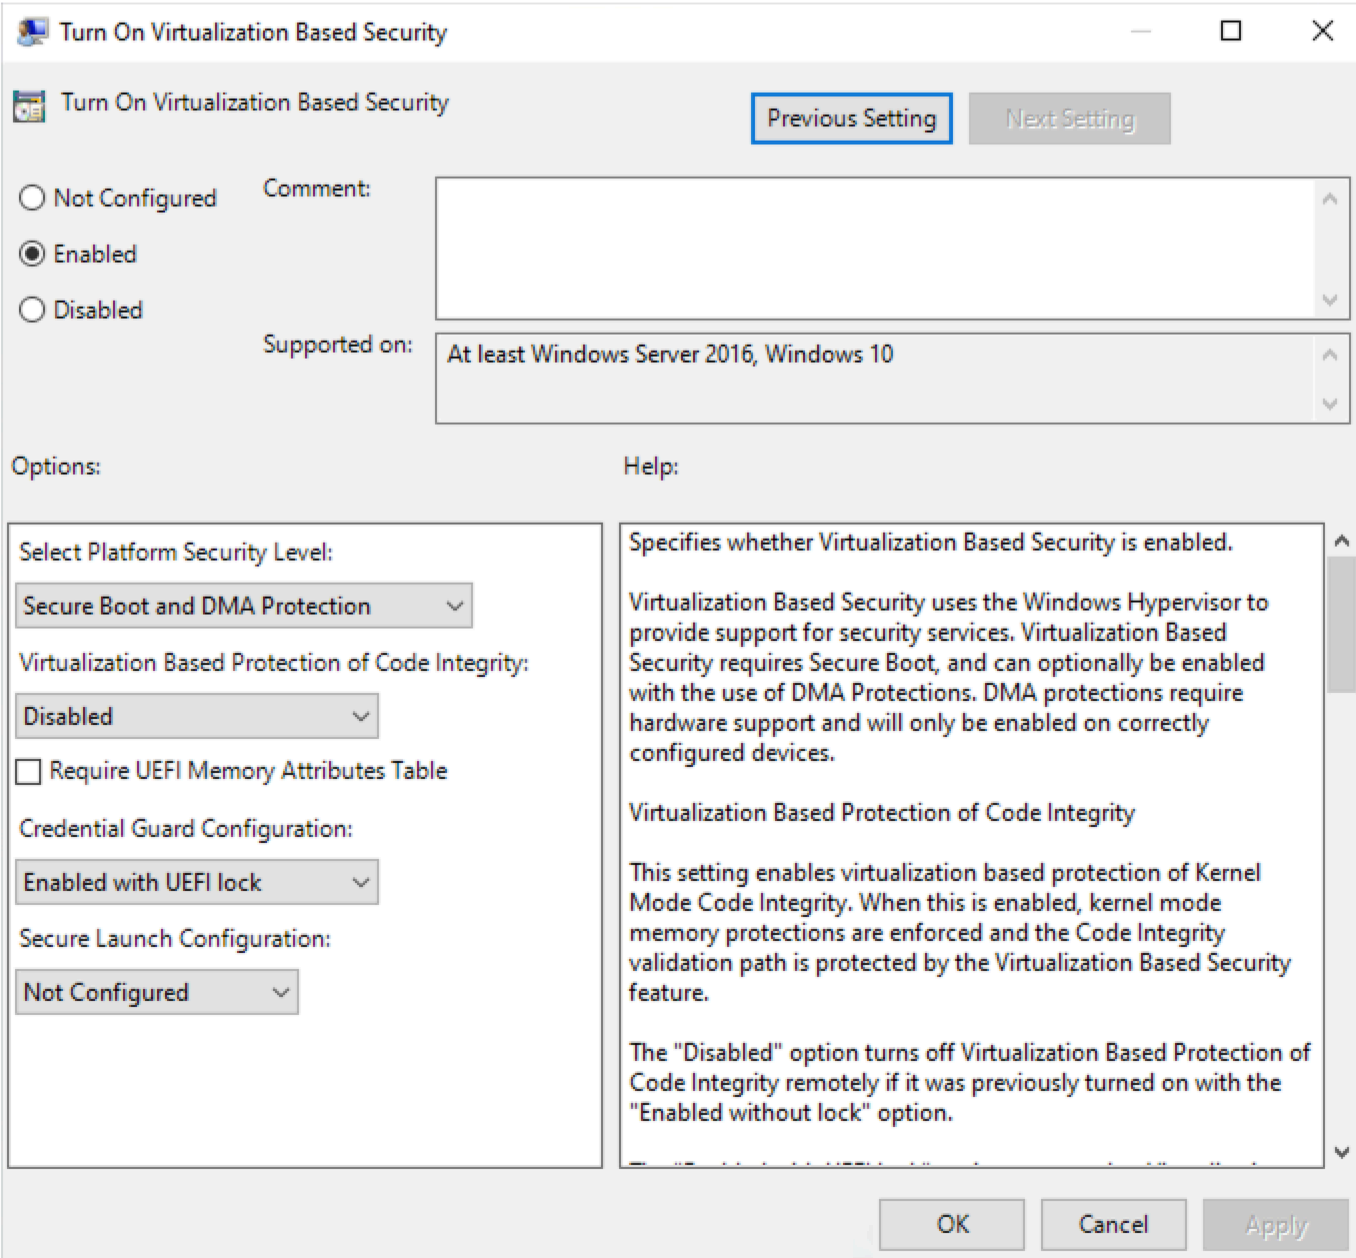
> **Important**
>
> Administrator privileges are required to perform the following steps to turn on Credential Guard.

To turn on Credential Guard

1. Connect to your instance as a user account with administrator privileges using the Remote Desktop Protocol (RDP). For more information, see the section called “Connect using an RDP client”.
2. Open the Start menu and search for **cmd** to start a command prompt.
3. Run the following command to open the Local Group Policy Editor: `gpedit.msc`
4. In the Local Group Policy Editor, choose **Computer Configuration**, **Administrative Templates**, **System**, **Device Guard**.
5. Select **Turn On Virtualization Based Security**, then select **Edit policy setting**.
6. Choose **Enabled** within the **Turn On Virtualization Based Security** menu.
7. For **Select Platform Security Level**, choose **Secure Boot and DMA Protection**.
8. For **Credential Guard Configuration**, choose **Enabled with UEFI lock**.

   > **Note**
   >
   > The remaining policy settings are not required to enable Credential Guard and can be left as **Not Configured**.

The following image displays the VBS settings configured as described previously:



9. Reboot the instance to apply the settings.

Verify that Credential Guard is running

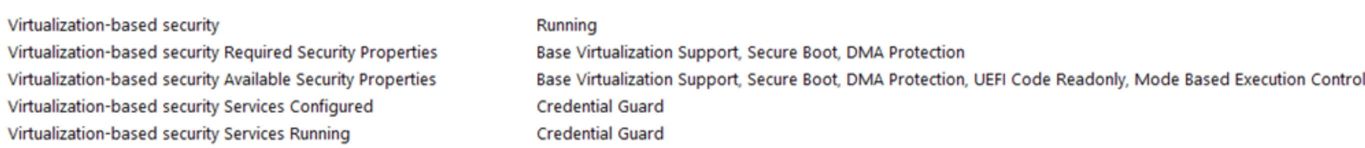
You can use the Microsoft System Information (`Msinfo32.exe`) tool to confirm that Credential Guard is running.

> **Important**
>
> You must first reboot the instance to finish applying the policy settings required to enable Credential Guard.

To verify Credential Guard is running

1. Connect to your instance using the Remote Desktop Protocol (RDP). For more information, see the section called “Connect using an RDP client”.
2. Within the RDP session to your instance, open the Start menu and search for **cmd** to start a command prompt.
3. Open System Information by running the following command: `msinfo32.exe`
4. The Microsoft System Information tool lists the details for VBS configuration. Next to Virtualization-based security Services, confirm that **Credential Guard** appears as **Running**.

   The following image displays VBS is running as described previously:



Virtualization-based security	Running
Virtualization-based security Required Security Properties	Base Virtualization Support, Secure Boot, DMA Protection
Virtualization-based security Available Security Properties	Base Virtualization Support, Secure Boot, DMA Protection, UEFI Code Readonly, Mode Based Execution Control
Virtualization-based security Services Configured	Credential Guard
Virtualization-based security Services Running	Credential Guard

Access Amazon EC2 using an interface VPC endpoint

You can improve the security posture of your VPC by creating a private connection between resources in your VPC and the Amazon EC2 API. You can access the Amazon EC2 API as if it were in your VPC, without the use of an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. EC2 instances in your VPC don't need public IP addresses to access the Amazon EC2 API.

For more information, see Access AWS services through AWS PrivateLink in the *AWS PrivateLink Guide*.

Contents

Create an interface VPC endpoint

Create an interface endpoint for Amazon EC2 using the following service name:

- **com.amazonaws.*region*.ec2** — Creates an endpoint for the Amazon EC2 API actions.

For more information, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

Create an endpoint policy

An endpoint policy is an IAM resource that you can attach to your interface endpoint. The default endpoint policy allows full access to the Amazon EC2 API through the interface endpoint. To control the access allowed to the Amazon EC2 API from your VPC, attach a custom endpoint policy to the interface endpoint.

An endpoint policy specifies the following information:

- The principals that can perform actions.
- The actions that can be performed.
- The resource on which the actions can be performed.

> **Important**
>
> When a non-default policy is applied to an interface VPC endpoint for Amazon EC2, certain failed API requests, such as those failing from `RequestLimitExceeded`, might not be logged to AWS CloudTrail or Amazon CloudWatch.

For more information, see Control access to services using endpoint policies in the *AWS PrivateLink Guide*.

The following example shows a VPC endpoint policy that denies permission to create unencrypted volumes or to launch instances with unencrypted volumes. The example policy also grants permission to perform all other Amazon EC2 actions.

Storage options for your Amazon EC2 instances

Amazon EC2 provides you with flexible, cost effective, and easy-to-use data storage options for your instances. Each option has a unique combination of performance and durability. These storage options can be used independently or in combination to suit your requirements.

Block storage

- Amazon EBS — Amazon EBS provides durable, block-level storage volumes that you can attach and detach from your instances. You can attach multiple EBS volumes to an instance. An EBS volume persists independently from the life of its associated instance. You can encrypt your EBS volumes. To keep a backup copy of your data, you can create snapshots from your EBS volumes. Snapshots are stored in Amazon S3. You can create an EBS volume from a snapshot.
- Instance store temporary block storage for EC2 instances — Instance store provides temporary block-level storage for instances. The number, size, and type of instance store volumes are determined by the instance type and instance size. The data on an instance store volume persists only during the life of the associated instance; if you stop, hibernate, or terminate an instance, any data on instance store volumes is lost.

Object storage

- Amazon S3 — Amazon S3 provides access to reliable and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. For example, you can use Amazon S3 to store backup copies of your data and applications. Amazon EC2 uses Amazon S3 to store EBS snapshots and instance store-backed AMIs.

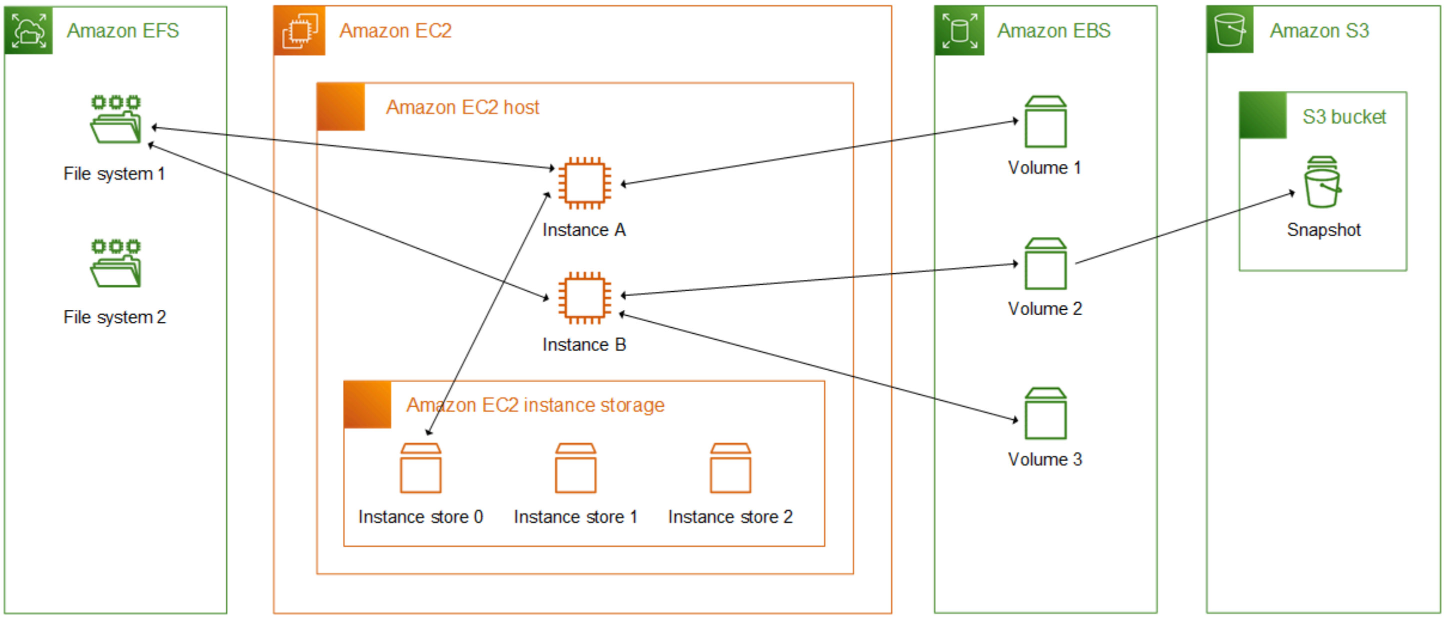
File storage

- Amazon EFS (Linux instances only) — Amazon EFS provides scalable file storage for use with Amazon EC2. You can create an EFS file system and configure your instances to mount the file system. You can use an EFS file system as a common data source for workloads and applications running on multiple instances.
- Amazon FSx — With Amazon FSx, you can launch, run, and scale feature-rich, high-performance file systems in the cloud. Amazon FSx is a fully-managed service that supports a wide range of workloads. You can choose between these widely-used file systems: Lustre, NetApp ONTAP, OpenZFS, and Windows File Server.

File caching

- Use Amazon File Cache with Amazon EC2 instances — Amazon File Cache provides temporary, high-performance cache on AWS for processing file data. The cache provides read and write data access to compute workloads on Amazon EC2 with sub-millisecond latencies, up to hundreds of GB/s of throughput, and up to millions of IOPS.

The following figure shows the relationship between these storage options and your instance.



AWS Storage pricing

Open AWS Pricing, scroll to **Pricing for AWS products** and select **Storage**. Choose the storage product to open its pricing page.

Amazon EBS persistent block storage for Amazon EC2 instances

Amazon Elastic Block Store (Amazon EBS) provides scalable, high-performance block storage resources that can be used with Amazon EC2 instances. With Amazon EBS, you can create and manage the following block storage resources:

- **Amazon EBS volumes** — These are storage volumes that you attach to Amazon EC2 instances. After you attach a volume to an instance, you can use it in the same way you would use block storage. The instance can interact with the volume just as it would with a local drive.

- **Amazon EBS snapshots** — These are point-in-time backups of Amazon EBS volumes that persist independently from the volume itself. You can create snapshots to back up the data on your Amazon EBS volumes. You can then restore new volumes from those snapshots at any time.

You can create and attach EBS volumes to an instance during launch, and you can create and attach EBS volumes to an instance at any time after launch. You can also increase the size or performance of your EBS volumes without detaching the volume or restarting your instance.

You can create EBS snapshots from an EBS volume at any time after creation. You can use EBS snapshots to back up the data stored on your volumes. You can then use those snapshots to instantly restore volumes, or to migrate data across AWS accounts, AWS Regions, or Availability Zones. You can use Amazon Data Lifecycle Manager or AWS Backup to automate the creation, retention, and deletion of your EBS snapshots.

A *managed EBS volume* is managed by a service provider, such as Amazon EKS Auto Mode. You can't directly modify the settings of a managed EBS volume. Managed EBS volumes are identified by a **true** value in the **Managed** field. For more information, see Amazon EC2 managed instances.

For more information about working with volumes and snapshots, see the Amazon EBS User Guide.

Amazon EBS volume limits for Amazon EC2 instances

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. If you exceed the volume attachment limit for an instance, the attachment request fails with the `AttachmentLimitExceeded` error.

When considering how many volumes to attach to your instance, you should consider whether you need increased I/O bandwidth or increased storage capacity.

Bandwidth versus capacity

For consistent and predictable bandwidth use cases, use Amazon EBS-optimized instances with General Purpose SSD volumes or Provisioned IOPS SSD volumes. For maximum performance, match the IOPS you have provisioned for your volumes with the bandwidth available for your instance type.

For RAID configurations, you might find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead. Test your individual application performance and tune it as required.

Contents

Volume limits for instances built on the Nitro System

The volume limits for instances built on the Nitro System depend on the instance type. Some Nitro instance types have a **dedicated EBS volume limit**, while most have a **shared volume limit**. To view the volume attachement limits for each instance type, see the following:

- Amazon EBS specifications – General purpose
- Amazon EBS specifications – Compute optimized
- Amazon EBS specifications – Memory optimized
- Amazon EBS specifications – Storage optimized
- Amazon EBS specifications – Accelerated computing
- Amazon EBS specifications – High-performance computing
- Amazon EBS specifications – Previous generation

Dedicated EBS volume limit

The following Nitro instance types have a dedicated EBS volume limit that varies depending on instance size. The limit is not shared with other device attachments. In other words, you can attach any number of EBS volumes up to the volume attachment limit, regardless of the number of attached devices, such as NVMe instance store volumes and network interfaces.

- **General purpose:** M7a | M7i | M7i-flex | M8g | M8gd | M8i | M8i-flex
- **Compute optimized:** C7a | C7i | C7i-flex | C8g | C8gd | C8gn
- **Memory optimized:** R7a | R7i | R7iz | R8g | R8gd | R8i | R8i-flex | U7i-6tb | U7i-8tb | U7i-12tb | U7in-16tb | U7in-24tb | U7in-32tb | U7inh-32tb | X8g
- **Storage optimized:** I7i | I7ie | I8g | I8ge

- **Accelerated computing:** F2 | G6 | G6e | G6f | Gr6 | Gr6f | P4d | P4de | P5 | P5e | P5en | P6-B200 | P6e-GB200 | Trn2 | Trn2u
- **High performance computing:** Hpc7a

Shared EBS volume limit

All other Nitro instance types (not listed in Dedicated EBS volume limit) have a volume attachment limit that is shared between Amazon EBS volumes, network interfaces, and NVMe instance store volumes. You can attach any number of Amazon EBS volumes up to that limit, less the number of attached network interfaces and NVMe instance store volumes. Keep in mind that every instance must have at least one network interface, and that NVMe instance store volumes are automatically attached at launch.

Most Nitro instances support a maximum of 28 attachments. The following examples demonstrate how to calculate how many EBS volumes you can attach.

Examples

- With an `m5.xlarge` instance with only the primary network interface, you can attach 27 EBS volumes.

  28 volumes - 1 network interface = 27
- With an `m5.xlarge` instance with two additional network interfaces, you can attach 25 EBS volumes.

  28 volumes - 3 network interfaces = 25
- With an `m5d.xlarge` instance with two additional network interfaces, you can attach 24 EBS volumes.

  28 volumes - 3 network interfaces - 1 NVMe instance store volume = 24

Volume limits for Xen-based instances

The volume limits for Xen-based instances, such as T2, depend on the operating system.

For more information, see Xen-based instances.

Linux instances

Attaching more than 40 volumes to a Xen-based Linux instance can cause boot failures. This number includes the root volume, plus any attached instance store volumes and Amazon EBS volumes.

If you experience boot problems on an instance with a large number of volumes, stop the instance, detach any volumes that are not essential to the boot process, start the instance, and then reattach the volumes after the instance is running.

> **Important**
>
> Attaching more than 40 volumes to a Xen-based Linux instance is supported on a best effort basis only and is not guaranteed.

Windows instances

The following table shows the volume limits for Xen-based Windows instances based on the driver used. That these numbers include the root volume, plus any attached instance store volumes and Amazon EBS volumes.

Driver	Volume Limit
AWS PV	26
Citrix PV	26
Red Hat PV	17

We recommend that you do not that attach more than 26 volumes to a Xen-based Windows instance with AWS PV or Citrix PV drivers, as it is likely to cause performance issues. To determine which PV drivers your instance is using, or to upgrade your Windows instance from Red Hat to Citrix PV drivers, see the section called “Upgrade PV drivers”.

> **Important**
>
> Attaching more than the following number of volumes to a Xen-based Windows instance is supported on a best effort basis only and is not guaranteed.

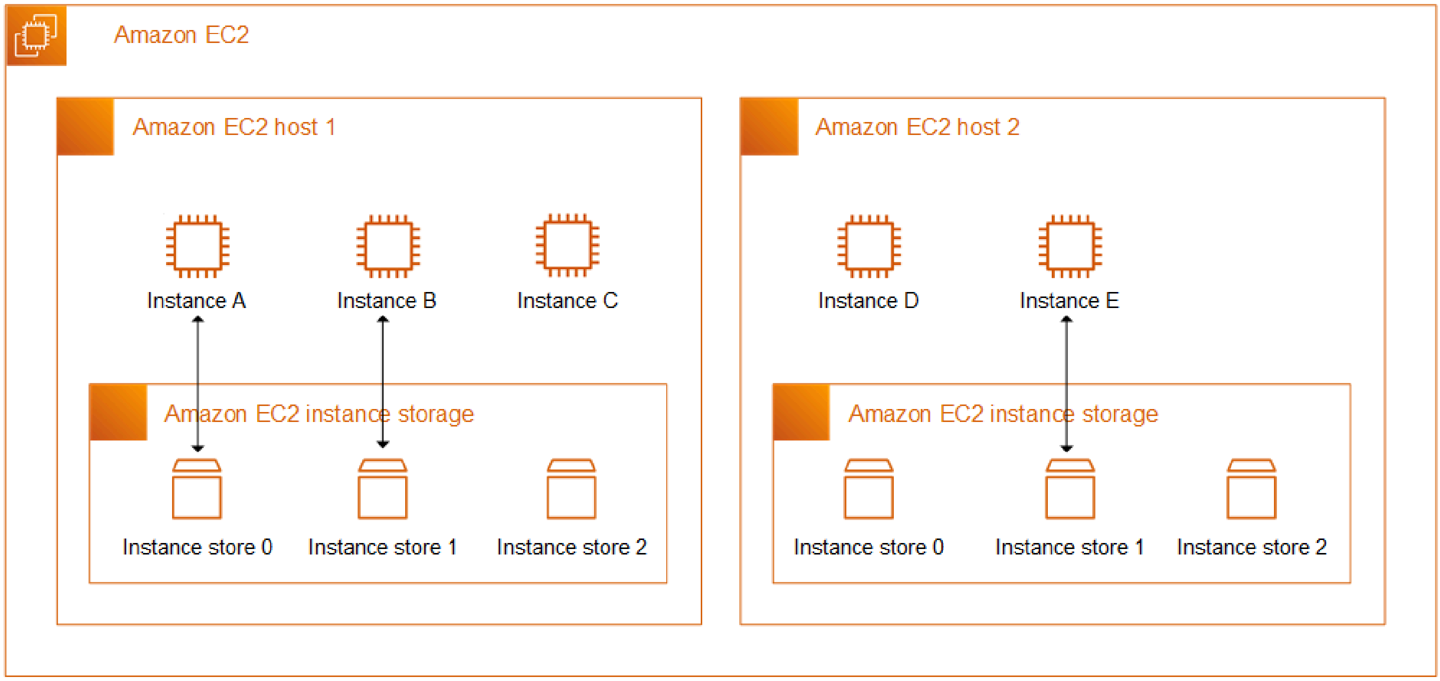
For more information about how device names are related to volumes, see How volumes are attached and mapped for Amazon EC2 Windows instances.

Instance store temporary block storage for EC2 instances

An *instance store* provides temporary block-level storage for your EC2 instance. This storage is provided by disks that are physically attached to the host computer. Instance store is ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content. It can also be used to store temporary data that you replicate across a fleet of instances, such as a load-balanced pool of web servers.

An instance store consists of one or more instance store volumes exposed as block devices. The size of an instance store as well as the number of devices available varies by instance type and instance size. For example, not every instance type provides instance store volumes. For more information, see Instance store volume limits for EC2 instances.

The virtual devices for instance store volumes are given virtual device names in order from `ephemeral0` to `ephemeral23`. For example, with an instance type that supports one instance store volume, the virtual device name of the one volume is `ephemeral0`. With an instance type that supports four instance store volumes, the virtual device names of the four volumes are as follows: `ephemeral0`, `ephemeral1`, `ephemeral2` and `ephemeral3`.



Instance store pricing

There is no additional charge to use the instance store volumes provided for your instance. Instance store volumes are included as part of the usage cost of the instance.

Contents

Data persistence for Amazon EC2 instance store volumes

Instance store volumes are attached only at instance launch. You can't attach instance store volumes after launch. You can’t detach an instance store volume from one instance and attach it to a different instance.

An instance store volume exists only during the lifetime of the instance to which it is attached. You can’t configure an instance store volume to persist beyond the lifetime of its associated instance.

The data on an instance store volume persists even if the instance is rebooted. However, the data does not persist if the instance is stopped, hibernated, or terminated. When the instance is stopped, hibernated, or terminated, every block of the instance store volume is cryptographically erased.

Therefore, do not rely on instance store volumes for valuable, long-term data. If you need to retain the data stored on an instance store volume beyond the lifetime of the instance, you need to manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system.

There are some events that can result in your data not persisting throughout the lifetime of the instance. The following table indicates whether data on instance store volumes is persisted during specific events, for both virtualized and bare metal instances.

Event	What happens to your data?
User-initiated instance lifecycle events	
The instance is rebooted	The data persists
The instance is stopped	The data does not persist
The instance is hibernated	The data does not persist
The instance is terminated	The data does not persist
The instance type is changed	The data does not persist *
An EBS-backed AMI is created from the instance	The data does not persist in the created AMI **
An instance store-backed AMI is created from the instance (Linux instances)	The data persists in the AMI bundle uploaded to Amazon S3 ***
User-initiated OS events	
A shutdown is initiated	The data does not persist †
A restart is initiated	The data persists
AWS scheduled events	

Event	What happens to your data?
Instance stop	The data does not persist
Instance reboot	The data persists
System reboot	The data persists
Instance retirement	The data does not persist
Unplanned events	
Simplified automatic recovery	The data does not persist
CloudWatch action based recovery	The data does not persist
The underlying disk fails	The data on the failed disk does not persist
Power failure	The data persists upon reboot

* If the new instance type supports instance store, the instance gets the number of instance store volumes supported by the new instance type, but the data does not transfer to the new instance. If the new instance type does not support instance store, the instance does not get the instance store volumes.

** The data is not included in the EBS-backed AMI, and it is not included on instance store volumes attached to instances launched from that AMI.

*** The data is included in the AMI bundle that is uploaded to Amazon S3. When you launch an instance from that AMI, the instance gets the instance store volumes bundled in the AMI with the data they contained at the time the AMI was created.

† Termination protection and stop protection do not protect instances against instance stops or terminations as a result of shutdowns initiated through the operating system on the instance. Data stored on instance store volumes does not persist in both instance stop and termination events.

Instance store volume limits for EC2 instances

The number, size, and type of instance store volumes are determined by the instance type. Some instance types, such as M6, C6, and R6, do not support instance store volumes, while other instance types, such as M5d, C6gd, and R6gd, do support instance store volumes. You can’t attach more instance store volumes to an instance than is supported by its instance type. For the instance types that do support instance store volumes, the number and size of the instance store volumes vary by instance size. For example, `m5d.large` supports 1 x 75 GB instance store volume, while `m5d.24xlarge` supports 4 x 900 GB instance store volumes.

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Then, after the instance has launched, you must format and mount the attached instance store volumes before you can use them. You can't attach an instance store volume after you launch the instance.

Some instance types use NVMe or SATA-based solid state drives (SSD), while others use SATA-based hard disk drives (HDD). SSDs deliver high random I/O performance with very low latency, but you don't need the data to persist when the instance terminates or you can take advantage of fault-tolerant architectures. For more information, see SSD instance store volumes for EC2 instances.

The data on NVMe instance store volumes and some HDD instance store volumes is encrypted at rest. For more information, see Data protection in Amazon EC2.

Available instance store volumes

The *Amazon EC2 Instance Types Guide* provides the quantity, size, type, and performance optimizations of instance store volumes available on each supported instance type. For more information, see the following:

- Instance store specifications – General purpose
- Instance store specifications – Compute optimized
- Instance store specifications – Memory optimized
- Instance store specifications – Storage optimized
- Instance store specifications – Accelerated computing
- Instance store specifications – High-performance computing
- Instance store specifications – Previous generation

Console

To retrieve instance store volume information

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instance Types**.
3. Add the filter **Local instance storage = true**. The **Storage** column indicates the total size of the instance storage for the instance type.
4. (Optional) Click the **Preferences** icon and then turn on **Storage disk count**. This column indicates the number of instance store volumes.
5. (Optional) Add filters to further scope to specific instance types of interest.

AWS CLI

To retrieve instance store volume information

Use the describe-instance-types command. The following example displays the total size of the instance storage for each instance type in the R6i instance families with instance store volumes.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=r6i*" "Name=instance-storage-
supported,Values=true" \
    --query "InstanceTypes[].[InstanceType, InstanceStorageInfo.TotalSizeInGB]" \
    --output table
```

The following is example output.

```
----------------------------
|  DescribeInstanceTypes   |
+----------------+---------+
|  r6id.16xlarge  |  3800   |
|  r6idn.16xlarge |  3800   |
|  r6idn.8xlarge  |  1900   |
|  r6id.2xlarge   |  474    |
|  r6idn.xlarge   |  237    |
|  r6id.12xlarge  |  2850   |
|  r6idn.2xlarge  |  474    |
|  r6id.xlarge    |  237    |
|  r6idn.24xlarge |  5700   |
```

```
|  r6id.4xlarge   |  950   |
|  r6id.32xlarge  |  7600  |
|  r6id.24xlarge  |  5700  |
|  r6idn.large    |  118   |
|  r6idn.4xlarge  |  950   |
|  r6id.large     |  118   |
|  r6id.8xlarge   |  1900  |
|  r6idn.32xlarge |  7600  |
|  r6idn.metal    |  7600  |
|  r6id.metal     |  7600  |
|  r6idn.12xlarge |  2850  |
+----------------+--------+
```

To get complete instance storage details for an instance type

Use the describe-instance-types command.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=r6id.16xlarge" \
    --query "InstanceTypes[].InstanceStorageInfo"
```

The example output shows that this instance type has two 1900 GB NVMe SSD volumes, for a total of 3800 GB of instance storage.

```
[
    {
        "TotalSizeInGB": 3800,
        "Disks": [
            {
                "SizeInGB": 1900,
                "Count": 2,
                "Type": "ssd"
            }
        ],
        "NvmeSupport": "required",
        "EncryptionSupport": "required"
    }
]
```

PowerShell

To retrieve instance store volume information

Use the Get-EC2InstanceType cmdlet. The following example displays the total size of the instance storage for each instance type in the R6i instance families with instance store volumes.

```
(Get-EC2InstanceType -Filter @{Name="instance-type"; 
 Values="r6i*"},@{Name="instance-storage-supported"; Values="true"})
 | Format-Table @{Name="InstanceType";Expression={$_.InstanceType}}, 
 @{Name="TotalSize";Expression={$_.InstanceStorageInfo.TotalSizeInGB}}
```

The following is example output.

```
InstanceType   TotalSize
------------   ---------
r6idn.16xlarge      3800
r6id.16xlarge       3800
r6id.xlarge          237
r6idn.8xlarge       1900
r6idn.2xlarge        474
r6id.12xlarge       2850
r6idn.xlarge         237
r6id.2xlarge         474
r6id.4xlarge         950
r6idn.24xlarge      5700
r6id.32xlarge       7600
r6id.24xlarge       5700
r6idn.large          118
r6id.large           118
r6idn.4xlarge        950
r6id.8xlarge        1900
r6id.metal          7600
r6idn.32xlarge      7600
r6idn.metal         7600
r6idn.12xlarge      2850
```

To get complete instance storage details for an instance type

Use the Get-EC2InstanceType cmdlet. The output is converted to JSON format.

```
(Get-EC2InstanceType -Filter @{Name="instance-type"; 
 Values="r6id.16xlarge"}).InstanceStorageInfo | ConvertTo-Json
```

The example output shows that this instance type has two 1900 GB NVMe SSD volumes, for a total of 3800 GB of instance storage.

```
{
  "Disks": [
    {
      "Count": 2,
      "SizeInGB": 1900,
      "Type": "ssd"
    }
  ],
  "EncryptionSupport": {
    "Value": "required"
  },
  "NvmeSupport": {
    "Value": "required"
  },
  "TotalSizeInGB": 3800
}
```

SSD instance store volumes for EC2 instances

Like other instance store volumes, you must map the SSD instance store volumes for your instance when you launch it. The data on an SSD instance volume persists only for the life of its associated instance. For more information, see Add instance store volumes to an EC2 instance.

NVMe SSD volumes

Some instances offer non-volatile memory express (NVMe) solid state drives (SSD) instance store volumes. For more information about the type of instance store volume supported by each instance type, see Instance store volume limits for EC2 instances.

The data on NVMe instance storage is encrypted using an XTS-AES-256 block cipher implemented in a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

Linux instances

To access NVMe volumes, the NVMe drivers must be installed. The following AMIs meet this requirement:

- AL2023

- Amazon Linux 2
- Amazon Linux AMI 2018.03 and later
- Ubuntu 14.04 or later with `linux-aws` kernel

> **Note**
>
> AWS Graviton-based instance types require Ubuntu 18.04 or later with `linux-aws` kernel

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Bottlerocket

After you connect to your instance, you can list the NVMe devices using the **lspci** command. The following is example output for an `i3.8xlarge` instance, which supports four NVMe devices.

```
[ec2-user ~]$ lspci
00:00.0 Host bridge: Intel Corporation 440FX - 82441FX PMC [Natoma] (rev 02)
00:01.0 ISA bridge: Intel Corporation 82371SB PIIX3 ISA [Natoma/Triton II]
00:01.1 IDE interface: Intel Corporation 82371SB PIIX3 IDE [Natoma/Triton II]
00:01.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 01)
00:02.0 VGA compatible controller: Cirrus Logic GD 5446
00:03.0 Ethernet controller: Device 1d0f:ec20
00:17.0 Non-Volatile memory controller: Device 1d0f:cd01
00:18.0 Non-Volatile memory controller: Device 1d0f:cd01
00:19.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1a.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1f.0 Unassigned class [ff80]: XenSource, Inc. Xen Platform Device (rev 01)
```

If you are using a supported operating system but you do not see the NVMe devices, verify that the NVMe module is loaded using the following command.

- Amazon Linux, Amazon Linux 2, Ubuntu 14/16, Red Hat Enterprise Linux, SUSE Linux Enterprise Server, CentOS 7

```
$ lsmod | grep nvme
nvme          48813  0
```

- Ubuntu 18

```
$ cat /lib/modules/$(uname -r)/modules.builtin | grep nvme
s/nvme/host/nvme-core.ko
kernel/drivers/nvme/host/nvme.ko
kernel/drivers/nvmem/nvmem_core.ko
```

The NVMe volumes are compliant with the NVMe 1.0e specification. You can use the NVMe commands with your NVMe volumes. With Amazon Linux, you can install the `nvme-cli` package from the repo using the **yum install** command. With other supported versions of Linux, you can download the `nvme-cli` package if it's not available in the image.

Windows instances

The latest AWS Windows AMIs for the following operating systems contain the AWS NVMe drivers used to interact with SSD instance store volumes that are exposed as NVMe block devices for better performance:

- Windows Server 2025
- Windows Server 2022
- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2

After you connect to your instance, you can verify that you see the NVMe volumes in Disk Manager. On the taskbar, open the context (right-click) menu for the Windows logo and choose **Disk Management**.

The AWS Windows AMIs provided by Amazon include the AWS NVMe driver. If you are not using the latest AWS Windows AMIs, you can install the current AWS NVMe driver.

Non-NVMe SSD volumes

The following instances support instance store volumes that use non-NVMe SSDs to deliver high random I/O performance: C3, I2, M3, R3, and X1. For more information about the instance store volumes supported by each instance type, see Instance store volume limits for EC2 instances.

SSD-based instance store volume I/O performance

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance do not have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10 percent of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you have written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see Instance store volume TRIM support.

Instance store volume TRIM support

Some instance types support SSD volumes with TRIM. For more information, see Instance store volume limits for EC2 instances.

Note

(Windows instances only) Instances running Windows Server 2012 R2 support TRIM as of AWS PV Driver version 7.3.0. Instances running earlier versions of Windows Server do not support TRIM.

Instance store volumes that support TRIM are fully trimmed before they are allocated to your instance. These volumes are not formatted with a file system when an instance launches, so you must format them before they can be mounted and used. For faster access to these volumes, you should skip the TRIM operation when you format them.

(Windows instances) To temporarily disable TRIM support during initial formatting, use the `fsutil behavior set DisableDeleteNotify 1` command. After formatting is complete, re-enable TRIM support by using `fsutil behavior set DisableDeleteNotify 0`.

With instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller when you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. On **Linux instances**, use the `fstrim` command to enable periodic TRIM. On **Windows instances**, use the `fsutil behavior set DisableDeleteNotify 0` command to ensure TRIM support is enabled during normal operation.

Add instance store volumes to an EC2 instance

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. They are automatically enumerated and assigned a device name on instance launch.

For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Block device mappings can be specified in the instance launch request or in the AMI used to launch the instance. The block device mapping includes a device name and the volume that it maps to. For more information, see [Block device mappings for volumes on Amazon EC2 instances]

> **Important**
>
> Instance store volumes can be attached to an instance only when you launch it. You can't attach instance store volumes to an instance after you've launched it.

After you launch an instance, you must ensure that the instance store volumes for your instance are formatted and mounted before you can use them. The root volume of an instance store-backed instance is mounted automatically.

Consideration for root volumes

A block device mapping always specifies the root volume for the instance. The root volume is always mounted automatically.

Linux instances – The root volume is either an Amazon EBS volume or an instance store volume. For instances with an instance store volume for the root volume, the size of this volume varies by AMI, but the maximum size is 10 GB. For more information, see Root device type.

Windows instances – The root volume must be an Amazon EBS volume. Instance store is not supported for the root volume.

Contents

Add instance store volumes to an Amazon EC2 AMI

You can create an AMI with a block device mapping that includes instance store volumes.

If you launch an instance that supports **non-NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance includes the instance store volumes. If the number of instance store volume block device mappings in the AMI exceeds the number of instance store volumes available to the instance, the additional instance store volume block device mappings are ignored.

If you launch an instance that supports **NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance store volume block device mappings are ignored. Instances that support NVMe instance store volumes get all of their supported instance store volumes, regardless of the block device mappings specified in the instance launch request and the AMI. The device mapping of these volumes depends on the order in which the operating system enumerates the volumes.

Considerations

- The number of available instance store volumes depends on the instance type. For more information, see the section called "Available instance store volumes".
- You must specify a device name for each block device. For more information, see Device names for volumes on Amazon EC2 instances.
- When you launch an instance, you can omit non-NVMe instance store volumes specified in the AMI block device mapping or add instance store volumes.
- For M3 instances, specify instance store volumes in the block device mapping of the instance, not the AMI. Amazon EC2 might ignore instance store volume block device mappings in the AMI.

Console

To add instance store volumes to an Amazon EBS-backed AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Actions**, **Image and templates**, **Create image**.
4. On the **Create image** page, enter a meaningful name and description for your image.
5. For each instance store volume to add, choose **Add volume**, from **Volume type** select an instance store volume, and from **Device** select a device name.
6. Choose **Create image**.

AWS CLI

To add instance store volumes to an AMI

Use the create-image command with the `--block-device-mappings` option to specify a block device mapping for an EBS-backed AMI. Use the register-image command with the `--block-device-mappings` option to specify a block device mapping for an instance store-backed AMI.

```
--block-device-mappings file://mapping.json
```

The following block device mapping adds two instance store volumes.

```
[
    {
        "DeviceName": "/dev/sdc",
        "VirtualName": "ephemeral0"
    },
    {
        "DeviceName": "/dev/sdd",
        "VirtualName": "ephemeral1"
    }
]
```

PowerShell

To add instance store volumes to an AMI

Use the New-EC2Image cmdlet with the `-BlockDeviceMapping` parameter to specify a block device mapping for an EBS-backed AMI. Use the Register-EC2Image cmdlet with the `-BlockDeviceMapping` parameter to specify a block device mapping for an instance store-backed AMI.

```
-BlockDeviceMapping $bdm
```

The following block device mapping adds two instance store volumes.

```
$bdm = @()

$sdc = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdc.DeviceName = "/dev/sdc"
$sdc.VirtualName = "ephemeral0"
$bdm += $sdc

$sdd = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdd.DeviceName = "/dev/sdd"
$sdd.VirtualName = "ephemeral1"
$bdm += $sdd
```

Add instance store volumes to an EC2 instance during launch

When you launch an instance type with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, X1, and X1e, you must specify the block device mappings for the instance store volumes that you want to attach at launch. The block device mappings must be specified in the instance launch request or in the AMI used to launch the instance.

If the AMI includes block device mappings for the instance store volumes, you do not need to specify block device mappings in the instance launch request, unless you need more instance store volumes than is included in the AMI.

If the AMI does not include block device mappings for instance store volumes, then you must specify the block device mappings in the instance launch request.

For instance types with NVMe instance store volumes, all of the supported instance store volumes are automatically attached to the instance at launch.

Considerations

- The number of available instance store volumes depends on the instance type. For more information, see the section called “Available instance store volumes”.
- You must specify a device name for each block device. For more information, see Device names for volumes on Amazon EC2 instances.
- For M3 instances, you might receive instance store volumes even if you do not specify them in the block device mapping for the instance.

Console

To specify a block device mapping in an instance launch request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the dashboard, choose **Launch instance**.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Configure storage** section, the **Instance store volumes** section lists the instance store volumes that can be attached to the instance.
5. For each instance store volume to attach, for **Device name**, select the device name to use.
6. Configure the remaining instance settings as needed, and then choose **Launch instance**.

AWS CLI

To specify a block device mapping in an instance launch request

Use the [run-instances](#) command with the `--block-device-mappings` option.

```
--block-device-mappings file://mapping.json
```

The following block device mapping adds two instance store volumes.

```
[
    {
        "DeviceName": "/dev/sdc",
        "VirtualName": "ephemeral0"
    },
    {
        "DeviceName": "/dev/sdd",
        "VirtualName": "ephemeral1"
    }
]
```

PowerShell

To specify a block device mapping in an instance launch request

Use the [New-EC2Instance](#) cmdlet with the `-BlockDeviceMapping` option.

```
-BlockDeviceMapping $bdm
```

The following block device mapping adds two instance store volumes.

```
$bdm = @()

$sdc = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdc.DeviceName = "/dev/sdc"
$sdc.VirtualName = "ephemeral0"
$bdm += $sdc

$sdd = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdd.DeviceName = "/dev/sdd"
$sdd.VirtualName = "ephemeral1"
$bdm += $sdd
```

Make instance store volume available for use on an EC2 instance

After you launch an instance with attached instance store volumes, you must mount the volumes before you can access them.

Linux instances

You can format volumes with the file system of your choice after you launch your instance.

To make an instance store volume available on Linux

1. Connect to the instance using an SSH client. For more information, see Connect to your Linux instance using SSH.
2. Use the `df -h` command to view the volumes that are formatted and mounted.

```
$ df -h
Filesystem      Size  Used Avail Use% Mounted on
devtmpfs        3.8G   72K  3.8G   1% /dev
tmpfs           3.8G     0  3.8G   0% /dev/shm
/dev/nvme0n1p1  7.9G  1.2G  6.6G  15% /
```

3. Use the `lsblk` to view any volumes that were mapped at launch but not formatted and mounted.

```
$ lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme0n1       259:1    0    8G  0 disk
##nvme0n1p1   259:2    0    8G  0 part /
##nvme0n1p128 259:3    0    1M  0 part
nvme1n1       259:0    0 69.9G  0 disk
```

4. To format and mount an instance store volume that was mapped only, do the following:

   a. Create a file system on the device using the `mkfs` command.

   ```
   $ sudo mkfs -t xfs /dev/nvme1n1
   ```

   b. Create a directory on which to mount the device using the `mkdir` command.

   ```
   $ sudo mkdir /data
   ```

   c. Mount the device on the newly created directory using the `mount` command.

```
$ sudo mount /dev/nvme1n1 /data
```

Windows instances

For Windows instances, we reformat the instance store volumes with the NTFS file system.

You can view the instance store volumes using Windows Disk Management. For more information, see List non-NVMe disks.

To manually mount an instance store volume

1. Choose **Start**, enter **Computer Management**, and then press **Enter**.
2. In left-hand panel, choose **Disk Management**.
3. If you are prompted to initialize the volume, choose the volume to initialize, select the required partition type depending on your use case, and then choose **OK**.
4. In the list of volumes, right-click the volume to mount, and then choose **New Simple Volume**.
5. On the wizard, choose **Next**.
6. On the Specify Volume Size screen, choose **Next** to use the maximum volume size. Alternatively, choose a volume size that is between the minimum and maximum disk space.
7. On the Assign a Drive Letter or Path screen, do one of the following, and choose **Next**.
   - To mount the volume with a drive letter, choose **Assign the following drive letter** and then choose the drive letter to use.
   - To mount the volume as a folder, choose **Mount in the following empty NTFS folder** and then choose **Browse** to create or select the folder to use.
   - To mount the volume without a drive letter or path, choose **Do not assign a drive letter or drive path**.
8. On the Format Partition screen, specify whether or not to format the volume. If you choose to format the volume, choose the required file system and unit size, and specify a volume label.
9. Choose **Next**, **Finish**.

Enable instance store swap volume for M1 and C1 EC2 instances

Note

This topic applies to `c1.medium` and `m1.small` Linux instances only.

The `c1.medium` and `m1.small` instance types have a limited amount of physical memory. Therefore, they are given a 900 MiB swap volume at launch time to act as virtual memory, or *swap space*, for the Linux system. Swap space in Linux can be used when a system requires more memory than it has been physically allocated. When swap space is enabled, Linux systems can swap infrequently used memory pages from physical memory to swap space (either a dedicated partition or a swap file in an existing file system) and free up that space for memory pages that require high-speed access.

Note

- Using swap space for memory paging is not as fast or efficient as using RAM. If your workload is regularly paging memory into swap space, you should consider migrating to a larger instance type with more RAM. For more information, see Amazon EC2 instance type changes.
- Although the Linux kernel sees this swap space as a partition on the root device, it is actually a separate instance store volume, regardless of your root device type.

Amazon Linux automatically enables and uses this swap space, but your AMI may require some additional steps to recognize and use this swap space. To see if your instance is using swap space, you can use the **swapon -s** command.

```
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

The above instance has a 900 MiB swap volume attached and enabled. If you don't see a swap volume listed with this command, you may need to enable swap space for the device. Check your available disks using the **lsblk** command.

```
[ec2-user ~]$ lsblk
```

```
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk
```

Here, the swap volume `xvda3` is available to the instance, but it is not enabled (notice that the `MOUNTPOINT` field is empty). You can enable the swap volume with the **swapon** command.

> **Note**
>
> You must prepend `/dev/` to the device name listed by **lsblk**. Your device may be named differently, such as `sda3`, `sde3`, or `xvde3`. Use the device name for your system in the command below.

```
[ec2-user ~]$ sudo swapon /dev/xvda3
```

Now the swap space should show up in **lsblk** and **swapon -s** output.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk [SWAP]
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

You also need to edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

Append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvda3       none    swap    sw  0       0
```

To use an instance store volume as swap space

Any instance store volume can be used as swap space. For example, the `m3.medium` instance type includes a 4 GB SSD instance store volume that is appropriate for swap space. If your instance store volume is much larger (for example, 350 GB), you may consider partitioning the volume with a smaller swap partition of 4-8 GB and the rest for a data volume.

> **Note**
>
> This procedure applies only to instance types that support instance storage. For a list of supported instance types, see Instance store volume limits for EC2 instances.

1. List the block devices attached to your instance to get the device name for your instance store volume.

```
[ec2-user ~]$ lsblk -p
NAME        MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
/dev/xvdb   202:16   0   4G  0 disk /media/ephemeral0
/dev/xvda1 202:1    0   8G  0 disk /
```

   In this example, the instance store volume is `/dev/xvdb`. Because this is an Amazon Linux instance, the instance store volume is formatted and mounted at `/media/ephemeral0`; not all Linux operating systems do this automatically.

2. (Optional) If your instance store volume is mounted (it lists a `MOUNTPOINT` in the **lsblk** command output), unmount it with the following command.

```
[ec2-user ~]$ sudo umount /dev/xvdb
```

3. Set up a Linux swap area on the device with the **mkswap** command.

```
[ec2-user ~]$ sudo mkswap /dev/xvdb
mkswap: /dev/xvdb: warning: wiping old ext3 signature.
Setting up swapspace version 1, size = 4188668 KiB
no label, UUID=b4f63d28-67ed-46f0-b5e5-6928319e620b
```

4. Enable the new swap space.

```
[ec2-user ~]$ sudo swapon /dev/xvdb
```

5. Verify that the new swap space is being used.

```
[ec2-user ~]$ swapon -s
```

```
Filename     Type  Size Used Priority
/dev/xvdb                              partition 4188668 0 -1
```

6. Edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

If your `/etc/fstab` file has an entry for `/dev/xvdb` (or `/dev/sdb`) change it to match the line below; if it does not have an entry for this device, append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvdb       none     swap     sw   0        0
```

Important

Instance store volume data is lost when an instance is stopped or hibernated; this includes the instance store swap space formatting created in Step 3. If you stop and restart an instance that has been configured to use instance store swap space, you must repeat Step 1 through Step 5 on the new instance store volume.

Initialize instance store volumes on EC2 instances

Because of the way that Amazon EC2 virtualizes disks, the first write to any location on some instance store volumes performs more slowly than subsequent writes. For most applications, amortizing this cost over the lifetime of the instance is acceptable. However, if you require high disk performance, we recommend that you initialize your drives by writing once to every drive location before production use.

Note

Instance types with direct-attached solid state drives (SSD) and TRIM support provide maximum performance at launch time, without initialization. For information about the instance store for each instance type, see Instance store volume limits for EC2 instances.

If you require greater flexibility in latency or throughput, we recommend using Amazon EBS.

To initialize the instance store volumes, use the following dd commands, depending on the store to initialize (for example, `/dev/sdb` or `/dev/nvme1n1`).

> **Note**
>
> Make sure to unmount the drive before performing this command.
> Initialization can take a long time (about 8 hours for an extra large instance).

To initialize the instance store volumes, use the following commands on the `m1.large`, `m1.xlarge`, `c1.xlarge`, `m2.xlarge`, `m2.2xlarge`, and `m2.4xlarge` instance types:

```
dd if=/dev/zero of=/dev/sdb bs=1M
dd if=/dev/zero of=/dev/sdc bs=1M
dd if=/dev/zero of=/dev/sdd bs=1M
dd if=/dev/zero of=/dev/sde bs=1M
```

To perform initialization on all instance store volumes at the same time, use the following command:

```
dd if=/dev/zero bs=1M|tee /dev/sdb|tee /dev/sdc|tee /dev/sde > /dev/sdd
```

Configuring drives for RAID initializes them by writing to every drive location. When configuring software-based RAID, make sure to change the minimum reconstruction speed:

```
echo $((30*1024)) > /proc/sys/dev/raid/speed_limit_min
```

Root volumes for your Amazon EC2 instances

When you launch an instance, we create a *root volume* for the instance. The root volume contains the image used to boot the instance. Each instance has a single root volume. You can add storage volumes to your instances during or after launch.

The AMI that you use to launch an instance determines the type of root volume. You can launch an instance from either an *Amazon EBS-backed AMI* (Linux and Windows instances) or an *instance store-backed AMI* (Linux instances only). There are significant differences between what you can do with each type of AMI. For more information about these differences, see Root device type.

We recommend that you use AMIs backed by Amazon EBS, because these instances launch faster and use persistent storage.

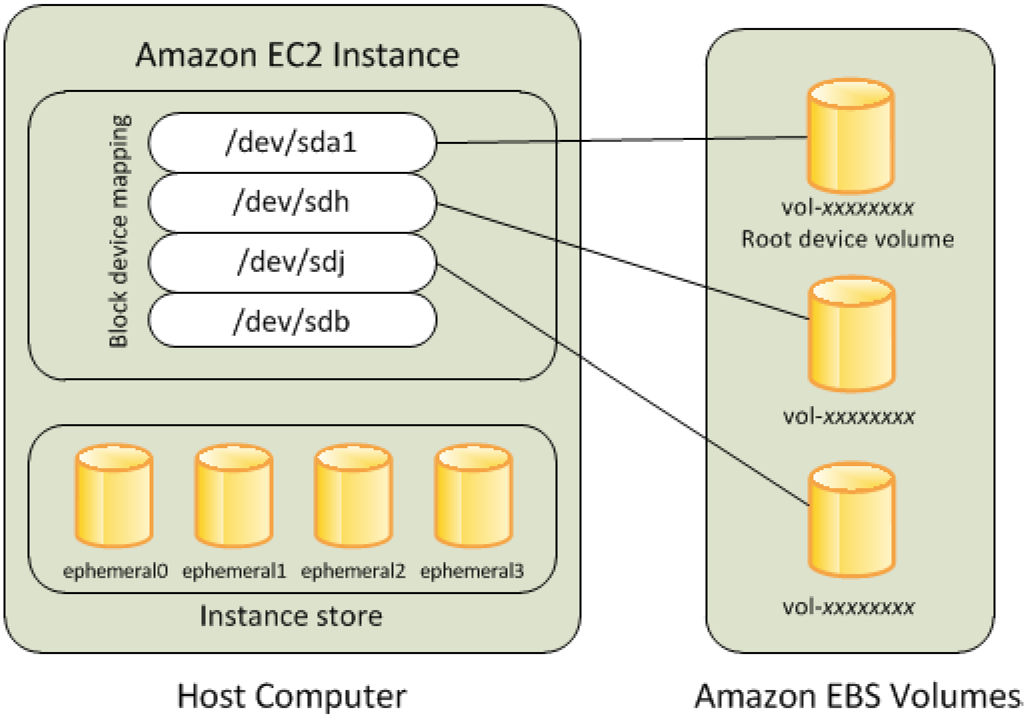
We reserve specific device names for root volumes. For more information, see Device names for volumes on Amazon EC2 instances.

Contents

Amazon EBS-backed instances

Instances that use Amazon EBS for the root volume automatically have an Amazon EBS volume attached. When you launch an Amazon EBS-backed instance, we create an Amazon EBS volume for each Amazon EBS snapshot referenced by the AMI you use. You can optionally use other Amazon EBS volumes or instance store volumes, depending on the instance type.

An Amazon EBS-backed instance can be stopped and later restarted without affecting data stored in the attached volumes. There are various instance– and volume-related tasks you can do when an Amazon EBS-backed instance is in a stopped state. For example, you can modify the properties of the instance, change its size, or update the kernel it is using, or you can attach your root volume to a different running instance for debugging or any other purpose. For more information, see Amazon EBS volumes.



Limitation

You can't use `st1` or `sc1` EBS volumes as root volumes.

Instance failure

If an Amazon EBS-backed instance fails, you can restore your session by following one of these methods:

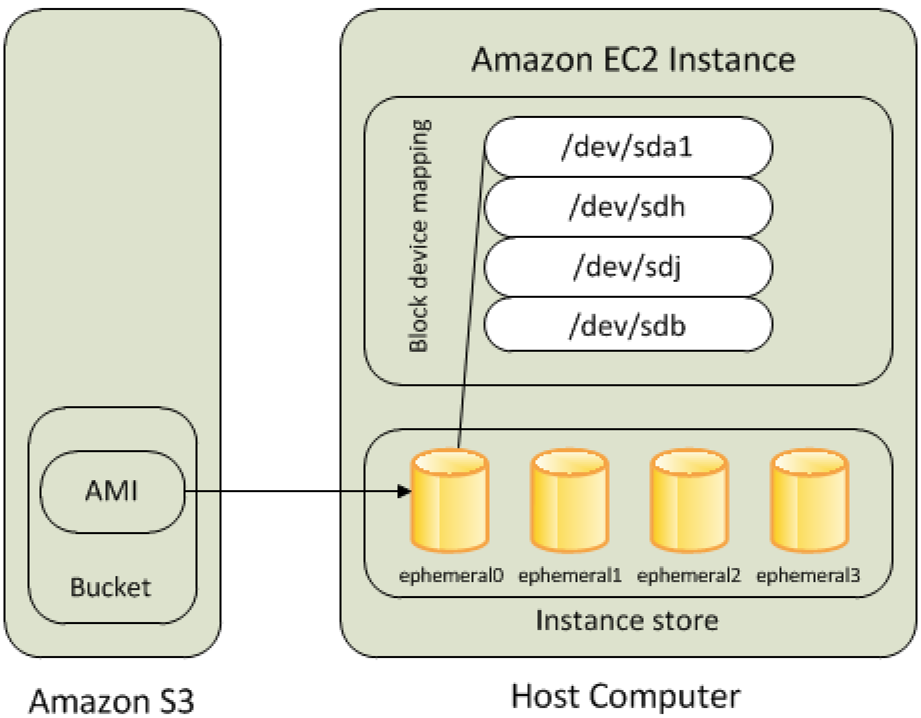
- Stop and then start again (try this method first).
- Automatically snapshot all relevant volumes and create a new AMI. For more information, see Create an Amazon EBS-backed AMI.
- Attach the volume to the new instance by following these steps:
  1. Create a snapshot of the root volume.
  2. Register a new AMI using the snapshot.
  3. Launch a new instance from the new AMI.
  4. Detach the remaining Amazon EBS volumes from the old instance.
  5. Reattach the Amazon EBS volumes to the new instance.

Instance store-backed instances (Linux instances only)

> **Note**
>
> Windows instances do not support instance-store backed root volumes.

Instances that use instance stores for the root volume automatically have one or more instance store volumes available, with one volume serving as the root volume. When an instance is launched, the image that is used to boot the instance is copied to the root volume. Note that you can optionally use additional instance store volumes, depending on the instance type.

Any data on the instance store volumes persists as long as the instance is running, but this data is deleted when the instance is terminated (instance store-backed instances do not support the **Stop** action) or if it fails (such as if an underlying drive has issues). For more information, see [Instance store temporary block storage for EC2 instances](#).



Supported instance types

Only the following instance types support an instance store volume as the root volume: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

Instance failure

After an instance store-backed instance fails or terminates, it cannot be restored. If you plan to use Amazon EC2 instance store-backed instances, we highly recommend that you distribute the data on your instance stores across multiple Availability Zones. You should also back up critical data from your instance store volumes to persistent storage on a regular basis.

Keep an Amazon EBS root volume after an Amazon EC2 instance terminates

By default, the Amazon EBS root volume for an instance is deleted when the instance terminates. You can change the default behavior to ensure that an Amazon EBS root volume persists after the instance terminates. To change the default behavior, set the `DeleteOnTermination` attribute to `false`. You can do so either at instance launch or later on.

Tasks

- Configure the root volume to persist during instance launch
- Configure the root volume to persist for an existing instance
- Confirm that a root volume is configured to persist

Configure the root volume to persist during instance launch

You can configure the root volume to persist when you launch an instance.

Console

To configure the root volume to persist when you launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and then choose **Launch instances**.
3. Choose an Amazon Machine Image (AMI), choose and instance type, choose a key pair, and configure your network settings.
4. For **Configure storage**, choose **Advanced**.
5. Expand the root volume.
6. For **Delete on termination**, choose **No**.
7. When you are finished configuring your instance, choose **Launch instance**.

AWS CLI

To configure the root volume to persist when you launch an instance

Use the run-instances command and include the following option.

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```
[
    {
        "DeviceName": "/dev/sda1",
        "Ebs": {
            "DeleteOnTermination": false
        }
    }
]
```

PowerShell

To configure the root volume to persist when you launch an instance

Use the New-EC2Instance cmdlet and include the following parameter.

```
-BlockDeviceMapping $bdm
```

Create a block device mapping that sets the `DeleteOnTermination` attribute to `$false`.

```
$ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
$ebs.DeleteOnTermination = $false
$bdm = New-Object Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "dev/xvda"
$bdm.Ebs = $ebs
```

Configure the root volume to persist for an existing instance

You can configure the root volume to persist for a running instance. Note that you can't complete this task using the Amazon EC2 console.

AWS CLI

To configure the root volume to persist for an existing instance

Use the modify-instance-attribute command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`.

```
[
    {
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "DeleteOnTermination": false
        }
    }
]
```

PowerShell

To configure the root volume to persist for an existing instance

Use the Edit-EC2InstanceAttribute cmdlet with a block device mapping that sets the `DeleteOnTermination` attribute to `$false`.

```
$ebs = New-Object Amazon.EC2.Model.EbsInstanceBlockDeviceSpecification
$ebs.DeleteOnTermination = $false
$bdm = New-Object Amazon.EC2.Model.InstanceBlockDeviceMappingSpecification
$bdm.DeviceName = "/dev/xvda"
$bdm.Ebs = $ebs
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -BlockDeviceMapping $bdm
```

Confirm that a root volume is configured to persist

You can confirm that a root volume is configured to persist.

Console

To confirm that a root volume is configured to persist

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Storage** tab, under **Block devices**, locate the entry for the root volume. If **Delete on termination** is No, the volume is configured to persist.

AWS CLI

To confirm that a root volume is configured to persist

Use the describe-instances command and verify that the `DeleteOnTermination` attribute is set to `false`.

```
aws ec2 describe-instances \
    --instance-id i-1234567890abcdef0 \
    --query "Reservations[].Instances[].BlockDeviceMappings"
```

The following is example output.

```
[
    [
        {
            "DeviceName": "/dev/xvda",
            "Ebs": {
                "AttachTime": "2024-07-12T04:05:33.000Z",
                "DeleteOnTermination": false,
                "Status": "attached",
                "VolumeId": "vol-1234567890abcdef0"

        }
    ]
]
```

PowerShell

To confirm that a root volume is configured to persist

Use the [Get-EC2Instance](#) cmdlet and verify that the `DeleteOnTermination` attribute is set to `False`.

```
(Get-EC2Instance -InstanceId i-
i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

The following is example output.

```
AssociatedResource  :
AttachTime          : 7/12/2024 4:05:33 AM
DeleteOnTermination : False
Operator            :
Status              : attached
VolumeId            : vol-1234567890abcdef0
```

Replace the root volume for an Amazon EC2 instance without stopping it

Amazon EC2 enables you to replace the root Amazon EBS volume for a running instance while retaining the following:

- Data stored on instance store volumes — Instance store volumes remain attached to the instance after the root volume has been restored.
- Data stored on data (non-root) Amazon EBS volumes — Non-root Amazon EBS volumes remain attached to the instance after the root volume has been restored.
- Network configuration — All network interfaces remain attached to the instance and they retain their IP addresses, identifiers, and attachment IDs. When the instance becomes available, all pending network traffic is flushed. Additionally, the instance remains on the same physical host, so it retains its public and private IP addresses and DNS name.
- IAM policies — IAM profiles and policies (such as tag-based policies) that are associated with the instance are retained and enforced.

Contents

- Replace a root volume

How root volume replacement works

When you replace the root volume for an instance, we create *root volume replacement task*. The original root volume is detached from the instance, and the new root volume is attached to the instance in its place. The instance's block device mapping is updated to reflect the ID of the replacement root volume.

When you replace the root volume for an instance, you must specify the source of the snapshot for the new volume. The following are the possible options.

Restore a root volume to its original state

This option replaces the current root volume with a volume that is based on the snapshot that was used to create it.

Considerations for using the launch state

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

Replace the root volume using a snapshot

This option replaces the current root volume with a replacement volume that is based on the snapshot that you specify. For example, a specific snapshot that you previously created from this root volume. This is useful if you need to recover from issues caused by corruption of the root volume or network configuration errors in the guest operating system.

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

Considerations for using a snapshot

- You can only use snapshots that were created directly from the instance's current or previous root volumes.
- You can't use snapshot copies created from snapshots that were taken from the root volume.
- After successfully replacing the root volume, you can still use snapshots taken from the original root volume to replace the new (replacement) root volume.

Replace the root volume using an AMI

This option replaces the current root volume using an AMI that you specify. This is useful if you need to perform operating system and application patching or upgrades. The AMI must have the same product code, billing information, architecture type, and virtualization type as the instance.

If the instance is enabled for ENA or sriov-net, then you must use an AMI that supports those features. If the instance is not enabled for ENA or sriov-net, then you can either select an AMI that doesn't include support for those features, or you can automatically add support if you select an AMI that supports ENA or sriov-net.

If the instance is enabled for NitroTPM, then you must use an AMI that has NitroTPM enabled. NitroTPM support is not enabled if the instance was not configured for it, regardless of the AMI that you select.

You can select an AMI with a different boot mode than that of the instance, as long as the instance supports the boot mode of the AMI. If the instance does not support the boot mode, the request fails. If the instance supports the boot mode, the new boot mode is propagated to the instance and its UEFI data is updated accordingly. If you manually modified the boot order or added a private UEFI Secure Boot key to load private kernel modules, the changes are lost during root volume replacement.

The replacement root volume gets the same volume type and delete on termination attribute as the original root volume, and it gets the size of the AMI root volume block device mapping.

> **Note**
>
> The size of the AMI root volume block device mapping must be equal to or greater than the size of the original root volume. If the size of the AMI root volume block device mapping is smaller than the size of the original root volume, the request fails.

After the root volume replacement task completes, the following new and updated information is reflected when you describe the instance using the console, AWS CLI or AWS SDKs:

- New AMI ID
- New volume ID for the root volume
- Updated boot mode configuration (if changed by the AMI)
- Updated NitroTPM configuration (if enabled by the AMI)

- Updated ENA configuration (if enabled by the AMI)
- Updated sriov-net configuration (if enabled by the AMI)

The new AMI ID is also reflected in the instance metadata.

Considerations for using an AMI:

- If you use an AMI that has multiple block device mappings, only the root volume of the AMI is used. The other (non-root) volumes are ignored.
- You can only use this feature if you have permissions to the AMI and its associated root volume snapshot. You cannot use this feature with AWS Marketplace AMIs.
- You can only use an AMI without a product code only if the instance does not have a product code.
- The size of the AMI root volume block device mapping must be equal to or greater than the size of the original root volume. If the size of the AMI root volume block device mapping is smaller than the size of the original root volume, the request fails.
- The instance identity documents for the instance are automatically updated.
- If the instance supports NitroTPM, the NitroTPM data for the instance is reset and new keys are generated.

You can choose whether to keep the original root volume after the root volume replacement process has completed. If you choose delete the original root volume after the replacement process completes, the original root volume is automatically deleted and becomes unrecoverable. If you choose to keep the original root volume after the process completes, the volume remains provisioned in your account; you must manually delete the volume when you no longer need it.

The root volume replacement task transitions through the following states:

- `pending` — The replacement volume is being created.
- `in-progress` — The original volume is being detached and the replacement volume is being attached.
- `succeeded` — The replacement volume has been successfully attached to the instance and the instance is available.
- `failing` — The replacement task is in the process of failing.
- `failed` — The replacement task has failed, but the root volume is still attached.

- `failing-detached` — The replacement task is in the process of failing and the instance might not have a root volume attached.
- `failed-detached` — The replacement task has failed and the instance doesn't have a root volume attached.

If the root volume replacement task fails, the instance is rebooted and the original root volume remains attached to the instance.

Considerations

Before you begin, consider the following.

Requirements

- The instance must be in the `running` state.
- The instance is automatically rebooted during the process. The contents of the memory (RAM) is erased during the reboot. No manual reboots are required.
- You can't replace the root volume if it is an instance store volume. Only instances with Amazon EBS root volumes are supported.
- You can replace the root volume for all virtualized instance types and EC2 Mac bare metal instances. No other bare metal instance types are supported.
- You can only use snapshots that were created directly from the instance's current or previous root volumes.
- If your account is enabled for Amazon EBS encryption by default in the current Region, the replacement root volume created by the root volume replacement task is always encrypted, regardless of the encryption status of the specified snapshot or the root volume of the specified AMI.

Encryption outcomes

The following table summarizes the possible encryption outcomes.

	Original root volume	Specified snapshot or AMI	Encryption by default	Replacement root volume	Encryption key used for replacement root volume
Restore replacement root volume to initial launch state	Encrypted	Not applicable	Not considered	Encrypted	Same KMS key as original root volume
	Unencrypted	Not applicable	Disabled	Unencrypted	Not applicable
	Unencrypted	Not applicable	Enabled	Encrypted	Account's default KMS key for Amazon EBS encryption
Restore replacement root volume from snapshot or AMI	Encrypted	Unencrypted	Not considered	Encrypted	Same KMS key as original root volume
	Encrypted	Encrypted	Not considered	Encrypted	Same KMS key as original root volume
	Unencrypted	Unencrypted	Disabled	Unencrypted	Not applicable
	Unencrypted	Unencrypted	Enabled	Encrypted	Account's default KMS key for Amazon EBS encryption

	Original root volume	Specified snapshot or AMI	Encryption by default	Replacement root volume	Encryption key used for replacement root volume
	Unencrypted	Encrypted	Not considered	Encrypted	If the AMI or snapshot is owned by the account, the replacement volume is encrypted with the AMI or snapshot's KMS key. If AMI or snapshot is shared with the account, replacement volume is encrypted with the account's default KMS key for Amazon EBS encryption.

Replace a root volume

When you replace the root volume for an instance, a *root volume replacement task* is created. You can use the root volume replacement task to monitor the progress and outcome of the replacement process.

Console

To replace the root volume

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance for which to replace the root volume and choose **Actions**, **Monitor and troubleshoot**, **Replace root volume**.

   > **Note**
   >
   > The **Replace root volume** action is disabled if the selected instance is not in the `running` state.

4. For **Restore**, choose one of the following options:
   - **Launch state** – Restore the replacement root volume from the snapshot that was used to create the current root volume.
   - **Snapshot** – Restore the replacement root volume to the snapshot that you specify. For **Snapshot**, select the snapshot to use.
   - **Image** – Restore the replacement root volume using the AMI that you specify. For **Image**, select the AMI to use.
5. (Optional) For **Volume initialization rate**, you can specify the Amazon EBS Provisioned Rate for Volume Initialization (volume initialization rate), in MiB/s, at which the snapshot blocks are to be downloaded from Amazon S3 to the volume. For more information, see Use an Amazon EBS Provisioned Rate for Volume Initialization. To use the default initialization rate or fast snapshot restore (if it is enabled for the selected snapshot), don't specify a rate.
6. (Optional) To delete the root volume that you are replacing, select **Delete replaced root volume**.
7. Choose **Create replacement task**.
8. To monitor the replacement task, choose the **Storage** tab for the instance and expand **Recent root volume replacement tasks**.

AWS CLI

To restore the replacement root volume to the launch state

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume. Omit the `--snapshot-id` and `--image-id` parameters. To delete the original root volume after it has been replaced, include `--delete-replaced-root-volume` and specify `true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `--volume-initialization-rate`, specify a value between `100` and `300` MiB/s.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--delete-replaced-root-volume \
--volume-initialization-rate 150
```

To restore the replacement root volume to a specific snapshot

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume. For `--snapshot-id`, specify the ID of the snapshot to use. To delete the original root volume after it has been replaced, include `--delete-replaced-root-volume` and specify `true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `--volume-initialization-rate`, specify a value between `100` and `300` MiB/s.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--snapshot-id snap-9876543210abcdef0 \
--delete-replaced-root-volume \
--volume-initialization-rate 150
```

To restore the replacement root volume using an AMI

Use the create-replace-root-volume-task command. For `--instance-id`, specify the ID of the instance for which to replace the root volume. For `--image-id`, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include `--delete-replaced-root-volume` and specify `true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `--volume-initialization-rate`, specify a value between `100` and `300` MiB/s.

```
aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--image-id ami-09876543210abcdef \
--delete-replaced-root-volume \
--volume-initialization-rate 150
```

To view the status of a root volume replacement task

Use the describe-replace-root-volume-tasks command and specify the IDs of the root volume replacement tasks to view.

```
aws ec2 describe-replace-root-volume-tasks \
    --replace-root-volume-task-ids replacevol-1234567890abcdef0 \
    --query ReplaceRootVolumeTasks[].TaskState
```

The following is example output.

```
[
    "succeeded"
]
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
$ aws ec2 describe-replace-root-volume-tasks \
    --filters Name=instance-id,Values=i-1234567890abcdef0
```

PowerShell

To restore the replacement root volume to the launch state

Use the New-EC2ReplaceRootVolumeTask command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume. Omit the `-SnapshotId` and `-ImageId` parameters. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `-VolumeInitializationRate`, specify a value between `100` and `300` MiB/s.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -VolumeInitializationRate 150 `
```

```
    -DeleteReplacedRootVolume $true
```

To restore the replacement root volume to a specific snapshot

Use the New-EC2ReplaceRootVolumeTask command. For `--InstanceId`, specify the ID of the instance for which to replace the root volume. For `-SnapshotId`, specify the ID of the snapshot to use. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `-VolumeInitializationRate`, specify a value between `100` and `300` MiB/s.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -SnapshotId snap-9876543210abcdef0 `
    -VolumeInitializationRate 150 `
    -DeleteReplacedRootVolume $true
```

To restore the replacement root volume using an AMI

Use the New-EC2ReplaceRootVolumeTask command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume. For `-ImageId`, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`. To specify the volume initialization rate at which the snapshot blocks are downloaded from Amazon S3 to the volume, for `-VolumeInitializationRate`, specify a value between `100` and `300` MiB/s.

```
New-EC2ReplaceRootVolumeTask `
    -InstanceId i-1234567890abcdef0 `
    -ImageId ami-0abcdef1234567890 `
    -VolumeInitializationRate 150 `
    -DeleteReplacedRootVolume $true
```

To view the status of a root volume replacement task

Use the Get-EC2ReplaceRootVolumeTask command and specify the IDs of the root volume replacement tasks to view.

```
(Get-EC2ReplaceRootVolumeTask `
    -ReplaceRootVolumeTaskIds replacevol-1234567890abcdef0).TaskState.Value
```

The following is example output.

```
Succeeded
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
PS C:\> Get-EC2ReplaceRootVolumeTask -Filters @{Name = 'instance-id'; Values =
 'i-1234567890abcdef0'} | Format-Table
```

Device names for volumes on Amazon EC2 instances

When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The number of volumes that your instance can support is determined by the operating system. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

Contents

Available device names

Linux instances

There are two types of virtualization available for Linux instances: paravirtual (PV) and hardware virtual machine (HVM). The virtualization type of an instance is determined by the AMI used to launch the instance. All instance types support HVM AMIs. Some previous generation instance types support PV AMIs. Be sure to note the virtualization type of your AMI because the recommended and available device names that you can use depend on the virtualization type of your instance. For more information, see Virtualization types.

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume.

Virtualization type	Available	Reserved for root volume	Recommended for EBS data volumes	Instance store volumes
Paravirtual	/dev/sd[a-z] /dev/sd[a-z][1-15] /dev/hd[a-z] /dev/hd[a-z][1-15]	/dev/sda1	/dev/sd[f-p] /dev/sd[f-p][1-6]	/dev/sd[b-e]
HVM	/dev/sd[a-z] /dev/xvd[a-c][a-z] /dev/xvdd[a-x]	Differs by AMI /dev/sda1 or /dev/xvda	/dev/sd[b-z] /dev/xvdb[b-z] *	/dev/sd[b-e] /dev/sd[b-h] (h1.16xlarge) /dev/sd[b-y] (d2.8xlarge) /dev/sd[b-i] (i2.8xlarge) **

* The device names that you specify for NVMe EBS volumes in a block device mapping are renamed using NVMe device names (`/dev/nvme[0-26]n1`). The block device driver can assign NVMe device names in a different order than you specified for the volumes in the block device mapping.

** NVMe instance store volumes are automatically enumerated and assigned an NVMe device name.

Windows instances

AWS Windows AMIs use one of the following sets of drivers to permit access to virtualized hardware:

- AWS PV: Paravirtual drivers for Windows instances
- AWS NVMe: AWS NVMe drivers

Device names for Nitro based instances

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume to a Nitro based instance.

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
AWS NVMe	xvd[a-z] xvd[a-c][a-z] xvdd[a-x] /dev/sda1	/dev/sda1	xvd[b-z] xvdb[b-z]	*

* NVMe instance store volumes are automatically enumerated and are assigned a Windows drive letter.

Device names for Xen based instances

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume to a Xen based instance.

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
AWS PV	xvd[b-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-z]	xvdc[a-x] xvd[a-e]
Citrix PV (no longer supported)	xvd[b-z] xvd[b-c][a-z] /dev/sda1	/dev/sda1	xvd[f-z]	xvdc[a-x] xvd[a-e]

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
	/dev/sd[b-e]			
Red Hat PV (no longer supported)	xvd[a-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-p]	xvdc[a-x] xvd[a-e]

For more information about instance store volumes, see Instance store temporary block storage for EC2 instances. For more information about NVMe EBS volumes (Nitro-based instances), including how to identify the EBS device, see Amazon EBS and NVMe in the *Amazon EBS User Guide*.

Device name considerations

Keep the following in mind when selecting a device name:

- The ending portion of device names that you use shouldn't overlap as it can cause issues when you start your instance. For example, avoid using combinations such as `/dev/xvdf` and `xvdf` for volumes attached to the same instance.
- Although you can attach your EBS volumes using the device names used to attach instance store volumes, we strongly recommend that you don't because the behavior can be unpredictable.
- The number of NVMe instance store volumes for an instance depends on the size of the instance. NVMe instance store volumes are automatically enumerated and assigned an NVMe device name (Linux instances) or a Windows drive letter (Windows instances).
- (Windows instances) AWS Windows AMIs come with additional software that prepares an instance when it first boots up. This is either the EC2Config service (Windows AMIs prior to Windows Server 2016) or EC2Launch (Windows Server 2016 and later). After the devices have been mapped to drives, they are initialized and mounted. The root drive is initialized and mounted as `C:\`. By default, when an EBS volume is attached to a Windows instance, it can show up as any drive letter on the instance. You can change the settings to set the drive letters of the volumes per your specifications. For instance store volumes, the default depends on the driver. AWS PV drivers and Citrix PV drivers assign instance store volumes drive letters going from Z: to A:. Red Hat drivers assign instance store volumes drive letters going from D: to Z:. For more

information, see Windows launch agents on Amazon EC2 Windows instances, and How volumes are attached and mapped for Amazon EC2 Windows instances.

- (Linux instances) Depending on the block device driver of the kernel, the device could be attached with a different name than you specified. For example, if you specify a device name of `/dev/sdh`, your device could be renamed `/dev/xvdh` or `/dev/hdh`. In most cases, the trailing letter remains the same. In some versions of Red Hat Enterprise Linux (and its variants, such as CentOS), the trailing letter could change (`/dev/sda` could become `/dev/xvde`). In these cases, the trailing letter of each device name is incremented the same number of times. For example, if `/dev/sdb` is renamed `/dev/xvdf`, then `/dev/sdc` is renamed `/dev/xvdg`. Amazon Linux creates a symbolic link for the name you specified to the renamed device. Other operating systems could behave differently.
- (Linux instances) HVM AMIs do not support the use of trailing numbers on device names, except for `/dev/sda1`, which is reserved for the root device, and `/dev/sda2`. While using `/dev/sda2` is possible, we do not recommend using this device mapping with HVM instances.
- (Linux instances) When using PV AMIs, you cannot attach volumes that share the same device letters both with and without trailing digits. For example, if you attach a volume as `/dev/sdc` and another volume as `/dev/sdc1`, only `/dev/sdc` is visible to the instance. To use trailing digits in device names, you must use trailing digits on all device names that share the same base letters (such as `/dev/sdc1`, `/dev/sdc2`, `/dev/sdc3`).
- (Linux instances) Some custom kernels might have restrictions that limit use to `/dev/sd[f-p]` or `/dev/sd[f-p][1-6]`. If you're having trouble using `/dev/sd[q-z]` or `/dev/sd[q-z][1-6]`, try switching to `/dev/sd[f-p]` or `/dev/sd[f-p][1-6]`.

Before you specify the device name that you've selected, verify that it is available. Otherwise, you'll get an error that the device name is already in use. To view the disk devices and their mount points, use the **lsblk** command (Linux instances), or the Disk Management utility or the **diskpart** command (Windows instances).

Block device mappings for volumes on Amazon EC2 instances

Each instance that you launch has an associated root device volume, which is either an Amazon EBS volume or an instance store volume. You can use block device mappings to specify additional EBS volumes or instance store volumes to attach to an instance when it's launched. You can also attach additional EBS volumes to a running instance. However, the only way to attach instance store volumes to an instance is to use block device mappings to attach the volumes as the instance is launched.

Contents

Block device mapping concepts

A *block device* is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer.

Amazon EC2 supports two types of block devices:

- Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
- EBS volumes (remote storage devices)

A *block device mapping* defines the block devices (instance store volumes and EBS volumes) to attach to an instance. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you launched the instance. Note that all NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in your block device mapping has no effect.

Contents

Block device mapping entries

When you create a block device mapping, you specify the following information for each block device that you need to attach to the instance:

- The device name used within Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume. The name assigned can be different from the name that Amazon EC2 recommends. For more information, see Device names for volumes on Amazon EC2 instances.

For Instance store volumes, you also specify the following information:

- The virtual device: `ephemeral[0-23]`. Note that the number and size of available instance store volumes for your instance varies by instance type.

For NVMe instance store volumes, the following information also applies:

- These volumes are automatically enumerated and assigned a device name; including them in your block device mapping has no effect.

For EBS volumes, you also specify the following information:

- The ID of the snapshot to use to create the block device (snap-*xxxxxxxx*). This value is optional as long as you specify a volume size. You can't specify the ID of an archived snapshot.
- The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
- Whether to delete the volume on instance termination (`true` or `false`). The default value is `true` for the root device volume and `false` for attached volumes. When you create an AMI, its block device mapping inherits this setting from the instance. When you launch an instance, it inherits this setting from the AMI.
- The volume type, which can be `gp2` and `gp3` for General Purpose SSD, `io1` and `io2` for Provisioned IOPS SSD, `st1` for Throughput Optimized HDD, `sc1` for Cold HDD, or `standard` for Magnetic.
- The number of input/output operations per second (IOPS) that the volume supports. (Used only with `io1` and `io2` volumes.)

Block device mapping instance store caveats

There are several caveats to consider when launching instances with AMIs that have instance store volumes in their block device mappings.

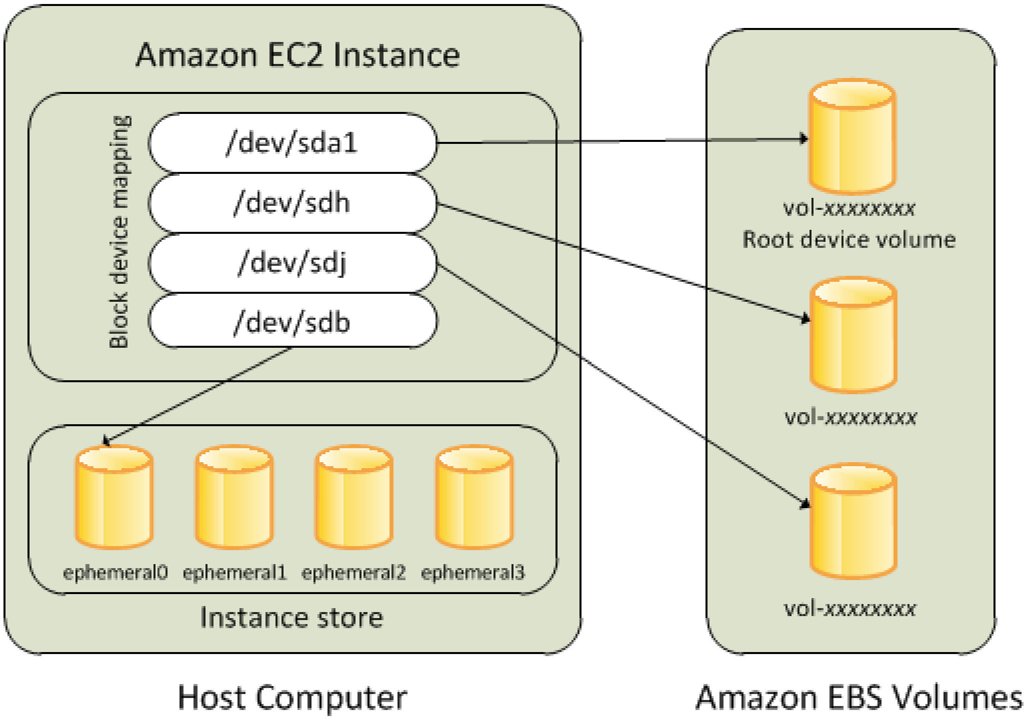
- Some instance types include more instance store volumes than others, and some instance types contain no instance store volumes at all. If your instance type supports one instance store volume, and your AMI has mappings for two instance store volumes, then the instance launches with one instance store volume.
- Instance store volumes can only be mapped at launch time. You cannot stop an instance without instance store volumes (such as the `t2.micro`), change the instance to a type that supports instance store volumes, and then restart the instance with instance store volumes. However, you can create an AMI from the instance and launch it on an instance type that supports instance store volumes, and map those instance store volumes to the instance.
- If you launch an instance with instance store volumes mapped, and then stop the instance and change it to an instance type with fewer instance store volumes and restart it, the instance store volume mappings from the initial launch still show up in the instance metadata. However, only the maximum number of supported instance store volumes for that instance type are available to the instance.

> **Note**
>
> When an instance is stopped, all data on the instance store volumes is lost.

- Depending on instance store capacity at launch time, M3 instances may ignore AMI instance store block device mappings at launch unless they are specified at launch. You should specify instance store block device mappings at launch time, even if the AMI you are launching has the instance store volumes mapped in the AMI, to ensure that the instance store volumes are available when the instance launches.

Example block device mapping

This figure shows an example block device mapping for an EBS-backed instance. It maps `/dev/sdb` to `ephemeral0` and maps two EBS volumes, one to `/dev/sdh` and the other to `/dev/sdj`. It also shows the EBS volume that is the root device volume, `/dev/sda1`.



Note that this example block device mapping is used in the example commands and APIs in this topic. You can find example commands and APIs that create block device mappings in Specify a block device mapping for an AMI and Update the block device mapping when launching an instance.

How devices are made available in the operating system

Device names like `/dev/sdh` and `xvdh` are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an EC2 instance. After a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

Linux instances – The device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots. The instance type determines which instance store volumes are formatted and mounted by default. You can mount additional instance store volumes at launch, as long as you don't exceed the number of instance store volumes available for your instance type. For more information, see Instance store temporary block storage for EC2 instances. The block device driver for the instance determines which devices are used when the volumes are formatted and mounted.

Windows instances – The device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots, and then the Ec2Config service initializes and mounts the drives. The root device volume is mounted as `C:\`. The instance store volumes are mounted as `Z:\`, `Y:\`, and so on. When an EBS volume is mounted, it can be mounted using any available drive letter. However, you can configure how drive letters are assigned to EBS volumes; for more information, see the section called "Windows launch agents".

Add block device mappings to an AMI

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. To add more block devices to an AMI, you must create your own AMI.

Contents

Specify a block device mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an instance store-backed AMI, you can add instance store volumes only by modifying the block device mapping entries in the image manifest file when registering the image.

> **Note**
>
> For M3 instances, you must specify instance store volumes in the block device mapping for the instance when you launch it. When you launch an M3 instance, instance store volumes specified in the block device mapping for the AMI may be ignored if they are not specified as part of the instance block device mapping.

Console

To add volumes to an AMI

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. Select an instance and choose **Actions**, **Image and templates**, **Create image**.
4. Enter a name and a description for the image.
5. The instance volumes appear under **Instance volumes**. To add another volume, choose **Add volume**.
6. For **Volume type**, choose the volume type. For **Device** choose the device name. For an EBS volume, you can specify additional details, such as a snapshot, volume size, volume type, IOPS, and encryption state.
7. Choose **Create image**.

AWS CLI

To add volumes to an AMI

Use the create-image command to specify a block device mapping for an EBS-backed AMI. Use the register-image command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the `--block-device-mappings` parameter. You can specified arguments encoded in JSON directly on the command line or by referencing a JSON file, as shown here.

```
--block-device-mappings file://mapping.json
```

To add an instance store volume, use the following mapping. Note that NVMe instance store volumes are added automatically.

```
{
    "DeviceName": "device_name",
    "VirtualName": "ephemeral0"
}
```

To add an empty 100 GiB volume, use the following mapping.

```
{
    "DeviceName": "device_name",
    "Ebs": {
      "VolumeSize": 100
    }
}
```

To add an EBS volume based on a snapshot, use the following mapping.

```
{
    "DeviceName": "device_name",
    "Ebs": {
      "SnapshotId": "snap-1234567890abcdef0"
    }
}
```

To omit a mapping for a device, use the following mapping.

```
{
    "DeviceName": "device_name",
    "NoDevice": ""
}
```

PowerShell

Use the New-EC2Image cmdlet to specify a block device mapping for an EBS-backed AMI. Use the Register-EC2Image cmdlet to specify a block device mapping for an instance store-backed AMI.

Add the `-BlockDeviceMapping` option, specifying the updates in `bdm`:

```
-BlockDeviceMapping $bdm
```

The following mapping adds a volume based on a snapshot.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.SnapshotId = "snap-1234567890abcdef0"
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "device_name"
$bdm.Ebs = $ebd
```

The following mapping adds an empty 100 GB volume.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.VolumeSize = 100
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "device_name"
$bdm.Ebs = $ebd
```

View the EBS volumes in an AMI block device mapping

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

Console

To view the EBS volumes for an AMI

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **AMIs**.
3. Choose **EBS images** from the **Filter** list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the **Details** tab. At a minimum, the following information is available for the root device:
   - **Root Device Type** (`ebs`)
   - **Root Device Name** (for example, `/dev/sda1`)
   - **Block Devices** (for example, `/dev/sda1=snap-1234567890abcdef0:8:true`)

   If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional volumes as well. (This screen doesn't display instance store volumes.)

AWS CLI

To view the EBS volumes for an AMI

Use the describe-images command.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
```

```
    --query Image[0].BlockDeviceMappings
```

PowerShell

To view the EBS volumes for an AMI

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).BlockDeviceMappings
```

Add block device mappings to Amazon EC2 instance

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI.

Limitations

- For the root volume, you can only modify the following: volume size, volume type, and the **Delete on Termination** flag.
- When you modify an EBS volume, you can't decrease its size. Therefore, you must specify a snapshot whose size is equal to or greater than the size of the snapshot specified in the block device mapping of the AMI.

Tasks

- Update the block device mapping when launching an instance
- Update the block device mapping of a running instance
- View the EBS volumes in an instance block device mapping
- View the instance block device mapping for instance store volumes

Update the block device mapping when launching an instance

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn't make a permanent change to the block device mapping of the AMI from which it was launched.

Console

To update the volumes for an instance at launch

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to update the volumes.
2. (Optional) To add a volume, choose **Configure storage**, **Add new volume**. Select the volume size and volume type.
3. (Optional) To suppress a volume that was specified by the block device mapping of the AMI, choose **Configure storage**, **Remove**.
4. (Optional) To modify the configuration of an EBS volume, on the **Configure storage** pane, choose **Advanced**. Expand the information for the volume, and make whatever changes you need.
5. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To update the volumes for an instance at launch

Use the run-instances command with the `--block-device-mappings` option.

```
--block-device-mappings file://mapping.json
```

For example, suppose that an AMI block device mapping specifies the following:

- `/dev/xvda` - EBS root volume
- `/dev/sdh` - EBS volume created from `snap-1234567890abcdef0`
- `/dev/sdj` - Empty EBS volume with a size of `100`
- `/dev/sdb` - Instance store volume `ephemeral0`

Suppose that the following is the instance block device mapping in `mapping.json`.

```
[
    {
```

```
            "DeviceName": "/dev/xvda",
            "Ebs": {
                "VolumeSize": 100
            }
        },
        {
            "DeviceName": "/dev/sdj",
            "NoDevice": ""
        },
        {
            "DeviceName": "/dev/sdh",
            "Ebs": {
                "VolumeSize": 300
            }
        },
        {
            "DeviceName": "/dev/sdc",
            "VirtualName": "ephemeral1"
        }
]
```

The instance block device mapping does the following:

- Overrides the size of the root volume, `/dev/xvda`, increasing it to 100 GiB.
- Prevents `/dev/sdj` from attaching to the instance.
- Overrides the size of `/dev/sdh`, increasing it to 300 GiB. Notice that you don't need to specify the snapshot ID again.
- Adds an ephemeral volume, `/dev/sdc`. If the instance type doesn't support multiple instance store volumes, this has no effect. If the instance type supports NVMe instance store volumes, they are automatically enumerated and included in the instance block device mapping and can't be overridden.

PowerShell

To update the volumes for an instance at launch

Use the `-BlockDeviceMapping` parameter with the New-EC2Instance cmdlet with the `-BlockDeviceMapping` parameter.

```
-BlockDeviceMapping $bdm
```

Suppose that the following is the instance block device mapping in `$bdm`.

```
$bdm = @()

$root = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$root.DeviceName = "/dev/xvda"
$ebs1 = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebs1.VolumeSize = 100
$root.Ebs = $ebs1
$bdm += $root

$sdj = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdj.DeviceName = "/dev/sdj"
$sdj.NoDevice = ""
$bdm += $sdj

$sdh = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdh.DeviceName = "/dev/sdh"
$ebs2 = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebs2.VolumeSize = 300
$sdh.Ebs = $ebs2
$bdm += $sdh

$sdc = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$sdc.DeviceName = "/dev/sdc"
$sdc.VirtualName = "ephemeral1"
$bdm += $sdc
```

The instance block device mapping does the following:

- Overrides the size of the root volume, `/dev/xvda`, increasing it to 100 GiB.
- Prevents `/dev/sdj` from attaching to the instance.
- Overrides the size of `/dev/sdh`, increasing it to 300 GiB. Notice that you don't need to specify the snapshot ID again.
- Adds an ephemeral volume, `/dev/sdc`. If the instance type doesn't support multiple instance store volumes, this has no effect. If the instance type supports NVMe instance store volumes, they are automatically enumerated and included in the instance block device mapping and can't be overridden.

Update the block device mapping of a running instance

You do not need to stop the instance before changing this attribute.

AWS CLI

To update the block device mapping of a running instance

Use the modify-instance-attribute command.

Add the `--block-device-mappings` option:

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify the updates. For example, the following update changes the root device volume to persist.

```
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

PowerShell

To update the block device mapping of a running instance

Use the Edit-EC2InstanceAttribute cmdlet.

Add the `-BlockDeviceMapping` option:

```
-BlockDeviceMapping $bdm
```

In bdm, specify the updates. For example, the following update changes the root device volume to persist.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.DeleteOnTermination = false
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
```

```
$bdm.DeviceName = "/dev/sda1"
$bdm.Ebs = $ebd
```

View the EBS volumes in an instance block device mapping

You can easily enumerate the EBS volumes mapped to an instance.

Console

To view the EBS volumes for an instance

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. Select the instance and look at the details displayed in the **Storage** tab. At a minimum, the following information is available for the root device:

   - **Root device type** (for example, **EBS**)
   - **Root device name** (for example, `/dev/xvda`)
   - **Block devices** (for example, `/dev/xvda`, `/dev/sdf`, and `/dev/sdj`)

   If the instance was launched with additional EBS volumes using a block device mapping, they appear under **Block devices**. Any instance store volumes do not appear on this tab.
4. To display additional information about an EBS volume, choose its volume ID to go to the volume page.

AWS CLI

To view the EBS volumes for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[*].Instances[0].BlockDeviceMappings
```

PowerShell

To view the EBS volumes for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-0bac57d7472c89bac).Instances.BlockDeviceMappings
```

View the instance block device mapping for instance store volumes

The instance type determines the number and type of instance store volumes that are available to the instance. If the number of instance store volumes in a block device mapping exceeds the number of instance store volumes available to an instance, the additional volumes are ignored. To view the instance store volumes for your instance, run the **lsblk** command (Linux instances) or open **Windows Disk Management** (Windows instances). To learn how many instance store volumes are supported by each instance type, see Amazon EC2 instance type specifications.

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. The method you use to view the instance store volumes for your instance depends on the volume type.

NVMe instance store volumes

Linux instances

You can use the NVMe command line package, nvme-cli, to query the NVMe instance store volumes in the block device mapping. Download and install the package on your instance, and then run the following command.

```
[ec2-user ~]$ sudo nvme list
```

The following is example output for an instance. The text in the Model column indicates whether the volume is an EBS volume or an instance store volume. In this example, both `/dev/nvme1n1` and `/dev/nvme2n1` are instance store volumes.

```
Node             SN                   Model
 Namespace
---------------- -------------------- ----------------------------------------
 ---------
/dev/nvme0n1     vol06afc3f8715b7a597 Amazon Elastic Block Store               1

/dev/nvme1n1     AWS2C1436F5159EB6614 Amazon EC2 NVMe Instance Storage         1
```

```
/dev/nvme2n1     AWSB1F4FF0C0A6C281EA Amazon EC2 NVMe Instance Storage         1
  ...
```

Windows instances

You can use Disk Management or PowerShell to list both EBS and instance store NVMe volumes. For more information, see the section called “Map NVME disks to volumes”.

HDD or SSD instance store volumes

You can use instance metadata to query the HDD or SSD instance store volumes in the block device mapping. NVMe instance store volumes are not included.

The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`. For more information, see Use instance metadata to manage your EC2 instance.

Linux instances

First, connect to your running instance. From the instance, use this query to get its block device mapping.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/block-device-mapping/
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/block-device-mapping/
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed `m1.small` instance looks like this.

```
ami
ephemeral0
root
swap
```

The ami device is the root device as seen by the instance. The instance store volumes are named ephemeral[0-23]. The swap device is for the page file. If you've also mapped EBS volumes, they appear as ebs1, ebs2, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

Windows instances

First, connect to your running instance. From the instance, use this query to get its block device mapping.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/block-device-mapping/
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed m1.small instance looks like this.

```
ami
ephemeral0
root
swap
```

The ami device is the root device as seen by the instance. The instance store volumes are named ephemeral[0-23]. The swap device is for the page file. If you've also mapped EBS volumes, they appear as ebs1, ebs2, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

How volumes are attached and mapped for Amazon EC2 Windows instances

> **Note**
>
> This topic applies to Windows instances only.

Your Windows instance comes with an EBS volume that serves as the root volume. If your Windows instance uses AWS PV or Citrix PV drivers, you can optionally add up to 25 volumes, making a total of 26 volumes. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

Depending on the instance type of your instance, you'll have from 0 to 24 possible instance store volumes available to the instance. To use any of the instance store volumes that are available to your instance, you must specify them when you create your AMI or launch your instance. You can also add EBS volumes when you create your AMI or launch your instance, or attach them while your instance is running.

When you add a volume to your instance, you specify the device name that Amazon EC2 uses. For more information, see Device names for volumes on Amazon EC2 instances. AWS Windows Amazon Machine Images (AMIs) contain a set of drivers that are used by Amazon EC2 to map instance store and EBS volumes to Windows disks and drive letters.

Methods to map disks to EBS volumes

- Map NVMe disks on Amazon EC2 Windows instance to volumes
- Map non-NVMe disks on Amazon EC2 Windows instance to volumes

Map NVMe disks on Amazon EC2 Windows instance to volumes

With Nitro-based instances, EBS volumes are exposed as NVMe devices. This topic explains how to view the **NVMe disks** that are available to the Windows operating system on your instance. It also shows how to map those NVMe disks to the underlying Amazon EBS volumes and the device names specified for the block device mappings used by Amazon EC2.

Topics

List NVMe disks

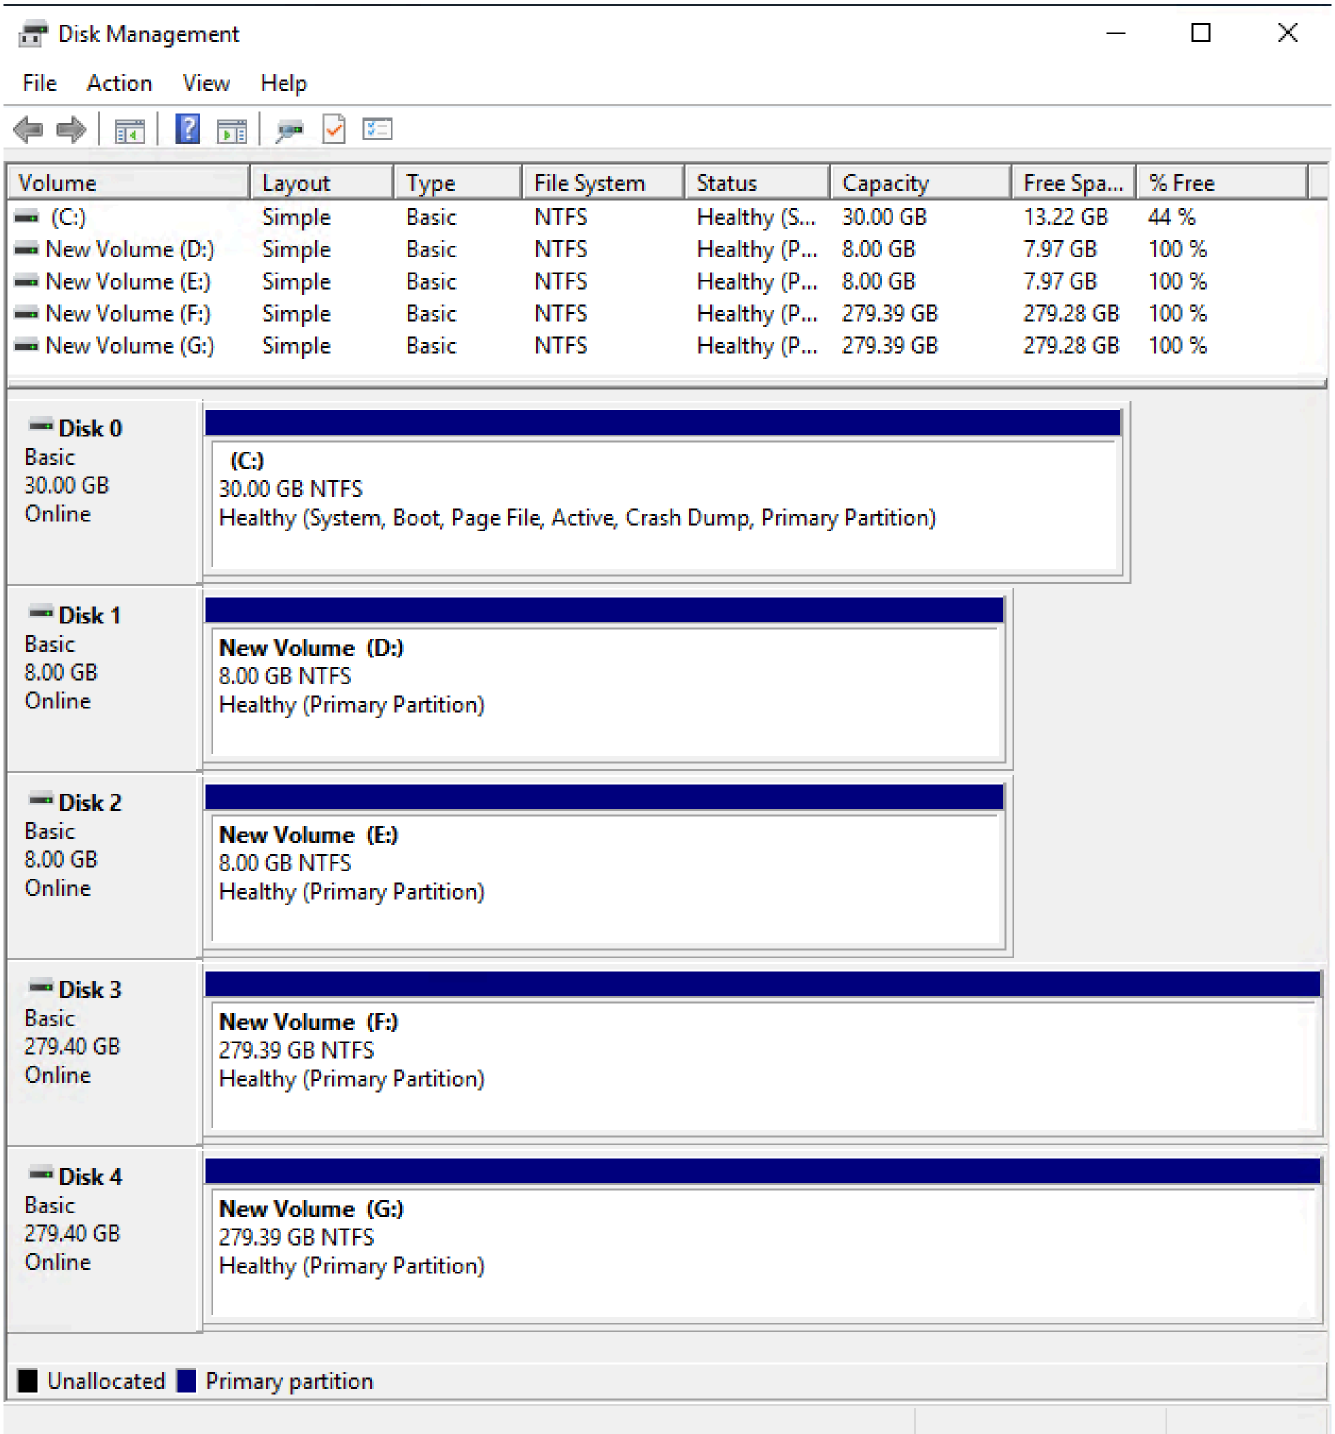
You can find the disks on your Windows instance using Disk Management or Powershell.

Disk Management

To find the disks on your Windows instance

1. Log in to your Windows instance using Remote Desktop. For more information, see Connect to your Windows instance using RDP.
2. Start the Disk Management utility.
3. Review the disks. The root volume is an EBS volume mounted as `C:\`. If there are no other disks shown, then you didn't specify additional volumes when you created the AMI or launched the instance.

   The following is an example that shows the disks that are available if you launch an `r5d.4xlarge` instance with two additional EBS volumes.



PowerShell

The following PowerShell script lists each disk and its corresponding device name and volume. It is intended for use with [Nitro-based instances](), which use NVMe EBS and instance store volumes.

Connect to your Windows instance and run the following command to enable PowerShell script execution.

```
Set-ExecutionPolicy RemoteSigned
```

Copy the following script and save it as `mapping.ps1` on your Windows instance.

```
# List the disks for NVMe volumes

function Get-EC2InstanceMetadata {
    param([string]$Path)
    (Invoke-WebRequest -Uri "http://169.254.169.254/latest/$Path").Content
}

function GetEBSVolumeId {
    param($Path)
    $SerialNumber = (Get-Disk -Path $Path).SerialNumber
    if($SerialNumber -clike 'vol*'){
        $EbsVolumeId = $SerialNumber.Substring(0,20).Replace("vol","vol-")
    }
    else {
       $EbsVolumeId = $SerialNumber.Substring(0,20).Replace("AWS","AWS-")
    }
    return $EbsVolumeId
}

function GetDeviceName{
    param($EbsVolumeId)
    if($EbsVolumeId -clike 'vol*'){

        $Device  = ((Get-EC2Volume -VolumeId $EbsVolumeId ).Attachment).Device
        $VolumeName = ""
    }
     else {
        $Device = "Ephemeral"
        $VolumeName = "Temporary Storage"
    }
    Return $Device,$VolumeName
}

function GetDriveLetter{
    param($Path)
    $DiskNumber =  (Get-Disk -Path $Path).Number
```

```
    if($DiskNumber -eq 0){
        $VirtualDevice = "root"
        $DriveLetter = "C"
        $PartitionNumber = (Get-Partition -DriveLetter C).PartitionNumber
    }
    else
    {
        $VirtualDevice = "N/A"
        $DriveLetter = (Get-Partition -DiskNumber $DiskNumber).DriveLetter
        if(!$DriveLetter)
        {
            $DriveLetter = ((Get-Partition -DiskId $Path).AccessPaths).Split(",")[0]
        }
        $PartitionNumber = (Get-Partition -DiskId $Path).PartitionNumber
    }

    return $DriveLetter,$VirtualDevice,$PartitionNumber

}

$Report = @()
foreach($Path in (Get-Disk).Path)
{
    $Disk_ID = ( Get-Partition -DiskId $Path).DiskId
    $Disk = ( Get-Disk -Path $Path).Number
    $EbsVolumeId  = GetEBSVolumeId($Path)
    $Size =(Get-Disk -Path $Path).Size
    $DriveLetter,$VirtualDevice, $Partition = (GetDriveLetter($Path))
    $Device,$VolumeName = GetDeviceName($EbsVolumeId)
    $Disk = New-Object PSObject -Property @{
      Disk          = $Disk
      Partitions    = $Partition
      DriveLetter   = $DriveLetter
      EbsVolumeId   = $EbsVolumeId
      Device        = $Device
      VirtualDevice = $VirtualDevice
      VolumeName= $VolumeName
    }
 $Report += $Disk
}

$Report | Sort-Object Disk | Format-Table -AutoSize -Property Disk, Partitions,
 DriveLetter, EbsVolumeId, Device, VirtualDevice, VolumeName
```

Run the script as follows:

```
PS C:\> .\mapping.ps1
```

The following is example output for an instance with a root volume, two EBS volumes, and two instance store volumes.

```
Disk Partitions DriveLetter EbsVolumeId           Device    VirtualDevice VolumeName
---- ---------- ----------- -----------           ------    ------------- ----------
   0          1 C           vol-03683f1d861744bc7 /dev/sda1 root
   1          1 D           vol-082b07051043174b9 xvdb      N/A
   2          1 E           vol-0a4064b39e5f534a2 xvdc      N/A
   3          1 F           AWS-6AAD8C2AEEE1193F0 Ephemeral N/A           Temporary
 Storage
   4          1 G           AWS-13E7299C2BD031A28 Ephemeral N/A           Temporary
 Storage
```

If you did not configure your credentials for Tools for Windows PowerShell on the Windows instance, the script cannot get the EBS volume ID and uses N/A in the `EbsVolumeId` column.

Map NVMe disks to volumes

You can use the Get-Disk command to map Windows disk numbers to EBS volume IDs.

```
PS C:\> Get-Disk
Number Friendly Name Serial Number                    HealthStatus
 OperationalStatus      Total Size Partition

                      Style
------ ------------- -------------                    ------------
 -----------------      ---------- ----------
3      NVMe Amazo... AWS6AAD8C2AEEE1193F0_00000001.   Healthy              Online
             279.4 GB MBR
4      NVMe Amazo... AWS13E7299C2BD031A28_00000001.   Healthy              Online
             279.4 GB MBR
2      NVMe Amazo... vol0a4064b39e5f534a2_00000001.   Healthy              Online
                 8 GB MBR
0      NVMe Amazo... vol03683f1d861744bc7_00000001.   Healthy              Online
                30 GB MBR
1      NVMe Amazo... vol082b07051043174b9_00000001.   Healthy              Online
                 8 GB MBR
```

You can also run the **ebsnvme-id** command to map NVMe disk numbers to EBS volume IDs and device names.

```
PS C:\> C:\PROGRAMDATA\Amazon\Tools\ebsnvme-id.exe
Disk Number: 0
Volume ID: vol-03683f1d861744bc7
Device Name: sda1

Disk Number: 1
Volume ID: vol-082b07051043174b9
Device Name: xvdb

Disk Number: 2
Volume ID: vol-0a4064b39e5f534a2
Device Name: xvdc
```

Map non-NVMe disks on Amazon EC2 Windows instance to volumes

For instances launched from a Windows AMI that uses AWS PV or Citrix PV drivers, you can use the relationships described on this page to map your Windows disks to your instance store and EBS volumes. This topic explains how to view the **non-NVMe disks** that are available to the Windows operating system on your instance. It also shows how to map those non-NVMe disks to the underlying Amazon EBS volumes and the device names specified for the block device mappings used by Amazon EC2.

Note

If you launch an instance If your Windows AMI uses Red Hat PV drivers, you can update your instance to use the Citrix drivers. For more information, see the section called "Upgrade PV drivers".

Topics

List non-NVMe disks

You can find the disks on your Windows instance using Disk Management or PowerShell.

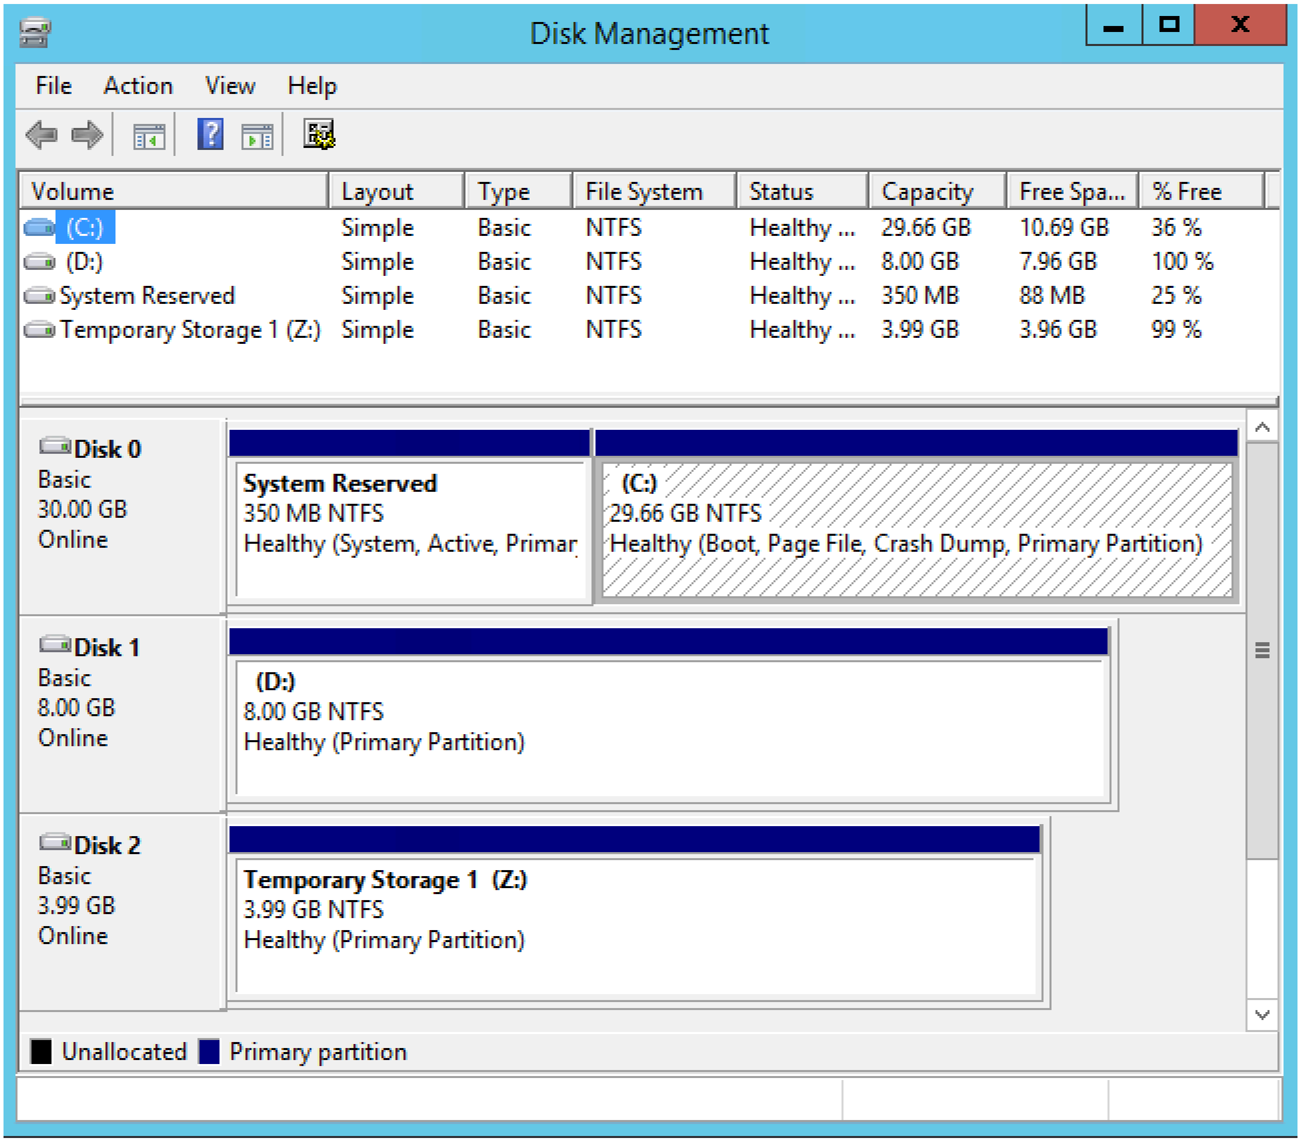
Disk Management

To find the disks on your Windows instance

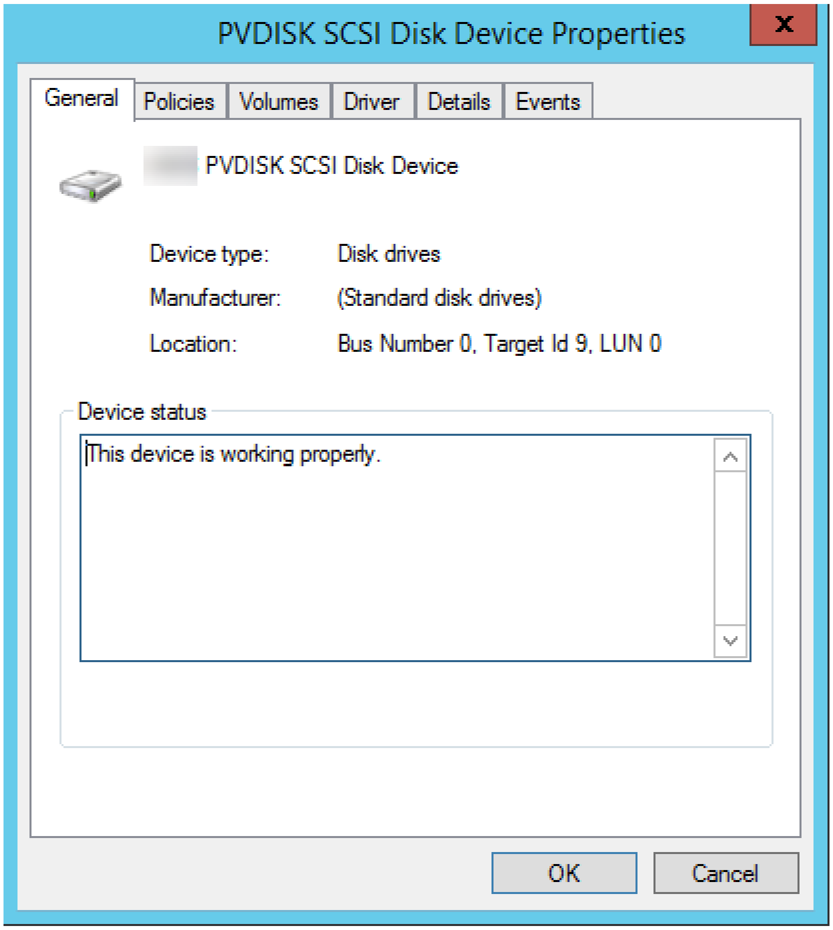
1. Log in to your Windows instance using Remote Desktop. For more information, see Connect to your Windows instance using RDP.
2. Start the Disk Management utility.

   On the taskbar, right-click the Windows logo, and then choose **Disk Management**.
3. Review the disks. The root volume is an EBS volume mounted as `C:\`. If there are no other disks shown, then you didn't specify additional volumes when you created the AMI or launched the instance.

   The following is an example that shows the disks that are available if you launch an `m3.medium` instance with an instance store volume (Disk 2) and an additional EBS volume (Disk 1).



4. Right-click the gray pane labeled Disk 1, and then select **Properties**. Note the value of **Location** and look it up in the tables in [Map non-NVMe disks to volumes](). For example, the following disk has the location Bus Number 0, Target Id 9, LUN 0. According to the table for EBS volumes, the device name for this location is `xvdj`.



PowerShell

The following PowerShell script lists each disk and its corresponding device name and volume.

Requirements and limitations

- Requires Windows Server 2012 or later.
- Requires credentials to get the EBS volume ID. You can configure a profile using the Tools for PowerShell, or attach an IAM role to the instance.
- Does not support NVMe volumes.
- Does not support dynamic disks.

Connect to your Windows instance and run the following command to enable PowerShell script execution.

```
Set-ExecutionPolicy RemoteSigned
```

Copy the following script and save it as `mapping.ps1` on your Windows instance.

```
# List the disks
function Convert-SCSITargetIdToDeviceName {
  param([int]$SCSITargetId)
  If ($SCSITargetId -eq 0) {
    return "sda1"
  }
  $deviceName = "xvd"
  If ($SCSITargetId -gt 25) {
    $deviceName += [char](0x60 + [int]($SCSITargetId / 26))
  }
  $deviceName += [char](0x61 + $SCSITargetId % 26)
  return $deviceName
}

          $DriveLetter = $array[0][$i]
          $DeviceName = $array[3][$i]
        }
        $i ++
      }
    }
    $BlockDevice = ""
    $BlockDeviceName = ($BlockDeviceMappings | Where-Object { $_.ebs.VolumeId -eq
 $EbsVolumeID }).DeviceName
  }
  ElseIf ($DiskDrive.path -like "*NETAPP*") {
    if ($DriveLetter -match '[^a-zA-Z0-9]') {
      $i = 0
      While ($i -ne ($array3.Count)) {
        if ($array[2][$i] -eq $EbsVolumeID) {
          $DriveLetter = $array[0][$i]
          $DeviceName = $array[3][$i]
        }
        $i ++
      }
    }
    $EbsVolumeID = "FSxN Volume"
    $BlockDevice = ""
    $BlockDeviceName = ($BlockDeviceMappings | Where-Object { $_.ebs.VolumeId -eq
 $EbsVolumeID }).DeviceName
  }
  Else {
    $BlockDeviceName = $null
    $BlockDevice = $null
  }
```

```
    New-Object PSObject -Property @{
      Disk          = $Disk;
      Partitions    = $Partitions;
      DriveLetter   = If ($DriveLetter -eq $null) { "N/A" } Else { $DriveLetter };
      EbsVolumeId   = If ($EbsVolumeID -eq $null) { "N/A" } Else { $EbsVolumeID };
      Device        = If ($BlockDeviceName -eq $null) { "N/A" } Else
 { $BlockDeviceName };
      VirtualDevice = If ($VirtualDevice -eq $null) { "N/A" } Else { $VirtualDevice };
      VolumeName    = If ($VolumeName -eq $null) { "N/A" } Else { $VolumeName };
      DeviceName    = If ($DeviceName -eq $null) { "N/A" } Else { $DeviceName };
    }
} | Sort-Object Disk | Format-Table -AutoSize -Property Disk, Partitions,
 DriveLetter, EbsVolumeId, Device, VirtualDevice, DeviceName, VolumeName
```

Run the script as follows:

```
PS C:\> .\mapping.ps1
```

The following is example output.

```
Disk  Partitions  DriveLetter   EbsVolumeId            Device      VirtualDevice
 DeviceName             VolumeName
----  ----------  -----------   -----------            ------      -------------
 ----------             ----------
   0           1            C   vol-0561f1783298efedd  /dev/sda1   N/A
 NVMe Amazon Elastic B   N/A
   1           1            D   vol-002a9488504c5e35a  xvdb        N/A
 NVMe Amazon Elastic B   N/A
   2           1            E   vol-0de9d46fcc907925d  xvdc        N/A
 NVMe Amazon Elastic B   N/A
```

If you did not provide your credentials on the Windows instance, the script cannot get the EBS volume ID and uses N/A in the `EbsVolumeId` column.

Map non-NVMe disks to volumes

The block device driver for the instance assigns the actual volume names when mounting volumes.

Mappings

- Instance store volumes

- EBS volumes

Instance store volumes

The following table describes how the Citrix PV and AWS PV drivers map non-NVMe instance store volumes to Windows volumes. The number of available instance store volumes is determined by the instance type. For more information, see Instance store volume limits for EC2 instances.

Location	Device name
Bus Number 0, Target ID 78, LUN 0	xvdca
Bus Number 0, Target ID 79, LUN 0	xvdcb
Bus Number 0, Target ID 80, LUN 0	xvdcc
Bus Number 0, Target ID 81, LUN 0	xvdcd
Bus Number 0, Target ID 82, LUN 0	xvdce
Bus Number 0, Target ID 83, LUN 0	xvdcf
Bus Number 0, Target ID 84, LUN 0	xvdcg
Bus Number 0, Target ID 85, LUN 0	xvdch
Bus Number 0, Target ID 86, LUN 0	xvdci
Bus Number 0, Target ID 87, LUN 0	xvdcj
Bus Number 0, Target ID 88, LUN 0	xvdck
Bus Number 0, Target ID 89, LUN 0	xvdcl

EBS volumes

The following table describes how the Citrix PV and AWS PV drivers map non-NVME EBS volumes to Windows volumes.

Location	Device name
Bus Number 0, Target ID 0, LUN 0	/dev/sda1
Bus Number 0, Target ID 1, LUN 0	xvdb
Bus Number 0, Target ID 2, LUN 0	xvdc
Bus Number 0, Target ID 3, LUN 0	xvdd
Bus Number 0, Target ID 4, LUN 0	xvde
Bus Number 0, Target ID 5, LUN 0	xvdf
Bus Number 0, Target ID 6, LUN 0	xvdg
Bus Number 0, Target ID 7, LUN 0	xvdh
Bus Number 0, Target ID 8, LUN 0	xvdi
Bus Number 0, Target ID 9, LUN 0	xvdj
Bus Number 0, Target ID 10, LUN 0	xvdk
Bus Number 0, Target ID 11, LUN 0	xvdl
Bus Number 0, Target ID 12, LUN 0	xvdm
Bus Number 0, Target ID 13, LUN 0	xvdn
Bus Number 0, Target ID 14, LUN 0	xvdo
Bus Number 0, Target ID 15, LUN 0	xvdp
Bus Number 0, Target ID 16, LUN 0	xvdq
Bus Number 0, Target ID 17, LUN 0	xvdr
Bus Number 0, Target ID 18, LUN 0	xvds
Bus Number 0, Target ID 19, LUN 0	xvdt

Location	Device name
Bus Number 0, Target ID 20, LUN 0	xvdu
Bus Number 0, Target ID 21, LUN 0	xvdv
Bus Number 0, Target ID 22, LUN 0	xvdw
Bus Number 0, Target ID 23, LUN 0	xvdx
Bus Number 0, Target ID 24, LUN 0	xvdy
Bus Number 0, Target ID 25, LUN 0	xvdz

Torn write prevention on Amazon EC2 Linux instances

Note

Torn write prevention is supported with Linux instances only.

Torn write prevention is a block storage feature designed by AWS to improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency. Relational databases that use InnoDB or XtraDB as the database engine, such as MySQL and MariaDB, will benefit from torn write prevention.

Typically, relational databases that use pages larger than the *power fail atomicity* of the storage device use *data logging* mechanisms to protect against torn writes. MariaDB and MySQL use a *doublewrite buffer* file to log data before writing it to data tables. In the event of incomplete or torn writes, as a result of operating system crashes or power loss during write transactions, the database can recover the data from the doublewrite buffer. The additional I/O overhead associated with writing to the doublewrite buffer impacts database performance and application latency, and it reduces the number transactions that can be processed per second. For more information about doublewrite buffer, see the MariaDB and MySQL documentation.

With *torn write prevention*, data is written to storage in *all-or-nothing* write transactions, which eliminates the need for using the doublewrite buffer. This prevents partial, or torn, data from being written to storage in the event of operating system crashes or power loss during write transactions.

The number of transactions processed per second can be increased by up to 30 percent, and write latency can be decreased by up to 50 percent, without compromising the resiliency of your workloads.

Pricing

There are no additional costs for using torn write prevention.

Contents

Block sizes for torn write prevention on Amazon EC2

Torn write prevention supports write operations for 4 KiB, 8 KiB, and 16 KiB blocks of data. The data block start logical block address (LBA) must be aligned to the respective block boundary size of 4 KiB, 8 KiB, or 16 KiB. For example, for 16 KiB write operations, the data block start LBA must be aligned to a block boundary size of 16 KiB.

The following table shows support across storage and instance types.

	4 KiB blocks	8 KiB blocks	16 KiB blocks
Instance store volumes	All NVMe instance store volumes attached to current generation I-family instances.	I4i, Im4gn, Is4gen, I7i, I7ie, I8g, and I8ge instances supported by AWS Nitro SSD.	
Amazon EBS volumes	All Amazon EBS volumes attached to Nitro-based instances.		

To confirm whether your instance and volume support torn write prevention, query to check if the instance supports torn write prevention and other details, like supported block and boundary sizes. For more information, see Check Amazon EC2 instance support for torn write prevention.

Requirements for using torn write prevention on Amazon EC2

For torn write prevention to work properly, an I/O operation must meet size, alignment, and boundary requirements, as specified in the `NTWPU`, `NTWGU`, `NTWBU` fields. You must configure your operating system to ensure that the specific storage subsystem (file system, LVM, RAID, etc) does not modify I/O properties down the storage stack, including block merges, splits, or block address relocation, before being submitted to the device.

Torn write prevent has been tested with the following configuration:

- An instance type and storage type that supports the required block size.
- Amazon Linux 2 with kernel version 5.10 or later.
- ext4 with `bigalloc` enabled and a cluster size of 16 KiB, and the most recent ext4 utilities (e2fsprogs 1.46.5 or later).
- `O_DIRECT` file access mode to bypass Linux kernel buffer cache.

> **Note**
>
> You do not need to disable I/O merging for MySQL and MariaDB workloads.

Check Amazon EC2 instance support for torn write prevention

To confirm whether your instance and volume supports torn write prevention, and to view the NVMe namespace vendor specific data that contains torn write prevention information, use the following command.

```
$ sudo nvme id-ns -v device_name
```

> **Note**
>
> The command returns the vendor-specific information in hex with ASCII interpretation. You might need to build a tool, similar to `ebsnvme-id`, into your applications that can read and parse the output.

For example, the following command returns the NVMe namespace vendor specific data that contains torn write prevention information for `/dev/nvme1n1`.

```
$ sudo nvme id-ns -v /dev/nvme1n1
```

If your instance and volume support torn write prevention, it returns the following AWS torn write prevention information in the NVMe namespace vendor specific data.

> **Note**
>
> The bytes in the following table represent the offset in bytes from the beginning of the NVMe namespace vendor specific data.

Bytes	Description
`0:31`	The name of the device attachment mount point, for example `/dev/xvda` . You provide this during volume attachment request and it can be used by the Amazon EC2 instance to create a symlink to the NVMe block device(`nvmeXn1`).
`32:63`	The volume ID. For example, `vol01234567890abcdef` . This field can be used to map the NVMe device to the attached volume.
`64:255`	Reserved for future use.
`256:257`	Namespace Torn Write Prevention Unit size (NTWPU). This field indicates the namespace specific size of the write operation guarantee d to be written atomically to the NVM during a power failure or error condition. This field is specified in logical blocks represented in zero based values.
`258:259`	Namespace Torn Write Prevention Granularity size (NTWPG). This field indicates the namespace specific size increments below `NTWPU` of the write operation guaranteed to be written atomically to the NVM during a power failure or error condition. That is, size should be `NTWPG * n <= NTWPU` where `n` is positive integer. The write operation LBA offset

Bytes	Description
	also must be aligned to this field. This field is specified in logical blocks represented in zero based values.
`260:263`	Namespace Torn Write Prevention Boundary size (NTWPB). This field indicates the atomic boundary size for this namespace for the `NTWPU` value. Writes to this namespace that cross atomic boundaries are not guaranteed to be written atomically to the NVM during a power failure or error condition. A value of `0h` indicates that there are no atomic boundaries for power fail or error conditions. All other values specify a size in terms of logical blocks using the same encoding as the `NTWPU` field.

Configure your workload on Amazon EC2 for torn write prevention

Torn write prevention is enabled by default on supported instance types with supported volumes. You do not need to enabled any additional settings to enable your volume or instance for torn write prevention.

> **Note**
>
> There is no performance impact on workloads that do not support torn write prevention. You do not need to make any changes for these workloads.
>
> Workloads that do support torn write prevention, but are not configured to use it, continue to use the doublewrite buffer and do not receive any performance benefits.

To configure your MySQL or MariaDB software stack to disable the doublewrite buffer and use torn write prevention, complete the following steps:

1. Configure your volume to use ext4 file system with the BigAlloc option and set the cluster size to 4 KiB, 8 KiB, or 16 KiB. Using BigAlloc with a cluster size of 4 KiB, 8 KiB, or 16 KiB ensures that the file system allocates files that align with the respective boundary.

   ```
   $ mkfs.ext4 -O bigalloc -C 4096|8192|16384 device_name
   ```

> **Note**
>
> For MySQL and MariaDB, you must use `-C 16384` to match the database page size. Setting allocation granularity to a value other than a multiple of the page size can result in allocations that might be mismatched with torn write prevention boundaries of the storage device.

For example:

```
$  mkfs.ext4 -O bigalloc -C 16384 /dev/nvme1n1
```

2. Configure InnoDB to use the `O_DIRECT` flushing method and turn off InnoDB doublewrite. Use your preferred text editor to open `/etc/my.cnf`, and update the `innodb_flush_method` and `innodb_doublewrite` parameters as follows:

```
innodb_flush_method=O_DIRECT
innodb_doublewrite=0
```

> **Important**
>
> If you are using Logical Volume Manager (LVM) or other storage virtualization layer, make sure that the starting offsets of the volumes are aligned on 16 KiB multiples. This is relative to the underlying NVMe storage to account for the metadata headers and superblocks used by the storage virtualization layer. If you add an offset to the LVM physical volume, it can cause misalignment between the file system allocations and the NVMe device's offsets, which would invalidate torn write prevention. For more information, see `--dataalignmentoffset` in the Linux manual page.

Application consistent Windows VSS based Amazon EBS snapshots

You can take application-consistent snapshots of all Amazon EBS volumes attached to your Amazon EC2 Windows instances using AWS Systems Manager Run Command. The snapshot process uses the Windows Volume Shadow Copy Service (VSS) to take EBS volume level backups of VSS-aware applications. The snapshots include data from pending transactions between these applications and the disk. You don't have to shut down your instances or disconnect them when you need to back up all attached volumes.

There is no additional cost to use VSS based EBS snapshots. You only pay for EBS snapshots created by the backup process. For more information, see How am I billed for my Amazon EBS snapshots?

Note

Application consistent Windows VSS based snapshots are supported with Windows instances only.

Contents

What is VSS?

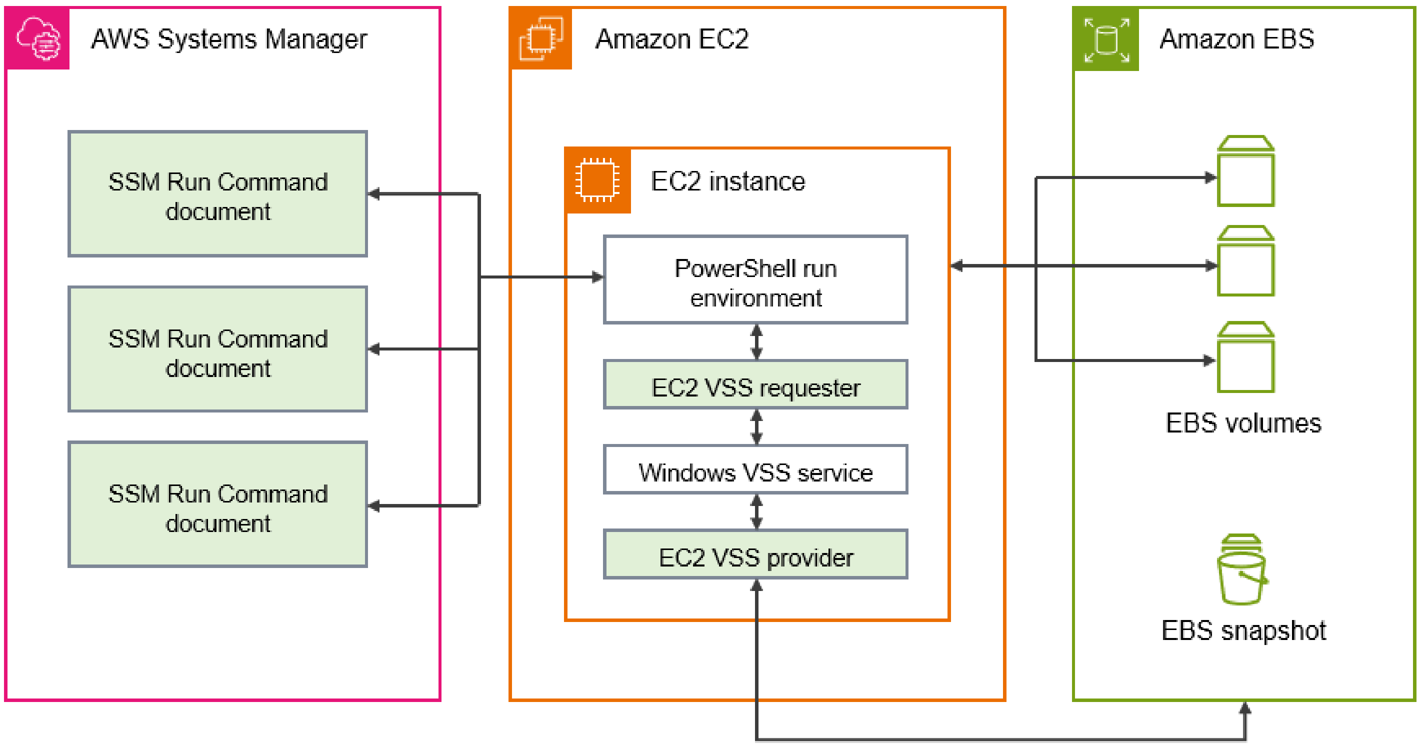
Volume Shadow Copy Service (VSS) is a backup and recovery technology included in Microsoft Windows. It can create backup copies, or snapshots, of computer files or volumes while they are in use. For more information, see Volume Shadow Copy Service.

To create an application-consistent snapshot, the following software components are involved.

- *VSS service* — Part of the Windows operating system
- *VSS requester* — The software that requests the creation of shadow copies
- *VSS writer* — Typically provided as part of an application, such as SQL Server, to ensure a consistent data set to back up

- *VSS provider* — The component that creates the shadow copies of the underlying volumes

The Windows VSS based Amazon EBS snapshot solution consists of multiple Systems Manager (SSM) Run Command documents that facilitate backup creation, and a Systems Manager Distributor package, called `AwsVssComponents`, that includes an *EC2 VSS requester* and an *EC2 VSS provider*. The `AwsVssComponents` package must be installed on EC2 Windows instances to take application-consistent snapshots of EBS volumes. The following diagram illustrates the relationship between these software components.



How the VSS based Amazon EBS snapshot solution works

The process for taking application-consistent, VSS based EBS snapshot scripts consists of the following steps.

1. Complete the Prerequisites to create Windows VSS based EBS snapshots.
2. Enter parameters for the `AWSEC2-VssInstallAndSnapshot` SSM document and run this document by using Run Command. For more information, see Run the AWSEC2-VssInstallAndSnapshot command document (recommended).
3. The Windows VSS service on your instance coordinates all ongoing I/O operations for running applications.

4. The system flushes all I/O buffers and temporarily pauses all I/O operations. The pause lasts, at most, ten seconds.
5. During the pause, the system creates snapshots of all volumes attached to the instance.
6. The pause is lifted and I/O resumes operation.
7. The system adds all newly-created snapshots to the list of EBS snapshots. The system tags all VSS based EBS snapshots successfully created by this process with **AppConsistent:true**.
8. If you need to restore from a snapshot, you can use the standard EBS process of creating a volume from a snapshot, or you can restore all volumes to an instance by using a sample script, as described in Use the AWS VSS solution to restore data for your instance.

Prerequisites to create Windows VSS based EBS snapshots

You can create VSS based EBS snapshots with Systems Manager Run Command, AWS Backup, or Amazon Data Lifecycle Manager. The following prerequisites apply for all solutions.

System requirements

Ensure that your EC2 Windows instance meets all of the system requirements to create VSS based snapshots, including supported versions of the Windows operating system, .NET framework, PowerShell, AWS Tools for Windows PowerShell, and the AWS Systems Manager Agent.

IAM permissions

The IAM role that's attached to your Amazon EC2 Windows instance must have permission to create application-consistent snapshots with VSS. To grant the necessary permissions, you can attach the `AWSEC2VssSnapshotPolicy` managed policy to your instance profile.

VSS components

To create application-consistent snapshots on Windows operating systems, the `AwsVssComponents` package must be installed on the instance. The package contains an on-instance EC2 VSS Agent that functions as the VSS requester, and an EC2 VSS provider for EBS volumes.

System requirements

Install the Systems Manager Agent

VSS is orchestrated by the Systems Manager Agent using PowerShell. Ensure that you have installed SSM Agent version `3.0.502.0` or later on your EC2 instance. If you are already using an older version of the SSM Agent, update it using Run Command. For more information, see [Setting up Systems Manager for Amazon EC2 instances] and [Working with SSM Agent on Amazon EC2 instances for Windows Server] in the *AWS Systems Manager User Guide*.

Amazon EC2 Windows instance requirements

VSS based EBS snapshots are supported for instances running Windows Server 2016 and later.

.NET Framework version

The `AwsVssComponents` package requires .NET Framework version `4.6` or later. Windows operating system versions prior to Windows Server 2016 default to an earlier version of the .NET Framework. If your instance uses an earlier version of the .NET Framework, you must install version `4.6` or later using Windows Update.

AWS Tools for Windows PowerShell version

Ensure that your instance is running AWS Tools for Windows PowerShell version `3.3.48.0` or later. To check your version, run the following command in the PowerShell terminal on the instance.

```
C:\> Get-AWSPowerShellVersion
```

If you need to update AWS Tools for Windows PowerShell on your instance, see [Installing the AWS Tools for Windows PowerShell] in the *AWS Tools for PowerShell User Guide*.

Windows PowerShell version

Ensure that your instance is running Windows PowerShell major version 3, 4, or 5. To check your version, run the following command in a PowerShell terminal on the instance.

```
C:\> $PSVersionTable.PSVersion
```

PowerShell language mode

Ensure that your instance has the PowerShell language mode set to `FullLanguage`. For more information, see [about_Language_Modes] in the Microsoft documentation.

Use an IAM managed policy to grant permissions for VSS based snapshots

The AWSEC2VssSnapshotPolicy managed policy enables Systems Manager to perform the following actions on your Windows instance:

- Create and tag EBS snapshots
- Create and tag Amazon Machine Images (AMIs)
- Attach metadata, such as the device ID, to the default snapshot tags that VSS creates.

This topic covers permission details for the VSS managed policy, and how to attach it to your EC2 instance profile IAM role.

Contents

AWSEC2VssSnapshotPolicy managed policy details

An AWS managed policy is a standalone policy that Amazon provides for AWS customers. AWS managed policies are designed to grant permissions for common use cases. You can't change the permissions that are defined in AWS managed policies. However, you can copy the policy and use it as a baseline for a customer managed policy that is specific to your use case.

For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

To use the **AWSEC2VssSnapshotPolicy** managed policy, you can attach it to the IAM role that's attached to your EC2 Windows Instances. This policy enables the EC2 VSS solution to create and add tags to Amazon Machine Images (AMIs) and EBS Snapshots. To attach the policy, see Attach the VSS snapshot managed policy to your instance profile role.

Permissions granted by AWSEC2VssSnapshotPolicy

The **AWSEC2VssSnapshotPolicy** policy includes the following Amazon EC2 permissions to allow Amazon EC2 to create and manage VSS snapshots on your behalf. You can attach this managed policy to the IAM instance profile role that you use for your EC2 Windows instances.

- **ec2:CreateTags** – Add tags to EBS snapshots and AMIs to help identify and categorize the resources.

- **ec2:DescribeInstanceAttribute** – Retrieve the EBS volumes and corresponding block device mappings that are attached to the target instance.
- **ec2:CreateSnapshots** – Create snapshots of EBS volumes.
- **ec2:CreateImage** – Create an AMI from a running EC2 instance.
- **ec2:DescribeImages** – Retrieve the information for EC2 AMIs and snapshots.
- **ec2:DescribeSnapshots** – Determine the create time and status of snapshots to verify application consistency.

> **Note**
>
> To view permission details for this policy, see AWSEC2VssSnapshotPolicy in the *AWS Managed Policy Reference*.

Streamline permissions for specific use cases - advanced

The `AWSEC2VssSnapshotPolicy` managed policy includes permissions for all of the ways that you can create VSS based snapshots. You can create a custom policy that includes only the permissions that you need.

Use case: Create AMI, Use case: Use AWS Backup service

If you exclusively use the `CreateAmi` option, or if you create VSS based snapshots only through the AWS Backup service, then you can streamline the policy statements as follows.

- Omit policy statements identified by the following statement IDs (SIDs):
  - `CreateSnapshotsWithTag`
  - `CreateSnapshotsAccessInstance`
  - `CreateSnapshotsAccessVolume`
- Adjust the `CreateTagsOnResourceCreation` statement as follows:
  - Remove `arn:aws:ec2:*:*:snapshot/*` from the resources.
  - Remove `CreateSnapshots` from the `ec2:CreateAction` condition.
- Adjust the `CreateTagsAfterResourceCreation` statement to remove `arn:aws:ec2:*:*:snapshot/*` from the resources.

- Adjust the `DescribeImagesAndSnapshots` statement to remove `ec2:DescribeSnapshots` from the statement action.

Use case: Snapshot only

If you don't use the `CreateAmi` option, then you can streamline the policy statements as follows.

- Omit policy statements identified by the following statement IDs (SIDs):
  - `CreateImageAccessInstance`
  - `CreateImageWithTag`
- Adjust the `CreateTagsOnResourceCreation` statement as follows:
  - Remove `arn:aws:ec2:*:*:image/*` from the resources.
  - Remove `CreateImage` from the `ec2:CreateAction` condition.
- Adjust the `CreateTagsAfterResourceCreation` statement to remove `arn:aws:ec2:*:*:image/*` from the resources.
- Adjust the `DescribeImagesAndSnapshots` statement to remove `ec2:DescribeImages` from the statement action.

> **Note**
>
> To ensure that your customized policy performs as expected, we recommend that you regularly review and incorporate updates to the managed policy.

Attach the VSS snapshot managed policy to your instance profile role

To grant permissions for VSS based snapshots for your EC2 Windows instance, you can attach the **AWSEC2VssSnapshotPolicy** managed policy to your instance profile role as follows. It's important to ensure that your instance meets all System requirements.

> **Note**
>
> To use the managed policy, your instance must have the `AwsVssComponents` package version `2.3.1` or later installed. For version history, see AwsVssComponents package versions.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles** to see a list of IAM roles that you have access to.
3. Select the **Role name** link for the role that's attached to your instance. This opens the role detail page.
4. To attach the managed policy, choose **Add permissions**, located in the upper right corner of the list panel. Then select **Attach policies** from the dropdown list.
5. To streamline results, enter the policy name in the search bar (`AWSEC2VssSnapshotPolicy`).
6. Select the checkbox next to the name of the policy to attach, and choose **Add permissions**.

Manage VSS components package for Windows VSS based EBS snapshots

Before you create VSS based EBS snapshots, ensure that you have the latest version of the VSS components package installed on your Windows instance. There are several ways that you can install the `AwsVssComponents` package onto an existing instance, as follows:

- (Recommended) Run the AWSEC2-VssInstallAndSnapshot command document (recommended). This automatically installs or updates if needed every time it runs.
- Manually install the VSS components on an EC2 Windows instance.
- Update the VSS components package on your EC2 Windows instance.

You can also create an AMI with EC2 Image Builder that uses the `aws-vss-components-windows` managed component to install the `AwsVssComponents` package for the image. The managed component uses AWS Systems Manager Distributor to install the package. After Image Builder creates the image, every instance that you launch from the associated AMI will have the VSS package installed on it. For more information about how you can create an AMI with the VSS package installed, see Distributor package managed components for Windows in the *EC2 Image Builder User Guide*.

Contents

Manually install the VSS components on an EC2 Windows instance

Your EC2 Windows instance must have VSS components installed before you can create application-consistent snapshots with Systems Manager. If you don't run the `AWSEC2-VssInstallAndSnapshot` command document to automatically install or update the package every time you create application-consistent snapshots, you must manually install the package.

You must also install manually if you plan to use one of the following methods to create application-consistent snapshots from your EC2 instance.

- Create VSS snapshots using AWS Backup
- Create VSS snapshots using Amazon Data Lifecycle Manager

If you need to perform a manual install, we recommend that you use the latest AWS VSS component package to improve the reliability and performance of application-consistent snapshots on your EC2 Windows instances.

> **Note**
>
> To automatically install or update the `AwsVssComponents` package whenever you create application-consistent snapshots, we recommend that you use Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` document. For more information, see Run the AWSEC2-VssInstallAndSnapshot command document (recommended).

To install the VSS components on an Amazon EC2 Windows instance, follow the steps for your preferred environment.

Console

To install the VSS components using SSM Distributor

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. For **Command document**, choose the button next to **AWS-ConfigureAWSPackage**.
5. For **Command parameters**, do the following:

a. Verify that **Action** is set to **Install**.

b. For **Name**, enter `AwsVssComponents`.

c. For **Version**, enter a version or leave the field empty so that Systems Manager installs the latest version.

6. For **Targets**, identify the instances on which you want to run this operation by specifying tags or selecting instances manually.

> **Note**
>
> If you choose to select instances manually, and an instance you expect to see is not included in the list, see Where Are My Instances? in the *AWS Systems Manager User Guide* for troubleshooting tips.

7. For **Other parameters**:

- (Optional) For **Comment**, type information about this command.
- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. (Optional) For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of instances on which to run the command at the same time.

> **Note**
>
> If you selected targets by choosing Amazon EC2 tags, and you are not certain how many instances use the selected tags, then limit the number of instances that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other instances after it fails on either a number or a percentage of instances. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Instances still processing the command might also send errors.

9. (Optional) For **Output options** section, if you want to save the command output to a file, select the box next to **Enable writing to an S3 bucket**. Specify the bucket and (optional) prefix (folder) names.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the instance, not those of the user performing this task. For more information, see [Configure EC2 instance permissions](#) in the *AWS Systems Manager User Guide*.

10. (Optional) Specify options for **SNS notifications**.

    For information about configuring Amazon SNS notifications for Run Command, see [Configuring Amazon SNS Notifications for AWS Systems Manager](#).

11. Choose **Run**.

AWS CLI

Use the following procedure to download and install the `AwsVssComponents` package on your instances by using Run Command from the AWS CLI. The package installs two components: a VSS requester and a VSS provider. The system copies these components to a directory on the instance, and then registers the provider DLL as a VSS provider.

To install the VSS package

Run the following command to download and install the required VSS components for Systems Manager.

```
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "i-1234567890abcdef0" \
    --parameters '{"action":["Install"],"name":["AwsVssComponents"]}'
```

PowerShell

Use the following procedure to download and install the `AwsVssComponents` package on your instances by using Run Command from the Tools for Windows PowerShell. The package installs two components: a VSS requester and a VSS provider. The system copies these components to a directory on the instance, and then registers the provider DLL as a VSS provider.

To install the VSS package

Run the following command to download and install the required VSS components for Systems Manager.

```
Send-SSMCommand `
    -DocumentName "AWS-ConfigureAWSPackage" `
    -InstanceId "i-1234567890abcdef0" `
    -Parameter @{'action'='Install';'name'='AwsVssComponents'}
```

Verify the signature on AWS VSS components

Use the following procedure to verify the signature on the `AwsVssComponents` package.

1. Connect to your Windows instance. For more information, see Connect to your Windows instance using RDP.
2. Navigate to C:\Program Files\Amazon\AwsVssComponents.
3. Open the context (right-click) menu for `ec2-vss-agent.exe`, and then choose **Properties**.
4. Navigate to the **Digital Signatures** tab and verify that the name of the signer is Amazon Web Services Inc.
5. Use the preceding steps to verify the signature on `Ec2VssInstaller` and `Ec2VssProvider.dll`.

Update the VSS components package on your EC2 Windows instance

We recommend that you keep the VSS components updated with the latest recommended version. There are several different ways that you can update components when a new version of the `AwsVssComponents` package is released.

Update methods

- You can repeat the steps described in Manually install the VSS components on an EC2 Windows instance when a new version of the AWS VSS components is released.
- You can configure a Systems Manager State Manager association to automatically download and install new or updated VSS components when the `AwsVssComponents` package becomes available.
- You can automatically install or update the `AwsVssComponents` package whenever you create application-consistent snapshots, when you use Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` document.

> **Note**
>
> We recommend that you use Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` command document, which automatically installs or updates the `AwsVssComponents` package before it creates the application-consistent snapshots. For more information, see Run the AWSEC2-VssInstallAndSnapshot command document (recommended).

To create a Systems Manager State Manager association, follow the steps for your preferred environment.

Console

When you create a Systems Manager State Manager association, there are two options for updating the `AwsVssComponents` package, as follows:

Uninstall and reinstall

This method downloads and installs the package with no additional prerequisites.

In-place update

This performs an in-place update for the package, and has the following prerequisites:

- The SSM Agent version that's installed on the instance must be version `3.3.808.0` or later. For more information, see Working with SSM Agent on EC2 instances for Windows Server in the *AWS Systems Manager User Guide*.
- If specified, the `AwsVssComponents` package version must be version `2.5.0` or later. Earlier versions don't support in-place update.

> **Note**
>
> if your instance doesn't meet these prerequisites, in-place update will fail. Use the **Uninstall and reinstall** option instead.

To create a State Manager association

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

2. In the navigation pane, choose **State Manager**.

   Or, if the Systems Manager homepage opens first, open the navigation pane and then choose **State Manager**.

3. Choose **Create association**.
4. In the **Name** field, enter a descriptive name.
5. In the **Document** list, choose **AWS-ConfigureAWSPackage**.
6. In the **Parameters** section, choose **Install** from the **Action** list.
7. For **Installation type**, choose either **Uninstall and reinstall** or **In-place update**.
8. In the **Name** field, enter `AwsVssComponents`. You can keep the **Version** and **Additional Arguments** fields empty.
9. In the **Targets** section, choose an option.

   > **Note**
   >
   > If you choose to target instances by using tags, and you specify tags that map to Linux instances, the association succeeds on the Windows instance but fails on the Linux instances. The overall status of the association shows **Failed**.

10. In the **Specify schedule** section, choose an option.
11. In the **Advanced options** section, for **Compliance severity**, choose a severity level for the association. For more information, see Learn about association compliance. For **Change Calendars**, select a preconfigured change calendar. For more information, see about AWS Systems Manager Change Calendar.
12. For **Rate control**, do the following:

    - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.
    - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes.

13. (Optional) For **Output options**, to save the command output to a file, select **Enable writing output to S3**. Enter the bucket and prefix (folder) names in the boxes.
14. Choose **Create association**, and then choose **Close**. The system attempts to create the association on the instances and immediately apply the state.

> **Note**
>
> If EC2 instances for Windows Server show a status of **Failed**, verify that the SSM Agent is running on the instance, and verify that the instance is configured with an AWS Identity and Access Management (IAM) role for Systems Manager. For more information, see [Setting up AWS Systems Manager](#).

AWS CLI

Use the [create-association](#) command to update a Distributor package on a schedule without taking the associated application offline. Only new or updated files in the package are replaced.

To create a State Manager association

Run the following command to create an association. The value of `--name`, the document name, is always `AWS-ConfigureAWSPackage`. The following command uses the key `InstanceIds` to specify target instances.

```
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage" \
    --parameters action=Install,installationType="Uninstall and
 reinstall",name=AwsVssComponents \
    --targets Key=InstanceIds,Values=i-1234567890abcdef0,i-000011112222abcde
```

PowerShell

To create a State Manager association

Use the [New-SSMAssociation](#) cmdlet.

```
New-SSMAssociation `
    -Name "AWS-ConfigureAWSPackage" `
    -Parameter  @{
        "action" = "Install"
        "installationType" = "Uninstall and reinstall"
        "name" = "AwsVssComponents"
    } `
    -Target @{
        "Key" = "InstanceIds"
        "Values" = @("i-1234567890abcdef0", "i-000011112222abcde")
```

```
    }
```

Create VSS based EBS snapshots for your EC2 Windows instance

After you've met all of the Prerequisites to create Windows VSS based EBS snapshots, you can use any of the following methods to create VSS based snapshots from your EC2 instance.

AWS Systems Manager command documents

Use Systems Manager command documents to create VSS based snapshots.

To automate backups, you can create an AWS Systems Manager maintenance window task that uses the `AWSEC2-VssInstallAndSnapshot` command document. For more information, see Working with Maintenance Windows (Console) in the *AWS Systems Manager User Guide*.

AWS Backup

You can create a VSS backup when using AWS Backup by enabling VSS in the console or CLI. For more information, see Creating Windows VSS backups in the *AWS Backup Developer Guide*.

> **Note**
>
> AWS Backup doesn't automatically install the `AwsVssComponents` package on your instance. You must perform a manual install on your instance. For more information, see Manually install the VSS components on an EC2 Windows instance.

Amazon Data Lifecycle Manager

You can create VSS snapshots using Amazon Data Lifecycle Manager by enabling pre and post scripts in your snapshot lifecycle policies. For more information, see Automating application-consistent snapshots in the *Amazon EBS User Guide*.

> **Note**
>
> Amazon Data Lifecycle Manager doesn't automatically install the `AwsVssComponents` package on your instance. You must perform a manual install on your instance. For more information, see Manually install the VSS components on an EC2 Windows instance.

Use Systems Manager command documents to create VSS based snapshots

You can use AWS Systems Manager command documents to create VSS based snapshots. The following content introduces the command documents that are available, and the runtime parameters that the documents use to create your snapshots.

Before you use any of the Systems Manager command documents, ensure that you've met all Prerequisites to create Windows VSS based EBS snapshots.

Topics

Parameters for Systems Manager VSS snapshot documents

The Systems Manager documents that create VSS snapshots all use the following parameters, except where noted:

AmiName (string, optional)

If the **CreateAmi** option is set to `True`, specify the name of the AMI that the backup creates.

description (string, optional)

Specify a description for the snapshots or image that this process creates.

CollectDiagnosticLogs (string, optional)

To collect more information during snapshot and AMI creation steps, set this parameter to "`True`". The default value for this parameter is "`False`". Consolidated diagnostic logs are saved as a `.zip` format archive at the following location on your instance:

`C:\ProgramData\Amazon\AwsVss\Logs\timestamp.zip`

CopyOnly (string, optional)

If you use the native SQL Server backup in addition to AWS VSS, performing a Copy-only backup prevents AWS VSS from breaking the native differential backup chain. To perform a Copy-only backup operation, set this parameter to `True`.

The default value for this parameter is `False`, which causes AWS VSS to perform a full backup operation.

CreateAmi (string, optional)

To create a VSS based Amazon Machine Image (AMI) to back up your instance, set this parameter to `True`. The default value for this parameter is `False`, which backs up your instance with an EBS snapshot instead.

For more information about creating an AMI from an instance, see Create an Amazon EBS-backed AMI.

executionTimeout (string, optional)

Specify the maximum time in seconds to run the snapshot creation process on the instance, or to create an AMI from the instance. Increasing this timeout allows the command to wait longer for VSS to start its freeze and complete tagging of the resources it creates. This timeout only applies to the snapshot or AMI creation steps. The initial step to install or update the `AwsVssComponents` package is not included in the timeout.

ExcludeBootVolume (string, optional)

This setting excludes boot volumes from the backup process if you create snapshots. To exclude boot volumes from your snapshots, set **ExcludeBootVolume** to `True`, and **CreateAmi** to `False`.

If you create an AMI for your backup, this parameter should be set to `False`. The default value for this parameter is `False`.

NoWriters (string, optional)

To exclude application VSS writers from the snapshot process, set this parameter to `True`. Excluding application VSS writers can help you resolve conflicts with third-party VSS backup components. The default value for this parameter is `False`.

If `SaveVssMetadata` is `True`, this parameter must be set to `False`.

SaveVssMetadata (string, optional)

To save VSS metadata files during every snapshot, set this parameter to `True`. The default value is `False`. VSS Metadata files help provide insights into which components or writers were included in a backup operation, and the associated files for each component.

Metadata files have the associated snapshot set id in their names. You can find them at the following location on your instance:

```
C:\ProgramData\Amazon\AwsVss\VssMetadata\
```

Warning

- Saving VSS metadata files requires `AwsVssComponents` package version 2.4.0 or later. If your instance has an earlier version installed, setting `SaveVssMetadata` to `True` causes the snapshot creation to fail.
- The `NoWriters` and `SaveVssMetadata` parameters are mutually exclusive. If both are set to `True` then snapshot creation fails.

tags (string, optional)

We recommend that you tag your snapshots and images to help you locate and manage your resources, for example, to restore volumes from a list of snapshots. The system adds the `Name` key, with a blank value where you can specify the name that you want to apply to your output snapshots or images.

If you want to specify additional tags, separate tags with a semicolon in between. For example, `Key=Environment,Value=Test;Key=User,Value=TestUser1`.

Note

Tag keys and values must only contain alphanumeric characters and the following special characters: `() ./\-"'@_+:={}`.

By default, the system adds the following reserved tags for VSS based snapshots and images.

- **Device** – For VSS based snapshots, this is the device name of the EBS volume that the snapshot captures.
- **AppConsistent** – This tag indicates the successful creation of a VSS based snapshot or AMI.
- **AwsVssConfig** – This identifies snapshots and AMIs that are created with VSS enabled. The tag includes meta information such as the `AwsVssComponents` version, and the Snapshot Set ID.

Warning

Specifying any of these reserved tags in your parameter list will cause an error.

VssVersion (string, optional)

For the `AWSEC2-VssInstallAndSnapshot` document only, you can specify the `VssVersion` parameter to install a specific version of `AwsVssComponents` package on your instance. Leave this parameter blank to install the recommended default version.

If the specified version of the `AwsVssComponents` package is already installed, the script skips the install step and moves on to the backup step. For a list of `AwsVssComponents` package versions and operating support, see AWS VSS solution version history.

Run Systems Manager VSS snapshot command documents

You can create VSS based EBS snapshots with AWS Systems Manager command documents as follows.

Run the AWSEC2-VssInstallAndSnapshot command document (recommended)

When you use AWS Systems Manager to run the `AWSEC2-VssInstallAndSnapshot` document, the script runs the following steps.

1. The script first installs or updates the `AwsVssComponents` package on your instance, depending on whether it's already installed.
2. The script creates the application-consistent snapshots after the first step completes.

To run the `AWSEC2-VssInstallAndSnapshot` document, follow the steps for your preferred environment.

Console

Create VSS based EBS snapshots from the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Run Command** from the navigation pane. This shows a list of commands that are currently running in your account, if applicable.
3. Choose **Run command**. This opens a list of command documents that you have access to.
4. Select `AWSEC2-VssInstallAndSnapshot` from the list of command documents. To streamline results, you can enter all or part of the document name. You can also filter by the owner, by platform types, or by tags.

When you select a command document, details populate below the list.

5. Select `Default version at runtime` from the **Document version** list.
6. Configure the **Command parameters** to define how `AWSEC2-VssInstallAndSnapshot` will install the `AwsVssComponents` package and back up with VSS snapshots or an AMI. For parameter details, see Parameters for Systems Manager VSS snapshot documents.
7. For **Target selection**, specify tags or select instances manually to identify the instances on which to run this operation.

> **Note**
>
> If you select instances manually, and an instance you expect to see is not included in the list, see Where Are My Instances? for troubleshooting tips.

8. For additional parameters to define Systems Manager Run Command behavior such as **Rate control**, enter values as described in Running commands from the console.
9. Choose **Run**.

   If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the Systems Manager command output for details about why the execution failed. If the command successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS volumes.

AWS CLI

You can run the following commands in the AWS CLI to create VSS based EBS snapshots and get the status of your snapshot creation.

Create VSS based EBS snapshots

Run the following command to create VSS based EBS snapshots. To create the snapshots, you must identify the instances with the `--instance-ids` parameter. For more information about other parameters that you can use, see Parameters for Systems Manager VSS snapshot documents.

```
aws ssm send-command \
```

```
 --document-name "AWSEC2-VssInstallAndSnapshot" \
 --instance-ids "i-01234567890abcdef" \
 --parameters '{"ExcludeBootVolume":["False"],"description":["Description"],"tags":
["Key=key_name,Value=tag_value"],"VssVersion":[""]}'
```

If successful, the command document populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed.

Get command status

To get the current status of the snapshots, run the following command using the command ID returned from **send-command**.

```
aws ssm get-command-invocation
 --instance-ids "i-01234567890abcdef" \
 --command-id "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" \
 --plugin-name "CreateVssSnapshot"
```

PowerShell

Run the following commands with AWS Tools for Windows PowerShell to create VSS based EBS snapshots and get the current runtime status for the creation of your output. Specify parameters described in the prior list to modify the behavior of the snapshot process.

Create VSS based EBS snapshots with Tools for Windows PowerShell

Run the following command to create VSS based EBS snapshots or AMIs.

```
Send-SSMCommand -DocumentName "AWSEC2-VssInstallAndSnapshot" -InstanceId
 "i-01234567890abcdef" -Parameter
 @{'ExcludeBootVolume'='False';'description'='a_description'
 ;'tags'='Key=key_name,Value=tag_value';'VssVersion'=''}
```

Get command status

To get the current status of the snapshots, run the following command using the command ID returned from **Send-SSMCommand**.

```
Get-SSMCommandInvocationDetail -InstanceId "i-01234567890abcdef" -CommandId
 "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111" -PluginName "CreateVssSnapshot"
```

If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed.

Run the AWSEC2-CreateVssSnapshot command document

To run the `AWSEC2-CreateVssSnapshot` document, follow the steps for your preferred environment.

Console

Create VSS based EBS snapshots from the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Run Command** from the navigation pane. This shows a list of commands that are currently running in your account, if applicable.
3. Choose **Run command**. This opens a list of command documents that you have access to.
4. Select `AWSEC2-CreateVssSnapshot` from the list of command documents. To streamline results, you can enter all or part of the document name. You can also filter by the owner, by platform types, or by tags.

   When you select a command document, details populate below the list.
5. Select `Default version at runtime` from the **Document version** list.
6. Configure the **Command parameters** to define how `AWSEC2-CreateVssSnapshot` will back up with VSS snapshots or an AMI. For parameter details, see Parameters for Systems Manager VSS snapshot documents.
7. For **Target selection**, specify tags or select instances manually to identify the instances on which to run this operation.

   > **Note**
   >
   > If you select instances manually, and an instance you expect to see is not included in the list, see Where Are My Instances? for troubleshooting tips.

8. For additional parameters to define Systems Manager Run Command behavior such as **Rate control**, enter values as described in [Running commands from the console](#).
9. Choose **Run**.

   If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the Systems Manager command output for details about why the execution failed. If the command successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS volumes.

AWS CLI

You can run the following command in the AWS CLI to create VSS based EBS snapshots.

Create VSS based EBS snapshots

Run the following command to create VSS based EBS snapshots. To create the snapshots, you must identify the instances with the `--instance-ids` parameter. For more information about other parameters that you can use, see [Parameters for Systems Manager VSS snapshot documents](#).

```
aws ssm send-command \
 --document-name "AWSEC2-CreateVssSnapshot" \
 --instance-ids "i-01234567890abcdef" \
 --parameters '{"ExcludeBootVolume":["False"],"description":["Description"],"tags":
["Key=key_name,Value=tag_value"]}'
```

If successful, the command document populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed.

PowerShell

Run the following command with AWS Tools for Windows PowerShell to create VSS based EBS snapshots.

Create VSS based EBS snapshots with Tools for Windows PowerShell

Run the following command to create VSS based EBS snapshots. To create the snapshots, you must identify the instances with the `InstanceId` parameter. You can specify more than one instance to create snapshots for. For more information about other parameters that you can use, see [Parameters for Systems Manager VSS snapshot documents](#).

```
Send-SSMCommand -DocumentName AWSEC2-CreateVssSnapshot -InstanceId
 "i-01234567890abcdef" -Parameter
 @{'ExcludeBootVolume'='False';'description'='a_description'
 ;'tags'='Key=key_name,Value=tag_value'}
```

If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed. If the command successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS snapshots.

Run command documents for a Windows Failover Cluster with shared EBS storage

You can use any of the command line procedures described in the previous section to create a VSS based snapshot. The command document (`AWSEC2-VssInstallAndSnapshot` or `AWSEC2-CreateVssSnapshot`) must run on the primary node in your cluster. The document will fail on the secondary nodes as they don't have access to the shared disks. If your primary and secondary change dynamically, you can run the AWS Systems Manager Run Command document on multiple nodes with the expectation that the command will succeed on the primary node and fail on secondary nodes.

> **Note**
>
> To automate backups, you can create an AWS Systems Manager maintenance window task that uses the `AWSEC2-VssInstallAndSnapshot` document. For more information, see [Working with Maintenance Windows (Console)](#) in the *AWS Systems Manager User Guide*.

Troubleshoot Windows VSS based EBS snapshots

Before you try any other troubleshooting steps, we recommend that you verify the following details.

- Ensure that you've met all Prerequisites to create Windows VSS based EBS snapshots.
- Verify that you're using the latest Windows OS version support of the `AwsVssComponents` package for your operating system. The issue that you've observed might have been addressed in newer versions.

Topics

Check log files

If you experience problems or receive error messages when you create VSS based EBS snapshots, you can view the command output in the Systems Manager console.

For Systems Manager documents that create VSS snapshots, you can set the `CollectDiagnosticLogs` parameter to "`True`" at runtime. When the `CollectDiagnosticLogs` parameter is set to "`True`", VSS collects additional logs to aid in debugging. For more information, see Collect additional diagnostic logs.

If you collect diagnostic logs, the Systems Manager document stores them on your instance at the following location: `C:\ProgramData\Amazon\AwsVss\Logs\timestamp.zip`. The default for the `CollectDiagnosticLogs` parameter is "`False`".

> **Note**
>
> For additional debugging help, you can send the `.zip` file to Support.

The following additional logs are available, whether you collect diagnostic logs or not:

- `%ProgramData%\Amazon\SSM\InstanceData\InstanceID\document\orchestration\SSMCommandID\awsrunPowerShellScript\runPowerShellScript\stdout`

- %ProgramData%\Amazon\SSM\InstanceData*InstanceID*\document\orchestration*SSMCommandID*\awsrunPowerShellScript\runPowerShellScript\stderr

You can also open the Event Viewer Windows application and choose **Windows Logs**, **Application** to view additional logs. To see events specifically from the EC2 Windows VSS Provider and the Volume Shadow Copy Service, filter by **Source** on the terms **Ec2VssSoftwareProvider** and **VSS**.

If you're using Systems Manager with VPC endpoints, and the Systems Manager send-command API action (**Run Command** in the console) failed, verify that you configured the following endpoint correctly: **com.amazonaws.*region*.ec2**.

Without the Amazon EC2 endpoint defined, the call to enumerate attached EBS volumes fails, which causes the Systems Manager command to fail. For more information about setting up VPC endpoints with Systems Manager, see Create a Virtual Private Cloud Endpoint in the *AWS Systems Manager User Guide*.

Collect additional diagnostic logs

To collect additional diagnostic logs when you use the Systems Manager send command to run the VSS snapshot document, set the `CollectDiagnosticLogs` input parameter to "`True`" at runtime. We recommend that you set this parameter to "`True`" when you troubleshoot.

To see a command line example, select one of the following tabs.

AWS CLI

The following example runs the `AWSEC2-CreateVssSnapshot` Systems Manager document in the AWS CLI:

```
aws ssm send-command \
    --document-name "AWSEC2-CreateVssSnapshot" \
    --instance-ids "i-1234567890abcdef0" \
    --parameters '{"description":["Example - create diagnostic logs at runtime."],"tags":["Key=tag_name,Value=tag_value"],"CollectDiagnosticLogs":["True"]}'
```

PowerShell

The following example runs the `AWSEC2-CreateVssSnapshot` Systems Manager document in PowerShell:

```
Send-SSMCommand `
    -DocumentName "AWSEC2-CreateVssSnapshot" `
    -InstanceId "i-1234567890abcdef0" `
    -Parameter @{'description'='Example - create diagnostic logs at
 runtime.';'tags'='Key=tag_name,Value=tag_value';'CollectDiagnosticLogs'='True'}
```

Use VSS on instances with proxy configured

If you experience problems when creating VSS based EBS snapshots on instances that use a proxy to reach EC2 endpoints, verify the following settings on your instance:

- Verify that the proxy is configured so that the EC2 service endpoints in the instance's Region and IMDS are reachable by AWS Tools for Windows PowerShell running as SYSTEM.
- To support using the system configured WinHTTP proxy, make sure that you've installed the latest `AwsVssComponents` version on your instance. For more information about configuring WinHTTP proxy, see Netsh Commands for Windows Hypertext Transfer Protocol (WINHTTP) on the Microsoft website.

Error: Thaw pipe connection timed out, error on thaw, timeout waiting for VSS Freeze, or other timeout errors

The EC2 Windows VSS Provider might time out due to activity or services on the instance preventing VSS based snapshots from proceeding in a timely manner. The Windows VSS Framework provides a non-configurable 10-second window during which communication to the file system is paused. During this time, `AWSEC2-CreateVssSnapshot` snapshots your volumes.

The following issues can cause the EC2 Windows VSS Provider to run into time limits during a snapshot:

- Excessive I/O to a volume
- Slow responsiveness of the EC2 API on the instance
- Fragmented volumes
- Incompatibility with some antivirus software
- Issues with a VSS Application writer
- When Module Logging is enabled for a large number of PowerShell modules, that can cause PowerShell scripts to run slowly

Most timeout issues that occur when you run the `AWSEC2-CreateVssSnapshot` command document are related to the workload on the instance being too high at the time of the backup. The following actions can help you take a successful snapshot:

- Retry the `AWSEC2-CreateVssSnapshot` command to see if the snapshot attempt is successful. If retrying succeeds in some cases, reducing the instance load might make snapshots more successful.
- Wait a while for the workload on the instance to decrease, and retry the `AWSEC2-CreateVssSnapshot` command. Alternatively, you can attempt snapshots when the instance is known to be under low stress.
- Attempt VSS snapshots when the antivirus software on the system is turned off. If this resolves the issue, refer to the antivirus software instructions and configure it to allow VSS snapshots.
- If there is a high volume of Amazon EC2 API calls in your account within the same Region where you're running a snapshot, API throttling might delay snapshot operations. To reduce throttling impact, use the latest `AwsVssComponents` package. This package utilizes the EC2 `CreateSnapshots` API action to reduce the number of mutating actions like per-volume snapshot creation and tagging.
- If you have multiple `AWSEC2-CreateVssSnapshot` command scripts running at the same time, you can take the following steps to reduce concurrency issues.
  - Consider scheduling snapshots during periods of lower API activity.
  - If you use **Run Command** in the Systems Manager console (or **SendCommand** in the API) to run the command script, you can use Systems Manager rate controls to reduce concurrency.

    You can also use Systems Manager rate controls to reduce concurrency for services like AWS Backup that use Systems Manager to run the command script.
- Run the command `vssadmin list writers` in a shell and see if it reports any errors in the **Last error** field for any writers on the system. If any writers report a **time out** error, consider retrying snapshots when the instance is under less load.
- When you use smaller instance types like *`t2 | t3 | t3a`*.nano or *`t2 | t3 | t3a`*.micro, timeouts due to memory and CPU constraints can occur. The following actions might help reduce timeout issues.
  - Try closing memory or CPU intensive applications before taking snapshots.
  - Try taking snapshots during periods of lower instance activity.

Error: Cannot invoke method. Method invocation is supported only on core types in this language mode

You will encounter this error when the PowerShell language mode is not set to `FullLanguage`. The `AWSEC2-CreateVssSnapshot` SSM document requires PowerShell to be configured to `FullLanguage` mode.

To verify the language mode, run the following command on the instance in a PowerShell console:

```
$ExecutionContext.SessionState.LanguageMode
```

For more information about language modes, see about_Language_Modes in the Microsoft documentation.

Use the AWS VSS solution to restore data for your instance

You can restore EBS volumes for a Windows instance from VSS based snapshots created by the AWS VSS solution. If your AWS VSS solution snapshots contain backups of a Microsoft SQL Server database, you can restore the database using the `AWSEC2-RestoreSqlServerDatabaseWithVss` AWS Systems Manager Automation runbook.

The database restore runbook automates the entire restore process, including creating volumes from the snapshots and attaching them to the instance. The automation leverages VSS technology to restore the database, allowing you to restore without stopping your SQL Server application or disconnecting any active connections.

For detailed instructions on how to use the Microsoft SQL Server database runbook, see Restore from VSS based snapshots in the *Microsoft SQL Server on Amazon EC2 User Guide*.

Customize a script to restore EBS volumes from AWS VSS solution snapshots

You can use the `RestoreVssSnapshotSampleScript.ps1` script as a model to create your own custom script that restores EBS volumes from AWS VSS solution snapshots. The sample script performs the following tasks:

- Stops an instance
- Removes all existing drives from the instance (except the boot volume, if it was excluded)
- Creates new volumes from the snapshots
- Attaches the volumes to the instance by using the device ID tag on the snapshot

- Restarts the instance

> **Important**
>
> The following script detaches all volumes attached to an instance, and then creates new volumes from a snapshot. Make sure that you have properly backed-up the instance. The old volumes are not deleted. If you want, you can edit the script to delete the old volumes.

To restore volumes from VSS based EBS snapshots

1. Download the RestoreVssSnapshotSampleScript.zip file and extract the file contents.
2. Open `RestoreVssSnapshotSampleScript.ps1` in a text editor and edit the sample call at the bottom of the script with a valid EC2 instance ID and EBS snapshot ID, and then run the script from PowerShell.

AWS VSS solution version history

This page includes release notes by version for the AWS VSS component package, as well as component and script version requirements for each supported version of Windows Server.

Topics

AwsVssComponents package versions

The following table describes the released versions of the AWS VSS component package.

Version	Details	Release date	Downloadable
2.5.1	Fixed a case where SQL database restoration could fail when the target database parameter is specified.	March 13, 2025	Yes

Version	Details	Release date	Downloadable
2.5.0	• Added the capability to read VSS metadata files and restore a Microsoft SQL Server database on the instance. For more information, see [Restore from VSS based snapshots]() in the *Microsoft SQL Server on Amazon EC2 User Guide*. • Added support for the in-place update option when installing or upgrading the `AwsVssComponents` package.	January 17, 2025	Yes
2.4.0	Added the capability to save VSS metadata files on snapshot creation. To enable this feature, see SaveVssMetadata in [Parameters for Systems Manager VSS snapshot documents]().	October 7, 2024	Yes
2.3.3	Updated the VSS agent to ensure that the `Ec2VssProvider` is used during snapshot creation.	June 25, 2024	Yes
2.3.2	Fixed a case where VSS provider registration is not removed on uninstallation.	May 9, 2024	Yes
2.3.1	Added new default tag `AwsVssConfig` to identify snapshots and AMIs created by AWS VSS.	March 7, 2024	Yes

Version	Details	Release date	Downloadable
2.2.1	- Added support for using the `DescribeInstanceAttribute` API. - Bug fixes and reliability improvements. - Deprecated support for Windows Server 2012 and 2012 R2. AWS VSS components version 2.2.1 installation on Windows Server 2012 and 2012 R2 will fail. AWS VSS components version 2.1.0 is the last version to support Windows Server 2012 and 2012 R2.	January 18, 2024	Yes
2.1.0	Added support for using the `CreateSnapshots` API.	November 6, 2023	Yes
2.0.1	Added support for using the WinHTTP proxy settings.	October 26, 2023	No
2.0.0	Added capability to the AWS VSS component to create snapshots and AMIs, which enables compatibility with PowerShell module logging, script block logging, and transcription features.	April 28, 2023	No
1.3.2.0	Fixed a case where installation failure is not reported correctly.	May 10, 2022	No

Version	Details	Release date	Downloadable
1.3.1.0	• Fixed snapshots failing on domain controllers in relation to an NTDS VSS writer logging error. • Fixed VSS agent error when uninstalling version 1.0 VSS provider.	February 6, 2020	Yes
1.3.00	• Improved logging by reducing unwanted verbosity. • Fixed regionalization issues during installation. • Fixed return codes for some provider registration error conditions. • Fixed various installation issues.	March 19, 2019	No
1.2.00	• Added command line parameters `-nw` (no-writers) and `-copy` (copy-only) to agent. • Fixed EventLog errors caused by improper memory allocation calls.	November 15, 2018	No
1.1	Fixed AWS VSS components that were being used incorrectly as the default Windows Backup and Restore provider.	December 12, 2017	No
1.0	Initial release.	November 20, 2017	No

Windows OS version support

The following table shows which AWS VSS solution versions you should run on each version of Windows Server on Amazon EC2.

Windows Server version	AwsVssComponents version	AWSEC2-VssInstallAndSnapshot version name	AWSEC2-CreateVssSnapshot version name
Windows Server 2025	default	default	default
Windows Server 2022	default	default	default
Windows Server 2019	default	default	default
Windows Server 2016	default	default	default
Windows Server 2012 R2	2.1.0	not supported	2012R2
Windows Server 2012	2.1.0	not supported	2012R2

Windows Server version	AwsVssComponents version	AWSEC2-VssInstallAndSnapshot version name	AWSEC2-CreateVssSnapshot version name
Windows Server 2008 R2	1.3.1.0	not supported	2008R2

Object storage, file storage, and file caching on Amazon EC2

Cloud file storage is a method for storing data in the cloud that provides servers and applications access to data through shared file systems. This compatibility makes cloud file storage ideal for workloads that rely on shared file systems and provides simple integration without code changes.

There are many file storage solutions that exist, ranging from a single node file server on a compute instance using block storage as the underpinnings with no scalability or few redundancies to protect the data, to a do-it-yourself clustered solution, to a fully-managed solution. The following content introduces some of the storage services provided by AWS for use with Amazon EC2 instances.

Contents

Use Amazon S3 with Amazon EC2 instances

Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance. You can use Amazon S3 to store and retrieve any amount of data for a range of use cases, such as data lakes, websites, backups, and big data analytics, from an Amazon EC2 instance or from anywhere over the internet. For more information, see What is Amazon S3?

Objects are the fundamental entities stored in Amazon S3. Every object stored in Amazon S3 is contained in a bucket. Buckets organize the Amazon S3 namespace at the highest level and identify the account responsible for that storage. Amazon S3 buckets are similar to internet domain names. Objects stored in the buckets have a unique key value and are retrieved using a URL. For example, if an object with a key value `/photos/mygarden.jpg` is stored in the `amzn-s3-demo-bucket1` bucket, then it is addressable using the URL `https://amzn-s3-demo-bucket1.s3.amazonaws.com/photos/mygarden.jpg`. For more information, see [How Amazon S3 works].

Usage examples

Given the benefits of Amazon S3 for storage, you might decide to use this service to store files and data sets for use with EC2 instances. There are several ways to move data to and from Amazon S3 to your instances. In addition to the examples discussed below, there are a variety of tools that people have written that you can use to access your data in Amazon S3 from your computer or your instance.

If you have permission, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

wget

> **Note**
>
> This method works for public objects only. If the object is not public, you receive an `ERROR 403: Forbidden` message. If you receive this error, you must use either the Amazon S3 console, AWS CLI, AWS API, AWS SDK, or AWS Tools for Windows PowerShell, and you must have the required permissions. For more information, see Identity and access management for Amazon S3 and Downloading an object in the *Amazon S3 User Guide*.

The **wget** utility is an HTTP and FTP client that allows you to download public objects from Amazon S3. It is installed by default in Amazon Linux and most other distributions, and available for download on Windows. To download an Amazon S3 object, use the following command, substituting the URL of the object to download.

```
[ec2-user ~]$ wget https://amzn-s3-demo-bucket.s3.amazonaws.com/path-to-file
```

PowerShell

You can use the AWS Tools for Windows PowerShell to move objects to and from Amazon S3.

Use the Copy-S3Object cmdlet to copy an Amazon S3 object to your Windows instance as follows.

```
Copy-S3Object `
    -BucketName amzn-s3-demo-bucket `
    -Key path-to-file `
    -LocalFile my_copied_file.ext
```

Alternatively, you can open the Amazon S3 console by using a web browser on the Windows instance.

AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to download restricted items from Amazon S3 and also to upload items. For more information, such as how to install and configure the tools, see the AWS Command Line Interface detail page.

The aws s3 cp command is similar to the Unix **cp** command. You can copy files from Amazon S3 to your instance, copy files from your instance to Amazon S3, and copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance.

```
aws s3 cp s3://amzn-s3-demo-bucket/my_folder/my_file.ext my_copied_file.ext
```

Use the following command to copy an object from your instance back into Amazon S3.

```
aws s3 cp my_copied_file.ext s3://amzn-s3-demo-bucket/my_folder/my_file.ext
```

The aws s3 sync command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance.

```
aws s3 sync s3://amzn-s3-demo-source-bucket local_directory
```

Amazon S3 API

If you are a developer, you can use an API to access data in Amazon S3. You can use this API to help develop your application and integrate it with other APIs and SDKs. For more information, see Code examples for Amazon S3 using AWS SDKs in the *Amazon Simple Storage Service API Reference*.

Use Amazon EFS with Amazon EC2 Linux instances

> **Note**
>
> Amazon EFS is not supported on Windows instances.

Amazon EFS provides scalable file storage for use with Amazon EC2. You can use an EFS file system as a common data source for workloads and applications running on multiple instances. For more information, see the Amazon Elastic File System product page.

This tutorial shows you how to create and attach an Amazon EFS file system using the Amazon EFS Quick Create wizard during instance launch. For a tutorial on how to create a file system using the Amazon EFS console, see Getting started with Amazon Elastic File System in the *Amazon Elastic File System User Guide*.

> **Note**
>
> When you create an EFS file system using EFS Quick Create, the file system is created with the following service recommended settings:
>
> - Automatic backups enabled.
> - Manage mount targets in the selected VPC.
> - General Purpose performance mode.
> - Bursting throughput mode.
> - Encryption of data at rest enabled using your default key for Amazon EFS (`aws/elasticfilesystem`).

- Amazon EFS lifecycle management enabled with a 30-day policy.

Tasks

- Create an EFS file system using Amazon EFS Quick Create
- Test the EFS file system
- Delete the EFS file system

Create an EFS file system using Amazon EFS Quick Create

You can create an EFS file system and mount it to your instance when you launch your instance using the Amazon EFS Quick Create feature of the Amazon EC2 launch instance wizard.

To create an EFS file system using Amazon EFS Quick Create

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch instance**.
3. (Optional) Under **Name and tags**, for **Name**, enter a name to identify your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose a Linux operating system, and then for **Amazon Machine Image (AMI)**, select a Linux AMI.
5. Under **Instance type**, for **Instance type**, select an instance type or keep the default.
6. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
7. Under **Network settings**, choose **Edit** (at right), and then for **Subnet**, select a subnet.

   > **Note**
   >
   > You must select a subnet before you can add an EFS file system.

8. Under **Configure storage**, choose **Edit** (at bottom right), and then do the following:

   a. For **File systems**, ensure that **EFS** is selected, and then choose **Create new shared file system**.

   b. For **File system name** enter a name for the Amazon EFS file system, and then choose **Create file system**.

   c. For **Mount point**, specify a custom mount point or keep the default.

d. To enable access to the file system, select **Automatically create and attach security groups**. By selecting this checkbox, the following security groups will be automatically created and attached to the instance and the mount targets of the file system:

   - Instance security group – Includes an outbound rule that allows traffic over the NFS 2049port, but includes no inbound rules.
   - File system mount targets security group – Includes an inbound rule that allows traffic over the NFS 2049 port from the instance security group (described above), and an outbound rule that allows traffic over the NFS 2049 port.

   > **Note**
   >
   > Alternatively, you can manually create and attach the security groups. If you want to manually create and attach the security groups, clear **Automatically create and attach the required security groups**.

e. To automatically mount the shared file system when the instance launches, select **Automatically mount shared file system by attaching required user data script**. To view the user data that is automatically generated, expand **Advanced details**, and scroll down to **User data**.

   > **Note**
   >
   > If you added user data before selecting this checkbox, the original user data is overwritten by the automatically generated user data.

9. Configure any other instance configuration settings as needed.
10. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

Test the EFS file system

You can connect to your instance and verify that the file system is mounted to the directory that you specified (for example, /mnt/efs).

To verify that the file system is mounted

1. Connect to your instance. For more information, see [Connect to your Linux instance using SSH]().
2. From the terminal window for the instance, run the **df -T** command to verify that the EFS file system is mounted.

```
$ df -T
Filesystem     Type              1K-blocks    Used          Available Use% Mounted
 on
/dev/xvda1     ext4                8123812 1949800            6073764  25% /
devtmpfs       devtmpfs            4078468      56            4078412   1% /dev
tmpfs          tmpfs               4089312       0            4089312   0% /dev/shm
efs-dns        nfs4       9007199254740992       0   9007199254740992   0% /mnt/efs
```

Note that the name of the file system, shown in the example output as *efs-dns*, has the following form.

```
file-system-id.efs.aws-region.amazonaws.com:/
```

3. (Optional) Create a file in the file system from the instance, and then verify that you can view the file from another instance.

   a. From the instance, run the following command to create the file.

   ```
   $ sudo touch /mnt/efs/test-file.txt
   ```

   b. From the other instance, run the following command to view the file.

   ```
   $ ls /mnt/efs
   test-file.txt
   ```

Delete the EFS file system

If you no longer need your file system, you can delete it.

To delete the file system

1. Open the Amazon Elastic File System console at https://console.aws.amazon.com/efs/.
2. Select the file system to delete.

3. Choose **Actions**, **Delete file system**.
4. When prompted for confirmation, enter the file system ID and choose **Delete file system**.

Use Amazon FSx with Amazon EC2 instances

The Amazon FSx family of services makes it easy to launch, run, and scale shared storage powered by popular commercial and open-source file systems. You can use the *new launch instance wizard* to automatically attach the following types of Amazon FSx file systems to your Amazon EC2 instances at launch:

- Amazon FSx for NetApp ONTAP provides fully managed shared storage in the AWS Cloud with the popular data access and management capabilities of NetApp ONTAP.
- Amazon FSx for OpenZFS provides fully managed cost-effective shared storage powered by the popular OpenZFS file system.

> **Note**
>
> - This functionality is available in the new launch instance wizard only. For more information, see Launch an EC2 instance using the launch instance wizard in the console
> - Amazon FSx for Windows File Server and Amazon FSx for Lustre file systems can't be mounted at launch. You must mount these file systems manually after launch.

You can choose to mount an existing file system that you created previously, or you can create a new file system to mount to an instance at launch.

Topics

- Security groups and user data script
- Mount an Amazon FSx file system at launch

Security groups and user data script

When you mount an Amazon FSx file system to an instance using the launch instance wizard, you can choose whether to automatically create and attach the security groups needed to enable access to the file system, and whether to automatically include the user data scripts needed to mount the file system and make it available for use.

Topics

- Security groups
- User data script

Security groups

If you choose to automatically create the security groups that are needed to enable access to the file system, the launch instance wizard creates and attaches two security groups - one security group is attached to the instance, and the other is attached to the file system. For more information about the security group requirements, see FSx for ONTAP file system access control with Amazon VPC and FSx for OpenZFS file system access control with Amazon VPC.

We add the tag `Name=instance-sg-1` to the security group that is created and attached to the instance. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following output rules, but no inbound rules.

Outbound rules

Protocol type	Port number	Destination
UDP	111	*file system security group*
UDP	20001 - 20003	*file system security group*
UDP	4049	*file system security group*
UDP	2049	*file system security group*
UDP	635	*file system security group*
UDP	4045 - 4046	*file system security group*
TCP	4049	*file system security group*
TCP	635	*file system security group*

Protocol type	Port number	Destination
TCP	2049	*file system security group*
TCP	111	*file system security group*
TCP	4045 - 4046	*file system security group*
TCP	20001 - 20003	*file system security group*
All	All	*file system security group*

The security group that is created and attached to the file system is tagged with `Name=fsx-sg-1`. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following rules.

Inbound rules

Protocol type	Port number	Source
UDP	2049	*instance security group*
UDP	20001 - 20003	*instance security group*
UDP	4049	*instance security group*
UDP	111	*instance security group*
UDP	635	*instance security group*
UDP	4045 - 4046	*instance security group*
TCP	4045 - 4046	*instance security group*
TCP	635	*instance security group*
TCP	2049	*instance security group*
TCP	4049	*instance security group*

Protocol type	Port number	Source
TCP	20001 - 20003	*instance security group*
TCP	111	*instance security group*

Outbound rules

Protocol type	Port number	Destination
All	All	0.0.0.0/0

User data script

If you choose to automatically attach user data scripts, the launch instance wizard adds the following user data to the instance. This script installs the necessary packages, mounts the file system, and updates your instance settings so that the file system will automatically re-mount whenever the instance restarts.

```
#cloud-config
package_update: true
package_upgrade: true
runcmd:
- yum install -y nfs-utils
- apt-get -y install nfs-common
- svm_id_1=svm_id
- file_system_id_1=file_system_id
- vol_path_1=/vol1
- fsx_mount_point_1=/mnt/fsx/fs1
- mkdir -p "${fsx_mount_point_1}"
- if [ -z "$svm_id_1" ]; then printf "\n${file_system_id_1}.fsx.eu-north-1.amazonaws.com:/${vol_path_1} ${fsx_mount_point_1} nfs4 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport,_netdev 0 0\n" >> /etc/fstab; else printf "\n${svm_id_1}.${file_system_id_1}.fsx.eu-north-1.amazonaws.com:/${vol_path_1} ${fsx_mount_point_1} nfs4 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport,_netdev 0 0\n" >> /etc/fstab; fi
- retryCnt=15; waitTime=30; while true; do mount -a -t nfs4 defaults; if [ $? = 0 ] || [ $retryCnt -lt 1 ]; then echo File system mounted successfully; break; fi; echo File system not available, retrying to mount.; ((retryCnt--)); sleep $waitTime; done;
```

Mount an Amazon FSx file system at launch

To mount a new or existing Amazon FSx file system at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and then choose **Launch instance** to open the launch instance wizard.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Instance type** section, select the instance type.
5. In the **Key pair** section, select an existing key pair or create a new one.
6. In the **Network settings** section, do the following:

   a. Choose **Edit**.

   b. If you want to **mount an existing file system**, for **Subnet**, choose the file system's preferred subnet. We recommend that you launch the instance into the same Availability Zone as the file system's preferred subnet to optimize performance.

      If you want to **create a new file system** to mount to an instance, for **Subnet**, choose the subnet into which to launch the instance.

      > **Important**
      >
      > You must select a subnet to enable the Amazon FSx functionality in the new launch instance wizard. If you do not select a subnet, you will not be able to mount an existing file system or create a new one.

7. In the **Storage** section, do the following:

   a. Configure the volumes as needed.

   b. Expand the **File systems** section and select **FSx**.

   c. Choose **Add shared file system**.

   d. For **File system**, select the file system to mount.

> **Note**
>
> The list displays all Amazon FSx for NetApp ONTAP and Amazon FSx for OpenZFS file systems in your account in the selected Region.

e. To automatically create and attach the security groups needed to enable access to the file system, select **Automatically create and attach security groups**. If you prefer to create the security groups manually, clear the checkbox. For more information, see Security groups.

f. To automatically attach the user data scripts needed to mount the file system, select **Automatically mount shared file system by attaching required user data script**. If you prefer to provide the user data scripts manually, clear the checkbox. For more information, see User data script.

8. In the **Advanced** section, configure the additional instance settings as needed.
9. Choose **Launch**.

Use Amazon File Cache with Amazon EC2 instances

Amazon File Cache provides a fully managed, high-speed cache on AWS that makes it easier to process file data, regardless of where the data is stored. Amazon File Cache serves as a temporary, high-performance storage location for data that's stored in on-premises file systems, AWS file systems, and Amazon Simple Storage Service (Amazon S3) buckets. You can use this capability to make dispersed datasets available to file-based applications on AWS with a unified view, and at high speeds—sub-millisecond latencies and high throughput. For more information, see the Amazon File Cache User Guide.

Amazon File Cache works with the most popular Linux AMIs, and is compatible with x86-based instance types and Graviton instance types. You can access your cache from your Amazon EC2 instances using the open-source Lustre client. You can mount your cache and then work with the files and directories in your cache using standard Linux commands. Amazon EC2 instances can access your cache from other Availability Zones within the same virtual private cloud (VPC), provided that your network configuration allows access across subnets within the VPC. You can also create a cache in a shared VPC.

To get started, see Getting started with Amazon File Cache in the *Amazon File Cache User Guide*.

Manage your Amazon EC2 resources

A *resource* is an entity that you can work with. Amazon EC2 creates resources as you use the features of the service. For example, Amazon EC2 resources include images, instances, fleets, key pairs, and security groups. All Amazon EC2 resource types include attributes that describe the resources. For example, names, descriptions, resource identifiers, and Amazon Resource Names (ARN).

Amazon EC2 resources are specific to the AWS Region or zone in which they reside. For example, an Amazon Machine Image (AMI) is specific to an AWS Region, but the instance that you launch from an AMI is specific to the zone in which you launch it. You can specify an Amazon EC2 resource in a permissions policy using its ARN.

Your AWS account has default quotas for Amazon EC2. These quotas define the maximum number of resources that you can create. For example, there are quotas for the maximum number of vCPUs across your running instances. If launching an instance or starting a stopped instance would cause you to exceed your quota, the operation fails.

You can search for specific resources in your AWS account by Region, using resource IDs or tags. To search for specific resources or resource types across multiple Regions, use Amazon EC2 Global View.

Contents

Select a Region for your Amazon EC2 resources

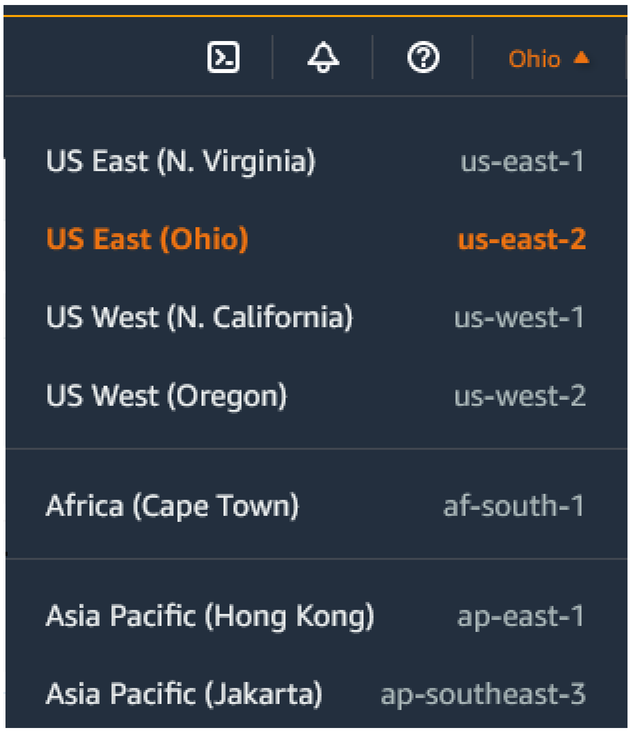
Amazon EC2 resources are specific to the AWS Region or zone in which they reside. When you create an Amazon EC2 resource, you select the Region for the resource.

Considerations

- Some AWS resources might not be available in all Regions. Ensure that you can create all the AWS resources that you need in a Region before you start creating resources in a Region.
- Some Regions are disabled by default. You must enable these Regions before you can use them. For more information , see AWS Regions.

To select a Region for a resource using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, choose the **Regions** selector and then choose the Region.



3. The Regions selector includes all resources that are available for use in your AWS account. Choose the underlined text near the bottom of the list to view the Regions that are not enabled for your account.

To select a Region for a resource using the AWS CLI

You can configure the AWS CLI to use a default Region. If you don't specify a Region in the command, the default Region is used. To use a different Region for a specific command, add the following option.

```
--region us-east-1
```

To select a Region for a resource using the Tools for PowerShell

You can configure the Tools for Windows PowerShell to use a default Region. If you don't specify a Region in a command, the default Region is used. To use a different Region for a specific command, add the following parameter.

```
-Region us-east-1
```

Find your Amazon EC2 resources

You can get a list of some types of resources using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include, or exclude, only the resources that match certain criteria.

Contents

List and filter resources using the console

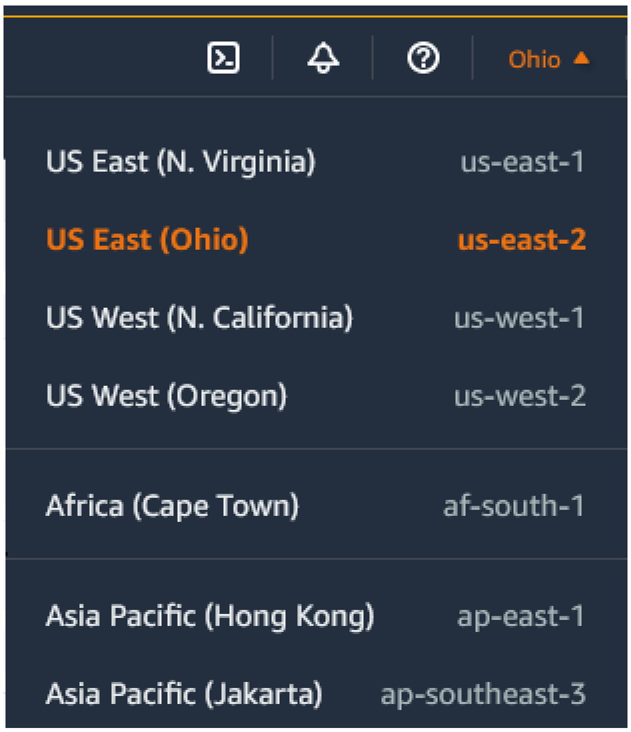
Contents

List resources using the console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.

To list EC2 resources using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Amazon EC2 resources are specific to an AWS Region. From the navigation bar, choose a Region from the **Regions** selector.



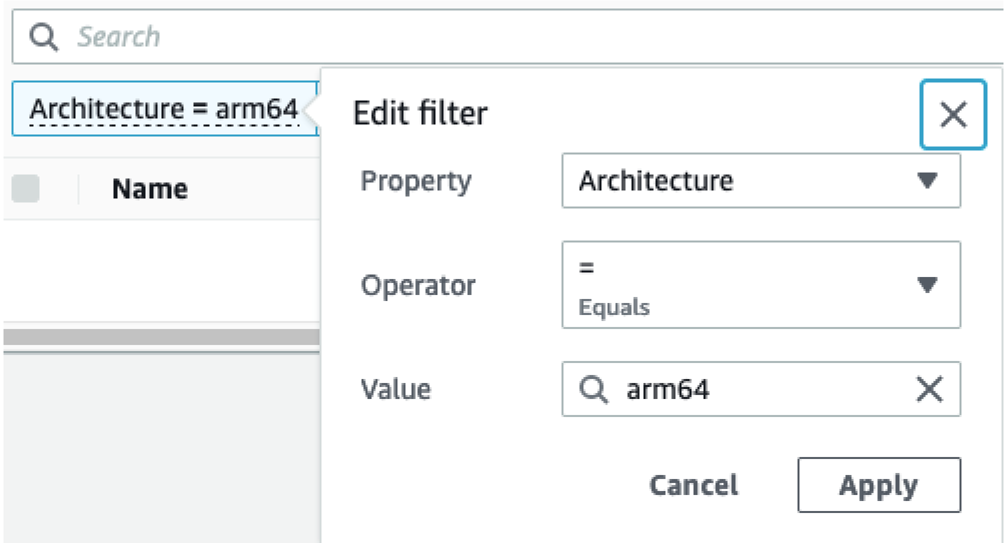
3. In the navigation pane, choose the option that corresponds to the resource type. For example, to list all your instances, choose **Instances**.

Filter resources using the console

To filter a list of resources

1. In the navigation pane, select a resource type (for example, **Instances**).
2. Choose the search field.
3. Select the filter from the list.

4. Select an operator, for example, **= (Equals)**. Some attributes have more available operators to select. Note that not all screens support selecting an operator.
5. Select a filter value.
6. To edit a selected filter, choose the filter token (blue box), make the required edits, and then choose **Apply**. Note that not all screens support editing the selected filter.



7. When you are finished, remove the filter.

Supported filters

The Amazon EC2 console supports two types of filtering.

- *API filtering* happens on the server side. The filtering is applied on the API call, which reduces the number of resources returned by the server. It allows for quick filtering across large sets of resources, and it can reduce data transfer time and cost between the server and the browser. API filtering supports **=** (equals) and **:** (contains) operators, and is always case sensitive.
- *Client filtering* happens on the client side. It enables you to filter down on data that is already available in the browser (in other words, data that has already been returned by the API). Client filtering works well in conjunction with an API filter to filter down to smaller data sets in the browser. In addition to **=** (equals) and **:** (contains) operators, client filtering can also support range operators, such as **>=** (greater than or equal), and negation (inverse) operators, such as **!=** (does not equal).

The Amazon EC2 console supports the following types of searches:

Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes or tags, without specifying an attribute or tag key to search.

> **Note**
>
> All keyword searches use *client filtering*.

To search by keyword, enter or paste what you're looking for in the search field, and then choose **Enter**. For example, searching for `123` matches all instances that have *123* in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID, or in any of their tags, such as the Name. If your free text search returns unexpected matches, apply additional filters.

Search by attribute

Searching by an attribute lets you search a specific attribute across all of your resources.

> **Note**
>
> Attribute searches use either *API filtering* or *client filtering*, depending on the selected attribute. When performing an attribute search, the attributes are grouped accordingly.

For example, you can search the **Instance state** attribute for all of your instances to return only instances that are in the `stopped` state. To do this:

1. In the search field on the **Instances** screen, start entering `Instance state`. As you enter the characters, the two types of filters appear for **Instance state**: **API filters** and **Client filters**.
2. To search on the server side, choose **Instance state** under **API filters**. To search on the client side, choose **Instance state (client)** under **Client filters**.

   A list of possible operators for the selected attribute appears.
3. Choose the **=** (Equals) operator.

   A list of possible values for the selected attribute and operator appears.
4. Choose **stopped** from the list.

Search by tag

Searching by a tag lets you filter the resources in the currently displayed table by a tag key or a tag value.

Tag searches use either *API filtering* or *client filtering*, depending on the settings in the Preferences window.

To ensure API filtering for tags

1. Open the **Preferences** window.
2. Clear the **Use regular expression matching** checkbox. If this checkbox is selected, client filtering is performed.
3. Select the **Use case sensitive matching** checkbox. If this checkbox is cleared, client filtering is performed.
4. Choose **Confirm**.

When searching by tag, you can use the following values:

- **(empty)** – Find all resources with the specified tag key, but there must be no tag value.
- **All values** – Find all resources with the specified tag key and any tag value.
- **Not tagged** – Find all resources that do not have the specified tag key.
- The displayed value – Find all resources with the specified tag key and the specified tag value.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do **not** match a specified value. In the **Instances** and **AMIs** screens, inverse searches are performed by selecting the **!=** (Does not equal) or **!:** (Does not contain) operator and then selecting a value. In other screens, inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character.

> **Note**
>
> Inverse search is supported with keyword searches and attribute searches on *client* filters only. It is not supported with attribute searches on API filters.

For example, you can search the **Instance state** attribute for all of your instances to exclude all instances that are in the `terminated` state. To do this:

1. In the search field on the **Instances** screen, start entering `Instance state`. As you enter the characters, the two types of filters appear for **Instance state**: **API filters** and **Client filters**.
2. Under **Client filters**, choose **Instance state (client)**. Inverse search is only supported on *client* filters.

   A list of possible operators for the selected attribute appears.
3. Choose **!=** (Does not equal), and then choose **terminated**.

To filter instances based on an instance state attribute, you can also use the search icons ( ) in the **Instance state** column. The search icon with a plus sign (**+**) displays all the instances that *match* that attribute. The search icon with a minus sign (**-**) *excludes* all instances that match that attribute.

Here is another example of using the inverse search: To list all instances that are **not** assigned the security group named `launch-wizard-1`, under **Client filters**, search by the **Security group name** attribute, choose **!=**, and in the search bar, enter `launch-wizard-1`.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword that you want to search for. On the **Instances** and **AMIs** screens, partial searches can only be performed with the **:** (Contains) operator. On other screens, you can select the client filter attribute and immediately enter only a part of the keyword that you want to search for. For example, on the **Instance type** screen, to search for all `t2.micro`, `t2.small`, and `t2.medium` instances, search by the **Instance Type** attribute, and for the keyword, enter `t2`.

Regular expression search

To use regular expression searches, you must select the **Use regular expression matching** checkbox in the **Preferences** window.

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for a value that starts with `s`, search for `^s`. To search for a value that ends with `xyz`, search for `xyz$`. Or to search for a value that starts with a number that is followed by one or more characters, search for `[0-9]+.*`.

> **Note**
>
> Regular expression search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

Case-sensitive search

To use case-sensitive searches, you must select the **Use case sensitive matching** checkbox in the **Preferences** window. The case-sensitive preference only applies to client and tag filters.

> **Note**
>
> API filters are always case-sensitive.

Wildcard search

Use the `*` wildcard to match zero or more characters. Use the `?` wildcard to match zero or one character. For example, if you have a data set with the values `prod`, `prods`, and `production`, a search of `prod*` matches all values, whereas `prod?` matches only `prod` and `prods`. To use the literal values, escape them with a backslash (\). For example, "`prod\*`" would match `prod*`.

> **Note**
>
> Wildcard search is supported with attribute and tag searches on API filters only. It is not supported with keyword searches, and with attribute and tag searches on client filters.

Combining searches

In general, multiple filters with the same attribute are automatically joined with `OR`. For example, searching for `Instance State : Running` and `Instance State : Stopped` returns all instances that are either running OR stopped. To join search with `AND`, search across different attributes. For example, searching for `Instance State : Running` and `Instance Type : c4.large` returns only instances that are of type `c4.large` AND that are in the running state.

Save filter sets using the console

A *saved filter set* is a customized group of filters that you can create and reuse to efficiently view your Amazon EC2 resources. This feature helps streamline your workflow, enabling quick access to specific resource views.

Saved filter sets are only supported in the Amazon EC2 console and are currently only available for the **Volumes** page.

Key features

- **Customization:** Create filter sets tailored to your needs. For example, you can create a filter set to display only your gp3 volumes that were created after a specified date.
- **Default filter:** Set a default filter set for a page, and the default filters are automatically applied when you navigate to the page. If no default is set, no filters are applied.
- **Easy application:** Select a saved filter set to apply it instantly. Amazon EC2 then displays the relevant resources, with the active filters indicated by blue tokens.
- **Flexibility:** Create, modify, and delete filter sets as needed.

Create a filter set

To create a new filter set

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Volumes**.

   > **Note**
   >
   > Saved filter sets are currently only available for **Volumes**.

3. In the search field, select filters for your filter set.
4. Choose the arrow next to the **Clear filters** button, and choose **Save new filter set**.
5. In the **Save filter set** window, do the following:

   a. For **Filter set name**, enter a name for the filter set.

   b. (Optional) For **Filter set description**, enter a description for the filter set.

   c. (Optional) To set the filter set as the default filter, select the **Set as default** checkbox.

> **Note**
>
> The default filter is automatically applied every time you open the console page.

d. Choose **Save**.

Modify a filter set

To modify a filter set

1. From the **Saved filter sets** list, select the filter to modify.
2. To add a filter, in the search field, select a filter to add to your filter set. To delete a filter in the set, choose the **X** on the filter token.
3. Choose the arrow next to the **Clear filters** button, and choose **Modify filter set**.
4. In the **Modify filter set** window, do the following:

   a. (Optional) To set the filter set as the default filter, select the **Set as default** checkbox.

   > **Note**
   >
   > The default filter is automatically applied every time you open the console page.

   b. Choose **Modify**.

Delete a filter set

To delete a filter set

1. From the **Saved filter sets** list, select the filter to delete.
2. Choose the arrow next to the **Clear filters** button, and choose **Delete filter set**.
3. In the **Delete filter set** window, review the filter to confirm this is the filter you want to delete, and then choose **Delete**.

List and filter using the command line

Each resource type has a corresponding API actions that you use to describe, list, or get resources of that type. The resulting lists of resources can be long, so it can be faster and more useful to filter the results to include only the resources that match specific criteria.

Filtering considerations

- You can specify up to 50 filters and up to 200 values per filter in a single request.
- Filter strings can be up to 255 characters in length.
- You can use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches zero or one character.
- Filter values are case sensitive.
- Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of `\*amazon\?\\` searches for the literal string `*amazon?\`.
- You can't specify a filter value of null. Instead, use client-side filtering. For example, the following command uses the **--query** option and returns the IDs of the instances that were launched without a key pair.

```
aws ec2 describe-instances \
    --query 'Reservations[*].Instances[?!not_null(KeyName)].InstanceId' \
    --output text
```

AWS CLI

Example Example: Specify a single filter

You can list your Amazon EC2 instances using describe-instances. Without filters, the response contains information for all of your resources. You can use the following option to include only the running instances in the output.

```
--filters Name=instance-state-name,Values=running
```

To list only the instance IDs for your running instances, add the `--query` option as follows.

```
--query "Reservations[*].Instances[*].InstanceId"
```

Example Example: Specify multiple filters or filter values

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the output.

You can use the following option to list all instances whose type is either `m5.large` or `m5d.large`.

```
--filters Name=instance-type,Values=m5.large,m5d.large
```

You can use the following option to list all stopped instances whose type is `t2.micro`.

```
--filters Name=instance-state-name,Values=stopped Name=instance-type,Values=t2.micro
```

Example Example: Use wildcards in a filter value

You can use the following option with [describe-snapshots]() to return only the snapshots whose description is "database".

```
--filters Name=description,Values=database
```

The * wildcard matches zero or more characters. You can use the following option to return only the snapshots whose description includes the word database.

```
--filters Name=description,Values=*database*
```

The ? wildcard matches exactly 1 character. You can use the following option to return only the snapshots whose description is "database" or "database" followed by one character.

```
--filters Name=description,Values=database?
```

You can use the following option to return only the snapshots whose description is "database" followed by up to four characters. This excludes descriptions with "database" followed by five or more characters.

```
--filters Name=description,Values=database????
```

Example Example: Filter based on date

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following describe-snapshots command displays the IDs of all snapshots created by the specified AWS account before the specified date. If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots \
    --filters Name=owner-id,Values=123456789012 \
    --query "Snapshots[?(StartTime<='2024-03-31')].[SnapshotId]" \
    --output text
```

The following example displays the IDs of all snapshots created in the specified date range.

```
aws ec2 describe-snapshots \
    --filters Name=owner-id,Values=123456789012 \
    --query "Snapshots[?(StartTime>='2024-01-01') && (StartTime<='2024-12-31')].
[SnapshotId]" \
    --output text
```

Example: Filter based on tags

For examples of how to filter a list of resources according to their tags, see Filter Amazon EC2 resources by tag.

PowerShell

Example Example: Specify a single filter

You can list your Amazon EC2 instances using Get-EC2Instance. Without filters, the response contains information for all of your resources. You can use the following parameter to include only the running instances in the output.

```
-Filter @{Name="instance-state-name"; Values="running"}
```

The following example lists only the instance IDs for your running instances.

```
(Get-EC2Instance -Filter @{Name="instance-state-name"; Values="stopped"}).Instances
 | Select InstanceId
```

Example Example: Specify multiple filters or filter values

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the results.

You can use the following option to list all instances whose type is either `m5.large` or `m5d.large`.

```
-Filter @{Name="instance-type"; Values="m5.large", "m5d.large"}
```

You can use the following option to list all stopped instances whose type is `t2.micro`.

```
-Filter @{Name="instance-state-name"; Values="stopped"}, @{Name="instance-type";
 Values="t2.micro"}
```

View resources across Regions using Amazon EC2 Global View

Amazon EC2 Global View enables you to view and search for Amazon EC2 and Amazon VPC resources in a single AWS Region, or across multiple Regions simultaneously in a single console. For more information, see View resources across Regions using AWS Global View.

View resources across Regions using AWS Global View

AWS Global View enables you to view some of your Amazon EC2 and Amazon VPC resources across a single AWS Region, or across multiple Regions in a single console. AWS Global View also provides *global search* functionality that lets you search for specific resources or specific resource types across multiple Regions simultaneously.

AWS Global View does not let you modify resources in any way.

Supported resources

Using AWS Global View, you can view a global summary of the following resources across all of the Regions for which your AWS account is enabled.

- Auto Scaling groups
- Capacity Reservations and Capacity Blocks

- DHCP option set
- Egress-only internet gateways
- Elastic IPs
- Endpoint services
- Instances
- Internet gateways
- Managed prefix lists
- NAT gateways
- Network ACLs
- Network interfaces
- Route tables
- Security groups
- Subnets
- Volumes
- VPCs
- VPC endpoints
- VPC peering connections

Required permissions

A user must have the following permissions to use AWS Global View.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
  {

    }
```

To use AWS Global View

Sign in to the [AWS Global View console](https://console.aws.amazon.com/ec2globalview/home).

> **Important**
>
> You cannot use a private window in Firefox to access AWS Global View.

The console consists of the following:

- **Resource explorer** – This page includes the following sections:
  - **Summary** – Provides a high-level overview of your resources across all Regions.

    Expand **Show all resource summary** indicates the number of Regions for which your AWS account is enabled. The remaining fields indicate the number of resources that you currently have in those Regions. Choose any of the links to view the resources of that type across all Regions. For example, if the link below the **Instances** label is **29 in 10 Regions**, it indicates that you currently have 29 instances across 10 Regions. Choose the link to view a list of all 29 instances.

- **Resource explorer –** Lists all of the AWS Regions (including those for which your account is not enabled) and provides totals for each resource type for each Region.

  Choose a Region name to view all resources of all types for that specific Region. For example, choose **Africa (Cape Town) af-south-1** to view all VPCs, subnets, instances, security groups, volumes, and Auto Scaling groups in that Region. Alternatively, select a Region and choose **View resources for selected Region**.

  Choose the value for a specific resource type in a specific Region to view only resources of that type in that Region. For example, choose the value for Instances for **Africa (Cape Town) af-south-1** to view only the instances in that Region.

- **Global search –** This page enables you to search for specific resources or specific resource types across a single Region or across multiple Regions. It also enables you to view details for a specific resource.

  To search for resources, enter the search criteria in the field preceding the grid. You can search by Region, by resource type, and by the tags assigned to resources.

  To view the details for a specific resource, select it in the grid. You can also choose the resource ID of a resource to open it in its respective console. For example, choose an instance ID to open the instance in the Amazon EC2 console, or choose a subnet ID to open the subnet in the Amazon VPC console.

- **Regions and Zones –** This page allows you to view and manage all available Regions, Availability Zones, Local Zones, and Wavelength Zones.

  From the **Regions** tab, you can view all the AWS Regions. The **Status** column shows the Regions that are enabled for your AWS account. From this page, you can select a Region to:

  - View details of the Region such as the Region code, Geography, and number of each type of Zone.

    You can also view the list of Availability Zones, Local Zones, and Wavelength Zones and the list of your resources in the Region.

  - Enable or disable the Region.

  From each zone tab, you can view the list of that zone type. From the **Local Zones** tab, you can opt-in to a Local Zone.

Tip

If you only use specific Regions or resource types, you can customize AWS Global View to display only those Regions and resource types. To customize the displayed Regions and resource types, in the navigation panel, choose **Settings**, and then on the **Resources** and **Regions** tabs, select the Regions and resource types that you do not want to be displayed in AWS Global View.

Tag your Amazon EC2 resources

To help you manage your instances, images, and other Amazon EC2 resources, you can assign your own metadata to each resource in the form of *tags*. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. This topic describes tags and shows you how to create them.

Warning

Tag keys and their values are returned by many different API calls. Denying access to `DescribeTags` doesn’t automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

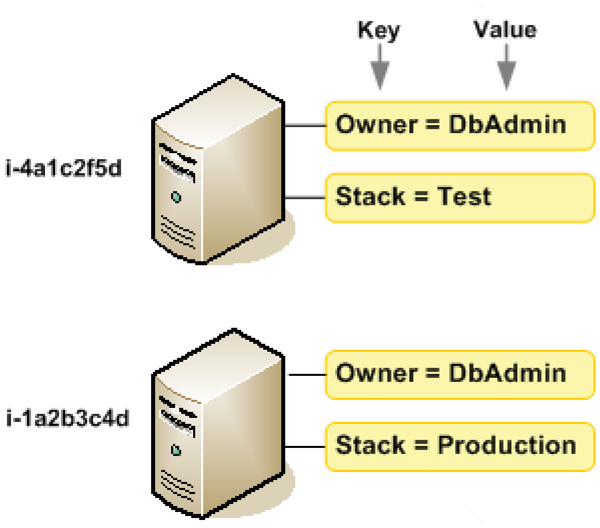
Contents

Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a *key* and an optional *value*, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account's Amazon EC2 instances that helps you track each instance's owner and stack level.

The following diagram illustrates how tagging works. In this example, you've assigned two tags to each of your instances—one tag with the key `Owner` and another with the key `Stack`. Each tag also has an associated value.



We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the Tagging Best Practices AWS Whitepaper.

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

> **Note**
>
> After you delete a resource, its tags might remain visible in the console, API, and CLI output for a short period. These tags will be gradually disassociated from the resource and be permanently deleted.

Tag your resources

When you use the Amazon EC2 console, you can apply tags to resources by using the **Tags** tab on the relevant resource screen, or you can use the **Tags Editor** in the AWS Resource Groups console. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of `Name` and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource creation). The console might organize resources according to the `Name` tag, but this tag doesn't have any semantic meaning to the Amazon EC2 service.

If you're using the Amazon EC2 API, the AWS CLI, or an AWS SDK, you can use the `CreateTags` EC2 API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation. For more information about enabling users to tag resources on creation, see [Grant permission to tag Amazon EC2 resources during creation].

You can apply tag-based resource-level permissions in your IAM policies to the Amazon EC2 API actions that support tagging on creation to implement granular control over the users and groups that can tag resources on creation. Your resources are properly secured from creation—tags are applied immediately to your resources, therefore any tag-based resource-level permissions controlling the use of resources are immediately effective. Your resources can be tracked and reported on more accurately. You can enforce the use of tagging on new resources, and control which tag keys and values are set on your resources.

You can also apply resource-level permissions to the `CreateTags` and `DeleteTags` Amazon EC2 API actions in your IAM policies to control which tag keys and values are set on your existing resources. For more information, see [Example: Tag resources].

For more information about tagging your resources for billing, see Using cost allocation tags in the *AWS Billing User Guide*.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Allowed characters
  - Although EC2 allows for any character in its tags, other AWS services are more restrictive. The allowed characters across all AWS services are: letters (`a-z`, `A-Z`), numbers (`0-9`), and spaces representable in UTF-8, and the following characters: `+ - = . _ : / @`.
  - If you enable instance tags in instance metadata, instance tag *keys* can only use letters (`a-z`, `A-Z`), numbers (`0-9`), and the following characters: `+ - = . , _ : @`. Instance tag *keys* can't contain spaces or `/`, and can't comprise only `.` (one period), `..` (two periods), or `_index`. For more information, see View tags for your EC2 instances using instance metadata.
- Tag keys and values are case-sensitive.
- The `aws:` prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the `aws:` prefix do not count against your tags per resource limit.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called `DeleteMe`, you must use the `DeleteSnapshots` action with the resource identifiers of the snapshots, such as `snap-1234567890abcdef0`.

When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

Tags and access management

If you're using AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to create, edit, or delete tags. For more information, see Grant permission to tag Amazon EC2 resources during creation.

You can also use resource tags to implement attribute-based control (ABAC). You can create IAM policies that allow operations based on the tags for the resource. For more information, see Control access using attribute-based access.

Tag your resources for billing

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. For more information about setting up a cost allocation report with tags, see Monthly cost allocation report in the *AWS Billing User Guide*. To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using cost allocation tags in the *AWS Billing User Guide*.

> **Note**
>
> If you've just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost allocation tags can indicate which resources are contributing to costs, but deleting or deactivating resources doesn't always reduce costs. For example, snapshot data that is referenced by another snapshot is preserved, even if the snapshot that contains the original data is deleted. For more information, see Amazon Elastic Block Store volumes and snapshots in the *AWS Billing User Guide*.

> **Note**
>
> Elastic IP addresses that are tagged do not appear on your cost allocation report.

Grant permission to tag Amazon EC2 resources during creation

Some resource-creating Amazon EC2 API actions enable you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see Tag your resources and Control access using attribute-based access.

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as `ec2:RunInstances` or `ec2:CreateVolume`. If tags are specified in the resource-creating action, Amazon performs additional authorization on the `ec2:CreateTags` action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the `ec2:CreateTags` action.

In the IAM policy definition for the `ec2:CreateTags` action, use the `Condition` element with the `ec2:CreateAction` condition key to give tagging permissions to the action that creates the resource.

The following example demonstrates a policy that allows users to launch instances and apply any tags to instances and volumes during launch. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:RunInstances"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
      "Condition": {
         "StringEquals": {
             "ec2:CreateAction" : "RunInstances"
          }
       }
    }
```

```
  ]
}
```

Similarly, the following policy allows users to create volumes and apply any tags to the volumes during volume creation. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateVolume"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:us-east-1:111122223333:*/*",
      "Condition": {
         "StringEquals": {
             "ec2:CreateAction" : "CreateVolume"
          }
       }
    }
  ]
}
```

The `ec2:CreateTags` action is only evaluated if tags are applied during the resource-creating action. Therefore, a user that has permissions to create a resource (assuming there are no tagging conditions) does not require permissions to use the `ec2:CreateTags` action if no tags are specified in the request. However, if the user attempts to create a resource with tags, the request fails if the user does not have permissions to use the `ec2:CreateTags` action.

The `ec2:CreateTags` action is also evaluated if tags are provided in a launch template. For an example policy, see Tags in a launch template.

Control access to specific tags

You can use additional conditions in the `Condition` element of your IAM policies to control the tag keys and values that can be applied to resources.

The following condition keys can be used with the examples in the preceding section:

- `aws:RequestTag`: To indicate that a particular tag key or tag key and value must be present in a request. Other tags can also be specified in the request.
  - Use with the `StringEquals` condition operator to enforce a specific tag key and value combination, for example, to enforce the tag `cost-center=cc123`:

    ```
    "StringEquals": { "aws:RequestTag/cost-center": "cc123" }
    ```

  - Use with the `StringLike` condition operator to enforce a specific tag key in the request; for example, to enforce the tag key `purpose`:

    ```
    "StringLike": { "aws:RequestTag/purpose": "*" }
    ```

- `aws:TagKeys`: To enforce the tag keys that are used in the request.
  - Use with the `ForAllValues` modifier to enforce specific tag keys if they are provided in the request (if tags are specified in the request, only specific tag keys are allowed; no other tags are allowed). For example, the tag keys `environment` or `cost-center` are allowed:

    ```
    "ForAllValues:StringEquals": { "aws:TagKeys": ["environment","cost-center"] }
    ```

  - Use with the `ForAnyValue` modifier to enforce the presence of at least one of the specified tag keys in the request. For example, at least one of the tag keys `environment` or `webserver` must be present in the request:

    ```
    "ForAnyValue:StringEquals": { "aws:TagKeys": ["environment","webserver"] }
    ```

These condition keys can be applied to resource-creating actions that support tagging, as well as the `ec2:CreateTags` and `ec2:DeleteTags` actions. To learn whether an Amazon EC2 API action supports tagging, see [Actions, resources, and condition keys for Amazon EC2](#).

To force users to specify tags when they create a resource, you must use the `aws:RequestTag` condition key or the `aws:TagKeys` condition key with the `ForAnyValue` modifier on the resource-creating action. The `ec2:CreateTags` action is not evaluated if a user does not specify tags for the resource-creating action.

For conditions, the condition key is not case-sensitive and the condition value is case-sensitive. Therefore, to enforce the case-sensitivity of a tag key, use the `aws:TagKeys` condition key, where the tag key is specified as a value in the condition.

For example IAM policies, see Example policies to control access the Amazon EC2 API. For more information, see Conditions with multiple context keys or values in the *IAM User Guide*.

Add and remove tags for Amazon EC2 resources

When you create an Amazon EC2 resource, such as an Amazon EC2 instance, you can specify the tags to add to the resource. You can also use the Amazon EC2 console to display the tags for a specific Amazon EC2 resource. You can also add or remove tags from an existing Amazon EC2 resource.

You can use the **Tag Editor** in the AWS Resource Groups console to view, add, or remove tags across of all of your AWS resources across all Regions. You can apply or remove tags from multiple types of resources at the same time. For more information, see the Tagging AWS Resources User Guide.

Tasks

- Add tags using the console
- Add tags using the AWS CLI
- Add tags using PowerShell
- Add tags using CloudFormation

Add tags using the console

You can add tags to an existing resource directly from the page for a resource.

To add tags to an existing resource

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region where the resource is located.
3. In the navigation pane, select a resource type (for example, **Instances**).
4. Select the resource from the list.

5. From the **Tags** tab, choose **Manage tags**.
6. Choose **Add new tag** and enter a key and a value for the tag.
7. Choose **Save**.

Add tags using the AWS CLI

You can add tags when you create a resource or to an existing resource.

To add a tag on resource creation

Use the `-tag-specifications` option to tag a resource on creation. A tag specification requires the type of resource to be tagged, the tag key, and the tag value. The following example creates a tag and adds it to a tag specification.

```
--tag-specifications 'ResourceType=instance,Tags=[{Key=stack,Value=production}]'
```

To add a tag to an existing resource

The following examples demonstrate how to add tags to existing resources using the create-tags command.

Example Example: Add a tag to a resource

The following command adds the tag **`Stack=production`** to the specified image, or overwrites an existing tag for the AMI where the tag key is stack. If the command succeeds, no output is returned.

```
aws ec2 create-tags \
    --resources ami-0abcdef1234567890 \
    --tags Key=stack,Value=production
```

Example Example: Add tags to multiple resources

This example adds (or overwrites) two tags for an AMI and an instance. One of the tags contains just a key (webserver), with no value (we set the value to an empty string). The other tag consists of a key (stack) and value (**`Production`**). If the command succeeds, no output is returned.

```
aws ec2 create-tags \
    --resources ami-0abcdef1234567890 i-1234567890abcdef0 \
```

```
    --tags Key=webserver,Value=  Key=stack,Value=Production
```

Example Example: Add tags with special characters

This example adds the tag [Group]=test to an instance. The square brackets ([and]) are special characters, which must be escaped.

If you are using Linux or OS X, to escape the special characters, enclose the element with the special character with double quotes ("), and then enclose the entire key and value structure with single quotes (').

```
aws ec2 create-tags \
    --resources i-1234567890abcdef0 \
    --tags 'Key="[Group]",Value=test'
```

If you are using Windows, to escape the special characters, enclose the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (****) as follows:

```
aws ec2 create-tags ^
    --resources i-1234567890abcdef0 ^
    --tags Key=\"[Group]\",Value=test
```

If you are using Windows PowerShell, to escape the special characters, enclose the value that has special characters with double quotes (**"**), precede each double quote character with a backslash (****), and then enclose the entire key and value structure with single quotes (**'**) as follows:

```
aws ec2 create-tags `
    --resources i-1234567890abcdef0 `
    --tags 'Key=\"[Group]\",Value=test'
```

Add tags using PowerShell

You can add tags when you create a resource or to an existing resource.

To add a tag on resource creation

Use the `-TagSpecification` parameter to tag a resource on creation. A tag specification requires the type of resource to be tagged, the tag key, and the tag value. The following example creates a tag and adds it to a tag specification.

```
$tag = @{Key="stack"; Value="production"}
$tagspec = new-object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "instance"
$tagspec.Tags.Add($tag)
```

The following example specifies this tag in the `-TagSpecification` parameter.

```
-TagSpecification $tagspec
```

To add a tag to an existing resource

Use the New-EC2Tag cmdlet. You must specify the resource, the tag key, and the tag value.

```
New-EC2Tag `
    -Resource i-1234567890abcdef0 `
    -Tag @{Key="purpose"; Value="production"}
```

Add tags using CloudFormation

With Amazon EC2 resource types, you specify tags using either a `Tags` or `TagSpecifications` property.

The following examples add the tag **`Stack=Production`** to AWS::EC2::Instance using its `Tags` property.

Example Example: Tags in YAML

```
Tags:
  - Key: "Stack"
    Value: "Production"
```

Example Example: Tags in JSON

```
"Tags": [
    {
        "Key": "Stack",
        "Value": "Production"
    }
]
```

The following examples add the tag **Stack=Production** to [AWS::EC2::LaunchTemplate LaunchTemplateData](#) using its `TagSpecifications` property.

Example Example: TagSpecifications in YAML

```
TagSpecifications:
  - ResourceType: "instance"
    Tags:
    - Key: "Stack"
      Value: "Production"
```

Example Example: TagSpecifications in JSON

```
"TagSpecifications": [
    {
        "ResourceType": "instance",
        "Tags": [
            {
                "Key": "Stack",
                "Value": "Production"
            }
        ]
    }
]
```

Filter Amazon EC2 resources by tag

After you add tags, you can filter your Amazon EC2 resources based tag keys and tag values.

Console

To filter resources by tag

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, select a resource type (for example, **Instances**).
3. Choose the search field.
4. In the list, under **Tags**, choose the tag key.
5. Choose the corresponding tag value from the list.
6. When you are finished, remove the filter.

For more information about using filters in the Amazon EC2 console, see Find your Amazon EC2 resources.

AWS CLI

To describe resources of a single type with the specified tag key

Add the following filter to a `describe` command to describe the resources of that type with a Stack tag, regardless of the value of the tag.

```
--filters Name=tag-key,Values=Stack
```

To describe resources of a single type with the specified tag

Add the following filter to a `describe` command to describe the resources of that type with the tag Stack=production.

```
--filters Name=tag:Stack,Values=production
```

To describe resources of a single type with the specified tag value

Add the following filter to a `describe` command to describe the resources of that type with a tag with the value production, regardless of the tag key.

```
--filters Name=tag-value,Values=production
```

To describe all EC2 resources with the specified tag

Add the following filter to the describe-tags command to describe all EC2 resources with the tag Stack=test.

```
--filters Name=key,Values=Stack Name=value,Values=test
```

PowerShell

To filter resources of a single type by tag key

Add the following filter to a `Get` cmdlet to describe the resources of that type with a Stack tag, regardless of the value of the tag.

```
-Filter @{Name="tag-key"; Values="Stack"}
```

To filter resources of a single type by tag

Add the following filter to a `Get` cmdlet to describe the resources of that type with the tag Stack=production.

```
-Filter @{Name="tag:Stack"; Values="production"}
```

To filter resources of a single type by tag value

Add the following filter to a `Get` cmdlet to describe the resources of that type with a tag with the value production, regardless of the value of the tag key.

```
-Filter @{Name="tag-value"; Values="production"}
```

To filter all EC2 resources by tag

Add the following filter to the [Get-EC2Tag](#) cmdlet to describe all EC2 resources with the tag Stack=test.

```
-Filter @{Name="tag:Stack"; Values="test"}
```

View tags for your EC2 instances using instance metadata

You can access an instance's tags from the instance metadata. By accessing tags from the instance metadata, you no longer need to use the `DescribeInstances` or `DescribeTags` API calls to retrieve tag information, which reduces your API transactions per second, and lets your tag retrievals scale with the number of instances that you control. Furthermore, local processes that are running on an instance can view the instance's tag information directly from the instance metadata.

By default, tags are not available from the instance metadata; you must explicitly allow access. You can allow access at instance launch, or after launch on a running or stopped instance. You can also allow access to tags by specifying this in a launch template. Instances that are launched by using the template allow access to tags in the instance metadata.

If you add or remove an instance tag, the instance metadata is updated while the instance is running, without needing to stop and then start the instance.

Tasks

- Enable access to tags in instance metadata
- Retrieve tags from instance metadata
- Disable access to tags in instance metadata

Enable access to tags in instance metadata

By default, there is no access to instance tags in the instance metadata. For each instance, you must explicitly enable access.

> **Note**
>
> If you allow access to tags in instance metadata, instance tag *keys* are subject to specific restrictions. Non-compliance will result in failed launches for new instances or an error for existing instances. The restrictions are:
>
> - Can only include letters (`a-z`, `A-Z`), numbers (`0-9`), and the following characters: `+ - = . , _ : @`.
> - Can't contain spaces or `/`.
> - Can't consist only of `.` (one period), `..` (two periods), or `_index`.
>
> For more information, see Tag restrictions.

Console

To enable access to tags in instance metadata during instance launch

1. Follow the procedure to launch an instance.
2. Expand **Advanced details**, and for **Allow tags in metadata**, choose **Enable**.
3. In the **Summary panel**, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

To enable access to tags in instance metadata after instance launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and then choose **Actions**, **Instance settings**, **Allow tags in instance metadata**.
4. To allow access to tags in instance metadata, select the **Allow** checkbox.
5. Choose **Save**.

AWS CLI

To enable access to tags in instance metadata during instance launch

Use the run-instances command and add the following `--metadata-options` option.

```
--metadata-options "InstanceMetadataTags=enabled"
```

To enable access to tags in instance metadata after instance launch

Use the following modify-instance-metadata-options command.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567890abcdef0 \
    --instance-metadata-tags enabled
```

To verify that access to tags in instance metadata is enabled

Use the describe-instances command and check the value of `InstanceMetadataTags`.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[*].Instances[].MetadataOptions[].InstanceMetadataTags"
```

The following is example output. The value is either `enabled` or `disabled`.

```
[
    "enabled"
]
```

PowerShell

To enable access to tags in instance metadata during instance launch

Use the New-EC2Instance cmdlet and add the following -MetadataOptions_InstanceMetadataTags parameter.

```
-MetadataOptions_InstanceMetadataTags enabled
```

To enable access to tags in instance metadata after instance launch

Use the Edit-EC2InstanceMetadataOption cmdlet.

```
Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -InstanceMetadataTags enabled
```

To verify that access to tags in instance metadata is enabled

Use the Get-EC2Instance cmdlet and check the value of `InstanceMetadataTags`.

```
(Get-EC2Instance `
    -
InstanceId i-1234567890abcdef0).Instances.MetadataOptions.InstanceMetadataTags.Value
```

The following is example output. The value is either `enabled` or `disabled`.

```
enabled
```

Retrieve tags from instance metadata

After you allow access to instance tags in the instance metadata, you can access the `tags/instance` category from the instance metadata. For more information, see Access instance metadata for an EC2 instance.

IMDSv2

Linux

Run the following command from your Linux instance to list all the tag keys for the instance.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example. The IMDSv2 request uses the stored token that was created using the command in the previous example. The token must not be expired.

```
curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

Windows

Run the following cmdlet from your Windows instance to list all the tag keys for the instance.

```
$token = Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example. The IMDSv2 request uses the stored token that was created using the command in the previous example. The token must not be expired.

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

IMDSv1

Linux

Run the following command from your Linux instance to list all the tag keys for the instance.

```
curl http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example.

```
curl http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

Windows

Run the following cmdlet from your Windows instance to list all the tag keys for the instance.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/tags/instance
```

This example gets the value of a key obtained in the previous example.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/tags/instance/tag-key
```

Disable access to tags in instance metadata

You can disable access to instance tags in the instance metadata. You don't need to disable access to instance tags on instance metadata at launch because it's turned off by default.

Console

To disable access to tags in instance metadata

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions**, **Instance settings**, **Allow tags in instance metadata**.
4. To turn off access to tags in instance metadata, clear the **Allow** checkbox.
5. Choose **Save**.

AWS CLI

To disable access to tags in instance metadata

Use the following modify-instance-metadata-options command.

```
aws ec2 modify-instance-metadata-options \
```

```
    --instance-id i-1234567890abcdef0 \
    --instance-metadata-tags disabled
```

PowerShell

To disable access to tags in instance metadata

Use the Edit-EC2InstanceMetadataOption cmdlet.

```
Edit-EC2InstanceMetadataOption `
    -InstanceId i-1234567890abcdef0 `
    -InstanceMetadataTag disabled
```

Amazon EC2 service quotas

When you create your AWS account, we set default *quotas* (also referred to as limits) on your AWS resources on a per-Region basis. If you attempt to exceed the quota for a resource, the request fails. For example, there is a maximum number of Amazon EC2 vCPUs that you can provision for On-Demand Instances in a Region. If you attempt to launch an instance in a Region and this request would cause your usage to exceed this quota, the request fails. If this happens, you can reduce your resource usage or request a quota increase.

The Service Quotas console is a central location where you can view and manage your quotas for AWS services, and request a quota increase for many of the resources that you use. Use the quota information that we provide to manage your AWS infrastructure. Plan to request any quota increases in advance of the time that you'll need them.

Related quota documentation

- Amazon EC2 endpoints and quotas
- Amazon EC2 instance type quotas
- Quotas for Amazon EBS
- Amazon VPC quotas

View your current quotas

You can view your quotas for each Region using the Service Quotas console.

To view your current quotas using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/.
2. From the navigation bar (at the top of the screen), select a Region.
3. On the **Manage quotas** pane, select a service; for example, **Amazon Elastic Compute Cloud (Amazon EC2)**. Choose **View quotas**.
4. Use the filter field to filter the list by resource name. For example, enter **`On-Demand`** to locate the quotas for On-Demand Instances.
5. To view more information, choose the quota name to open the details page for the quota.

Request an increase

You can request a quota increase for each Region.

To request an increase using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/.
2. From the navigation bar (at the top of the screen), select a Region.
3. Use the filter field to filter the list by resource name. For example, enter **`On-Demand`** to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose **Request quota increase**.
5. For **Change quota value**, enter the new quota value.
6. Choose **Request**.
7. To view any pending or recently resolved requests in the console, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number with Support. Choose the case number to open the ticket for your request.

For more information, including how to use the AWS CLI or SDKs to request a quota increase, see Requesting a quota increase in the *Service Quotas User Guide*.

Restriction on email sent using port 25

By default, Amazon EC2 allows outbound traffic over port 25 only to private IPv4 addresses. Traffic over port 25 is blocked to public IPv4 addresses and IPv6 addresses.

You can request that this restriction be removed. For more information, see How do I remove the restriction on port 25 from my Amazon EC2 instance or Lambda function?

This restriction does not apply to outbound traffic over port 25 destined for:

- IP addresses in the primary CIDR block of the VPC in which the originating network interface exists.
- IP addresses in the CIDRs defined in RFC 1918, RFC 6598, and RFC 4193.

Monitor Amazon EC2 resources

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon EC2 instances and your AWS solutions. You should collect monitoring data from all of the parts in your AWS solutions so that you can more easily debug a multi-point failure if one occurs.

AWS provides various tools that you can use to monitor Amazon EC2. The Amazon EC2 and CloudWatch console dashboards provide an at-a-glance view of the state of your Amazon EC2 environment. In addition, we provide the following:

- **System status checks** – Monitor the AWS systems required to use your instance to ensure that they are working properly. These checks detect problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue or you can resolve it yourself (for example, by stopping and restarting or terminating and replacing an instance). Examples of problems that cause system status checks to fail include:
  - Loss of network connectivity
  - Loss of system power
  - Software issues on the physical host
  - Hardware issues on the physical host that impact network reachability

  For more information, see Status checks for Amazon EC2 instances.
- **Instance status checks** – Monitor the software and network configuration of your individual instance. These checks detect problems that require your involvement to repair. When an instance status check fails, typically you will need to address the problem yourself (for example, by rebooting the instance or by making modifications in your operating system). Examples of problems that may cause instance status checks to fail include:
  - Failed system status checks
  - Misconfigured networking or startup configuration
  - Exhausted memory
  - Corrupted file system
  - Incompatible kernel

  For more information, see Status checks for Amazon EC2 instances.
- **Amazon CloudWatch alarms** – Watch a single metric over a time period you specify, and perform one or more actions based on the value of the metric relative to a given threshold over

a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms will not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitor your instances using CloudWatch.

- **Amazon EventBridge events** – Automate your AWS services and respond automatically to system events. Events from AWS services are delivered to EventBridge in near real time, and you can specify automated actions to take when an event matches a rule you write. For more information, see the section called "Automate using EventBridge".
- **AWS CloudTrail logs** – Capture detailed information about the calls made to the Amazon EC2 API and stores them as log files in Amazon S3. You can use CloudTrail logs to determine which calls were made, the source IP address for the call, who made the call, and when the call was made. For more information, see the section called "Log API calls using CloudTrail".
- **CloudWatch agent** – Collect logs and system-level metrics from both hosts and guests on your EC2 instances and on-premises servers. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the *Amazon CloudWatch User Guide*.

Monitor the status of your Amazon EC2 instances

You can monitor the status of your instances by viewing status checks and scheduled events for your instances.

A status check gives you the information that results from automated checks performed by Amazon EC2. These automated checks detect whether specific issues are affecting your instances. The status check information, together with the data provided by Amazon CloudWatch, gives you detailed operational visibility into each of your instances.

You can also see the status of specific events that are scheduled for your instances. The status of events provides information about upcoming activities that are planned for your instances, such as rebooting or retirement. They also provide the scheduled start and end time of each event.

Contents

Status checks for Amazon EC2 instances

With instance status monitoring, you can quickly determine whether Amazon EC2 has detected any problems that might prevent your instances from running applications. Amazon EC2 performs automated checks on every running EC2 instance to identify hardware and software issues. You can view the results of these status checks to identify specific and detectable problems. The event status data augments the information that Amazon EC2 already provides about the state of each instance (such as `pending`, `running`, `stopping`) and the utilization metrics that Amazon CloudWatch monitors (CPU utilization, network traffic, and disk activity).

Status checks are performed every minute, returning a pass or a fail status. If all checks pass, the overall status of the instance is **OK**. If one or more checks fail, the overall status is **impaired**. Status checks are built into Amazon EC2, so they cannot be disabled or deleted.

When a status check fails, the corresponding CloudWatch metric for status checks is incremented. For more information, see Status check metrics. You can use these metrics to create CloudWatch alarms that are triggered based on the result of the status checks. For example, you can create an alarm to warn you if status checks fail on a specific instance. For more information, see Create CloudWatch alarms for Amazon EC2 instances that fail status checks.

You can also create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying issue. For more information, see Automatic instance recovery.

Contents

Types of status checks

There are three types of status checks.

- System status checks
- Instance status checks
- Attached EBS status checks

System status checks

System status checks monitor the AWS systems on which your instance runs. These checks detect underlying problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue, or you can resolve it yourself. For instances backed by Amazon EBS, you can stop and start the instance yourself, which in most cases results in the instance being migrated to a new host. For instances backed by instance store (supported only for Linux instances), you can terminate and replace the instance. Note that instance store volumes are ephemeral and all data is lost when the instance is stopped.

The following are examples of problems that can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

If a system status check fails, we increment the StatusCheckFailed_System metric.

Bare metal instances

If you perform a restart from the operating system on a bare metal instance, the system status check might temporarily return a fail status. When the instance becomes available, the system status check should return a pass status.

Instance status checks

Instance status checks monitor the software and network connectivity of your individual instance. Amazon EC2 checks the health of the instance by sending an address resolution protocol (ARP) request to the network interface (NIC). These checks detect problems that require your involvement to repair. When an instance status check fails, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes).

> **Note**
>
> Recent Linux distributions that use `systemd-networkd` for network configuration might report on health checks differently from earlier distributions. During the boot process, this type of network can start earlier and potentially finish before other startup tasks that can

also affect instance health. Status checks that depend on network availability can report a healthy status before other tasks complete.

The following are examples of problems that can cause instance status checks to fail:

- Failed system status checks
- Incorrect networking or startup configuration
- Exhausted memory
- Corrupted file system
- Incompatible kernel
- During a reboot, an instance status check reports a failure until the instance becomes available again.

If an instance status check fails, we increment the StatusCheckFailed_Instance metric.

Bare metal instances

If you perform a restart from the operating system on a bare metal instance, the instance status check might temporarily return a fail status. When the instance becomes available, the instance status check should return a pass status.

Attached EBS status checks

Attached EBS status checks monitor if the Amazon EBS volumes attached to an instance are reachable and able to complete I/O operations. The `StatusCheckFailed_AttachedEBS` metric is a binary value that indicates impairment if one or more of the EBS volumes attached to the instance are unable to complete I/O operations. These status checks detect underlying issues with the compute or Amazon EBS infrastructure. When the attached EBS status check metric fails, you can either wait for AWS to resolve the issue, or you can take actions, such as replacing the affected volumes or stopping and restarting the instance.

The following are examples of issues that can cause attached EBS status checks to fail:

- Hardware or software issues on the storage subsystems underlying the EBS volumes
- Hardware issues on the physical host that impact reachability of the EBS volumes
- Connectivity issues between the instance and EBS volumes

You can use the `StatusCheckFailed_AttachedEBS` metric to help improve the resilience of your workload. You can use this metric to create Amazon CloudWatch alarms that are triggered based on the result of the status check. For example, you could fail over to a secondary instance or Availability Zone when you detect a prolonged impact. Alternatively, you can monitor the I/O performance of each attached volume using EBS CloudWatch metrics to detect and replace the impaired volume. If your workload is not driving I/O to any EBS volumes attached to your instance, and the EBS status check indicates an impairment, you can stop and start the instance to move it to a new host. This can resolve underlying host issues that are impacting the reachability of the EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS.

You can also configure your Amazon EC2 Auto Scaling groups to detect attached EBS status check failures, and then replace the affected instance with a new one. For more information, see Monitor and replace Auto Scaling instances with impaired Amazon EBS volumes in the *Amazon EC2 Auto Scaling User Guide*.

> **Note**
>
> The attached EBS status check metric is available only for Nitro instances.

View status checks for Amazon EC2 instances

If your instance has a failed status check, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes). To troubleshoot system or instance status check failures yourself, see Troubleshoot Amazon EC2 Linux instances with failed status checks.

Console

To view status checks

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. On the **Instances** page, the **Status check** column lists the operational status of each instance.
4. To view the status of a specific instance, select the instance, and then choose the **Status and alarms** tab.

5. To review the CloudWatch metrics for status checks, on the **Status and alarms** tab, expand **Metrics** to see the graphs for the following metrics:

   - **Status check failed for system**
   - **Status check failed for instance**
   - **Status check failed for attached EBS**

   For more information, see the section called "Status check metrics".

AWS CLI

To view status checks

Use the describe-instance-status command.

Example: Get the status of all running instances

```
aws ec2 describe-instance-status
```

Example: Get the status of all instances

```
aws ec2 describe-instance-status --include-all-instances
```

Example: Get the status of a single running instance

```
aws ec2 describe-instance-status --instance-ids i-1234567890abcdef0
```

Example: Get all instances with a status of `impaired`

```
aws ec2 describe-instance-status \
--filters Name=instance-status.status,Values=impaired
```

PowerShell

To view status checks

Use the Get-EC2InstanceStatus command.

Example: Get the status of all running instances

```
Get-EC2InstanceStatus
```

Example: Get the status of all instances

```
Get-EC2InstanceStatus -IncludeAllInstance $true
```

Example: Get the status of a single running instance

```
Get-EC2InstanceStatus -InstanceId i-1234567890abcdef0
```

Example: Get all instances with a status of `impaired`

```
Get-EC2InstanceStatus \
-Filter @{Name="instance-status.status"; Values="impaired"}
```

Create CloudWatch alarms for Amazon EC2 instances that fail status checks

You can use the [status check metrics](https://docs.aws.amazon.com/) to create CloudWatch alarms to notify you when an instance has a failed status check.

Status checks and status check alarms can temporarily enter an *insufficient data* state if there are missing metric data points. Although rare, this can happen when there is an interruption in the metric reporting systems, even when an instance is healthy. We recommend that you treat this state as missing data instead of a status check failure or alarm breach. This is especially important when taking stop, terminate, reboot, or recover actions on the instance in response.

Console

This example configures an alarm that sends a notification when an instance fails a status check. You can optionally stop, terminate, or recover the instance.

To create a status check alarm

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, choose the **Status Checks** tab, and choose **Actions**, **Create status check alarm**.

4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Create an alarm**.
5. For **Alarm notification**, turn the toggle on to configure Amazon Simple Notification Service (Amazon SNS) notifications. Select an existing Amazon SNS topic or enter a name to create a new topic.

   If you add an email address to the list of recipients or create a new topic, Amazon SNS sends a confirmation email to each new address. Each recipient must choose the confirmation link in the email. Only confirmed addresses receive alert notifications.
6. For **Alarm action**, turn the toggle on to specify an action to take when the alarm is triggered. Select the action.
7. For **Alarm thresholds**, specify the metric and criteria for the alarm.

   You can leave the default settings for **Group samples by** (**Average**) and **Type of data to sample** (**Status check failed:either**), or you can change them to suit your needs.

   For **Consecutive period**, set the number of periods to evaluate and, in **Period**, enter the evaluation period duration before triggering the alarm and sending an email.
8. (Optional) For **Sample metric data**, choose **Add to dashboard**.
9. Choose **Create**.

If you need to change an instance status alarm, you can edit it.

To edit a status check alarm

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitoring**, **Manage CloudWatch alarms**.
4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Edit an alarm**.
5. For **Search for alarm**, choose the alarm.
6. When you are finished making changes, choose **Update**.

AWS CLI

In the following example, the alarm publishes a notification to an SNS topic when the instance fails either the instance check or system status check for at least two consecutive periods. The CloudWatch metric used is `StatusCheckFailed`.

To create a status check alarm

1. Select an existing SNS topic or create a new one. For more information, see Accessing Amazon SNS in the AWS CLI in the *AWS Command Line Interface User Guide*.
2. Use the following list-metrics command to view the available Amazon CloudWatch metrics for Amazon EC2.

```
aws cloudwatch list-metrics --namespace AWS/EC2
```

3. Use the following put-metric-alarm command to create the alarm.

```
aws cloudwatch put-metric-alarm \
    --alarm-name StatusCheckFailed-Alarm-for-i-1234567890abcdef0 \
    --metric-name StatusCheckFailed \
    --namespace AWS/EC2 \
    --statistic Maximum \
    --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
    --unit Count \
    --period 300 \
    --evaluation-periods 2 \
    --threshold 1 \
    --comparison-operator GreaterThanOrEqualToThreshold \
    --alarm-actions arn:aws:sns:us-west-2:111122223333:my-sns-topic
```

The period is the time frame, in seconds, in which Amazon CloudWatch metrics are collected. This example uses 300, which is 60 seconds multiplied by 5 minutes. The evaluation period is the number of consecutive periods for which the value of the metric must be compared to the threshold. This example uses 2. The alarm actions are the actions to perform when this alarm is triggered.

PowerShell

To create a status check alarm

Use the Write-CWMetricAlarm cmdlet as follows to publish notifications to an SNS topic when the instance fails status checks for at least two consecutive periods.

```
Write-CWMetricAlarm `
    -AlarmName "StatusCheckFailed-Alarm-for-i-1234567890abcdef0" `
    -MetricName "StatusCheckFailed" `
    -Namespace "AWS/EC2" `
    -Statistic "Maximum" `
    -Dimension @{Name="InstanceId"; Values="i-1234567890abcdef0"} `
    -Unit "Count" `
    -Period 300 `
    -EvaluationPeriod 2 `
    -Threshold 1 `
    -ComparisonOperator "GreaterThanOrEqualToThreshold" `
    -AlarmAction "arn:aws:sns:us-west-2:111122223333:my-sns-topic"
```

The period is the time frame, in seconds, in which Amazon CloudWatch metrics are collected. This example uses 300, which is 60 seconds multiplied by 5 minutes. The evaluation period is the number of consecutive periods for which the value of the metric must be compared to the threshold. This example uses 2. The alarm actions are the actions to perform when this alarm is triggered.

State change events for Amazon EC2 instances

Amazon EC2 sends an `EC2 Instance State-change Notification` event to Amazon EventBridge when the state of an instance changes.

The following is example data for this event. In this example, the instance entered the `pending` state.

```
{
   "id":"7bf73129-1428-4cd3-a780-95db273d1602",
   "detail-type":"EC2 Instance State-change Notification",
   "source":"aws.ec2",
   "account":"123456789012",
   "time":"2021-11-11T21:29:54Z",
   "region":"us-east-1",
   "resources":[
      "arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"
   ],
```

```
    "detail":{
       "instance-id":"i-1234567890abcdef0",
       "state":"pending"
    }
}
```

The possible values for `state` are:

- `pending`
- `running`
- `stopping`
- `stopped`
- `shutting-down`
- `terminated`

When you launch or start an instance, it enters the `pending` state and then the `running` state. When you stop an instance, it enters the `stopping` state and then the `stopped` state. When you terminate an instance, it enters the `shutting-down` state and then the `terminated` state. For more information, see [Amazon EC2 instance state changes](#).

Create an alarm that sends an email when an Amazon EC2 instance changes state

To receive email notifications when your instance changes state, create an Amazon SNS topic and then create an EventBridge rule for the `EC2 Instance State-change Notification` event.

To create an SNS topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Topics**.
3. Choose **Create topic**.
4. For **Type**, choose **Standard**.
5. For **Name**, enter a name for your topic.
6. Choose **Create topic**.
7. Choose **Create subscription**.
8. For **Protocol**, choose **Email**.

9. For **Endpoint**, enter the email address that receives the notifications.
10. Choose **Create subscription**.
11. You'll receive an email message with the following subject line: AWS Notification - Subscription Confirmation. Follow the directions to confirm your subscription.

To create an EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose **Create rule**.
3. For **Name**, enter a name for your rule.
4. For **Rule type**, choose **Rule with an event pattern**.
5. Choose **Next**.
6. For **Event pattern**, do the following:

   a. For **Event source**, choose **AWS services**.

   b. For **AWS service**, choose **EC2**.

   c. For **Event type**, choose **EC2 Instance State-change Notification**.

   d. By default, we send notifications for any state change for any instance. If you prefer, you can select specific states or specific instances.
7. Choose **Next**.
8. Specify a target as follows:

   a. For **Target types**, choose **AWS service**.

   b. For **Select a target**, choose **SNS topic**.

   c. For **Topic**, choose the SNS topic that you created in the previous procedure.
9. Choose **Next**.
10. (Optional) Add tags to your rule.
11. Choose **Next**.
12. Choose **Create rule**.
13. To test your rule, initiate a state change. For example, start a stopped instance, stop a running instance, or launch an instance. You'll receive email messages with the following subject line: AWS Notification Message. The body of the email contains the event data.

Scheduled events for Amazon EC2 instances

To ensure infrastructure reliability and performance, AWS can schedule events to reboot, stop, and retire your instances. These events do not occur frequently.

If one of your instances will be affected by a scheduled event, AWS notifies you in advance by email, using the email address that's associated with your AWS account. The email provides details about the event, such as the start and end dates. Depending on the event type, you might be able to take action to control the timing of the event. AWS also sends an AWS Health event, which you can monitor and manage by using Amazon EventBridge. For more information, see Monitoring events in AWS Health with Amazon EventBridge.

Scheduled events are managed by AWS. You can't schedule events for your instances. However, you can:

- View scheduled events for your instances.
- Customize scheduled event notifications to include or remove tags from the email notification.
- Reschedule certain scheduled events.
- Create custom event windows for scheduled events.
- Take action when an instance is scheduled to reboot, stop, or retire.

To ensure that you receive notifications of scheduled events, verify your contact information on the Account page.

Note

When an instance is affected by a scheduled event, and it is part of an Auto Scaling group, Amazon EC2 Auto Scaling eventually replaces it as part of its health checks, with no further action necessary on your part. For more information about the health checks performed by Amazon EC2 Auto Scaling, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

Types of scheduled events

Amazon EC2 can create the following types of scheduled events for your instances, where the event occurs at a scheduled time:

Event type	Event code	Event action
Instance stop	`instance-stop`	At the scheduled time, the instance is stopped. When you start it again, it's migrated to a new host. Applies only to instances with an Amazon EBS root volume.
Instance retirement	`instance-retirement`	At the scheduled time, the instance is stopped if it has an Amazon EBS root volume, or terminated if it has an instance store root volume.
Instance reboot	`instance-reboot`	At the scheduled time, the instance is rebooted. The instance stays on the host, and during the reboot, the host undergoes maintenance. This is known as an in-place reboot.
System reboot	`system-reboot`	At the scheduled time, the instance is rebooted and migrated to a new host. This is known as a reboot migration.
System maintenance	`system-maintenance`	At the scheduled time, the instance might be temporarily affected by network maintenance or power maintenance.

Determine the event type

You can check what type of event is scheduled for your instance.

Console

To determine the event type

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. In the table, the event code appears in the **Event type** column.
4. To filter the table to show only the events for instances, in the search field choose **Resource type: instance** from the filter list.

AWS CLI

To determine the event type for an instance

Use the describe-instance-status command. If the instance has an associated scheduled event, the output provides information about the scheduled event.

```
aws ec2 describe-instance-status \
    --instance-id i-1234567890abcdef0 \
    --query InstanceStatuses[].Events
```

The following is example output. The scheduled event code is `system-reboot`.

```
[
    "Events": [
        {
            "InstanceEventId": "instance-event-0d59937288b749b32",
            "Code": "system-reboot",
            "Description": "The instance is scheduled for a reboot",
            "NotAfter": "2020-03-14T22:00:00.000Z",
            "NotBefore": "2020-03-14T20:00:00.000Z",
            "NotBeforeDeadline": "2020-04-05T11:00:00.000Z"
        }
    ]
]
```

PowerShell

To determine the event type for an instance

Use the Get-EC2InstanceStatus cmdlet. If the instance has an associated scheduled event, the output provides information about the scheduled event.

```
(Get-EC2InstanceStatus `
    -InstanceId i-1234567890abcdef0).Events
```

The following is example output. The scheduled event code is `system-reboot`.

```
Code               : system-reboot
Description        : The instance is scheduled for a reboot
InstanceEventId    : instance-event-0d59937288b749b32
NotAfter           : 2020-03-14T22:00:00.000Z
NotBefore          : 2020-03-14T20:00:00.000Z
NotBeforeDeadline  : 2020-04-05T11:00:00.000Z
```

Contents

Manage Amazon EC2 instances scheduled to stop or retire

When AWS detects irreparable failure of the underlying host for your instance, it schedules the instance to either stop or terminate, depending on the instance's root volume type.

- If the instance has an Amazon EBS root volume, the instance is scheduled to stop.
- If the instance has an instance store root volume, the instance is scheduled to terminate.

For more information, see Instance retirement.

> **Important**
>
> Any data stored on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. Be sure to save data from your instance store volumes that you might need later before the instance is stopped, hibernated, or terminated.

Actions you can take

Actions you can take for instances with an EBS root volume

When you receive a scheduled `instance-stop` event notification, you can take one of the following actions:

- **Wait for scheduled stop:** You can wait for the instance to stop within its scheduled maintenance window.
- **Perform manual stop and start:** You can stop and start the instance yourself at a time that suits you, which migrates it to a new host. This is not the same as rebooting the instance. For more information, see Stop and start Amazon EC2 instances.
- **Automate stop and start:** You can automate an immediate stop and start in response to a scheduled `instance-stop` event. For more information, see Running operations on EC2 instances automatically in response to events in AWS Health in the *AWS Health User Guide*.

Actions you can take for instances with an instance store root volume

When you receive a scheduled `system-retirement` event notification, and you want to retain your data, you can take the following actions:

1. Launch a replacement instance from your most recent AMI.
2. Migrate all necessary data to the replacement instance before the instance is scheduled to terminate.
3. Terminate the original instance, or wait for it to terminate as scheduled.

For more information about the actions you can take, see Instance retirement.

Manage Amazon EC2 instances scheduled for reboot

When AWS must perform tasks such as installing updates or maintaining the underlying host, it can schedule an instance reboot. During the scheduled reboot, the instance either stays on the same host, or migrates to a different host, depending on the event, as follows:

- `instance-reboot` event
  - During the reboot, the instance remains on the host. This is known as an *in-place reboot*.
  - The current host undergoes maintenance.
  - Typically completes in seconds.
- `system-reboot` event
  - During the reboot, the instance is migrated to a new host. This is known as a *reboot migration*.
  - Typically completes in minutes.

To check what type of event is scheduled for your instance, see Determine the event type.

Actions you can take

When you receive a scheduled `instance-reboot` or `system-reboot` event notification, you can take one of the following actions:

- **Wait for scheduled reboot:** You can wait for the instance reboot to occur within its scheduled maintenance window.
- **Reschedule the reboot:** You can reschedule the instance reboot to a date and time that suits you.
- **Perform a user-initiated reboot:** You can manually reboot the instance yourself at a time that suits you. However, the outcome depends on the event:
  - `instance-reboot` event – Your instance remains on the current hardware (in-place reboot), no host maintenance takes place, and the event stays open.
  - `system-reboot` event
    - If reboot migration is enabled on your instance, a user-initiated reboot attempts to migrate your instance to new hardware. If successful, the event is cleared. If unsuccessful, an in-place reboot occurs and the event remains scheduled.
    - If reboot migration is disabled on your instance, a user-initiated reboot keeps the instance on the same hardware (in-place reboot), no host maintenance takes place, and the event

remains scheduled. When the scheduled event eventually takes place, AWS will move your instance to new hardware (reboot migration).

After AWS reboots your instance

The following applies after AWS reboots your instance:

- The scheduled event is cleared.
- The event description is updated.
- For an `instance-reboot` event:
  - Maintenance of the underlying host is complete.
- For a `system-reboot` event:
  - The instance moves to a new host.
  - The instance retains its IP address and DNS name.
  - Any data on local instance store volumes is preserved.
- You can use your instance after it has fully booted.

Alternative options

If you can't reschedule the reboot event or enable reboot migration for a user-initiated reboot, but want to maintain normal operation during the scheduled maintenance window, you can do the following:

- **For an instance with an EBS root volume**
  - Manually stop and start the instance to migrate it to a new host. This is not the same as manually rebooting the instance, where the instance stays on the same host.
  - Optionally, automate an immediate instance stop and start in response to the scheduled reboot event. For more information, see Running operations on EC2 instances automatically in response to events in AWS Health in the *AWS Health User Guide*.

> **Important**
>
> The data on instance store volumes is lost when an instance is stopped. For more information, see Stop and start Amazon EC2 instances.

- **For an instance with an instance store root volume**

1. Launch a replacement instance from your most recent AMI.
2. Migrate all necessary data to the replacement instance before the scheduled maintenance window.
3. Terminate the original instance.

Enable or disable reboot migration

When an instance is scheduled for a `system-reboot` event, you can reboot it before the event. The outcome of a user-initiated reboot depends on the instance's reboot migration setting:

- Enabled – A user-initiated reboot attempts to migrate your instance to new hardware (reboot migration). If successful, the event is cleared. If unsuccessful, an in-place reboot occurs and the event remains scheduled. Note that even when enabled, reboot migration can only occur if your instance meets the reboot migration requirements.
- Disabled – A user-initiated reboot keeps the instance on the same hardware (in-place reboot), no host maintenance takes place, and the event remains scheduled. When the scheduled event eventually takes place, AWS will move your instance to new hardware (reboot migration).

A reboot with migration takes longer than an in-place reboot:

- In-place reboot: Approximately 30 seconds
- Reboot with migration: Several minutes

> **Note**
>
> Instances that receive a `system-reboot` event notification are enabled for user-initiated reboot migration by default.

Requirements for enabling reboot migration

Reboot migration can be enabled on instances that meet the following criteria:

Instance types

Not all instance types support enabling reboot migration. You can view the instance types that support enabling reboot migration.

Console

To view the instance types that support enabling reboot migration

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instance Types**.
3. In the filter bar, enter **Reboot Migration support: supported**. As you enter the characters and the filter name appears, you can select it.

   The **Instance types** table displays all the instance types that support enabling reboot migration.

AWS CLI

To view the instance types that support enabling reboot migration

Use the describe-instance-types command with the `reboot-migration-support` filter.

```
aws ec2 describe-instance-types \
    --filters Name=reboot-migration-support,Values=supported \
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

PowerShell

To view the instance types that support enabling reboot migration

Use the Get-EC2InstanceType cmdlet with the `reboot-migration-support` filter.

```
Get-EC2InstanceType `
    -Filter @{Name="reboot-migration-support";Values="true"} | `
    Select InstanceType | Sort-Object InstanceType
```

Tenancy

- Shared
- Dedicated Instance

For more information, see Amazon EC2 Dedicated Instances.

Limitations

Reboot migration is **not** supported for instances with the following characteristics:

- Platform: Instances running natively on the Xen hypervisor
- Instance size: `metal` instances
- Tenancy: Dedicated Host. For Dedicated Hosts, use Dedicated Host Auto Recovery instead.
- Storage: Instances with instance store volumes
- Networking: Instances using an Elastic Fabric Adapter
- Auto Scaling: Instances that are part of an Auto Scaling group

Steps for enabling or disabling reboot migration

When an instance receives a `system-reboot` event, it is enabled for reboot migration by default. You can disable reboot migration so that during a user-initiated reboot, the instance stays on the same hardware (in-place reboot).

The `default` configuration doesn't enable reboot migration for an unsupported instance. For more information, see Requirements for enabling reboot migration.

You can disable or enable reboot migration on a running or stopped instance.

AWS CLI

To disable reboot migration

Use the modify-instance-maintenance-options command and set the `--reboot-migration` parameter to `disabled`.

```
aws ec2 modify-instance-maintenance-options \

    --instance-id i-0abcdef1234567890 \

    --reboot-migration disabled
```

To enable reboot migration

Use the modify-instance-maintenance-options command and set the `--reboot-migration` parameter to `default`.

```
aws ec2 modify-instance-maintenance-options \
```

```
    --instance-id i-0abcdef1234567890 \

    --reboot-migration default
```

PowerShell

To disable reboot migration

Use the Edit-EC2InstanceMaintenanceOption cmdlet.

```
Edit-EC2InstanceMaintenanceOption `
    -InstanceId  `
    -RebootMigration Disabled
```

To enable reboot migration

Use the Edit-EC2InstanceMaintenanceOption cmdlet.

```
Edit-EC2InstanceMaintenanceOption `
    -InstanceId i-1234567890abcdef0 `
    -RebootMigration Enabled
```

Manage Amazon EC2 instances scheduled for maintenance

When AWS must maintain the underlying host for an instance, it schedules the instance for maintenance. There are two types of maintenance events: network maintenance and power maintenance.

- During network maintenance, scheduled instances lose network connectivity for a brief period of time. Normal network connectivity to your instance is restored after maintenance is complete.
- During power maintenance, scheduled instances are taken offline for a brief period, and then rebooted. When a reboot is performed, all of your instance's configuration settings are retained.

After your instance has rebooted (this normally takes a few minutes), verify that your application is working as expected. At this point, your instance should no longer have a scheduled event associated with it, or if it does, the description of the scheduled event begins with **[Completed]**. It sometimes takes up to 1 hour for the instance status description to refresh. Completed maintenance events are displayed on the Amazon EC2 console dashboard for up to a week.

Actions you can take

Actions you can take for instances with an EBS root volume

When you receive a `system-maintenance` event notification, you can take one of the following actions:

- **Wait for scheduled maintenance:** You can wait for the maintenance to occur as scheduled.
- **Perform manual stop and stop:** You can stop and start the instance, which migrates it to a new host. This is not the same as rebooting the instance. For more information, see Stop and start Amazon EC2 instances.
- **Automate stop and start:** You can automate an immediate stop and start in response to a scheduled maintenance event. For more information, see Running operations on EC2 instances automatically in response to events in AWS Health in the *AWS Health User Guide*.

Actions you can take for instances with an instance store root volume

When you receive a `system-maintenance` event notification, you can take one of the following actions:

- **Wait for scheduled maintenance:** You can wait for the maintenance to occur as scheduled.
- **Launch a replacement instance:** If you want to maintain normal operation during the scheduled maintenance window:
  1. Launch a replacement instance from your most recent AMI.
  2. Migrate all necessary data to the replacement instance before the scheduled maintenance window.
  3. Terminate the original instance.

View scheduled events that affect your Amazon EC2 instances

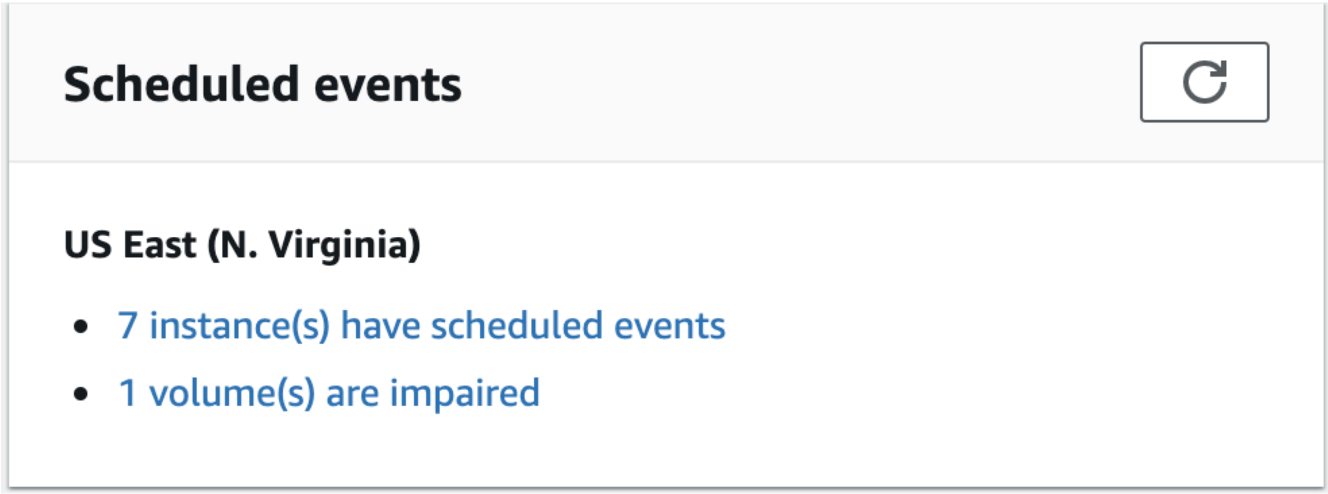
In addition to receiving notification of scheduled events in email, you can check for scheduled events.

Console

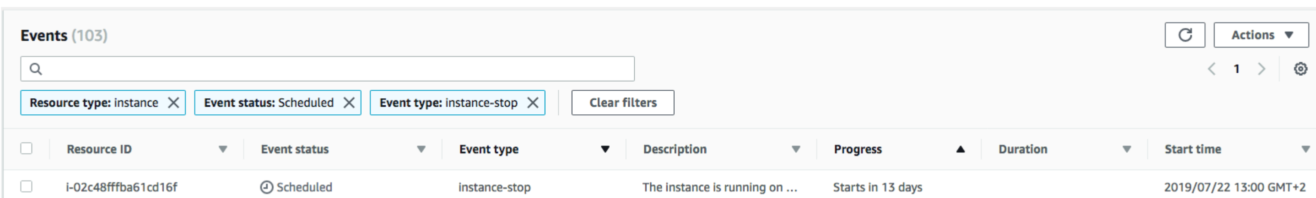
To view scheduled events for your instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. The dashboard displays any resources with an associated event under **Scheduled events**.



3. For more detail, choose **Events** in the navigation pane. Any resources with an associated event are displayed. You can filter by characteristics such as event type, resource type, and Availability Zone.



AWS CLI

To view scheduled events for your instances

Use the describe-instance-status command.

```
aws ec2 describe-instance-status \
    --instance-id i-1234567890abcdef0 \
    --query "InstanceStatuses[].Events"
```

The following example output shows a reboot event.

```
[
    "Events": [
        {
            "InstanceEventId": "instance-event-0d59937288b749b32",
            "Code": "system-reboot",
            "Description": "The instance is scheduled for a reboot",
```

```
                "NotAfter": "2019-03-15T22:00:00.000Z",
                "NotBefore": "2019-03-14T20:00:00.000Z",
                "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"
            }

    ]
]
```

The following example output shows an instance retirement event.

```
[
    "Events": [
        {
            "InstanceEventId": "instance-event-0e439355b779n26",

            "Code": "instance-stop",
            "Description": "The instance is running on degraded hardware",
            "NotBefore": "2015-05-23T00:00:00.000Z"
        }
    ]
]
```

PowerShell

To view scheduled events for your instances

Use the following Get-EC2InstanceStatus command.

```
(Get-EC2InstanceStatus -InstanceId i-1234567890abcdef0).Events
```

The following example output shows an instance retirement event.

```
Code          : instance-stop
Description   : The instance is running on degraded hardware
NotBefore     : 5/23/2015 12:00:00 AM
```

Instance metadata

To view scheduled events for your instances using instance metadata

You can retrieve information about active maintenance events for your instances from the instance metadata by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/events/maintenance/scheduled
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/events/maintenance/scheduled
```

The following is example output with information about a scheduled system reboot event, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "21 Jan 2019 09:17:23 GMT",
    "State" : "active"
  }
]
```

To view event history about completed or canceled events for your instances using instance metadata

You can retrieve information about completed or canceled events for your instances from instance metadata by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/events/maintenance/history
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/events/maintenance/
history
```

The following is example output with information about a system reboot event that was canceled, and a system reboot event that was completed, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Canceled] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "21 Jan 2019 09:17:23 GMT",
    "State" : "canceled"
  },
  {
    "NotBefore" : "29 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Completed] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "29 Jan 2019 09:17:23 GMT",
    "State" : "completed"
  }
]
```

AWS Health

You can use the AWS Health Dashboard to learn about events that can affect your instance. The AWS Health Dashboard organizes issues in three groups: open issues, scheduled changes, and other notifications. The scheduled changes group contains items that are ongoing or upcoming.

For more information, see Getting started with your AWS Health Dashboard in the *AWS Health User Guide*.

Customize scheduled event notifications for your EC2 instances

You can customize scheduled event notifications to include tags in the email notification. This makes it easier to identify the affected resource (instances or Dedicated Hosts) and to prioritize actions for the upcoming event.

When you customize event notifications to include tags, you can choose to include:

- All of the tags that are associated with the affected resource
- Only specific tags that are associated with the affected resource

For example, suppose that you assign `application`, `costcenter`, `project`, and `owner` tags to all of your instances. You can choose to include all of the tags in event notifications. Alternatively, if you'd like to see only the `owner` and `project` tags in event notifications, then you can choose to include only those tags.

After you select the tags to include, the event notifications will include the resource ID (instance ID or Dedicated Host ID) and the tag key and value pairs that are associated with the affected resource.

Tasks

- Include tags in event notifications
- Remove tags from event notifications
- View the tags to be included in event notifications

Include tags in event notifications

The tags that you choose to include apply to all resources (instances and Dedicated Hosts) in the selected Region. To customize event notifications in other Regions, first select the required Region and then perform the following steps.

Console

To include tags in event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event notifications**.
4. Turn on **Include tags in event notifications**.
5. Do one of the following, depending on the tags that you want to include in event notifications:
    - To include all tags associated with the affected instance or Dedicated Host, select **Include all tags**.

- To select the tags to include, select **Choose the tags to include** and then select or enter the tag keys.

6. Choose **Save**.

AWS CLI

To include all tags in event notifications

Use the register-instance-event-notification-attributes command and set the `IncludeAllTagsOfInstance` parameter to `true`.

```
aws ec2 register-instance-event-notification-attributes \
    --instance-tag-attribute "IncludeAllTagsOfInstance=true"
```

To include specific tags in event notifications

Use the register-instance-event-notification-attributes command and specify the tags to include by using the `InstanceTagKeys` parameter.

```
aws ec2 register-instance-event-notification-attributes \
    --instance-tag-attribute 'InstanceTagKeys=["tag_key_1", "tag_key_2",
 "tag_key_3"]'
```

PowerShell

To include all tags in event notifications

Use the Register-EC2InstanceEventNotificationAttribute cmdlet.

```
Register-EC2InstanceEventNotificationAttribute `
    -InstanceTagAttribute_IncludeAllTagsOfInstance $true
```

To include specific tags in event notifications

Use the Register-EC2InstanceEventNotificationAttribute cmdlet.

```
Register-EC2InstanceEventNotificationAttribute `
    -InstanceTagAttribute_InstanceTagKey tag_key_1, tag_key_2, tag_key_3
```

Remove tags from event notifications

You can remove tags from event notifications.

Console

To remove tags from event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event notifications**.
4. To remove all tags from event notifications, turn off **Include tags in event notifications**.
5. To remove specific tags from event notifications, choose the **X**) for the corresponding tag keys.
6. Choose **Save**.

AWS CLI

To remove all tags from event notifications

Use the deregister-instance-event-notification-attributes command and set the `IncludeAllTagsOfInstance` parameter to `false`.

```
aws ec2 deregister-instance-event-notification-attributes \
    --instance-tag-attribute "IncludeAllTagsOfInstance=false"
```

To remove a tag from event notifications

Use the deregister-instance-event-notification-attributes command and specify the tags to remove by using the `InstanceTagKeys` parameter.

```
aws ec2 deregister-instance-event-notification-attributes \
    --instance-tag-attribute 'InstanceTagKeys=["tag_key_3"]'
```

PowerShell

To remove all tags from event notifications

Use the Unregister-EC2InstanceEventNotificationAttribute cmdlet.

```
Unregister-EC2InstanceEventNotificationAttribute `
    -InstanceTagAttribute_IncludeAllTagsOfInstance $false
```

To remove a tag from event notifications

Use the Unregister-EC2InstanceEventNotificationAttribute cmdlet.

```
Unregister-EC2InstanceEventNotificationAttribute `
    -InstanceTagAttribute_InstanceTagKey tag_key_3
```

View the tags to be included in event notifications

You can view the tags that are to be included in event notifications.

Console

To view the tags that are to be included in event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event notifications**.

AWS CLI

To view the tags to be included in event notifications

Use the describe-instance-event-notification-attributes command.

```
aws ec2 describe-instance-event-notification-attributes
```

PowerShell

To view the tags to be included in event notifications

Use the Get-EC2InstanceEventNotificationAttribute cmdlet.

```
Get-EC2InstanceEventNotificationAttribute
```

Reschedule a scheduled event for an EC2 instance

You can reschedule an event so that it occurs at a specific date and time that suits you. After you reschedule an event, it might take a minute or two before the the updated date is displayed.

Limitations

- Only events with an event deadline date can be rescheduled. The event can be rescheduled up to the event deadline date. The event deadline date is indicated in the **Deadline** column (console) and the `NotBeforeDeadline` field (AWS CLI).
- Only events that have not yet started can be rescheduled. The start time is indicated in the **Start time** column (console) and the `NotBefore` field (AWS CLI). Events that are scheduled to start in the next 5 minutes can't be rescheduled.
- The new event start time must be at least 60 minutes from the current time.
- If you reschedule multiple events using the console, the event deadline date is determined by the event with the earliest event deadline date.

Console

To reschedule an event

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Resource type: instance** from the filter list.
4. Select one or more instances, and then choose **Actions**, **Schedule event**.

   Only events that have an event deadline date, indicated by a value for **Deadline**, can be rescheduled. If one of the selected events does not have a deadline date, **Actions**, **Schedule event** is disabled.
5. For **New start time**, enter a new date and time for the event. The new date and time must occur before the **Event deadline**.
6. Choose **Save**.

   It might take a minute or two for the updated event start time to be reflected in the console.

AWS CLI

To reschedule an event

Use the modify-instance-event-start-time command.

```
aws ec2 modify-instance-event-start-time \
    --instance-id i-1234567890abcdef0 \
    --instance-event-id instance-event-0d59937288b749b32 \
    --not-before 2020-03-25T10:00:00.000
```

PowerShell

To reschedule an event

Use the Edit-EC2InstanceEventStartTime cmdlet.

```
Edit-EC2InstanceEventStartTime `
    -InstanceId i-1234567890abcdef0 `
    -InstanceEventId instance-event-0d59937288b749b32 `
    -NotBefore 2020-03-25T10:00:00.000
```

Create custom event windows for scheduled events that affect your Amazon EC2 instances

You can define custom event windows that recur weekly for scheduled events that reboot, stop, or terminate your Amazon EC2 instances. You can associate one or more instances with an event window. If a scheduled event for those instances is planned, AWS will schedule the events within the associated event window.

You can use event windows to maximize workload availability by specifying event windows that occur during off-peak periods for your workload. You can also align the event windows with your internal maintenance schedules.

You define an event window by specifying a set of time ranges. The minimum time range is 2 hours. The combined time ranges must total at least 4 hours.

You can associate one or more instances with an event window by using either instance IDs or instance tags. You can also associate Dedicated Hosts with an event window by using the host ID.

> **Warning**
>
> Event windows are applicable only for scheduled events that stop, reboot, or terminate instances.
> Event windows are not applicable for:
>
> - Expedited scheduled events and network maintenance events.
> - Unscheduled maintenance such as automatic instance recovery and unplanned reboots.

Work with event windows

- Considerations
- Create an event window
- Associate a target with an event window
- Disassociate a target from an event window
- Modify an event window
- Delete an event window

Considerations

- All event window times are in UTC.
- The minimum weekly event window duration is 4 hours.
- The time ranges within an event window must each be at least 2 hours.
- Only one target type (instance ID, Dedicated Host ID, or instance tag) can be associated with an event window.
- A target (instance ID, Dedicated Host ID, or instance tag) can only be associated with one event window.
- A maximum of 100 instance IDs, or 50 Dedicated Host IDs, or 50 instance tags can be associated with an event window. The instance tags can be associated with any number of instances.
- A maximum of 200 event windows can be created per AWS Region.
- Multiple instances that are associated with event windows can potentially have scheduled events occur at the same time.
- If AWS has already scheduled an event, modifying an event window won't change the time of the scheduled event. If the event has a deadline date, you can reschedule the event.

- You can stop and start an instance before the scheduled event. This migrates the instance to a new host and clears the event.

Create an event window

You can create one or more event windows. For each event window, you specify one or more blocks of time. For example, you can create an event window with blocks of time that occur every day at 4 AM for 2 hours. Or you can create an event window with blocks of time that occur on Sundays from 2 AM to 4 AM and on Wednesdays from 3 AM to 5 AM.

Event windows recur weekly until you delete them.

Console

To create an event window

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event windows**.
4. Choose **Create instance event window**.
5. For **Event window name**, enter a descriptive name for the event window.
6. For **Event window schedule**, choose to specify the blocks of time in the event window by using the cron schedule builder or by specifying time ranges.
   - If you choose **Cron schedule builder**, specify the following:
     1. For **Days (UTC)**, specify the days of the week on which the event window occurs.
     2. For **Start time (UTC)**, specify the time when the event window begins.
     3. For **Duration**, specify the duration of the blocks of time in the event window. The minimum duration per block of time is 2 hours. The minimum duration of the event window must equal or exceed 4 hours in total. All times are in UTC.
   - If you choose **Time ranges**, choose **Add new time range** and specify the start day and time and the end day and time. Repeat for each time range. The minimum duration per time range is 2 hours. The minimum duration for all time ranges combined must equal or exceed 4 hours in total.
7. (Optional) For **Target details**, associate one or more instances with the event window. Use instance IDs or instance tags to associate instances. Use host IDs to associate Dedicated

Hosts. When these targets are scheduled for maintenance, the event will occur during this event window.

Note that you can create the event window without associating a target with the window. Later, you can modify the window to associate one or more targets.

8. (Optional) For **Event window tags**, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
9. Choose **Create event window**.

AWS CLI

To create an event window with a time range

Use the create-instance-event-window command.

```
aws ec2 create-instance-event-window \
    --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8 \
    --tag-specifications "ResourceType=instance-event-
window,Tags=[{Key=K1,Value=V1}]" \
    --name myEventWindowName
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
```

```
        ]
    }
}
```

To create an event window with a cron expression

Use the create-instance-event-window command.

```
aws ec2 create-instance-event-window \
    --cron-expression "* 21-23 * * 2,3" \
    --tag-specifications "ResourceType=instance-event-
window,Tags=[{Key=K1,Value=V1}]" \
    --name myEventWindowName
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

PowerShell

To create an event window with a time range

Use the New-EC2InstanceEventWindow cmdlet.

```
$timeRange = New-Object Amazon.EC2.Model.InstanceEventWindowTimeRangeRequest
$timeRange.StartWeekDay = "monday"
$timeRange.EndWeekDay = "wednesday"
$timeRange.StartHour = 2
$timeRange.EndHour = 8
```

```
$tag = @{Key="key1"; Value="value1"}
$tagspec = New-Object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "instance-event-window"
$tagspec.Tags.Add($tag)
New-EC2InstanceEventWindow `
    -Name my-event-window `
    -TagSpecification $tagspec `
    -TimeRange @($timeRange)
```

The following is example output.

```
AssociationTarget     :
CronExpression        :
InstanceEventWindowId : iew-0abcdef1234567890
Name                  : my-event-window
State                 : creating
Tags                  : {key1}
TimeRanges            : {Amazon.EC2.Model.InstanceEventWindowTimeRange}
```

To create an event window with a cron expression

Use the New-EC2InstanceEventWindow cmdlet.

```
$tag = @{Key="key1"; Value="value1"}
$tagspec = New-Object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "instance-event-window"
$tagspec.Tags.Add($tag)
New-EC2InstanceEventWindow `
    -Name my-event-window `
    -TagSpecification $tagspec`
    -CronExpression "* 21-23 * * 2,3"
```

The following is example output.

```
AssociationTarget     :
CronExpression        : * 21-23 * * 2,3
InstanceEventWindowId : iew-0abcdef1234567890
Name                  : my-event-window
State                 : creating
Tags                  : {key1}
TimeRanges            : {}
```

Associate a target with an event window

After you create an event window, you can associate targets with the event window. You can associate only one type of target with an event window. You can specify instance IDs, Dedicated Host IDs, or instance tags.

Console

To associate targets with an event window

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Select the event window to modify.
4. Choose **Actions**, **Modify instance event window**.

AWS CLI

To associate instance tags with an event window

Use the associate-instance-event-window command.

```
aws ec2 associate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceTags=[{Key=k2,Value=v2},{Key=k1,Value=v1}]"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [
                {
                    "Key": "k2",
                    "Value": "v2"
                },
                {
                    "Key": "k1",
```

```
                    "Value": "v1"
                }
            ],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To associate instance IDs with an event window

Use the associate-instance-event-window command.

```
aws ec2 associate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356eba48d7"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [
                "i-1234567890abcdef0",
                "i-0598c7d356eba48d7"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To associate a Dedicated Host with an event window

Use the associate-instance-event-window command.

```
aws ec2 associate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
```

```
    --association-target "DedicatedHostIds=h-029fa35a02b99801d"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": [
                "h-029fa35a02b99801d"
            ]
        },
        "State": "creating"
    }
}
```

PowerShell

To associate instance tags with an event window

Use the Register-EC2InstanceEventWindow cmdlet.

```
$tag1 = @{Key="key1"; Value="value1"}
$tag2 = @{Key="key2"; Value="value2"}
Register-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceTag @($tag1,$tag2)
```

To associate instance IDs with an event window

Use the Register-EC2InstanceEventWindow cmdlet.

```
Register-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceId i-1234567890abcdef0, i-0598c7d356eba48d7
```

To associate a Dedicated Host with an event window

Use the Register-EC2InstanceEventWindow cmdlet.

```
Register-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_DedicatedHostId h-029fa35a02b99801d
```

Disassociate a target from an event window

Console

To disassociate targets with an event window

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Select the event window to modify.
4. Choose **Actions**, **Modify instance event window**.

AWS CLI

To disassociate instance tags from an event window

Use the disassociate-instance-event-window command.

```
aws ec2 disassociate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceTags=[{Key=k2,Value=v2},{Key=k1,Value=v1}]"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
```

```
}
```

To disassociate instance IDs from an event window

Use the disassociate-instance-event-window command.

```
aws ec2 disassociate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356eba48d7"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

To disassociate a Dedicated Host from an event window

Use the disassociate-instance-event-window command.

```
aws ec2 disassociate-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --association-target DedicatedHostIds=h-029fa35a02b99801d
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
```

```
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating"
    }
}
```

PowerShell

To disassociate instance tags from an event window

Use the Unregister-EC2InstanceEventWindow cmdlet.

```
$tag1 = @{Key="key1"; Value="value1"}
$tag2 = @{Key="key2"; Value="value2"}
Unregister-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceTag @($tag1, $tag2)
```

To disassociate instance IDs from an event window

Use the Unregister-EC2InstanceEventWindow cmdlet.

```
Unregister-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_InstanceId i-1234567890abcdef0, i-0598c7d356eba48d7
```

To disassociate a Dedicated Host from an event window

Use the Unregister-EC2InstanceEventWindow cmdlet.

```
Unregister-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -AssociationTarget_DedicatedHostId h-029fa35a02b99801d
```

Modify an event window

You can modify all of the fields of an event window except its ID. For example, when daylight savings begin, you might want to modify the event window schedule. For existing event windows, you might want to add or remove targets.

You can modify either a time range or a cron expression when modifying the event window, but not both.

Console

To modify an event window

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event windows**.
4. Select the event window to modify, and then choose **Actions**, **Modify instance event window**.
5. Modify the fields in the event window, and then choose **Modify event window**.

AWS CLI

To modify the time range of an event window

Use the modify-instance-event-window command.

```
aws ec2 modify-instance-event-window
    --instance-event-window-id iew-0abcdef1234567890 \
    --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "AssociationTarget": {
```

```
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acb8ba01f0"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

To modify a set of time ranges for an event window

Use the modify-instance-event-window command.

```
aws ec2 modify-instance-event-window
    --instance-event-window-id iew-0abcdef1234567890 \
    --time-range '[{"StartWeekDay": "monday", "StartHour": 2, "EndWeekDay":
 "wednesday", "EndHour": 8},
   {"StartWeekDay": "thursday", "StartHour": 2, "EndWeekDay": "friday",
 "EndHour": 8}]'
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            },
            {
                "StartWeekDay": "thursday",
                "StartHour": 2,
```

```
                "EndWeekDay": "friday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acb8ba01f0"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

To modify the cron expression of an event window

Use the modify-instance-event-window command.

```
aws ec2 modify-instance-event-window
    --instance-event-window-id iew-0abcdef1234567890 \
    --cron-expression "* 21-23 * * 2,3"
```

The following is example output.

```
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acb8ba01f0"
            ],
```

```
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

PowerShell

To modify the time range of an event window

Use the Edit-EC2InstanceEventWindow cmdlet.

```
$timeRange1 = New-Object Amazon.EC2.Model.InstanceEventWindowTimeRangeRequest
$timeRange1.StartWeekDay = "monday"
$timeRange1.EndWeekDay = "wednesday"
$timeRange1.StartHour = 2
$timeRange1.EndHour = 8
$timeRange2 = New-Object Amazon.EC2.Model.InstanceEventWindowTimeRangeRequest
$timeRange2.StartWeekDay = "thursday"
$timeRange2.EndWeekDay = "friday"
$timeRange2.StartHour = 1
$timeRange2.EndHour = 6
Edit-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -TimeRange @($timeRange1, $timeRange2)
```

To modify the cron expression of an event window

Use the Edit-EC2InstanceEventWindow cmdlet.

```
Edit-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -CronExpression "* 21-23 * * 2,3"
```

Delete an event window

You can delete one event window at a time.

Console

To delete an event window

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Events**.
3. Choose **Actions**, **Manage event windows**.
4. Select the event window to delete, and then choose **Actions**, **Delete instance event window**.
5. When prompted, enter **`delete`**, and then choose **Delete**.

AWS CLI

To delete an event window

Use the delete-instance-event-window command and specify the event window to delete.

```
aws ec2 delete-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890
```

To force-delete an event window

Use the `--force-delete` parameter if the event window is currently associated with targets.

```
aws ec2 delete-instance-event-window \
    --instance-event-window-id iew-0abcdef1234567890 \
    --force-delete
```

PowerShell

To delete an event window

Use the Remove-EC2InstanceEventWindow cmdlet.

```
Remove-EC2InstanceEventWindow `
```

```
    -InstanceEventWindowId iew-0abcdef1234567890
```

To force-delete an event window

Use the Remove-EC2InstanceEventWindow cmdlet.

```
Remove-EC2InstanceEventWindow `
    -InstanceEventWindowId iew-0abcdef1234567890 `
    -ForceDelete $true
```

Monitor your instances using CloudWatch

You can monitor your instances using Amazon CloudWatch, which collects and processes raw data from Amazon EC2 into readable, near real-time metrics. These statistics are recorded for a period of 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing.

By default, Amazon EC2 sends metric data to CloudWatch in 5-minute periods. To send metric data for your instance to CloudWatch in 1-minute periods, you can enable detailed monitoring on the instance. For more information, see Manage detailed monitoring for your EC2 instances.

The Amazon EC2 console displays a series of graphs based on the raw data from Amazon CloudWatch. Depending on your needs, you might prefer to get data for your instances from Amazon CloudWatch instead of the graphs in the console.

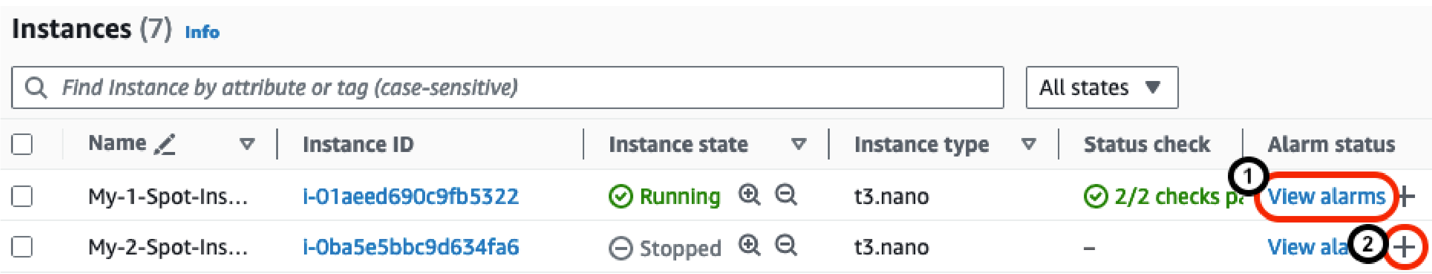
For Amazon CloudWatch billing and cost information, see CloudWatch billing and cost in the *Amazon CloudWatch User Guide*.

Contents

- [Create alarms that stop, terminate, reboot, or recover an instance]

Manage CloudWatch alarms for your EC2 instances in the Amazon EC2 console

From the **Instances** screen in the Amazon EC2 console, you can manage the Amazon CloudWatch alarms for your instances. In the **Instances** table, the **Alarm status** column provides two console controls: a control for viewing alarms, and another for creating or editing them. The following screenshot indicates these console controls, numbered **1** (**View alarms**) and **2** (a **+** sign for creating or editing an alarm).



View alarms from the Instances screen

You can view each instance's alarms from the **Instances** screen.

To view an instance's alarm from the Instances screen

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/].
2. In the navigation pane, choose **Instances**.
3. In the **Instances** table, for your chosen instance, choose **View alarms** (numbered **1** in the preceding screenshot).
4. In the **Alarm details for *i-1234567890abcdef0*** window, choose the alarm name to view the alarm in the CloudWatch console.

Create alarms from the Instances screen

You can create an alarm for each instance from the **Instances** screen.

To create an alarm for an instance from the Instances screen

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/].

2. In the navigation pane, choose **Instances**.
3. In the **Instances** table, for your chosen instance, choose the plus sign (numbered **2** in the preceding screenshot).
4. In the **Manage CloudWatch alarms** screen, create your alarm. For more information, see [Create a CloudWatch alarm for an instance](#).

Edit alarms from the Instances screen

You can edit the alarm for an instance from the **Instances** screen.

To edit an alarm for an instance from the Instances screen

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. In the **Instances** table, for your chosen instance, choose the plus sign (numbered **2** in the preceding screenshot).
4. In the **Manage CloudWatch alarms** screen, edit your alarm. For more information, see Edit or delete a CloudWatch alarm in the *Amazon CloudWatch User Guide*.

Manage detailed monitoring for your EC2 instances

Amazon CloudWatch provides two categories of monitoring: *basic monitoring* and *detailed monitoring*. By default, your instance is configured for basic monitoring. You can optionally enable detailed monitoring to help you more quickly identify and act on operational issues. You can enable or turn off detailed monitoring at launch or when the instance is running or stopped.

Enabling detailed monitoring on an instance does not affect the monitoring of its attached EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS.

The following table highlights the differences between basic monitoring and detailed monitoring for your instances.

Monitoring type	Description	Charges
Basic monitoring	Status check metrics are available in 1-minute periods. All other metrics are available in 5-minute periods.	No charge.

Monitoring type	Description	Charges
Detailed monitoring	All metrics, including status check metrics, are available in 1-minute periods. To get this level of data, you must specifically enable it for the instance. For the instances where you've enabled detailed monitorin g, you can also get aggregated data across groups of similar instances.	You are charged per metric that Amazon EC2 sends to CloudWatc h. You are not charged for data storage. For more information, see **Paid tier** and **Example 1 - EC2 Detailed Monitoring** on the Amazon CloudWatch pricing page.

Contents

Required permissions

To enable detailed monitoring for an instance, your user must have permission to use the MonitorInstances API action. To turn off detailed monitoring for an instance, your user must have permission to use the UnmonitorInstances API action.

Enable detailed monitoring at launch

Use the following procedures to enable detailed monitoring at launch. By default, your instance uses basic monitoring.

Console

To enable detailed monitoring when launching an instance

When launching an instance using the Amazon EC2 console, under **Advanced details**, select the **Detailed CloudWatch monitoring** checkbox.

AWS CLI

To enable detailed monitoring when launching an instance

Use the run-instances command with the `--monitoring` option.

```
--monitoring Enabled=true
```

PowerShell

To enable detailed monitoring when launching an instance

Use the New-EC2Instance cmdlet with the `-Monitoring` parameter.

```
-Monitoring $true
```

Manage detailed monitoring

Use the following procedures to manage detailed monitoring for a running or stopped instance.

Console

To manage detailed monitoring

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Monitor and troubleshoot**, **Manage detailed monitoring**.
5. On the **Detailed monitoring** page, for **Detailed monitoring**, do one of the following:
   - Detailed monitoring – Select **Enable**.
   - Basic monitoring – Clear **Enable**.
6. Choose **Confirm**.

AWS CLI

To enable detailed monitoring

Use the following monitor-instances command.

```
aws ec2 monitor-instances --instance-ids i-1234567890abcdef0
```

To disable detailed monitoring

Use the unmonitor-instances command.

```
aws ec2 unmonitor-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To enable detailed monitoring

Use the Start-EC2InstanceMonitoring cmdlet.

```
Start-EC2InstanceMonitoring -InstanceId i-1234567890abcdef0
```

To disable detailed monitoring

Use the Stop-EC2InstanceMonitoring cmdlet.

```
Stop-EC2InstanceMonitoring -InstanceId i-1234567890abcdef0
```

CloudWatch metrics that are available for your instances

Amazon EC2 sends metrics to Amazon CloudWatch. You can use the AWS Management Console, the AWS CLI, or an API to list the metrics that Amazon EC2 sends to CloudWatch. By default, each data point covers the 5 minutes that follow the start time of activity for the instance. If you've enabled detailed monitoring, each data point covers the next minute of activity from the start time. Note that for the Minimum, Maximum, and Average statistics, the minimum granularity for the metrics that EC2 provides is 1 minute.

For information about how to view the available metrics using the AWS Management Console or the AWS CLI, see View available metrics in the *Amazon CloudWatch User Guide*.

For information about getting the statistics for these metrics, see Statistics for CloudWatch metrics for your instances.

- Amazon EC2 usage metrics

Instance metrics

The `AWS/EC2` namespace includes the following instance metrics.

Metric	Description	Unit	Meaningful statistics
`CPUUtilization`	The percentage of physical CPU time that Amazon EC2 uses to run the EC2 instance, which includes time spent to run both the user code and the Amazon EC2 code. At a very high level, `CPUUtilization` is the sum of guest `CPUUtilization` and hypervisor `CPUUtilization`. Tools in your operating system can show a different percentage than CloudWatch due to factors such as legacy device simulation, configuration of non-legacy devices, interrupt-heavy workloads, live migration, and live update.	Percent	• Average • Minimum • Maximum
`DiskReadOps`	Completed read operations from all instance store volumes available to the instance in a specified period of time. To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period.	Count	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	If there are no instance store volumes, either the value is 0 or the metric is not reported.		
`DiskWriteOps`	Completed write operations to all instance store volumes available to the instance in a specified period of time. To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Count	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`DiskReadBytes`	Bytes read from all instance store volumes available to the instance. This metric is used to determine the volume of the data the application reads from the hard disk of the instance. This can be used to determine the speed of the application. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the bytes per second. For example, if you have graphed `DiskReadBytes` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in bytes/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`DiskWriteBytes`	Bytes written to all instance store volumes available to the instance. This metric is used to determine the volume of the data the application writes onto the hard disk of the instance. This can be used to determine the speed of the application. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the bytes per second. For example, if you have graphed `DiskWriteBytes` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in bytes/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*. If there are no instance store volumes, either the value is 0 or the metric is not reported.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
MetadataNoToken	The number of times the Instance Metadata Service (IMDS) was successfully accessed using a method that does not use a token. This metric is used to determine if there are any processes accessing instance metadata that are using Instance Metadata Service Version 1 (IMDSv1), which does not use a token. If all requests use token-backed sessions, i.e., Instance Metadata Service Version 2 (IMDSv2), the value is 0. For more information, see Transition to using Instance Metadata Service Version 2.	Nitro instances: None Xen instances : Count	• Sum • Percentiles
MetadataNoTokenRejected	The number of times an IMDSv1 call was attempted after IMDSv1 was disabled. If this metric appears, it indicates that an IMDSv1 call was attempted and rejected. You can either re-enable IMDSv1 or make sure all of your calls use IMDSv2. For more information, see Transition to using Instance Metadata Service Version 2.	Nitro instances: None Xen instances : Count	• Sum • Percentiles

Metric	Description	Unit	Meaningful statistics
`NetworkIn`	The number of bytes received by the instance on all network interfaces. This metric identifies the volume of incoming network traffic to a single instance. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60.	Bytes	• Sum • Average • Minimum • Maximum
`NetworkOut`	The number of bytes sent out by the instance on all network interfaces. This metric identifies the volume of outgoing network traffic from a single instance. The number reported is the number of bytes sent during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
NetworkPa cketsIn	The number of packets received by the instance on all network interfaces. This metric identifies the volume of incoming traffic in terms of the number of packets on a single instance. This metric is available for basic monitorin g only (5-minute periods). To calculate the number of packets per second (PPS) your instance received for the 5 minutes, divide the Sum statistic value by 300.	Count	• Sum • Average • Minimum • Maximum
NetworkPa cketsOut	The number of packets sent out by the instance on all network interfaces. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single instance. This metric is available for basic monitorin g only (5-minute periods). To calculate the number of packets per second (PPS) your instance sent for the 5 minutes, divide the Sum statistic value by 300.	Count	• Sum • Average • Minimum • Maximum

CPU credit metrics

The AWS/EC2 namespace includes the following CPU credit metrics for your burstable performance instances.

Metric	Description	Unit	Meaningful statistics
`CPUCreditUsage`	The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes). CPU credit metrics are available at a 5-minute frequency only. If you specify a period greater than five minutes, use the `Sum` statistic instead of the `Average` statistic.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum
`CPUCreditBalance`	The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the `CPUCreditBalance` also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit. The credits in the `CPUCreditBalance` are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the `CPUCreditBalance` do not expire. When	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	a T3 or T3a instance stops, the `CPUCreditBalance` value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the `CPUCreditBalance` value does not persist, and all accrued credits are lost. CPU credit metrics are available at a 5-minute frequency only.		
`CPUSurplusCreditBalance`	The number of surplus credits that have been spent by an `unlimited` instance when its `CPUCreditBalance` value is zero. The `CPUSurplusCreditBalance` value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. CPU credit metrics are available at a 5-minute frequency only.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`CPUSurplusCreditsCharged`	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when any of the following occurs: • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from `unlimited` to `standard`. CPU credit metrics are available at a 5-minute frequency only.	Credits (vCPU-minutes)	• Sum • Average • Minimum • Maximum

Dedicated Host metrics

The `AWS/EC2` namespace includes the following metrics for T3 Dedicated Hosts.

Metric	Description	Unit	Meaningful statistics
`DedicatedHostCPUUtilization`	The percentage of allocated compute capacity that is currently in use by the instances running on the Dedicated Host.	Percent	• Sum • Average • Minimum • Maximum

Amazon EBS metrics for Nitro-based instances

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances.

Metric	Description	Unit	Meaningful statistics
EBSReadOps	Completed read operations from all Amazon EBS volumes attached to the instance in a specified period of time. To calculate the average read I/O operations per second (Read IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Read IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the operations per second. For example, if you have graphed EBSReadOps in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in operations/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.	Count	• Sum • Average • Minimum • Maximum
EBSWriteOps	Completed write operations to all EBS volumes attached to the instance in a specified period of time. To calculate the average write I/O operation s per second (Write IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you	Count	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Write IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the operations per second. For example, if you have graphed `EBSWriteOps` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in operations/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.		
`EBSReadBytes`	Bytes read from all EBS volumes attached to the instance in a specified period of time. The number reported is the number of bytes read during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Read Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the bytes per second. For example, if you have graphed `EBSReadBytes` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in bytes/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.	Bytes	• Sum • Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
`EBSWriteBytes`	Bytes written to all EBS volumes attached to the instance in a specified period of time. The number reported is the number of bytes written during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Write Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function `DIFF_TIME` to find the bytes per second. For example, if you have graphed `EBSWriteBytes` in CloudWatch as `m1`, the metric math formula `m1/(DIFF_TIME(m1))` returns the metric in bytes/second. For more information about `DIFF_TIME` and other metric math functions, see Use metric math in the *Amazon CloudWatch User Guide*.	Bytes	• Sum • Average • Minimum • Maximum
`EBSIOBalance%`	Provides information about the percentage of I/O credits remaining in the burst bucket. This metric is available for basic monitoring only. This metric is available only for some `*.4xlarge` instance sizes and smaller that burst to their maximum performance for only 30 minutes at least once every 24 hours. The `Sum` statistic is not applicable to this metric.	Percent	• Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
EBSByteBalance%	Provides information about the percentage of throughput credits remaining in the burst bucket. This metric is available for basic monitoring only. This metric is available only for some *.4xlarge instance sizes and smaller that burst to their maximum performance for only 30 minutes at least once every 24 hours. The Sum statistic is not applicable to this metric.	Percent	• Minimum • Maximum

For information about the metrics provided for your EBS volumes, see Metrics for Amazon EBS volumes in the *Amazon EBS User Guide*. For information about the metrics provided for your EC2 Fleets and Spot Fleets, see Monitor your EC2 Fleet or Spot Fleet using CloudWatch.

Status check metrics

By default, status check metrics are available at a 1-minute frequency at no charge. For a newly-launched instance, status check metric data is only available after the instance has completed the initialization state (within a few minutes of the instance entering the running state). For more information about EC2 status checks, see Status checks for Amazon EC2 instances.

The AWS/EC2 namespace includes the following status check metrics.

Metric	Description	Unit	Meaningful statistics
StatusCheckFailed	Reports whether the instance has passed all status checks in the last minute. This metric can be either 0 (passed) or 1 (failed).	Count	• Average • Minimum • Maximum

Metric	Description	Unit	Meaningful statistics
	By default, this metric is available at a 1-minute frequency at no charge.		
`StatusCheckFailed_Instance`	Reports whether the instance has passed the instance status check in the last minute. This metric can be either `0` (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge.	Count	• Average • Minimum • Maximum
`StatusCheckFailed_System`	Reports whether the instance has passed the system status check in the last minute. This metric can be either `0` (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge.	Count	• Average • Minimum • Maximum
`StatusCheckFailed_AttachedEBS`	Reports whether the instance has passed the attached EBS status check in the last minute. This metric can be either `0` (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge.	Count	• Average • Minimum • Maximum

The `AWS/EBS` namespace includes the following status check metric.

Metric	Description	Unit	Meaningful statistics
VolumeStalledIOCheck	**Note:** For Nitro instances only. Not published for volumes attached to Amazon ECS and AWS Fargate tasks. Reports whether a volume has passed or failed a *stalled IO check* in the last minute. This metric can be either `0` (passed) or `1` (failed).	None	• Average • Minimum • Maximum

Traffic mirroring metrics

The `AWS/EC2` namespace includes metrics for mirrored traffic. For more information, see Monitor mirrored traffic using Amazon CloudWatch in the *Amazon VPC Traffic Mirroring Guide*.

Auto Scaling group metrics

The `AWS/AutoScaling` namespace includes metrics for Auto Scaling groups. For more information, see Monitor CloudWatch metrics for your Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

Amazon EC2 metric dimensions

You can use the following dimensions to refine the metrics listed in the previous tables.

Dimension	Description
`AutoScalingGroupName`	This dimension filters the data you request for all instances in a specified capacity group. An *Auto Scaling group* is a collection of instances you define if you're using Auto Scaling. This dimension is available only for Amazon EC2 metrics when the instances are in such an Auto Scaling group. Available for instances with Detailed or Basic Monitoring enabled.
`ImageId`	This dimension filters the data you request for all instances running this Amazon EC2 Amazon Machine Image (AMI). Available for instances with Detailed Monitoring enabled.

Dimension	Description
`InstanceId`	This dimension filters the data you request for the identified instance only. This helps you pinpoint an exact instance from which to monitor data.
`InstanceType`	This dimension filters the data you request for all instances running with this specified instance type. This helps you categorize your data by the type of instance running. For example, you might compare data from an m1.small instance and an m1.large instance to determine which has the better business value for your application. Available for instances with Detailed Monitoring enabled.

Amazon EC2 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon EC2 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see AWS usage metrics in the *Amazon CloudWatch User Guide*.

Amazon EC2 publishes the following metrics in the `AWS/Usage` namespace.

Metric	Description
`ResourceCount`	The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric. The most useful statistic for this metric is `MAXIMUM`, which represents the maximum number of resources used during the 1-minute period.

The following dimensions are used to refine the usage metrics that are published by Amazon EC2.

Dimension	Description
`Service`	The name of the AWS service containing the resource. For Amazon EC2 usage metrics, the value for this dimension is `EC2`.
`Type`	The type of entity that is being reported. Currently, the only valid value for Amazon EC2 usage metrics is `Resource`.
`Resource`	The type of resource that is running. Currently, the only valid value for Amazon EC2 usage metrics is `vCPU`, which returns information on instances that are running.
`Class`	The class of resource being tracked. For Amazon EC2 usage metrics with `vCPU` as the value of the `Resource` dimension, the valid values are `Standard/OnDemand` , `F/OnDemand` , `G/OnDemand` , `Inf/OnDemand` , `P/OnDemand` , and `X/OnDemand` . The values for this dimension define the first letter of the instance types that are reported by the metric. For example, `Standard/OnDemand` returns information about all running instances with types that start with A, C, D, H, I, M, R, T, and Z, and `G/OnDemand` returns information about all running instances with types that start with G.

Install and configure the CloudWatch agent using the Amazon EC2 console to add additional metrics

Installing and configuring the CloudWatch agent using the Amazon EC2 console is in beta for Amazon EC2 and is subject to change.

By default, Amazon CloudWatch provides basic metrics, such as `CPUUtilization` and `NetworkIn`, for monitoring your Amazon EC2 instances. To collect additional metrics, you can install the CloudWatch agent on your EC2 instances, and then configure the agent to emit selected metrics. Instead of manually installing and configuring the CloudWatch agent on every EC2 instance, you can use the Amazon EC2 console to do this for you.

This topic explains how you can use the Amazon EC2 console to install the CloudWatch agent on your instances and configure the agent to emit selected metrics.

For the manual steps for this process, see Installing the CloudWatch agent using AWS Systems Manager in the *Amazon CloudWatch User Guide*. For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

Topics

Prerequisites

To use Amazon EC2 to install and configure the CloudWatch agent, you must meet the user and instance prerequisites described in this section.

User prerequisites

To use this feature, your IAM console user or role must have the permissions required for using Amazon EC2 and the following IAM permissions:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameter",
                "ssm:PutParameter"
            ],
            "Resource": "arn:aws:ssm:*:*:parameter/EC2-Custom-Metrics-*"
        },
        {

                "Action": [
                    "iam:GetInstanceProfile",
                    "iam:SimulatePrincipalPolicy"
                ],
                "Resource": "*"
            }
        ]
}
```

Instance prerequisites

- Instance state: `running`
- Supported operating system: Linux
- AWS Systems Manager Agent (SSM Agent): Installed. Two notes about SSM Agent:
  - SSM Agent is preinstalled on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. For information about the supported AMIs and the instructions for installing SSM Agent, see Amazon Machine Images (AMIs) with SSM Agent preinstalled in the *AWS Systems Manager User Guide*.
  - If you experience issues with the SSM Agent, see Troubleshooting SSM Agent in the *AWS Systems Manager User Guide*.
- IAM permissions for the instance: The following AWS managed policies must be added to an IAM role that is attached to the instance:
  - AmazonSSMManagedInstanceCore – Enables an instance to use Systems Manager to install and configure the CloudWatch agent.
  - CloudWatchAgentServerPolicy – Enables an instance to use the CloudWatch agent to write data to CloudWatch.

For information about how to add IAM permissions to your instance, see [Use instance profiles](#) in the *IAM User Guide*.

How it works

Before you can use the Amazon EC2 console to install and configure the CloudWatch agent, you must make sure that your IAM user or role, and the instances on which you want to add metrics, meet certain prerequisites. Then, you can use the Amazon EC2 console to install and configure the CloudWatch agent on your selected instances.

First meet the prerequisites

- **You need the required IAM permissions –** Before you get started, make sure that your console user or role has the required IAM permissions to use this feature.
- **Instances –** To use the feature, your EC2 instances must be Linux instances, have the SSM Agent installed, have the required IAM permissions, and be running.

Then you can use the feature

1. **Select your instances –** In the Amazon EC2 console, you select the instances on which to install and configure the CloudWatch agent. You then start the process by choosing **Configure CloudWatch agent**.
2. **Validate SSM Agent –** Amazon EC2 checks that the SSM Agent is installed and started on each instance. Any instances that fail this check are excluded from the process. The SSM Agent is used for performing actions on the instance during this process.
3. **Validate IAM permissions –** Amazon EC2 checks that each instance has the required IAM permissions for this process. Any instances that fail this check are excluded from the process. The IAM permissions enable the CloudWatch agent to collect metrics from the instance and integrate with AWS Systems Manager to use the SSM Agent.
4. **Validate CloudWatch agent –** Amazon EC2 checks that the CloudWatch agent is installed and running on each instance. If any instances fail this check, Amazon EC2 offers to install and start the CloudWatch agent for you. The CloudWatch agent will collect the selected metrics on each instance once this process is completed.
5. **Select metric configuration –** You select the metrics for the CloudWatch agent to emit from your instances. Once selected, Amazon EC2 stores a configuration file in Parameter Store, where it remains until the process is completed. Amazon EC2 will delete the configuration file from

Parameter Store unless the process is interrupted. Note that if you don't select a metric, but you previously added it to your instance, it will be removed from your instance when this process is completed.

6. **Update CloudWatch agent configuration** – Amazon EC2 sends the metric configuration to the CloudWatch agent. This is the last step in the process. If it succeeds, your instances can emit data for the selected metrics and Amazon EC2 deletes the configuration file from Parameter Store.

Costs

Additional metrics that you add during this process are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

Install and configure the CloudWatch agent

You can use the Amazon EC2 console to install and configure the CloudWatch agent to add additional metrics.

> **Note**
>
> Every time you perform this procedure, you overwrite the existing CloudWatch agent configuration. If you don't select a metric that was selected previously, it will be removed from the instance.

To install and configure the CloudWatch agent using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instances on which to install and configure the CloudWatch agent.
4. Choose **Actions**, **Monitor and troubleshoot**, **Configure CloudWatch agent**.

   > **Tip**
   >
   > This feature is not available in all AWS Regions. If **Configure CloudWatch agent** is not available, try another Region.

5. For each step in the process, read the console text, and then choose **Next**.
6. To complete the process, in the final step, choose **Complete**.

Statistics for CloudWatch metrics for your instances

You can get statistics for the CloudWatch metrics for your instances. *Statistics* are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other services in AWS to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify. The following table describes the available statistics.

Statistic	Description
`Minimum`	The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.
`Maximum`	The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.
`Sum`	All values submitted for the matching metric added together. This statistic can be useful for determining the total volume of a metric.
`Average`	The value of `Sum` / `SampleCount` during the specified period. By comparing this statistic with the `Minimum` and `Maximum`, you can determine the full scope of a metric and how close the average use is to the `Minimum` and `Maximum`. This comparison helps you to know when to increase or decrease your resources as needed.
`SampleCount`	The count (number) of data points used for the statistical calculation.
`pNN.NN`	The value of the specified percentile. You can specify any percentile, using up to two decimal places (for example, p95.45).

Contents

Get statistics for a specific instance

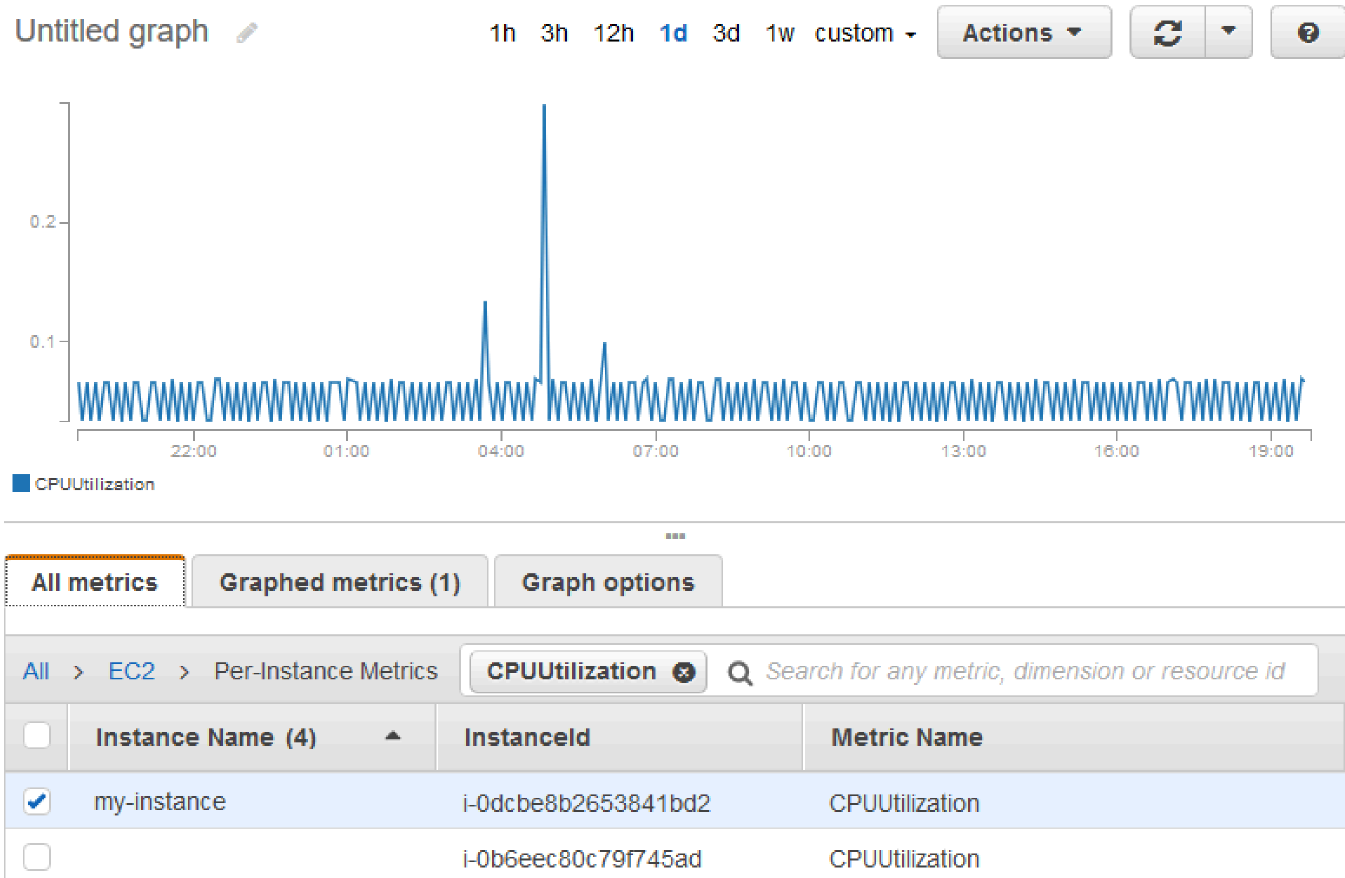
You can use the AWS Management Console or the AWS CLI to get statistics for a specific instance. The following examples show you how to use the AWS Management Console or the AWS CLI to determine the maximum CPU utilization of a specific EC2 instance.

Requirements

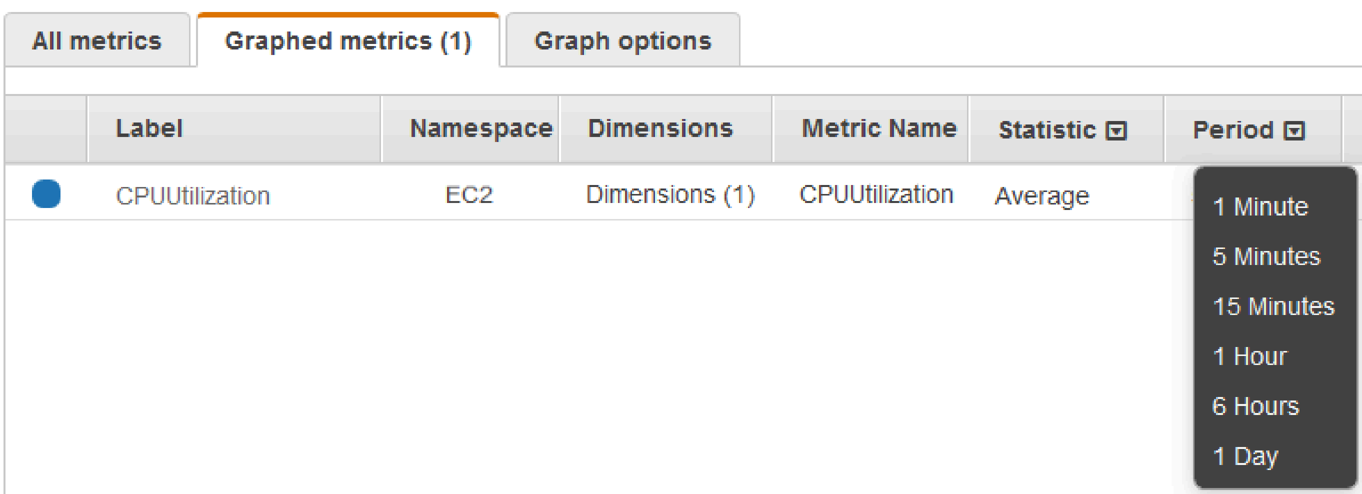
- You must have the ID of the instance. You can get the instance ID using the AWS Management Console or the describe-instances command.
- By default, basic monitoring is enabled, but you can enable detailed monitoring. For more information, see Manage detailed monitoring for your EC2 instances.

To display the CPU utilization for a specific instance (console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** metric namespace.
4. Choose the **Per-Instance Metrics** dimension.
5. In the search field, enter **`CPUUtilization`** and press Enter. Choose the row for the specific instance, which displays a graph for the **CPUUtilization** metric for the instance. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.



6. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.



To get the CPU utilization for a specific instance (AWS CLI)

Use the following get-metric-statistics command to get the **CPUUtilization** metric for the specified instance, using the specified period and time interval:

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization
 --period 3600 \
--statistics Maximum --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
--start-time 2022-10-18T23:18:00 --end-time 2022-10-19T23:18:00
```

The following is example output. Each value represents the maximum CPU utilization percentage for a single EC2 instance.

```
{
    "Datapoints": [
        {
            "Timestamp": "2022-10-19T00:18:00Z",
            "Maximum": 0.33000000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-19T03:18:00Z",
            "Maximum": 99.670000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-19T07:18:00Z",
            "Maximum": 0.34000000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-19T12:18:00Z",
            "Maximum": 0.34000000000000002,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Aggregate statistics across instances

Aggregate statistics are available for instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics aggregated across instances, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods.

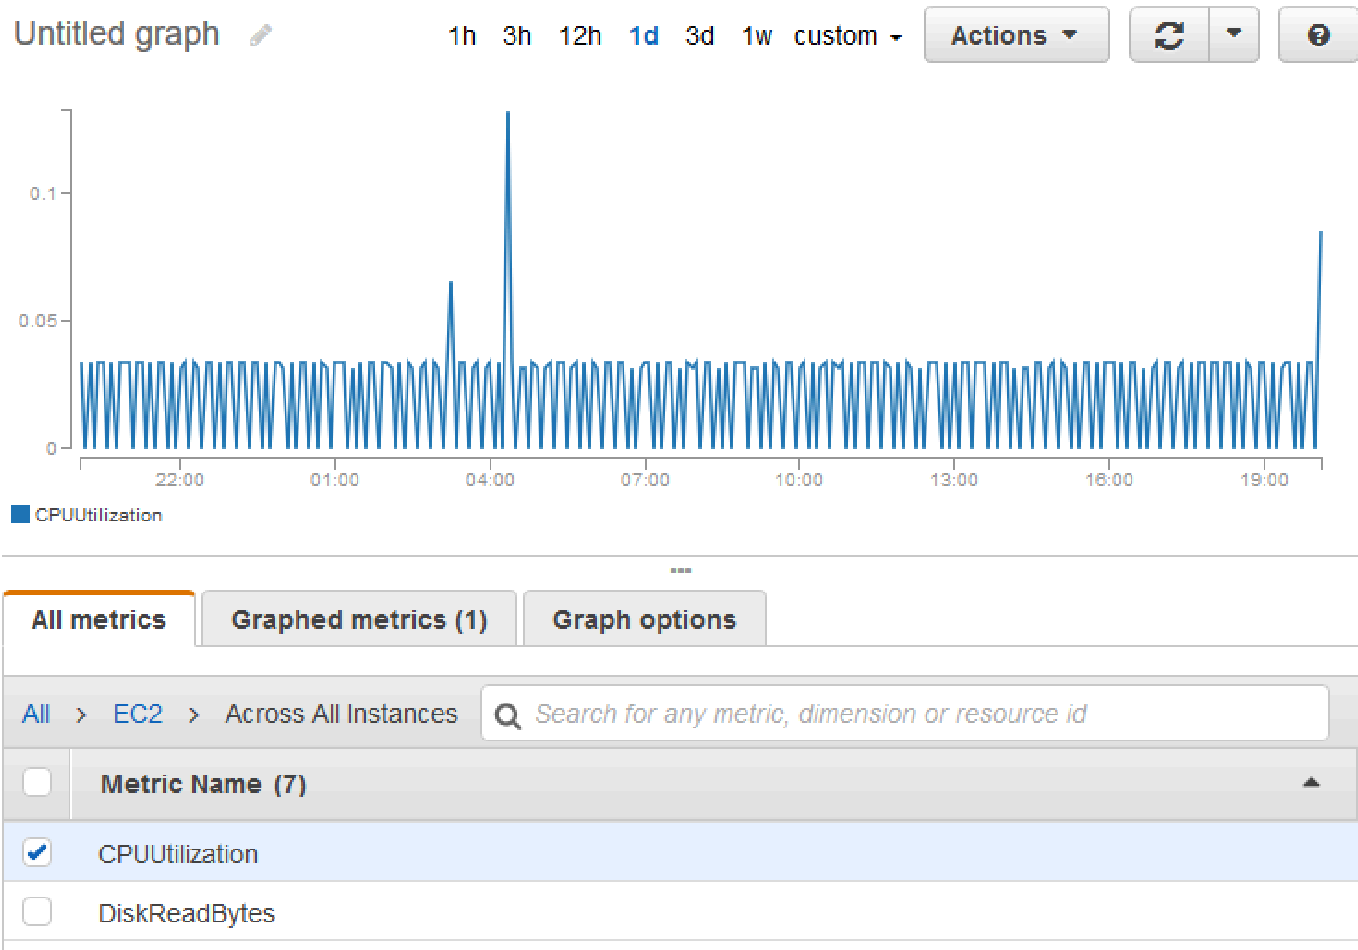
Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to use detailed monitoring to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the `AWS/EC2` namespace.

> **Important**
>
> This technique for retrieving all dimensions across an AWS namespace does not work for custom namespaces that you publish to Amazon CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

To display average CPU utilization across your instances (console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **Across All Instances**.
4. Choose the row that contains **CPUUtilization**, which displays a graph for the metric for all your EC2 instances. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.



5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get average CPU utilization across your instances (AWS CLI)

Use the get-metric-statistics command as follows to get the average of the **CPUUtilization** metric across your instances.

```
aws cloudwatch get-metric-statistics \
    --namespace AWS/EC2 \
    --metric-name CPUUtilization \
    --period 3600  --statistics "Average" "SampleCount" \
    --start-time 2022-10-11T23:18:00 \
    --end-time 2022-10-12T23:18:00
```

The following is example output:

```
{
    "Datapoints": [
        {
            "SampleCount": 238.0,
            "Timestamp": "2022-10-12T07:18:00Z",
            "Average": 0.038235294117647062,
            "Unit": "Percent"
        },
        {
            "SampleCount": 240.0,
            "Timestamp": "2022-10-12T09:18:00Z",
            "Average": 0.16670833333333332,
            "Unit": "Percent"
        },
        {
            "SampleCount": 238.0,
            "Timestamp": "2022-10-11T23:18:00Z",
            "Average": 0.041596638655462197,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Aggregate statistics by Auto Scaling group

You can aggregate statistics for the EC2 instances in an Auto Scaling group. Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to retrieve the total bytes written to disk for one Auto Scaling group. The total is computed for 1-minute periods for a 24-hour interval across all EC2 instances in the specified Auto Scaling group.

To display DiskWriteBytes for the instances in an Auto Scaling group (console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **By Auto Scaling Group**.
4. Choose the row for the **DiskWriteBytes** metric and the specific Auto Scaling group, which displays a graph for the metric for the instances in the Auto Scaling group. To name the graph,

choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.

5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To display DiskWriteBytes for the instances in an Auto Scaling group (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name DiskWriteBytes
 --period 360 \
--statistics "Sum" "SampleCount" --dimensions Name=AutoScalingGroupName,Value=my-asg --
start-time 2022-10-16T23:18:00 --end-time 2022-10-18T23:18:00
```

The following is example output:

```
{
    "Datapoints": [
        {
            "SampleCount": 18.0,
            "Timestamp": "2022-10-19T21:36:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        },
        {
            "SampleCount": 5.0,
            "Timestamp": "2022-10-19T21:42:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        }
    ],
    "Label": "DiskWriteBytes"
}
```

Aggregate statistics by AMI

You can aggregate statistics by AMI for your instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics aggregated across instances, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods.

Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to determine average CPU utilization for all instances that use a specific Amazon Machine Image (AMI). The average is over 60-second time intervals for a one-day period.

To display the average CPU utilization by AMI (console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **EC2** namespace and then choose **By Image (AMI) Id**.
4. Choose the row for the **CPUUtilization** metric and the specific AMI, which displays a graph for the metric for the specified AMI. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.
5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get the average CPU utilization for an image ID (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization
 --period 3600 \
--statistics Average --dimensions Name=ImageId,Value=ami-3c47a355 --start-
time 2022-10-10T00:00:00 --end-time 2022-10-11T00:00:00
```

The following is example output. Each value represents an average CPU utilization percentage for the EC2 instances running the specified AMI.

```
{
    "Datapoints": [
        {
            "Timestamp": "2022-10-10T07:00:00Z",
            "Average": 0.041000000000000009,
            "Unit": "Percent"
        },
        {
```

```
            "Timestamp": "2022-10-10T14:00:00Z",
            "Average": 0.079579831932773085,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2022-10-10T06:00:00Z",
            "Average": 0.036000000000000011,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

View the monitoring graphs for your instances

After you launch an instance, you can open the Amazon EC2 console and view the monitoring graphs for the instance on the **Monitoring** tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs are available:

- Average CPU Utilization (Percent)
- Average Disk Reads (Bytes)
- Average Disk Writes (Bytes)
- Maximum Network In (Bytes)
- Maximum Network Out (Bytes)
- Summary Disk Read Operations (Count)
- Summary Disk Write Operations (Count)
- Summary Status (Any)
- Summary Status Instance (Count)
- Summary Status System (Count)

For more information about the metrics and the data they provide to the graphs, see CloudWatch metrics that are available for your instances.

Graph metrics using the CloudWatch console

You can also use the CloudWatch console to graph metric data generated by Amazon EC2 and other AWS services. For more information, see Graphing metrics in the *Amazon CloudWatch User Guide*.

Create a CloudWatch alarm for an instance

You can create a CloudWatch alarm that monitors CloudWatch metrics for one of your instances. CloudWatch will automatically send you a notification when the metric reaches a threshold you specify. You can create a CloudWatch alarm using the Amazon EC2 console, or using the more advanced options provided by the CloudWatch console.

To create an alarm using the CloudWatch console

For examples, see Creating Amazon CloudWatch Alarms in the *Amazon CloudWatch User Guide*.

To create an alarm using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.
4. On the **Manage CloudWatch alarms** detail page, under **Add or edit alarm**, select **Create an alarm**.
5. For **Alarm notification**, choose whether to configure Amazon Simple Notification Service (Amazon SNS) notifications. Enter an existing Amazon SNS topic or enter a name to create a new topic.
6. For **Alarm action**, choose whether to specify an action to take when the alarm is triggered. Choose an action from the list.
7. For **Alarm thresholds**, select the metric and criteria for the alarm. For example, to create an alarm that is triggered when CPU utilization reaches 80% for a 5 minute period, do the following:

    a. Keep the default setting for **Group samples by** (**Average**) and **Type of data to sample** (**CPU utilization**).
    b. Choose **>=** for **Alarm when** and enter `0.80` for **Percent**.
    c. Enter **1** for **Consecutive period** and select **5 minutes** for **Period**.
8. (Optional) For **Sample metric data**, choose **Add to dashboard**.

9. Choose **Create**.

You can edit your CloudWatch alarm settings from the Amazon EC2 console or the CloudWatch console. If you want to delete your alarm, you can do so from the CloudWatch console. For more information, see Edit or delete a CloudWatch alarm in the *Amazon CloudWatch User Guide*.

Create alarms that stop, terminate, reboot, or recover an instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

> **Note**
>
> For Amazon CloudWatch alarms billing and pricing information, see CloudWatch billing and cost in the *Amazon CloudWatch User Guide*.

The `AWSServiceRoleForCloudWatchEvents` service-linked role enables AWS to perform alarm actions on your behalf. The first time you create an alarm in the AWS Management Console, the AWS CLI, or the IAM API, CloudWatch creates the service-linked role for you.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which can help you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily start a stopped instance if you need to run it again later, and you can keep the same instance ID and root volume. However, you cannot start a terminated instance. Instead, you must launch a new instance. When an instance is stopped or terminated, data on instance store volumes is lost.

You can add the stop, terminate, reboot, or recover actions to any alarm that is set on an Amazon EC2 per-instance metric, including basic and detailed monitoring metrics provided by Amazon CloudWatch (in the `AWS/EC2` namespace), as well as any custom metrics that include the `InstanceId` dimension, as long as its value refers to a valid running Amazon EC2 instance.

> **Important**
>
> Status check alarms can temporarily enter the `INSUFFICIENT_DATA` state if there are missing metric data points. Although rare, this can happen when there is an interruption in the metric reporting systems, even when an instance is healthy. We recommend that you treat the `INSUFFICIENT_DATA` state as missing data instead of an alarm breach, especially when configuring the alarm to stop, terminate, reboot, or recover an instance.

Console support

You can create alarms using the Amazon EC2 console or the CloudWatch console. The procedures in this documentation use the Amazon EC2 console. For procedures that use the CloudWatch console, see [Create alarms that stop, terminate, reboot, or recover an instance](#) in the *Amazon CloudWatch User Guide*.

Permissions

You must have the `iam:CreateServiceLinkedRole` to create or modify an alarm that performs EC2 alarm actions. A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

Contents

Add stop actions to Amazon CloudWatch alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an Amazon Simple Notification Service (Amazon SNS) notification so that you receive an email when the alarm is triggered.

Instances that use an Amazon EBS volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated. Data on instance store volumes is lost when the instance is terminated or stopped.

To create an alarm to stop an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (+) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person (A2P) messaging]() in the *Amazon Simple Notification Service Developer Guide*.

   c. Toggle on **Alarm action**, and choose **Stop**.

   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **CPU utilization**.

   e. For **Alarm When** and **Percent**, specify the metric threshold. In this example, specify **<=** and **10** percent.

   f. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, specify **1** consecutive period of **5 Minutes**.

   g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

> **Note**
>
> You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

h. Choose **Create**.

Add terminate actions to Amazon CloudWatch alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don't need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. Data on instance store volumes is lost when the instance is terminated. For information about enabling and disabling termination protection for an instance, see [Change instance termination protection](#).

To create an alarm to terminate an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (
   +
) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person (A2P) messaging](#) in the *Amazon Simple Notification Service Developer Guide*.

c. Toggle on **Alarm action**, and choose **Terminate**.

d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **CPU utilization**.

e. For **Alarm When** and **Percent**, specify the metric threshold. In this example, specify **=>** and **10** percent.

f. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, specify **24** consecutive periods of **1 Hour**.

g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

> **Note**
>
> You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

h. Choose **Create**.

Add reboot actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and restarting your instance. Data on instance store volumes is retained when the instance is rebooted. The instance store volumes must be re-mounted into the filesystem after a reboot. For more information, see Reboot your Amazon EC2 instance.

> **Important**
>
> To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each. For more information, see Evaluating an alarm in the *Amazon CloudWatch User Guide*.

To create an alarm to reboot an instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (
   +
) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the *Amazon Simple Notification Service Developer Guide*.

   c. Toggle on **Alarm action**, and choose **Reboot**.

   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **Status check failed: instance**.

   e. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, enter **3** consecutive periods of **1 Minute**. If **1 Minute is disabled**, you must enable detailed monitoring, or you can choose **5 Minutes** instead.

   f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

   g. Choose **Create**.

Add recover actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance. If the instance becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair, you can automatically recover the instance. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

CloudWatch prevents you from adding a recovery action to an alarm that is on an instance which does not support recovery actions.

When the `StatusCheckFailed_System` alarm is triggered, and the recover action is initiated, you are notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic receives an email notification that includes the status of the recovery attempt and any further instructions. You notice an instance reboot on the recovered instance.

> **Note**
>
> The recover action can be used only with `StatusCheckFailed_System`, not with `StatusCheckFailed_Instance`.

The following problems can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

The recover action is supported only on instances that meet certain characteristics. For more information, see [Automatic instance recovery](#).

If your instance has a public IP address, it retains the public IP address after recovery.

> **Important**
>
> To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each. For more information, see Evaluating an alarm in the *Amazon CloudWatch User Guide*.

To create an alarm to recover an instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **Manage CloudWatch alarms**.

   Alternatively, you can choose the plus sign (
   +
) in the **Alarm status** column.
4. On the **Manage CloudWatch alarms** page, do the following:

   a. Choose **Create an alarm**.

   b. To receive an email when the alarm is triggered, for **Alarm notification**, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the *Amazon Simple Notification Service Developer Guide*.

   > **Note**
   >
   > Users must subscribe to the specified SNS topic to receive email notifications when the alarm is triggered. The AWS account root user always receives email notifications when automatic instance recovery actions occur, even if an SNS topic is not specified or the root user is not subscribed to the specified SNS topic.

   c. Toggle on **Alarm action**, and choose **Recover**.

   d. For **Group samples by** and **Type of data to sample**, choose a statistic and a metric. In this example, choose **Average** and **Status check failed: system**.

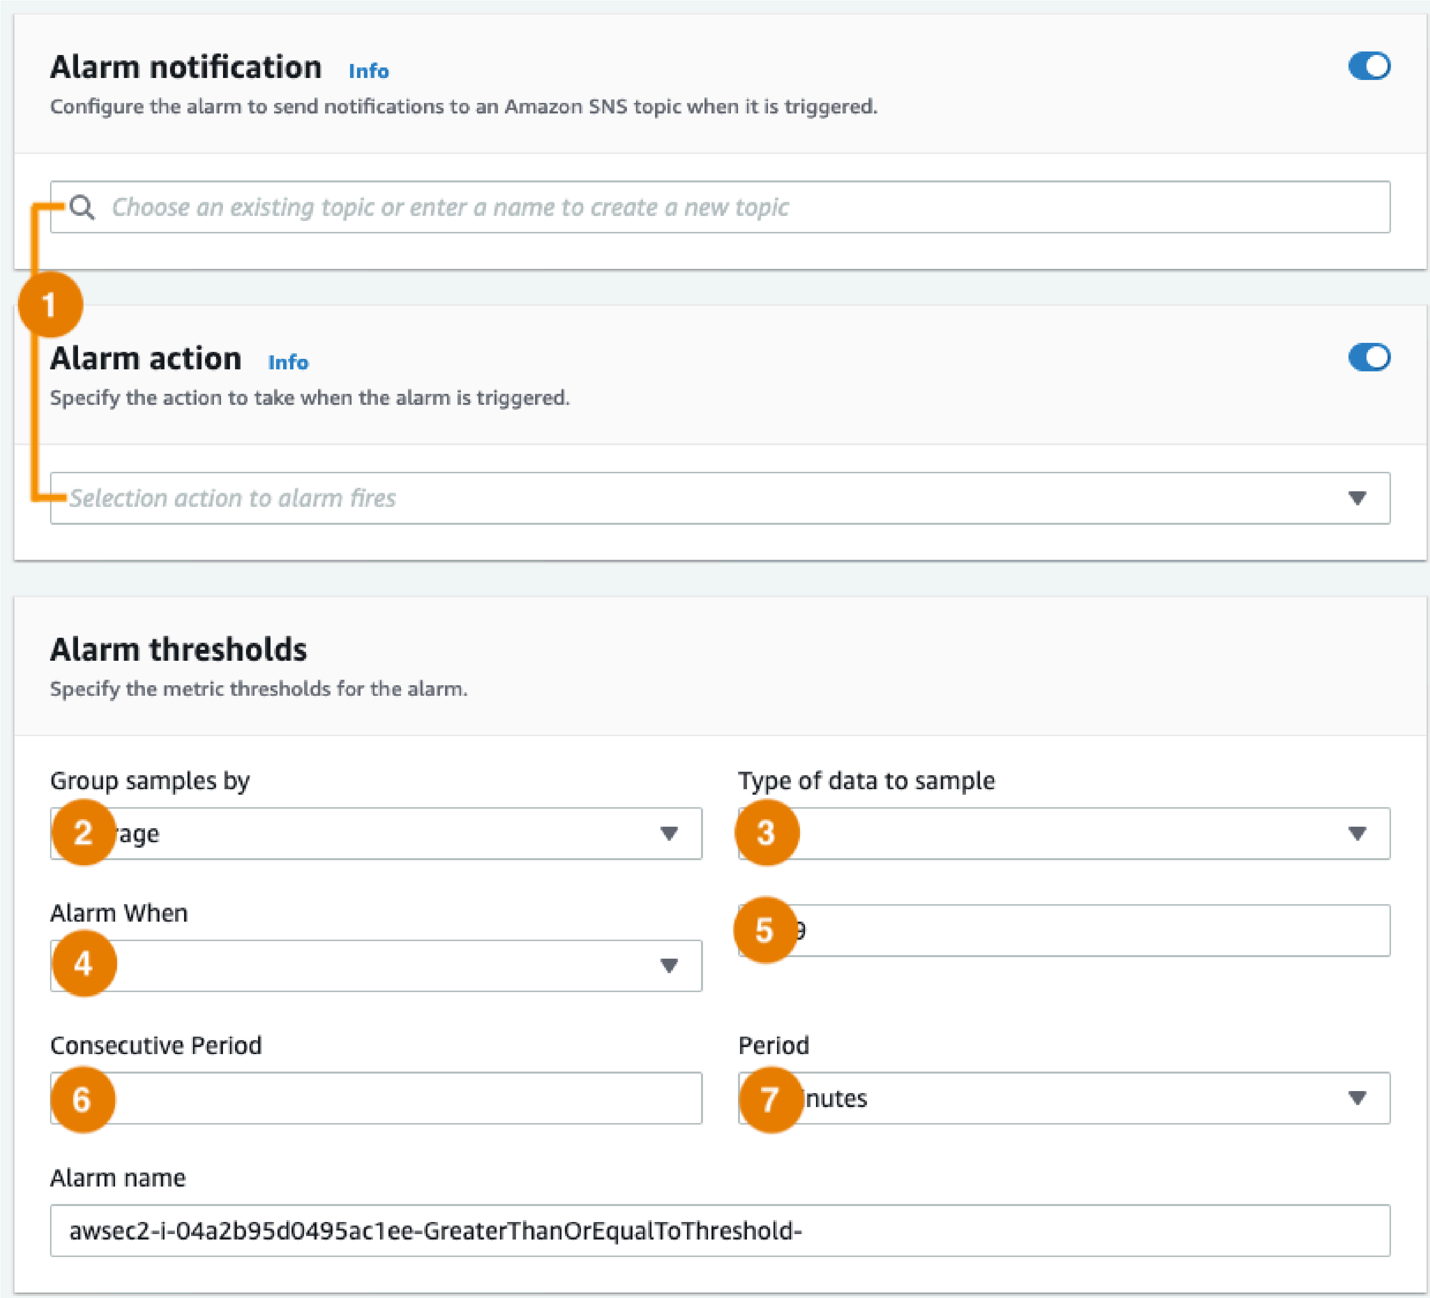
e. For **Consecutive period** and **Period**, specify the evaluation period for the alarm. In this example, enter **2** consecutive periods of **1 Minute**. If **1 Minute is disabled**, you must enable detailed monitoring, or you can choose **5 Minutes** instead.

f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for **Alarm name**, enter a new name. Alarm names must contain only ASCII characters.

g. Choose **Create**.

Amazon CloudWatch alarm action scenarios

You can use the Amazon EC2 console to create alarm actions that stop or terminate an Amazon EC2 instance when certain conditions are met. In the following screen capture of the console page where you set the alarm actions, we've numbered the settings. We've also numbered the settings in the scenarios that follow, to help you create the appropriate actions.



Scenario 1: Stop idle development and test instances

Create an alarm that stops an instance used for software development or testing when it has been idle for at least an hour.

Setting	Value
1	Stop

Setting	Value
2	Maximum
3	CPU Utilization
4	<=
5	10%
6	1
7	1 Hour

Scenario 2: Stop idle instances

Create an alarm that stops an instance and sends an email when the instance has been idle for 24 hours.

Setting	Value
1	Stop and email
2	Average
3	CPU Utilization
4	<=
5	5%
6	24
7	1 Hour

Scenario 3: Send email about web servers with unusually high traffic

Create an alarm that sends email when an instance exceeds 10 GB of outbound network traffic per day.

Setting	Value
1	Email
2	Sum
3	Network Out
4	>
5	10 GB
6	24
7	1 Hour

Scenario 4: Stop web servers with unusually high traffic

Create an alarm that stops an instance and send a text message (SMS) if outbound traffic exceeds 1 GB per hour.

Setting	Value
1	Stop and send SMS
2	Sum
3	Network Out
4	>
5	1 GB
6	1
7	1 Hour

Scenario 5: Stop an impaired instance

Create an alarm that stops an instance that fails three consecutive status checks (performed at 5-minute intervals).

Setting	Value
1	Stop
2	Average
3	Status Check Failed: System
4	-
5	-
6	1
7	15 Minutes

Scenario 6: Terminate instances when batch processing jobs are complete

Create an alarm that terminates an instance that runs batch jobs when it is no longer sending results data.

Setting	Value
1	Terminate
2	Maximum
3	Network Out
4	<=
5	100,000 bytes
6	1

Setting	Value
7	5 Minutes

Automate Amazon EC2 using EventBridge

You can use Amazon EventBridge to automate your AWS services and respond automatically to system events, such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can create rules to indicate which events you're interested in, and the actions to take when an event matches a rule. The actions that can be automatically triggered include the following:

- Invoke an AWS Lambda function
- Invoke Amazon EC2 Run Command
- Relay the event to Amazon Kinesis Data Streams
- Activate an AWS Step Functions state machine
- Notify an Amazon SNS topic
- Notify an Amazon SQS queue

The following are examples of how you can use EventBridge with Amazon EC2:

- Activate a Lambda function whenever an instance enters the running state.
- Notify an Amazon SNS topic when an Amazon EBS volume is created or modified.
- Send a command to one or more Amazon EC2 instances using Amazon EC2 Run Command whenever a certain event in another AWS service occurs.

For more information, see the Amazon EventBridge User Guide.

Amazon EC2 event types

Amazon EC2 supports the following event types:

- EC2 AMI State Change
- EC2 Fast Launch State-change Notification

- EC2 Fleet Error
- EC2 Fleet Information
- EC2 Fleet Instance Change
- EC2 Fleet Spot Instance Request Change
- EC2 Fleet State Change
- EC2 Instance Rebalance Recommendation
- EC2 Instance State-change Notification
- EC2 Spot Fleet Error
- EC2 Spot Fleet Information
- EC2 Spot Fleet Instance Change
- EC2 Spot Fleet Spot Instance Request Change
- EC2 Spot Fleet State Change
- EC2 Spot Instance Interruption Warning
- EC2 Spot Instance Request Fulfillment
- EC2 ODCR Underutilization Notification

For information about the event types supported by Amazon EBS, see Amazon EventBridge for Amazon EBS.

Log Amazon EC2 API calls using AWS CloudTrail

The Amazon EC2 API is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all Amazon EC2 API calls as events. The calls captured include calls made by the console. Using the information collected by CloudTrail, you can determine the request that was made to the Amazon EC2 API, the IP address from which the request was made, and when it was made.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.

- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a trail for your AWS account and Creating a trail for an organization in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

Amazon EC2 API management events in CloudTrail

Management events provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

All Amazon EC2 API actions are logged as management events. For a list of the API actions that are logged to CloudTrail, see the Amazon EC2 API Reference. For example, calls to the RunInstances, DescribeInstances, and StopInstances actions are logged as management events.

Amazon EC2 API event examples

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

The following log file record shows that a user terminated an instance.

```
{
   "Records":[
      {
         "eventVersion":"1.03",
         "userIdentity":{
            "type":"Root",
            "principalId":"123456789012",
            "arn":"arn:aws:iam::123456789012:root",
            "accountId":"123456789012",
            "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
            "userName":"user"
         },
         "eventTime":"2016-05-20T08:27:45Z",
         "eventSource":"ec2.amazonaws.com",
         "eventName":"TerminateInstances",
         "awsRegion":"us-west-2",
         "sourceIPAddress":"198.51.100.1",

         "requestParameters":{
```

```
            "instancesSet":{
               "items":[{
                  "instanceId":"i-1a2b3c4d"
               }]
            }
         },
         "responseElements":{
            "instancesSet":{
               "items":[{
                  "instanceId":"i-1a2b3c4d",
                  "currentState":{
                     "code":32,
                     "name":"shutting-down"
                  },
                  "previousState":{
                     "code":16,
                     "name":"running"
                  }
               }]
            }
         },
         "requestID":"be112233-1ba5-4ae0-8e2b-1c302EXAMPLE",
         "eventID":"6e12345-2a4e-417c-aa78-7594fEXAMPLE",
         "eventType":"AwsApiCall",
         "recipientAccountId":"123456789012"
      }
   ]
}
```

For information about CloudTrail record contents, see CloudTrail record contents in the *AWS CloudTrail User Guide*.

Audit connections made using EC2 Instance Connect

You can use AWS CloudTrail to audit the users that connect to your instances using EC2 Instance Connect.

To audit SSH activity via EC2 Instance Connect using the AWS CloudTrail console

1. Open the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. Verify that you are in the correct Region.
3. In the navigation pane, choose **Event history**.

4. For **Filter**, choose **Event source**, **ec2-instance-connect.amazonaws.com**.
5. (Optional) For **Time range**, select a time range.
6. Choose the **Refresh events** icon.
7. The page displays the events that correspond to the SendSSHPublicKey API calls. Expand an event using the arrow to view additional details, such as the user name and AWS access key that was used to make the SSH connection, and the source IP address.
8. To display the full event information in JSON format, choose **View event**. The **requestParameters** field contains the destination instance ID, OS username, and public key that were used to make the SSH connection.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "ABCDEFGONGNOMOOCB6XYTQEXAMPLE",
        "arn": "arn:aws:iam::1234567890120:user/IAM-friendly-name",
        "accountId": "123456789012",
        "accessKeyId": "ABCDEFGUKZHNAW4OSN2AEXAMPLE",
        "userName": "IAM-friendly-name",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2018-09-21T21:37:58Z"}
        }
    },
    "eventTime": "2018-09-21T21:38:00Z",
    "eventSource": "ec2-instance-connect.amazonaws.com",
    "eventName": "SendSSHPublicKey ",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "123.456.789.012",
    "userAgent": "aws-cli/1.15.61 Python/2.7.10 Darwin/16.7.0 botocore/1.10.60",
    "requestParameters": {
        "instanceId": "i-0123456789EXAMPLE",
        "osUser": "ec2-user",
        "SSHKey": {
            "publicKey": "ssh-rsa ABCDEFGHIJKLMNO01234567890EXAMPLE"
        }
     },
    "responseElements": null,
    "requestID": "1a2s3d4f-bde6-11e8-a892-f7ec64543add",
    "eventID": "1a2w3d4r5-a88f-4e28-b3bf-30161f75be34",
```

```
    "eventType": "AwsApiCall",
    "recipientAccountId": "0987654321"
}
```

If you have configured your AWS account to collect CloudTrail events in an S3 bucket, you can download and audit the information programmatically. For more information, see Getting and viewing your CloudTrail log files in the *AWS CloudTrail User Guide*.

Monitor .NET and SQL Server applications using CloudWatch Application Insights

CloudWatch Application Insights helps you monitor your .NET and SQL Server applications that use Amazon EC2 instances along with other AWS application resources. It identifies and sets up key metrics logs and alarms across your application resources and technology stack (for example, your Microsoft SQL Server database, web (IIS) and application servers, OS, load balancers, and queues). It continuously monitors the metrics and logs to detect and correlate anomalies and errors. When errors and anomalies are detected, Application Insights generates events that you can use to set up notifications or take actions. To aid with troubleshooting, it creates automated dashboards for the detected problems, which include correlated metric anomalies and log errors, along with additional insights to point you to the potential root cause. The automated dashboards help you to take swift remedial actions to keep your applications healthy and to prevent impact to the end users of your application.

Information provided about detected problems:

- A short summary of the problem
- The start time and date of the problem
- The problem severity: High/Medium/Low
- The status of the detected problem: In-progress/Resolved
- Insights: Automatically generated insights on the detected problem and possible root cause
- Feedback on insights: Feedback you have provided about the usefulness of the insights generated by CloudWatch Application Insights for .NET and SQL Server
- Related observations: A detailed view of the metric anomalies and error snippets of relevant logs related to the problem across various application components

Feedback

You can provide feedback on automatically generated insights on detected problems by designating them useful or not useful. Your feedback on the insights, along with your application diagnostics (metric anomalies and log exceptions), are used to improve the future detection of similar problems.

For more information, see the CloudWatch Application Insights documentation in the *Amazon CloudWatch User Guide*.

Track your Free Tier usage for Amazon EC2

When you create your AWS account, you can get started with Amazon EC2 for free using the AWS Free Tier. Your Free Tier benefits are different depending on whether you created your account before July 15, 2025, or on or after July 15, 2025. For more information, see Explore AWS services with AWS Free Tier in the *AWS Billing User Guide*.

Free Tier benefits before and after July 15, 2025

The following table compares your Free Tier benefits based on your AWS account creation date:

Free Tier benefit	Account created before July 15, 2025	Account created on or after July 15, 2025
Instance types marked **Free tier eligible**	`t2.micro`, `t3.micro`	`t3.micro`, `t3.small`, `t4g.micro` , `t4g.small` , `c7i-flex.large` , `m7i-flex.large`
AMIs marked **Free tier eligible**	Check for AMIs marked **Free tier eligible**.	Check for AMIs marked **Free tier eligible**.
Usage limit	Restricted to usage limits, after which you are billed pay-as-you-go rates.	Receive USD $100 sign-up credit and earn up to $100 in additional credits.
Free Tier duration	Your Free Tier lasts for 12 months from the date you create your account. During	Your Free Tier lasts for 6 months from the date you created your account, or when

Free Tier benefit	Account created before July 15, 2025	Account created on or after July 15, 2025
	this time, if you exceed your Free Tier usage limits, you are billed pay-as-you-go rates.	your credits are used up, whichever happens first. You can't exceed your Free Tier limits.

To list the instance types that are free tier eligible

Use the describe-instance-types command with the `free-tier-eligible` filter.

```
aws ec2 describe-instance-types \
    --filters Name=free-tier-eligible,Values=true \
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

To list the AMIs that are free tier eligible

Use the describe-images command with the `free-tier-eligible` filter.

```
aws ec2 describe-images \
    --filters Name=free-tier-eligible,Values=true \
    --query "Images[*].[ImageId]" \
    --output text | sort
```

Track Free Tier usage for accounts created before July 15, 2025

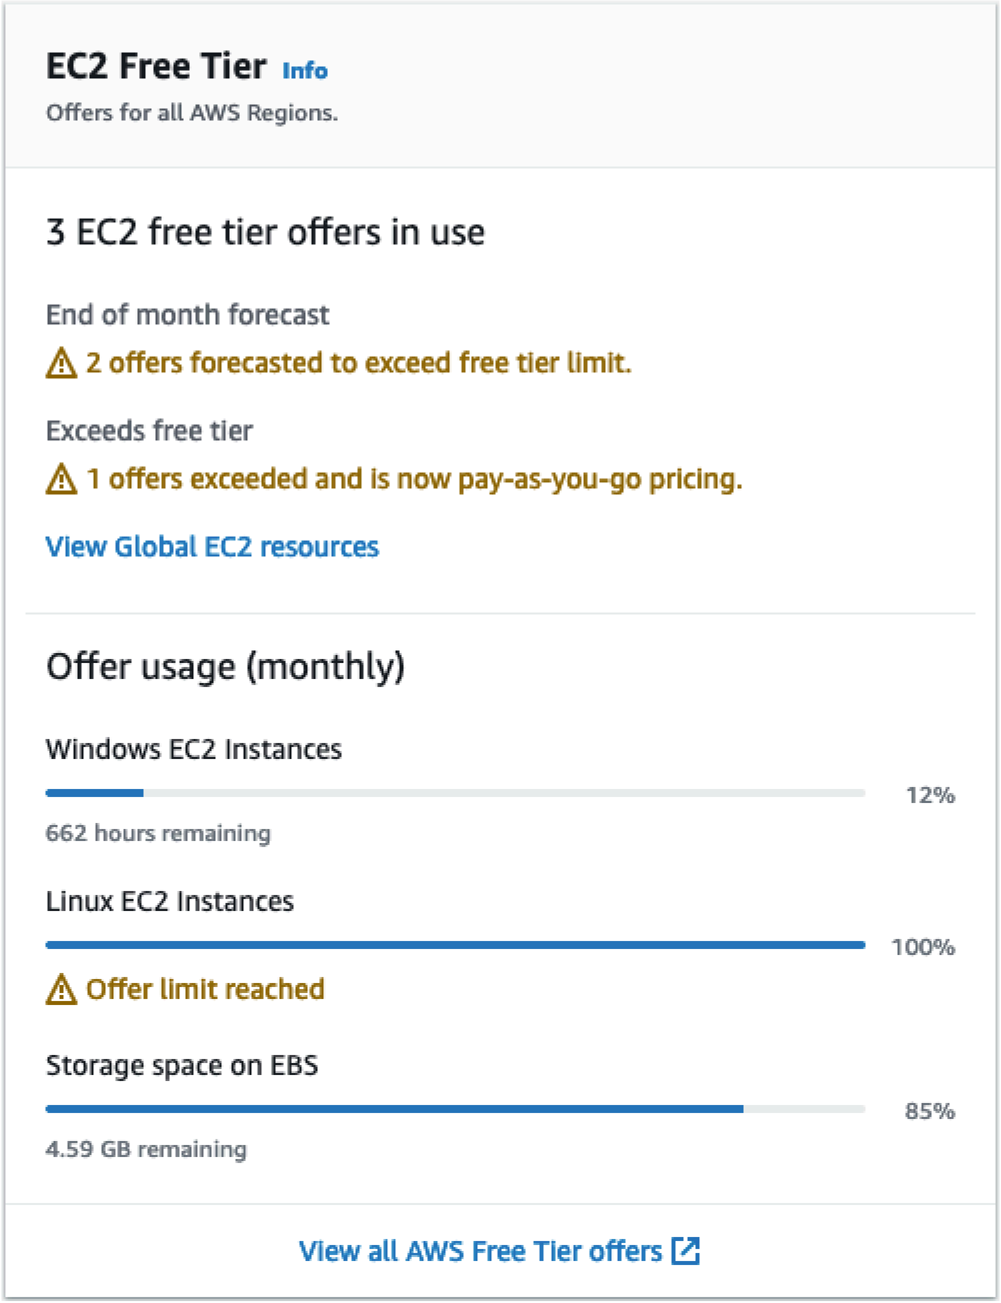
> **Note**
>
> ***This section only applies to Free Tier users who created AWS accounts before July 15, 2025. If you created your account on or after July 15, 2025, see Tracking your AWS Free Tier usage in the AWS Billing User Guide.***

If you created your account before July 15, 2025, you can use Amazon EC2 without incurring charges if you've been an AWS customer for less than 12 months and you stay within the AWS Free Tier usage limits. It's important to track your Free Tier usage to avoid billing surprises. If you exceed the Free Tier limits, you'll incur standard pay-as-go charges. For more information, see AWS Free Tier.

> **Note**
>
> If you've been an AWS customer for more than 12 months, you're no longer eligible for Free Tier usage and you won't see the **EC2 Free Tier** box that is described in the following procedure.

To track your Free Tier usage

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **EC2 Dashboard**.
3. Find the **EC2 Free Tier** box (at top right).



4. In the **EC2 Free Tier** box, check your Free Tier usage, as follows:

   - Under **EC2 Free Tier offers in use**, take note of the warnings:
     - **End of month forecast** – This warns that you will incur charges this month if you continue with your current usage pattern.
     - **Exceeds Free Tier** – This warns that you've exceeded your Free Tier limits and you're already incurring charges.

- Under **Offer usage (monthly)**, take note of your usage of Linux instances, Windows instances, and EBS storage. The percentage indicates how much of your Free Tier limits you've used this month. If you're at 100%, you will incur charges for further use.

> **Note**
>
> This information appears only after you've created an instance. However, usage information is not updated in real time; it's updated three times a day.

5. To avoid incurring further charges, delete any resources that are either incurring charges now, or will incur charges if you exceed your Free Tier limit usage.

   - For the instructions to delete your instance, see Terminate Amazon EC2 instances.
   - To check if you have resources in other Regions that might be incurring charges, in the **EC2 Free Tier** box, choose **View Global EC2 resources** to open the **EC2 Global View**. For more information, see View resources across Regions using AWS Global View.

6. To view your resource usage for all AWS services under the AWS Free Tier, at the bottom of the **EC2 Free Tier** box, choose **View all AWS Free Tier offers**. For more information, see Trying services using AWS Free Tier in the *AWS Billing User Guide*.

Understand codes for Amazon EC2 in billing and usage reports

When you use Amazon EC2, we include related codes in your AWS billing and usage reports. Reviewing these codes helps you understand your costs and usage patterns for Amazon EC2. Tracking and managing your expenses is essential for optimizing your costs.

The following tables describe the codes for Amazon EC2 that appear in your billing and usage reports. For a list of the Region codes used in the billing and usage reports, see AWS Region billing codes.

Billing codes for:

- Instances
- Bare metal instances
- Dedicated Hosts
- Dedicated Instances
- EBS optimization

- Capacity Reservations

Related resources

- the section called “Billing and purchasing options”
- the section called “Understand AMI billing”
- Amazon EC2 pricing

Instances

Code	Description	Units
region-BoxUsage :*instance-type*	The running time for On-Demand Instances.	Hours
region-HostBoxUsage :*instance-type*	The running time for instances on Dedicated Hosts.	Hours
region-SpotUsage :*instance-type*	The running time for Spot Instances.	Hours

Bare metal instances

Code	Description	Units
region-BoxUsage :*instance-family* .metal	The running time for bare metal On-Demand Instances.	Hours
region-HostBoxUsage :*instance-family* .metal	The running time for bare metal instances on Dedicated Hosts.	Hours

Code	Description	Units
region-SpotUsage :*instance-family* .metal	The running time for bare metal Spot Instances.	Hours

Dedicated Hosts

Code	Description	Units
region-HostUsage :*host-type*	The time that Dedicated Hosts are provisioned.	Hours
region-ReservedHostUsage :*host-type*	The time that Dedicated Host Reservations are applied.	Hours

Dedicated Instances

Code	Description	Units
region-DedicatedUsage :*instance-type*	The running time for Dedicated Instances.	Hours + per-Region fee

EBS optimization

Code	Description	Units
region-EBSOptimized :*instance-type*	The time that EBS optimization is enabled.	Hours

Capacity Reservations

Code	Description	Units
region-Reservation :*instance-type*	The reserved instance time for Capacity Reservations.	Hours
region-UnusedBox :*instance-type*	The unused reserved instance time for Capacity Reservations.	Hours
region-DedicatedRes :*instance-type*	The reserved instance time for Dedicated Capacity Reservations.	Hours
region-UnusedDed :*instance-type*	The unused reserved instance time for Dedicated Capacity Reservations.	Hours

Troubleshoot issues with Amazon EC2 instances

The following procedures and tips can help you troubleshoot issues with your Amazon EC2 instances.

Issues

Troubleshoot Amazon EC2 instance launch issues

The following are troubleshooting tips to help you solve issues when launching an Amazon EC2 instance.

Launch Issues

- The requested configuration is currently not supported. Please check the documentation for supported configurations.
- Instance terminates immediately
- Insufficient permissions
- High CPU usage shortly after Windows starts (Windows instances only)

Invalid device name

Description

You get the `Invalid device name` *`device_name`* error when you try to launch a new instance.

Cause

If you get this error when you try to launch an instance, the device name specified for one or more volumes in the request has an invalid device name. Possible causes include:

- The device name might be in use by the selected AMI.
- The device name might be reserved for root volumes.
- The device name might be used for another volume in the request.
- The device name might not be valid for the operating system.

Solution

To resolve the issue:

- Ensure that the device name is not used in the AMI that you selected. Run the following command to view the device names used by the AMI.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890 --query
 'Images[*].BlockDeviceMappings[].DeviceName'
```

- Ensure that you are not using a device name that is reserved for root volumes. For more information, see Available device names.
- Ensure that each volume specified in your request has a unique device name.
- Ensure that the device names that you specified are in the correct format. For more information, see Available device names.

Instance limit exceeded

Description

You get the `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance.

Cause

If you get an `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance, you have reached the limit on the number of instances that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run on a per-Region basis.

Solution

You can request an instance limit increase on a per-region basis. For more information, see Amazon EC2 service quotas.

Insufficient instance capacity

Description

You get the `InsufficientInstanceCapacity` error when you try to launch a new instance or restart a stopped instance.

Cause

If you get this error when you try to launch an instance or restart a stopped instance, AWS does not currently have enough available On-Demand capacity to fulfill your request.

Solution

To resolve the issue, try the following:

- Wait a few minutes and then submit your request again; capacity can shift frequently.
- Submit a new request with a reduced number of instances. For example, if you're making a single request to launch 15 instances, try making 3 requests for 5 instances, or 15 requests for 1 instance instead.
- If you're launching an instance, submit a new request without specifying an Availability Zone.

- If you're launching an instance, submit a new request using a different instance type (which you can resize at a later stage). For more information, see Amazon EC2 instance type changes.
- If you are launching instances into a cluster placement group, you can get an insufficient capacity error.

The requested configuration is currently not supported. Please check the documentation for supported configurations.

Description

You get the `Unsupported` error when you try to launch a new instance because the instance configuration is not supported.

Cause

The error message provides additional details. For example, an instance type or instance purchasing option might not be supported in the specified Region or Availability Zone.

Solution

Try a different instance configuration. To search for an instance type that meets your requirements, see Find an Amazon EC2 instance type.

Instance terminates immediately

Description

Your instance goes from the `pending` state to the `terminated` state.

Cause

The following are a few reasons why an instance might immediately terminate:

- You've exceeded your EBS volume limits. For more information, see Amazon EBS volume limits for Amazon EC2 instances.
- An EBS snapshot is corrupted.
- The root EBS volume is encrypted and you do not have permissions to access the KMS key for decryption.

- A snapshot specified in the block device mapping for the AMI is encrypted and you do not have permissions to access the KMS key for decryption or you do not have access to the KMS key to encrypt the restored volumes.
- The instance store-backed AMI that you used to launch the instance is missing a required part (an image.part.*xx* file).

For more information, get the termination reason using one of the following methods.

To get the termination reason using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and select the instance.
3. On the first tab, find the reason next to **State transition reason**.

To get the termination reason using the AWS CLI

1. Use the describe-instances command and specify the instance ID.

```
aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

2. Review the JSON response returned by the command and note the values in the `StateReason` response element.

   The following code block shows an example of a `StateReason` response element.

```
"StateReason": {
  "Message": "Client.VolumeLimitExceeded: Volume limit exceeded",
  "Code": "Server.InternalError"
},
```

To get the termination reason using AWS CloudTrail

For more information, see Viewing events with CloudTrail event history in the *AWS CloudTrail User Guide*.

Solution

Depending on the termination reason, take one of the following actions:

- **`Client.VolumeLimitExceeded: Volume limit exceeded`** — Delete unused volumes. You can submit a request to increase your volume limit.
- **`Client.InternalError: Client error on launch`** — Ensure that you have the permissions required to access the AWS KMS keys used to decrypt and encrypt volumes. For more information, see Using key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

Insufficient permissions

Description

You get the `"errorMessage": "You are not authorized to perform this operation."` error when you try to launch a new instance, and the launch fails.

Cause

If you get this error when you try to launch an instance, you don't have the required IAM permissions to launch the instance.

Possible missing permissions include:

- `ec2:RunInstances`
- `iam:PassRole`

Other permissions might also be missing. For the list of permissions required to launch an instance, see the example IAM policies under Example: Use the EC2 launch instance wizard and Launch instances (RunInstances).

Solution

To resolve the issue:

- If you are making requests as an IAM user, verify that you have the following permissions:
  - `ec2:RunInstances` with a wildcard resource ("*")
  - `iam:PassRole` with the resource matching the role ARN (for example, `arn:aws:iam::999999999999:role/ExampleRoleName`)
- If you don't have the preceding permissions, edit the IAM policy associated with the IAM role or user to add the missing required permissions.

If your issue is not resolved and you continue receiving a launch failure error, you can decode the authorization failure message included in the error. The decoded message includes the permissions that are missing from the IAM policy. For more information, see How do I decode an authorization failure message after I receive an "UnauthorizedOperation" error during an EC2 instance launch?

High CPU usage shortly after Windows starts (Windows instances only)

Note

This troubleshooting tip is for Windows instances only.

If Windows Update is set to **Check for updates but let me choose whether to download and install them** (the default instance setting) this check can consume anywhere from 50 - 99% of the CPU on the instance. If this CPU consumption causes problems for your applications, you can manually change Windows Update settings in **Control Panel** or you can use the following script in the Amazon EC2 user data field:

```
reg add "HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\WindowsUpdate\Auto Update" /v
 AUOptions /t REG_DWORD /d 3 /f net stop wuauserv net start wuauserv
```

When you run this script, specify a value for /d. The default value is 3. Possible values include the following:

1. Never check for updates
2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically

After you modify the user data for your instance, you can run it. For more information, see Run commands on your Windows instance at launch.

Troubleshoot Amazon EC2 instance stop issues

If your Amazon EBS-backed instance appears stuck in the `stopping` state, the issue might be with the underlying host computer.

To resolve the issue, follow these steps:

1. **Force stop the instance**

   Use the Amazon EC2 console or the AWS CLI to force stop the instance. For the steps, see Force stop an instance.

   The instance will first attempt a graceful shutdown, which includes flushing file system caches and metadata (although you can optionally bypass the graceful shutdown). If the graceful shutdown fails to complete within the timeout period, the instance shuts down forcibly without flushing the file system caches and metadata.

2. **After force stop**

   Perform file system check and repair procedures.

   > **Important**
   >
   > Performing these procedures is crucial because a forced stop prevents flushing of file system caches and metadata.

3. **If force stop fails**

   If, after 10 minutes, the instance has not stopped, do the following:

   a. Post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you've already taken.

   b. Alternatively, if you have a support plan, create a technical support case in the Support Center.

   c. While waiting for assistance, you can create a replacement instance if needed. For the steps, see (Optional) Create a replacement instance.

There is no cost for instance usage while an instance is in the `stopping` state or in any other state except `running`. You are only charged for instance usage when an instance is in the `running` state.

Contents

Force stop an instance

You can force an instance to stop. If, after 10 minutes, the instance has not stopped, post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the Support Center.

> **Note**
>
> Using the console, you can force an instance to stop while the instance is in the `stopping` state only. Using the AWS CLI, you can force an instance to stop while the instance is in the `pending`, `running`, or `stopping` state.

Console

To force stop an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance state**, **Force stop instance**.

   Note that **Force stop instance** is only available in the console if your instance is in the `stopping` state. If your instance is in another state (except `shutting-down` and `terminated`) you can use the AWS CLI to force stop your instance.
4. (Optional) To bypass the graceful OS shutdown during the force stop, select the **Skip OS shutdown** checkbox.
5. Choose **Force stop**.

AWS CLI

To force stop an instance

Use the stop-instances command with the `--force` option.

```
aws ec2 stop-instances \
    --instance-ids i-1234567890abcdef0 \
    --force
```

To bypass the graceful OS shutdown during force stop, include the `--skip-os-shutdown` option.

```
aws ec2 stop-instances \
    --instance-ids i-1234567890abcdef0 \
    --force \
    --skip-os-shutdown
```

PowerShell

To force stop an instance

Use the Stop-EC2Instance cmdlet and set `-Enforce` to `true`.

```
Stop-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true
```

To bypass the graceful OS shutdown during force stop, include `-SkipOsShutdown $true`.

```
Stop-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true `
    -SkipOsShutdown $true
```

(Optional) Create a replacement instance

While you are waiting for assistance from AWS re:Post or the Support Center, you can create a replacement instance if needed. Create an AMI from the stuck instance, and launch a new instance using the new AMI.

> **Important**
>
> You can create a replacement instance if the stuck instance produces system status checks only, as instance status checks will result in the AMI copying over an exact replica of the broken operating system. After you've confirmed the status message, create the AMI and launch a new instance using the new AMI.

Console

To create a replacement instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions**, **Image and templates**, **Create image**.
4. On the **Create image** page, do the following:
   a. Enter a name and description for the AMI.
   b. Clear **Reboot instance**.
   c. Choose **Create image**.

   For more information, see the section called “Create an AMI from an instance”.
5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose **Actions**, **Instance state**, **Terminate (delete) instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:

(Alternate) To create a replacement instance using the console

1. Select the instance and choose **Description**, **Block devices**. Select each volume and make note of its volume ID. Be sure to note which volume is the root volume.
2. In the navigation pane, choose **Volumes**. Select each volume for the instance, and choose **Actions**, **Create Snapshot**.
3. In the navigation pane, choose **Snapshots**. Select the snapshot that you just created, and choose **Actions**, **Create Volume**.
4. Launch an instance with the same operating system as the stuck instance. Note the volume ID and device name of its root volume.
5. In the navigation pane, choose **Instances**, select the instance that you just launched, and choose **Instance state**, **Stop instance**.

6. In the navigation pane, choose **Volumes**, select the root volume of the stopped instance, and choose **Actions**, **Detach Volume**.
7. Select the root volume that you created from the stuck instance, choose **Actions**, **Attach Volume**, and attach it to the new instance as its root volume (using the device name that you made note of). Attach any additional non-root volumes to the instance.
8. In the navigation pane, choose **Instances** and select the replacement instance. Choose **Instance state**, **Start instance**. Verify that the instance is working.
9. Select the stuck instance, choose **Instance state**, **Terminate (delete) instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

AWS CLI

To create a replacement instance

1. Create an AMI from the stuck instance using the create-image command with the `--no-reboot` option.

```
aws ec2 create-image \
    --instance-id i-1234567890abcdef0 \
    --name "my-replacement-ami" \
    --description ""AMI for replacement instance" \
    --no-reboot
```

2. Launch a new instance from the AMI that you just created, using the run-instances command.
3. Verify that the new instance is working.
4. (Optional) Terminate the stuck instance using the terminate-instances command.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To create a replacement instance

1. Create an AMI from the stuck instance using the New-EC2Image cmdlet and set `-NoReboot` to `true`.

```
New-EC2Image `
    -InstanceId i-1234567890abcdef0 `
    -Name "my-replacement-ami" `
    -Description "AMI for replacement instance" `
    -NoReboot $true
```

2. Launch a new instance from the AMI that you just created, using the New-EC2Instance cmdlet.
3. Verify that the new instance is working.
4. (Optional) Terminate the stuck instance using the Remove-EC2Instance cmdlet.

```
Remove-EC2Instance -InstanceId i-1234567890abcdef0
```

Troubleshoot Amazon EC2 instance termination issues

Shutting down or deleting your instance is known as instance termination. The following information can help you troubleshoot issues when you terminate your instance.

You are not billed for any instance usage while an instance is not in the `running` state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to `shutting-down`.

Instance terminates immediately

Several issues can cause your instance to terminate immediately on start-up. See Instance terminates immediately for more information.

Delayed instance termination

If your instance remains in the `shutting-down` state longer than a few minutes, it might be because:

- The instance is running shutdown scripts.
- There's a problem with the underlying host computer.

After several hours in the `shutting-down` state, Amazon EC2 treats the instance as stuck and forcibly terminates it.

To resolve a stuck instance yourself:

1. **Force terminate the instance**

   Use the Amazon EC2 console or the AWS CLI to force terminate the instance. For the steps, see Force terminate an instance.

   The instance will first attempt a graceful shutdown, which includes flushing file system caches and metadata (although you can optionally bypass the graceful shutdown). If the graceful shutdown fails to complete within the timeout period, the instance shuts down forcibly without flushing the file system caches and metadata.
2. **If force terminate fails**

   If, after several hours, the instance has not terminated and it appears stuck terminating, do the following:

   a. Post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you've already taken.
   b. Alternatively, if you have a support plan, create a technical support case in the Support Center.

Force terminate an instance

If it appears that your instance is stuck terminating, you can force your instance to terminate. If, after several hours, the instance has not terminated, post a request for help to AWS re:Post. To help expedite a resolution, include the instance ID and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the Support Center.

Console

To force terminate an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance state**, **Force terminate instance**.

   Note that **Force terminate instance** is only available in the console if your instance is in the `stopping` state. If your instance is in another state (except `shutting-down` and `terminated`) you can use the AWS CLI to force terminate your instance.

4. (Optional) To bypass the graceful OS shutdown during the force terminate, select the **Skip OS shutdown** checkbox.
5. Choose **Force terminate**.

AWS CLI

To force terminate an instance

Use the terminate-instances command with the `--force` option.

```
aws ec2 terminate-instances \
    --instance-ids i-1234567890abcdef0 \
    --force
```

To bypass the graceful OS shutdown during force terminate, include the `--skip-os-shutdown` option.

```
aws ec2 terminate-instances \
    --instance-ids i-1234567890abcdef0 \
    --force \
    --skip-os-shutdown
```

PowerShell

To force terminate an instance

Use the Remove-EC2Instance cmdlet and set `-Enforce` to `true`.

```
Remove-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true
```

To bypass the graceful OS shutdown during force terminate, include `-SkipOsShutdown $true`.

```
Remove-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Enforce $true `
    -SkipOsShutdown $true
```

Terminated instance still displayed

After you terminate an instance, it remains visible for a short while before being deleted. The state shows as `terminated`. If the entry is not deleted after several hours, contact Support.

Error: The instance may not be terminated. Modify its 'disableApiTermination' instance attribute

If you try to terminate an instance and get the `The instance i-1234567890abcdef0 may not be terminated. Modify its 'disableApiTermination' instance attribute` error message, it indicates that the instance has been enabled for termination protection. Termination protection prevents the instance from being accidentally terminated.

You must disable termination protection before you can terminate the instance.

For more information, see Change instance termination protection.

Instances automatically launched or terminated

Generally, the following behaviors mean that you've used Amazon EC2 Auto Scaling, EC2 Fleet, or Spot Fleet to scale your computing resources automatically based on criteria that you've defined:

- You terminate an instance and a new instance launches automatically.
- You launch an instance and one of your instances terminates automatically.
- You stop an instance and it terminates and a new instance launches automatically.

To stop automatic scaling, find the Auto Scaling group or the fleet that is launching the instances and either set its capacity to 0 or delete it.

Troubleshoot an unreachable Amazon EC2 instance

The following information can help you troubleshoot unreachable Amazon EC2 instances. You can capture screenshots or access console output to help diagnose problems and determine if you should reboot your instance. For unreachable Windows instances, troubleshoot by reviewing screenshots returned by the service.

Contents

- [Instance console output]
- [Capture a screenshot of an unreachable instance]
- [Common screenshots to troubleshoot unreachable Windows instances]
- [Instance recovery when a host computer fails]
- [Instance appeared offline and unexpectedly rebooted]

Instance reboot

The ability to reboot instances that are otherwise unreachable is valuable for both troubleshooting and general instance management.

Just as you can reset a computer by pressing the reset button, you can reset EC2 instances using the Amazon EC2 console, CLI, or API. For more information, see Reboot your Amazon EC2 instance.

Instance console output

Console output is a valuable tool for problem diagnosis. It is especially useful for troubleshooting kernel problems and service configuration issues that could cause an instance to terminate or become unreachable before its SSH daemon can be started.

- **Linux instances** – The instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. The console output returns buffered information that was posted shortly after an instance transition state (start, stop, reboot, and terminate). The posted output is not continuously updated; only when it is likely to be of the most value.
- **Windows instances –** The instance console output includes the last three system event log errors.

Only the instance owner can access the console output.

You can retrieve the latest serial console output during the instance lifecycle. This option is only supported on Nitro-based instances.

Console

To get console output

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the left navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

AWS CLI

To get console output

Use the get-console-output command.

```
aws ec2 get-console-output --instance-id i-1234567890abcdef0
```

PowerShell

To get console output

Use the Get-EC2ConsoleOutput cmdlet.

```
Get-EC2ConsoleOutput -InstanceId i-1234567890abcdef0
```

Capture a screenshot of an unreachable instance

If you are unable to connect to your instance, you can capture a screenshot of your instance and view it as an image. The image can provide visibility as to the status of the instance, and allows for quicker troubleshooting.

You can generate screenshots while the instance is running or after it has crashed. The image is generated in JPG format and is no larger than 100 kb. There is no data transfer cost for the screenshot.

Limitations

This feature is not supported for the following:

- Bare metal instances (instances of type `*.metal`)
- Instance is using an NVIDIA GRID driver
- Instances powered by Arm-based Graviton processors

- Windows instances on AWS Outposts
- Windows instances on AWS Local Zones

Region support

This feature is not available in the following Regions:

- Asia Pacific (Thailand)
- Mexico (Central)
- GovCloud Regions

Console

To get a screenshot of an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance to capture.
4. Choose **Actions**, **Monitor and troubleshoot**, **Get instance screenshot**.
5. Choose **Download**, or right-click the image to download and save it.

AWS CLI

To capture a screenshot of an instance

Use the get-console-screenshot command. The output is base64-encoded.

```
aws ec2 get-console-screenshot --instance-id i-1234567890abcdef0
```

PowerShell

To capture a screenshot of an instance

Use the Get-EC2ConsoleScreenshot cmdlet. The output is base64-encoded.

```
Get-EC2ConsoleScreenshot -InstanceId i-1234567890abcdef0
```

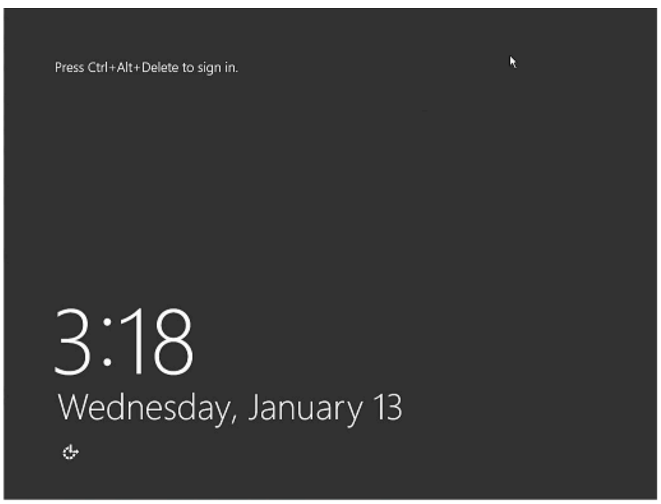
Common screenshots to troubleshoot unreachable Windows instances

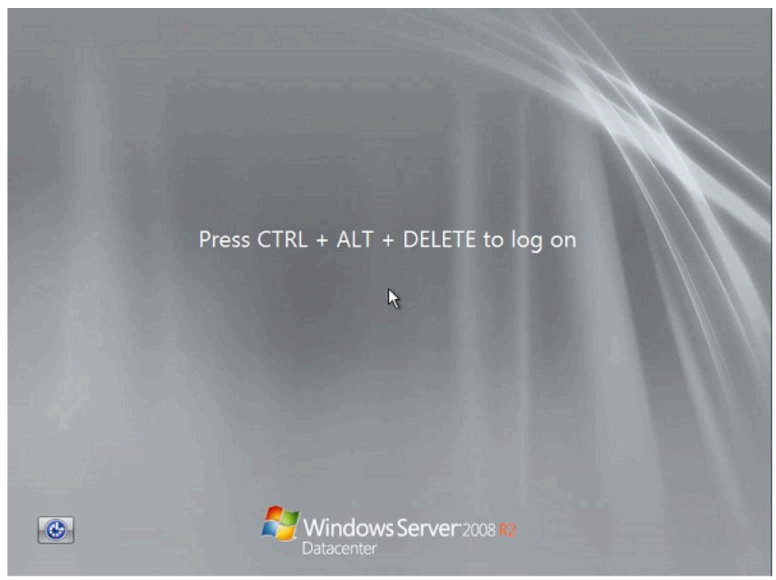
You can use the following information to help you troubleshoot an unreachable Windows instance based on screenshots returned by the service.

- Log on screen (Ctrl+Alt+Delete)
- Recovery console screen
- Windows boot manager screen
- Sysprep screen
- Getting ready screen
- Windows Update screen
- Chkdsk

Log on screen (Ctrl+Alt+Delete)

Console Screenshot Service returned the following.





If an instance becomes unreachable during logon, there could be a problem with your network configuration or Windows Remote Desktop Services. An instance can also be unresponsive if a process is using large amounts of CPU.

Network configuration

Use the following information to verify that your AWS, Microsoft Windows, and local (or on-premises) network configurations aren't blocking access to the instance.

AWS network configuration

Configuration	Verify
Security group configuration	Verify that port 3389 is open for your security group. Verify you are connecting to the right public IP address. If the instance was not associated with an Elastic IP, the public IP changes after the instance stops/starts. For more information, see Remote Desktop can't connect to the remote computer.
VPC configuration (Network ACLs)	Verify that the access control list (ACL) for your Amazon VPC is not blocking access. For information, see Network ACLs in the *Amazon VPC User Guide*.
VPN configuration	If you are connecting to your VPC using a virtual private network (VPN), verify VPN tunnel connectivity. For more information, see Troubleshooting AWS Client VPN: Tunnel connectivity issues to a VPC.

Windows network configuration

Configuration	Verify
Windows Firewall	Verify that Windows Firewall isn't blocking connections to your instance. Disable Windows Firewall as described in bullet 7 of the remote desktop troubleshooting section, Remote Desktop can't connect to the remote computer.
Advanced TCP/IP configuration (Use of static IP)	The instance may be unresponsive because you configured a static IP address. For a VPC, create a network interface and attach it to the instance.

Local or on-premises network configuration

Verify that a local network configuration isn't blocking access. Try to connect to another instance in the same VPC as your unreachable instance. If you can't access another instance, work with your local network administrator to determine whether a local policy is restricting access.

Remote Desktop Services issues

If the instance can't be reached during logon, there could a problem with Remote Desktop Services (RDS) on the instance.

> **Tip**
>
> You can use the `AWSSupport-TroubleshootRDP` runbook to check and modify various settings that might affect Remote Desktop Protocol (RDP) connections. For more information, see [`AWSSupport-TroubleshootRDP`] in the *AWS Systems Manager Automation runbook reference*.

Remote Desktop Services configuration

Configuration	Verify
RDS is running	Verify that RDS is running on the instance. Connect to the instance using the Microsoft Management Console (MMC) Services snap-in (`services.msc`). In the list of services, verify that **Remote Desktop Services** is **Running**. If it isn't, start it and then set the startup type to **Automatic**. If you can't connect to the instance by using the Services snap-in, detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, attach the original volume to another instance in the same Availability Zone as a secondary volume, and modify the Start registry key. When you are finished, reattach the root volume to the original instance.
RDS is enabled	Even if the service is started, it might be disabled. Detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, attach the original volume to another instance in the same Availability Zone as a secondary volume,

Configuration	Verify
	and enable the service by modifying the **Terminal Server** registry key as described in Enable Remote Desktop on an EC2 instance with remote registry. When you are finished, reattach the root volume to the original instance.

High CPU usage

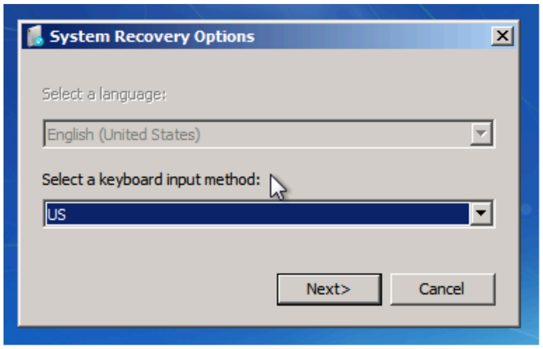
Check the **CPUUtilization (Maximum)** metric on your instance by using Amazon CloudWatch. If **CPUUtilization (Maximum)** is a high number, wait for the CPU to go down and try connecting again. High CPU usage can be caused by:

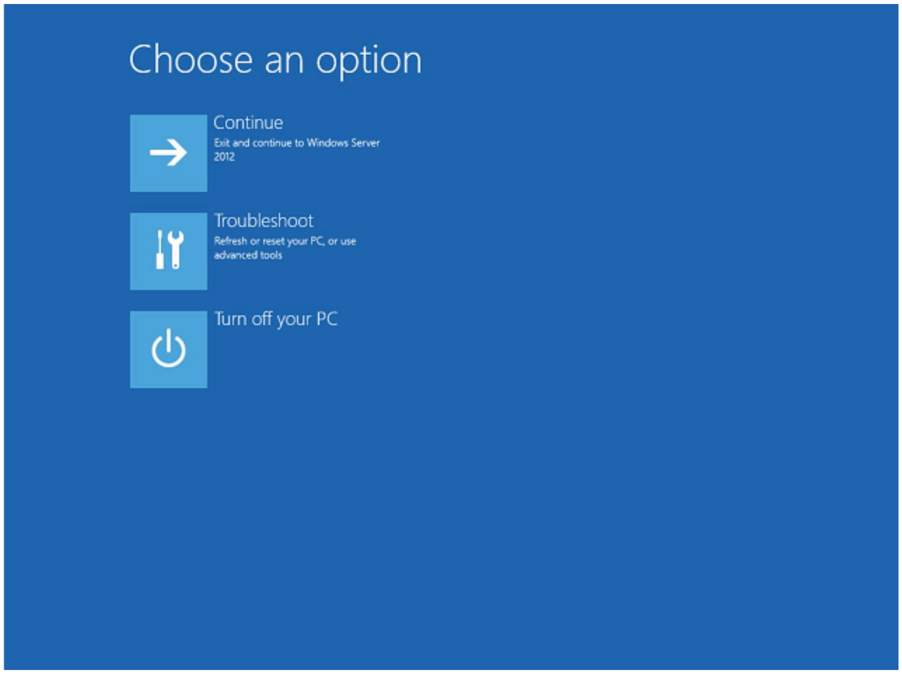
- Windows Update
- Security Software Scan
- Custom Startup Script
- Task Scheduler

For more information, see Get Statistics for a Specific Resource in the *Amazon CloudWatch User Guide*. For additional troubleshooting tips, see High CPU usage shortly after Windows starts (Windows instances only).

Recovery console screen

Console Screenshot Service returned the following.





The operating system might boot into the Recovery console and get stuck in this state if the `bootstatuspolicy` is not set to `ignoreallfailures`. Use the following procedure to change the `bootstatuspolicy` configuration to `ignoreallfailures`.

By default, the policy configuration for public Windows AMIs provided by AWS is set to `ignoreallfailures`.

1. Stop the unreachable instance.
2. Create a snapshot of the root volume. The root volume is attached to the instance as `/dev/sda1`.

   Detach the root volume from the unreachable instance, take a snapshot of the volume or create an AMI from it, and attach it to another instance in the same Availability Zone as a secondary volume.

   > **Warning**
   >
   > If your temporary instance and the original instance were launched using the same AMI, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. If you must create a temporary instance using the same AMI, to avoid a disk signature collision, complete the steps in [Disk signature collision](#).

Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses an AMI for Windows Server 2016, launch the temporary instance using an AMI for Windows Server 2019.

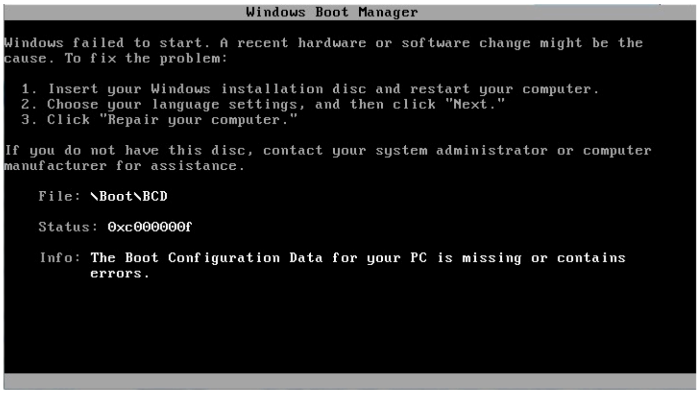
3. Log in to the instance and run the following command from a command prompt to change the `bootstatuspolicy` configuration to `ignoreallfailures`.

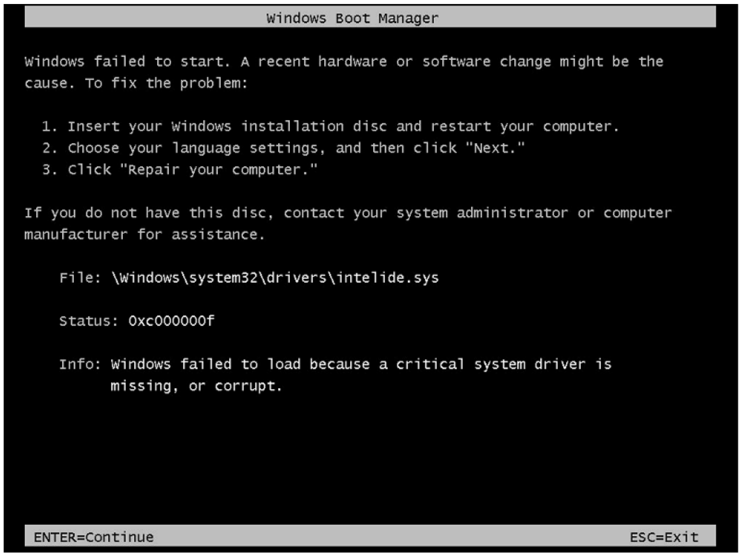
```
bcdedit /store Drive Letter:\boot\bcd /set {default} bootstatuspolicy
 ignoreallfailures
```

4. Reattach the volume to the unreachable instance and start the instance again.

Windows boot manager screen

Console Screenshot Service returned the following.

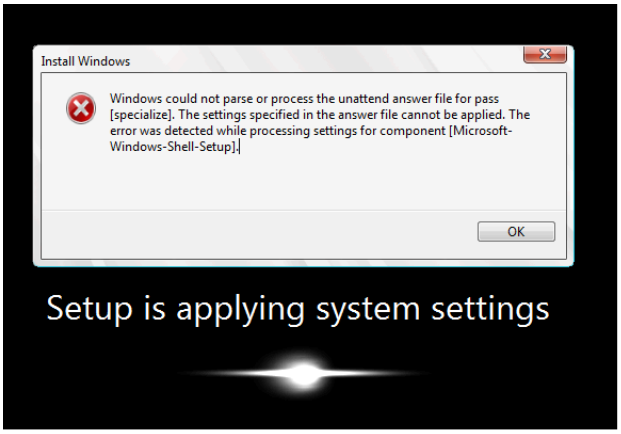


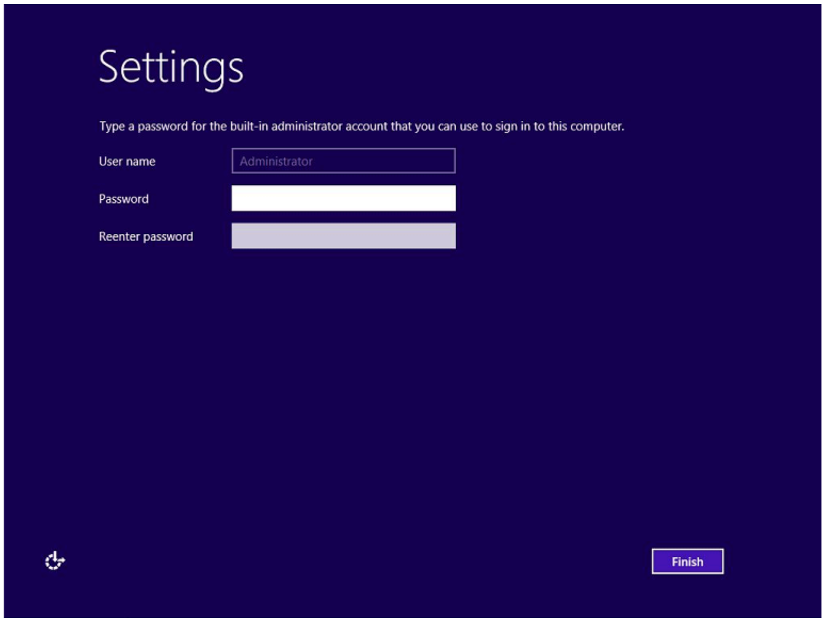


The operating system experienced a fatal corruption in the system file and/or the registry. When the instance is stuck in this state, you should recover the instance from a recent backup AMI or launch a replacement instance. If you need to access data on the instance, detach any root volumes from the unreachable instance, take a snapshot of those volume or create an AMI from them, and attach them to another instance in the same Availability Zone as a secondary volume.

Sysprep screen

Console Screenshot Service returned the following.

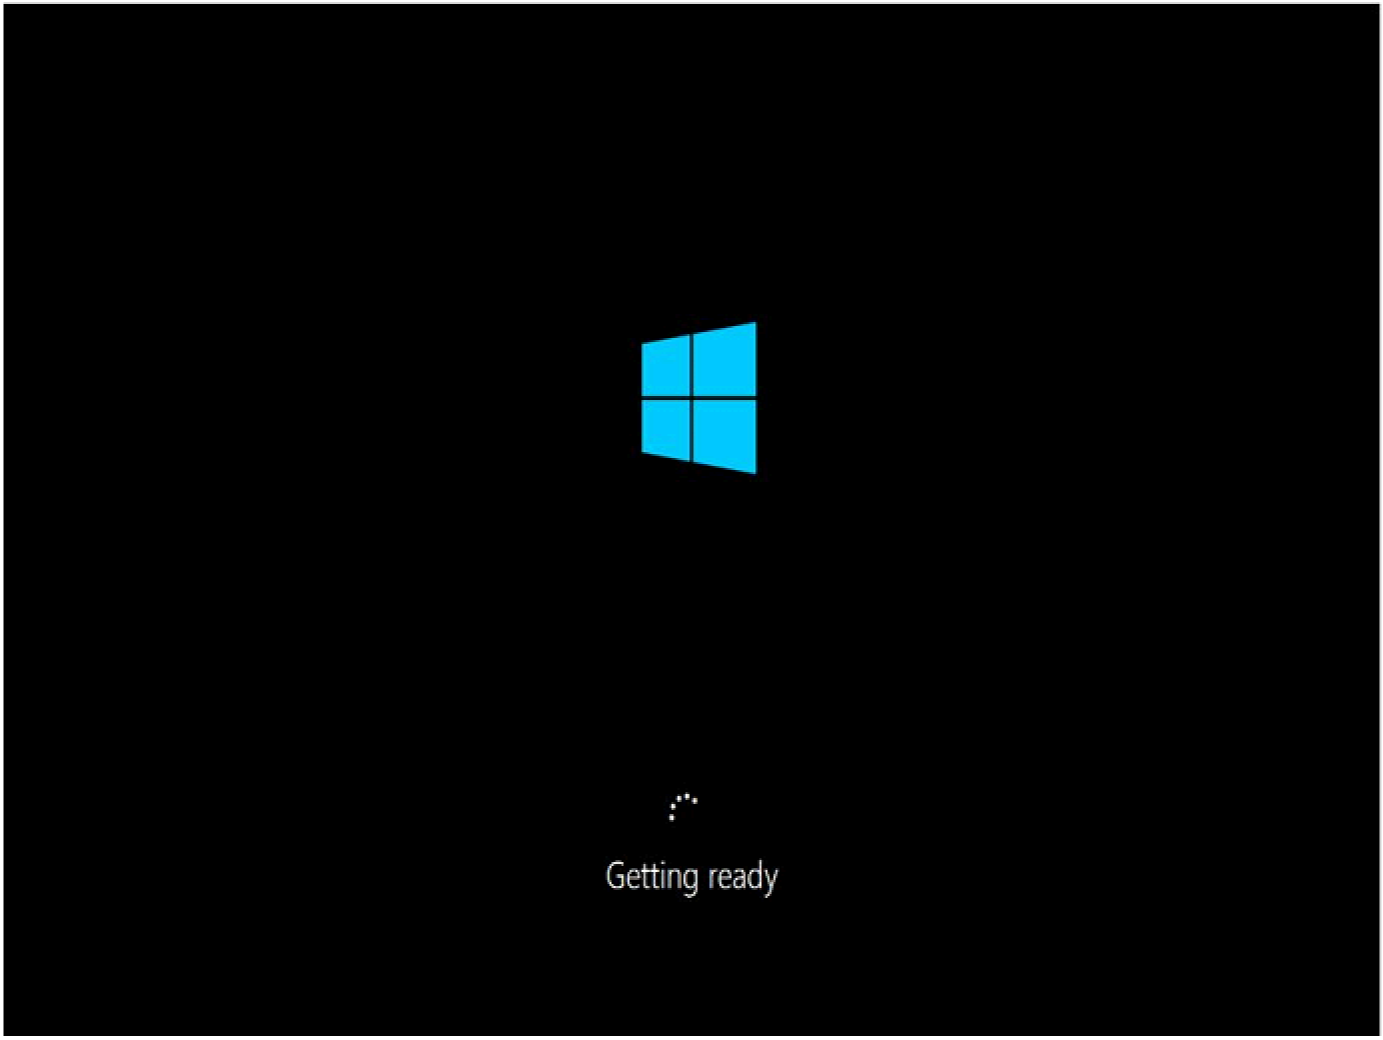




You may see this screen if you did not use the EC2Config Service to call Sysprep or if the operating system failed while running Sysprep. You can reset the password using EC2Rescue. Otherwise, see Create an Amazon EC2 AMI using Windows Sysprep.

Getting ready screen

Console Screenshot Service returned the following.



Refresh the Instance Console Screenshot Service repeatedly to verify that the progress ring is spinning. If the ring is spinning, wait for the operating system to start up. You can also check the **CPUUtilization (Maximum)** metric on your instance by using Amazon CloudWatch to see if the operating system is active. If the progress ring is not spinning, the instance may be stuck at the boot process. Reboot the instance. If rebooting does not solve the problem, recover the instance from a recent backup AMI or launch a replacement instance. If you need to access data on the instance, detach the root volume from the unreachable instance, take a snapshot of the volume or create an AMI from it. Then attach it to another instance in the same Availability Zone as a secondary volume.

Windows Update screen

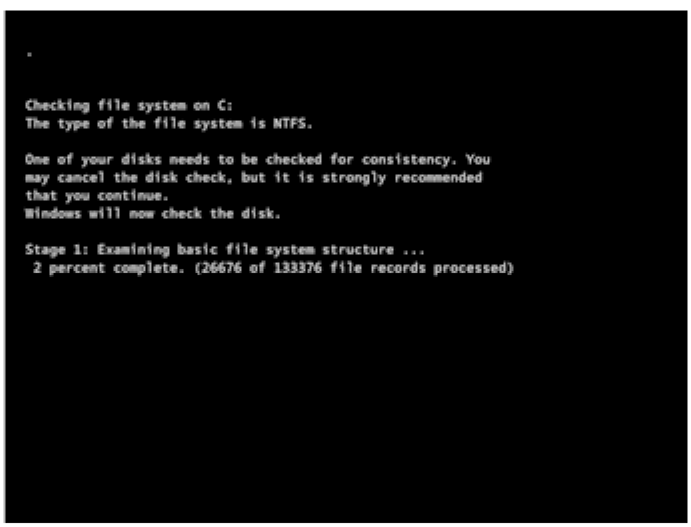
Console Screenshot Service returned the following.

The Windows Update process is updating the registry. Wait for the update to finish. Do not reboot or stop the instance as this may cause data corruption during the update.

> **Note**
>
> The Windows Update process can consume resources on the server during the update. If you experience this problem often, consider using faster instance types and faster EBS volumes.

Chkdsk

Console Screenshot Service returned the following.



Windows is running the chkdsk system tool on the drive to verify file system integrity and fix logical file system errors. Wait for process to complete.

Instance recovery when a host computer fails

If there is an unrecoverable issue with the hardware of an underlying host computer, AWS may schedule an instance stop event. You are notified of such an event ahead of time by email.

To recover an Amazon EBS-backed instance running on a host computer that failed

1. Back up any important data on your instance store volumes to Amazon EBS or Amazon S3.
2. Stop the instance.
3. Start the instance.
4. Restore any important data.

For more information, see Stop and start Amazon EC2 instances.

To recover an instance store-backed instance running on a host computer that failed

1. Create an AMI from the instance.
2. Upload the image to Amazon S3.
3. Back up important data to Amazon EBS or Amazon S3.
4. Terminate the instance.
5. Launch a new instance from the AMI.
6. Restore any important data to the new instance.

Instance appeared offline and unexpectedly rebooted

If your instance appears to have been offline and then unexpectedly rebooted, it might have undergone automatic instance recovery. This happens when AWS detects that the instance is unavailable due to an underlying hardware or software issue, and either simplified automatic recovery or CloudWatch action based recovery is enabled on the instance.

During the recovery process, AWS attempts to restore the instance's availability by migrating it to different hardware. To verify whether automatic instance recovery occurred for your instance, see Verify if automatic instance recovery occurred.

> **Note**
>
> If your workload or application is unresponsive, check whether it's running on the instance. If it's not, start it manually. To prevent this issue in the future, implement a recovery plan to ensure your workload or application functions properly after instance recovery.

Troubleshoot issues connecting to your Amazon EC2 Linux instance

The following information and common errors can help you troubleshoot connecting to your Linux instance.

Connection issues

Common causes for connection issues

We recommend that you start to troubleshoot instance connection problems by verifying that you have accurately performed the following tasks.

Verify the username for your instance

You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

- **Get the username for your user account.**

  For more information about how to create a user account, see Manage system users on your Amazon EC2 Linux instance.

- **Get the default username for the AMI that you used to launch your instance.**

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

Verify that your security group rules allow traffic

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard enables SSH traffic by default. For steps to add a rule for inbound SSH traffic to your Linux instance, see Rules to connect to instances from your computer. For steps to verify, see Error connecting to your instance: Connection timed out.

Verify that your instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready to accept connection requests. Check your instance to make sure it is running and has passed its status checks.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. Verify the following:
    a. In the **Instance state** column, verify that your instance is in the `running` state.
    b. In the **Status check** column, verify that your instance has passed all status checks.

Verify that you've satisfied all prerequisites to connect

Ensure that you have all the information that you need to connect. For more information, see Connect to your Linux instance using SSH.

Connect from Linux or macOS X

If your local computer operating system is Linux or macOS X, check the following for specific prerequisites for connecting to a Linux instance:

- SSH client
- EC2 Instance Connect
- AWS Systems Manager Session Manager

Connect from Windows

If your local computer operating system is Windows, check the following for specific prerequisites for connecting to a Linux instance:

- OpenSSH
- PuTTY
- AWS Systems Manager Session Manager
- Windows Subsystem for Linux

Check if the instance is a managed instance

User-initiated connections to managed instances are not allowed. To determine if the instance is managed, find the **Managed** field for the instance. If the value is **true**, it's a managed instance. For more information, see Amazon EC2 managed instances.

Error connecting to your instance: Connection timed out

If you try to connect to your instance and get the error message `Network error: Connection timed out` or `Error connecting to [instance], reason: -> Connection timed out: connect`, try the following:

Check your security group rules.

You need a security group rule that allows inbound traffic from your local computer's public IPv4 address on the proper port.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Security** tab at the bottom of the console page, under **Inbound rules**, check the list of rules that are in effect for the selected instance. Verify that there is a rule that allows traffic from your local computer to port 22 (SSH).

   If your security group does not have a rule that allows inbound traffic from your local computer, add a rule to your security group. For more information, see Rules to connect to instances from your computer.
4. For the rule that allows inbound traffic, check the **Source** field. If the value is a single IP address, and if the IP address is not static, a new IP address will be assigned each time you restart your computer. This will result in the rule not including your computer's IP address traffic. The IP address might not be static if your computer is on a corporate network, or you're connecting through an internet service provider (ISP), or your computer IP address is dynamic and changes each time you restart your computer. To ensure that your security group rule

allows inbound traffic from your local computer, instead of specifying a single IP address for **Source**, rather specify the range of IP addresses used by your client computers.

For more information about security group rules, see Security group rules in the *Amazon VPC User Guide*.

Check the route table for the subnet.

You need a route that sends all traffic destined outside the VPC to the internet gateway for the VPC.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Networking** tab, make note of the values for **VPC ID** and **Subnet ID**.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create internet gateway**, enter a name for the internet gateway, and choose **Create internet gateway**. Then, for the internet gateway you created, choose **Actions**, **Attach to VPC**, select your VPC, and then choose **Attach internet gateway** to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-*xxxxxxxx*) to navigate to the route table.

   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target. For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

   c. Choose **Save routes**.

Check the network access control list (ACL) for the subnet.

The network ACLs must allow inbound SSH traffic from your local IP address on port 22. It must also allow outbound traffic to the ephemeral ports (1024-65535).

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Subnets**.
3. Select your subnet.
4. On the **Network ACL** tab, for **Inbound rules**, verify that the rules allow inbound traffic from your computer on the required port. Otherwise, delete or modify the rule that is blocking the traffic.
5. For **Outbound rules**, verify that the rules allow outbound traffic to your computer on the ephemeral ports. Otherwise, delete or modify the rule that is blocking the traffic.

If your computer is on a corporate network

Ask your network administrator whether the internal firewall allows inbound and outbound traffic from your computer on port 22.

If you have a firewall on your computer, verify that it allows inbound and outbound traffic from your computer on port 22.

Check that your instance has a public IPv4 address.

If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses.

Check the CPU load on your instance; the server may be overloaded.

AWS automatically provides data such as Amazon CloudWatch metrics and instance status, which you can use to see how much CPU load is on your instance and, if necessary, adjust how your loads are handled. For more information, see Monitor your instances using CloudWatch.

- If your load is variable, you can automatically scale your instances up or down using Auto Scaling and Elastic Load Balancing.
- If your load is steadily growing, you can move to a larger instance type. For more information, see Amazon EC2 instance type changes.

To connect to your instance using an IPv6 address, check the following:

- Your subnet must be associated with a route table that has a route for IPv6 traffic (`::/0`) to an internet gateway.

- Your security group rules must allow inbound traffic from your local IPv6 address on port 22.
- Your network ACL rules must allow inbound and outbound IPv6 traffic.
- If you launched your instance from an older AMI, it might not be configured for DHCPv6 (IPv6 addresses are not automatically recognized on the network interface). For more information, see Configure IPv6 on your instances in the *Amazon VPC User Guide*.
- Your local computer must have an IPv6 address, and must be configured to use IPv6.

Error: unable to load key ... Expecting: ANY PRIVATE KEY

If you try to connect to your instance and get the error message, `unable to load key ... Expecting: ANY PRIVATE KEY`, the file in which the private key is stored is incorrectly configured. If the private key file ends in `.pem`, it might still be incorrectly configured. A possible cause for an incorrectly configured private key file is a missing certificate.

If the private key file is incorrectly configured, follow these steps to resolve the error

1. Create a new key pair. For more information, see Create a key pair using Amazon EC2.

   Note

   Alternatively, you can create a new key pair using a third-party tool. For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2.

2. Add the new key pair to your instance. For more information, see I've lost my private key. How can I connect to my instance?.
3. Connect to your instance using the new key pair.

Error: User key not recognized by server

If you use SSH to connect to your instance

- Use `ssh -vvv` to get triple verbose debugging information while connecting:

```
ssh -vvv -i path/key-pair-name.pem instance-user-
name@ec2-203-0-113-25.compute-1.amazonaws.com
```

The following sample output demonstrates what you might see if you were trying to connect to your instance with a key that was not recognized by the server:

```
open/ANT/myusername/.ssh/known_hosts).
debug2: bits set: 504/1024
debug1: ssh_rsa_verify: signature correct
debug2: kex_derive_keys
debug2: set_newkeys: mode 1
debug1: SSH2_MSG_NEWKEYS sent
debug1: expecting SSH2_MSG_NEWKEYS
debug2: set_newkeys: mode 0
debug1: SSH2_MSG_NEWKEYS received
debug1: Roaming not allowed by server
debug1: SSH2_MSG_SERVICE_REQUEST sent
debug2: service_accept: ssh-userauth
debug1: SSH2_MSG_SERVICE_ACCEPT received
debug2: key: boguspem.pem ((nil))
debug1: Authentications that can continue: publickey
debug3: start over, passed a different list publickey
debug3: preferred gssapi-keyex,gssapi-with-mic,publickey,keyboard-
interactive,password
debug3: authmethod_lookup publickey
debug3: remaining preferred: keyboard-interactive,password
debug3: authmethod_is_enabled publickey
debug1: Next authentication method: publickey
debug1: Trying private key: boguspem.pem
debug1: read PEM private key done: type RSA
debug3: sign_and_send_pubkey: RSA 9c:4c:bc:0c:d0:5c:c7:92:6c:8e:9b:16:e4:43:d8:b2
debug2: we sent a publickey packet, wait for reply
debug1: Authentications that can continue: publickey
debug2: we did not send a packet, disable method
debug1: No more authentication methods to try.
Permission denied (publickey).
```

If you use PuTTY to connect to your instance

- Verify that your private key (.pem) file has been converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance using PuTTY.

> **Note**
>
> In PuTTYgen, load your private key file and select **Save Private Key** rather than **Generate**.

- Verify that you are connecting with the appropriate username for your AMI. Enter the username in the **Host name** box in the **PuTTY Configuration** window.

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

- Verify that you have an inbound security group rule to allow inbound traffic to the appropriate port. For more information, see [Rules to connect to instances from your computer].

Error: Permission denied or connection closed by [instance] port 22

If you connect to your instance using SSH and get any of the following errors, `Host key not found in [directory]`, `Permission denied (publickey)`, `Authentication failed,` `permission denied`, or `Connection closed by [instance] port 22`, verify that you are connecting with the appropriate username for your AMI *and* that you have specified the proper private key (`.pem`) file for your instance.

The appropriate usernames are as follows:

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`
RHEL	`ec2-user` or `root`
SUSE	`ec2-user` or `root`
Ubuntu	`ubuntu`
Oracle	`ec2-user`
Bitnami	`bitnami`
Rocky Linux	`rocky`
Other	Check with the AMI provider

For example, to use an SSH client to connect to an Amazon Linux instance, use the following command:

```
ssh -i /path/key-pair-name.pem instance-user-
name@ec2-203-0-113-25.compute-1.amazonaws.com
```

Confirm that you are using the private key file that corresponds to the key pair that you selected when you launched the instance.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Instances** and then select your instance.
3. On the **Details** tab, under **Instance details**, verify the value of **Key pair name**.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the `.pem` file for your key pair, you can replace the key pair with a new one. For more information, see I've lost my private key. How can I connect to my instance?.

If you generated your own key pair, ensure that your key generator is set up to create RSA keys. DSA keys are not accepted.

If you get a `Permission denied (publickey)` error and none of the above applies (for example, you were able to connect previously), the permissions on the home directory of your instance may have been changed. Permissions for `/home/instance-user-name/.ssh/authorized_keys` must be limited to the owner only.

To verify the permissions on your instance

1. Stop your instance and detach the root volume. For more information, see Stop and start Amazon EC2 instances.
2. Launch a temporary instance in the same Availability Zone as your current instance (use a similar or the same AMI as you used for your current instance), and attach the root volume to the temporary instance.
3. Connect to the temporary instance, create a mount point, and mount the volume that you attached.
4. From the temporary instance, check the permissions of the `/home/instance-user-name/` directory of the attached volume. If necessary, adjust the permissions as follows:

```
[ec2-user ~]$ chmod 600 mount_point/home/instance-user-name/.ssh/authorized_keys
```

```
[ec2-user ~]$ chmod 700 mount_point/home/instance-user-name/.ssh
```

```
[ec2-user ~]$ chmod 700 mount_point/home/instance-user-name
```

5. Unmount the volume, detach it from the temporary instance, and re-attach it to the original instance. Ensure that you specify the correct device name for the root volume; for example, /dev/xvda.
6. Start your instance. If you no longer require the temporary instance, you can terminate it.

Error: Unprotected private key file

Your private key file must be protected from read and write operations from any other users. If your private key can be read or written to by anyone but you, then SSH ignores your key and you see the following warning message below.

```
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
@         WARNING: UNPROTECTED PRIVATE KEY FILE!          @
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
Permissions 0777 for '.ssh/my_private_key.pem' are too open.
It is required that your private key files are NOT accessible by others.
This private key will be ignored.
bad permissions: ignore key: .ssh/my_private_key.pem
Permission denied (publickey).
```

If you see a similar message when you try to log in to your instance, examine the first line of the error message to verify that you are using the correct public key for your instance. The above example uses the private key `.ssh/my_private_key.pem` with file permissions of `0777`, which allow anyone to read or write to this file. This permission level is very insecure, and so SSH ignores this key.

If you are connecting from macOS or Linux, run the following command to fix this error, substituting the path for your private key file.

```
[ec2-user ~]$ chmod 0400 .ssh/my_private_key.pem
```

If you are connecting to a Linux instance from Windows, perform the following steps on your local computer.

1. Navigate to your .pem file.
2. Right-click on the .pem file and select **Properties**.
3. Choose the **Security** tab.

4. Select **Advanced**.
5. Verify that you are the owner of the file. If not, change the owner to your username.
6. Select **Disable inheritance** and **Remove all inherited permissions from this object**.
7. Select **Add**, **Select a principal**, enter your username, and select **OK**.
8. From the **Permission Entry** window, grant **Read** permissions and select **OK**.
9. Click **Apply** to ensure all settings are saved.
10. Select **OK** to close the **Advanced Security Settings** window.
11. Select **OK** to close the **Properties** window.
12. You should be able to connect to your Linux instance from Windows using SSH.

From a Windows command prompt, run the following commands.

1. From the command prompt, navigate to the file path location of your .pem file.
2. Run the following command to reset and remove explicit permissions:

```
icacls.exe $path /reset
```

3. Run the following command to grant Read permissions to the current user:

```
icacls.exe $path /GRANT:R "$($env:USERNAME):(R)"
```

4. Run the following command to disable inheritance and remove inherited permissions.

```
icacls.exe $path /inheritance:r
```

5. You should be able to connect to your Linux instance from Windows using SSH.

Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"

If you use a third-party tool, such as **ssh-keygen**, to create an RSA key pair, it generates the private key in the OpenSSH key format. When you connect to your instance, if you use the private key in the OpenSSH format to decrypt the password, you'll get the error `Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"`.

To resolve the error, the private key must be in the PEM format. Use the following command to create the private key in the PEM format:

```
ssh-keygen -m PEM
```

Error: Host key verification failed

This error occurs if there is a mismatch between the host key stored on the instance in the `known_hosts` file and on the client. For example, a mismatch can occur if you connect to an instance using one public IP address, and then try to connect to it again using a different public IP address. This can happen after you add or remove an Elastic IP address, as doing so changes the public IP address of an instance.

To resolve this error, start by confirming that there was an expected change to the host key or the network configuration of the instance. Before you connect to the instance, you might also want to verify the host fingerprint. After you connect to the instance, you can remove the old host key from the `known_hosts` file. For instructions, refer to the documentation for the Linux distribution in use on your instance.

Error: Server refused our key *or* No supported authentication methods available

If you use PuTTY to connect to your instance and get either of the following errors, Error: Server refused our key or Error: No supported authentication methods available, verify that you are connecting with the appropriate username for your AMI. Type the username in **User name** in the **PuTTY Configuration** window.

The appropriate usernames are as follows:

AMI used to launch instance	Default username
Amazon Linux	`ec2-user`
CentOS	`centos` or `ec2-user`
Debian	`admin`
Fedora	`fedora` or `ec2-user`

AMI used to launch instance	Default username
RHEL	ec2-user or root
SUSE	ec2-user or root
Ubuntu	ubuntu
Oracle	ec2-user
Bitnami	bitnami
Rocky Linux	rocky
Other	Check with the AMI provider

You should also verify that:

- You are using the latest version of PuTTY. For more information, see the PuTTY web page.
- Your private key (.pem) file has been correctly converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance using PuTTY.

Cannot ping instance

The `ping` command is a type of ICMP traffic — if you are unable to ping your instance, ensure that your inbound security group rules allow ICMP traffic for the `Echo Request` message from all sources, or from the computer or instance from which you are issuing the command.

If you are unable to issue a `ping` command from your instance, ensure that your outbound security group rules allow ICMP traffic for the `Echo Request` message to all destinations, or to the host that you are attempting to ping.

`Ping` commands can also be blocked by a firewall or time out due to network latency or hardware issues. You should consult your local network or system administrator for help with further troubleshooting.

Error: Server unexpectedly closed network connection

If you are connecting to your instance with PuTTY and you receive the error "Server unexpectedly closed network connection," verify that you have enabled keepalives on the Connection page of the PuTTY Configuration to avoid being disconnected. Some servers disconnect clients when they do not receive any data within a specified period of time. Set the Seconds between keepalives to 59 seconds.

If you still experience issues after enabling keepalives, try to disable Nagle's algorithm on the Connection page of the PuTTY Configuration.

Error: Host key validation failed for EC2 Instance Connect

If you rotate your instance host keys, the new host keys are not automatically uploaded to the AWS trusted host keys database. This causes host key validation to fail when you try to connect to your instance using the EC2 Instance Connect browser-based client, and you're unable to connect to your instance.

To resolve the error, you must run the `eic_harvest_hostkeys` script on your instance, which uploads your new host key to EC2 Instance Connect. The script is located at `/opt/aws/bin/` on Amazon Linux 2 instances, and at `/usr/share/ec2-instance-connect/` on Ubuntu instances.

Amazon Linux 2

To resolve the host key validation failed error on an Amazon Linux 2 instance

1. Connect to your instance using SSH.

   You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For Amazon Linux 2, the default username is `ec2-user`.

   For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

For more information about connecting to your instance, see [Connect to your Linux instance using an SSH client](#).

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /opt/aws/bin/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

Ubuntu

To resolve the host key validation failed error on an Ubuntu instance

1. Connect to your instance using SSH.

You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For Ubuntu, the default username is `ubuntu`.

For example, if your instance was launched using Ubuntu, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance using an SSH client](#).

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /usr/share/ec2-instance-connect/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

Can't connect to Ubuntu instance using EC2 Instance Connect

If you use EC2 Instance Connect to connect to your Ubuntu instance and you get an error when attempting to connect, you can use the following information to try to fix the issue.

Possible cause

The `ec2-instance-connect` package on the instance is not the latest version.

Solution

Update the `ec2-instance-connect` package on the instance to the latest version, as follows:

1. Connect to your instance using a method other than EC2 Instance Connect.
2. Run the following command on your instance to update the `ec2-instance-connect` package to the latest version.

```
apt update && apt upgrade
```

I've lost my private key. How can I connect to my instance?

If you lose the private key for an EBS-backed instance, you can regain access to your instance. You must stop the instance, detach its root volume and attach it to another instance as a data volume, modify the `authorized_keys` file with a new public key, move the volume back to the original instance, and restart the instance. For more information about launching, connecting to, and stopping instances, see Amazon EC2 instance state changes.

This procedure is only supported for instances with EBS root volumes. If the root device is an instance store volume, you cannot use this procedure to regain access to your instance; you must have the private key to connect to the instance. To determine the root device type of your instance, open the Amazon EC2 console, choose **Instances**, select the instance, choose the **Storage** tab, and in the **Root device details** section, check the value of **Root device type**.

The value is either `EBS` or `INSTANCE-STORE`.

In addition to the following steps, there are other ways to connect to your Linux instance if you lose your private key. For more information, see [How can I connect to my Amazon EC2 instance if I lost my SSH key pair after its initial launch?](#)

Steps for connecting to an EBS-backed instance with a different key pair

- Step 1: Create a new key pair
- Step 2: Get information about the original instance and its root volume
- Step 3: Stop the original instance
- Step 4: Launch a temporary instance
- Step 5: Detach the root volume from the original instance and attach it to the temporary instance
- Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance
- Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance
- Step 8: Connect to the original instance using the new key pair
- Step 9: Clean up

Step 1: Create a new key pair

Create a new key pair using either the Amazon EC2 console or a third-party tool. If you want to name your new key pair exactly the same as the lost private key, you must first delete the existing key pair. For information about creating a new key pair, see Create a key pair using Amazon EC2 or Create a key pair using a third-party tool and import the public key to Amazon EC2.

Step 2: Get information about the original instance and its root volume

Make note of the following information because you'll need it to complete this procedure.

To get information about your original instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Choose **Instances** in the navigation pane, and then select the instance that you'd like to connect to. (We'll refer to this as the *original* instance.)
3. On the **Details** tab, make note of the instance ID and AMI ID.
4. On the **Networking** tab, make note of the Availability Zone.
5. On the **Storage** tab, under **Root device name**, make note of the device name for the root volume (for example, `/dev/xvda`). Then, under **Block devices**, find this device name and make note of the volume ID (for example, vol-0a1234b5678c910de).

Step 3: Stop the original instance

Choose **Instance state**, **Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

Step 4: Launch a temporary instance

To launch a temporary instance

1. In the navigation pane, choose **Instances**, and then choose **Launch instances**.
2. In the **Name and tags** section, for **Name**, enter **Temporary**.
3. In the **Application and OS Images** section, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see Create an Amazon EBS-backed AMI.
4. In the **Instance type** section, keep the default instance type.
5. In the **Key pair** section, for **Key pair name**, select the existing key pair to use or create a new one.
6. In the **Network settings** section, choose **Edit**, and then for **Subnet**, select a subnet in the same Availability Zone as the original instance.
7. In the **Summary** panel, choose **Launch**.

Step 5: Detach the root volume from the original instance and attach it to the temporary instance

1. In the navigation pane, choose **Volumes** and select the root device volume for the original instance (you made note of its volume ID in a previous step). Choose **Actions**, **Detach volume**, and then choose **Detach**. Wait for the state of the volume to become `available`. (You might need to choose the Refresh icon.)
2. With the volume still selected, choose **Actions**, and then choose **Attach volume**. Select the instance ID of the temporary instance, make note of the device name specified under **Device name** (for example, `/dev/sdf`), and then choose **Attach volume**.

> **Note**
>
> If you launched your original instance from an AWS Marketplace AMI and your volume contains AWS Marketplace codes, you must first stop the temporary instance before you can attach the volume.

Step 6: Add the new public key to `authorized_keys` on the original volume mounted to the temporary instance

1. Connect to the temporary instance.
2. From the temporary instance, mount the volume that you attached to the instance so that you can access its file system. For example, if the device name is `/dev/sdf`, use the following commands to mount the volume as `/mnt/tempvol`.

> **Note**
>
> The device name might appear differently on your instance. For example, devices mounted as `/dev/sdf` might show up as `/dev/xvdf` on the instance. Some versions of Red Hat (or its variants, such as CentOS) might even increment the trailing letter by 4 characters, where `/dev/sdf` becomes `/dev/xvdk`.

   a. Use the **lsblk** command to determine if the volume is partitioned.

```
[ec2-user ~]$ lsblk
```

```
NAME     MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda     202:0    0    8G  0 disk
##xvda1 202:1    0    8G  0 part /
xvdf     202:80   0  101G  0 disk
##xvdf1 202:81   0  101G  0 part
xvdg     202:96   0   30G  0 disk
```

In the preceding example, /dev/xvda and /dev/xvdf are partitioned volumes, and /dev/xvdg is not. If your volume is partitioned, you mount the partition (/dev/xvdf1) instead of the raw device (/dev/xvdf) in the next steps.

b. Create a temporary directory to mount the volume.

```
[ec2-user ~]$ sudo mkdir /mnt/tempvol
```

c. Mount the volume (or partition) at the temporary mount point, using the volume name or device name that you identified earlier. The required command depends on your operating system's file system. Note that the device name might appear differently on your instance. See the note in Step 6 for more information.

- Amazon Linux, Ubuntu, and Debian

```
[ec2-user ~]$ sudo mount /dev/xvdf1 /mnt/tempvol
```

- Amazon Linux 2, CentOS, SUSE Linux 12, and RHEL 7.x

```
[ec2-user ~]$ sudo mount -o nouuid /dev/xvdf1 /mnt/tempvol
```

Note

If you get an error stating that the file system is corrupt, run the following command to use the **fsck** utility to check the file system and repair any issues:

```
[ec2-user ~]$ sudo fsck /dev/xvdf1
```

3. From the temporary instance, use the following command to update authorized_keys on the mounted volume with the new public key from the authorized_keys for the temporary instance.

> **Important**
>
> The following examples use the Amazon Linux username `ec2-user`. You might need to substitute a different username, such as `ubuntu` for Ubuntu instances.

```
[ec2-user ~]$ cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/
authorized_keys
```

If this copy succeeded, you can go to the next step.

(Optional) Otherwise, if you don't have permission to edit files in `/mnt/tempvol`, you must update the file using **sudo** and then check the permissions on the file to verify that you are able to log into the original instance. Use the following command to check the permissions on the file.

```
[ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
total 4
-rw------- 1 222 500 398 Sep 13 22:54 authorized_keys
```

In this example output, *222* is the user ID and *500* is the group ID. Next, use **sudo** to re-run the copy command that failed.

```
[ec2-user ~]$ sudo cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/
authorized_keys
```

Run the following command again to determine whether the permissions changed.

```
[ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
```

If the user ID and group ID have changed, use the following command to restore them.

```
[ec2-user ~]$ sudo chown 222:500 /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
```

Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance

1. From the temporary instance, unmount the volume that you attached so that you can reattach it to the original instance. For example, use the following command to unmount the volume at `/mnt/tempvol`.

   ```
   [ec2-user ~]$ sudo umount /mnt/tempvol
   ```

2. Detach the volume from the temporary instance (you unmounted it in the previous step): From the Amazon EC2 console, choose **Volumes** in the navigation pane, select the root device volume for the original instance (you made note of the volume ID in a previous step), choose **Actions**, **Detach volume**, and then choose **Detach**. Wait for the state of the volume to become `available`. (You might need to choose the Refresh icon.)

3. Reattach the volume to the original instance: With the volume still selected, choose **Actions**, **Attach volume**. Select the instance ID of the original instance, specify the device name that you noted earlier in Step 2 for the original root device attachment (`/dev/sda1` or `/dev/xvda`), and then choose **Attach volume**.

   > **Important**
   >
   > If you don't specify the same device name as the original attachment, you cannot start the original instance. Amazon EC2 expects the root device volume at `sda1` or `/dev/xvda`.

Step 8: Connect to the original instance using the new key pair

Select the original instance, choose **Instance state**, **Start instance**. After the instance enters the `running` state, you can connect to it using the private key file for your new key pair.

> **Note**
>
> If the name of your new key pair and corresponding private key file is different from the name of the original key pair, ensure that you specify the name of the new private key file when you connect to your instance.

Step 9: Clean up

(Optional) You can terminate the temporary instance if you have no further use for it. Select the temporary instance, and choose **Instance state**, **Terminate (delete) instance**.

Troubleshoot Amazon EC2 Linux instances with failed status checks

The following information can help you troubleshoot issues if your Linux instance fails a status check. First determine whether your applications are exhibiting any problems. If you verify that the instance is not running your applications as expected, review the status check information and the system logs.

For examples of problems that can cause status checks to fail, see Status checks for Amazon EC2 instances.

Contents

- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch)
- XENBUS: Device with no driver...
- ... days without being checked, check forced (File system check required)
- fsck died with exit status... (Missing device)
- GRUB prompt (grubdom>)
- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)
- Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)
- XENBUS: Timeout connecting to devices (Xenbus timeout)

Review status check information

To investigate impaired instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. Select the **Status and alarms** tab to see the individual results for all **System status checks**, **Instance status checks**, and **Attached EBS status checks**.

If a status check has failed, you can try one of the following options:

- Create an alarm to recover the instance in response to the failed status check. For more information, see Create alarms that stop, terminate, reboot, or recover an instance.
- (Instance status checks) If you changed the instance type to a Nitro-based instance, status checks fail if you migrated from an instance that does not have the required ENA and NVMe drivers. For more information, see Compatibility for changing the instance type.
- For an EBS-backed instance, stop and restart the instance. For more information, see Stop and start Amazon EC2 instances.
- For an instance-store backed instance, terminate the instance and launch a replacement instance. For more information, see Terminate Amazon EC2 instances.
- Wait for Amazon EC2 to resolve the issue.

- Contact Support or post your issue to AWS re:Post.
- If your instance is in an Auto Scaling group:
  - (System status checks and instance status checks) By default, Amazon EC2 Auto Scaling automatically launches a replacement instance. For more information, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.
  - (Attached EBS status checks) You must configure Amazon EC2 Auto Scaling to automatically launch a replacement instance. For more information, see Monitor and replace Auto Scaling instances with impaired Amazon EBS volumes in the *Amazon EC2 Auto Scaling User Guide*.
- Retrieve the system log and look for errors. For more information, see Retrieve the system logs.

Retrieve the system logs

If an instance status check fails, you can reboot the instance and retrieve the system logs. The logs may reveal an error that can help you troubleshoot the issue. Rebooting clears unnecessary information from the logs.

To reboot an instance and retrieve the system log

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and select your instance.
3. Choose **Instance state**, **Reboot instance**. It might take a few minutes for your instance to reboot.
4. Verify that the problem still exists; in some cases, rebooting may resolve the problem.
5. When the instance is in the `running` state, choose **Actions**, **Monitor and troubleshoot**, **Get system log**.
6. Review the log that appears on the screen, and use the list of known system log error statements below to troubleshoot your issue.
7. If your issue is not resolved, you can post your issue to AWS re:Post.

Troubleshoot system log errors for Linux instances

For Linux instances that have failed an instance status check, such as the instance reachability check, verify that you followed the steps above to retrieve the system log. The following list contains some common system log errors and suggested actions you can take to resolve the issue for each error.

Memory Errors

- Out of memory: kill process
- ERROR: mmu_update failed (Memory management update failed)

Device Errors

- I/O error (block device failure)
- I/O ERROR: neither local nor remote disk (Broken distributed block device)

Kernel Errors

- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules)
- ERROR Invalid kernel (EC2 incompatible kernel)

File System Errors

- fsck: No such file or directory while trying to open... (File system not found)
- General error mounting filesystems (failed mount)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch)
- XENBUS: Device with no driver...
- ... days without being checked, check forced (File system check required)
- fsck died with exit status... (Missing device)

Operating System Errors

- GRUB prompt (grubdom>)

- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)
- Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)
- XENBUS: Timeout connecting to devices (Xenbus timeout)

Out of memory: kill process

An out-of-memory error is indicated by a system log entry similar to the one shown below.

```
[115879.769795] Out of memory: kill process 20273 (httpd) score 1285879
or a child
[115879.769795] Killed process 1917 (php-cgi) vsz:467184kB, anon-
rss:101196kB, file-rss:204kB
```

Potential cause

Exhausted memory

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Stop the instance, and modify the instance to use a different instance type, and start the instance again. For example, a larger or a memory-optimized instance type. • Reboot the instance to return it to a non-impaired status. The problem will probably occur again unless you change the instance type.
Instance store-backed	Do one of the following: • Terminate the instance and launch a new instance, specifying a different instance

For this instance type	Do this
	type. For example, a larger or a memory-optimized instance type. • Reboot the instance to return it to an unimpaired status. The problem will probably occur again unless you change the instance type.

ERROR: mmu_update failed (Memory management update failed)

Memory management update failures are indicated by a system log entry similar to the following:

```
...
Press `ESC' to enter the menu... 0   [H[J  Booting 'Amazon Linux 2011.09
 (2.6.35.14-95.38.amzn1.i686)'

root (hd0)

 Filesystem type is ext2fs, using whole disk

kernel /boot/vmlinuz-2.6.35.14-95.38.amzn1.i686 root=LABEL=/ console=hvc0 LANG=

en_US.UTF-8 KEYTABLE=us

initrd /boot/initramfs-2.6.35.14-95.38.amzn1.i686.img

ERROR: mmu_update failed with rc=-22
```

Potential cause

Issue with Amazon Linux

Suggested action

Post your issue to AWS re:Post or contact Support.

I/O error (block device failure)

An input/output error is indicated by a system log entry similar to the following example:

```
[9943662.053217] end_request: I/O error, dev sde, sector 52428288
[9943664.191262] end_request: I/O error, dev sde, sector 52428168
[9943664.191285] Buffer I/O error on device md0, logical block 209713024
[9943664.191297] Buffer I/O error on device md0, logical block 209713025
[9943664.191304] Buffer I/O error on device md0, logical block 209713026
[9943664.191310] Buffer I/O error on device md0, logical block 209713027
[9943664.191317] Buffer I/O error on device md0, logical block 209713028
[9943664.191324] Buffer I/O error on device md0, logical block 209713029
[9943664.191332] Buffer I/O error on device md0, logical block 209713030
[9943664.191339] Buffer I/O error on device md0, logical block 209713031
[9943664.191581] end_request: I/O error, dev sde, sector 52428280
[9943664.191590] Buffer I/O error on device md0, logical block 209713136
[9943664.191597] Buffer I/O error on device md0, logical block 209713137
[9943664.191767] end_request: I/O error, dev sde, sector 52428288
[9943664.191970] end_request: I/O error, dev sde, sector 52428288
[9943664.192143] end_request: I/O error, dev sde, sector 52428288
[9943664.192949] end_request: I/O error, dev sde, sector 52428288
[9943664.193112] end_request: I/O error, dev sde, sector 52428288
[9943664.193266] end_request: I/O error, dev sde, sector 52428288
...
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	A failed Amazon EBS volume
Instance store-backed	A failed physical drive

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance.

For this instance type	Do this
	2. Detach the volume. 3. Attempt to recover the volume. **Note** It's good practice to snapshot your Amazon EBS volumes often. This dramatically decreases the risk of data loss as a result of failure. 4. Re-attach the volume to the instance. 5. Start the instance.
Instance store-backed	Terminate the instance and launch a new instance. **Note** Data cannot be recovered. Recover from backups. **Note** It's a good practice to use either Amazon S3 or Amazon EBS for backups. Instance store volumes are directly tied to single host and single disk failures.

I/O ERROR: neither local nor remote disk (Broken distributed block device)

An input/output error on the device is indicated by a system log entry similar to the following example:

```
...
block drbd1: Local IO failed in request_timer_fn. Detaching...

Aborting journal on device drbd1-8.

block drbd1: IO ERROR: neither local nor remote disk

Buffer I/O error on device drbd1, logical block 557056

lost page write due to I/O error on drbd1

JBD2: I/O error detected when updating journal superblock for drbd1-8.
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	A failed Amazon EBS volume
Instance store-backed	A failed physical drive

Suggested action

Terminate the instance and launch a new instance.

For an Amazon EBS-backed instance you can recover data from a recent snapshot by creating an image from it. Any data added after the snapshot cannot be recovered.

request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)

This condition is indicated by a system log similar to the one shown below. Using an unstable or old Linux kernel (for example, 2.6.16-xenU) can cause an interminable loop condition at startup.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1
20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007

BIOS-provided physical RAM map:

 Xen: 0000000000000000 - 0000000026700000 (usable)

0MB HIGHMEM available.
...

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c

request_module: runaway loop modprobe binfmt-464c
```

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use a newer kernel, either GRUB-based or static, using one of the following options: Option 1: Terminate the instance and launch a new instance, specifying the `-kernel` and `-ramdisk` parameters. Option 2: 1. Stop the instance. 2. Modify the kernel and ramdisk attributes to use a newer kernel. 3. Start the instance.

For this instance type	Do this
Instance store-backed	Terminate the instance and launch a new instance, specifying the `-kernel` and `-ramdisk` parameters.

"FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch)

This condition is indicated by a system log similar to the one shown below.

```
Linux version 2.6.16.33-xenU (root@dom0-0-50-45-1-a4-ee.z-2.aes0.internal)
(gcc version 4.1.1 20070105 (Red Hat 4.1.1-52)) #2 SMP Wed Aug 15 17:27:36 SAST 2007
...
FATAL: kernel too old
Kernel panic - not syncing: Attempted to kill init!
```

Potential causes

Incompatible kernel and userland

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Modify the configuration to use a newer kernel. 3. Start the instance.
Instance store-backed	Use the following procedure: 1. Create an AMI that uses a newer kernel. 2. Terminate the instance.

For this instance type	Do this
	3. Start a new instance from the AMI you created.

"FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules)

This condition is indicated by a system log similar to the one shown below.

```
[    0.370415] Freeing unused kernel memory: 1716k freed
Loading, please wait...
WARNING: Couldn't open directory /lib/modules/2.6.34-4-virtual: No such file or
 directory
FATAL: Could not open /lib/modules/2.6.34-4-virtual/modules.dep.temp for writing: No
 such file or directory
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
Couldn't get a file descriptor referring to the console
Begin: Loading essential drivers... ...
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory

Begin: Waiting for root file system... ...
Done.
Gave up waiting for root device.  Common problems:
 - Boot args (cat /proc/cmdline)
   - Check rootdelay= (did the system wait long enough?)
   - Check root= (did the system wait for the right device?)
 - Missing modules (cat /proc/modules; ls /dev)
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or
 directory
```

```
ALERT! /dev/sda1 does not exist. Dropping to a shell!

BusyBox v1.13.3 (Ubuntu 1:1.13.3-1ubuntu5) built-in shell (ash)
Enter 'help' for a list of built-in commands.

(initramfs)
```

Potential causes

One or more of the following conditions can cause this problem:

- Missing ramdisk
- Missing correct modules from ramdisk
- Amazon EBS root volume not correctly attached as `/dev/sda1`

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Select corrected ramdisk for the Amazon EBS volume. 2. Stop the instance. 3. Detach the volume and repair it. 4. Attach the volume to the instance. 5. Start the instance. 6. Modify the AMI to use the corrected ramdisk.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance with the correct ramdisk. 2. Create a new AMI with the correct ramdisk.

ERROR Invalid kernel (EC2 incompatible kernel)

This condition is indicated by a system log similar to the one shown below.

```
...
root (hd0)

 Filesystem type is ext2fs, using whole disk

kernel /vmlinuz root=/dev/sda1 ro

initrd /initrd.img

ERROR Invalid kernel: elf_xen_note_check: ERROR: Will only load images
built for the generic loader or Linux images
xc_dom_parse_image returned -1

Error 9: Unknown boot failure

  Booting 'Fallback'

root (hd0)

 Filesystem type is ext2fs, using whole disk

kernel /vmlinuz.old root=/dev/sda1 ro

Error 15: File not found
```

Potential causes

One or both of the following conditions can cause this problem:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure:

For this instance type	Do this
	1. Stop the instance. 2. Replace with working kernel. 3. Install a fallback kernel. 4. Modify the AMI by correcting the kernel.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance with the correct kernel. 2. Create an AMI with the correct kernel. 3. (Optional) Seek technical assistance for data recovery using Support.

fsck: No such file or directory while trying to open... (File system not found)

This condition is indicated by a system log similar to the one shown below.

```
  Welcome to Fedora
  Press 'I' to enter interactive startup.
Setting clock : Wed Oct 26 05:52:05 EDT 2011 [  OK  ]

Starting udev: [  OK  ]

Setting hostname localhost:  [  OK  ]

No devices found
Setting up Logical Volume Management: File descriptor 7 left open
  No volume groups found
[  OK  ]

Checking filesystems
Checking all file systems.
[/sbin/fsck.ext3 (1) -- /] fsck.ext3 -a /dev/sda1
/dev/sda1: clean, 82081/1310720 files, 2141116/2621440 blocks
[/sbin/fsck.ext3 (1) -- /mnt/dbbackups] fsck.ext3 -a /dev/sdh
fsck.ext3: No such file or directory while trying to open /dev/sdh
```

```
/dev/sdh:
The superblock could not be read or does not describe a correct ext2
filesystem.  If the device is valid and it really contains an ext2
filesystem (and not swap or ufs or something else), then the superblock
is corrupt, and you might try running e2fsck with an alternate superblock:
    e2fsck -b 8193 <device>

[FAILED]

*** An error occurred during the file system check.
*** Dropping you to a shell; the system will reboot
*** when you leave the shell.
Give root password for maintenance
(or type Control-D to continue):
```

Potential causes

- A bug exists in ramdisk filesystem definitions /etc/fstab
- Misconfigured filesystem definitions in /etc/fstab
- Missing/failed drive

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance, detach the root volume, repair/modify /etc/fstab the volume, attach the volume to the instance, and start the instance. 2. Fix ramdisk to include modified /etc/fstab (if applicable). 3. Modify the AMI to use a newer ramdisk.

For this instance type	Do this
	The sixth field in the fstab defines availabil ity requirements of the mount – a nonzero value implies that an fsck will be done on that volume and *must* succeed. Using this field can be problematic in Amazon EC2 because a failure typically results in an interactive console prompt that is not currently available in Amazon EC2. Use care with this feature and read the Linux man page for fstab.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance. 2. Detach any errant Amazon EBS volumes and the reboot instance. 3. (Optional) Seek technical assistance for data recovery using Support.

General error mounting filesystems (failed mount)

This condition is indicated by a system log similar to the one shown below.

```
Loading xenblk.ko module
xen-vbd: registered block device major 8

Loading ehci-hcd.ko module
Loading ohci-hcd.ko module
Loading uhci-hcd.ko module
USB Universal Host Controller Interface driver v3.0

Loading mbcache.ko module
Loading jbd.ko module
Loading ext3.ko module
Creating root device.
Mounting root filesystem.
kjournald starting.  Commit interval 5 seconds
```

```
EXT3-fs: mounted filesystem with ordered data mode.

Setting up other filesystems.
Setting up new root fs
no fstab.sys, mounting internal defaults
Switching to new root and running init.
unmounting old /dev
unmounting old /proc
unmounting old /sys
mountall:/proc: unable to mount: Device or resource busy
mountall:/proc/self/mountinfo: No such file or directory
mountall: root filesystem isn't mounted
init: mountall main process (221) terminated with status 1

General error mounting filesystems.
A maintenance shell will now be started.
CONTROL-D will terminate this shell and re-try.
Press enter for maintenance
(or type Control-D to continue):
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	• Detached or failed Amazon EBS volume. • Corrupted filesystem. • Mismatched ramdisk and AMI combination (such as Debian ramdisk with a SUSE AMI).
Instance store-backed	• A failed drive. • A corrupted file system. • A mismatched ramdisk and combination (for example, a Debian ramdisk with a SUSE AMI).

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Detach the root volume. 3. Attach the root volume to a known working instance. 4. Run filesystem check (fsck -a /dev/...). 5. Fix any errors. 6. Detach the volume from the known working instance. 7. Attach the volume to the stopped instance. 8. Start the instance. 9. Recheck the instance status.
Instance store-backed	Try one of the following: • Start a new instance. • (Optional) Seek technical assistance for data recovery using Support.

VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch)

This condition is indicated by a system log similar to the one shown below.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1
 20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007
...
Kernel command line:  root=/dev/sda1 ro 4
...
Registering block device major 8
...
```

```
Kernel panic - not syncing: VFS: Unable to mount root fs on unknown-block(8,1)
```

Potential causes

Instance type	Potential cause
Amazon EBS-backed	• Device not attached correctly. • Root device not attached at correct device point. • Filesystem not in expected format. • Use of legacy kernel (such as 2.6.16-XenU). • A recent kernel update on your instance (faulty update, or an update bug)
Instance store-backed	Hardware device failure.

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Stop and then restart the instance. • Modify root volume to attach at the correct device point, possible /dev/sda1 instead of /dev/sda. • Stop and modify to use modern kernel. • Refer to the documentation for your Linux distribution to check for known update bugs. Change or reinstall the kernel.
Instance store-backed	Terminate the instance and launch a new instance using a modern kernel.

Error: Unable to determine major/minor number of root device... (Root file system/device mismatch)

This condition is indicated by a system log similar to the one shown below.

```
...
XENBUS: Device with no driver: device/vif/0
XENBUS: Device with no driver: device/vbd/2048
drivers/rtc/hctosys.c: unable to open rtc device (rtc0)
Initializing network drop monitor service
Freeing unused kernel memory: 508k freed
:: Starting udevd...
done.
:: Running Hook [udev]
:: Triggering uevents...<30>udevd[65]: starting version 173
done.
Waiting 10 seconds for device /dev/xvda1 ...
Root device '/dev/xvda1' doesn't exist. Attempting to create it.
ERROR: Unable to determine major/minor number of root device '/dev/xvda1'.
You are being dropped to a recovery shell
    Type 'exit' to try and continue booting
sh: can't access tty; job control turned off
[ramfs /]#
```

Potential causes

- Missing or incorrectly configured virtual block device driver
- Device enumeration clash (sda versus xvda or sda instead of sda1)
- Incorrect choice of instance kernel

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Detach the volume. 3. Fix the device mapping problem.

For this instance type	Do this
	4. Start the instance. 5. Modify the AMI to address device mapping issues.
Instance store-backed	Use the following procedure: 1. Create a new AMI with the appropriate fix (map block device correctly). 2. Terminate the instance and launch a new instance from the AMI you created.

XENBUS: Device with no driver...

This condition is indicated by a system log similar to the one shown below.

```
XENBUS: Device with no driver: device/vbd/2048
drivers/rtc/hctosys.c: unable to open rtc device (rtc0)
Initializing network drop monitor service
Freeing unused kernel memory: 508k freed
:: Starting udevd...
done.
:: Running Hook [udev]
:: Triggering uevents...<30>udevd[65]: starting version 173
done.
Waiting 10 seconds for device /dev/xvda1 ...
Root device '/dev/xvda1' doesn't exist. Attempting to create it.
ERROR: Unable to determine major/minor number of root device '/dev/xvda1'.
You are being dropped to a recovery shell
    Type 'exit' to try and continue booting
sh: can't access tty; job control turned off
[ramfs /]#
```

Potential causes

- Missing or incorrectly configured virtual block device driver
- Device enumeration clash (sda versus xvda)
- Incorrect choice of instance kernel

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the instance. 2. Detach the volume. 3. Fix the device mapping problem. 4. Start the instance. 5. Modify the AMI to address device mapping issues.
Instance store-backed	Use the following procedure: 1. Create an AMI with the appropriate fix (map block device correctly). 2. Terminate the instance and launch a new instance using the AMI you created.

... days without being checked, check forced (File system check required)

This condition is indicated by a system log similar to the one shown below.

```
...
Checking filesystems
Checking all file systems.
[/sbin/fsck.ext3 (1) -- /] fsck.ext3 -a /dev/sda1
/dev/sda1 has gone 361 days without being checked, check forced
```

Potential causes

Filesystem check time passed; a filesystem check is being forced.

Suggested actions

- Wait until the filesystem check completes. A filesystem check can take a long time depending on the size of the root filesystem.
- Modify your filesystems to remove the filesystem check (fsck) enforcement using tune2fs or tools appropriate for your filesystem.

fsck died with exit status... (Missing device)

This condition is indicated by a system log similar to the one shown below.

```
Cleaning up ifupdown....
Loading kernel modules...done.
...
Activating lvm and md swap...done.
Checking file systems...fsck from util-linux-ng 2.16.2
/sbin/fsck.xfs: /dev/sdh does not exist
fsck died with exit status 8
[31mfailed (code 8).[39;49m
```

Potential causes

- Ramdisk looking for missing drive
- Filesystem consistency check forced
- Drive failed or detached

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Try one or more of the following to resolve the issue: • Stop the instance, attach the volume to an existing running instance. • Manually run consistency checks. • Fix ramdisk to include relevant utilities.

For this instance type	Do this
	• Modify filesystem tuning parameters to remove consistency requirements (not recommended).
Instance store-backed	Try one or more of the following to resolve the issue: • Rebundle ramdisk with correct tooling. • Modify file system tuning parameters to remove consistency requirements (not recommended). • Terminate the instance and launch a new instance. • (Optional) Seek technical assistance for data recovery using Support.

GRUB prompt (grubdom>)

This condition is indicated by a system log similar to the one shown below.

```
    GNU GRUB  version 0.97  (629760K lower / 0K upper memory)

       [ Minimal BASH-like line editing is supported.   For

         the   first   word,  TAB  lists  possible  command

         completions.  Anywhere else TAB lists the possible

         completions of a device/filename. ]

grubdom>
```

Potential causes

Instance type	Potential causes
Amazon EBS-backed	• Missing GRUB configuration file. • Incorrect GRUB image used, expecting GRUB configuration file at a different location. • Unsupported filesystem used to store your GRUB configuration file (for example, converting your root file system to a type that is not supported by an earlier version of GRUB).
Instance store-backed	• Missing GRUB configuration file. • Incorrect GRUB image used, expecting GRUB configuration file at a different location. • Unsupported filesystem used to store your GRUB configuration file (for example, converting your root file system to a type that is not supported by an earlier version of GRUB).

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Option 1: Modify the AMI and relaunch the instance: 1. Modify the source AMI to create a GRUB configuration file at the standard location (/ boot/grub/menu.lst). 2. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary.

For this instance type	Do this
	3. Pick the appropriate GRUB image, (hd0-1st drive or hd00 – 1st drive, 1st partition). 4. Terminate the instance and launch a new one using the AMI that you created. Option 2: Fix the existing instance: 1. Stop the instance. 2. Detach the root filesystem. 3. Attach the root filesystem to a known working instance. 4. Mount filesystem. 5. Create a GRUB configuration file. 6. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary. 7. Detach filesystem. 8. Attach to the original instance. 9. Modify kernel attribute to use the appropria te GRUB image (1st disk or 1st partition on 1st disk). 10Start the instance.

For this instance type	Do this
Instance store-backed	Option 1: Modify the AMI and relaunch the instance: 1. Create the new AMI with a GRUB configuration file at the standard location (/boot/grub/menu.lst). 2. Pick the appropriate GRUB image, (hd0-1st drive or hd00 – 1st drive, 1st partition). 3. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary. 4. Terminate the instance and launch a new instance using the AMI you created. Option 2: Terminate the instance and launch a new instance, specifying the correct kernel. **Note** To recover data from the existing instance, contact Support.

Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)

This condition is indicated by a system log similar to the one shown below.

```
...
Bringing up loopback interface:  [  OK  ]

Bringing up interface eth0:  Device eth0 has different MAC address than expected,
 ignoring.
[FAILED]
```

```
Starting auditd: [  OK  ]
```

Potential causes

There is a hardcoded interface MAC in the AMI configuration

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Modify the AMI to remove the hardcoding and relaunch the instance. • Modify the instance to remove the hardcoded MAC address. OR Use the following procedure: 1. Stop the instance. 2. Detach the root volume. 3. Attach the volume to another instance and modify the volume to remove the hardcoded MAC address. 4. Attach the volume to the original instance. 5. Start the instance.
Instance store-backed	Do one of the following: • Modify the instance to remove the hardcoded MAC address. • Terminate the instance and launch a new instance.

Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)

This condition is indicated by a system log similar to the one shown below.

```
audit(1313445102.626:2): enforcing=1 old_enforcing=0 auid=4294967295
Unable to load SELinux Policy. Machine is in enforcing mode. Halting now.
Kernel panic - not syncing: Attempted to kill init!
```

Potential causes

SELinux has been enabled in error:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Use the following procedure: 1. Stop the failed instance. 2. Detach the failed instance's root volume. 3. Attach the root volume to another running Linux instance (later referred to as a recovery instance). 4. Connect to the recovery instance and mount the failed instance's root volume. 5. Disable SELinux on the mounted root volume. This process varies across Linux distributions; for more information, consult your OS-specific documentation.

For this instance type	Do this
	Note On some systems, you disable SELinux by setting `SELINUX=disabled` in the `/mount_point/etc/sysconfig/selinux` file, where *mount_point* is the location that you mounted the volume on your recovery instance. 6. Unmount and detach the root volume from the recovery instance and reattach it to the original instance. 7. Start the instance.
Instance store-backed	Use the following procedure: 1. Terminate the instance and launch a new instance. 2. (Optional) Seek technical assistance for data recovery using Support.

XENBUS: Timeout connecting to devices (Xenbus timeout)

This condition is indicated by a system log similar to the one shown below.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1
20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007
...
XENBUS: Timeout connecting to devices!
...
Kernel panic - not syncing: No init found.  Try passing init= option to kernel.
```

Potential causes

- The block device is not connected to the instance
- This instance is using an old instance kernel

Suggested actions

For this instance type	Do this
Amazon EBS-backed	Do one of the following: • Modify the AMI and instance to use a modern kernel and relaunch the instance. • Reboot the instance.
Instance store-backed	Do one of the following: • Terminate the instance. • Modify the AMI to use a modern kernel, and launch a new instance using this AMI.

Troubleshoot an Amazon EC2 Linux instance booting from wrong volume

In some situations, a volume other than the volume attached to `/dev/xvda` or `/dev/sda` becomes the root volume of a Linux instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume.

This is due to how the initial ramdisk in Linux works. It chooses the volume defined as / in the `/etc/fstab`, and in some distributions, this is determined by the label attached to the volume partition. Specifically, you find that your `/etc/fstab` looks something like the following:

```
LABEL=/ / ext4 defaults,noatime 1 1
tmpfs /dev/shm tmpfs defaults 0 0
devpts /dev/pts devpts gid=5,mode=620 0 0
```

```
sysfs /sys sysfs defaults 0 0
proc /proc proc defaults 0 0
```

If you check the label of both volumes, you see that they both contain the / label:

```
[ec2-user ~]$ sudo e2label /dev/xvda1
/
[ec2-user ~]$ sudo e2label /dev/xvdf1
/
```

In this example, you could end up having `/dev/xvdf1` become the root device that your instance boots to after the initial ramdisk runs, instead of the `/dev/xvda1` volume from which you had intended to boot. To solve this, use the same **e2label** command to change the label of the attached volume that you do not want to boot from.

In some cases, specifying a UUID in `/etc/fstab` can resolve this. However, if both volumes come from the same snapshot, or the secondary is created from a snapshot of the primary volume, they share a UUID.

```
[ec2-user ~]$ sudo blkid
/dev/xvda1: LABEL="/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"
 PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
/dev/xvdf1: LABEL="old/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"
 PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
```

To change the label of an attached ext4 volume

1. Use the **e2label** command to change the label of the volume to something other than /.

   ```
   [ec2-user ~]$ sudo e2label /dev/xvdf1 old/
   ```

2. Verify that the volume has the new label.

   ```
   [ec2-user ~]$ sudo e2label /dev/xvdf1
   old/
   ```

To change the label of an attached xfs volume

- Use the **xfs_admin** command to change the label of the volume to something other than /.

```
[ec2-user ~]$ sudo xfs_admin -L old/ /dev/xvdf1
writing all SBs
new label = "old/"
```

After changing the volume label as shown, you should be able to reboot the instance and have the proper volume selected by the initial ramdisk when the instance boots.

> **Important**
>
> If you intend to detach the volume with the new label and return it to another instance to use as the root volume, you must perform the above procedure again and change the volume label back to its original value. Otherwise, the other instance does not boot because the ramdisk is unable to find the volume with the label /.

Troubleshoot issues connecting to your Amazon EC2 Windows instance

The following information and common errors can help you troubleshoot issues when connecting to your Windows instance.

Connection issues

- Remote Desktop can't connect to the remote computer
- Error using the macOS RDP client
- RDP displays a black screen instead of the desktop
- Unable to remotely log on to an instance with a user that is not an administrator
- Troubleshooting Remote Desktop issues using AWS Systems Manager
- Enable Remote Desktop on an EC2 instance with remote registry
- I've lost my private key. How can I connect to my Windows instance?

Remote Desktop can't connect to the remote computer

Try the following to resolve issues related to connecting to your instance:

- Verify that you're using the correct public DNS hostname. (In the Amazon EC2 console, select the instance and check **Public DNS (IPv4)** in the details pane.) If your instance is in a VPC and you do not see a public DNS name, you must enable DNS hostnames. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.
- Verify that your instance has a public IPv4 address. If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses.
- To connect to your instance using an IPv6 address, check that your local computer has an IPv6 address and is configured to use IPv6. For more information, see Configure IPv6 on your instances in the *Amazon VPC User Guide*.
- Verify that your security group has a rule that allows RDP access on port 3389.
- If you copied the password but get the error `Your credentials did not work`, try typing them manually when prompted. It's possible that you missed a character or got an extra white space character when you copied the password.
- Verify that the instance has passed status checks. For more information, see Status checks for Amazon EC2 instances and the section called "Linux instance failed status checks".
- Verify that the route table for the subnet has a route that sends all traffic destined outside the VPC to the internet gateway for the VPC. For more information, see Creating a custom route table (Internet Gateways) in the *Amazon VPC User Guide*.
- Verify that Windows Firewall, or other firewall software, is not blocking RDP traffic to the instance. We recommend that you disable Windows Firewall and control access to your instance using security group rules. Try one of the following options:
  - Use AWSSupport-TroubleshootRDP to disable the Windows Firewall profiles using SSM Agent. This option requires that the instance is configured for AWS Systems Manager.
  - Use AWSSupport-ExecuteEC2Rescue.
  - Stop the instance, detach the root volume, and attach the volume to a temporary instance as a data volume. Connect to the temporary instance and bring the volume online. Load the registry hive from the data volume. Under `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SharedAccess\Parameters\FirewallPolicyStandardProfile`, set `EnableFirewall` to 0. Unload the registry hive and then bring the volume offline. Detach the volume from the temporary instance and attach it to the original instance as the root volume. Start the original instance.
- Verify that Network Level Authentication is disabled on instances that are not part of an Active Directory domain (use AWSSupport-TroubleshootRDP to disable NLA).

- Verify that the Remote Desktop Service (TermService) Startup Type is Automatic and the service is started (use AWSSupport-TroubleshootRDP to enable and start the RDP service).
- Verify that you are connecting to the correct Remote Desktop Protocol port, which by default is 3389 (use AWSSupport-TroubleshootRDP to read the current RDP port and change it back to 3389).
- Verify that Remote Desktop connections are allowed on your instance (use AWSSupport-TroubleshootRDP to enable Remote Desktop connections).
- Verify that the password has not expired. If the password has expired, you can reset it. For more information, see Reset the Windows administrator password for an Amazon EC2 Windows instance.
- If you attempt to connect using a user that you created on the instance and receive the error `The user cannot connect to the server due to insufficient access privileges`, verify that you granted the user the right to log on locally. For more information, see Grant a Member the Right to Logon Locally.
- If you attempt more than the maximum allowed concurrent RDP sessions, your session is terminated with the message `Your Remote Desktop Services session has ended. Another user connected to the remote computer, so your connection was lost.` By default, you are allowed two concurrent RDP sessions to your instance.

Error using the macOS RDP client

If you are connecting to a Windows Server instance using the Remote Desktop Connection client from the Microsoft website, you may get the following error:

```
Remote Desktop Connection cannot verify the identity of the computer that you want to
 connect to.
```

Download the Microsoft Remote Desktop app from the Mac App Store and use the app to connect to your instance.

RDP displays a black screen instead of the desktop

Try the following to resolve this issue:

- Check the console output for additional information. To get the console output for your instance using the Amazon EC2 console, select the instance, and then choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

- Verify that you are running the latest version of your RDP client.
- Try the default settings for the RDP client.
- If you are using Remote Desktop Connection, try starting it with the `/admin` option as follows.

```
mstsc /v:instance /admin
```

- If the server is running a full-screen application, it might have stopped responding. Use Ctrl +Shift+Esc to start Windows Task Manager, and then close the application.
- If the server is over-utilized, it might have stopped responding. To monitor the instance using the Amazon EC2 console, select the instance and then select the **Monitoring** tab. If you need to change the instance type to a larger size, see Amazon EC2 instance type changes.

Unable to remotely log on to an instance with a user that is not an administrator

If you are not able to remotely log on to a Windows instance with a user that is not an administrator account, ensure that you have granted the user the right to log on locally. See Grant a user or group the right to log on locally to the domain controllers in the domain.

Troubleshooting Remote Desktop issues using AWS Systems Manager

You can use AWS Systems Manager to troubleshoot issues connecting to your Windows instance using RDP.

AWSSupport-TroubleshootRDP

The AWSSupport-TroubleshootRDP automation document allows the user to check or modify common settings on the target instance that can impact Remote Desktop Protocol (RDP) connections, such as the **RDP Port**, **Network Layer Authentication (NLA)**, and **Windows Firewall** profiles. By default, the document reads and outputs the values of these settings.

The AWSSupport-TroubleshootRDP automation document can be used with EC2 instances, on-premises instances, and virtual machines (VMs) that are enabled for use with AWS Systems Manager (managed instances). In addition, it can also be used with EC2 instances for Windows Server that are *not* enabled for use with Systems Manager. For information about enabling instances for use with AWS Systems Manager, see Managed nodes in the*AWS Systems Manager User Guide*.

To troubleshoot using the AWSSupport-TroubleshootRDP document

1. Log in to the Systems Manager Console.
2. Verify that you are in the same Region as the impaired instance.
3. Choose **Documents** from the left navigation pane.
4. On the **Owned by Amazon** tab, enter `AWSSupport-TroubleshootRDP` in the search field. When the `AWSSupport-TroubleshootRDP` document appears, select it.
5. Choose **Execute automation**.
6. For **Execution Mode**, choose **Simple execution**.
7. For **Input parameters**, **InstanceId**, enable **Show interactive instance picker**.
8. Choose your Amazon EC2 instance.
9. Review the examples, then choose **Execute**.
10. To monitor the execution progress, for **Execution status**, wait for the status to change from **Pending** to **Success**. Expand **Outputs** to view the results. To view the output of individual steps, in **Executed Steps**, choose an item from **Step ID.**

AWSSupport-TroubleshootRDP examples

The following examples show you how to accomplish common troubleshooting tasks using AWSSupport-TroubleshootRDP. You can use either the example AWS CLI start-automation-execution command or the provided link to the AWS Management Console.

Example Example: Check the current RDP status

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-
TroubleshootRDP?region=region#documentVersion=$LATEST
```

Example Example: Disable the Windows Firewall

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP"
 --parameters "InstanceId=i-1234567890abcdef0, Action=Custom, Firewall=Disable" --
region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-
TroubleshootRDP?region=region_code#documentVersion=$LATEST&Firewall=Disable
```

Example Example: Disable Network Level Authentication

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, NLASettingAction=Disable" --
region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-
TroubleshootRDP?region=region_code#documentVersion
```

Example Example: Set RDP Service Startup Type to Automatic and start the RDP service

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, RDPServiceStartupType=Auto,
 RDPServiceAction=Start" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/
AWSSupport-TroubleshootRDP?region=region_code#documentVersion=
$LATEST&RDPServiceStartupType=Auto&RDPServiceAction=Start
```

Example Example: Restore the default RDP Port (3389)

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, RDPPortAction=Modify" --
region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-
TroubleshootRDP?region=region_code#documentVersion=$LATEST&RDPPortAction=Modify
```

Example Example: Allow remote connections

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --
parameters "InstanceId=i-1234567890abcdef0, Action=Custom, RemoteConnections=Enable" --
region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-
TroubleshootRDP?region=region_code#documentVersion=$LATEST&RemoteConnections=Enable
```

AWSSupport-ExecuteEC2Rescue

The AWSSupport-ExecuteEC2Rescue automation document uses EC2Rescue for Windows Server to automatically troubleshoot and restore EC2 instance connectivity and RDP issues. For more information, see Run the EC2Rescue tool on unreachable instances.

The AWSSupport-ExecuteEC2Rescue automation document requires a stop and restart of the instance. Systems Manager Automation stops the instance and creates an Amazon Machine Image (AMI). Data stored in instance store volumes is lost. The public IP address changes if you are not using an Elastic IP address. For more information, see Run the EC2Rescue tool on unreachable instances in the *AWS Systems Manager User Guide*.

To troubleshoot using the AWSSupport-ExecuteEC2Rescue document

1. Open the Systems Manager console.
2. Verify that you are in the same Region as the impaired Amazon EC2 instance.
3. In the navigation panel, choose **Documents**.

4. Search for and select the `AWSSupport-ExecuteEC2Rescue` document, and then choose **Execute automation**.
5. In **Execution Mode**, choose **Simple execution**.
6. In the **Input parameters** section, for **UnreachableInstanceId**, enter the Amazon EC2 instance ID of the unreachable instance.
7. (Optional) For **LogDestination**, enter the Amazon Simple Storage Service (Amazon S3) bucket name if you want to collect operating system logs for troubleshooting your Amazon EC2 instance. Logs are automatically uploaded to the specified bucket.
8. Choose **Execute**.
9. To monitor the execution progress, in **Execution status**, wait for the status to change from **Pending** to **Success**. Expand **Outputs** to view the results. To view the output of individual steps, in **Executed Steps**, choose the **Step ID**.

Enable Remote Desktop on an EC2 instance with remote registry

If your unreachable instance is not managed by AWS Systems Manager Session Manager, then you can use remote registry to enable Remote Desktop.

1. From the EC2 console, stop the unreachable instance.
2. Detach the root volume of the unreachable instance and attach it to a reachable instance in the same Availability Zone as a storage volume. If you don't have a reachable instance in the same Availability Zone, launch one. Note the device name of the root volume on the unreachable instance.
3. On the reachable instance, open Disk Management. You can do so by running the following command in the Command Prompt window.

```
diskmgmt.msc
```

4. Right click the newly attached volume that came from the unreachable instance, and then choose **Online**.
5. Open the Windows Registry Editor. You can do so by running the following command in the Command Prompt window.

```
regedit
```

6. In Registry Editor, choose **HKEY_LOCAL_MACHINE**, then select **File**, **Load Hive**.

7. Select the drive of the attached volume, navigate to `\Windows\System32\config\`, select `SYSTEM`, and then choose **Open**.
8. For **Key Name**, enter a unique name for the hive and choose **OK**.
9. Back up the registry hive before making any changes to the registry.

   a. In the Registry Editor console tree, select the hive that you loaded: **HKEY_LOCAL_MACHINE***your-key-name*.
   b. Choose **File**, **Export**.
   c. In the Export Registry File dialog box, choose the location to which you want to save the backup copy, and then type a name for the backup file in the **File name** field.
   d. Choose **Save**.
10. In Registry Editor, navigate to `HKEY_LOCAL_MACHINE\your key name\ControlSet001\Control\Terminal Server`, and then, in the details pane, double-click **fDenyTSConnections**.
11. In the **Edit DWORD** value box, enter `0` in the **Value data** field.
12. Choose **OK**.

> **Note**
>
> If the value in the **Value data** field is `1`, then the instance will deny remote desktop connections. A value of `0` allows remote desktop connections.

13. In Registry Editor, choose **HKEY_LOCAL_MACHINE***your-key-name*, then select **File**, **Unload Hive**.
14. Close Registry Editor and Disk Management.
15. From the EC2 console, detach the volume from the reachable instance and then reattach it to the unreachable instance. When attaching the volume to the unreachable instance, enter the device name that you saved earlier in the **device** field.
16. Restart the unreachable instance.

I've lost my private key. How can I connect to my Windows instance?

When you connect to a newly-launched Windows instance, you decrypt the password for the Administrator account using the private key for the key pair that you specified when you launched the instance.

If you lose the Administrator password and you no longer have the private key, you must reset the password or create a new instance. For more information, see Reset the Windows administrator password for an Amazon EC2 Windows instance. For steps to reset the password using an Systems Manager document, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

Troubleshoot Amazon EC2 Windows instance start issues

The following are troubleshooting tips to help you solve password and activation issues with Amazon EC2 Windows instances.

Issues

- "Password is not available"
- "Password not available yet"
- "Cannot retrieve Windows password"
- "Waiting for the metadata service"
- "Unable to activate Windows"
- "Windows is not genuine (0x80070005)"
- "No Terminal Server License Servers available to provide a license"
- "Some settings are managed by your organization"

"Password is not available"

To connect to a Windows instance using Remote Desktop, you must specify an account and password. The accounts and passwords provided are based on the AMI that you used to launch the instance. You can either retrieve the auto-generated password for the Administrator account, or use the account and password that were in use in the original instance from which the AMI was created.

You can generate a password for the Administrator account for instances launched using a custom Windows AMI. To generate the password, you will need to configure some settings in the operating system before the AMI is created. For more information, see Create an Amazon EBS-backed AMI.

If your Windows instance isn't configured to generate a random password, you'll receive the following message when you retrieve the auto-generated password using the console:

```
Password is not available.
The instance was launched from a custom AMI, or the default password has changed. A
password cannot be retrieved for this instance. If you have forgotten your password,
 you can
reset it using the Amazon EC2 configuration service. For more information, see
 Passwords for a
Windows Server instance.
```

Check the console output for the instance to see whether the AMI that you used to launch it was created with password generation disabled. If password generation is disabled, the console output contains the following:

```
Ec2SetPassword: Disabled
```

If password generation is disabled and you don't remember the password for the original instance, you can reset the password for this instance. For more information, see Reset the Windows administrator password for an Amazon EC2 Windows instance.

"Password not available yet"

To connect to a Windows instance using Remote Desktop, you must specify an account and password. The accounts and passwords provided are based on the AMI that you used to launch the instance. You can either retrieve the auto-generated password for the Administrator account, or use the account and password that were in use in the original instance from which the AMI was created.

Your password should be available within a few minutes. If the password isn't available, you'll receive the following message when you retrieve the auto-generated password using the console:

```
Password not available yet.
Please wait at least 4 minutes after launching an instance before trying to retrieve
 the
auto-generated password.
```

If it's been longer than four minutes and you still can't get the password, it's possible that the launch agent for your instance is not configured to generate a password. Verify by checking whether the console output is empty. For more information, see Unable to get console output.

Also verify that the AWS Identity and Access Management (IAM) account being used to access the Management Portal has the `ec2:GetPasswordData` action allowed. For more information about IAM permissions, see What is IAM?.

"Cannot retrieve Windows password"

To retrieve the auto-generated password for the Administrator account, you must use the private key for the key pair that you specified when you launched the instance. If you didn't specify a key pair when you launched the instance, you'll receive the following message.

```
Cannot retrieve Windows password
```

You can terminate this instance and launch a new instance using the same AMI, making sure to specify a key pair.

"Waiting for the metadata service"

A Windows instance must obtain information from its instance metadata before it can activate itself. By default, the `WaitForMetaDataAvailable` setting ensures that the EC2Config service waits for the instance metadata to be accessible before continuing with the boot process. For more information, see Use instance metadata to manage your EC2 instance.

If the instance is failing the instance reachability test, try the following to resolve this issue.

- Check the CIDR block for your VPC. A Windows instance cannot boot correctly if it's launched into a VPC that has an IP address range from `224.0.0.0` to `255.255.255.255` (Class D and Class E IP address ranges). These IP address ranges are reserved, and should not be assigned to host devices. We recommend that you create a VPC with a CIDR block from the private (non-publicly routable) IP address ranges as specified in RFC 1918.
- It's possible that the system has been configured with a static IP address. Try creating a network interface and attaching it to the instance.
- **To enable DHCP on a Windows instance that you can't connect to**

  1. Stop the affected instance and detach its root volume.
  2. Launch a temporary instance in the same Availability Zone as the affected instance.

> **Warning**
>
> If your temporary instance is based on the same AMI that the original instance is based on, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses the AWS Windows AMI for Windows Server 2016, launch the temporary instance using the AWS Windows AMI for Windows Server 2019.

3. Attach the root volume from the affected instance to this temporary instance. Connect to the temporary instance, open the **Disk Management** utility, and bring the drive online.

4. From the temporary instance, open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SYSTEM`, and specify a key name when prompted (you can use any name).

5. Select the key that you just loaded and navigate to `ControlSet001\Services\Tcpip\Parameters\Interfaces`. Each network interface is listed by a GUID. Select the correct network interface. If DHCP is disabled and a static IP address assigned, `EnableDHCP` is set to 0. To enable DHCP, set `EnableDHCP` to 1, and delete the following keys if they exist: `NameServer`, `SubnetMask`, `IPAddress`, and `DefaultGateway`. Select the key again, and from the **File** menu, choose **Unload Hive**.

> **Note**
>
> If you have multiple network interfaces, you'll need to identify the correct interface to enable DHCP. To identify the correct network interface, review the following key values `NameServer`, `SubnetMask`, `IPAddress`, and `DefaultGateway`. These values display the static configuration of the previous instance.

6. (Optional) If DHCP is already enabled, it's possible that you don't have a route to the metadata service. Updating EC2Config can resolve this issue.

   a. Download and install the latest version of the EC2Config service. For more information about installing this service, see the section called “Install EC2Config”.

   b. Extract the files from the `.zip` file to the `Temp` directory on the drive you attached.

c. Open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SOFTWARE`, and specify a key name when prompted (you can use any name).

d. Select the key that you just loaded and navigate to `Microsoft\Windows\CurrentVersion`. Select the `RunOnce` key. (If this key doesn't exist, right-click `CurrentVersion`, point to **New**, select **Key**, and name the key `RunOnce`.) Right-click, point to **New**, and select **String Value**. Enter `Ec2Install` as the name and `C:\Temp\Ec2Install.exe -q` as the data.

e. Select the key again, and from the **File** menu, choose **Unload Hive**.

7. (Optional) If your temporary instance is based on the same AMI that the original instance is based on, you must complete the following steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision.

> **Warning**
>
> The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see [Configure the Registry](#).

a. Open a command prompt, type **regedit.exe**, and press Enter.

b. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.

c. Type **Windows Boot Manager** and then choose **Find Next**.

d. Choose the key named `11000001`. This key is a sibling of the key you found in the previous step.

e. In the right pane, choose `Element` and then choose **Modify** from the context menu (right-click).

f. Locate the four-byte disk signature at offset 0x38 in the data. Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is `E9EB3AA5`:

```
...
0030  00 00 00 00 01 00 00 00
0038  A5 3A EB E9 00 00 00 00
0040  00 00 00 00 00 00 00 00
```

```
...
```

g. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

h. Run the following DiskPart command to select the volume. (You can verify that the disk number is 1 using the **Disk Management** utility.)

```
DISKPART> select disk 1

Disk 1 is now the selected disk.
```

i. Run the following DiskPart command to get the disk signature.

```
DISKPART>  uniqueid disk

Disk ID: 0C764FA8
```

j. If the disk signature shown in the previous step doesn't match the disk signature from BCD that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

8. Using the **Disk Management** utility, bring the drive offline.

> **Note**
>
> The drive is automatically offline if the temporary instance is running the same operating system as the affected instance, so you won't need to bring it offline manually.

9. Detach the volume from the temporary instance. You can terminate the temporary instance if you have no further use for it.
10. Restore the root volume of the affected instance by attaching the volume as `/dev/sda1`.
11. Start the affected instance.

If you are connected to the instance, open an Internet browser from the instance and enter the following URL for the metadata server:

```
http://169.254.169.254/latest/meta-data/
```

If you can't contact the metadata server, try the following to resolve the issue:

- Download and install the latest version of the EC2Config service. For more information about installing this service, see the section called "Install EC2Config".
- Check whether the Windows instance is running Red Hat PV drivers. If so, update to Citrix PV drivers. For more information, see the section called "Upgrade PV drivers".
- Verify that the firewall, IPSec, and proxy settings do not block outgoing traffic to the metadata service (`169.254.169.254`) or the AWS KMS servers (the addresses are specified in `TargetKMSServer` elements in `C:\Program Files\Amazon\Ec2ConfigService\Settings\ActivationSettings.xml`).
- Verify that you have a route to the metadata service (`169.254.169.254`) using the following command.

  ```
  route print
  ```

- Check for network issues that might affect the Availability Zone for your instance. Go to http://status.aws.amazon.com/.

"Unable to activate Windows"

Windows instances use Windows AWS KMS activation. You can receive this message: `A problem occurred when Windows tried to activate. Error Code 0xC004F074`, if your instance can't reach the AWS KMS server. Windows must be activated every 180 days. EC2Config attempts to contact the AWS KMS server before the activation period expires to ensure that Windows remains activated.

If you encounter a Windows activation issue, use the following procedure to resolve the issue.

For EC2Config (Windows Server 2012 R2 AMIs and earlier)

1. Download and install the latest version of the EC2Config service. For more information about installing this service, see the section called "Install EC2Config".

2. Log onto the instance and open the following file: `C:\Program Files\Amazon\Ec2ConfigService\Settings\config.xml`.
3. Locate the **Ec2WindowsActivate** plugin in the `config.xml` file. Change the state to **Enabled** and save your changes.
4. In the Windows Services snap-in, restart the EC2Config service or reboot the instance.

If this does not resolve the activation issue, follow these additional steps.

1. Set the AWS KMS target: **C:\> slmgr.vbs /skms 169.254.169.250:1688**
2. Activate Windows: **C:\> slmgr.vbs /ato**

For EC2Launch (Windows Server 2016 AMIs and later)

1. From a PowerShell prompt with administrative rights, import the EC2Launch module:

```
PS C:\> Import-Module "C:\ProgramData\Amazon\EC2-Windows\Launch\Module
\Ec2Launch.psd1"
```

2. Call the Add-Routes function to see the list of new routes:

```
PS C:\> Add-Routes
```

3. Call the Set-ActivationSettings function:

```
PS C:\> Set-Activationsettings
```

4. Then, run the following script to activate Windows:

```
PS C:\> cscript "${env:SYSTEMROOT}\system32\slmgr.vbs" /ato
```

For both EC2Config and EC2Launch, if you are still receiving an activation error, verify the following information.

- Verify that you have routes to the AWS KMS servers. Open `C:\Program Files\Amazon\Ec2ConfigService\Settings\ActivationSettings.xml` and locate the `TargetKMSServer` elements. Run the following command and check whether the addresses for these AWS KMS servers are listed.

```
route print
```

- Verify that the AWS KMS client key is set. Run the following command and check the output.

  ```
  C:\Windows\System32\slmgr.vbs /dlv
  ```

  If the output contains Error: product key not found, the AWS KMS client key isn't set. If the AWS KMS client key isn't set, look up the client key as described in this Microsoft article: [AWS KMS client activation and product keys](), and then run the following command to set the AWS KMS client key.

  ```
  C:\Windows\System32\slmgr.vbs /ipk client_key
  ```

- Verify that the system has the correct time and time zone. If you are using a time zone other than UTC, add the following registry key and set it to 1 to ensure that the time is correct: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation\RealTimeIsUniversal`.
- If Windows Firewall is enabled, temporarily disable it using the following command.

  ```
  netsh advfirewall set allprofiles state off
  ```

"Windows is not genuine (0x80070005)"

Windows instances use Windows AWS KMS activation. If an instance is unable to complete the activation process, it reports that the copy of Windows is not genuine.

Try the suggestions for ["Unable to activate Windows"]().

"No Terminal Server License Servers available to provide a license"

By default, Windows Server is licensed for two simultaneous users through Remote Desktop. If you need to provide more than two users with simultaneous access to your Windows instance through Remote Desktop, you can purchase a Remote Desktop Services client access license (CAL) and install the Remote Desktop Session Host and Remote Desktop Licensing Server roles.

Check for the following issues:

- You've exceeded the maximum number of concurrent RDP sessions.

- You've installed the Windows Remote Desktop Services role.
- Licensing has expired. If the licensing has expired, you can't connect to your Windows instance as a user. You can try the following:
  - Connect to the instance from the command line using an `/admin` parameter, for example:

    ```
    mstsc /v:instance /admin
    ```

    For more information, see the following Microsoft article: [Access Remote Desktop Via Command Line](#).
  - Stop the instance, detach its Amazon EBS volumes, and attach them to another instance in the same Availability Zone to recover your data.

"Some settings are managed by your organization"

Instances launched from the latest Windows Server AMIs might show a Windows Update dialog message stating "Some settings are managed by your organization." This message appears as a result of changes in Windows Server and does not impact the behavior of Windows Update or your ability to manage update settings.

To remove the warning

1. Open `gpedit.msc` and navigate to **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Windows updates**. Edit **Configure Automatic Update**, and set it to **enabled**.
2. In a command prompt, update group policy using **gpupdate /force**.
3. Close and reopen the Windows Update Settings. You will see the above message about your settings being managed by your organization, followed by "We'll automatically download updates, except on metered connections (where charges may apply). In that case, we'll automatically download those updates required to keep Windows running smoothly."
4. Return to `gpedit.msc` and set the group policy back to **not configured**. Run **gpupdate /force** again.
5. Close the command prompt and wait a few minutes.
6. Reopen the Windows Update Settings. You should not see the message "Some settings are managed by your organization."

Troubleshoot issues with Amazon EC2 Windows instances

The following are troubleshooting tips to help you solve the issues with Amazon EC2 Windows instances.

Issues

Unable to connect AWS Systems Manager Sessions Manager to a Windows Server 2025 instance

You may encounter an issue connecting AWS Systems Manager Sessions Manager to a Windows Server 2025 instance. To address this issue, log onto the instance, then navigate to `Settings > Apps > Optional Features`, and add `WMIC`. Restart the SSM Agent service or reboot the instance, and Sessions Manager should connect.

You can also use the following PowerShell command to perform the same action:

```
Start-Process -FilePath "$env:SystemRoot\system32\Dism.exe" -ArgumentList @('/
Online', '/Add-Capability', '/CapabilityName:WMIC~~~~') -Wait; Restart-Service -Name
 AmazonSSMAgent
```

EBS volumes don't initialize on Windows Server 2016 and 2019

Instances created from Amazon Machine Images (AMIs) for Windows Server 2016 and 2019 use the EC2Launch v1 agent for a variety of startup tasks, including initializing EBS volumes. By default, EC2Launch v1 doesn't initialize secondary volumes. However, you can configure EC2Launch v1 to initialize these disks automatically, as follows.

Map drive letters to volumes

1. Connect to the instance to configure and open the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\DriveLetterMappingConfig.json` file in a text editor.
2. Specify the volume settings as follows:

```
{
"driveLetterMapping": [
 {
   "volumeName": "sample volume",
   "driveLetter": "H"
 }]
}
```

3. Save your changes and close the file.
4. Open Windows PowerShell and use the following command to run the EC2Launch v1 script that initializes the disks:

```
PS C:\>  C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1
```

To initialize the disks each time the instance boots, add the `-Schedule` flag as follows:

```
PS C:\>  C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1 -
Schedule
```

The EC2Launch v1 agent can run instance initialization scripts such as `initializeDisks.ps1` in parallel with the `InitializeInstance.ps1` script. If the `InitializeInstance.ps1` script reboots the instance, it might interrupt other scheduled tasks that run at instance startup. To avoid any potential conflicts, we recommend that you add logic to your `initializeDisks.ps1` script to ensure that instance initialization has finished first.

> **Note**
>
> If the EC2Launch script does not initialize the volumes, ensure that the volumes are online. If the volumes are offline, run the following command to bring all disks online.

```
PS C:\> Get-Disk | Where-Object IsOffline -Eq $True | Set-Disk -IsOffline
 $False
```

Boot an EC2 Windows instance into Directory Services Restore Mode (DSRM)

If an instance running Microsoft Active Directory experiences a system failure or other critical issues you can troubleshoot the instance by booting into a special version of Safe Mode called *Directory Services Restore Mode* (DSRM). In DSRM you can repair or recover Active Directory.

Driver support for DSRM

How you enable DSRM and boot into the instance depends on the drivers the instance is running. In the EC2 console you can view driver version details for an instance from the System Log. The following table shows which drivers are supported for DSRM.

Driver Versions	DSRM Supported?	Next Steps
Citrix PV 5.9	No	Restore the instance from a backup. You cannot enable DSRM.
AWS PV 7.2.0	No	Though DSRM is not supported for this driver, you can still detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, and attach it to another instance in the same Availability Zone as a secondary volume. You can then enable DSRM (as described in this section).
AWS PV 7.2.2 and later	Yes	Detach the root volume, attach it to another instance, and enable DSRM (as described in this section).
Enhanced Networking	Yes	Detach the root volume, attach it to another instance, and enable DSRM (as described in this section).

For information about how to enable enhanced networking, see the section called “Elastic Network Adapter (ENA)”. For information about upgrading AWS PV drivers, see Upgrade PV drivers on Windows instances.

Configure an instance to boot into DSRM

EC2 Windows instances do not have network connectivity before the operating system is running. For this reason, you cannot press the F8 button on your keyboard to select a boot option. You must use one of the following procedures to boot an EC2 Windows Server instance into DSRM.

If you suspect that Active Directory has been corrupted and the instance is still running, you can configure the instance to boot into DSRM using either the System Configuration dialog box or the command prompt.

To boot an online instance into DSRM using the System Configuration dialog box

1. In the **Run** dialog box, type `msconfig` and press Enter.
2. Choose the **Boot** tab.
3. Under **Boot options** choose **Safe boot**.
4. Choose **Active Directory repair** and then choose **OK**. The system prompts you to reboot the server.

To boot an online instance into DSRM using the command line

From a Command Prompt window, run the following command:

```
bcdedit /set safeboot dsrepair
```

If an instance is offline and unreachable, you must detach the root volume and attach it to another instance to enable DSRM mode.

To boot an offline instance into DSRM

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Locate and select the affected instance. Choose **Instance state**, **Stop instance**.
4. Choose **Launch instances** and create a temporary instance in the same Availability Zone as the affected instance. Choose an instance type that uses a different version of Windows.

For example, if your instance is Windows Server 2016, then choose a Windows Server 2019 instance.

> **Important**
>
> If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the navigation pane, choose **Volumes**.
6. Locate the root volume of the affected instance. Detach the volume and attach it to the temporary instance you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to make the volume available for use.
8. Open a command prompt and run the following command. Replace *D* with the actual drive letter of the secondary volume you just attached:

```
bcdedit /store D:\Boot\BCD /set {default} safeboot dsrepair
```

9. In the Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
10. In the EC2 console, detach the affected volume from the temporary instance and reattach it to your original instance with the device name `/dev/sda1`. You must specify this device name to designate the volume as a root volume.
11. Start the instance.
12. After the instance passes the health checks in the EC2 console, connect to the instance using Remote Desktop and verify that it boots into DSRM mode.
13. (Optional) Delete or stop the temporary instance you created in this procedure.

Instance loses network connectivity or scheduled tasks don't run when expected

If you restart your instance and it loses network connectivity, it's possible that the instance has the wrong time.

By default, Windows instances use Coordinated Universal Time (UTC). If you set the time for your instance to a different time zone and then restart it, the time becomes offset and the instance temporarily loses its IP address. The instance regains network connectivity eventually, but this can take several hours. The amount of time that it takes for the instance to regain network connectivity depends on the difference between UTC and the other time zone.

This same time issue can also result in scheduled tasks not running when you expect them to. In this case, the scheduled tasks do not run when expected because the instance has the incorrect time.

To use a time zone other than UTC persistently, you must set the **RealTimeIsUniversal** registry key. Without this key, an instance uses UTC after you restart it.

To resolve time issues that cause a loss of network connectivity

1. Ensure that you are running the recommended PV drivers. For more information, see the section called “Upgrade PV drivers”.
2. Verify that the following registry key exists and is set to 1: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation\RealTimeIsUniversal**

Unable to get console output

For Windows instances, the instance console displays the output from tasks performed during the Windows boot process. If Windows boots successfully, the last message logged is `Windows is Ready to use`. You can also display event log messages in the console, but this feature might not be enabled by default depending on your version of Windows. For more information, see the section called “Windows launch agents”.

To get the console output for your instance using the Amazon EC2 console, select the instance, and then choose **Actions**, **Monitor and troubleshoot**, **Get system log**. To get the console output using the command line, use one of the following commands: get-console-output (AWS CLI) or Get-EC2ConsoleOutput (AWS Tools for Windows PowerShell).

For instances running Windows Server 2012 R2 and earlier, if the console output is empty, it could indicate an issue with the EC2Config service, such as a misconfigured configuration file, or that Windows failed to boot properly. To fix the issue, download and install the latest version of EC2Config. For more information, see the section called “Install EC2Config”.

Windows Server 2012 R2 not available on the network

For information about troubleshooting a Windows Server 2012 R2 instance that is not available on the network, see Windows Server 2012 R2 loses network and storage connectivity after an instance reboot.

Disk signature collision

You can check for and resolve disk signature collisions using EC2Rescue for Windows Server. Or, you can manually resolve disk signature issues by performing the following steps.

> **Warning**
>
> The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see Configure the Registry.

1. Open a command prompt, type **regedit.exe**, and press Enter.
2. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.
3. Type **Windows Boot Manager** and then choose **Find Next**.
4. Choose the key named `11000001`. This key is a sibling of the key you found in the previous step.
5. In the right pane, choose `Element` and then choose **Modify** from the context menu (right-click).
6. Locate the four-byte disk signature at offset 0x38 in the data. This is the Boot Configuration Database signature (BCD). Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is `E9EB3AA5`:

```
...
0030  00 00 00 00 01 00 00 00
0038  A5 3A EB E9 00 00 00 00
0040  00 00 00 00 00 00 00 00
...
```

7. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

8. Run the `select disk` DiskPart command and specify the disk number for the volume with the disk signature collision.

> **Tip**
>
> To check the disk number for the volume with the disk signature collision, use the **Disk Management** utility. Open a command prompt, type `compmgmt.msc` and press **Enter**. In the left-hand navigation panel, double-click **Disk Management**. In the **Disk Management** utility, check the disk number for the offline volume with the disk signature collision.

```
DISKPART> select disk 1
Disk 1 is now the selected disk.
```

9. Run the following DiskPart command to get the disk signature.

```
DISKPART>  uniqueid disk
Disk ID: 0C764FA8
```

10. If the disk signature shown in the previous step doesn't match the disk signature that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

Reset the Windows administrator password for an Amazon EC2 Windows instance

If you are no longer able to connect to your Amazon EC2 Windows instance because the Windows administrator password is lost or expired, you can reset the password.

> **Note**
>
> There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

The manual methods to reset the administrator password use EC2Launch v2, EC2Config, or EC2Launch.

- For all supported Windows AMIs that include the EC2Launch v2 agent, use EC2Launch v2.
- For Windows AMIs before Windows Server 2016, use the EC2Config service.
- For Windows Server 2016 and later AMIs, use the EC2Launch service.

These procedures also describe how to connect to an instance if you lost the key pair that was used to create the instance. Amazon EC2 uses a public key to encrypt a piece of data, such as a password, and a private key to decrypt the data. The public and private keys are known as a *key pair*. With Windows instances, you use a key pair to obtain the administrator password and then log in using RDP.

> **Note**
>
> If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

Contents

Reset Windows admin password for EC2 instance using EC2Launch v2

If you have lost your Windows administrator password and are using a supported Windows AMI that includes the EC2Launch v2 agent, you can use EC2Launch v2 to generate a new password.

If you are using a Windows Server 2016 or later AMI that does not include the EC2Launch v2 agent, see Reset Windows admin password for EC2 instance using EC2Launch.

If you are using a Windows Server AMI earlier than Windows Server 2016 that does not include the EC2Launch v2 agent, see Reset Windows admin password for EC2 instance using EC2Config.

> **Note**
>
> If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

> **Note**
>
> There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Launch v2, you need to do the following:

- Step 1: Verify that the EC2Launch v2 agent is running
- Step 2: Detach the root volume from the instance
- Step 3: Attach the volume to a temporary instance
- Step 4: Delete the .run-once file
- Step 5: Restart the original instance

Step 1: Verify that the EC2Launch v2 agent is running

Before you attempt to reset the administrator password, verify that the EC2Launch v2 agent is installed and running. You use the EC2Launch v2 agent to reset the administrator password later in this section.

To verify that the EC2Launch v2 agent is running

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and then select the instance that requires a password reset. This instance is referred to as the *original* instance in this procedure.
3. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.
4. Locate the EC2 Launch entry, for example, **Launch: EC2Launch v2 service v2.0.124**. If you see this entry, the EC2Launch v2 service is running.

   If the system log output is empty, or if the EC2Launch v2 agent is not running, troubleshoot the instance using the Instance Console Screenshot service. For more information, see Capture a screenshot of an unreachable instance.

Step 2: Detach the root volume from the instance

You can't use EC2Launch v2 to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Instance state**, **Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.

   a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.

b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.

c. With the instance selected, choose **Actions**, **Image and templates**, **Create image**. Type a name and a description for the image and choose **Create image**.

d. In the navigation pane, choose **AMIs**. Wait for the image status to change to **available**. Then, select the image and choose **Launch instance from AMI**.

e. Complete the fields to launch an instance, making sure to select the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch instance**.

f. When prompted, choose the key pair that you created for the new instance, and then choose **Launch instance**.

g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.

5. Detach the root volume from the original instance as follows:

   a. Select the original instance and choose the **Storage** tab. Note the name of the root device under **Root device name**. Find the volume with this device name under **Block devices**, and note the volume ID.

   b. In the navigation pane, choose **Volumes**.

   c. In the list of volumes, select the volume that you noted as the root device, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

6. If you created a new instance to replace your original instance, you can terminate the original instance now. It's no longer needed. For the remainder of this procedure, all references to the original instance apply to the new instance that you created.

Step 3: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to modify the configuration file.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:

a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

> **Important**
>
> To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

b. Leave the default instance type and choose **Next: Configure Instance Details**.

c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

> **Important**
>
> The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

d. On the **Review Instance Launch** page, choose **Launch**.

e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.

2. Attach the volume to the temporary instance as a secondary volume as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.

   c. For **Device**, type **`xvdf`** (if it isn't already there), and choose **Attach**.

Step 4: Delete the .run-once file

You must now delete the `.run-once` file from the offline volume attached to the instance. This directs EC2Launch v2 to run all tasks with a frequency of `once`, which includes setting the administrator password. The file path in the secondary volume that you attached will be similar to `D:\ProgramData\Amazon\EC2Launch\state\.run-once`.

To delete the .run-once file

1. Open the **Disk Management** utility, and bring the drive online using these instructions: Make an Amazon EBS volume available for use.
2. Locate the `.run-once` file in the disk you brought online.
3. Delete the .run-once file.

> **Important**
>
> Any scripts set to run once will be triggered by this action.

Step 5: Restart the original instance

After you have deleted the `.run-once` file, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

1. Reattach the volume to the original instance as follows:

    a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions**, **Attach Volume**.

    b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.

    c. For **Device**, type **`/dev/sda1`**.

    d. Choose **Attach**. After the volume status changes to `in-use`, continue to the next step.
2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state**, **Start instance**. After the instance state changes to `Running`, continue to the next step.
3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see Connect to your Windows instance using RDP.

    > **Important**
    >
    > The instance gets a new public IP address after you stop and start it. Make sure to connect to the instance using its current public DNS name. For more information, see Amazon EC2 instance state changes.

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State**, **Terminate instance**.

Reset Windows admin password for EC2 instance using EC2Launch

If you have lost your Windows administrator password and are using a Windows Server 2016 or later AMI, you can use the EC2Rescue tool, which uses the EC2Launch service to generate a new password.

If you are using a Windows Server 2016 or later AMI that does not include the EC2Launch v2 agent, you can use EC2Launch v2 to generate a new password.

If you are using a Windows Server AMI earlier than Windows Server 2016, see Reset Windows admin password for EC2 instance using EC2Config.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

> **Note**
>
> If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

> **Note**
>
> There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Launch, you need to do the following:

Step 1: Detach the root volume from the instance

You can't use EC2Launch to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Instance state**, **Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.

    a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.

    b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.

    c. With the instance selected, choose **Actions**, **Image and templates**, **Create image**. Type a name and a description for the image and choose **Create image**.

    d. In the navigation pane, choose **AMIs**. Wait for the image status to change to **available**. Then, select the image and choose **Launch instance from AMI**.

    e. Complete the fields to launch an instance, making sure to select the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch instance**.

    f. When prompted, choose the key pair that you created for the new instance, and then choose **Launch instance**.

    g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.

5. Detach the root volume from the original instance as follows:

    a. Select the original instance and choose the **Storage** tab. Note the name of the root device under **Root device name**. Find the volume with this device name under **Block devices**, and note the volume ID.

    b. In the navigation pane, choose **Volumes**.

    c. In the list of volumes, select the volume that you noted as the root device, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

6. If you created a new instance to replace your original instance, you can terminate the original instance now. It's no longer needed. For the remainder of this procedure, all references to the original instance apply to the new instance that you created.

Step 2: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to run EC2Launch.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:

    a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

    > **Important**
    >
    > To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

    b. Leave the default instance type and choose **Next: Configure Instance Details**.

    c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

> **Important**
>
> The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

   d. On the **Review Instance Launch** page, choose **Launch**.
   e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.

2. Attach the volume to the temporary instance as a secondary volume as follows:
   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions**, **Attach Volume**.
   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.
   c. For **Device**, type `xvdf` (if it isn't already there), and choose **Attach**.

Step 3: Reset the administrator password

Next, connect to the temporary instance and use EC2Launch to reset the administrator password.

To reset the administrator password

1. Connect to the temporary instance and use the EC2Rescue for Windows Server tool on the instance to reset the administrator password as follows:
   a. Download the EC2Rescue for Windows Server zip file, extract the contents, and run **EC2Rescue.exe**.
   b. On the **License Agreement** screen, read the license agreement, and, if you accept the terms, choose **I Agree**.
   c. On the **Welcome to EC2Rescue for Windows Server** screen, choose **Next**.
   d. On the **Select mode** screen, choose **Offline instance**.
   e. On the **Select a disk** screen, select the **xvdf** device and choose **Next**.
   f. Confirm the disk selection and choose **Yes**.
   g. After the volume has loaded, choose **OK**.

h. On the **Select Offline Instance Option** screen, choose **Diagnose and Rescue**.

i. On the **Summary** screen, review the information and choose **Next**.

j. On the **Detected possible issues** screen, select **Reset Administrator Password** and choose **Next**.

k. On the **Confirm** screen, choose **Rescue**, **OK**.

l. On the **Done** screen, choose **Finish**.

m. Close the EC2Rescue for Windows Server tool, disconnect from the temporary instance, and then return to the Amazon EC2 console.

2. Detach the secondary (`xvdf`) volume from the temporary instance as follows:

   a. In the navigation pane, choose **Instances** and select the temporary instance.

   b. On the **Storage** tab for the temporary instance, note the ID of the EBS volume listed as **xvdf**.

   c. In the navigation pane, choose **Volumes**.

   d. In the list of volumes, select the volume noted in the previous step, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

Step 4: Restart the original instance

After you have reset the administrator password using EC2Launch, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

To restart the original instance

1. Reattach the volume to the original instance as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.

   c. For **Device**, type **`/dev/sda1`**.

   d. Choose **Attach**. After the volume status changes to `in-use`, continue to the next step.

2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state**, **Start instance**. After the instance state changes to `Running`, continue to the next step.
3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see Connect to your Windows instance using RDP.
4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State**, **Terminate instance**.

Reset Windows admin password for EC2 instance using EC2Config

If you have lost your Windows administrator password and are using a Windows AMI before Windows Server 2016, you can use the EC2Config agent to generate a new password.

If you are using a Windows Server 2016 or later AMI, see Reset Windows admin password for EC2 instance using EC2Launch or, you can use the EC2Rescue tool, which uses the EC2Launch service to generate a new password.

> **Note**
>
> If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see Use EC2Rescue for Windows Server with Systems Manager Run Command.

> **Note**
>
> There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see Reset passwords and SSH keys on EC2 instances in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Config, you need to do the following:

- Step 1: Verify that the EC2Config service is running
- Step 2: Detach the root volume from the instance

- [Step 3: Attach the volume to a temporary instance]
- [Step 4: Modify the configuration file]
- [Step 5: Restart the original instance]

Step 1: Verify that the EC2Config service is running

Before you attempt to reset the administrator password, verify that the EC2Config service is installed and running. You use the EC2Config service to reset the administrator password later in this section.

To verify that the EC2Config service is running

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and then select the instance that requires a password reset. This instance is referred to as the *original* instance in this procedure.
3. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.
4. Locate the EC2 Agent entry, for example, **EC2 Agent: Ec2Config service v3.18.1118**. If you see this entry, the EC2Config service is running.

   If the system log output is empty, or if the EC2Config service is not running, troubleshoot the instance using the Instance Console Screenshot service. For more information, see Capture a screenshot of an unreachable instance.

Step 2: Detach the root volume from the instance

You can't use EC2Config to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Instance state**, **Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.

4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.

    a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.

    b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.

    c. With the instance selected, choose **Actions**, **Image and templates**, **Create image**. Type a name and a description for the image and choose **Create image**.

    d. In the navigation pane, choose **AMIs**. Wait for the image status to change to **available**. Then, select the image and choose **Launch instance from AMI**.

    e. Complete the fields to launch an instance, making sure to select the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch instance**.

    f. When prompted, choose the key pair that you created for the new instance, and then choose **Launch instance**.

    g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.

5. Detach the root volume from the original instance as follows:

    a. Select the original instance and choose the **Storage** tab. Note the name of the root device under **Root device name**. Find the volume with this device name under **Block devices**, and note the volume ID.

    b. In the navigation pane, choose **Volumes**.

    c. In the list of volumes, select the volume that you noted as the root device, and choose **Actions**, **Detach Volume**. After the volume status changes to **available**, continue with the next step.

6. If you created a new instance to replace your original instance, you can terminate the original instance now. It's no longer needed. For the remainder of this procedure, all references to the original instance apply to the new instance that you created.

Step 3: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to modify the configuration file.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:

   a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

      > **Important**
      >
      > To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

   b. Leave the default instance type and choose **Next: Configure Instance Details**.

   c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

      > **Important**
      >
      > The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

   d. On the **Review Instance Launch** page, choose **Launch**.

   e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.

2. Attach the volume to the temporary instance as a secondary volume as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.

   c. For **Device**, type `xvdf` (if it isn't already there), and choose **Attach**.

Step 4: Modify the configuration file

After you have attached the volume to the temporary instance as a secondary volume, modify the `Ec2SetPassword` plugin in the configuration file.

To modify the configuration file

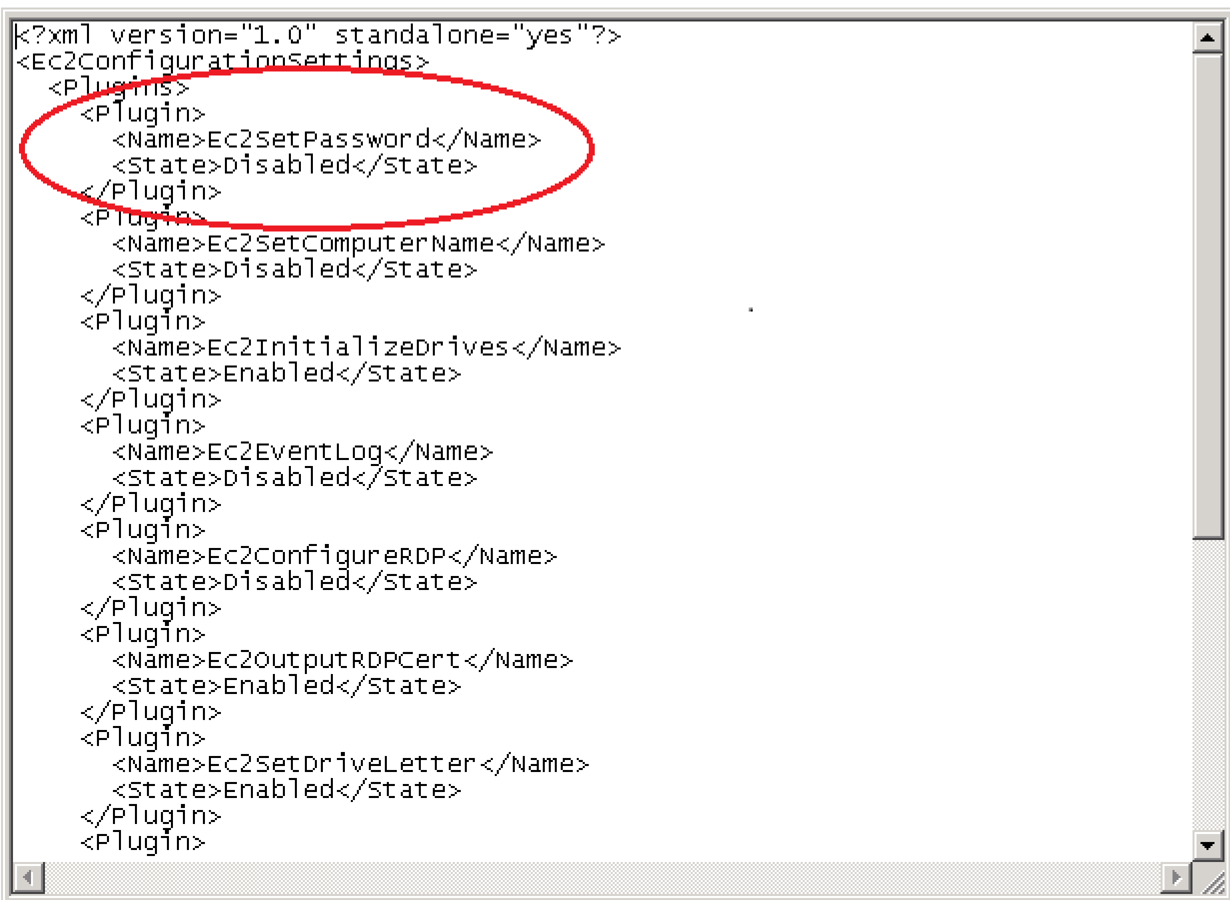
1. From the temporary instance, modify the configuration file on the secondary volume as follows:

   a. Launch and connect to the temporary instance.

   b. Use the following instructions to bring the drive online: [Make an Amazon EBS volume available for use](#).

   c. Navigate to the secondary volume, and open `\Program Files\Amazon\Ec2ConfigService\Settings\config.xml` using a text editor, such as Notepad.

   d. At the top of the file, find the plugin with the name `Ec2SetPassword`, as shown in the screenshot. Change the state from `Disabled` to `Enabled` and save the file.



```
<?xml version="1.0" standalone="yes"?>
<Ec2ConfigurationSettings>
  <Plugins>
    <Plugin>
      <Name>Ec2SetPassword</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2SetComputerName</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2InitializeDrives</Name>
      <State>Enabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2EventLog</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2ConfigureRDP</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2OutputRDPCert</Name>
      <State>Enabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2SetDriveLetter</Name>
      <State>Enabled</State>
    </Plugin>
    <Plugin>
```

2. After you have modified the configuration file, detach the secondary volume from the temporary instance as follows:

   a. Using the **Disk Management** utility, bring the volume offline.

   b. Disconnect from the temporary instance and return to the Amazon EC2 console.

   c. In the navigation pane, choose **Volumes**, select the volume, and then choose **Actions**, **Detach Volume**. After the volume's status changes to **available**, continue with the next step.

Step 5: Restart the original instance

After you have modified the configuration file, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

1. Reattach the volume to the original instance as follows:

   a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions**, **Attach Volume**.

   b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.

   c. For **Device**, type **`/dev/sda1`**.

   d. Choose **Attach**. After the volume status changes to `in-use`, continue to the next step.

2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state**, **Start instance**. After the instance state changes to `Running`, continue to the next step.

3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see Connect to your Windows instance using RDP.

   > **Important**
   >
   > The instance gets a new public IP address after you stop and start it. Make sure to connect to the instance using its current public DNS name. For more information, see Amazon EC2 instance state changes.

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State**, **Terminate instance**.

Troubleshoot Sysprep issues with Amazon EC2 Windows instances

If you experience problems or receive error messages during image preparations, review the following logs. Log location varies depending on whether you are running EC2Config, EC2Launch v1, or EC2Launch v2 with Sysprep.

- `%WINDIR%\Panther\Unattendgc` (EC2Config, EC2Launch v1, and EC2Launch v2)
- `%WINDIR%\System32\Sysprep\Panther` (EC2Config, EC2Launch v1, and EC2Launch v2)
- `C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt` (EC2Config only)
- `C:\ProgramData\Amazon\Ec2Config\Logs` (EC2Config only)
- `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\EC2Launch.log` (EC2Launch v1 only)
- `%ProgramData%\Amazon\EC2Launch\log\agent.log` (EC2Launch v2 only)

If you receive an error message during image preparation with Sysprep, the OS might not be reachable. To review the log files, you must stop the instance, attach its root volume to another healthy instance as a secondary volume, and then review the logs mentioned earlier on the secondary volume. For more information about the purpose of the log files by name, see Windows Setup-Related Log Files in the Microsoft documentation.

If you locate errors in the Unattendgc log file, use the Microsoft Error Lookup Tool to get more details about the error. The following issue reported in the Unattendgc log file is typically the result of one or more corrupted user profiles on the instance:

```
Error [Shell Unattend] _FindLatestProfile failed (0x80070003) [gle=0x00000003]
Error [Shell Unattend] CopyProfile failed (0x80070003) [gle=0x00000003]
```

There are two options for resolving this issue:

Option 1

Use Regedit on the instance to search for the following key. Verify that there are no profile registry keys for a deleted user.

`[HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\ProfileList\`

Option 2

1. Edit the relevant file, as follows:
   - Windows Server 2012 R2 and earlier – Edit the EC2Config answer file (`C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml`).
   - Windows Server 2016 and 2019 – Edit the unattend.xml answer file (`C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep\Unattend.xml`).
   - Windows Server 2022 – Edit the unattend.xml answer file (`C:\ProgramData\Amazon\EC2Launch\sysprep\unattend.xml`).
2. Change `<CopyProfile>true</CopyProfile>` to `<CopyProfile>false</CopyProfile>`.
3. Run Sysprep again. Note that this configuration change will delete the built-in administrator user profile after Sysprep completes.

Troubleshoot impaired Amazon EC2 Linux instance using EC2Rescue

EC2Rescue for Linux is an easy-to-use, open-source tool that can be run on an Amazon EC2 Linux instance to diagnose, troubleshoot, and remediate common issues using its library of over 100 *modules*. Modules are YAML files that contain either a BASH or a Python script and the necessary metadata.

Some generalized use cases for EC2Rescue for Linux instances include:

- Gathering syslog and package manager logs
- Collecting resource utilization data
- Diagnosing and remediating known problematic kernel parameters and common OpenSSH issues

Note

The `AWSSupport-TroubleshootSSH` AWS Systems Manager Automation runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent an SSH connection to a Linux instance. For more information, see AWSSupport-TroubleshootSSH.

If you are using a Windows instance, see the section called “EC2Rescue for Windows instances”.

Topics

Install EC2Rescue on an Amazon EC2 Linux instance

The EC2Rescue for Linux tool can be installed on an Amazon EC2 Linux instance that meets the following prerequisites.

Prerequisites

- Supported operating systems:
  - Amazon Linux 2
  - Amazon Linux 2016.09+
  - SUSE Linux Enterprise Server 12+
  - RHEL 7+
  - Ubuntu 16.04+
- Software requirements:
  - Python 2.7.9+ or 3.2+

Install EC2Rescue

The `AWSSupport-TroubleshootSSH` runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see Support-TroubleshootSSH.

If your system has the required Python version, you can install the standard build. Otherwise, you can install the bundled build, which includes a minimal copy of Python.

To install the standard build

1. From a working Linux instance, download the EC2Rescue for Linux tool:

```
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz
```

2. (*Optional*) Verify the signature of the EC2Rescue for Linux installation file. For more information, see (Optional) Verify the signature of EC2Rescue for Linux.
3. Download the sha256 hash file:

```
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sha256
```

4. Verify the integrity of the tarball:

```
sha256sum -c ec2rl.tgz.sha256
```

5. Unpack the tarball:

```
tar -xzvf ec2rl.tgz
```

6. Verify the installation by listing out the help file:

```
cd ec2rl-<version_number>
./ec2rl help
```

To install the bundled build

For a link to the download and a list of limitations, see EC2Rescue for Linux on github.

(Optional) Verify the signature of EC2Rescue for Linux

The following is the recommended process of verifying the validity of the EC2Rescue for Linux package for Linux-based operating systems.

When you download an application from the internet, we recommend that you authenticate the identity of the software publisher and check that the application has not been altered or corrupted after it was published. This protects you from installing a version of the application that contains a virus or other malicious code.

If, after running the steps in this topic, you determine that the software for EC2Rescue for Linux is altered or corrupted, do not run the installation file. Instead, contact Amazon Web Services.

EC2Rescue for Linux files for Linux-based operating systems are signed using GnuPG, an open-source implementation of the Pretty Good Privacy (OpenPGP) standard for secure digital signatures. GnuPG (also known as GPG) provides authentication and integrity checking through a digital signature. AWS publishes a public key and signatures that you can use to verify the downloaded EC2Rescue for Linux package. For more information about PGP and GnuPG (GPG), see https://www.gnupg.org/.

The first step is to establish trust with the software publisher. Download the public key of the software publisher, check that the owner of the public key is who they claim to be, and then add the public key to your keyring. Your keyring is a collection of known public keys. After you establish the authenticity of the public key, you can use it to verify the signature of the application.

Tasks

- Authenticate and import the public key
- Verify the signature of the package

Authenticate and import the public key

The next step in the process is to authenticate the EC2Rescue for Linux public key and add it as a trusted key in your GPG keyring.

To authenticate and import the EC2Rescue for Linux public key

1. At a command prompt, use the following command to obtain a copy of our public GPG build key:

```
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.key
```

2. At a command prompt in the directory where you saved `ec2rl.key`, use the following command to import the EC2Rescue for Linux public key into your keyring:

   ```
   gpg2 --import ec2rl.key
   ```

   The command returns results similar to the following:

   ```
   gpg: /home/ec2-user/.gnupg/trustdb.gpg: trustdb created
   gpg: key 2FAE2A1C: public key "ec2autodiag@amazon.com <EC2 Rescue for Linux>"
    imported
   gpg: Total number processed: 1
   gpg:               imported: 1  (RSA: 1)
   ```

   Tip

   If you see an error stating that the command cannot be found, install the GnuPG utility with `apt-get install gnupg2` (Debian-based Linux) or `yum install gnupg2` (Red Hat- based Linux).

Verify the signature of the package

After you've installed the GPG tools, authenticated and imported the EC2Rescue for Linux public key, and verified that the EC2Rescue for Linux public key is trusted, you are ready to verify the signature of the EC2Rescue for Linux installation script.

To verify the EC2Rescue for Linux installation script signature

1. At a command prompt, run the following command to download the signature file for the installation script:

   ```
   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sig
   ```

2. Verify the signature by running the following command at a command prompt in the directory where you saved `ec2rl.tgz.sig` and the EC2Rescue for Linux installation file. Both files must be present.

```
gpg2 --verify ./ec2rl.tgz.sig
```

The output should look something like the following:

```
gpg: Signature made Thu 12 Jul 2018 01:57:51 AM UTC using RSA key ID 6991ED45
gpg: Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: E528 BCC9 0DBF 5AFA 0F6C  C36A F780 4843 2FAE 2A1C
     Subkey fingerprint: 966B 0D27 85E9 AEEC 1146  7A9D 8851 1153 6991 ED45
```

If the output contains the phrase `Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"`, it means that the signature has successfully been verified, and you can proceed to run the EC2Rescue for Linux installation script.

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and do not run the installation file that you downloaded previously.

The following are details about the warnings that you might see:

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.** This refers to your personal level of trust in your belief that you possess an authentic public key for EC2Rescue for Linux. In an ideal world, you would visit an Amazon Web Services office and receive the key in person. However, more often you download it from a website. In this case, the website is an Amazon Web Services website.
- **gpg2: no ultimately trusted keys found.** This means that the specific key is not "ultimately trusted" by you (or by other people whom you trust).

For more information, see https://www.gnupg.org/.

Run EC2Rescue commands on an Amazon EC2 Linux instance

EC2Rescue is a command line tool. After you have installed EC2Rescue on your Linux instance, you can get general help on how to use the tool by running `./ec2rl help`. You can view the available modules by running `./ec2rl list`, and you can get help on a specific module by running `./ec2rl help module_name`.

The following are common tasks you can perform to get started using this tool.

Tasks

- Run EC2Rescue modules
- Upload the EC2Rescue module results
- Create backups of an Amazon EC2 Linux instance

Run EC2Rescue modules

To run all EC2Rescue modules

Use the **./ec2rl run** command without specifying any additional parameters. Some modules require root access. If you are not a root user, use **sudo** when you run the command.

```
./ec2rl run
```

To run a specific EC2Rescue module

Use the **./ec2rl run** command and for `--only-modules`, specify the name of the module to run. Some modules require *arguments* to use them.

```
./ec2rl run --only-modules=module_name --arguments
```

For example, to run the **dig** module to query the `amazon.com` domain, use the following command.

```
./ec2rl run --only-modules=dig --domain=amazon.com
```

To view the results of an EC2Rescue module

Run the module then view the log file in `cat /var/tmp/ec2rl/logfile_location`. For example, the log file for the **dig** module can be found in the following location:

```
cat /var/tmp/ec2rl/timestamp/mod_out/run/dig.log
```

Upload the EC2Rescue module results

If Support has requested the results for a EC2Rescue module, you can upload the log file using the EC2Rescue tool. You can upload the results either to a location provided by Support or to an Amazon S3 bucket that you own.

To upload results to a location provided by Support

Use the **./ec2rl upload** command. For `--upload-directory`, specify the location of the log file. For `--support-url`, specify the URL provided by Support.

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/logfile_location --support-url="url_provided_by_aws_support"
```

To upload results to an Amazon S3 bucket

Use the **./ec2rl upload** command. For `--upload-directory`, specify the location of the log file. For `--presigned-url`, specify a presigned URL for the S3 bucket. For more information about generating pre-signed URLs for Amazon S3, see Uploading Objects Using Pre-Signed URLs.

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/logfile_location --presigned-url="presigned_s3_url"
```

Create backups of an Amazon EC2 Linux instance

You can use EC2Rescue to backup your Linux instance by creating an AMI or by creating snapshots of it's attached volumes.

To create an AMI

Use the `./ec2rl run` command and for --`backup`, specify `ami`.

```
./ec2rl run --backup=ami
```

To create multi-volume snapshots of all attached volumes

Use the `./ec2rl run` command and for --`backup`, specify `allvolumes`.

```
./ec2rl run --backup=allvolumes
```

To create a snapshot of a specific attached volume

Use the `./ec2rl run` command and for `--backup`, specify the ID of the volume to back up.

```
./ec2rl run --backup=vol-01234567890abcdef
```

Develop EC2Rescue modules for Amazon EC2 Linux instances

Modules are written in YAML, a data serialization standard. A module's YAML file consists of a single document, representing the module and its attributes.

Add module attributes

The following table lists the available module attributes.

Attribute	Description
name	The name of the module. The name should be less than or equal to 18 characters in length.
version	The version number of the module.
title	A short, descriptive title for the module. This value should be less than or equal to 50 characters in length.

helptext	The extended description of the module. Each line should be less than or equal to 75 characters in length. If the module consumes arguments, required or optional, include them in the helptext value.
	
	For example:
	
	`helptext: !!str |`
	`  Collect output from ps for system analysis`
	`  Consumes --times= for number of times to repeat`
	`  Consumes --period= for time period between repetition`

Attribute	Description
placement	The stage in which the module should be run. Supported values: • prediagnostic • run • postdiagnostic
language	The language that the module code is written in. Supported values: • bash • python **Note** Python code must be compatible with both Python 2.7.9+ and Python 3.2+.
remediation	Indicates whether the module supports remediation. Supported values are `True` or `False`. The module defaults to `False` if this is absent, making it an optional attribute for those modules that do not support remediation.
content	The entirety of the script code.
constraint	The name of the object containing the constraint values.

Attribute	Description
domain	A descriptor of how the module is grouped or classified. The set of included modules uses the following domains: • application • net • os • performance
class	A descriptor of the type of task performed by the module. The set of included modules uses the following classes: • collect (collects output from programs) • diagnose (pass/fail based on a set of criteria) • gather (copies files and writes to specific file)
distro	The list of Linux distributions that this module supports. The set of included modules uses the following distributions: • **alami** (Amazon Linux) • **rhel** • **ubuntu** • **suse**
required	The required arguments that the module is consuming from the CLI options.
optional	The optional arguments that the module can use.

Attribute	Description
software	The software executables used in the module. This attribute is intended to specify software that is not installed by default. The EC2Rescue for Linux logic ensures that these programs are present and executable before running the module.
package	The source software package for an executabl e. This attribute is intended to provide extended details on the package with the software, including a URL for downloading or getting further information.
sudo	Indicates whether root access is required to run the module. You do not need to implement sudo checks in the module script. If the value is true, then the EC2Rescue for Linux logic only runs the module when the executing user has root access.
perfimpact	Indicates whether the module can have significant performance impact upon the environment in which it is run. If the value is true and the `--perfimpact=true` argument is not present, then the module is skipped.
parallelexclusive	Specifies a program that requires mutual exclusivity. For example, all modules specifyin g "bpf" run in a serial manner.

Add environment variables

The following table lists the available environment variables.

Environment Variable	Description
EC2RL_CALLPATH	The path to ec2rl.py. This path can be used to locate the lib directory and use vendored Python modules.
EC2RL_WORKDIR	The main tmp directory for the diagnostic tool. Default value: /var/tmp/ec2rl .
EC2RL_RUNDIR	The directory where all output is stored. Default value: /var/tmp/ec2rl/<date&timestamp> .
EC2RL_GATHEREDDIR	The root directory for placing gathered module data. Default value:/var/tmp/ec2rl/<date&timestamp>/mod_out/gathered/ .
EC2RL_NET_DRIVER	The driver in use for the first, alphabetically ordered, non-virtual network interface on the instance. Examples: • xen_netfront • ixgbevf • ena
EC2RL_SUDO	True if EC2Rescue for Linux is running as root; otherwise, false.
EC2RL_VIRT_TYPE	The virtualization type as provided by the instance metadata. Examples:

Environment Variable	Description
	• default-hvm • default-paravirtual
EC2RL_INTERFACES	An enumerated list of interfaces on the system. The value is a string containing names, such as eth0, eth1, etc. This is generated via the functions.bash and is only available for modules that have sourced it.

Use YAML syntax

The following should be noted when constructing your module YAML files:

- The triple hyphen (---) denotes the explicit start of a document.
- The !ec2rlcore.module.Module tag tells the YAML parser which constructor to call when creating the object from the data stream. You can find the constructor inside the module.py file.
- The !!str tag tells the YAML parser to not attempt to determine the type of data, and instead interpret the content as a string literal.
- The pipe character (|) tells the YAML parser that the value is a literal-style scalar. In this case, the parser includes all whitespace. This is important for modules because indentation and newline characters are kept.
- The YAML standard indent is two spaces, which can be seen in the following examples. Ensure that you maintain standard indentation (for example, four spaces for Python) for your script and then indent the entire content two spaces inside the module file.

Example modules

Example one (mod.d/ps.yaml):

```
--- !ec2rlcore.module.Module
# Module document. Translates directly into an almost-complete Module object
name: !!str ps
path: !!str
```

```
version: !!str 1.0
title: !!str Collect output from ps for system analysis
helptext: !!str |
  Collect output from ps for system analysis
  Requires --times= for number of times to repeat
  Requires --period= for time period between repetition
placement: !!str run
package:
  - !!str
language: !!str bash
content: !!str |
  #!/bin/bash
  error_trap()
  {
      printf "%0.s=" {1..80}
      echo -e "\nERROR: "$BASH_COMMAND" exited with an error on line ${BASH_LINENO[0]}"
      exit 0
  }
  trap error_trap ERR

  # read-in shared function
  source functions.bash
  echo "I will collect ps output from this $EC2RL_DISTRO box for $times times every
 $period seconds."
  for i in $(seq 1 $times); do
      ps auxww
      sleep $period
  done
constraint:
  requires_ec2: !!str False
  domain: !!str performance
  class: !!str collect
  distro: !!str alami ubuntu rhel suse
  required: !!str period times
  optional: !!str
  software: !!str
  sudo: !!str False
  perfimpact: !!str False
  parallelexclusive: !!str
```

Troubleshoot impaired Amazon EC2 Windows instance using EC2Rescue

EC2Rescue for Windows Server is an easy-to-use tool that you run on an Amazon EC2 Windows Server instance to diagnose and troubleshoot possible problems. It is valuable for collecting log files and troubleshooting issues and also proactively searching for possible areas of concern. It can even examine Amazon EBS root volumes from other instances and collect relevant logs for troubleshooting Windows Server instances using that volume. The following are some common issues that EC2Rescue can address:

- Instance connectivity issues due to firewall, Remote Desktop Protocol (RDP), or network interface configuration
- Operating system boot issues due to a stop error, boot loop, or corrupted registry
- Issues that might need advanced log analysis and troubleshooting

EC2Rescue for Windows Server has two different modules:

- A **data collector module** that collects data from all different sources
- An **analyzer module** that parses the data collected against a series of predefined rules to identify issues and provide suggestions

The EC2Rescue for Windows Server tool only runs on Amazon EC2 instances running Windows Server 2012 and later. When the tool starts, it checks whether it is running on an Amazon EC2 instance.

> **Note**
>
> The `AWSSupport-ExecuteEC2Rescue` AWS Systems Manager Automation runbook uses the EC2Rescue tool to troubleshoot and, where possible, fix common connectivity issues with the specified EC2 instance. For more information, and to run this automation, see >AWSSupport-ExecuteEC2Rescue.

If you are using a Linux instance, see the section called “EC2Rescue for Linux instances”.

Troubleshoot impaired Windows instance with the EC2Rescue GUI

EC2Rescue for Windows Server can perform the following analysis on **offline instances**:

Option	Description

Diagnose and Rescue	EC2Rescue for Windows Server can detect and address issues with the following service settings:
	
	• System Time
	  ◦ **RealTimeisUniversal** - Detects whether the `RealTimeisUniversal` registry key is enabled. If disabled, Windows system time drifts when the timezone is set to a value other than UTC.
	
	• Windows Firewall
	  ◦ **Domain networks** - Detects whether this Windows Firewall profile is enabled or disabled.
	  ◦ **Private networks** - Detects whether this Windows Firewall profile is enabled or disabled.
	  ◦ **Guest or public networks** - Detects whether this Windows Firewall profile is enabled or disabled.
	
	• Remote Desktop
	  ◦ **Service Start** - Detects whether the Remote Desktop service is enabled.

Option	Description
	• **Remote Desktop Connections** - Detects whether this is enabled. • **TCP Port** - Detects which port the Remote Desktop service is listening on. • EC2Config (Windows Server 2012 R2 and earlier) • **Installation** - Detects which EC2Config version is installed. • **Service Start** - Detects whether the EC2Config service is enabled. • **Ec2SetPassword** - Generates a new administrator password. • **Ec2HandleUserData** - Allows you to run a user data script on the next boot of the instance. • EC2Launch (Windows Server 2016 and later) • **Installation** - Detects which EC2Launch version is installed. • **Ec2SetPassword** - Generates a new administrator password. • Network Interface • **DHCP Service Startup** - Detects whether the DHCP service is enabled. • **Ethernet detail** - Displays informati on about the network driver version, if detected. • **DHCP on Ethernet** - Detects whether DHCP is enabled.

Option	Description
	• Disk signature status ◦ **Signature on disk** and **Signature on Boot Configuration Database (BCD)** - Detects whether the disk signature and the BCD signature are the same. If the values are different, EC2Rescue attempts to overwrite the disk signature with the signature on BCD.
Restore	Perform one of the following actions: • **Last Known Good Configuration** - Attempts to boot the instance into the last known bootable state. • **Restore registry from backup** - Restores the registry from `\Windows\System32\config\RegBack` .
Capture Logs	Allows you to capture logs on the instance for analysis.

EC2Rescue for Windows Server can collect the following data from **active and offline instances**:

Item	Description
Event Log	Collects application, system, and EC2Config event logs.
Registry	Collects `SYSTEM` and `SOFTWARE` hives.
Windows Update Log	Collects log files generated by Windows Update.

Item	Description
	Note In Windows Server 2016 and later, the log is collected in Event Tracing for Windows (ETW) format.
Sysprep Log	Collects log files generated by the Windows System Preparation tool.
Driver Setup Log	Collects Windows SetupAPI logs (`setupapi.dev.log` and `setupapi.setup.log`).
Boot Configuration	Collects `HKEY_LOCAL_MACHINE\BCD00000000` hive.
Memory Dump	Collects any memory dump files that exist on the instance.
EC2Config File	Collects log files generated by the EC2Config service.
EC2Launch File	Collects log files generated by the EC2Launch scripts.
SSM Agent File	Collects log files generated by SSM Agent and Patch Manager logs.
EC2 ElasticGPUs File	Collects event logs related to elastic GPUs.
ECS	Collects logs related to Amazon ECS.
CloudEndure	Collects log files related to CloudEndure Agent.
AWS Replication Agent for MGN or DRS Log Files	Collects log files related to AWS Application Migration Service or AWS Elastic Disaster Recovery.

EC2Rescue for Windows Server can collect the following additional data from **active instances**:

Item	Description
System Information	Collects MSInfo32.
Group Policy Result	Collects a Group Policy report.

Analyze an offline instance

The **Offline Instance** option is useful for debugging boot issues with Windows instances.

To perform an action on an offline instance

1. From a working Windows Server instance, download the [EC2Rescue for Windows Server](https://s3.amazonaws.com/ec2rescue/windows/EC2Rescue_latest.zip) tool and extract the files.

   You can run the following PowerShell command to download EC2Rescue without changing your Internet Explorer Enhanced Security Configuration (ESC):

   ```
   Invoke-WebRequest https://s3.amazonaws.com/ec2rescue/windows/EC2Rescue_latest.zip -
   OutFile $env:USERPROFILE\Desktop\EC2Rescue_latest.zip
   ```

   This command will download the EC2Rescue .zip file to the desktop of the currently logged in user.

   > **Note**
   >
   > If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:
   >
   > ```
   > [Net.ServicePointManager]::SecurityProtocol =
   >  [Net.SecurityProtocolType]::Tls12
   > ```

2. Stop the faulty instance, if it is not stopped already.

3. Detach the EBS root volume from the faulty instance and attach the volume to a working Windows instance that has EC2Rescue for Windows Server installed.
4. Run the EC2Rescue for Windows Server tool on the working instance and choose **Offline Instance**.
5. Select the disk of the newly mounted volume and choose **Next**.
6. Confirm the disk selection and choose **Yes**.
7. Choose the offline instance option to perform and choose **Next**.

The EC2Rescue for Windows Server tool scans the volume and collects troubleshooting information based on the selected log files.

Collect data from an active instance

You can collect logs and other data from an active instance.

To collect data from an active instance

1. Connect to your Windows instance.
2. Download the EC2Rescue for Windows Server tool to your Windows instance and extract the files.

   You can run the following PowerShell command to download EC2Rescue without changing your Internet Explorer Enhanced Security Configuration (ESC):

   ```
   Invoke-WebRequest https://s3.amazonaws.com/ec2rescue/windows/EC2Rescue_latest.zip -
   OutFile $env:USERPROFILE\Desktop\EC2Rescue_latest.zip
   ```

   This command will download the EC2Rescue .zip file to the desktop of the currently logged in user.

   > **Note**
   >
   > If you receive an error when downloading the file, and you are using Windows Server 2016 or earlier, TLS 1.2 might need to be enabled for your PowerShell terminal. You can enable TLS 1.2 for the current PowerShell session with the following command and then try again:

```
[Net.ServicePointManager]::SecurityProtocol =
 [Net.SecurityProtocolType]::Tls12
```

3. Open the EC2Rescue for Windows Server application and accept the license agreement.
4. Choose **Next**, **Current instance**, **Capture logs**.
5. Select the data items to collect and choose **Collect...**. Read the warning and choose **Yes** to continue.
6. Choose a file name and location for the ZIP file and choose **Save**.
7. After EC2Rescue for Windows Server completes, choose **Open Containing Folder** to view the ZIP file.
8. Choose **Finish**.

Troubleshoot impaired Windows instance with the EC2Rescue CLI

The EC2Rescue for Windows Server command line interface (CLI) allows you to run an EC2Rescue for Windows Server plugin (referred as an "action") programmatically.

The EC2Rescue for Windows Server tool has two execution modes:

- **/online**—This allows you to take action on the instance that EC2Rescue for Windows Server is installed on, such as collect log files.
- **/offline:<device_id>**—This allows you to take action on the offline root volume that is attached to a separate Amazon EC2 Windows instance, on which you have installed EC2Rescue for Windows Server.

Download the EC2Rescue for Windows Server tool to your Windows instance and extract the files. You can view the help file using the following command:

```
EC2RescueCmd.exe /help
```

EC2Rescue for Windows Server can perform the following actions on an Amazon EC2 Windows instance:

- Collect action
- Rescue action

- Restore action

Collect action

> **Note**
>
> You can collect all logs, an entire log group, or an individual log within a group.

EC2Rescue for Windows Server can collect the following data from **active and offline instances**.

Log group	Available logs	Description
`all`		Collects all available logs.
`eventlog`	• `'Application'` • `'System'` • `'EC2ConfigService'`	Collects application, system, and EC2Config event logs.
`memory-dump`	• `'Memory Dump File'` • `'Mini Dump Files'`	Collects any memory dump files that exist on the instance.
`ec2config`	• `'Log Files'` • `'Configuration Files'`	Collects log files generated by the EC2Config service.
`ec2launch`	• `'Logs'` • `'Config'`	Collects log files generated by the EC2Launch scripts.
`ssm-agent`	• `'Log Files'` • `'Patch Baseline Logs'` • `'InstanceData'`	Collects log files generated by SSM Agent and Patch Manager logs.
`sysprep`	`'Log Files'`	Collects log files generated by the Windows System Preparation tool.

Log group	Available logs	Description
`driver-setup`	• `'SetupAPI Log Files'` • `'DPInst Log File'` • `'AWS PV Setup Log File'`	Collects Windows SetupAPI logs (`setupapi.dev.log` and `setupapi.setup.log`).
`registry`	• `'SYSTEM'` • `'SOFTWARE'` • `'BCD'`	Collects `SYSTEM` and `SOFTWARE` hives.
`egpu`	• `'Event Log'` • `'System Files'`	Collects event logs related to elastic GPUs.
`boot-config`	`'BCDEDIT Output'`	Collects `HKEY_LOCAL_MACHINE\BCD00000000` hive.
`windows-update`	`'Log Files'`	Collects log files generated by Windows Update. **Note** In Windows Server 2016 and later, the log is collected in Event Tracing for Windows (ETW) format.
`cloudendure`	• `'Migrate Script Logs'` • `'Driver Logs'` • `'CloudEndure File List'`	Collects log files related to CloudEndure Agent.

EC2Rescue for Windows Server can collect the following additional data from **active instances**.

Log group	Available logs	Description
`system-info`	`'MSInfo32 Output'`	Collects `MSInfo32`.
`gpresult`	`'GPResult Output'`	Collects a Group Policy report.

The following are the available options:

- **/output:<outputFilePath>** - Required destination file path location to save collected log files in zip format.
- **/no-offline** - Optional attribute used in offline mode. Does not set the volume offline after completing the action.
- **/no-fix-signature** - Optional attribute used in offline mode. Does not fix a possible disk signature collision after completing the action.

Examples

The following are examples using the EC2Rescue for Windows Server CLI.

Online mode examples

Collect all available logs:

```
EC2RescueCmd /accepteula /online /collect:all /output:<outputFilePath>
```

Collect only a specific log group:

```
EC2RescueCmd /accepteula /online /collect:ec2config /output:<outputFilePath>
```

Collect individual logs within a log group:

```
EC2RescueCmd /accepteula /online /collect:'ec2config.Log Files,driver-setup.SetupAPI
 Log Files' /output:<outputFilePath>
```

Offline mode examples

Collect all available logs from an EBS volume. The volume is specified by the device_id value.

```
EC2RescueCmd /accepteula /offline:xvdf /collect:all /output:<outputFilePath>
```

Collect only a specific log group:

```
EC2RescueCmd /accepteula /offline:xvdf /collect:ec2config /output:<outputFilePath>
```

Rescue action

EC2Rescue for Windows Server can detect and address issues with the following service settings:

Service group	Available actions	Description
`all`		
`system-time`	`'RealTimeIsUniversal'`	System Time • **RealTimeisUniversal** - Detects whether the `RealTimeisUniversal` registry key is enabled. If disabled, Windows system time drifts when the timezone is set to a value other than UTC.
`firewall`	• `'Domain networks'` • `'Private networks'` • `'Guest or public networks'`	Windows Firewall • **Domain networks** - Detects whether this Windows Firewall profile is enabled or disabled. • **Private networks** - Detects whether this Windows Firewall profile is enabled or disabled.

Service group	Available actions	Description
		• **Guest or public networks** - Detects whether this Windows Firewall profile is enabled or disabled.
rdp	• `'Service Start'` • `'Remote Desktop Connections'` • `'TCP Port'`	Remote Desktop • **Service Start** - Detects whether the Remote Desktop service is enabled. • **Remote Desktop Connections** - Detects whether this is enabled. • **TCP Port** - Detects which port the Remote Desktop service is listening on.
`ec2config`	• `'Service Start'` • `'Ec2SetPassword'` • `'Ec2HandleUserData'`	EC2Config • **Service Start** - Detects whether the EC2Config service is enabled. • **Ec2SetPassword** - Generates a new administr ator password. • **Ec2HandleUserData** - Allows you to run a user data script on the next boot of the instance.
`ec2launch`	`'Reset Administrator Password'`	Generates a new Windows administrator password.

Service group	Available actions	Description
`network`	`'DHCP Service Startup'`	Network Interface • **DHCP Service Startup** - Detects whether the DHCP service is enabled.

The following are the available options:

- **/level:<level>** - Optional attribute for the check level that the action should trigger. Allowed values are: `information`, `warning`, `error`, `all`. By default, it is set to `error`.
- **/check-only** - Optional attribute that generates a report but makes no modifications to the offline volume.

> **Note**
>
> If EC2Rescue for Windows Server detects a possible disk signature collision, it corrects the signature after the offline process completes by default, even when you use the `/check-only` option. You must use the `/no-fix-signature` option to prevent the correction.

- **/no-offline** - Optional attribute that prevents the volume from being set offline after completing the action.
- **/no-fix-signature** - Optional attribute that does not fix a possible disk signature collision after completing the action.

Rescue examples

The following are examples using the EC2Rescue for Windows Server CLI. The volume is specified using the device_id value.

Attempt to fix all identified issues on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:all
```

Attempt to fix all issues within a service group on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:firewall
```

Attempt to fix a specific item within a service group on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:rdp.'Service Start'
```

Specify multiple issues to attempt to fix on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:'system-
time.RealTimeIsUniversal,ec2config.Service Start'
```

Restore action

EC2Rescue for Windows Server can detect and address issues with the following service settings:

Service Group	Available Actions	Description
Restore Last Known Good Configuration	`lkgc`	**Last Known Good Configura tion** - Attempts to boot the instance into the last known bootable state.
Restore Windows registry from latest backup	`regback`	**Restore registry from backup** - Restores the registry from `\Windows\System32\config\RegBack` .

The following are the available options:

- **/no-offline**—Optional attribute that prevents the volume from being set offline after completing the action.
- **/no-fix-signature**—Optional attribute that does not fix a possible disk signature collision after completing the action.

Restore examples

The following are examples using the EC2Rescue for Windows Server CLI. The volume is specified using the device_id value.

Restore last known good configuration on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /restore:lkgc
```

Restore the last Windows registry backup on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /restore:regback
```

Troubleshoot impaired Windows instance with EC2Rescue and Systems Manager

Support provides you with a Systems Manager Run Command document to interface with your Systems Manager-enabled instance to run EC2Rescue for Windows Server. The Run Command document is called `AWSSupport-RunEC2RescueForWindowsTool`.

This Systems Manager Run Command document performs the following tasks:

- Downloads and verifies EC2Rescue for Windows Server.
- Imports a PowerShell module to ease your interaction with the tool.
- Runs EC2RescueCmd with the provided command and parameters.

The Systems Manager Run Command document accepts three parameters:

- **Command**—The EC2Rescue for Windows Server action. The current allowed values are:
  - **ResetAccess**—Resets the local Administrator password. The local Administrator password of the current instance will be reset and the randomly generated password will be securely stored in Parameter Store as `/EC2Rescue/Password/<INSTANCE_ID>`. If you select this action and provide no parameters, passwords are encrypted automatically with the default KMS key. Optionally, you can specify a KMS key ID in Parameters to encrypt the password with your own key.
  - **CollectLogs**—Runs EC2Rescue for Windows Server with the `/collect:all` action. If you select this action, `Parameters` must include an Amazon S3 bucket name to upload the logs to.

- **FixAll**—Runs EC2Rescue for Windows Server with the `/rescue:all` action. If you select this action, `Parameters` must include the block device name to rescue.
- **Parameters**—The PowerShell parameters to pass for the specified command.

Requirements

To run the **ResetAccess** action, your Amazon EC2 instance must have the a policy attached that grants permissions to write the encrypted password to Parameter Store. After attaching the policy, wait a few minutes before attempting to reset the password of an instance after you have attached this policy to the related IAM role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": [
        "arn:aws:ssm:us-east-1:111122223333:parameter/EC2Rescue/
Passwords/<instanceid>"
      ]
    }
  ]
}
```

If you are using a custom KMS key, not the default KMS key, use this policy instead.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": [
        "arn:aws:ssm:us-east-1:111122223333:parameter/EC2Rescue/
Passwords/<instanceid>"
      ]
    },

      "Resource": [
        "arn:aws:kms:us-east-1:111122223333:key/<kmskeyid>"
      ]
    }
  ]
}
```

View the JSON for the document

The following procedure describes how to view the JSON for this document.

To view the JSON for the Systems Manager Run Command document

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, expand **Change Management Tools** and choose **Documents**.
3. In the search bar, enter `AWSSupport-RunEC2RescueForWindowsTool`, and then select the `AWSSupport-RunEC2RescueForWindowsTool` document.
4. Choose the **Content** tab.

Examples

Here are some examples on how to use the Systems Manager Run Command document to run EC2Rescue for Windows Server, using the AWS CLI. For more information about sending commands using the AWS CLI, see send-command.

Examples

- Attempt to fix all identified issues on an offline root volume
- Collect logs from the current Amazon EC2 Windows instance
- Reset the local Administrator password

Attempt to fix all identified issues on an offline root volume

Attempt to fix all identified issues on an offline root volume attached to an Amazon EC2 Windows instance:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --parameters "Command=FixAll, Parameters='xvdf'" --output text
```

Collect logs from the current Amazon EC2 Windows instance

Collect all logs from the current online Amazon EC2 Windows instance and upload them to an Amazon S3 bucket:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --parameters "Command=CollectLogs, Parameters='amzn-s3-demo-bucket'" --output text
```

Reset the local Administrator password

The following examples show methods you can use to reset the local Administrator password. The output provides a link to Parameter Store, where you can find the randomly generated secure password you can then use to RDP to your Amazon EC2 Windows instance as the local Administrator.

Reset the local Administrator password of an online instance using the default AWS KMS key alias/aws/ssm:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --parameters "Command=ResetAccess" --output text
```

Reset the local Administrator password of an online instance using a KMS key:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --parameters "Command=ResetAccess, Parameters=a133dc3c-a2g4-4fc6-a873-6c0720104bf0" --output text
```

Note

In this example, the KMS key is `a133dc3c-a2g4-4fc6-a873-6c0720104bf0`.

EC2 Serial Console for instances

With the EC2 serial console, you have access to your Amazon EC2 instance's serial port, which you can use to troubleshoot boot, network configuration, and other issues. The serial console does not require your instance to have any networking capabilities. With the serial console, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console session lasts during instance reboot and stop. During reboot, you can view all of the boot messages from the start.

Access to the serial console is not available by default. Your organization must grant account access to the serial console and configure IAM policies to grant your users access to the serial console. Serial console access can be controlled at a granular level by using instance IDs, resource tags, and other IAM levers. For more information, see Configure access to the EC2 Serial Console.

The serial console can be accessed by using the EC2 console or the AWS CLI.

The serial console is available at no additional cost.

Topics

- Prerequisites for the EC2 Serial Console
- Configure access to the EC2 Serial Console
- Connect to the EC2 Serial Console
- Disconnect from the EC2 Serial Console
- Troubleshoot your Amazon EC2 instance using the EC2 Serial Console

Prerequisites for the EC2 Serial Console

To connect to the EC2 Serial Console and use your chosen tool for troubleshooting, the following prerequisites must be in place:

- AWS Regions
- Wavelength Zones and AWS Outposts
- Local Zones
- Instance types
- Grant access
- Support for browser-based client
- Instance state
- Amazon EC2 Systems Manager
- Configure your chosen troubleshooting tool

AWS Regions

Supported in all AWS Regions except Asia Pacific (Taipei).

Wavelength Zones and AWS Outposts

Not supported.

Local Zones

Supported in all Local Zones.

Instance types

Supported instance types:

- **Linux**
  - All virtualized instances built on the Nitro System.
  - All bare metal instances except:
    - General purpose: `a1.metal`, `mac1.metal`, `mac2.metal`
    - Accelerated computing: `g5g.metal`

  - Memory optimized: `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, `u-24tb1.metal`
- **Windows**

  All virtualized instances built on the Nitro System. Not supported on bare metal instances.

Grant access

You must complete the configuration tasks to grant access to the EC2 Serial Console. For more information, see Configure access to the EC2 Serial Console.

Support for browser-based client

To connect to the serial console using the browser-based client, your browser must support WebSocket. If your browser does not support WebSocket, connect to the serial console using your own key and an SSH client.

Instance state

Must be `running`.

You can't connect to the serial console if the instance is in the `pending`, `stopping`, `stopped`, `shutting-down`, or `terminated` state.

For more information about the instance states, see Amazon EC2 instance state changes.

Amazon EC2 Systems Manager

If the instance uses Amazon EC2 Systems Manager, then SSM Agent version 3.0.854.0 or later must be installed on the instance. For information about SSM Agent, see Working with SSM Agent in the *AWS Systems Manager User Guide*.

Configure your chosen troubleshooting tool

To troubleshoot your instance via the serial console, you can use GRUB or SysRq on Linux instances, and Special Admin Console (SAC) on Windows instances. Before you can use these tools, you must first perform configuration steps on every instance on which you'll use them.

Use the instructions for your instance's operating system to configure your chosen troubleshooting tool.

(Linux instances) Configure GRUB

To configure GRUB, choose one of the following procedures based on the AMI that was used to launch the instance.

Amazon Linux 2

To configure GRUB on an Amazon Linux 2 instance

1. Connect to your Linux instance using SSH
2. Add or change the following options in `/etc/default/grub`:

   - Set `GRUB_TIMEOUT=1`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

   The following is an example of `/etc/default/grub`. You might need to change the configuration based on your system setup.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0
 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0"
GRUB_TIMEOUT=1
GRUB_DISABLE_RECOVERY="true"
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

Ubuntu

To configure GRUB on an Ubuntu instance

1. Connect to your instance.
2. Add or change the following options in `/etc/default/grub.d/50-cloudimg-settings.cfg`:

   - Set `GRUB_TIMEOUT=1`.

- Add GRUB_TIMEOUT_STYLE=menu.
- Add GRUB_TERMINAL="console serial".
- Remove GRUB_HIDDEN_TIMEOUT.
- Add GRUB_SERIAL_COMMAND="serial --speed=115200".

The following is an example of /etc/default/grub.d/50-cloudimg-settings.cfg. You might need to change the configuration based on your system setup.

```
# Cloud Image specific Grub settings for Generic Cloud Images
# CLOUD_IMG: This file was created/modified by the Cloud Image build process

# Set the recordfail timeout
GRUB_RECORDFAIL_TIMEOUT=0

# Do not wait on grub prompt
GRUB_TIMEOUT=1
GRUB_TIMEOUT_STYLE=menu

# Set the default commandline
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0
 nvme_core.io_timeout=4294967295"

# Set the grub console type
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed 115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo update-grub
```

RHEL

To configure GRUB on a RHEL instance

1. Connect to your instance.
2. Add or change the following options in /etc/default/grub:

   - Remove GRUB_TERMINAL_OUTPUT.

- Add GRUB_TERMINAL="console serial".
- Add GRUB_SERIAL_COMMAND="serial --speed=115200".

The following is an example of `/etc/default/grub`. You might need to change the configuration based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_CMDLINE_LINUX="console=tty0 console=ttyS0,115200n8 net.ifnames=0
 rd.blacklist=nouveau nvme_core.io_timeout=4294967295 crashkernel=auto"
GRUB_DISABLE_RECOVERY="true"
GRUB_ENABLE_BLSCFG=true
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg --update-bls-cmdline
```

For RHEL 9.2 and earlier, use the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

CentOS

For instances that are launched using a CentOS AMI, GRUB is configured for the serial console by default.

The following is an example of `/etc/default/grub`. Your configuration might be different based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_TERMINAL="serial console"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

```
GRUB_CMDLINE_LINUX="console=tty0 crashkernel=auto console=ttyS0,115200"
GRUB_DISABLE_RECOVERY="true"
```

(Linux instances) Configure SysRq

To configure SysRq, you enable the SysRq commands for the current boot cycle. To make the configuration persistent, you can also enable the SysRq commands for subsequent boots.

To enable all SysRq commands for the current boot cycle

1. Connect to your instance.
2. Run the following command.

   ```
   [ec2-user ~]$ sudo sysctl -w kernel.sysrq=1
   ```

   Note

   This setting will clear on the next reboot.

To enable all SysRq commands for subsequent boots

1. Create the file `/etc/sysctl.d/99-sysrq.conf` and open it in your favorite editor.

   ```
   [ec2-user ~]$ sudo vi /etc/sysctl.d/99-sysrq.conf
   ```

2. Add the following line.

   ```
   kernel.sysrq=1
   ```

3. Reboot the instance to apply the changes.

   ```
   [ec2-user ~]$ sudo reboot
   ```

4. At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
5. At the `Password` prompt, enter the password, and then press **Enter**.

(Windows instances) Enable SAC and the boot menu

> **Note**
>
> If you enable SAC on an instance, the EC2 services that rely on password retrieval will not work from the Amazon EC2 console. Windows on Amazon EC2 launch agents (EC2Config, EC2Launch v1, and EC2Launch v2) rely on the serial console to execute various tasks. These tasks do not perform successfully when you enable SAC on an instance. For more information about Windows on Amazon EC2 launch agents, see the section called "Configure Windows instances". If you enable SAC, you can disable it later. For more information, see Disable SAC and the boot menu.

Use one of the following methods to enable SAC and the boot menu on an instance.

PowerShell

To enable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from an elevated PowerShell command line.
2. Enable SAC.

```
bcdedit /ems '{current}' on
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

3. Enable the boot menu.

```
bcdedit /set '{bootmgr}' displaybootmenu yes
bcdedit /set '{bootmgr}' timeout 15
bcdedit /set '{bootmgr}' bootems yes
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Command prompt

To enable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from the command prompt.
2. Enable SAC.

```
bcdedit /ems {current} on
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

3. Enable the boot menu.

```
bcdedit /set {bootmgr} displaybootmenu yes
bcdedit /set {bootmgr} timeout 15
bcdedit /set {bootmgr} bootems yes
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Configure access to the EC2 Serial Console

To configure access to the serial console, you must grant serial console access at the account level and then configure IAM policies to grant access to your users. For Linux instances you must also configure a password-based user on every instance so that your users can use the serial console for troubleshooting.

Before commencing, be sure to check the prerequisites.

Contents

Levels of access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level. For more information, see Manage account access to the EC2 Serial Console.

You can use a service control policy (SCP) to allow access to the serial console within your organization. You can then have granular access control at the user level by using an IAM policy to control access. By using a combination of SCP and IAM policies, you have different levels of access control to the serial console.

Organization level

You can use a service control policy (SCP) to allow access to the serial console for member accounts within your organization. For more information about SCPs, see Service control policies in the *AWS Organizations User Guide*.

Instance level

You can configure the serial console access policies by using IAM PrincipalTag and ResourceTag constructions and by specifying instances by their ID. For more information, see Configure IAM policies for EC2 Serial Console access.

User level

You can configure access at the user level by configuring an IAM policy to allow or deny a specified user the permission to push the SSH public key to the serial console service of a particular instance. For more information, see Configure IAM policies for EC2 Serial Console access.

OS level (Linux instances only)

You can set a user password at the guest OS level. This provides access to the serial console for some use cases. However, to monitor the logs, you don't need a password-based user. For more information, see Set an OS user password on a Linux instance.

Manage account access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level.

Note

This setting is configured at the account level, either directly in the account or by using a declarative policy. It must be configured in each AWS Region where you want to grant access to the serial console. Using a declarative policy allows you to apply the setting across multiple Regions simultaneously, as well as across multiple accounts simultaneously. When a declarative policy is in use, you can't modify the setting directly within an account. This topic describes how to configure the setting directly within an account. For information about using declarative policies, see Declarative policies in the *AWS Organizations User Guide*.

Contents

Grant permission to users to manage account access

To allow your users to manage account access to the EC2 serial console, you need to grant them the required IAM permissions.

The following policy grants permissions to view the account status, and to allow and prevent account access to the EC2 serial console.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:GetSerialConsoleAccessStatus",
                "ec2:EnableSerialConsoleAccess",
                "ec2:DisableSerialConsoleAccess"
            ],
```

```
                "Resource": "*"
            }
        ]
    }
```

For more information, see Creating IAM policies in the *IAM User Guide*.

View account access status to the serial console

Console

To view account access to the serial console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. On the **EC2 Serial Console** tab, the value of **EC2 Serial Console access** is either **Allowed** or **Prevented**.

AWS CLI

To view account access to the serial console

Use the get-serial-console-access-status command.

```
aws ec2 get-serial-console-access-status
```

The following is example output. A value of `true` indicates that the account is allowed access to the serial console.

```
{
    "SerialConsoleAccessEnabled": true,
    "ManagedBy": "account"
}
```

The `ManagedBy` field indicates the entity that configured the setting. The possible values are `account` (configured directly) or `declarative-policy`. For more information, see Declarative policies in the *AWS Organizations User Guide*.

PowerShell

To view account access to the serial console

Use the Get-EC2SerialConsoleAccessStatus cmdlet.

```
Get-EC2SerialConsoleAccessStatus -Select *
```

The following is example output. A value of `True` indicates that the account is allowed access to the serial console.

```
ManagedBy SerialConsoleAccessEnabled
--------- --------------------------
account   True
```

The `ManagedBy` field indicates the entity that configured the setting. The possible values are `account` (configured directly) or `declarative-policy`. For more information, see Declarative policies in the *AWS Organizations User Guide*.

Grant account access to the serial console

Console

To grant account access to the serial console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To allow access to the EC2 serial console of all instances in the account, select the **Allow** checkbox.
6. Choose **Update**.

AWS CLI

To grant account access to the serial console

Use the enable-serial-console-access command.

```
aws ec2 enable-serial-console-access
```

The following is example output.

```
{
    "SerialConsoleAccessEnabled": true
}
```

PowerShell

To grant account access to the serial console

Use the Enable-EC2SerialConsoleAccess cmdlet.

```
Enable-EC2SerialConsoleAccess
```

The following is example output.

```
True
```

Deny account access to the serial console

Console

To deny account access to the serial console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To prevent access to the EC2 serial console of all instances in the account, clear the **Allow** checkbox.
6. Choose **Update**.

AWS CLI

To deny account access to the serial console

Use the disable-serial-console-access command.

```
aws ec2 disable-serial-console-access
```

The following is example output.

```
{
    "SerialConsoleAccessEnabled": false
}
```

PowerShell

To deny account access to the serial console

Use the Disable-EC2SerialConsoleAccess cmdlet.

```
Disable-EC2SerialConsoleAccess
```

The following is example output.

```
False
```

Configure IAM policies for EC2 Serial Console access

By default, your users do not have access to the serial console. Your organization must configure IAM policies to grant your users the required access. For more information, see Creating IAM policies in the *IAM User Guide*.

For serial console access, create a JSON policy document that includes the `ec2-instance-connect:SendSerialConsoleSSHPublicKey` action. This action grants a user permission to push the public key to the serial console service, which starts a serial console session. We recommend restricting access to specific EC2 instances. Otherwise, all users with this permission can connect to the serial console of all EC2 instances.

Example IAM policies

- Explicitly allow access to the serial console
- Explicitly deny access to the serial console

- Use resource tags to control access to the serial console

Explicitly allow access to the serial console

By default, no one has access to the serial console. To grant access to the serial console, you need to configure a policy to explicitly allow access. We recommend configuring a policy that restricts access to specific instances.

The following policy allows access to the serial console of a specific instance, identified by its instance ID.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the * (asterisk), must be specified for these actions.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDescribeInstances",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
             "Resource": "*"
        },
        {
            "Sid": "AllowinstanceBasedSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws:ec2:us-
east-1:111122223333:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Explicitly deny access to the serial console

The following IAM policy allows access to the serial console of all instances, denoted by the * (asterisk), and explicitly denies access to the serial console of a specific instance, identified by its ID.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "DenySerialConsoleAccess",
            "Effect": "Deny",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws:ec2:us-
east-1:111122223333:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Use resource tags to control access to the serial console

You can use resource tags to control access to the serial console of an instance.

Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows a user to initiate a serial console connection for an instance only if that instance's resource tag and the principal's tag have the same `SerialConsole` value for the tag key.

For more information about using tags to control access to your AWS resources, see [Controlling access to AWS resources](#) in the *IAM User Guide*.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the `*` (asterisk), must be specified for these actions.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDescribeInstances",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowTagBasedSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/SerialConsole":
 "${aws:PrincipalTag/SerialConsole}"
                }
            }
        }
    ]
}
```

Set an OS user password on a Linux instance

> **Note**
>
> This section applies to Linux instances only.

You can connect to the serial console without a password. However, to *use* the serial console for troubleshooting a Linux instance, the instance must have a password-based OS user.

You can set the password for any OS user, including the root user. Note that the root user can modify all files, while each OS user might have limited permissions.

You must set a user password for every instance for which you will use the serial console. This is a one-time requirement for each instance.

> **Note**
>
> The following instructions are applicable only if you launched your instance using a Linux AMI provided by AWS because, by default, AMIs provided by AWS are not configured with a password-based user. If you launched your instance using an AMI that already has the root user password configured, you can skip these instructions.

To set an OS user password on a Linux instance

1. Connect to your instance. You can use any method for connecting to your instance, except the EC2 Serial Console connection method.
2. To set the password for a user, use the **passwd** command. In the following example, the user is `root`.

   ```
   [ec2-user ~]$ sudo passwd root
   ```

   The following is example output.

   ```
   Changing password for user root.
   New password:
   ```
3. At the `New password` prompt, enter the new password.

4. At the prompt, re-enter the password.

Connect to the EC2 Serial Console

You can connect to the serial console of your EC2 instance by using the Amazon EC2 console or via SSH. After connecting to the serial console, you can use it for troubleshooting boot, network configuration, and other issues. For more information about troubleshooting, see Troubleshoot your Amazon EC2 instance using the EC2 Serial Console.

Considerations

- Only 1 active serial console connection is supported per instance.
- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.

  The duration of the connection is not determined by the duration of your IAM credentials. If your IAM credentials expire, the connection continues to persist until the maximum duration of the serial console connection is reached. When using the EC2 Serial Console console experience, if your IAM credentials expire, terminate the connection by closing the browser page.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.
- Supported serial console ports: `ttyS0` (Linux instances) and `COM1` (Windows instances)
- When you connect to the serial console, you might observe a slight drop in your instance’s throughput.

Topics

- Connect using the browser-based client
- Connect using your own key and SSH client
- EC2 Serial Console endpoints and fingerprints

Connect using the browser-based client

You can connect to your EC2 instance's serial console by using the browser-based client. You do this by selecting the instance in the Amazon EC2 console and choosing to connect to the serial console. The browser-based client handles the permissions and provides a successful connection.

EC2 serial console works from most browsers, and supports keyboard and mouse input.

Before connecting, make sure you have completed the prerequisites.

To connect to your instance's serial port using the browser-based client (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions**, **Monitor and troubleshoot**, **EC2 Serial Console**, **Connect**.

   Alternatively, select the instance and choose **Connect**, **EC2 Serial Console**, **Connect**.

   An in-browser terminal window opens.
4. Press **Enter**. If a login prompt returns, you are connected to the serial console.

   If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

   - **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console.
   - (Linux instances only) **Use SysRq to connect to the serial console.** SysRq does not require that you connect via the browser-based client. For more information, see (Linux instances) Use SysRq to troubleshoot your instance.
   - (Linux instances only) **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

     ```
     [ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
     ```
   - **Reboot your instance.** You can reboot your instance by using SysRq (Linux instances), the EC2 console, or the AWS CLI. For more information, see (Linux instances) Use SysRq to troubleshoot your instance (Linux instances) or Reboot your Amazon EC2 instance.
5. (Linux instances only) At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
6. (Linux instances only) At the `Password` prompt, enter the password, and then press **Enter**.

You are now logged onto the instance and can use the serial console for troubleshooting.

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the serial console API. This enables you to benefit from the serial console capability to push a public key to the instance.

Before connecting, make sure you have completed the prerequisites.

To connect to an instance's serial console using SSH

1. **Push your SSH public key to the instance to start a serial console session**

   Use the send-serial-console-ssh-public-key command to push your SSH public key to the instance. This starts a serial console session.

   If a serial console session has already been started for this instance, the command fails because you can only have one session open at a time. It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

```
aws ec2-instance-connect send-serial-console-ssh-public-key \
    --instance-id i-001234a4bf70dec41EXAMPLE \
    --serial-port 0 \
    --ssh-public-key file://my_key.pub \
    --region us-east-1
```

2. **Connect to the serial console using your private key**

   Use the **ssh** command to connect to the serial console before the public key is removed from the serial console service. You have 60 seconds before it is removed.

   Use the private key that corresponds to the public key.

   The username format is `instance-id.port0`, which comprises the instance ID and port 0. In the following example, the username is `i-001234a4bf70dec41EXAMPLE.port0`.

   The endpoint of the serial console service is different for each Region. See the EC2 Serial Console endpoints and fingerprints table for each Region's endpoint. In the following example, the serial console service is in the us-east-1 Region.

```
ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-
connect.us-east-1.aws
```

The following example uses `timeout 3600` to set your SSH session to terminate after 1 hour. Processes started during the session may continue running on your instance after the session terminates.

```
timeout 3600 ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.aws
```

3. **(Optional) Verify the fingerprint**

   When you connect for the first time to the serial console, you are prompted to verify the fingerprint. You can compare the serial console fingerprint with the fingerprint that's displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to the serial console.

   The following fingerprint is for the serial console service in the us-east-1 Region. For the fingerprints for each Region, see EC2 Serial Console endpoints and fingerprints.

```
SHA256:dXwn5ma/xadVMeBZGEru5l2gx+yI5LDiJaLUcz0FMmw
```

> **Note**
>
> The fingerprint only appears the first time you connect to the serial console.

4. Press **Enter**. If a prompt returns, you are connected to the serial console.

   If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

   - **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console.
   - (Linux instances only) **Use SysRq to connect to the serial console.** SysRq does not require that you connect via SSH. For more information, see (Linux instances) Use SysRq to troubleshoot your instance.
   - (Linux instances only) **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

```
[ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
```

- **Reboot your instance.** You can reboot your instance by using SysRq (Linux instances only), the EC2 console, or the AWS CLI. For more information, see (Linux instances) Use SysRq to troubleshoot your instance (Linux instances only) or Reboot your Amazon EC2 instance.

5. (Linux instances only) At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
6. (Linux instances only) At the `Password` prompt, enter the password, and then press **Enter**.

You are now logged onto the instance and can use the serial console for troubleshooting.

EC2 Serial Console endpoints and fingerprints

The following are the service endpoints and fingerprints for EC2 Serial Console. To connect programmatically to an instance's serial console, you use an EC2 Serial Console endpoint. The EC2 Serial Console endpoints and fingerprints are unique for each AWS Region.

Region Name	Region	Endpoint	Fingerprint
US East (Ohio)	us-east-2	serial-console.ec2-instance-connect.us-east-2.aws	SHA256:EhwPkTzRtTY7TRSzz26XbB0/HvV9jRM7mCZN0xw/d/0
US East (N. Virginia)	us-east-1	serial-console.ec2-instance-connect.us-east-1.aws	SHA256:dXwn5ma/xadVMeBZGEru5l2gx+yI5LDiJaLUcz0FMmw
US West (N. California)	us-west-1	serial-console.ec2-instance-connect.us-west-1.aws	SHA256:OHldlcMET8u7QLSX3jmRTRAPFHVtqbyoLZBMUCqiH3Y

Disconnect from the EC2 Serial Console

If you no longer need to be connected to your instance's EC2 Serial Console, you can disconnect from it. When you disconnect from the serial console, any shell session running on the instance will continue to run. If you want to end the shell session, you'll need to end it before disconnecting from the serial console.

Considerations

- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

The way to disconnect from the serial console depends on the client.

Browser-based client

To disconnect from the serial console, close the serial console in-browser terminal window.

Standard OpenSSH client

To disconnect from the serial console, use the following command to close the SSH connection. This command must be run immediately following a new line.

```
~.
```

The command that you use for closing an SSH connection might be different depending on the SSH client that you're using.

Troubleshoot your Amazon EC2 instance using the EC2 Serial Console

By using EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues by connecting to your instance's serial port.

Use the instructions for your instance's operating system and for the tool you've configured on your instance.

Tools

- (Linux instances) Use GRUB to troubleshoot your instance
- (Linux instances) Use SysRq to troubleshoot your instance
- (Windows instances) Use SAC to troubleshoot your instance

Prerequisites

Before you begin, make sure you have completed the prerequisites, including configuring your chosen troubleshooting tool.

(Linux instances) Use GRUB to troubleshoot your instance

GNU GRUB (short for GNU GRand Unified Bootloader, commonly referred to as GRUB) is the default boot loader for most Linux operating systems. From the GRUB menu, you can select which kernel to boot into, or modify menu entries to change how the kernel will boot. This can be useful when troubleshooting a failing instance.

The GRUB menu is displayed during the boot process. The menu is not accessible via normal SSH, but you can access it via the EC2 Serial Console.

You can boot into single user mode or emergency mode. Single user mode will boot the kernel at a lower runlevel. For example, it might mount the filesystem but not activate the network, giving you the opportunity to perform the maintenance necessary to fix the instance. Emergency mode is similar to single user mode except that the kernel runs at the lowest runlevel possible.

To boot into single user mode

1. Connect to the instance's serial console.
2. Reboot the instance using the following command.

```
[ec2-user ~]$ sudo reboot
```

3. During reboot, when the GRUB menu appears, press any key to stop the boot process.
4. In the GRUB menu, use the arrow keys to select the kernel to boot into, and press `e` on your keyboard.
5. Use the arrow keys to locate your cursor on the line containing the kernel. The line begins with either `linux` or `linux16` depending on the AMI that was used to launch the instance. For Ubuntu, two lines begin with `linux`, which must both be modified in the next step.
6. At the end of the line, add the word `single`.

   The following is an example for Amazon Linux 2.

```
linux /boot/vmlinuz-4.14.193-149.317.amzn2.aarch64 root=UUID=d33f9c9a-\
dadd-4499-938d-ebbf42c3e499 ro  console=tty0 console=ttyS0,115200n8 net.ifname\
```

```
s=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.she\
ll=0 single
```

7. Press **Ctrl+X** to boot into single user mode.
8. At the `login` prompt, enter the username of the password-based user that you set up previously, and then press **Enter**.
9. At the `Password` prompt, enter the password, and then press **Enter**.

To boot into emergency mode

Follow the the same steps as single user mode, but at step 6, add the word `emergency` instead of `single`.

(Linux instances) Use SysRq to troubleshoot your instance

The System Request (SysRq) key, which is sometimes referred to as "magic SysRq", can be used to directly send the kernel a command, outside of a shell, and the kernel will respond, regardless of what the kernel is doing. For example, if the instance has stopped responding, you can use the SysRq key to tell the kernel to crash or reboot. For more information, see Magic SysRq key in Wikipedia.

You can use SysRq commands in the EC2 Serial Console browser-based client or in an SSH client. The command to send a break request is different for each client.

To use SysRq, choose one of the following procedures based on the client that you are using.

Browser-based client

To use SysRq in the serial console browser-based client

1. Connect to the instance's serial console.
2. To send a break request, press `CTRL+0` (zero). If your keyboard supports it, you can also send a break request using the Pause or Break key.

   ```
   [ec2-user ~]$ CTRL+0
   ```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press h.

```
[ec2-user ~]$ h
```

The h command outputs something similar to the following.

```
[ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-
tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems
(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-
tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r
) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-
buffer(z)
```

SSH client

To use SysRq in an SSH client

1. Connect to the instance's serial console.
2. To send a break request, press ~B (tilde, followed by uppercase B).

```
[ec2-user ~]$ ~B
```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press h.

```
[ec2-user ~]$ h
```

The h command outputs something similar to the following.

```
[ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-
tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems
(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-
tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r
) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-
buffer(z)
```

> **Note**
>
> The command that you use for sending a break request might be different depending on the SSH client that you're using.

(Windows instances) Use SAC to troubleshoot your instance

The Special Admin Console (SAC) capability of Windows provides a way to troubleshoot a Windows instance. By connecting to the instance's serial console and using SAC, you can interrupt the boot process and boot Windows in safe mode.

> **Note**
>
> If you enable SAC on an instance, the EC2 services that rely on password retrieval will not work from the Amazon EC2 console. Windows on Amazon EC2 launch agents (EC2Config, EC2Launch v1, and EC2Launch v2) rely on the serial console to execute various tasks. These tasks do not perform successfully when you enable SAC on an instance. For more information about Windows on Amazon EC2 launch agents, see the section called "Configure Windows instances". If you enable SAC, you can disable it later. For more information, see Disable SAC and the boot menu.

Tasks

- Use SAC
- Use the boot menu
- Disable SAC and the boot menu

Use SAC

To use SAC

1. Connect to the serial console.

   If SAC is enabled on the instance, the serial console displays the SAC> prompt.

```
Computer is booting, SAC started and initialized.

Use the "ch -?" command for information about using channels.
Use the "?" command for general help.

SAC>?
EVENT: The CMD command is now available.
SAC_
```

2. To display the SAC commands, enter ?, and then press **Enter**.

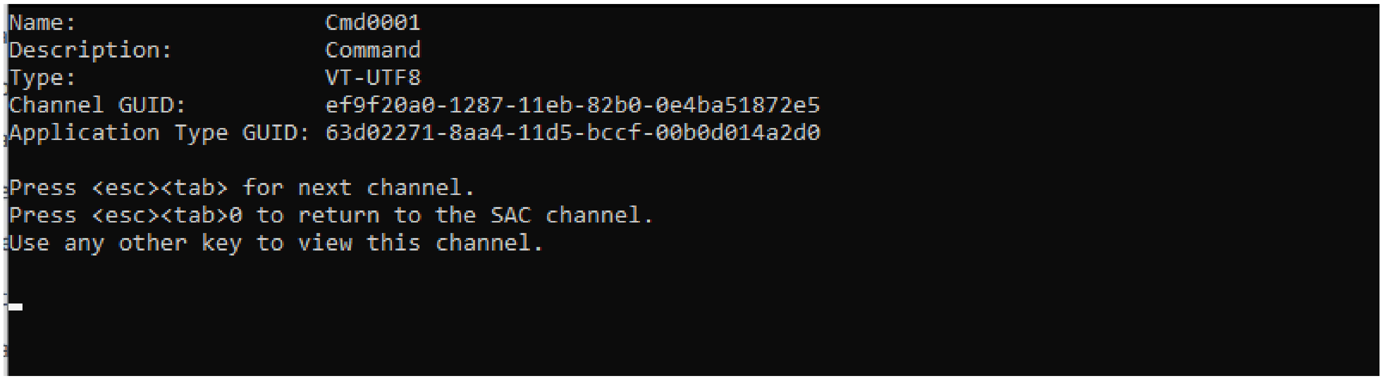
   Expected output

```
SAC>?
ch                    Channel management commands.  Use ch -? for more help.
cmd                   Create a Command Prompt channel.
d                     Dump the current kernel log.
f                     Toggle detailed or abbreviated tlist info.
? or help             Display this list.
i                     List all IP network numbers and their IP addresses.
i <#> <ip> <subnet> <gateway> Set IPv4 addr., subnet and gateway.
id                    Display the computer identification information.
k <pid>               Kill the given process.
l <pid>               Lower the priority of a process to the lowest possible.
lock                  Lock access to Command Prompt channels.
m <pid> <MB-allow>    Limit the memory usage of a process to <MB-allow>.
p                     Toggle paging the display.
r <pid>               Raise the priority of a process by one.
s                     Display the current time and date (24 hour clock used).
s mm/dd/yyyy hh:mm    Set the current time and date (24 hour clock used).
t                     Tlist.
restart               Restart the system immediately.
shutdown              Shutdown the system immediately.
crashdump             Crash the system. You must have crash dump enabled.
```

3. To create a command prompt channel (such as `cmd0001` or `cmd0002`), enter cmd, and then press **Enter**.

4. To view the command prompt channel, press **ESC**, and then press **TAB**.

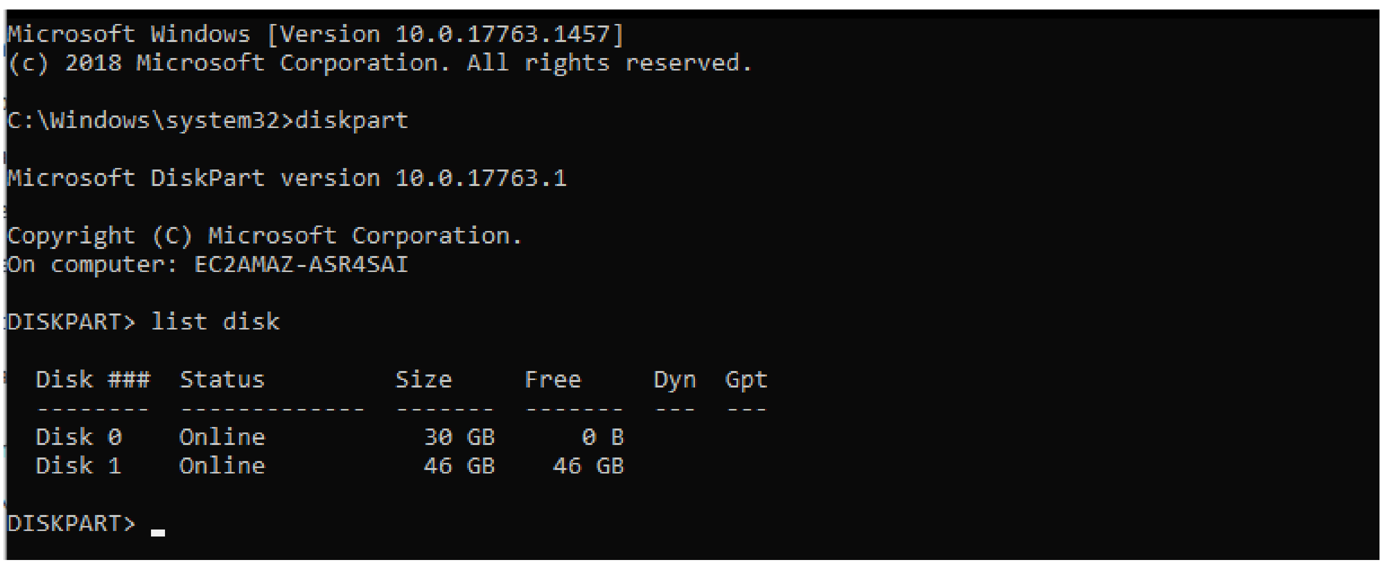
   Expected output



5. To switch channels, press **ESC+TAB+channel number** together. For example, to switch to the `cmd0002` channel (if it has been created), press **ESC+TAB+2**.

6. Enter the credentials required by the command prompt channel.

The command prompt is the same full-featured command shell that you get on a desktop, but with the exception that it does not allow the reading of characters that were already output.



PowerShell can also be used from the command prompt.

Note that you might need to set the progress preference to silent mode.

```
PS C:\Windows\system32> $ProgressPreference="SilentlyContinue"
PS C:\Windows\system32> $computerInfo = Get-ComputerInfo
PS C:\Windows\system32> $computerInfo.Csprocessors[0].Name
Intel(R) Xeon(R) Platinum 8124M CPU @ 3.00GHz
PS C:\Windows\system32> $computerInfo.Csprocessors[0].Description
Intel64 Family 6 Model 85 Stepping 4
PS C:\Windows\system32> _
```

Use the boot menu

If the instance has the boot menu enabled and is restarted after connecting via SSH, you should see the boot menu, as follows.

```
                          Windows Boot Manager

Choose an operating system to start, or press TAB to select a tool:
(Use the arrow keys to highlight your choice, then press ENTER.)

    Windows Server [EMS Enabled]                                    >

To specify an advanced option for this choice, press F8.

Tools:

    Windows Memory Diagnostic

 ENTER=Choose                      TAB=Menu                           ESC=Cancel
```

Boot menu commands

ENTER

Starts the selected entry of the operating system.

TAB

Switches to the Tools menu.

ESC

Cancels and restarts the instance.

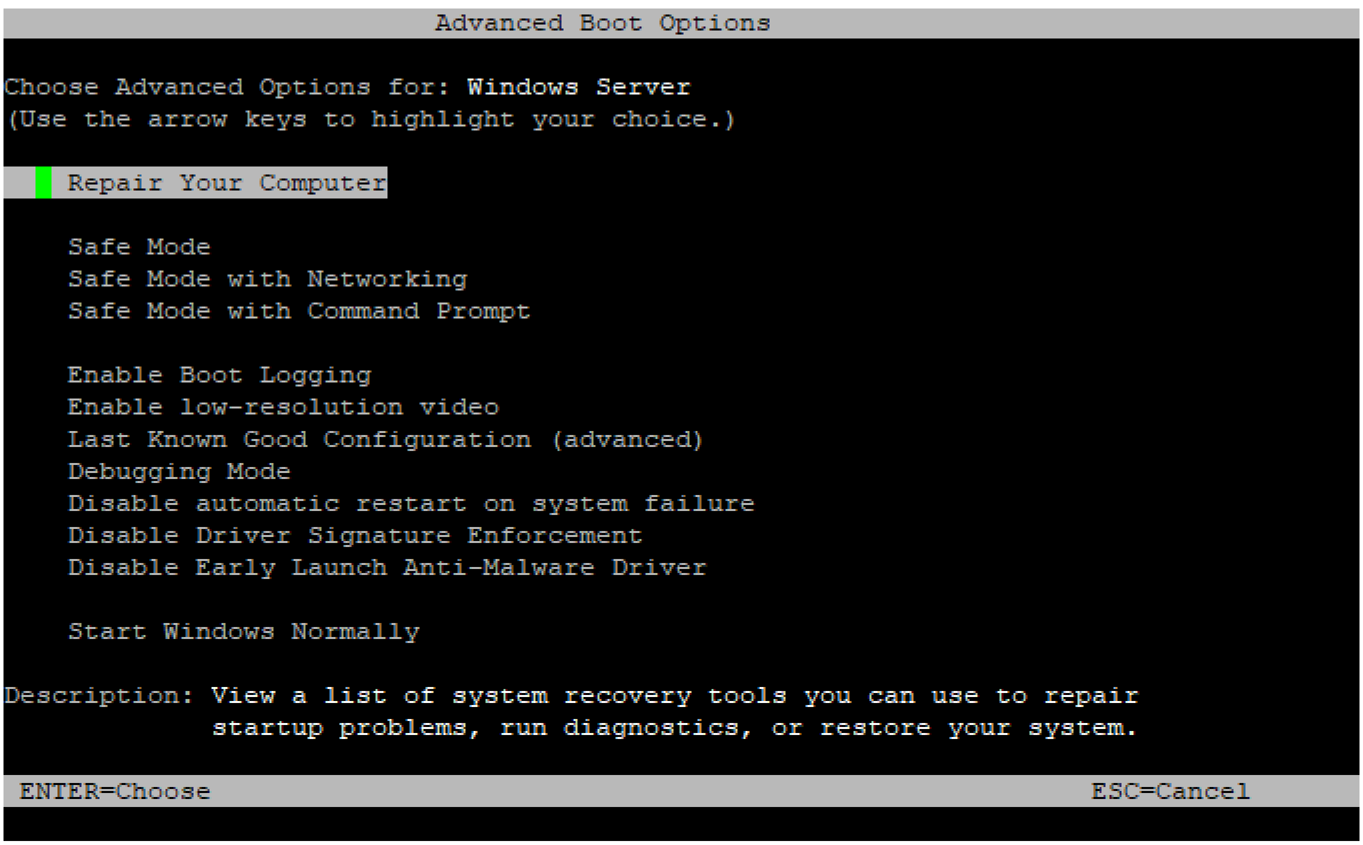
ESC followed by 8

Equivalent to pressing **F8**. Shows advanced options for the selected item.

ESC key + left arrow

Goes back to the initial boot menu.

> **Note**
>
> The ESC key alone does not take you back to the main menu because Windows is waiting to see if an escape sequence is in progress.



Disable SAC and the boot menu

If you enable SAC and the boot menu, you can disable these features later.

Use one of the following methods to disable SAC and the boot menu on an instance.

PowerShell

To disable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from an elevated PowerShell command line.
2. First disable the boot menu by changing the value to no.

```
bcdedit /set '{bootmgr}' displaybootmenu no
```

3. Then disable SAC by changing the value to `off`.

```
bcdedit /ems '{current}' off
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Command prompt

To disable SAC and the boot menu on a Windows instance

1. Connect to your instance and perform the following steps from the command prompt.
2. First disable the boot menu by changing the value to no.

```
bcdedit /set {bootmgr} displaybootmenu no
```

3. Then disable SAC by changing the value to `off`.

```
bcdedit /ems {current} off
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Send a diagnostic interrupt to debug an unreachable Amazon EC2 instance

> **Warning**
>
> Diagnostic interrupts are intended for use by advanced users. Incorrect usage could negatively impact your instance. Sending a diagnostic interrupt to an instance could trigger an instance to crash and reboot, which could lead to the loss of data.

You can send a diagnostic interrupt to an unreachable or unresponsive instance to manually trigger a *kernel panic* for a Linux instance, or a *stop error* (commonly referred to as a *blue screen error*) for a Windows instance.

Linux instances

Linux operating systems typically crash and reboot when a kernel panic occurs. The specific behavior of the operating system depends on its configuration. A kernel panic can also be used to cause the instance's operating system kernel to perform tasks, such as generating a crash dump file. You can then use the information in the crash dump file to conduct root cause analysis and debug the instance. The crash dump data is generated locally by the operating system on the instance itself.

Windows instances

In general, Windows operating systems crash and reboot when a stop error occurs, but the specific behavior depends on its configuration. A stop error can also cause the operating system to write debugging information, such as a kernel memory dump, to a file. You can then use this information to conduct root cause analysis to debug the instance. The memory dump data is generated locally by the operating system on the instance itself.

Before sending a diagnostic interrupt to your instance, we recommend that you consult the documentation for your operating system and then make the necessary configuration changes.

Contents

Supported instance types

Diagnostic interrupt is supported on all Nitro-based instance types, except those powered by AWS Graviton processors. For more information, see instances built on the AWS Nitro System and AWS Graviton.

Prerequisites

Before using a diagnostic interrupt, you must configure your instance's operating system. This ensures that it performs the actions that you need when a kernel panic (Linux instances) or stop error (Windows instances) occurs.

Linux instances

To configure Amazon Linux 2 or Amazon Linux 2023 to generate a crash dump when a kernel panic occurs

1. Connect to your instance.
2. Install **kexec** and **kdump**.

```
[ec2-user ~]$ sudo yum install kexec-tools -y
```

3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance. Open the `/etc/default/grub` file using your preferred text editor, locate the line that starts with `GRUB_CMDLINE_LINUX_DEFAULT`, and then add the `crashkernel` parameter in the following format: `crashkernel=`*`memory_to_reserve`*. For example, to reserve 256MB, modify the `grub` file as follows:

```
GRUB_CMDLINE_LINUX_DEFAULT="crashkernel=256M console=tty0 console=ttyS0,115200n8
 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff
 rd.shell=0"
GRUB_TIMEOUT=0
GRUB_DISABLE_RECOVERY="true"
```

4. Save the changes and close the `grub` file.
5. Rebuild the GRUB2 configuration file.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

6. On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an *unknown non-maskable interrupt* (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.

```
kernel.unknown_nmi_panic=1
```

7. Reboot and reconnect to your instance.

8. Verify that the kernel has been booted with the correct `crashkernel` parameter.

```
$ grep crashkernel /proc/cmdline
```

The following example output indicates successful configuration.

```
BOOT_IMAGE=/boot/vmlinuz-4.14.128-112.105.amzn2.x86_64 root=UUID=a1e1011e-
e38f-408e-878b-fed395b47ad6 ro crashkernel=256M console=tty0 console=ttyS0,115200n8
 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff
 rd.shell=0
```

9. Verify that the **kdump** service is running.

```
[ec2-user ~]$ systemctl status kdump.service
```

The following example output shows the result if the **kdump** service is running.

```
kdump.service - Crash recovery kernel arming
   Loaded: loaded (/usr/lib/systemd/system/kdump.service; enabled; vendor preset:
 enabled)
   Active: active (exited) since Fri 2019-05-24 23:29:13 UTC; 22s ago
  Process: 2503 ExecStart=/usr/bin/kdumpctl start (code=exited, status=0/SUCCESS)
 Main PID: 2503 (code=exited, status=0/SUCCESS)
```

Note

By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

To configure SUSE Linux Enterprise, Ubuntu, or Red Hat Enterprise Linux

On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an *unknown non-maskable interrupt* (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI by adjusting the configuration file for your operating system. For information about how to configure the kernel to crash, see the documentation for your operating system:

- SUSE Linux Enterprise
- Ubuntu
- Red Hat Enterprise Linux (RHEL)

Windows instances

To configure Windows to generate a memory dump when a stop error occurs

1. Connect to your instance.
2. Open the **Control Panel** and choose **System**, **Advanced system settings**.
3. In the **System Properties** dialog box, choose the **Advanced** tab.
4. In the **Startup and Recovery** section, choose **Settings...**.
5. In the **System failure** section, configure the settings as needed, and then choose **OK**.

For more information about configuring Windows stop errors, see Overview of memory dump file options for Windows.

Send a diagnostic interrupt

After you have completed the necessary configuration changes, you can send a diagnostic interrupt to your instance using the AWS CLI or Amazon EC2 API.

AWS CLI

To send a diagnostic interrupt to your instance

Use the send-diagnostic-interrupt command.

```
aws ec2 send-diagnostic-interrupt --instance-id i-1234567890abcdef0
```

PowerShell

To send a diagnostic interrupt to your instance

Use the Send-EC2DiagnosticInterrupt cmdlet.

```
Send-EC2DiagnosticInterrupt -InstanceId i-1234567890abcdef0
```

Document history for the Amazon EC2 User Guide

The following table describes important additions to the Amazon EC2 User Guide starting in 2019. We also update the guide frequently to address the feedback that you send us.

Change	Description	Date
Amazon EC2 Mac Dedicated Host updates	Amazon EC2 Mac Dedicated Hosts support Dedicated Host auto recovery and reboot-based host maintenance.	August 28, 2025
AMI copies for Local Zones	You can now copy Amazon EBS-backed AMIs to and from Local Zones.	August 28, 2025
AmazonEC2ImageReferencesAccessPolicy – new managed policy	Amazon EC2 added the AmazonEC2ImageReferencesAccessPolicy managed policy to provide permission to scan all resources types supported by the EC2 DescribeImageReferences API.	August 26, 2025
AMI usage reports	If you share your Amazon Machine Images (AMIs) with other AWS accounts—whether with specific AWS accounts, organizations, organizational units (OUs), or publicly—you can see how these AMIs are used by creating AMI usage reports. The reports provide visibility into which AWS accounts are using your AMIs in EC2	August 26, 2025

	instances or launch templates , and how many instances or launch templates are referencing each AMI.	
AMI references	You can identify your AWS resources that reference specified Amazon Machine Images (AMIs), regardless of whether the AMIs are public or private, or who owns them. This visibility helps you ensure your resources use the latest compliant AMIs.	August 26, 2025
Modify EC2 Instance Connect Endpoint	You can now modify an existing EC2 Instance Connect Endpoint using the AWS CLI or an SDK.	August 14, 2025
Capacity Reservation sharing enhancements	You can now share Capacity Reservations that you create in cluster placement groups.	August 12, 2025

Updated managed policy for EC2 Instance Connect Endpoint	To support the modification of existing EC2 Instance Connect Endpoints, Amazon EC2 updated the `Ec2InstanceConnectEndpoint` policy to add permissions to assign and unassign IPv6 addresses and modify security groups on network interfaces created by EC2 Instance Connect Endpoint. Amazon EC2 also updated this policy to replace the `Null` condition operator with the `StringLike` condition operator.	July 31, 2025
Instance topology - additional Region support	The DescribeInstanceTopology API is now available in Asia Pacific (Melbourne).	July 31, 2025
Force terminate	You can now force terminate your instance.	July 31, 2025
Instance topology - additional Region support	The DescribeInstanceTopology API is now available in AWS GovCloud (US-West).	July 24, 2025
Skip OS shutdown during instance termination	You can skip the graceful operating system (OS) shutdown when terminating an instance.	July 23, 2025
Skip OS shutdown during instance stop	You can skip the graceful operating system (OS) shutdown when stopping an instance.	July 23, 2025

P6-B200 Capacity Blocks in us-east-1	P6-B200 Capacity Blocks are now available in US East (N. Virginia) - `us-east-1` .	July 23, 2025
Updated managed policy for the EC2 Fast Launch service linked role	To help prevent orphaned resources, Amazon EC2 updated this policy to add permission to describe volumes, volume attributes and network interfaces, and to delete volumes and net work interfaces that EC2 Fast Launch created.	July 17, 2025
EC2 Serial Console - additiona l Region support	EC2 Serial Console is now also available in Asia Pacific (Thailand) and Mexico (Central).	July 15, 2025
EC2 Instance Connect - additional Region support	EC2 Instance Connect is now also available in Asia Pacific (Thailand) and Mexico (Central).	July 15, 2025
Hardware packet timestamp ing	You can enable hardware packet timestamping on your EC2 instance to add a 64-bit nanosecond-precision timestamp to every incoming network packet.	June 23, 2025
Delete snapshots during AMI deregistration	When deregistering an AMI, you can automatically delete its associated snapshots at the same time.	May 28, 2025

User-initiated reboot migration	When your instance receives an EC2 scheduled reboot event notification, it is enabled by default for instance migration when you reboot the instance before the event.	May 20, 2025
SIP configuration for Amazon EC2 Mac instances	You can configure System Integrity Protection (SIP) settings for x86 Mac instances and Apple silicon Mac instances.	May 20, 2025
Root volume ownership delegation	You can now automate root volume ownership delegatio n for the Amazon EBS root volume when updating the operating system on Apple silicon Mac instances.	May 20, 2025
Instance topology for P6-B200 instances	You can get the instance topology information for `p6-b200.48xlarge` instances.	May 15, 2025

Updated managed policies for the EC2 Fast Launch service linked role	Updated the EC2 Fast Launch service linked role policy with access to create and maintain Amazon EventBridge event rules, and other actions to enhance the EC2 Fast Launch experience. For more information about permissions granted by the service linked role, see Permissions granted by `EC2FastLaunchServiceRolePolicy` .	May 14, 2025
Updated managed policies for the EC2 Fast Launch full access policy	Updated the EC2 Fast Launch full access policy with permission to Create and Modify Launch Template operations, to create network and security group resources , authorize ingress rules, and delete resources that EC2 Fast Launch created. The policy can additionally describe and create CloudFormation stacks, and delete stacks that EC2 Fast Launch created.	May 14, 2025
Simplified onboarding for EC2 Fast Launch	Updated EC2 Fast Launch to simplify the onboarding process.	May 14, 2025

AWS Config integration with Allowed AMIs	Use the ec2-instance-launched-with-allowed-ami AWS Config rule to check if running or stopped instances were launched with AMIs that meet your Allowed AMIs criteria.	March 11, 2025
Updated AWSEC2CapacityReservationFleetRolePolicy managed policy	Amazon EC2 updated the `AWSEC2CapacityReservationFleetRolePolicy` managed policy to use the `ArnLike` condition operator instead of the `StringLike` condition operator.	March 3, 2025
Time-based AMI copies	You can now request a completion duration for EBS-backed AMI copy operations to ensure that AMI copies are completed within a specific timeframe.	February 25, 2025
Updated AmazonEC2ReadOnlyAccess policy	Amazon EC2 added the `GetSecurityGroupsForVpc` operation to the existing AmazonEC2ReadOnlyAccess policy.	December 27, 2024
Managed instances	You can now view Amazon EC2 managed instances in the EC2 console.	December 1, 2024

Declarative policies	You can now use declarative policies to apply account-level settings across multiple Regions and accounts simultaneously. Declarative policies are supported for configuring EC2 serial console access, Allowed AMIs, IMDS defaults, and block public access settings for VPCs, AMIs, and snapshots. For more information, see Declarative policies in the *AWS Organizations User Guide*, as well as the specific documentation for each supported feature.	December 1, 2024
Allowed AMIs	You can now control the discovery and use of AMIs in Amazon EC2 by specifying criteria that AMIs must meet.	December 1, 2024
Instant Capacity Blocks	You can now reserve Capacity Blocks for ML, that can start as soon as 30 minutes.	November 21, 2024
Future-dated Capacity Reservations	You can now request Capacity Reservations for a future date.	November 21, 2024
Extend Capacity Block	You can now extend the duration of existing Capacity Blocks.	November 21, 2024
6 month Capacity Blocks	You can now reserve Capacity Blocks for ML for up to 6 months (182 days).	November 21, 2024

Saved filter sets	You can now create customized groups of filters and reuse them to efficiently view your EC2 resources.	November 20, 2024
Performance protection	When using attribute-based instance type selection for your EC2 Fleet or Spot Fleet, you can now enable performance protection to ensure that the selected instance types are similar to or exceed a specified performance baseline.	November 20, 2024
Capacity Reservations only	You can now specify that instances will only run in a Capacity Reservation or Capacity Reservation resource group.	November 20, 2024
Identify source AMI	You can now identify the source AMI that was used to create an AMI.	November 13, 2024
Split capacity	You can split off capacity from an existing Capacity Reservation to create a new reservation.	October 30, 2024
Move capacity	You can now move capacity from one Capacity Reservation to another.	October 30, 2024

Beginner tutorials	Two new tutorials for beginners: Launch my very first EC2 instance and Launch a test EC2 instance and connect to it.	October 21, 2024
Windows Server 2025 support	Add support for Windows Server 2025.	October 16, 2024
EC2 Global View	EC2 Global View now enables you to view Capacity Reservations and Capacity Blocks in your account across all Regions.	October 16, 2024
Live migration host maintenance	Amazon EC2 Dedicated Hosts now support live migration host maintenance, which automatically migrates sup ported instances from an impaired Dedicated Host to a replacement Dedicated Host without stopping and res tarting them.	October 15, 2024
Billing assignment for shared Capacity Reservations	You can now assign the billing of any available capacity of a shared Capacity Reservati on to a consumer account that belongs to the same AWS organization.	October 14, 2024
PTP hardware clock - additional Region support	The PTP hardware clock is now also available in US East (Ohio) and Asia Pacific (Malaysia).	September 23, 2024

EC2 Instance Connect supports IPv6	You can now use EC2 Instance Connect to connect to the public IPv6 address of your instance.	September 23, 2024
EC2 Instance Connect prefix lists	You can now select a managed prefix list for IPv4 or IPv6 addresses when creating rules in your security groups to allow SSH traffic from the EC2 Instance Connect service.	September 23, 2024
New capabilities to manage On-Demand Capacity Reservations	You can now split your Capacity Reservation, move capacity between Capacity Reservations, and modify the instance eligibility attribute of your Capacity Reservation.	August 14, 2024
Hibernation support for C6g, C6gn, C6gd, C7g, C7gd, M6g, M6gd, M7g, M7gd, R6g, and R6gd	Hibernate your newly-lau nched instances running on C6g, C6gn, C6gd, C7g, C7gd, M6g, M6gd, M7g, M7gd, R6g, and R6gd instance types.	July 30, 2024
Hibernation support for AMIs that support Graviton instance types	Hibernate your newly-lau nched instances that were launched from an Amazon Linux or Ubuntu AMI that supports Graviton instance types.	July 30, 2024
Additional instance types supported for Credential Guard	You can now enable Credentia l Guard for C7i, C7-flex, M7i, M7i-flex, R7i, R7i-flex, and T3 instances.	June 26, 2024

EC2 M1 Ultra Mac instances	New general purpose instance type that features Apple M1 Ultra processors.	June 17, 2024
EC2 instance type finder – additional parameters	The EC2 instance type finder now provides additional parameters for you to specify more detailed requirements for your workload.	June 5, 2024
U7i-12tb, U7in-16tb, U7in-24tb, and U7in-32tb instances	New high memory instance types that feature 4th generation Intel Xeon Sca lable processors.	May 28, 2024
New managed policy for EC2 Fast Launch	Added the EC2FastLa unchFullAccess policy to perform API actions related to the EC2 Fast Launch feature from an instance.	May 14, 2024
AMI deregistration protection	You can turn on deregistr ation protection on an AMI to prevent accidental or malicious deletion.	April 23, 2024
PTP hardware clock – instance type support	The PTP hardware clock is now available on M7a, M7g, M7i, R7a, and R7i instance types.	April 22, 2024
Added Nitro performance considerations for enhanced networking	This page focuses on network considerations to help with performance tuning for your Nitro based Amazon EC2 instances.	April 4, 2024

New managed policy for VSS based EBS snapshots	Amazon EC2 VSS has a new IAM managed policy available that you can add to your ins tance profile role to ensure that your permissions stay up-to-date and follow best practices.	March 28, 2024
PTP hardware clock – US East (N. Virginia)	The PTP hardware clock is now available in the US East (N. Virginia) Region.	March 26, 2024
Set IMDSv2 as the account default	You can set all new EC2 instance launches in your account to use Instance Metadata Service Version 2 (I MDSv2) by default.	March 25, 2024
Tag new Linux AMIs created from a snapshot	When you create a Linux AMI from a snapshot, you can tag the new AMI.	March 7, 2024
Tag new AMIs and snapshots when copying	When you copy an AMI, you can tag the new AMI and the new snapshots with the same tags, or you can tag them with different tags.	March 7, 2024

Remove AWS Management Pack pages	The AWS Management Pack was primarily used with Windows Server 2012 and prior. Those legacy OS platform versions are no longer supported. To manage and troubleshoot your fleet of servers running on AWS and on-premises, see AWS Systems Manager Fleet Manager.	February 12, 2024
EC2 Instance Connect preinstalled on macOS AMIs	EC2 Instance Connect now comes preinstalled on macOS Sonoma 14.2.1 or later, macOS Ventura 13.6.3 or later, and macOS Monterey 12.7.2 or later AMIs.	January 26, 2024
EC2 Instance Connect support for CentOS, macOS, and RHEL	You can now install EC2 Instance Connect on supported CentOS, macOS, and RHEL AMIs.	December 6, 2023
Hibernation support for C7a, C7i, R7a, R7i, and R7iz	Hibernate your newly-lau nched instances running on C7a, C7i, R7a, R7i, and R7iz instance types.	December 1, 2023

[Amazon Q EC2 instance type selector]()	Amazon Q EC2 instance type selector considers your use case, workload type, and CPU manufacturer preference, as well as how you prioritize price and performance. It then uses this data to provide guidance and suggestions for Amazon EC2 instance types that are best suited for your new workloads.	November 28, 2023
[EC2 Free Tier]()	You can track your EC2 Free Tier usage from the EC2 Dashboard.	November 26, 2023
[Console-to-Code]()	Console-to-Code can help you get started with your automation code. Console-to-Code records your console actions, and then uses generative AI to suggest code in your preferred infrastructure-as code format. You can use the code as a starting point, customizing it to make it production-ready for your specific use case.	November 26, 2023

Configurable idle connection tracking timeouts	Security group connections that remain idle can lead to connection tracking exhaustio n and cause connections not to be tracked and packets to be dropped. You can now set the timeout in seconds for security group connection tracking on an Elastic network interface.	November 17, 2023
PTP hardware clock	Supported instances now have a Precision Time Protocol (PTP) hardware clock. The PTP hardware clock supports either NTP or a direct PTP connection.	November 16, 2023
Change instance type of instance enabled for hibernati on	You can now change the instance type of an instance enabled for hibernation when it is in the `stopped` state.	November 16, 2023
Instance topology	You can use the DescribeI nstanceTopology API to detect the location of your instances, and then use this information to optimize HPC and ML jobs by running them on instances that are physicall y closer to each other.	November 13, 2023

EC2 Fast Launch shared AMI support	You can now enable EC2 Fast Launch on an AMI that's shared with you. When you enable EC2 Fast Launch on a shared AMI, the pre-provi sioned snapshots for faster launching are created in your account.	November 6, 2023
Capacity Blocks for ML	You can now reserve GPU instances on a future date to support your short duration machine learning (ML) workloads.	October 31, 2023
Spot Instance hibernation	You can now hibernate your Spot Instances using the same hibernation experience and instance families that are currently available for On-Demand Instances.	October 24, 2023
Default settings for block public access for AMIs	Block public access for AMIs is now enabled by default for all new accounts and for existing accounts with no public AMIs.	October 20, 2023
Amazon EC2 Global View	Amazon EC2 Global View supports additional resource types and customizable display options.	October 18, 2023
Hibernation support for Ubuntu 22.04.2 LTS (Jammy Jellyfish)	Hibernate your newly-lau nched instances that were launched from the Ubuntu 22.04.2 LTS (Jammy Jellyfish) AMI.	October 16, 2023

Disable an AMI	You can disable an AMI to prevent it from being used for instance launches.	October 12, 2023
Attached EBS status checks	You can use the attached EBS status checks to monitor if the Amazon EBS volumes attached to an instance are reachable.	October 11, 2023
Hibernation support for Red Hat Enterprise Linux 9	Hibernate your newly-lau nched instances that were launched from the Red Hat Enterprise Linux 9 AMI.	October 2, 2023
Hibernation support for Microsoft Windows Server 2022	Hibernate your newly-lau nched instances that were launched from the Microsoft Windows Server 2022 AMI.	October 2, 2023
Hibernation support for AL2023	Hibernate your newly-lau nched instances that were launched from the AL2023 AMI.	October 2, 2023
Initiate interruption of Spot Instances in a Spot Fleet	You can select a Spot Fleet in the Amazon EC2 console and initiate an interruption of Spot Instances in the fleet so that you can test how the applications on your Spot Instances handle being interrupted.	September 21, 2023
Block public access to AMIs	You can enable *block public access for AMIs* at the account level to block any attempts to make your AMIs public.	September 12, 2023

Hibernation support for M7i and M7i-flex	Hibernate your newly-lau nched instances running on M7i and M7i-flex instance types.	August 22, 2023
EC2-Classic has been deprecated	With EC2-Classic, EC2 instances ran in a single, flat network shared with other customers. Amazon VPC replaces EC2-Classic. With Amazon VPC, your instances run in a virtual private cloud (VPC) that's logically isolated to your AWS account.	August 8, 2023
Dedicated Hosts	You can allocate Dedicated Hosts on specific hardware assets on an Outpost.	June 20, 2023
EC2 Instance Connect Endpoint	You can now connect to an instance via SSH or RDP without requiring the instance to have a public IPv4 address.	June 13, 2023
IMDS Package Analyzer	You can now use the IMDS Packet Analyzer to identify sources of IMDSv1 calls on your EC2 instances.	June 1, 2023
EC2 Serial Console bare metal instances	The EC2 serial console now supports connectivity to the serial port of selected bare metal instances.	April 11, 2023

Launch template quotas	You can now view your quotas for launch templates and launch template versions in the Service Quotas console and by using the Service Quotas CLI.	April 3, 2023
Capacity Reservation utilizati on notifications	AWS Health now sends notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.	April 3, 2023
Capacity Reservation groups	You can now add Capacity Reservations that are shared with you to Capacity Reservati on groups that you own.	March 30, 2023
Modify instance metadata options	You can now use the Amazon EC2 console to modify instance metadata options.	March 20, 2023
In-place macOS operating system updates	You can now perform in-place Apple macOS operating system updates on M1 Mac instances.	March 14, 2023
UEFI preferred	You can now create a single AMI that supports both Unified Extensible Firmware Interface (UEFI) and Legacy BIOS boot modes.	March 3, 2023
Modify an AMI for IMDSv2	Modify your existing AMI so that instances launched from the AMI require IMDSv2 by default.	February 28, 2023

Windows Virtualization-based security - Credential Guard	You can enable Credential Guard, a Virtualization-based security (VBS) feature, on supported Amazon EC2 instances.	January 31, 2023
New managed policy for EC2 Instance Connect Endpoint	Added the `Ec2InstanceConnectEndpoint` policy, which is attached to the **AWSServiceRoleForEC2InstanceConnect** service-linked role, to allow Amazon EC2 to perform actions on your behalf when you create an EC2 Instance Connect Endpoint.	January 24, 2023
AMI alias in launch templates	You can specify an AWS Systems Manager parameter instead of the AMI ID in your launch templates to avoid having to update the templates every time the AMI ID changes.	January 19, 2023
Hibernation support for C6i, I3en, and M6i	Hibernate your newly-launched instances running on C6i, I3en, and M6i instance types.	December 19, 2022

Torn write prevention	Improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency with torn write prevention, a block storage feature.	November 29, 2022
ENA Express	Increase throughput and minimize tail latency of network traffic between EC2 instances with ENA Express.	November 28, 2022
Copy AMI tags	When you copy an AMI, you can copy your user-defined AMI tags at the same time.	November 18, 2022
AMI size for store and restore	The size of an AMI (before compression) that can be stored and restored to and from an Amazon S3 bucket can now be up to 5,000 GB.	November 16, 2022
priceCapacityOptimized allocation strategy for Spot Instances	A Spot Fleet that uses the `priceCapacityOptimized` allocation strategy looks at both price and capacity to select the Spot Instances pools that are the least likely to be interrupted and have the lowest possible price.	November 10, 2022

price-capacity-optimized allocation strategy for Spot Instances	An EC2 Fleet that uses the `price-capacity-optimized` allocation strategy looks at both price and capacity to select the Spot Instances pools that are the least likely to be interrupted and have the lowest possible price.	November 10, 2022
Cancel having an AMI shared with your account	If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions.	November 4, 2022
Transfer Elastic IP addresses	You can now transfer Elastic IP addresses from one AWS account to another.	October 31, 2022
Replace root volume	You can replace the root Amazon EBS volume for a running instance using an AMI.	October 27, 2022
Automatically connect instance to database	Use the automatic connection feature to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.	October 10, 2022
AMI quotas	Quotas now apply to creating and sharing AMIs.	October 10, 2022

Configure AMI for IMDSv2	Configure your AMI so that instances launched from the AMI require IMDSv2 by default.	October 3, 2022
Initiate Spot Instance interruption	You can select a Spot Instance in the Amazon EC2 console and initiate an interruption so that you can test how the applications on your Spot Instances handle being interrupted.	September 26, 2022
Verified AMI provider	In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked **Verified provider**.	July 22, 2022
Placement groups on AWS Outposts	Added a host spread strategy for placement groups on an Outpost.	June 30, 2022
Dedicated Hosts on AWS Outposts	You can allocate Dedicated Hosts on AWS Outposts.	May 31, 2022
Instance stop protection	To prevent your instance from being accidentally stopped, you can enable stop protectio n for the instance.	May 24, 2022
UEFI Secure Boot	UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2 and provides additional defense-i n-depth that helps customers secure software from threats that persist across reboots.	May 10, 2022

NitroTPM	Nitro Trusted Platform Module (NitroTPM) is a virtual device that is provided by the AWS Nitro System and conforms to the TPM 2.0 specification.	May 10, 2022
AMI state change events	Amazon EC2 now generates an event when an AMI changes state. You can use Amazon EventBridge to detect and react to these events.	May 9, 2022
Describe public keys	You can query the public key and creation date of an Amazon EC2 key pair.	April 28, 2022
Create key pairs	You can specify the key format (PEM or PPK) when creating a new key pair.	April 28, 2022
Mount Amazon FSx file systems at launch	You can mount a new or existing Amazon FSx for NetApp ONTAP or Amazon FSx for OpenZFS file system at launch using the new launch instance wizard.	April 12, 2022
New launch instance wizard	A new and improved launch experience in the Amazon EC2 console, providing a quicker and easier way to launch an EC2 instance.	April 5, 2022

Automatically deprecate public AMIs	By default, the deprecation date of all public AMIs is set to two years from the AMI creation date.	March 31, 2022
Instance metadata category: autoscaling/target-lifecycle-state	When using Auto Scaling groups, you can access an instance's target lifecycle state from the instance metadata.	March 24, 2022
AMI last launched time	The `lastLaunchedTime` indicates when your AMI was last used to launch an instance.	February 28, 2022
ED25519 keys	ED25519 keys are now supported for EC2 Instance Connect and EC2 Serial Console.	January 20, 2022
Additional RHEL platforms for Capacity Reservations	Additional Red Hat Enterprise Linux platforms for On-Demand Capacity Reservations.	January 11, 2022
Configure Windows AMIs for faster launching	Configure Windows AMIs to launch instances up to 65% faster, using pre-provisioned snapshots.	January 10, 2022
Instance tags in instance metadata	You can access an instance's tags from the instance metadata.	January 6, 2022
Capacity Reservations in cluster placement groups	You can create Capacity Reservations in cluster placement groups.	January 6, 2022

Spot Fleet launch-before-terminate	Spot Fleet can terminate the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched.	November 4, 2021
EC2 Fleet launch-before-terminate	EC2 Fleet can terminate the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched.	November 4, 2021
Compare timestamps	You can determine the true time of an event by comparing the timestamp of your Amazon EC2 Linux instance with ClockBound.	November 2, 2021
Share AMIs with organizations and OUs	You can now share AMIs with the following AWS resources : organizations and organizational units (OUs).	October 29, 2021
Spot placement score	Get a recommendation for an AWS Region or Availability Zone based on your Spot capacity requirements.	October 27, 2021
Attribute-based instance type selection for Spot Fleet	Specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes.	October 27, 2021

Attribute-based instance type selection for EC2 Fleet	Specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes.	October 27, 2021
On-Demand Capacity Reservation Fleet	You can use a Capacity Reservation Fleet to launch a group, or fleet, of Capacity Reservations.	October 5, 2021
Hibernation support for Ubuntu 20.04 LTS - Focal	Hibernate your newly-lau nched instances that were launched from the Ubuntu 20.04 LTS - Focal AMI.	October 4, 2021
EC2 Fleet and targeted On-Demand Capacity Reservati ons	EC2 Fleet can launch On-Demand Instances into `targeted` Capacity Reservati ons.	September 22, 2021
T3 instances on Dedicated Hosts	Support for T3 instances on Amazon EC2 Dedicated Host.	September 14, 2021
Hibernation support for RHEL, Fedora, and CentOS	Hibernate your newly-lau nched instances that were launched from RHEL, Fedora, and CentOS AMIs.	September 9, 2021
Amazon EC2 Global View	Amazon EC2 Global View enables you to view VPCs, subnets, instances, security groups, and volumes across multiple AWS Regions in a single console.	September 1, 2021

Hibernation support for C5d, M5d, and R5d	Hibernate your newly-launched instances running on C5d, M5d, and R5d instance types.	August 19, 2021
Amazon EC2 key pairs	Amazon EC2 now supports ED25519 keys on Linux and Mac instances.	August 17, 2021
Prefixes for network interfaces	You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces.	July 22, 2021
Event windows	You can define custom, weekly-recurring event windows for scheduled events that reboot, stop, or terminate your Amazon EC2 instances.	July 15, 2021
Resource IDs and tagging support for security group rules	You can refer to security group rules by resource ID. You can also add tags to your security group rules.	July 7, 2021
Deprecate an AMI	You can now specify when an AMI is deprecated.	June 11, 2021
Windows per-second billing	Amazon EC2 charges for Windows- and SQL Server-based usage by the second, with a one-minute minimum charge.	June 10, 2021
Capacity Reservations on AWS Outposts	You can now use Capacity Reservations on AWS Outposts.	May 24, 2021

Capacity Reservation sharing	You can now share Capacity Reservations created in Local Zones and Wavelength Zones.	May 24, 2021
Root volume replacement	You can now use root volume replacement tasks to replace the root EBS volume for running instances.	April 22, 2021
Store and restore an AMI using S3	Store EBS-backed AMIs in S3 and restore them from S3 to enable cross-partition copying of AMIs.	April 6, 2021
EC2 Serial Console	Troubleshoot boot and network connectivity issues by establishing a connectio n to the serial port of an instance.	March 30, 2021
Boot modes	Amazon EC2 now supports UEFI boot on selected AMD- and Intel-based EC2 instances .	March 22, 2021
Create a reverse DNS record	You can now set up reverse DNS lookup for your Elastic IP addresses.	February 3, 2021
Tag AMIs and snapshots on AMI creation	When you create an AMI, you can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.	December 4, 2020

Use Amazon EventBridge to monitor Spot Fleet events	Create EventBridge rules that trigger programmatic actions in response to Spot Fleet state changes and errors.	November 20, 2020
Use Amazon EventBridge to monitor EC2 Fleet events	Create EventBridge rules that trigger programmatic actions in response to EC2 Fleet state changes and errors.	November 20, 2020
Delete instant fleets	Delete an EC2 Fleet of type `instant` and terminate all the instances in the fleet in a single API call.	November 18, 2020
Hibernation support for T3 and T3a	Hibernate your newly-lau nched instances running on T3 and T3a instance types.	November 17, 2020
Amazon EFS Quick Create	You can create and mount an Amazon EFS file system to an instance at launch using Amazon EFS Quick Create.	November 9, 2020
Instance metadata category: events/recommendations/rebalance	The approximate time, in UTC, when the EC2 instance rebalance recommendation notification is emitted for the instance.	November 4, 2020
EC2 instance rebalance recommendation	A signal that notifies you when a Spot Instance is at elevated risk of interruption.	November 4, 2020
Capacity Reservations in Wavelength Zones	Capacity Reservations can now be created and used in Wavelength Zones.	November 4, 2020

Capacity Rebalancing	Configure Spot Fleet or EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance rec ommendation.	November 4, 2020
Hibernation support for I3, M5ad, and R5ad	Hibernate your newly-lau nched instances running on I3, M5ad, and R5ad instance types.	October 21, 2020
Spot Instance vCPU limits	Spot Instance limits are now managed in terms of the number of vCPUs that your running Spot Instances are either using or will use pending the fulfillment of open requests.	October 1, 2020
Capacity Reservations in Local Zones	Capacity Reservations can now be created and used in Local Zones.	September 30, 2020
Hibernation support for M5a and R5a	Hibernate your newly-lau nched instances running on M5a and R5a instance types.	August 28, 2020
Instance metadata provides instance location and placement information	New instance metadata fields under the `placement` category: Region, placement group name, partition number, host ID, and Availabil ity Zone ID.	August 24, 2020

Capacity Reservation groups	You can use AWS Resource Groups to create logical collections of Capacity Reservations, and then target instance launches into those groups.	July 29, 2020
EC2Launch v2	You can use EC2Launch v2 to perform tasks during instance startup, if an instance is stopped and later started, if an instance is restarted, and on demand. EC2Launch v2 supports all versions of Windows Server and replaces EC2Launch and EC2Config.	June 30, 2020
Bring your own IPv6 addresses	You can bring part or all of your IPv6 address range from your on-premises network to your AWS account.	May 21, 2020
Launch instances using a Systems Manager parameter	You can specify a AWS Systems Manager parameter instead of an AMI when you launch an instance.	May 5, 2020
Customize scheduled event notifications	You can customize scheduled event notifications to include tags in the email notification.	May 4, 2020
Windows Server on Dedicated Hosts	You can use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts.	April 7, 2020

Stop and start a Spot Instance	Stop your Spot Instances backed by Amazon EBS and start them at will, instead of relying on the stop interrupt ion behavior.	January 13, 2020
Resource tagging	You can tag egress-only internet gateways, local gateways, local gateway route tables, local gateway virtual interfaces, local gateway virtual interface groups, local gateway route table VPC associations, and local gateway route table virtual interface group associations.	January 10, 2020
Connect to your instance using Session Manager	You can start a Session Manager session with an instance from the Amazon EC2 console.	December 18, 2019
Dedicated Hosts and host resource groups	Dedicated Hosts can now be used with host resource groups.	December 2, 2019
Dedicated Host sharing	You can now share your Dedicated Hosts across AWS accounts.	December 2, 2019
Default credit specification at the account level	You can set the default credit specification per burstable performance instance family at the account level per AWS Region.	November 25, 2019
Instance type discovery	You can find an instance type that meets your needs.	November 22, 2019

Dedicated Hosts	You can now configure a Dedicated Host to support multiple instance types in an instance family.	November 21, 2019
Instance Metadata Service Version 2	You can use Instance Metadata Service Version 2, which is a session-oriented method for requesting instance metadata.	November 19, 2019
Elastic Fabric Adapter	Elastic Fabric Adapters can now be used with Intel MPI 2019 Update 6.	November 15, 2019
Hibernation support for On-Demand Windows instances	You can hibernate On-Demand Windows instances.	October 14, 2019
Queued purchases of Reserved Instances	You can queue the purchase of a Reserved Instance up to three years in advance.	October 4, 2019
Diagnostic interrupt	You can send a diagnostic interrupt to an unreachable or unresponsive instance to trigger a kernel panic.	August 14, 2019
Capacity optimized allocation strategy	Using EC2 Fleet or Spot Fleet, you can launch Spot Instances from Spot pools with optimal capacity for the number of instances that are launching.	August 12, 2019
On-Demand Capacity Reservation sharing	You can now share your Capacity Reservations across AWS accounts.	July 29, 2019

Elastic Fabric Adapter	EFA now supports Open MPI 3.1.4 and Intel MPI 2019 Update 4.	July 26, 2019
EC2 Instance Connect	EC2 Instance Connect is a simple and secure way to connect to your instances usi ng Secure Shell (SSH).	June 27, 2019
Host recovery	Automatically restart your instances on a new host in the event of an unexpected har dware failure on a Dedicated Host.	June 5, 2019
VSS application-consistent snapshots	Take application-consistent snapshots of all Amazon EBS volumes attached to your Windows instances using AWS Systems Manager Run Command.	May 13, 2019
Windows to Linux Replatfor ming Assistant for Microsoft SQL Server Databases	Move existing Microsoft SQL Server workloads from a Windows to a Linux operating system. Updated link points to the Microsoft SQL Server on Amazon EC2 User Guide.	May 8, 2019
Windows Automated Upgrade	Perform automated upgrades of EC2 Windows instances using AWS Systems Manager.	May 6, 2019
Elastic Fabric Adapter	You can attach an Elastic Fabric Adapter to your instances to accelerate High Performance Computing (HPC) applications.	April 29, 2019

For information about the instance type releases for Amazon EC2, see Document history in the *Amazon EC2 Instance Types Guide*.

History for 2018 and earlier

The following table describes important additions to the Amazon EC2 User Guide in 2018 and earlier years.

Feature	API version	Description	Release date
Partition placement groups	2016-11-15	Partition placement groups spread instances across logical partitions, ensuring that instances in one partition do not share underlying hardware with instances in other partitions. For more information, see Partition placement groups.	20 December 2018
Hibernate EC2 Linux instances	2016-11-15	You can hibernate a Linux instance if it's enabled for hibernation and it meets the hibernation prerequisites. For more information, see Hibernate your Amazon EC2 instance.	28 November 2018
Amazon Elastic Inference Accelerators	2016-11-15	You can attach an Amazon EI accelerator to your instances to add GPU-powered acceleration to reduce the cost of running deep learning inference.	28 November 2018
Spot console recommends a fleet of instances	2016-11-15	The Spot console recommends a fleet of instances based on Spot best practice (instance diversification) to meet the minimum hardware specifications (vCPUs, memory, and storage) for your application need. For more information, see Create a Spot Fleet.	20 November 2018
New EC2 Fleet request type: instant	2016-11-15	EC2 Fleet now supports a new request type, `instant`, that you can use to synchronously provision capacity across instance	14 November 2018

Feature	API version	Description	Release date
		types and purchase models. The `instant` request returns the launched instances in the API response, and takes no further action, enabling you to control if and when instances are launched. For more information, see EC2 Fleet and Spot Fleet request types.	
Spot savings information	2016-11-15	You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. For more information, see Savings from purchasing Spot Instances.	5 November 2018
Console support for optimizing CPU options	2016-11-15	When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs using the Amazon EC2 console. For more information, see CPU options for Amazon EC2 instances.	31 October 2018
Console support for creating a launch template from an instance	2016-11-15	You can create a launch template using an instance as the basis for a new launch template using the Amazon EC2 console. For more information, see Create an Amazon EC2 launch template.	30 October 2018
On-Demand Capacity Reservations	2016-11-15	You can reserve capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This allows you to create and manage capacity reservations independently from the billing discounts offered by Reserved Instances (RI). For more information, see Reserve compute capacity with EC2 On-Demand Capacity Reservations.	25 October 2018

Feature	API version	Description	Release date
Bring Your Own IP Addresses (BYOIP)	2016-11-15	You can bring part or all of your public IPv4 address range from your on-premises network to your AWS account. After you bring the address range to AWS, it appears in your account as an address pool. You can create an Elastic IP address from your address pool and use it with your AWS resources. For more information, see Bring your own IP addresses (BYOIP) to Amazon EC2.	23 October 2018
Dedicated Host tag on create and console support	2016-11-15	You can tag your Dedicated Hosts on creation, and you can manage your Dedicated Host tags using the Amazon EC2 console. For more information, see Allocate an Amazon EC2 Dedicated Host for use in your account.	08 October 2018
Console support for scheduled scaling for Spot Fleet	2016-11-15	Increase or decrease the current capacity of the fleet based on the date and time. For more information, see Scheduled scaling: Scale Spot Fleet on a schedule.	20 September 2018
Allocation strategies for EC2 Fleets	2016-11-15	You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity.	26 July 2018

Feature	API version	Description	Release date
Allocation strategies for Spot Fleets	2016-11-15	You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity.	26 July 2018
Automate snapshot lifecycle	2016-11-15	You can use Amazon Data Lifecycle Manager to automate creation and deletion of snapshots for your EBS volumes. For more information, see Amazon Data Lifecycle Manager.	12 July 2018
Launch template CPU options	2016-11-15	When you create a launch template using the command line tools, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Create an Amazon EC2 launch template.	11 July 2018
Tag Dedicated Hosts	2016-11-15	You can tag your Dedicated Hosts.	3 July 2018
Get latest console output	2016-11-15	You can retrieve the latest console output for some instance types when you use the get-console-output AWS CLI command.	9 May 2018
Optimize CPU options	2016-11-15	When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs. For more information, see CPU options for Amazon EC2 instances.	8 May 2018

Feature	API version	Description	Release date
EC2 Fleet	2016-11-15	You can use EC2 Fleet to launch a group of instances across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchasing models. For more information, see EC2 Fleet and Spot Fleet.	2 May 2018
On-Demand Instances in Spot Fleets	2016-11-15	You can include a request for On-Demand capacity in your Spot Fleet request to ensure that you always have instance capacity. For more information, see EC2 Fleet and Spot Fleet.	2 May 2018
Tag EBS snapshots on creation	2016-11-15	You can apply tags to snapshots during creation.	2 April 2018
Change placement groups	2016-11-15	You can move an instance in or out of a placement group, or change its placement group. For more information, see Change the placement for an EC2 instance.	1 March 2018
Longer resource IDs	2016-11-15	You can enable the longer ID format for more resource types.	9 February 2018
Network performance improvements	2016-11-15	Instances outside of a cluster placement group can now benefit from increased bandwidth when sending or receiving network traffic between other instances or Amazon S3.	24 January 2018
Tag Elastic IP addresses	2016-11-15	You can tag your Elastic IP addresses.	21 December 2017

Feature	API version	Description	Release date
Amazon Time Sync Service	2016-11-15	You can use the Amazon Time Sync Service to keep accurate time on your instance. For more information, see Precision clock and time synchronization on your EC2 instance.	29 November 2017
T2 Unlimited	2016-11-15	T2 Unlimited instances can burst above the baseline for as long as required. For more information, see Burstable performance instances.	29 November 2017
Launch templates	2016-11-15	A launch template can contain all or some of the parameters to launch an instance, so that you don't have to specify them every time you launch an instance. For more information, see Store instance launch parameters in Amazon EC2 launch templates.	29 November 2017
Spread placement	2016-11-15	Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. For more information, see Spread placement groups.	29 November 2017
Spot Instance hibernation	2016-11-15	The Spot service can hibernate Spot Instances in the event of an interruption.	28 November 2017
Spot Fleet target tracking	2016-11-15	You can set up target tracking scaling policies for your Spot Fleet. For more information, see Target tracking scaling: Scale Spot Fleet by targeting a value for a specific metric.	17 November 2017
Spot Fleet integrates with Elastic Load Balancing	2016-11-15	You can attach one or more load balancers to a Spot Fleet.	10 November 2017

Feature	API version	Description	Release date
Merge and split Convertible Reserved Instances	2016-11-15	You can exchange (merge) two or more Convertible Reserved Instances for a new Convertible Reserved Instance. You can also use the modification process to split a Convertible Reserved Instance into smaller reservations. For more information, see Exchange Convertible Reserved Instances.	6 November 2017
Modify VPC tenancy	2016-11-15	You can change the instance tenancy attribute of a VPC from `dedicated` to `default`. For more information, see Change the instance tenancy of a VPC.	16 October 2017
Per second billing	2016-11-15	Amazon EC2 charges for Linux-based usage by the second, with a one-minute minimum charge.	2 October 2017
Stop on interruption	2016-11-15	You can specify whether Amazon EC2 should stop or terminate Spot Instances when they are interrupted. For more information, see Behavior of Spot Instance interruptions.	18 September 2017
Tag NAT gateways	2016-11-15	You can tag your NAT gateway. For more information, see Tag your resources.	7 September 2017
Security group rule descriptions	2016-11-15	You can add descriptions to your security group rules.	31 August 2017
Elastic Graphics	2016-11-15	Attach Elastic Graphics accelerators to your instances to accelerate the graphics performance of your applications.	29 August 2017

Feature	API version	Description	Release date
Recover Elastic IP addresses	2016-11-15	If you release an Elastic IP address for use in a VPC, you might be able to recover it.	11 August 2017
Tag Spot Fleet instances	2016-11-15	You can configure your Spot Fleet to automatically tag the instances that it launches.	24 July 2017
Tag resources during creation	2016-11-15	You can apply tags to instances and volumes during creation. For more information, see Tag your resources. In addition, you can use tag-based resource-level permissions to control the tags that are applied. For more information see, Grant permission to tag Amazon EC2 resources during creation.	28 March 2017
Perform modifications on attached EBS volumes	2016-11-15	With most EBS volumes attached to most EC2 instances, you can modify volume size, type, and IOPS without detaching the volume or stopping the instance.	13 February 2017
Attach an IAM role	2016-11-15	You can attach, detach, or replace an IAM role for an existing instance. For more information, see IAM roles for Amazon EC2.	9 February 2017
Dedicated Spot Instances	2016-11-15	You can run Spot Instances on single-tenant hardware in a virtual private cloud (VPC). For more information, see Launch on single-tenant hardware.	19 January 2017
IPv6 support	2016-11-15	You can associate an IPv6 CIDR with your VPC and subnets, and assign IPv6 addresses to instances in your VPC. For more information, see Amazon EC2 instance IP addressing.	1 December 2016

Feature	API version	Description	Release date
Automatic scaling for Spot Fleet		You can now set up scaling policies for your Spot Fleet. For more information, see Understand automatic scaling for Spot Fleet.	1 September 2016
Elastic Network Adapter (ENA)	2016-04-01	You can now use ENA for enhanced networking. For more information, see Enhanced networking on Amazon EC2 instances.	28 June 2016
Enhanced support for viewing and modifying longer IDs	2016-04-01	You can now view and modify longer ID settings for other IAM users, IAM roles, or the root user.	23 June 2016
Copy encrypted Amazon EBS snapshots between AWS accounts	2016-04-01	You can now copy encrypted EBS snapshots between AWS accounts.	21 June 2016
Capture a screenshot of an instance console	2015-10-01	You can now obtain additional information when debugging instances that are unreachable. For more information, see Capture a screenshot of an unreachable instance.	24 May 2016
Two new EBS volume types	2015-10-01	You can now create Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes.	19 April 2016
Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2		Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2. For more information, see Instance metrics.	23 March 2016
CloudWatch metrics for Spot Fleet		You can now get CloudWatch metrics for your Spot Fleet. For more information, see Monitor your EC2 Fleet or Spot Fleet using CloudWatch.	21 March 2016

Feature	API version	Description	Release date
Scheduled Instances	2015-10-01	Scheduled Reserved Instances (Scheduled Instances) enable you to purchase capacity reservations that recur on a daily, weekly, or monthly basis, with a specified start time and duration.	13 January 2016
Longer resource IDs	2015-10-01	We're gradually introducing longer length IDs for some Amazon EC2 and Amazon EBS resource types. During the opt-in period, you can enable the longer ID format for supported resource types.	13 January 2016
ClassicLink DNS support	2015-10-01	You can enable ClassicLink DNS support for your VPC so that DNS hostnames that are addressed between linked EC2-Classic instances and instances in the VPC resolve to private IP addresses and not public IP addresses.	11 January 2016
Dedicated hosts	2015-10-01	An Amazon EC2 Dedicated host is a physical server with instance capacity dedicated for your use. For more information, see Amazon EC2 Dedicated Hosts.	23 November 2015
Spot Instance duration	2015-10-01	You can now specify a duration for your Spot Instances. Spot blocks is not supported (January 2023).	6 October 2015
Spot Fleet modify request	2015-10-01	You can now modify the target capacity of your Spot Fleet request. For more information, see Modify a Spot Fleet request.	29 September 2015

Feature	API version	Description	Release date
Spot Fleet diversified allocation strategy	2015-04-15	You can now allocate Spot Instances in multiple Spot pools using a single Spot Fleet request. For more information, see Use allocation strategies to determine how EC2 Fleet or Spot Fleet fulfills Spot and On-Demand capacity.	15 September 2015
Spot Fleet instance weighting	2015-04-15	You can now define the capacity units that each instance type contributes to your application's performance, and adjust the amount you are willing to pay for Spot Instances for each Spot pool accordingly. For more information, see Use instance weighting to manage cost and performance of your EC2 Fleet or Spot Fleet.	31 August 2015
New reboot alarm action and new IAM role for use with alarm actions		Added the reboot alarm action and new IAM role for use with alarm actions. For more information, see Create alarms that stop, terminate, reboot, or recover an instance.	23 July 2015
Spot Fleets	2015-04-15	You can manage a collection, or fleet, of Spot Instances instead of managing separate Spot Instance requests. For more information, see EC2 Fleet and Spot Fleet.	18 May 2015
Migrate Elastic IP addresses to EC2-Classic	2015-04-15	You can migrate an Elastic IP address that you've allocated for use in EC2-Classic to be used in a VPC..	15 May 2015
Importing VMs with multiple disks as AMIs	2015-03-01	The VM Import process now supports importing VMs with multiple disks as AMIs. For more information, see Importing a VM as an Image Using VM Import/Export in the *VM Import/Export User Guide* .	23 April 2015

Feature	API version	Description	Release date
Systems Manager		Systems Manager enables you to configure and manage your EC2 instances.	17 February 2015
Systems Manager for Microsoft SCVMM 1.5		You can now use Systems Manager for Microsoft SCVMM to launch an instance and to import a VM from SCVMM to Amazon EC2.	21 January 2015
Automatic recovery for EC2 instances		You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. A recovered instance is identical to the original instance, including the instance ID, IP addresses, and all instance metadata. For more information, see Automatic instance recovery.	12 January 2015
ClassicLink	2014-10-01	ClassicLink enables you to link your EC2-Classic instance to a VPC in your account. You can associate VPC security groups with the EC2-Classic instance, enabling communication between your EC2-Classic instance and instances in your VPC using private IP addresses.	7 January 2015

Feature	API version	Description	Release date
Spot Instance termination notices		The best way to protect against Spot Instance interruption is to architect your application to be fault tolerant. In addition, you can take advantage of Spot Instance termination notices, which provide a two-minute warning before Amazon EC2 must terminate your Spot Instance. For more information, see Spot Instance interruption notices.	5 January 2015
Systems Manager for Microsoft SCVMM		Systems Manager for Microsoft SCVMM provides a simple, easy-to-use interface for managing AWS resources, such as EC2 instances, from Microsoft SCVMM.	29 October 2014
`DescribeVolumes` pagination support	2014-09-01	The `DescribeVolumes` API call now supports the pagination of results with the `MaxResults` and `NextToken` parameters. For more information, see DescribeVolumes in the *Amazon EC2 API Reference*.	23 October 2014
Added support for Amazon CloudWatch Logs		You can use Amazon CloudWatch Logs to monitor, store, and access your system, application, and custom log files from your instances or other sources. You can then retrieve the associated log data from CloudWatch Logs using the Amazon CloudWatch console, the CloudWatch Logs commands in the AWS CLI, or the CloudWatch Logs SDK.	10 July 2014

Feature	API version	Description	Release date
New **EC2 Service Limits** page		Use the **EC2 Service Limits** page in the Amazon EC2 console to view the current limits for resources provided by Amazon EC2 and Amazon VPC, on a per-region basis.	19 June 2014
Amazon EBS General Purpose SSD Volumes	2014-05-01	General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies, the ability to burst to 3,000 IOPS for extended periods of time, and a base performance of 3 IOPS/GiB. General Purpose SSD volumes can range in size from 1 GiB to 1 TiB.	16 June 2014
AWS Management Pack		AWS Management Pack now supports for System Center Operations Manager 2012 R2.	22 May 2014
Amazon EBS encryption	2014-05-01	Amazon EBS encryption offers seamless encryption of EBS data volumes and snapshots, eliminating the need to build and maintain a secure key management infrastructure. EBS encryption enables data at rest security by encrypting your data using AWS managed keys. The encryption occurs on the servers that host EC2 instances, providing encryption of data as it moves between EC2 instances and EBS storage.	21 May 2014
Amazon EC2 Usage Reports		Amazon EC2 Usage Reports is a set of reports that shows cost and usage data of your usage of EC2.	28 January 2014

Feature	API version	Description	Release date
Importing Linux virtual machines	2013-10-15	The VM Import process now supports the importation of Linux instances. For more information, see the VM Import/Export User Guide.	16 December 2013
Resource-level permissions for RunInstances	2013-10-15	You can now create policies in AWS Identity and Access Management to control resource-level permissions for the Amazon EC2 RunInstances API action. For more information and example policies, see Identity and access management for Amazon EC2.	20 November 2013
Launching an instance from the AWS Marketplace		You can now launch an instance from the AWS Marketplace using the Amazon EC2 launch wizard. For more information, see Launch an Amazon EC2 instance from an AWS Marketplace AMI.	11 November 2013
New launch wizard		There is a new and redesigned EC2 launch wizard. For more information, see Launch an EC2 instance using the launch instance wizard in the console.	10 October 2013
Modifying instance types of Reserved Instances	2013-10-01	You can now modify the instance type of Linux Reserved Instances within the same family (for example, M1, M2, M3, C1). For more information, see Modify Reserved Instances.	09 October 2013
Modifying Amazon EC2 Reserved Instances	2013-08-15	You can now modify Reserved Instances in a Region. For more information, see Modify Reserved Instances.	11 September 2013

Feature	API version	Description	Release date
Assigning a public IP address	2013-07-15	You can now assign a public IP address when you launch an instance in a VPC. For more information, see Assign a public IPv4 address at launch.	20 August 2013
Granting resource-level permissions	2013-06-15	Amazon EC2 supports new Amazon Resource Names (ARNs) and condition keys. For more information, see Identity-based policies for Amazon EC2.	8 July 2013
Incremental Snapshot Copies	2013-02-01	You can now perform incremental snapshot copies.	11 June 2013
AWS Management Pack		The AWS Management Pack links Amazon EC2 instances and the Windows or Linux operating systems running inside them. The AWS Management Pack is an extension to Microsoft System Center Operations Manager.	8 May 2013
New **Tags** page		There is a new **Tags** page in the Amazon EC2 console. For more information, see Tag your Amazon EC2 resources.	04 April 2013
Copy an AMI from one Region to another	2013-02-01	You can copy an AMI from one Region to another, enabling you to launch consistent instances in more than one AWS Region quickly and easily. For more information, see Copy an Amazon EC2 AMI.	11 March 2013

Feature	API version	Description	Release date
Launch instances into a default VPC	2013-02-01	Your AWS account is capable of launching instances into either EC2-Classic or a VPC, or only into a VPC, on a region-by-region basis. If you can launch instances only into a VPC, we create a default VPC for you. When you launch an instance, we launch it into your default VPC, unless you create a nondefault VPC and specify it when you launch the instance.	11 March 2013
EBS snapshot copy	2012-12-01	You can use snapshot copies to create backups of data, to create new Amazon EBS volumes, or to create Amazon Machine Images (AMIs).	17 December 2012
Updated EBS metrics and status checks for Provisioned IOPS SSD volumes	2012-10-01	Updated the EBS metrics to include two new metrics for Provisioned IOPS SSD volumes. Also added new status checks for Provisioned IOPS SSD volumes.	20 November 2012
Spot Instance request status	2012-10-01	Spot Instance request status makes it easy to determine the state of your Spot requests.	14 October 2012
Amazon EC2 Reserved Instance Marketplace	2012-08-15	The Reserved Instance Marketplace matches sellers who have Amazon EC2 Reserved Instances that they no longer need with buyers who are looking to purchase additional capacity. Reserved Instances bought and sold through the Reserved Instance Marketplace work like any other Reserved Instances, except that they can have less than a full standard term remaining and can be sold at different prices.	11 September 2012

Feature	API version	Description	Release date
Provisioned IOPS SSD for Amazon EBS	2012-07-20	Provisioned IOPS SSD volumes deliver predictable, high performance for I/O intensive workloads, such as database applications, that rely on consistent and fast response times.	31 July 2012
IAM roles on Amazon EC2 instances	2012-06-01	IAM roles for Amazon EC2 provide: • AWS access keys for applications running on Amazon EC2 instances. • Automatic rotation of the AWS access keys on the Amazon EC2 instance. • Granular permissions for applications running on Amazon EC2 instances that make requests to your AWS services.	11 June 2012

Feature	API version	Description	Release date
Spot Instance features that make it easier to get started and handle the potential of interruption.		You can now manage your Spot Instances as follows: • Specify the amount you are willing to pay for Spot Instances using Auto Scaling launch configurations, and set up a schedule for specifying the amount you are willing to pay for Spot Instances. For more information, see [Request Spot Instances](#) in the *Amazon EC2 Auto Scaling User Guide*. • Get notifications when instances are launched or terminated. • Use AWS CloudFormation templates to launch Spot Instances in a stack with AWS resources.	7 June 2012
EC2 instance export and timestamps for status checks for Amazon EC2	2012-05-01	Added support for exporting Windows Server instances that you originally imported into EC2. Added support for timestamps on instance status and system status to indicate the date and time that a status check failed.	25 May 2012
EC2 instance export, and timestamps in instance and system status checks for Amazon VPC	2012-05-01	Added support for EC2 instance export to Citrix Xen, Microsoft Hyper-V, and VMware vSphere. Added support for timestamps in instance and system status checks.	25 May 2012
AWS Marketplace AMIs	2012-04-01	Added support for AWS Marketplace AMIs.	19 April 2012

Feature	API version	Description	Release date
Reserved Instance pricing tiers	2011-12-15	Added a new section discussing how to take advantage of the discount pricing that is built into the Reserved Instance pricing tiers.	5 March 2012
Elastic Network Interfaces (ENIs) for EC2 instances in Amazon Virtual Private Cloud	2011-12-01	Added new section about elastic network interfaces (ENIs) for EC2 instances in a VPC. For more information, see Elastic network interfaces.	21 December 2011
New offering types for Amazon EC2 Reserved Instances	2011-11-01	You can choose from a variety of Reserved Instance offerings that address your projected use of the instance.	01 December 2011
Amazon EC2 instance status	2011-11-01	You can view additional details about the status of your instances, including scheduled events planned by AWS that might have an impact on your instances. These operational activities include instance reboots required to apply software updates or security patches, or instance retirements required where there are hardware issues. For more information, see Monitor the status of your Amazon EC2 instances.	16 November 2011
Spot Instances in Amazon VPC	2011-07-15	Added information about the support for Spot Instances in Amazon VPC. With this update, users can launch Spot Instances a virtual private cloud (VPC). By launching Spot Instances in a VPC, users of Spot Instances can enjoy the benefits of Amazon VPC.	11 October 2011

Feature	API version	Description	Release date
Simplified VM import process for users of the CLI tools	2011-07-15	The VM Import process is simplified with the enhanced functionality of `ImportInstance` and `ImportVolume`, which now will perform the upload of the images into Amazon EC2 after creating the import task. In addition, with the introduction of `ResumeImport`, users can restart an incomplete upload at the point the task stopped.	15 September 2011
Support for importing in VHD file format		VM Import can now import virtual machine image files in VHD format. The VHD file format is compatible with the Citrix Xen and Microsoft Hyper-V virtualization platforms. With this release, VM Import now supports RAW, VHD and VMDK (VMware ESX-compatible) image formats. For more information, see the VM Import/Export User Guide.	24 August 2011
Update to the Amazon EC2 VM Import Connector for VMware vCenter		Added information about the 1.1 version of the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). This update includes proxy support for Internet access, better error handling, improved task progress bar accuracy, and several bug fixes.	27 June 2011

Feature	API version	Description	Release date
Spot Instances Availability Zone pricing changes	2011-05-15	Added information about the Spot Instances Availability Zone pricing feature. In this release, we've added new Availability Zone pricing options as part of the information returned when you query for Spot Instance requests and Spot price history. These additions make it easier to determine the price required to launch a Spot Instance into a particular Availability Zone.	26 May 2011
AWS Identity and Access Management		Added information about AWS Identity and Access Management (IAM), which enables users to specify which Amazon EC2 actions a user can use with Amazon EC2 resources in general. For more information, see Identity and access management for Amazon EC2.	26 April 2011
Dedicated instances		Launched within your Amazon Virtual Private Cloud (Amazon VPC), Dedicated Instances are instances that are physically isolated at the host hardware level. Dedicated Instances let you take advantage of Amazon VPC and the AWS cloud, with benefits including on-demand elastic provisioning and pay only for what you use, while isolating your Amazon EC2 compute instances at the hardware level. For more information, see Amazon EC2 Dedicated Instances.	27 March 2011
Reserved Instances updates to the AWS Management Console		Updates to the AWS Management Console make it easier for users to view their Reserved Instances and purchase additional Reserved Instances, including Dedicated Reserved Instances.	27 March 2011

Feature	API version	Description	Release date
Metadata informati on	2011-01-0 1	Added information about metadata to reflect changes in the 2011-01-01 release. For more information, see Use instance metadata to manage your EC2 instance and Instance metadata categories.	11 March 2011
Amazon EC2 VM Import Connector for VMware vCenter		Added information about the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). The Connector is a plug-in for VMware vCenter that integrate s with VMware vSphere Client and provides a graphical user interface that you can use to import your VMware virtual machines to Amazon EC2.	3 March 2011
Force volume detachment		You can now use the AWS Managemen t Console to force the detachment of an Amazon EBS volume from an instance.	23 February 2011
Instance termination protection		You can now use the AWS Management Console to prevent an instance from being terminated. For more information, see Change instance termination protection.	23 February 2011
VM Import	2010-11-1 5	Added information about VM Import, which allows you to import a virtual machine or volume into Amazon EC2. For more informati on, see the VM Import/Export User Guide.	15 December 2010
Basic monitoring for instances	2010-08-3 1	Added information about basic monitoring for EC2 instances.	12 December 2010

Feature	API version	Description	Release date
Filters and Tags	2010-08-31	Added information about listing, filtering, and tagging resources. For more information, see Find your Amazon EC2 resources and Tag your Amazon EC2 resources.	19 September 2010
Idempotent Instance Launch	2010-08-31	Added information about ensuring idempotency when running instances.	19 September 2010
AWS Identity and Access Management for Amazon EC2		Amazon EC2 now integrates with AWS Identity and Access Management (IAM). For more information, see Identity and access management for Amazon EC2.	2 September 2010
Amazon VPC IP Address Designation	2010-06-15	Amazon VPC users can now specify the IP address to assign an instance launched in a VPC.	12 July 2010
Amazon CloudWatch monitoring for Amazon EBS Volumes		Amazon CloudWatch monitoring is now automatically available for Amazon EBS volumes.	14 June 2010
Reserved Instances with Windows		Amazon EC2 now supports Reserved Instances with Windows.	22 February 2010
